Northbrook, Thomas George Baring, 1st Earl of (1826——), the eldest son of the first baron (long known as Sir Francis Baring), was born on 22nd January 1826, and educated at Christ Church, Oxford, where he graduated with honours in 1846. He entered upon a political career, and was successively private secretary to Mr Labouchere (Lord Taunton), Sir George Grey, and Sir Charles Wood. In 1857 he was returned to the House of Commons in the Liberal interest for Penryn and Falmouth, which constituency he continued to represent until he became a peer on the death of his father in 1866. Mr Baring was a Lord of the Admiralty in 1857–58; Under-Secretary for War, 1861; for India, 1861–64; for the Home Department, 1864–66; and Secretary to the Admiralty, 1866. When Mr Gladstone acceded to power in 1868, Lord Northbrook was again appointed Under-Secretary for War, and this office he held until February 1872, when, upon the assassination of the earl of Mayo, he was appointed Governor-General of India. The terrible famine in Bengal, which began in January 1874, taxed the administrative powers of the Indian authorities to the uttermost, but it was successfully grappled with. Another important event was the visit of the Prince of Wales to India. In February 1876 Lord Northbrook resigned. It is now admitted that his Government recommended the conclusion of arrangements with Shere Ali which would have prevented the second Afghan war; but the Viceroy's policy was overruled by the duke of Argyll, then Secretary of State. During a debate on Indian affairs in the House of Lords in February 1880, Lord Northbrook delivered a remarkable speech, which attracted a great deal of attention at home and abroad. Having traced the developments of Russian and British policy in northern India, he asked whether no stop could be put to a rivalry which was detrimental to the interests of both countries; and he affirmed that, to any one who looked beyond the events of the moment, there was something almost appalling in the position of the British and Russian empires in Asia. In recognition of his distinguished public services, he was created in 1876 Viscount Baring of Lee in the county of Kent, and earl of Northbrook in the county of Southampton. From 1880 to 1885 the earl held the post of First Lord of the Admiralty in Mr Gladstone's second Government. In 1884 Lord Northbrook was sent to Egypt as Lord High Commissioner to inquire into its finances and condition, and the result was a loan of nine millions sterling. When Mr Gladstone formed his third ministry in 1886 Lord Northbrook held aloof, being opposed to the Home Rule policy of the Premier; and he then ceased to take a prominent part in political life. In 1890 he was appointed lord-lieutenant of Hampshire.

North Carolina, one of the southern states of the American Union, with Virginia on the N., Tennessee on the W., South Carolina on the S., and the Atlantic on the E. The harbour facilities are poor, and for a long time the people were a body of small farmers without towns, manufactures, or easy access to the world beyond. At the middle of the 19th century came an impetus to railway building, and in 1865 the abolition of slave labour. One of these forces put the state into quick communication with the outside world, and the other made agriculture so much less profitable that a considerable number of small farmers became factory hands. Thus, though agriculture is still the chief industry, a movement towards urban manufacturing communities developed in the closing years of the 19th century. Of this the most striking form has been the manufacture of cotton products, as the following figures show:—

Year.	Number of Mills.	Looms.	Spindles.
1880	49	1,790	92,385
1894	167	15,058	703,997
1900	224	29,689	1,297,771

In 1890 North Carolina was tenth in the list of cotton manufacturing states of America; in 1900 it was third, while of the Southern states it was first in the number of mills, but second in output. In 1899 its mills consumed as much cotton as was produced in the state. In 1900 the total capital invested in the manufacture of cotton goods amounted to $33,011,516. The industry employed 30,273 hands, and the value of the products was $28,372,789. The greater part of this development has been due to home capital. Next to cotton manufacturing is the lumber industry. The diminution of the forests of the North and West has brought Southern lumber into demand, especially pine lumber. In 1880 the whole lumber product of the state was worth $2,672,796. In 1893, in forty-two pine-producing counties of the east it was worth $4,558,280. In 1898 and 1899 there was a still greater development in the same line, and more capital was embarked. In the western part there are vast forests of hard wood still untouched. In 1900 the total lumber and timber products of the state were worth $14,862,593. Tobacco manufacturing is largely followed in some towns, notably in Durham and Winston-Salem. Here are some of the largest smoking and plug tobacco and cigarette factories in the world. In 1900 the state contained 80 tobacco factories, which had an output valued at $13,620,816. In manufactures of all kinds North Carolina ranks twenty-eighth among the states of the Union.

The general development of manufacturing during the decade 1890–1900 is set forth in the following table:—

	1890.	1900.	Per cent. of Increase.
Number of establishments .	3,667	7,226	97·1
Capital	$32,745,995	$76,503,894	133·6
Salaried officials, clerks, &c.	2,589[1]	3,001	15·9
Salaries	$1,278,415[1]	$2,434,621	90·4
Wage-earners, average number	33,625	70,570	109·9
Total wages . . .	$6,552,121	$13,868,430	111·7
Miscellaneous expenses .	$3,329,101	$9,118,637	173·9
Cost of materials used .	$22,789,187	$53,072,388	132·9
Value of products . .	$40,375,450	$94,919,663	135·1

[1] Includes proprietors and firm members, with their salaries.

Agriculture.—Agriculture, which continues to absorb most of the industrial energy, has been devoted to the one-crop form. For this reason it has not been very profitable. Cotton and tobacco have been the chief products, but in recent years these have brought unexpectedly low prices, and real distress has followed. Efforts have been made to secure the adoption of more diversified farming, and with some success, so that the outlook for agriculture is somewhat better. In those counties of the east which have adequate railway facilities, truck farming has assumed large proportions. In the west considerable progress has been made in raising apples for winter markets. The building of towns has tended to produce diversified farming. In 1900 the number of farms was 224,637, comprising 22,749,356 acres, of which 36·6 per cent. was improved land. The total value of farm property was $233,834,693, in which was included: land, improvements, and buildings, $194,655,920; implements and machinery, $9,072,600; live stock, $30,106,173. The total value of farm products in the preceding year was $89,309,638. In 1900 the statistics of the chief crops were: Indian corn, 29,790,180 bushels, valued at $16,980,403; wheat, 5,960,803 bushels, valued at $4,887,858; cotton, 503,825 bales, valued at $18,145,257. As to tobacco, statistics are wanting since 1889, in which year the product amounted to 36,375,258 lb.

Mining.—Mining, which was once thought to have large industrial probabilities, has made no considerable advance. A Geological Survey was established in 1899, and has done good in surveying the mineral resources. Gold continues to be mined in paying quantities in a number of small mines; in 1899 the total reported product was $43,000. An attempt to smelt iron in well-equipped modern furnaces has proved a financial failure. The increased prices for copper have resulted in a revival of copper mining. Certain deposits of mica, corundum, talc, graphite, monazite, and some precious gems have been mined with profit. Yet none of these results are sufficient to make the state a considerable mining state. Building-stone has also been worked in several places, and some of the granite deposits have established a reputation.

Fisheries.—Fisheries have long been largely worked in the extensive sounds on the coast, and the increase in transportation facilities has given them an added impetus. In 1899 the capital employed was $1,218,459, and the total catch was worth $1,316,017.

Population.—Social conditions have followed the development of industry. In 1880 the population was 1,399,750, of whom 867,242 were whites and 531,277 were coloured. In 1890 it was 1,617,947, of whom 1,055,382 were white and 561,018 were coloured. In 1900 it was 1,893,810, of whom 1,263,603 were white, 624,469 negro, 5687 Indians, and 51 Chinese. The males numbered 938,677 and the females 955,133; the native-born 1,889,318 and the foreign-born 4492. The total number of square miles of land surface in the state is 48,580, and the average number of persons to the square mile was 39 in 1900, as compared with 33·3 in 1890. In 1880 there were 50,778 persons in the state living in towns having a population of 2000 and over; in 1890, 102,053, and in 1900, 202,274. The growth of manufacturing explains in large part this increase. The most important towns and their populations are as follows:—

Town.	1880.	1890.	1900.
Wilmington	17,350	20,056	20,976
Raleigh	9,265	12,678	13,643
Charlotte	7,094	11,557	18,091
Winston-Salem	4,194	10,729	13,650
Ashville	2,616	10,235	14,694
Durham	2,041	5,485	6,679
Greensboro	2,105	3,317	10,035

The migration into the state is slight but appreciable. Some come for health to the mountains of the west and to the pine-covered plains in the middle part, and others come as skilled labourers in the factories. In 1880 the male population over ten years of age was 465,268, and of these 393,211, or 84·51 per cent., were engaged in gainful occupations. In 1890 this population was 559,764, of whom 422,171, or 75·42 per cent., were likewise engaged. Of females over ten years of age in 1880 there were 494,683, of whom 86,976, or 17·58 per cent., were engaged in gainful occupations; and in 1890 there were 586,682 females of such an age, of whom 115,192, or 19·6 per cent., were likewise engaged.

Education.—The development of public schools has been a matter of severe difficulty. The state is not wealthy, and there are a vast number of negroes who pay small taxes, or none at all, and who are yet as much in need of education as any class in the community. It is to the credit of the state that the blacks are allowed an equal share of the school fund. This fund is realized chiefly from taxation. In 1898 it amounted to $986,514; the average length of the term was 14·06 weeks for the whites and 11·75 for the blacks. In 1898 there were 415,262 white children of school age, of whom 144,357 attended school. In the same year the coloured children of school age were 213,218, of whom 68,894 attended school. In 1890 there were 4701 teachers in the state, of whom 1817 were males and 2884 were females. The native white population above ten years of age in 1880 was 605,244, of whom 191,913, or 31·71 per cent., were illiterate. The same population in 1890 was 751,302, of whom 173,545, or 23·10 per cent., were illiterate. The coloured population of the same age in 1880 was 351,145, of whom 271,943, or 77·44 per cent., were illiterate. The same population in 1890 was 392,589, of whom 235,981, or 60·11 per cent., were illiterate. In 1900 the total white male population over twenty-one years of age numbered 289,263, of whom 54,474, or 18·83 per cent., were illiterate; at the same time the coloured male population over twenty-one years numbered 128,315, of whom 68,184, or 53·13 per cent., were illiterate. The general opinion of competent observers is that the illiteracy of the negroes is steadily decreasing. A hopeful feature is the fact that most of the towns have levied special taxes to establish modern graded schools. These are usually open during nine months in the year, and may be considered a permanent feature of the new urban life. In higher education the progress has been good. A number of the smaller colleges, so-called, have been relegated to the position of high schools or closed altogether, whereas new institutions of a higher grade have been established and old ones strengthened. The state has established an agricultural and mechanical college for each race, and a normal and industrial college for white women. The Baptists, the Lutherans, the Quakers, the Christians, and the Roman Catholics have founded institutions of higher learning, and the Methodists have so increased the equipment of their college of Trinity as to make it practically a new institution. The state university has more than doubled its attendance. The higher education of the coloured people is cared for by six institutions, established chiefly through the aid of philanthropic Northern persons or organizations. In 1897 there were 2868 students, male and female, attending institutions of higher learning in the state, with 253 instructors.

Religion.—North Carolina is a decidedly Protestant state, having in 1890 only 2640 Roman Catholics. The most important churches are the Baptists, with 3124 organizations and 310,920 communicants; the Methodists, with 2413 organizations and 276,336 communicants; the Presbyterians, with 411 organizations and 36,102 communicants; the Christians, with 158 organizations and 12,437 communicants; the Lutherans, with 131 organizations and 12,326 communicants; and the Episcopalians, with 178 organizations and 8186 communicants.

Charitable and Penal Institutions.—There are for the whites two asylums for the insane, at Raleigh and at Morganton, and one for the blacks at Goldsboro. In 1896 these had respectively 420, 654, and 425 inmates. There is also an institution for the deaf, dumb, and blind in Raleigh, with 275 inmates, and another for the deaf and dumb in Morganton, with 175 inmates. There is a soldiers' home at Raleigh, with 105 inmates. All these are supported by the state. The state has a penitentiary in Raleigh, in which in 1896 there were 1127 inmates. This institution has connected with it certain farms and other works at which a part of the convicts are kept.

Transportation.—The chief railway systems are: the Southern, which has in the state 1226 miles of track, valued at $15,479,002; the Atlantic Coast Line, with a mileage of 949 and a valuation of $13,932,026; and the Seaboard Air Line, with a mileage of 614 and a valuation of $8,683,861; and other lines with a total mileage of 861 and a valuation of $4,298,837. Thus the railways of the state have a total mileage of 3650 and a total valuation of $42,393,726. The steamboat lines are mainly on the sounds and rivers of the east. In 1900 there were 45 steamboats, valued at $145,214. The foreign commerce of the state is not great. The ports are Wilmington, New Berne, Beaufort, and Edenton; but only the first two reported imports and exports in 1899, the total of imports being worth $145,260, and of exports, $7,590,381.

Finance.—The total assessed valuation of real and personal property, including transportation and telegraph lines, in 1900 was $287,339,288. The state tax rate was for the same year 25 cents on the $100 valuation for ordinary purposes, and 18 cents on the $100 for public schools. A poll-tax is collected which by the constitution is equal to the property-tax on $300 in cash. This poll-tax for state and county must not exceed $2, so that it is impossible for the state and county property-tax combined to be more than 66⅔ cents on each $100 valuation. The state debt in 1900 was $6,527,770.

Banks.—The statistics of banking in 1901 (except for national banks, for which the figures are for 1897), are as follows:—

Kind of Bank.	Capital.	Deposits.
National	$2,701,000	$5,462,497
State	2,578,643	7,083,784
Private	165,500	630,220
Savings banks	238,384	2,159,419

In 1900 there were 29 building and loan associations, of which 28 had their home office in the state, and 1 had it out of it.

Political Development.—From 1880 till 1894 the political control of the state was in the hands of the Democratic party. In 1892 the People's party was organized in the state. It was greatly helped by the feeling on the part of many of the farmers that the control of the old parties was manipulated against their interests. This party was defeated in 1892, but in 1894 it made a combination with the Republicans which carried the state. Two United States senators were to be elected, and by previous agreement each of the victors elected one. In 1898 the Democrats made the election issue the opposition to negro office-holders. They were able to do this because their opponents had not been able to withstand the pressure from within their own ranks, and in some cases had appointed negroes to minor political offices. After a bitter campaign, in which a great deal of race feeling was aroused, the Democrats regained control of the legislature. So great was the feeling on the race question that the party was impelled to propose an amendment to the state constitution, the purport of which was to disfranchize the negro voters. This amendment provided (1) that every voter shall be able to read and write a section of the constitution and shall have paid his poll-tax, and (2) that no male person who was a qualified voter in 1867, and no lineal descendant of the same, shall be denied the franchise because of inability to read and write, provided he shall be duly registered by 1st November 1908. The latter clause was inserted confessedly because it was believed that without some such guarantee it would be impossible to carry the illiterate white voters for the measure. The amendment, which eliminated about half of the negro vote, was submitted to the people 2nd August 1900, and carried by a majority of 60,000, after a hotly conducted campaign in which there was not wanting a certain amount of force to terrorize the negro voters.

North Dakota, one of the north-western group of states of the American Union, lies between 96° 25′ and 104° W. and 45° 55′ and 49° N. It has an extreme length east and west of 360 miles, an extreme width north and south of 210 miles, and an area of 70,795 square miles. Its vast expanse of level or rolling prairies is well supplied with surface water by several river systems and numerous small lakes. The most important rivers are the Red River of the North along the eastern border of the state, the Missouri in the western portion, and the Sheyenne and James in the central portion. The surface features of the state may in a general way be classified as follows: plains of the Red river valley, highlands of the Pembina and Turtle mountains, the rolling prairies of the central region, and the western Coteau of the Missouri. The uniformly level character of its surface, the absence of uplifts, and the lack of deep erosion over the greater part of the state have given it no very marked geological features. The formations occurring include rocks of the Archæan, Cambrian, Silurian, Cretaceous, and Tertiary ages, as well as Glacial drift and alluvial deposits. The Dakota sandstone of the Cretaceous group is especially important as being the water-bearing stratum of the Great Artesian belt, occupying a large part of the state. Many of the clay deposits of the Cretaceous and Tertiary formations, particularly those near Dickinson, Stark county, are remarkably pure, and are utilized in the manufacture of excellent fire and pressed brick. To the same formations belong the immense beds of lignite coal extending west of the Missouri river, from north of the Great Northern Railway into South Dakota. In portions of the Red river valley the drift and alluvial deposits attain a depth of 300 feet, giving a remarkably strong subsoil and a deep and rich upper soil of black vegetable mould. These deposits thin out westwards, with the gradually increasing altitude, till the high rolling prairies of the central portion of the state are reached.

Flora and Fauna.—Except along river banks, a few isolated lakes, and over a small area in the Pembina and Turtle mountain regions, the moisture has been insufficient for the growth of forest trees. There are nine or ten principal varieties of trees and about twenty different varieties of shrubs in the state, and over one hundred varieties of prairie grasses and forage plants. With the advent of the herdsman and farmer, the bison, which formerly roamed these prairies in vast numbers, have vanished, and the scattered elk, antelope, mountain sheep, and deer are rapidly disappearing. The brown and, very rarely, the grizzly bears, the prairie and timber wolves, the mountain lion, lynx, prairie dog, and rattlesnake are still found in the "bad lands" in the south-western part. Among the few remaining fur-bearing animals are the otter, mink, beaver, badger, and raccoon. The gopher or spermophile, by its ubiquity, has given to the state the sobriquet "Flickertail." Grouse, prairie chicken, geese, ducks, and swans furnish excellent hunting in their season.

Climate.—The climate is remarkably dry, cool, and invigorating. The temperature occasionally rises to 95° F. in summer, and occasionally falls to −40° in winter, but neither the exceptional heat of summer nor the exceptional cold of winter entails the discomfort attending a similar range of temperature in more humid climates. The summer nights are always cool. The mean temperature at many signal stations in the state for July and January, the hottest and coldest months, during the years 1892–98 inclusive, was 68·9° and 3·7° F. respectively. The mean temperature for the year was 39°. The average precipitation is 17·23 inches a year, ranging from more than 20 inches in the extreme eastern part to less than 10 inches in the extreme western. Fully three-fourths of the precipitation occurs during the growing season (April to August inclusive), and is sufficient for successful dry farming as far west as the 100th meridian. Beyond that meridian, save in localities of exceptional rainfall, the country is better adapted to stock-raising than to agriculture.

Agriculture.—Agriculture is the leading industry in the eastern half of the state, as stock-raising is in the western half. In 1900 there were in the state 45,332 farms, containing altogether 15,542,640 acres, of which about 62 per cent. was improved land. The total value of farm property was $255,266,751, comprising land, improvements, and buildings, $198,780,700; implements and machinery, $14,055,560; and live stock, $42,430,491. The total value of farm products in the preceding year was $64,252,494. The

	Quantity or Number.	Value.
Indian corn	1,284,870 bushels	$397,278
Wheat	59,888,817 ,,	31,733,763
Oats	22,125,331 ,,	5,852,615
Barley	6,752,060 ,,	1,996,082
Rye	368,240 ,,	138,771
Flax-seed	7,766,610 ,,	7,735,640
Hay and forage	1,748,213 tons	5,182,917
Potatoes	2,257,350 bushels	587,498
Dairy cows	125,503	4,078,546
Other neat cattle	531,931	11,732,091
Horses	359,948	22,728,511
Mules and asses	6,976	489,597
Sheep (not including lambs)	451,437	1,605,730
Swine	191,798	930,470
Wool	3,030,478 lb	503,744
Milk, butter, and cheese	...	2,853,133
Animals sold	...	3,902,074
Animals slaughtered on farms	...	1,573,588

leading crops are wheat, oats, barley, flax, rye, corn, and potatoes. The most important crop is wheat. Spring wheat is grown exclusively, mostly of the Scottish Fife variety, and ranking as No. 1 Hard, the best grade known to the market. Apples, pears, and peaches are not grown to any extent, but all the small fruits, wild and domestic grasses, and all root crops are grown in great profusion and of excellent quality. The foregoing table shows the yield and estimated value of the leading crops for the year 1899, together with the number and estimated value of live stock and dairy products.

Manufactures and Mines.—The following table is a comparative summary of the manufacturing and mechanical industries as returned at the censuses of 1890 and 1900, with the percentage of increase :—

	1890.	1900.	Percentage of Increase.
Number of establishments	382	1,130	195·8
Capital	$2,894,553	$5,396,490	86·4
Wage - earners, average number . . .	1,499	2,398	60·0
Wages	$759,132	$1,222,472	61·0
Cost of material used .	$3,087,161	$5,615,793	81·9
Value of products . .	$5,028,107	$9,183,114	82·6

The principal products are those of flour and grist mills. While manufacturing is increasing, agriculture and stock-raising are still the principal industries. The western half of North Dakota is largely underlaid with lignite coal of a superior quality. The mining of this coal, from comparatively recent beginnings, is rapidly becoming an important industry. It is expected that it will soon become the chief source of fuel supply.

Charitable and Penal Institutions.—The state maintains the following charitable and penal institutions :—The state asylum for the insane, and school for the feeble-minded at Jamestown (inmates, 24th April 1902, 413 ; 231 males, 182 females) ; the school for the deaf at Devils Lake (attendance, 1st January 1902, 57—males 31, females 26 pupils) ; soldiers' home at Lisbon (number of inmates, 1902, 36) ; the state penitentiary at Bismarck (inmates, 1st January 1902, 122 males, 1 female).

Religion.—The chief religious denominations are the Baptists, Roman Catholics, Congregationalists, Lutherans, Methodists, Presbyterians, and Episcopalians. These denominations all have substantial church homes and a large membership in all the important towns. The following statistics are for the year 1901 :—

Denomination.	Organizations.	Edifices.	Value of Church Property.	Membership.
Baptists . . .	67	48	$122,800	3,493
Roman Catholics . .	121	121	171,550[1]	26,427[1]
Congregationalists .	104	62	150,000	3,450
Episcopalians . .	35	41	101,647	1,932
Lutherans[2] . . .	237	244	136,275[1]	43,603
Methodists . . .	215	180	335,000	5,655
Presbyterians . .	115	100	175,000	4,179

In the Roman Catholic and Lutheran churches all persons who have been baptized are counted as members.

Education.—There were, on 30th June 1900, 77,680 pupils enrolled in the public schools of the state, with 4083 teachers, and school property, not including lands, valued at $2,587,865. The census of 1890 showed the percentage of illiteracy to be 4·9 for males ten years of age and over, and 7·4 for females. The census of 1900 showed the percentage of illiteracy of males over twenty-one years of age to be 3·8 for the native-born and 6·6 for the foreign-born. The state maintains a state university and school of mines at Grand Forks ; an agricultural college and school of mechanic arts at Fargo ; three normal schools, at Mayville, University, and Valley City respectively ; an industrial school at Ellendale ; and a school for the deaf at Devils Lake. There are about 110 teachers employed in these schools, with more than 2000 pupils in attendance. All grades of public instruction are closely articulated under the supervision of a Board of Commissioners, consisting of the governor, superintendent of public instruction, and the president of the state university. One-eighteenth of all lands (aggregating 2,531,200 acres) was early set aside for the use of the common schools, while grants ranging from 20,000 to 130,000 acres each were made to the state educational institutions. None of these lands may be sold for less than $10 an acre, the proceeds to constitute a perpetual fund, whose integrity is guaranteed by the state for the use of these schools.

[1] Census of 1890.

[2] Norwegian and Swedish Lutherans. In addition to these there are about 13,000 Danish, English, German, and Icelandic Lutherans.

Transportation.—There were, in 1899, 2866 miles of railway in the state, including sidings. The Great Northern, Northern Pacific and St Paul, Minneapolis, and Sault Ste Marie are the leading railways, the two former crossing the state from east to west near the lines of the 47th and 48th parallels respectively on their way to the Pacific coast, and the latter crossing the state diagonally from the south-east to north-west and connecting with a branch of the Canadian Pacific at the international boundary line. The Chicago, Milwaukee, and St Paul and the Chicago and North-Western railways both have short branch lines in the southern part of the state. The Bismarck, Washburn, and Great Falls Railway has been constructed for a distance of about 40 miles north from Bismarck.

The Red River of the North is navigable as far south as Fargo, although boats do not ordinarily go south of Grand Forks. The Missouri river is navigable throughout its entire course in the state.

Finances.—The assessed valuation in 1901 was $124,115,341 (real estate, $77,858,024 ; personal property, $27,739,423 ; railways, $17,983,367 ; express companies, $139,220 ; telephone companies, $108,017 ; telegraph companies, $287,290), representing an actual value of approximately $400,000,000. The bonded indebtedness, 1st January 1900, was $845,300. The constitution limits the bonded indebtedness of the state to $200,000 additional to North Dakota's share of the bonded indebtedness of Dakota territory. The tax rate for state purposes is limited by the constitution to four mills on the dollar of the assessed valuation of the state. This rate, on the basis of the assessment of March 1902, yields an income of about half a million dollars a year.

Banks.—There were, 1st January 1900, 23 national banks, with a paid-up capital of $1,450,000 and a surplus of $194,900, and deposits (7th September 1899) of $5,000,186 ; 169 state banks (1902) with a paid-up capital of $1,641,000 and deposits of $9,391,594. Recent legislation has forced all private banks to take out charters as state banks.

Population.—The population in 1880 of that part of Dakota territory embraced in the present state of North Dakota was 36,909 ($\frac{5}{10}$ to the square mile) ; the population in 1890 was 182,719 ($2\frac{5}{10}$ to the square mile) ; and in 1900 it was 319,146 ($4\frac{5}{10}$ to the square mile), showing an increase for the decade of 74·7 per cent. Of the population in 1890, 101,590 were males, 81,129 females ; 101,258 native-born, 81,461 foreign-born ; 7980 Indians, 373 negroes. Of the population in 1900, 177,493 were males, 141,653 females ; 206,055 were native-born, 113,091 foreign-born ; 311,712 were white, 286 negroes, 180 Chinese and Japanese, 6968 Indians. Fargo (population in 1900, 9589) and Grand Forks (population in 1900, 7652), the leading towns, are the centres of a large wholesale and retail trade. Bismarck, the capital (population in 1900, 3319), is situated near the centre of the state, at the junction of the Northern Pacific Railway with the Missouri river.

History.—Dakota was a part of the Louisiana purchase of 1803. It was organized as an independent territory in 1861. The territory was divided by Act of Congress, 22nd February 1889, and North Dakota admitted as a state 2nd November of the same year. In politics the state has been uniformly Republican, except in 1892, when it was carried by the combined Democrats and Populists by a plurality on the Presidential ticket of 181. (W. Me.)

North-Eastern Rhodesia. See Central Africa, British.

Northeim, a town of Prussia, province of Hanover, 12 miles by rail north of Göttingen. It has an interesting church (1519), containing old wood-carving and stained glass. The place is said to date from the 9th century, was a member of the Hanseatic League, and was stormed by the Imperialists in 1627. There are tobacco, sugar, and boot manufactures, besides flour-milling, tanning, and brewing. Population (1900), 7833.

North Plainfield, a borough of Somerset county, New Jersey, U.S.A., in the northern part of the state. It was organized from a part of North Plainfield township. Population (1900), 5009, of whom 749 were foreign-born and 182 negroes.

North Sea.—The North Sea is bounded on the E. by the continent of Europe and on the W. by Great Britain. At its southern end it communicates by the narrow Strait of Dover with the English Channel, and so with the Atlantic, and towards the north it widens out gradually to 345 miles between St Abb's Head and the coast of Denmark, and narrows

Position and boundaries.

again to 270 miles between Duncansby Head and the coast of Norway. To the north of Scotland it communicates with the Atlantic westwards by the Pentland Firth and the channel between the Orkney and Shetland Islands, and northwards with the Norwegian Sea.

Area and relief.

Its total area is given by Murray as 162,600 square miles, and by Krümmel as 547,623 square kilometres, or 159,131 square miles. Murray estimates the volume of the North Sea at 11,200 cubic miles, and Krümmel at 48,718 cubic kilometres or 7634 cubic miles, giving mean depths of 61 and 48 fathoms respectively. The North Sea is thus on the whole shallow; its bed is part of the continental shelf on which the British Isles stand, and it slopes upwards with fair regularity from north to south. In the south and east there is a broad coastal strip over which the depth nowhere exceeds 20 fathoms, and the whole south-eastern part of the area is less than 30 fathoms deep. In about its middle latitude the Dogger Bank crosses the North Sea from east to west, extending for about one-third of the whole distance; near the English coast the depth here is under 10 fathoms, and it increases eastwards to about 20 fathoms. South of the Dogger there are local depressions, mostly of small area, in which the depth is as much as 45 fathoms, as in the "Silver Pit." Krümmel points out that a line drawn from the northern edge of the Dogger to the middle of the Skagerrack constitutes a rough boundary of the shallow southern basin, the depth increasing very slowly beyond this line to the "Norwegian Channel"—a deep gully closely following the Scandinavian coast, and extending into the Skagerrack, in which the depth increases to as much as 400 fathoms.

History.

According to Jukes-Browne, the North Sea, in its present form, first took shape as a result of the tectonic movements indicated by the break between the older and newer Pliocene deposits. The southern end of the North Sea was probably little affected by the general subsidence which occurred during the Glacial period; its boundary in this direction was apparently within the present land area of France and Belgium, while a narrow inlet may have run westwards between France and England in the present position of the Strait of Dover. Meanwhile immense quantities of ice detritus from Scotland and Scandinavia were deposited in the North Sea, to a thickness of perhaps 600 feet, and the whole region was subsequently raised above sea-level, constituting the "structural surface" upon which the present river system was developed as a series of tributaries to a great river which formed a continuation of the Rhine. Finally, the land subsided again, the plain of the North Sea was again submerged, and the western inlet of Pleistocene times became the Strait of Dover.

Coasts.

For reasons which will be sufficiently obvious from the historical sketch just given, the coasts of the southern part of the North Sea are of no great height. In England they consist of low cliffs with sandy beaches, while on the Continental side are immense flats and marshes, with parts below sea-level protected by sand-dunes and artificial dykes. Suess has shown that no evidence is forthcoming of tectonic movement since the Bronze Age, and the rapid changes of coast-line now taking place in many parts are therefore wholly due to the action of the sea, which is probably specially effective on account of the relatively recent opening of the Strait of Dover. The erosion of the North Sea coasts has been made a subject of minute study (in England especially by the British Association), and recently Harmer has obtained interesting results by comparing the British and Continental coasts as characteristic "weather" and "lee" shores.

Circulation.

The physical conditions of the waters of the North Sea have been extensively studied by expeditions sent out by the Swedish, Norwegian, Danish, German, and British Governments. Professor Pettersson of Stockholm, to whose initiative much of this work is due, classifies the waters found in the North Sea as follows:—(1) oceanic water of 35 *pro mille* salinity or more; (2) water of salinity 34 to 35 *pro mille*, called "North Sea" water; (3) water of salinity 32 to 34 *pro mille*, found along the coasts of Holland, Germany, Denmark, and Norway, and called "bank-water"; (4) water of 32 *pro mille* salinity or less, belonging to the stream flowing out from the Baltic. Of these (1) and (4) are to be regarded as "in-flowing" waters, while the others are due to mixture, which may or may not take place in the North Sea itself. The oceanic water consists of a mixture of waters of Atlantic and Polar origin; it enters the North Sea from the north-west, and makes its way southwards along the coast of Scotland, especially during the summer months. Dr Fulton, scientific adviser of the Scottish Fishery Board, has, by using floats or "drifters," traced a movement of water southwards along the English coast as far as the Wash, and thence in an east-north-east direction towards the coast of Denmark. The supply of water from the Baltic varies with the seasons (see BALTIC SEA).

Apart from its effect on the quantity and composition of the inflowing waters, the mixing and circulation in the North Sea are almost wholly under the control of the winds. Dickson has shown that (*a*) calm weather favours the spreading of a thin layer of "North Sea" water over a great part of the surface; (*b*) strong northerly winds tend to broaden the area covered by oceanic water, and to drive back the fresher out-flowing waters—an important effect of this is to send "bank-water" southwards along the west coast of Norway; (*c*) westerly and south-westerly winds tend to form a continuous band of oceanic water along the central axis of the North Sea, and there is strong upwelling of water along the British coasts; and (*d*) easterly winds reduce the salinity as a whole by spreading the fresher waters over the surface. The distribution and circulation are therefore liable to great variations at different seasons and in different years.

Tides.

The tides of the North Sea are of great complexity, and have not as yet been fully investigated. The tidal wave of the Atlantic enters by the Strait of Dover and by the channels in the north. In the latter place a division into two parts takes place, one wave travelling southwards along the coast of Scotland in comparatively shallow water, while another moves with greater speed across the deeper water to the Norwegian Channel, and thence southwards to the Skagerrack and the Danish coast. The southwards-moving waves are greatly retarded in the shallow water over the Dogger Bank; the trough of the "Silver Pit," accordingly, gives the Scottish wave a strong easterly component, and the three systems—the Scottish, Norwegian, and Channel waves—meet to the east of the Dogger, producing complicated interference phenomena. Along the English coasts the tidal streams are for the most part normal, the flood stream running south to south-east and the ebb north to north-west, but on the Continental coast the movements become very complex, on account of the varying influence of the waves from different sources.

Fauna.

The North Sea is particularly rich in organisms of all kinds, and the abundance of food attracts fish in such quantities that the North Sea fisheries are the most productive in the world. Flat fishes, and those feeding at the bottom on smooth ground, are chiefly caught by means of the trawl. The favourite trawling-grounds are the Dogger Bank in winter, and the shallow waters off the Continental coasts in summer; these yield halibut, soles, turbot, brill, plaice, cod, haddock, whiting, &c. In rough ground where the trawl cannot be used, hook- and line-fishing are carried on most successfully, and "mid-water" fish are also taken in this way, although the trawl and line-fishing overlap considerably. Herring and mackerel are caught by means of drift-nets. The herring fishing off the British coasts exhibits a remarkable variation during summer and autumn, beginning in Shetland in June, and becoming progressively later southwards, until it ends off the Norfolk coast in November. Various attempts have been made to connect this succession with the physical changes already described, especially with the periodic influx of Atlantic water, but no very definite relation has as yet been established.

North Sea and Baltic Canal. See CANALS.

North Tonawanda, a city of Niagara county, New York, U.S.A., on the Niagara river, at the mouth of Tonawanda creek, in the western part of the state. It is entered by three railways, and has had a rapid growth, aided by the development of power at Niagara Falls. Population (1890), 4793; (1900), 9069, of whom 2402 were foreign-born.

Northumberland, a northern maritime county of England, on the Scottish border, bounded on the E.

by the North Sea, on the S. by Durham, on the W. by Cumberland, and on the N.W. by Roxburgh and Berwick.

Area and Population.—The area of the ancient county is 1,289,756 acres, or 2015 square miles, with a population in 1881 of 433,711, in 1891 of 506,030, of whom 252,283 were males and 253,747 females, and in 1901 of 602,859, the number of persons per square mile being 299, and of acres to a person 2·14. The area of the administrative county (including the county borough of Newcastle-on-Tyne) and the area of the registration county are identical with that of the ancient county. Of the population in 1891, 360,000 were urban and 145,230 rural. The increase of population between 1881 and 1891 was 17·01 per cent., and between 1891 and 1901, 19·1 per cent. Between 1881 and 1891 the excess of births over deaths was 66,340, but this was exceeded by the increase of the population, which was 72,319. The following table gives the numbers of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898 :—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	3428	15,204	9,032	469	447
1890	4314	16,553	10,239	379	384
1898	5028	18,326	11,169	358	358

The number of marriages in 1899 was 5112, of births 19,123, and of deaths 11,474.

The following table gives the marriage-, birth-, and death-rates, with the percentage of illegitimate births, for a series of years :—

	1870–79.	1880.	1880–89.	1890.	1888–97.	1898.
Marriage-rate .	18·7	15·9	15·9	17·2	16·1	17·8
Birth-rate . .	38·3	35·2	34·3	33·0	32·7	32·5
Death-rate . .	22·9	20·9	19·9	20·5	19·1	19·8
Percentage of illegitimacy . .	5·9	6·0	5·3	4·6	4·5	3·9

Both the birth-rate and the death-rate are above the average. In 1891 there were in the county 26,155 natives of Scotland, 10,414 natives of Ireland, and 3686 foreigners.

Constitution and Government.—The county is divided into four parliamentary divisions, and it also includes the parliamentary boroughs of Newcastle-on-Tyne, returning two members, and of Morpeth and Tynemouth, returning one member each. It contains four municipal boroughs: Berwick-on-Tweed (13,437), Morpeth (6158), Newcastle-on-Tyne (214,803), and Tynemouth (51,514). Newcastle-on-Tyne is a county borough. The following are urban districts: Alnwick (6716), Amble (4426), Ashington (13,956), Bedlingtonshire (18,768), Benwell and Fenham (18,347), Brackley (2467), Cowpen (17,803), Cramlington (6437), Earsdon (9190), Gosforth (10,605), Hexham (7071), Newbiggin-by-the-Sea (2022), Newburn (12,503), Rothbury (1303), Seghill (2213), South Blyth (5472), Walker (13,335), Wallsend (20,932), Weetslade (5453), Whitley and Monkseaton (7705), and Wellington Quay (8046). The county is in the north-eastern circuit, and assizes are held at Newcastle-on-Tyne. The boroughs of Berwick-on-Tweed and Newcastle-on-Tyne have separate courts of quarter sessions and separate commissions of the peace, and the borough of Tynemouth has only a separate commission of the peace. The ancient county—which is in the diocese of Newcastle-on-Tyne—contains 159 entire ecclesiastical parishes or districts.

Education.—In Newcastle-on-Tyne are the Durham College of Medicine and the Durham College of Science. In connexion with the College of Science there is a day training college for schoolmasters and schoolmistresses. In Newcastle-on-Tyne is also the Northern Counties Institution for the Deaf, and at Benwell the Royal Victorial School for the Blind. The total number of elementary schools on 31st August 1899 was 349, of which 79 were board and 270 voluntary schools, the latter including 179 National Church of England schools, 1 Wesleyan, 28 Roman Catholic, and 62 "British and other." The average attendance at board schools was 37,117, and at voluntary schools 45,468. The total school board receipts for the year ended 29th September 1899 were £152,399. The income under the Technical Instruction Act was £616, and that under the Agricultural Rates Act was over £1214.

Agriculture.—Only about five-ninths of the total area is under cultivation, and of this nearly five-sevenths is in permanent pasture. There are also about 470,000 acres under hill pasture, and about 50,000 acres under woods. Northumberland is one of the largest sheep-rearing counties in Great Britain, being much on a par with Argyll, and exceeded only by Lincoln and Yorkshire. Cattle are also very largely raised, chiefly for fattening purposes. The bulk of the acreage under corn crops, which has greatly diminished, is under oats and barley, and turnips occupy as much as five-sixths of the area under green crops, potatoes occupying only about a tenth. The following table gives the principal divisions of the cultivated area at intervals from 1880 :—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	704,778	130,743	56,096	85,662	417,184	15,080
1885	714,432	118,565	53,383	90,731	440,269	11,476
1890	717,698	106,610	50,916	92,743	458,803	8,221
1895	707,407	92,860	47,617	84,792	476,182	5,436
1900	707,486	88,527	45,889	76,657	492,160	3,681

The following table gives the numbers of the principal live stock for the same years :—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	18,052	92,927	19,964	930,393	10,428
1885	17,889	107,300	25,197	935,874	13,244
1890	17,505	104,953	25,067	1,002,928	14,277
1895	18,723	108,022	25,010	1,000,038	13,377
1900	17,449	113,724	26,518	1,065,206	10,250

Industries and Trade.—According to the report for 1898 of the chief inspector of factories (1900), the total number of persons employed in 1897 in factories and workshops was 56,394, as compared with 56,208 in 1896. The number employed in non-textile factories was 48,753, there being an increase between 1895 and 1896 of 17·3 per cent., and between 1896 and 1897 of 0·6 per cent. As many as 30,467 were employed in the manufacture of machines, appliances, conveyances, and tools, chiefly in the shipbuilding yards and ironworks on the north bank of the Tyne, from Newcastle to the sea, 4742 in the founding and conversion of metal, 1744 in clay and stone industries, 2115 in the manufacture of paper, &c., and 1634 in the manufacture of chemicals, most of the other classified industries being also represented. Of the 7334 persons employed in workshops 3809 were employed in clothing industries. The total number of persons employed in connexion with mines and quarries in 1899 was 39,388. In the same year 302,546 tons of clay were raised, 108,682 tons of igneous rocks, 132,462 tons of sandstone, and 103,528 tons of limestone. No iron ore is dug, but some pig-iron is made at Elswick. Lead has almost ceased to be raised. The following table gives particulars regarding the more valuable minerals in 1890 and 1899 :—

Year.	Barytes.		Fireclay.		Coal.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.
1890	6486	£12,972	183,759	£25,267	6,751,308	£2,503,610
1899	7309	£14,618	185,266	£27,790	11,184,072	£3,946,579

In 1899 there was landed 343,136 cwt. of fish (more than two-thirds at North Shields), valued at £253,800.

Northumberland Strait, the strait separating Prince Edward Island from Nova Scotia and New Brunswick.

North-Western Rhodesia.—See Central Africa, British.

North-West Frontier Province, The, a new province of British India, constituted on 9th November 1901, and placed under a Chief Commissioner and Agent to the Governor-General. It was formed by separating from the Punjab two entire districts (Peshawar and Kohat) and portions of three more (Bannu, Dera Ismail Khan, and Hazara) lying mainly beyond the Indus, together with the political charge of a large area occupied by frontier tribes extending from Baluchistan to Chitral.

The capital is at Peshawar. The total area of the districts under British administration is 13,197 square miles, with a population (1901) of 2,044,000. The cultivated area is 2,559,000 acres, of which 717,000 are irrigated from canals. The land revenue is Rs.21,56,000, and the total expenditure is estimated at Rs.67,83,824.

North-Western Provinces and Oudh, formerly the name of a province of British India, under the administration of a lieutenant-governor. It comprises two native states — Garhwal amid the Himalaya, and Rampur in the centre of Rohilkhand. Total area, 112,612 square miles; population (1891), 47,697,576; (1901), 48,545,999. The capital is Allahabad. The title of the province had long been a misnomer. After the creation of the North-West Frontier province in 1901, it was resolved to change the name to The United Provinces of Agra and Oudh.

The following table gives the area and population of the several divisions and districts of the North-Western Provinces and Oudh, together with the two native states, in 1891 and 1901 :—

Area and Population of the North-Western Provinces and Oudh (1891 and 1901).

Divisions.	Districts.	Area in Square Miles.	Number of Towns and Villages.	Population, 1891.	Population, 1901.			Density of Population to Square Mile.

[1] Between the census of 1891 and the census of 1901 the districts of Kumaun and Tarai were redistributed, two new districts, Almora and Naini Tal, being organized out of them.

[2] The population of the former district of Lalitpur is enumerated under Jhansi in the 1901 census.

Area and Population of the North-Western Provinces and Oudh (1891 and 1901)—continued.

Since 1891 the population has increased by little more than 1·6 per cent., which is much below the rate of increase for India generally. In the central Doab there is an actual decrease, while the highest rates of increase are to be found in the Himalayan districts and in the submontane tracts, where waste land is still available for tillage. Elsewhere, it may almost be said that population has reached the stationary stage. It is noteworthy that the urban population, which forms 12 per cent. of the total, has increased at a slower rate than the population generally. The density of population is greatest in the east, where the conditions approximate to those of Behar. The purely agricultural districts of Azamgarh and Ballia each support more than 800 persons per square mile. For Oudh alone the average density is 557 persons per square mile. In Bundelkhand (Allahabad) it falls to less than half, and in the Himalayan districts to only 85 persons per square mile.

Classified according to religion, and excluding native states, Hindus in 1891 numbered 40,413,250, or 86 per cent. of the total population. They were slightly more numerous, in proportion to Mahommedans, in Oudh than in the North-West proper; and it is noteworthy that they have increased somewhat faster than the Mahommedans, which is contrary to the experience of India generally. Mahommedans numbered 6,346,710, or 13 per cent., being proportionately most numerous in Rohilkhand, where they formed 23 per cent. of the population. Christians numbered 58,441, or ·1 per cent., of whom 27,995 were Europeans and 7040 Eurasians, leaving 23,406 for native converts, who were proportionately most numerous in the Himalayan districts and in Rohilkhand. Jains (including Buddhists) numbered 85,988, or ·2 per cent, being most numerous in Meerut, Agra, and Jhansi. "Others," chiefly Sikhs, Parsis, and Jews, numbered 696. The census for the North-Western Provinces ignores aboriginal tribes.

In the North-West proper, out of a total area of 52,597,361 acres, 6,159,711 acres were included under the Bengal permanent settlement, the incidence of assessment being nearly 15 annas per acre. On the temporarily settled tract, where the assessment is liable to revision every thirty years, the incidence is R.1 : 2 : 6 per acre. Similarly, in Oudh, out of a total area of 15,537,846 acres, the amount in five districts that has been granted in permanent settlement is 1,112,921 acres, on an average assessment of nearly 15 annas per acre; while the incidence on the temporarily settled portion is R.1 : 1 : 9 per acre. In 1896–97, in the North-West proper, the total cultivated area was 22,742,416 acres, of which 4,272,569 were cropped more than once. The irrigated area was 7,432,218 acres, of which 2,083,118 acres were watered from Government canals, and the rest from wells, &c. The principal crops are rice, wheat, barley, millet, pulse, maize, cotton, and sugar-cane. Indigo was grown on 413,724 acres, chiefly in the Doab; opium on 199,163 acres, chiefly in the permanently settled tract; tea on 7919 acres, in Dehra Dun and Kumaun. The Government canals are classified under the headings of (1) protective, (2) major works, and (3) minor works. The following table gives the financial results of the first two of these classes for 1897–98 :—

	Capital Outlay.	Total Receipts.	Working Expenses.	Interest.	Net Result.	Profit per cent.
Protective—	Rs.	Rs.	Rs.	Rs.	Rs.	
Betwa Canal	43,02,017	1,37,700	1,14,824	1,62,954	*−1,40,078*	*−3·26*
Major Works—						
Ganges Canal	2,99,43,303	43,51,132	11,51,384	11,25,955	20,73,793	6·92
Lower Ganges Canal	3,49,19,049	31,18,612	9,35,709	12,98,424	8,84,479	2·53
Agra Canal	95,31,879	9,74,061	2,42,961	3,54,115	3,76,985	3·95
Eastern Jumna Canal	38,54,711	16,65,275	3,52,985	1,44,349	11,67,941	30·29
Fatehpur Ganges Canal	24,00,670	...	...	70,482	*−70,482*	*−2·93*
Total	8,06,49,612	1,01,09,080	26,83,039	29,93,325	44,32,716	5·50

In the case of the minor works, on which interest is not charged, the net receipts amounted to Rs.1,66,990, being 5·58 per cent. on a capital outlay of Rs.29,90,331.

There are no great industries in the North-Western Provinces corresponding to the cotton of Bombay or the jute of Bengal. The chief manufacturing centre is Cawnpore, with 4 cotton mills, 1 woollen mill, 1 jute mill, and several large tanneries and leather factories. There are in all 6 cotton mills, with 1638 looms and 257,622 spindles, employing 7496 hands, of whom nearly all are male adults. The out-turn in 1897–98 was 26,746,853 ℔ of yarn, mostly between counts Nos. 10 and 20; and 3,042,991 ℔ of cloth, mostly grey goods. There are breweries at the hill stations, and also at Lucknow; and a large factory for refining sugar and distilling rum near Shahjahanpur. No coal-mines exist, nor any important iron-works. The province is well supplied with railways. The main line of the East Indian runs throughout south of the Ganges, which is bridged at Benares and Cawnpore. North of the river, the Oudh and Rohilkhand system connects with Bengal on the one hand and with the Punjab on the other. From Allahabad, Cawnpore, and Agra trade finds an outlet to the sea at Bombay as well as at Calcutta. In 1897–98 the total rail-borne traffic with other provinces amounted to 57,557,329 maunds (say, two million tons), valued at Rs.37,12,12,027. The principal imports are cotton goods, grain, salt, coal, metals, and railway materials. The principal exports are wheat, oil-seeds, hides, sugar, raw cotton, indigo, opium, and lac. In 1900–01 the total trade with other provinces by rail amounted to 75,765,863 maunds (2,783,000 tons) valued at Rs.43,73,99,947, and by river to 24,665,124 maunds (906,000 tons), valued at Rs.2,35,38,535. The frontier trade is registered with Nepal and with Tibet. In 1897–1898 the imports from Nepal were valued at Rs.59,54,383, of which nearly half was rice, other important articles being oil-seeds, *ghi*, timber, and drugs. The exports to Nepal were valued at Rs.33,32,331, of which more than two-thirds were cotton goods, other important articles being salt, sugar, and spices. The imports from Tibet were valued at Rs.6,34,949, chiefly wool, borax, and salt. The exports into Tibet were valued at Rs.7,84,830, mostly food-grains, with some sugar and cotton goods.

The administration of the North-Western Provinces is conducted by a lieutenant-governor, who is also chief commissioner of Oudh, with a chief secretary, 2 secretaries, and 3 under-secretaries. As in Bengal, there is no executive council; but there is a board of revenue, consisting of 2 members. For legislative purposes the lieutenant-governor has a council, first constituted in 1886 and augmented in 1893. It consists of 15 members, of whom not more than 7 may be officials. Of the remaining members, 6 are nominated on the recommendation of groups of municipalities and district boards, selected public associations, and the senate of Allahabad University. The whole of Oudh, and also the Kumaun division, rank as "non-regulation." Including Oudh, the number of divisions or commissionerships is 9, with 48 districts or independent charges under a collector or deputy commissioner. The total number of civil and revenue judges is 727, and of magistrates of all kinds 992. In 1898 the total strength of the police force was 24,888 officers and men, being 1 policeman to every 3673 of the population. In addition, the railway police numbered 783.

Since the reorganization of the Indian army in 1895, the North-Western Provinces and Oudh form part of the Bengal command, containing two first-class and the larger part of three second-class districts. The chief military stations are Meerut, Lucknow, Allahabad, and Bareilly. The volunteer force consists of 5 administrative battalions, with an enrolled strength in 1898 of 4301 men, of whom 372 were mounted.

The number of municipalities is 104, with an aggregate population of 3,267,308; of these, 7 have more than 100,000 inhabitants, and 10 between 50,000 and 100,000. In all but 6 of them the majority of the boards are elected by the ratepayers, who form about 2 per cent. of the municipal population. In the six largest towns the district magistrate is *ex-officio* chairman of the board, and elsewhere he is almost always elected to that office. Out of a total of 1608 municipal commissioners, 1229 are elected and 338 nominated; 315 are officials and 1293 non-officials; 1403 are Indians and 205 Europeans. In 1897–98 the aggregate municipal income was Rs.44,83,166, of which Rs.32,25,223 was derived from taxation, mainly from octroi. The average incidence of taxation was just under R.1 per head, but at both Naini Tal and Mussoorie it was more than Rs.5. The aggregate expenditure was Rs.44,86,884, of which Rs.9,90,127 was devoted to conservancy, Rs.6,43,578 to public safety, Rs.5,28,226 to water supply, Rs.3,92,785 to public works, Rs.1,81,087 to drainage, Rs.1,74,890 to hospitals, and Rs.1,45,436 to education. The aggregate debt outstanding was Rs.85,43,343. The average death-rate was 45·55 per thousand, compared with 37·69 in the preceding year.

The number of district boards is 44, composed of 1245 elected, 193 nominated, and 100 *ex-officio* members, of whom 63 are Europeans. In every case the magistrate of the district is chairman. In addition, there are 4 district committees, composed entirely of *ex-officio* and nominated members. These bodies, which were first constituted in 1883, possess no power of taxation, but administer certain funds made over to them by the Government. In 1897–98 their aggregate income was Rs.39,51,080, of which Rs.28,03,415 was derived from rates. Their aggregate expenditure was Rs.39,67,371, of which Rs.20,16,123 was devoted to public works, Rs.13,16,951 to education, and Rs.5,53,119 to dispensaries, vaccination, &c.

The following was the net revenue and expenditure of the North-Western Provinces and Oudh for 1897–98 (in tens of rupees), distributed under the three heads of imperial, provincial, and local:—Net revenue—Imperial, 5,068,159; provincial, 2,291,411; local, 824,411; total, 8,183,981. Net expenditure—Imperial, 586,682; provincial, 2,078,539; local, 1,037,283; total, 3,702,504.

The following table gives the gross revenue under five principal heads (in tens of rupees) for the two years 1887–88 and 1897–98:—

	1887–88. Rx.	1897–98. Rx.
Land	5,699,841	5,602,180
Stamps . . .	658,887	732,196
Excise . . .	557,241	451,496
Forests . . .	124,745	138,667
Assessed taxes . .	218,828	250,129

The following table gives the chief statistics of education in the North-Western Provinces and Oudh for the years 1886–87 and 1896–97:—

	1886–87.		1896–97.	
	Schools.	Pupils.	Schools.	Pupils.
Colleges . . .	18	1,311	29	2,435
Secondary schools .	620	66,579	500	59,172
Primary schools . .	5,322	181,473	6,292	216,273
Special schools . .	61	3,163	55	3,581
Private institutions .	6,866	77,055	5,630	71,511
Total . .	12,887	329,581	12,506	352,972

However these figures be looked at, they show little progress. If we compare the number of pupils with the estimated population of school-going age (15 per cent. of the total population), the proportion has remained stationary at 5 per cent. Taking girls alone, the number at school has risen in ten years from 13,242 to 15,461, and the proportion to the female population of school-going age from ·4 to ·5 per cent. In every respect the standard of education in the North-West falls far below that of India generally. But it should be said that a considerable improvement has recently been effected. The following table gives the expenditure on education for the same years, according to sources:—

	1886–87. Rs.	1896–97. Rs.
Provincial revenues .	5,36,902	6,20,410
Local funds . .	13,57,832	13,83,614
Municipal funds . .	75,567	1,06,091
Fees	3,30,010	7,66,235
Other sources . .	5,67,994	7,63,556
Total .	28,68,305	36,39,906

The total expenditure on education steadily increased. But the most notable feature was the large increase under fees, which more than doubled during the period. Altogether, the proportion of the total borne by public funds fell in ten years from 69 to 58 per cent., though it was still higher than for India generally. In secondary schools alone public funds contributed only 43 per cent. Collegiate education was stimulated by the foundation in 1887 of an independent university at Allahabad, whose examinations give a larger place to science than in the Calcutta university. During the five years ending 1896–97 the total number of students who matriculated was 3621, while 740 graduated B.A. and 108 M.A., and 183 passed examinations in law. At present there is no faculty of medicine.

The North-Western Provinces suffered severely from the famine of 1896–97. Distress first made itself felt in Bundelkhand in March 1896, and relief operations had to be continued until October 1897. Altogether 19 districts were officially recognized as famine-stricken, while in 18 more districts the distress was held to reach the point of scarcity. For several months more than one million persons were in receipt of relief, the maximum being 1,696,722 at the end of February 1897. The total expenditure incurred by Government was Rs.2,17,00,000, the daily cost of each person relieved being just over one anna (= one penny). The Famine Commission reported that the result was a "conspicuous success and a great administrative feat." During the twelve months ending September 1897 the mortality in the famine-stricken districts rose only to 39 per thousand, compared with a normal death-rate of 33 per thousand. The North-West was fortunate in almost entirely escaping the subsequent famine of 1899–1900; nor has it suffered from the plague in an epidemic form. Down to April 1899 the total number of deaths recorded from plague was only 117, but the disease has since taken a firmer hold of the eastern districts. (J. S. Co.)

North-West Territories.—Under this name are comprised the portion of the Labrador peninsula not included in Quebec or the Labrador coast strip, the Arctic islands between 62° W. and 141° W., and all that part of British North America which lies between Manitoba and Keewatin on the east, and British Columbia and Yukon on the west. It includes the districts of Ungava (see LABRADOR), Assiniboia, Alberta, Saskatchewan, Athabasca, Mackenzie, and Franklin. It formerly included Yukon also, but the latter was erected into a separate territory in 1898.

Physical features.

The Laurentian "plateau" occupies the greater portion of Ungava and Mackenzie and the eastern half of Athabasca. The most striking features are the innumerable lakes, with intervening rocky elevations, forest-clad if in the south, but usually bare or covered with moss and lichens in the north, forming the so-called "barren lands." In this area there are, in addition to the Laurentian rocks, outliers referred to the Cambrian as well as bands of Huronian rocks. Minerals of economic value are almost entirely confined to the latter, and, though undeveloped, include gold, iron, mica, phosphate, graphite, marble, and copper. The continental plain is bounded on the E. by the Laurentian plateau, and on the W. by the Rocky Mountains. It extends from the 49th parallel, where it has a width of about 800 miles, north-westward to the Arctic Ocean, where its width has diminished to about 300 miles. South of the North Saskatchewan it includes the prairie country of western Canada, an area of nearly 200,000 square miles; beyond it becomes a forest region with occasional tracts of prairie. East of the Missouri Coteau—a line of escarpment that crosses the 49th parallel in 103° 30′ W. long., and extends in a north-westerly direction to the North Saskatchewan—the general elevation is about 1600 feet; to the west it is about 3000 feet, and rises gradually to the foothills of the Rocky Mountains. With the exception of a belt of Cambro-Silurian, Silurian, and Devonian along the eastern and north-eastern border of the plain, it is underlain by Cretaceous and Tertiary rocks to the Peace river; beyond the latter the Devonian rocks occupy the greater portion of the area and continue to the Arctic, there forming a great part of the northern archipelago. There are immense beds of bituminous and lignite coals in the Cretaceous; natural gas has been found in large quantities in the Devonian, and extensive outcrops of sandstone saturated with tar evidence the existence of very large deposits of petroleum. The Rocky Mountains extend, with a width seldom exceeding 60 miles, in a north-westerly direction from the international boundary to the Arctic. They are composed of a series of roughly parallel mountain ridges of Cambrian quartzites and slates, and Carboniferous and Devonian limestones. They are, as a rule, forest-clad, the growth being more luxuriant on the western slopes, and have, in the southern portion, several summits exceeding 11,000 feet, notably Robson peak, 13,700; Athabasca, 13,500; Assiniboine, 11,830; Freshfield, 12,000; Victoria, 11,250; Lefroy, 11,080; Alberta, 13,000; Lyell, 12,000; Mummery, 12,000; Temple, 11,658; and Geikie, 11,000; also Brown, 9050.

Rivers.

The principal river is the Mackenzie, 2350 miles long, including its great tributary the Peace; the Athabasca, 740 miles long; the Liard, 650 miles long. Other important tributaries of the Mackenzie are the Hay, Nahanni, Dahadinni, Arctic Red, Peel, and Great Bear rivers. The Anderson, Coppermine (475 miles long), and Backs river (560 miles) also discharge into the Arctic; the Dubawnt (660 miles) into Chesterfield inlet; the Churchill (925 miles) and the Nelson (1450 miles long), including its great tributary the Saskatchewan, into Hudson Bay.

Lakes.

The principal lakes in Saskatchewan are Cedar, Moose, Playgreen, an expansion of the Nelson, La Plonge, and the northern portion of Winnipegosis; in Athabasca, Reindeer, with an area of 2490 square miles, and 1150 feet above the sea; Wollaston, area 900 square miles, and altitude, 1300 feet; Athabasca, 3085 square miles, and 690 feet above the sea; Clair, La Ronge, Lesser Slave, and Ile a la Crosse, altitude, 1330 feet: in Mackenzie, Kasba, 1270 feet; Dubawnt, 500 feet, and an area of 1700 square miles; Pelly, Aylmer, Clinton-Colden, Great Slave, 9770 square miles, and altitude 520 feet, and Great Bear, 11,200 square miles, and 340 feet above the sea.

Climate.

The salient features of the climate of the southern Territories are a bright, dry, and bracing atmosphere, cold winters and warm summers, with a small rainfall and snowfall. In the northern Territories a short, hot summer is followed by a long cold winter with extremely low temperatures. The percentage of bright sunshine at Battleford is 42 per cent., and at Winnipeg 46 per cent. The table below gives the average temperature and precipitation at a number of stations in the Territories:—

	Elevation.	Mean Temperature.		Average Precipitation.
		Summer.	Winter.	
	Feet.	Degrees.	Degrees.	Inches.

Flora.

The broad and level or rolling plains of Assiniboia and southern Alberta are, with the exception of the river valleys and more undulating lands, almost treeless. Saskatchewan, Athabasca, southern Mackenzie, and northern Alberta are traversed by a belt of forest varying from 550 to 800 miles wide, and including an area of about 1,500,000 square miles. The principal trees are Banksian pine (*Pinus banksiana*), white spruce (*Picea alba*), black spruce (*Picea nigra*), tamarack (*Larix americana*), aspen poplar (*Populus tremuloides*), balsam poplar (*Populus balsamifera*), and paper birch (*Betula papyrifera*). The principal trees of the Rocky Mountains are aspen and balsam poplars, white spruce, Engelmann's spruce (*Picea engelm.*), mountain balsam (*Abies subalpina*), Douglas fir (*Pseudotsuga douglasii*), Rocky Mountain pine (*Pinus flexilis*), black pine (*Pinus murrayana*), and mountain larch (*Larix lyallii*).

Area and population.

In 1895 the unorganized portion of the North-West Territories was divided into the districts of Ungava, Mackenzie, and Franklin, and the eastern boundary of Athabasca was shifted eastwards from approximate 111° 38′ W. to 100° W. In 1898 the district of Yukon was constituted a separate territory.

Ungava comprises the whole of the Labrador peninsula north of Quebec, and west of the Labrador coast strip, and has an area of 347,000 square miles.

Assiniboia (89,535 square miles) is bounded on the E. by Manitoba, on the S. by the states of North Dakota and Montana, on the W. by Alberta, and on the N. by Saskatchewan. The principal towns are:—Regina (population, 2645), the capital of the Territories; Broadview, Moosejaw, Swift Current, Medicine Hat, Moosomin, Yorkton, Estevan, and Qu'Appelle.

Alberta (106,100 square miles) is bounded on the E. by Assiniboia and Saskatchewan, on the S. by the state of Montana, on the W. by the summit of the Rocky Mountains, and on the N. by Athabasca. The principal towns are Calgary (population, 4152); Edmonton (2626), the distributing point for the country drained by the Athabasca, Peace, and Mackenzie rivers, and, till the construction of the White Pass and Yukon Railway, the most northerly railway station in America; Lethbridge (2279), with its coal mines and at the junction of a railway from Great Falls, Mon., with the Crow Nest Pass line of the Canadian Pacific; Macleod, at the junction of the last-named line with a branch from Calgary and in a fine ranching district; Red Deer, in the midst of an excellent farming district, and Banff, in the Rocky Mountains, with its national park and famous hot springs.

Saskatchewan (107,090 square miles) is bounded on the E. and S.E. by the Nelson river, Lake Winnipeg, and Manitoba, on the S. by Assiniboia, on the W. by Alberta, and on the N. by Athabasca and Keewatin. The principal towns are Prince Albert (population, 2193), on the right bank of the North Saskatchewan, and the terminus of a branch of the Canadian Pacific, Battleford, Carlton, and Saskatoon.

Athabasca (245,740 square miles) is bounded on the E. by Keewatin, on the S. by Saskatchewan and Alberta, on the W. by British Columbia, and on the N. by Mackenzie. There are small settlements at Dunvegan, in the valley of the Peace; Chipewyan, on Lake Athabasca, and the see of a Roman Catholic bishop; Peace River Landing and Lesser Slave. There are also several Hudson Bay Company's posts; Lesser Slave, at the head of Lesser Slave Lake, Stanley, Vermilion, McKay, Ile a la Crosse, and Brochet.

Mackenzie (530,000 square miles) is bounded on the N. by the Arctic Ocean, on the E. by Keewatin, on the S. by Athabasca and British Columbia, and on the W. and S.W. by Yukon territory.

Fort Smith is on the Slave river at the first interruption to navigation from the Arctic Ocean, Resolution and Rae on Great Slave Lake, Providence, Simpson, Norman, Wrigley, and Good Hope on the Mackenzie, and M'Pherson on Peel river, the most northerly civilized community in British North America.

Franklin (approximately 590,000 square miles) includes all the Arctic islands of British North America and Boothia and Melville (26,000 square miles) peninsulas. The larger islands and "lands," with their approximate areas, are Baffin Land, 230,000 square miles (including Cockburn Land); North Devon, 22,000; Ellesmere Land, 18,000; Grinnell Land, 86,000; North Somerset, 10,000; Prince of Wales Land, 15,800; King William Land, 6000; Prince Albert Land, Victoria Land, and Wollaston Land, 80,000; Banks Land and Baring Land, 80,000; Prince Patrick and the Parry Island group, including Melville, 17,000; and Bathurst Islands.

The following table shows the population in the census years 1881 and 1891 and in 1901, including the district of Keewatin:—

	1881.	1891.	1901.
Alberta	25,515	25,277	145,000
Assiniboia		30,372	
Saskatchewan		11,150	
Other Territories	30,931[1,2]	32,168[1,2]	75,000
	56,446	98,967	220,000[1]

In 1901 there were 27,057 Indians in the North-West Territories and Keewatin, made up as follows:—Assiniboia, 3214; Alberta, 5697; Saskatchewan, 5993; Athabasca, 3716; Mackenzie, 2041; Keewatin and Franklin, 5834; and Ungava, 562. In the same year there were 14,266 half-breeds in Manitoba and the Territories, as follows: Assiniboia, 2155; Alberta, 3686; Saskatchewan, 5677; Athabasca, 2395; and other territories, 373. The Indian population of Manitoba and the treaty limits of the North-West Territories numbered, in 1893, 23,608, and in 1898, 21,316, a decrease of 2292.

In 1901 there was in Alberta 1 person to 1·6 square miles; in Assiniboia, 1 to 1·3 miles; in Saskatchewan, 1 to 4·2 miles. In the same year there were in the Territories 100,641 males and 83,789 females; the urban population, 20·7 per cent., and rural, 79·3 per cent. In 1891 there were 13,804 persons engaged in agriculture and mining; 2291 in domestic and personal service; 1669 in manufactures and mechanical industries; 2299 in trade and transportation; 1690 in professional avocations, and non-productive, 178. Principal nationalities (by birth) in 1901: Canada, 116,846; England, 10,989; Scotland, 4259; Ireland, 2500. There were 2691 births, 937 deaths, and 827 marriages in 1901.

Immigration. The total number of declared settlers that arrived in Canada in the year 1901–02 was 63,700, most of whom settled in Manitoba and the Territories. There were 41,000 from Great Britain and other European countries, and 22,700 from the United States. In 1899 about 8000 Russian Doukhobors settled in the Swan river district in Manitoba.

Government. The North-West Territories were at first under the lieutenant-governor of Manitoba, then under a lieutenant-governor and council nominated by the Dominion Government; by degrees further powers were conferred, and their affairs are now administered by a lieutenant-governor appointed by the Governor in Council, and an executive council consisting of three members, responsible to the legislative assembly, which consists of thirty-one members. The powers conferred on the legislature are the same as in other provinces of Canada, except that they cannot borrow money on the credit of the Territories. While Ungava, Mackenzie, and Franklin are under the control of the government of the North-West Territories, and while the latter has power to pass laws dealing with internal matters, the Dominion Government assumes the right of legislating with regard to these districts, and did so in 1898 when creating the territory of Yukon.

Religion. Classified according to religion, the principal denominations were in 1901 as follows:—

Roman Catholics	35,200	Baptists	5,416
Presbyterians	27,857	Doukhobors	8,700
Church of England	29,027	Other denominations	25,459
Methodists	24,772	Not specified	15,901
Lutherans	12,098		

In 1901 it was estimated that there were, in the Territories and Keewatin, 18,627 Indians professing the Roman Catholic faith, 4160 Anglicans, 1477 Methodists, 795 Presbyterians, 5606 pagans, and 6392 unknown, but probably pagans.

Education. The educational system is under the control of a council of public instruction, consisting of the executive committee of three, and of three appointed members without votes. A school district may comprise an area of not more than 25 square miles, and must contain four resident heads of families and a school population—children between the ages of five and twenty—of not less than ten. In 1901 there were 564 schools, with a total of 23,837 pupils and 682 teachers. The total expenditure for school purposes amounted to $548,809.

Finance. The principal sources of revenue are the subsidy from the Dominion Government, $425,359 in 1902, and fees received from the sale of liquor licences, &c.

Minerals and Mining. There are immense beds of coal in the Territories, and it has been estimated that, to the south of the 56th parallel, an area of 60,000 square miles is underlain by beds of bituminous and lignite coals. The lignites are found in the undisturbed prairie region, bituminous in the foothills, and bituminous and anthracite in the Rocky Mountains. The principal mines in operation are at Lethbridge, Banff, and Canmore, Alberta; they produced in 1901, 351,950 tons, valued at $839,375. Great outcrops of Cretaceous sandstone, saturated with inspissated petroleum, are found along the Athabasca river, evidencing the existence of extensive deposits of petroleum in the underlying Devonian rocks. Natural gas has been found in considerable quantities in borings, notably in a bore-hole sunk near the confluence of the Pelican and Athabasca rivers, to test the presence of petroleum, which eventually caused the suspension of the boring operations. Gold, supposed to have been concentrated from drift deposits, has been washed from the sands of the Saskatchewan for years; yield in 1901, $15,000.

Agriculture. The soil in southern Assiniboia and Alberta is of a very fertile character, and produces good crops, though in some sections irrigation is required. In 1901 there were 169 irrigation ditches, with a total of 469 miles, constructed at a cost of $500,000; increased value of the land estimated at $1,229,368, and land susceptible of irrigation from constructed ditches, 614,684 acres. To the north of this more or less arid belt are immense partly-wooded districts, with a rich and fertile soil favourable for mixed farming. Up to 1901, 6,500,000 acres had been brought to the uses of the farmer, and 605,795 acres were covered by grazing leases. The following are crop statistics for 1901:—

	Acres.	Bushels.	Yield per acre.
Wheat	508,564	12,923,343	25·40
Barley	20,044	736,749	36·75
Oats	229,439	11,113,066	48·43

Total acreage, wheat, barley, and oats, 1891, 183,915 acres, and 1901, 758,047 acres. In 1900 the Indians in the southern Territories raised the following crops: wheat, 31,930 bushels; oats, 36,333; barley, 4359; potatoes, 31,286; other roots, 10,693; hay and other fodder, 38,442 tons.

Manufactures. The population of the Territories being essentially an agricultural one, the manufactures are as yet insignificant. In the census year 1891 the industrial establishments numbered 375; fixed capital, $670,502; working capital, $1,042,677; persons employed, 1081; wages per annum, $425,153; raw material, $846,017; and value of finished product, $1,827,310.

Commerce. The following table gives statistics of exports, &c., at five-year intervals, for the period 1879–1901:—

	1879.	1884.	1889.	1894.	1901.
	$	$	$	$	$
Imports	60,139	...	...	79,494	1,520,936
Exports	157,462	486,739	128,755	117,398	1,436,249
Duty	21,970	70,148	24,549	11,012	140,952

Railways. In 1901 the railway lines in Assiniboia, Saskatchewan, and Alberta aggregated 2056 miles, equal to 1 mile of track to 147 square miles of area. The systems operating in the Territories are—the Canadian Pacific, Canadian Northern, and Alberta Railway and Coal Company. (J. WH*.)

Northwich, a market town in the Northwich parliamentary division of Cheshire, England, at the confluence of the rivers Weaver and Dane, 18 miles east-north-east of Chester by rail, connected with the Manchester Ship Canal. The amount of white and rock salt exported from this locality (including Winsford, 6 miles distant) is about 1,500,000 tons annually. The white salt is chiefly shipped to America, Belgium and Prussia importing rock salt. Population (1891), 14,914; (1901), 17,609.

Norton, Charles Eliot (1827–——), American scholar and author, was born in Cambridge, Massachusetts,

[1] Including Keewatin. [2] Estimated.

16th November 1827, being the son of Andrews Norton, a Unitarian theologian and doctrinal writer of prominence in his time. Having graduated at Harvard in 1846, Norton travelled in India and Europe, and on his return devoted himself to a life of letters and culture. From 1864 to 1868 he edited, with James Russell Lowell, the *North American Review*, and from 1875 to his resignation in 1898 he was professor of the history of art at Harvard. Beginning with *Notes of Travel and Study in Italy* (1859), his principal books have been *Historical Studies of Church-Building in the Middle Ages: Venice, Siena, Florence* (1880), annotations on Turner's *Liber Studiorum* and Blake's *Job*, a bibliography of Michael Angelo, and a translation of Dante's *New Life* and of the *Divine Comedy* in prose, the publication of the several parts of which extended from 1858 to 1892. His version of the *New Life*, in particular, is noteworthy for accuracy and felicity. He took a prominent part in the work of editing and publishing letters and other writings of Emerson and Carlyle, after their death, and was appointed his literary executor by John Ruskin.

Norton, Thomas (1532–1584), lawyer, politician, and writer of verse, was born in London in 1532. He was educated at Cambridge, and early became a secretary to the Protector Somerset. In 1555 he was admitted a student at the Inner Temple, and married Margaret Cranmer, the daughter of the archbishop. Several years before this, indeed from his eighteenth year, Norton had begun to compose in verse. We find him connected with Jasper Heywood; as a writer of "sonnets" he contributed to *Tottel's Miscellany*, and in 1560 he composed, in company with Sackville, the earliest English tragedy, *Gorboduc*, a remarkable work in blank verse, which was performed before Queen Elizabeth in the Inner Temple on the 18th of January 1561. In 1562 Norton, who had served in an earlier Parliament as the representative of Gatton, became M.P. for Berwick, and entered with great activity into politics; he was eminent in the House as a "wise, bold, and eloquent" orator. In his attitude to religion he was inspired by the sentiments of his great deceased father-in-law, and was in possession of Cranmer's MS. code of ecclesiastical law; this he permitted Foxe to publish in 1571. Norton, in fact, became one of the extremest Puritans of that pro-puritanic age. He went to Rome on legal business in 1579, and from 1580 to 1583 frequently visited the Channel Islands as a commissioner to inquire into the status of these possessions. Norton's Calvinism grew with years, and towards the end of his career he became a rabid fanatic. His punishment of the Catholics, as their official censor from 1581 onwards, led to his being nicknamed "Rackmaster-General." Among the more illustrious victims of his tortures were Edmund Campion and Francis Throgmorton. At last his turbulent puritanism made him an object of fear even to the English bishops; he was deprived of his office and thrown into the Tower. Walsingham presently released him, but Norton's health was undermined, and on the 10th of March 1584 he died in his house at Sharpenhoe, Bedfordshire. The famous tragedy of *Gorboduc* was first published, very corruptly, in 1565, and, in better form, as *The Tragedy of Ferrex and Porrex*, in 1570. Norton's early lyrics have in the main disappeared. The most interesting of his numerous anti-Catholic pamphlets are those on the rebellion of Northumberland and on the projected marriage of Mary Queen of Scots to the duke of Norfolk. Norton also translated Calvin's *Institutes* and Nowell's *Catechism.* By far the best account of Thomas Norton is that published in 1895 by Mr Sidney Lee, who destroys the notion, which had gradually grown up among the historians of English literature, that the credit of *Gorboduc* was entirely, or at all events mainly, due to Sackville. There is more evidence for an opposite thesis, namely, that the principal credit for starting English tragedy is due to Thomas Norton. (E. G.)

Norwalk, a town of Fairfield county, Connecticut, U.S.A., on Long Island Sound, in the south-western part of the state. The town has an area of 25 square miles of hilly country, within which are the cities of South Norwalk and Norwalk and the villages of East and West Norwalk, Winnipauk, Four Corners, and Five Corners. It is traversed by the New York, New Haven, and Hartford Railroad. South Norwalk has an excellent harbour, with regular steamboat communication with New York and Sound ports, giving it a large coasting trade. It has extensive and varied manufactures, the capital invested amounting, according to the census of 1900, to $4,129,841, and the value of the product to $5,097,720. Population of the town (1890), 17,747; (1900), 19,932; of the city (1900), 6125, of whom 1023 were foreign-born.

Norwalk, a city of Ohio, U.S.A., capital of Huron county, in the northern part of the state, on the Lake Shore and Michigan Southern and the Wheeling and Lake Erie railways, at an altitude of 718 feet. It is in a farming district, and has varied manufactures. Population (1890), 7195; (1900), 7074.

NORWAY.

I. Geography and Statistics.

NORWAY is the western section of the Scandinavian peninsula, lying between 57° 58′ and 71° 11′ N. and 4° 30′ and 31° 12′ E., bounded on the N. by the Arctic Ocean, on the E. by Lapland and Sweden, on the S. by the Skagerrack and the North Sea, and on the W. by the Atlantic. So far as physical features are concerned, the article in the earlier volumes of this Encyclopædia (xvii. 575) gives a full account, which it is unnecessary to supplement with further details here; and it only remains to give the statistics for more recent years.

Population and Area.—During the course of the 19th century the population of Norway increased 152·7 per cent., from 883,038 in 1801 to 2,231,395 in 1900. During the seven years 1892–98 inclusive the marriage-rate per thousand of the population averaged 6·58 annually, the birth-rate 31·6, and the death-rate 16·00. Of the births 7·67 per cent. were illegitimate. During the fourteen years 1880–93 inclusive an average of 18,290 persons emigrated every year; during 1894–99 inclusive, an average of 4852. Almost the whole of them went to the United States. In 1900 the rural population amounted to 1,606,864, or 72 per cent. of the whole, and the urban to 624,531, or 28 per cent. In 1891 there were 20,786 Lapps and 9378 Finns (Kvæns). The lunatics numbered 1659 in 1899, as compared with 1581 in 1895. Deaf mutes numbered 2139 in 1891, and blind persons 2565. In the twelve years 1887–98 the suicides averaged 128 annually.

The following table gives the population and density of the counties in 1891 and 1900, together with the areas:—

Counties.	Population as per Census, 1891.	Population as per Census, 1900.	Area in Sq. Miles.	Density per Sq. Mile in 1900.
Smaalenene	120,360	136,298	1,600	85·1
Akershus	99,111	115,113	2,054	56·0
Christiania	151,239	225,686[1]	6·5	34,720·9
Hedemarken	119,129	125,856	10,618	11·8
Christians	108,076	115,615	9,790	11·8
Buskerud	104,769	112,608	5,789	19·2
Jarlsberg and Laurvik	100,957	103,772	896	115·8
Bratsberg	92,034	98,788	5,863	16·8
Nedenes	81,043	79,605	3,608·5	22·0
Lister and Mandal	78,738	81,454	2,804	29·0
Stavanger	117,008	127,192	3,530·5	36·0
South Bergenhus	128,213	135,337	6,024·5	22·3
Bergen	53,684[2]	72,179	5·5	13,123·4
North Bergenhus	87,552	88,948	7,130	12·4
Romsdal	127,806	135,899	5,786	23·5
South Trondhjem	123,817	135,133	7,182	18·8
North Trondhjem	81,236	83,344	8,788·5	9·5
Nordland	131,850	151,537	14,513	10·4
Tromsö	65,125	74,296	10,131	7·3

Totals	2,000,917[3]	2,231,395	124,411	17·9

Classified according to occupations, the population (total number and percentage) was distributed as follows in the year 1891 :—

	Agriculture and Forestry.	Domestic Labour.	Industry.	Fishing.	Commerce and Trade.	Navigation.	Independent.	Children.
Total number	335,093	480,672	175,641	57,667	42,649	45,368	57,686	709,639
Per cent.	16·7	24·0	8·7	2·9	2·1	2·3	2·9	35·4

Religion and Education.—Except for 30,685 persons (in 1896), of whom 8200 were Free Lutherans, 8200 Methodists, and 4000 Baptists, the population are adherents of the Evangelical Lutheran Church. Notwithstanding the sparseness of the population and the great distances, education in Norway has reached a high standard, being free, and all children between seven and fourteen being obliged to attend school. In the rural districts there are about 6000 primary schools, at which 257,440 out of 272,562 children of school age were educated in 1897 at a cost of £232,274, an average of 18s. 0½d. per child, or an addition of over 50 per cent. of the cost in 1875. In the towns 69,475 children were educated out of 90,832 of school age in 1897, the total cost being £211,526, or at the rate of £3, 0s. 10½d. per child. Secondary education is in a transitional stage, the old classical standards having been discarded in 1896. In 1897 there were 154 communal burgher and communal middle schools and state lyceums, in which 19,207 children were taught, private secondary schools being also included. The special schools embrace an agricultural high school, 3 technical schools, 2 commercial schools, a military school, and a naval school. There is one university, state-aided, at Christiania.

Agriculture.—Although 75 per cent. of the total area is unproductive, and less than 1 per cent. is arable land, the number of people dependent upon agriculture exceeds any other group in the country. Including those who breed and tend live stock, and those employed in the forest industries, agriculture gave occupation to 335,093 persons in 1891, or 28 per cent. of the total working population. The Government help to maintain a flock of Cheviot sheep on the island of Rennes, near Stavanger. There is a higher school of agriculture at Aas (20 miles south of Christiania), and 18 agricultural schools in other parts of the country. Barley is almost the only cereal found north of 68° N.; hay and potatoes ripen as far north as Tromsö and Hammerfest (70° 39′ N.). The next table shows the number of acres under the principal crops in the years cited :—

Year.	Oats.	Barley.	Oats and Barley mixed.	Rye.	Total Cereals.	Potatoes.
1875	249,250	138,000	51,000	35,650	525,850	95,900
1890	241,650	127,900	36,650	34,000	459,450	96,650

In 1897 and 1898 there were some tentative attempts to grow tobacco. In 1890 the live stock numbered 150,900 horses, 1,006,500 cattle, 1,417,500 sheep, 272,500 goats, 121,100 swine, and 170,100 reindeer (domesticated).

Manufacturing Industry.—The next largest group of occupations embraces the manufacturing industries, namely, 175,641 persons, or 15 per cent. of the working population. During the last decade of the 19th century a great number of waterfalls were sold for industrial purposes to manufacturers or their agents, English and German capital being invested as well as Norwegian. A powerful impulse was given to the development of industrial enterprise in Norway by the expiration and non-renewal of the customs treaty with Sweden in 1897, the effect being virtually to establish in Norway a protective system against the sister kingdom. At the same time (between 1896 and the middle of 1899) there was an extraordinary increase in the number of new factories, whilst the importation into Norway of manufactured goods from Sweden very greatly decreased in 1898. In 1885 there were altogether 1925 factories, employing 45,313 workpeople; in 1895, 1910 factories employing 59,796 workpeople; and in 1899, no less than 3074 factories, employing 79,136 workpeople. The chief industrial centre is Christiania (with 402 factories and 17,294 workpeople in 1899); next come Fredrikstad and Sarpsborg, then Bergen, Drammen, Skien and Porsgrund, Fredrikshald, Trondhjem, and Stavanger. The most important branches of industry are saw-mills and planing-mills and wood-pulp factories (17,650 men in 1899); foundries and engineering shops (17,385 men); spinning and weaving mills (8943); brick and tile works, breweries, paper mills, tobacco factories, flour mills, glass works and potteries (6958 men); nail works, shipbuilding yards, match factories, margarine factories, rope walks, factories for preserved foods, fish guano, boots, hosiery; distilleries and tanneries. The building of small wooden vessels, formerly a very active industry, is rapidly decreasing. Including wood-pulp, but excluding the produce of the forests and fishing-grounds, the total export of the industrial products of Norway amounted to £1,303,000 in 1887, £3,080,700 in 1897, and about £2,469,200 in 1900.

Fisheries.—In respect of the value of the product, the fisheries of Norway rank next after her timber. The fish principally taken are cod and herrings, with ling and coal-fish (sayc), salmon and sea-trout, mackerel, lobsters, and oysters. The total annual value of the coast fisheries of Norway ranges generally from one million to one million and a half sterling. There are three principal fishing-grounds for cod: (i.) the Lofoten, from January to April, when the fishing is carried on by 25,000 to 32,500 men, using 6000 to 8000 boats; (ii.) the Finmark, carried on by a fluctuating number of men, 12,000 to 29,000, and of boats, 4000 to 7500; (iii.) the Romsdal, employing 12,250 to 17,000 men and 2000 to 3000 boats. During the whole of the year 1899 the cod fisheries of Norway gave employment to a total of 77,139 men; the number of boats employed was 17,892, and the aggregate number of fish caught was 37,584,000, a little more than half the annual average for the years 1888–97, their value being £617,900 (average for the years 1888–97, £781,600). Since 1898 there has been a sensible falling-off in these fisheries, so much so that in 1901 less than 20 million cod were taken in the Lofoten and Finmark catches, the lowest for many years. The principal fishing-grounds for herrings are off the coast of Nordland, the west coast between Trondhjem and Bergen, off Bukken Fjord and in Christiania Fjord, and along the south coast. In 1897 some 203,600 tons of herrings were caught, the largest quantity since 1874, their value being £441,888; in 1900 only 120,000 tons were taken, but they realized £489,000. As a rule the annual take of herrings ranges between £200,000 and £350,000. Of salmon and sea-trout 709 tons, valued at £52,590, were taken in 1899; average value, 1881 to 1897 inclusive, £35,000. To these must be added £17,000 to £18,000 for the salmon caught in the fresh-water rivers and lakes. Coal-fish and ling were caught along the coast of Finmark to the value of £259,100 in 1899; average for 1881 to 1897, £156,700. The value of the mackerel (south coast), lobsters, and oysters caught in 1899 was £51,300. Norwegian fishermen, especially from Tönsberg and the northern ports of Tromsö, Hammerfest, Vardö, and Vadsö, take part in the Arctic whale, seal, shark, and walrus hunting. In 1900 a fishery board for the administration of all the Norwegian fisheries was established at Bergen.

Mercantile Marine.—Next after the fisheries comes the merchant navy. It was in 1879 that Norway first took a relatively high

[1] The increase is partly due to the extension of the municipal boundaries.

[2] The municipal boundaries were extended between the census of 1875 and the census of 1891.

[3] Or, including Norwegian sailors serving abroad on Norwegian vessels, 2,004,102.

place. In that year 5 per cent. of the total measured tonnage of the world flew the Norwegian flag. It should, however, be mentioned that now there are a large number of British-owned vessels sailing under the Norwegian flag. The principal ship-owning ports in 1899 were, in the order of tonnage: Bergen (579,950 calculated[1]) tons, Christiania (393,600 tons), Tönsberg (261,800), Stavanger (162,400), Arendal (109,450), Haugesund (107,300), Drammen, Grimstad, Porsgrund, Fredrikstad, Kragerö, and Christiansand. The growth of the Norwegian mercantile marine will be apparent from the following table:—

Year.	Steam-ships.	Tonnage.	Sailing Ships.	Tonnage.	Total Vessels.	Total Calculated Tonnage.
1887	514	438,458	6755	1,381,778	7269	1,820,236
1897	1004	1,379,232	6143	1,169,079	7147	2,548,311
1900	1128	1,736,089	5698	1,052,687	6826	2,788,776

The rugged coast of Norway is well protected by lighthouses.

Commerce.—The subjoined table gives particulars of the total trade with all foreign countries:—

Year.	Imports.	Per Head of Population.	Exports.	Per Head of Population.	Total Imports and Exports.	Per Head of Population.
1887	£7,427,300	£$3\frac{3}{4}$	£5,923,800	£3	£13,351,100	£$6\frac{3}{4}$
1897	14,651,020	7	9,316,480	$4\frac{3}{8}$	23,967,500	$11\frac{3}{8}$
1900	17,951,350	8	9,834,400	$4\frac{3}{8}$	27,785,750	$12\frac{3}{8}$

In 1887 Great Britain supplied imports to the total value of £1,965,000 (26·5 per cent.), and received exports to £1,921,000 (32·4 per cent.); in 1897 she supplied £3,752,000 (25·6 per cent.) of the imports and received £3,632,600 of the exports (39 per cent.). In 1900 Great Britain sent 30 per cent. of the imports, and received 42·5 per cent. of the exports; and in the same year the United States contributed 5·5 per cent. of Norway's imports, and took 1·1 per cent. of her exports. The most important exports are fish and fish products (£3,295,000 in 1899), timber (£2,197,700), wood-pulp (£1,016,500), paper (£452,000), butter and condensed milk (£476,100). Next in order come textiles, hides and leather, mineral ores and metals, nails, hewn stone and bricks, ships, matches, and ice. The imports of greatest value are cereals and flour (£2,843,450), textiles (£1,393,600), groceries and preserved fruits (£1,342,800), ironmongery (£1,536,100), coal (£1,334,400), raw cotton, wool, &c., and yarn (£767,500), ships (£1,041,450), raw metals (£749,400), machinery, &c. (£595,400), with timber, skins, bacon and meat, wines and spirits, glass and pottery, books, paper, salt, &c. In 1897 Great Britain took 60 per cent. of the timber, Cape Colony 4·5 per cent., and Australia 2·8 per cent. of the total of 74 million cubic feet.

The subjoined table shows the number of vessels which entered at Norwegian ports in the years mentioned, together with their aggregate tonnage:—

Year.	Total.		British.		German.		United States.	
	Vessels.	Tonnage.	Vessels.	Tonnage.	Vessels.	Tonnage.	Vessels.	Tonnage.
1886	11,209	2,316,278	3348	1,104,243	972	272,417	48	59,861
1896	13,201	2,908,946	3805	1,458,051	1061	340,159	57	98,143

In 1898 all the Norwegian ports together were entered and cleared by an aggregate of 6,297,400 tons, of which 4,197,250 tons were Norwegian, 737,000 British, 521,300 Danish, and 414,100 Swedish.

Forests.—In 1897 it was estimated that 33,582 square miles, or 26·9 per cent. of the entire area, was under forests. They occupy all the eastern and middle parts of the country from 58° up to 68° N. Of the timber standing in 1897 it was estimated that 73 per cent. was pine wood (red and white), and the rest umbrageous trees, amongst which the birch predominated.

Mining.—Norway has mines of copper pyrites, silver, nickel, zinc, cobalt, molybdenum, iron, and apatite, but none of these is worked on a very extensive scale. In the years 1888–98 inclusive from 1650 to 2500 men were employed annually in mining in Norway; and in 1900 the number was 2750. The total value dropped from £206,555 in 1889 to £147,777 in 1893, but in 1900 rose to £210,800. The average for the ten years 1887–96 was £165,746. In 1897 the yield was the largest ever known, and embraced 90,000 tons of copper pyrites and 1450 tons of pure copper, and the aggregate value of the ores delivered at Norwegian ports for export was £207,182. The pyrites and copper mines are at Röros (100 miles south-south-east of Trondhjem by rail), Sulitjelma (at the head of Salten Fjord, in 67° 20′), Ranen (on the west coast, in 66° 15′), Lyngen and Alten in the extreme north, at Killingdal, Drogset in Meldal, and on Ytterö. Silver is mined at Kongsberg; iron in Hardanger, at Ulefos, and near Arendal; cobalt at Modum; molybdenum at Knaben; nickel at Evje in Sætersdal, north from Christiansand; zinc at Sand, between Stavanger and Bergen; and apatite at Ödegaard, between Laurvik and Kragerö. Coal exists on Andenäs in the Lofotens. Granite is extensively quarried in the vicinity of Fredrikstad, Fredrikshald, and Sarpsborg, and exported as paving setts and kerbstones, mostly to Great Britain and Germany. Fine beds of marble, in some parts running 10 to 12 miles on end and several yards thick, are worked near Fredrikshald. Other beds occur in the Salten and Ranen districts.

Communications.—Norway possesses only one line of railway of any considerable length, namely, that which runs north from Christiania to Trondhjem; but there are several short lines, such as the connexions eastwards with the Swedish railway systems from Christiania and Trondhjem, the lines connecting the capital with Drammen and Skien, the Sætersdal railway, the Jæderen railway, and the line from Bergen to Vossevangen. This last is now being continued towards Christiania. Another important line, perhaps the most northerly in the world, is that intended to connect Narvik or Victoria Harbour (on the Ofoten Fjord, in 68° 30′ N.) with the iron mines of Gellivara in Sweden. Altogether there were 1230 miles of railways open in 1900, of which 1119 were State lines; the gross earnings for the year 1899 being £804,450, of which £259,450 was net profit. In 1895 there were 5991 miles of main roads and 10,776 of communal roads. Most of these have been reconstructed since 1850, and several of them exhibit evidence of considerable engineering skill. By the aid of Government subventions, regular steamboat communication is maintained all the year round on the fjords, coasts, and larger lakes. Even in winter steamboats run regularly to Hammerfest and Vadsö. Both telegraph and telephone systems are exceptionally extensive for such a country as Norway. The annexed table gives particulars of the telegraph system:—

Year.	Total Length.		Receipts.	Net Profits.	No. of Telegrams.	
	Of Lines.	Of Wires.			At Home.	Abroad.
1899	7164	20,650	£120,150	£15,950	1,340,708	818,062

In 1887 an aggregate total of 15,801,600 home letters and post-cards passed through the post office, and in 1899, 36,700,000; received from and despatched to foreign countries, 2,694,800 in 1887 and 11,797,800 in 1899. The book post and parcel post packets for home numbered 21,557,900 in 1887 and 54,877,400 in 1899; those from and for foreign countries numbered 809,300 in 1887 and 5,643,900 in 1899. The gross earnings of the post office in 1899 amounted to £267,870, and the net profits to £13,560.

Banks and Finances.—There are two State banks—the Bank of Norway and the Mortgage Bank of the Kingdom of Norway. The former is a joint-stock bank, owned in great part by the Government, its directors being elected by the Storthing or Parliament, except the president of the head office, who is nominated by the king. It is the only bank in Norway authorized to issue bank-notes. There were, further, 411 savings banks in 1900, having 671,241 depositors, with £16,829,400 (or an average of £25, 1s. 5d. per head, as compared with £23, 5s. 7d. in 1870) deposits to their credit. Budget particulars, and the amount of the national debt, are contained in the following table:—

Year.	Receipts.	Expenditure.	Receipts from Customs Dues.	Receipts from Indirect Taxes.[1]	National Debt.	National Debt per Inhabitant.
1887	£2,387,600	£2,449,200	£1,141,600	£1,419,500	£6,023,760	£3 1 1
1897	3,835,950	4,262,800	1,578,700	2,019,800	10,074,700	4 15 6
1899	5,315,850	4,959,100	2,079,000	2,731,350	11,030,500	4 18 0

The income-tax was first levied in 1892; in 1895 it was made "graduated," the lowest income to be taxed being 1000 kroner (=£55, 6s. 8d.). The produce of the tax increased from £158,900 in 1892 to £280,229 in 1899; and the total incomes upon which the tax was levied increased during the same period from £17,028,000 to £24,383,400.

Government.—In 1899, after long and heated parliamentary action, and after being twice vetoed by the king, Norway extorted the right to remove the sign of union with Sweden from the flag of her merchant marine. There was also a violent agitation for Norwegian consuls abroad distinct from Swedish consuls. In 1898 parliamentary franchise was made universal, the right to vote being given to every man of Norwegian nationality who is twenty-five years of age, who has dwelt five years in the country, and who possesses the necessary property and legal qualifications. In

[1] One steam ton is taken as equivalent to 3·6 sailing tons.

[1] This includes the figures given under the column headed "Receipts from Customs Dues."

each town and bailiwick there is a court of arbitration, over which two authorities preside who have been selected by the (elected) parliamentary voters. As a rule all civil disputes are, in the first instance, brought before these arbitrators. There are now only three courts of appeal, each with three justices, at Christiania, Bergen, and Trondhjem respectively.

Army and Navy.—The army embraces the line, the militia or reserve, and the second reserve. All men of twenty-two years of age and upwards are liable for conscription, and when called they serve five years in the line, four years with the reserve, and four years with the second reserve. The men of the line are the only troops who can be sent out of the country for purposes of war. But, though the nominal period of service is altogether thirteen years, the men only meet for annual military training for periods of eighteen to seventy days in each year. The peace establishment of the line amounts to 12,000 men, with 750 officers; its war footing to 18,000 men, or more. The navy consists of about 850 officers and men on permanent service; but all seafaring men between the ages of twenty-two and thirty-five are liable for maritime conscription, and are all put through some preliminary training. The war vessels embrace four turret-ships of 3500 tons each, and about a dozen other modern vessels, some small gunboats, and a torpedo flotilla—the whole being intended for coast defence only.

(J. T. BE.)

II. HISTORY.

Events leading to the union with Sweden.

After a union of nearly 400 years between Norway and Denmark, the Danish king, Frederick VI., without consulting the Norwegians, ceded Norway to Sweden by the treaty of Kiel (14th January 1814). By this arbitrary act—one of the results of the great European upheaval in the early years of the 19th century—Norway, as events proved, benefited more than most European states. Some time previously Sweden had joined the Allied Powers in their struggle against Napoleon, while Denmark had, unwisely, sided with the French. In 1813 the Swedish crown prince, Carl Johan (formerly Bernadotte, one of Napoleon's marshals[1]), proceeded to Germany and took command of one of the armies of the Allied Powers. After the power of Napoleon had been broken at the battle of Leipzig, Carl Johan advanced against Denmark, and King Frederick soon saw himself compelled to accede to the Swedish demand—the cession of Norway, the possession of which had long been the aspiration of the Swedes, especially after the loss of Finland in 1809. In the treaty of Kiel Frederick VI. absolved the Norwegians from their oath of allegiance, and called upon them to become the loyal subjects of the Swedish king. But the Norwegians, who had not been consulted in the matter, refused to acknowledge the treaty, declaring that, while the Danish king might renounce his right to the Norwegian crown, it was contrary to international law to dispose of an entire kingdom without the consent of its people. They would not tamely submit to be handed over as mere chattels to Sweden; they asserted their independence and their right to decide their own fate. A meeting of delegates from all parts of the country was convened at Eidsvold, not far from the Norwegian capital, where, on the 17th of May 1814, a constitution, framed upon the constitutions of America, of France (1791), and of Spain (1812), was adopted. Among its most important features are that the Storthing or National Assembly is a single-chamber institution, and that the king is not given an absolute veto, or the right to dissolve the Storthing. The then Danish governor of Norway, Prince Christian Frederick, was unanimously elected king. Soon afterwards the Swedes, under Carl Johan, the Swedish crown prince, invaded Norway. They met with a gallant resistance, but Prince Christian soon saw the hopelessness of the struggle, and declared himself willing to abdicate. The hostilities lasted only a fortnight, when Carl Johan opened negotiations with the Norwegians. A convention was held at Moss, where it was proposed that the Norwegians should accept the Swedish king as their sovereign, on the condition that their constitution of the 17th of May should remain intact, except with such alterations as the union might render necessary. An extraordinary Storthing was then summoned at Christiania, and on the 4th of November 1814 Norway was declared to be "a free, independent, and indivisible kingdom, united with Sweden under one king." A month previously Prince Christian Frederick had laid down his crown and left the country.

The union was more fully defined by the "Act of Union," which was accepted by the National Assemblies of both countries in the following year. In the preamble to the Act it is clearly stated that the union between the two peoples was accomplished "not by force of arms, but by free conviction," and the Swedish foreign minister declared to the European Powers, on behalf of Sweden, that the treaty of Kiel had been abandoned, and that it was not to this treaty, but to the confidence of the Norwegian people in the Swedish, that the latter owed the union with Norway. The constitution framed at Eidsvold was retained and forms the *Grundlov*, or fundamental law of the kingdom. It is generally acknowledged to be the freest and most democratic constitution of all monarchical states. The union thus concluded between the two countries was really an offensive and defensive alliance under a common king, each country retaining its own government, parliament, army, navy, customs, &c. The relations between the two countries may be more clearly understood when it is realized that a Norwegian is a foreigner in Sweden, and a Swede in Norway, and that consequently a Norwegian can hold no official appointment in Sweden, and *vice versa*.

In Sweden the people received only an imperfect and erroneous insight into the nature of the union, and for a long time believed it to be an achievement of the Swedish arms, while to the leading men of the country, who knew the terms of the union better, it was a great disappointment. They had hoped to make Norway a province of Sweden, and now they had entered into a union in which both countries were equally independent. During the first fifteen years the king was represented in Norway by a Swedish viceroy, while the Government was, of course, composed only of Norwegians, selected from various parties in the country. Count Wedel Jarlsberg was the first to be entrusted with the important office of head of the Norwegian Government, while several of Prince Christian Frederick's councillors of state were retained, or replaced by others holding their political views. The Swedish Count v. Essen was appointed the first viceroy of Norway, and was succeeded two years afterwards by his countryman Count v. Mörner, over both of whom Count Wedel exercised considerable influence.

Strained relations between king and Storthing.

During the first years of the union the condition of Norway was in many respects most unprosperous. The country suffered from poverty and depression of trade, and the finances were in a deplorable condition. The first Storthing was chiefly occupied with financial and other practical measures. In order to improve the finances of the country a Bank of Norway was founded, and the army was reduced to one half, as the defence of the country was not considered to be of great importance now that the union

[1] In 1810 he was elected heir to the Swedish throne, in succession to the childless King Carl XIII., who died in 1818.

had been concluded. The paid-up capital of the bank was procured by the assessment of an extraordinary tax, and this, together with the growing discontent among the peasantry, brought about a rising in Hedemarken and the neighbouring districts, the object of which was to dissolve the Storthing and to obtain a reduction in the taxation. It was also rumoured that the organizers of this agitation intended establishing an absolute government, and many therefore imagined they saw the machinations of the royal power behind the rising; while, on the other hand, the king himself believed he had to deal with Danish intrigues. The rising, however, soon subsided, and the bountiful harvest of 1819 brought more prosperous times to the peasantry. Meanwhile, however, the financial position of the country had nearly endangered its independence. The settlement with Denmark with regard to Norway's share of the national debt common to both, which had so long been deferred, and could not be evaded, had assumed threatening proportions. In the interest of Denmark, the Allied Powers asked for a speedy settlement, and in order to escape their collective intervention, Carl Johan, who had now succeeded to the throne of Sweden and Norway, on the death (5th February 1818) of the old King Carl XIII., accepted England's mediation, and was enabled in September 1819 to conclude a convention with Denmark, according to which Norway was held liable for only 3,000,000 specie dollars (nearly £700,000). But the Norwegians considered that this was still too much, and the attitude of the Storthing in 1821 had nearly occasioned a fresh interference of the Powers. The Storthing, however, yielded at last, and agreed to raise a loan and pay the amount stipulated in the convention. Although this matter now seemed to be in a fair way of being settled, the king evidently had his doubts as to whether the Norwegians really intended to fulfil their obligations. As his relations with the Storthing had already become strained, and as he was occupied at that time with plans, which it is now known meant nothing less than a *coup d'état* in connexion with the revision of the Norwegian constitution, he decided to adopt military preparations, and in July 1821 he collected a force of 3000 Swedish and 3000 Norwegian troops in the neighbourhood of Christiania, ostensibly for the mere purpose of holding some manœuvres, but his object was undoubtedly to impress the Storthing with his authority and to frighten it into submission. In a circular note (1st June) to the European Powers, signed by the Swedish foreign minister, Engström—but it is not difficult to recognize the hand of the king as the real author—the minister complained bitterly of the treatment the king had met with at the hands of the Storthing, and represented the Norwegians in anything but a favourable light to the Powers, the intention being to obtain their sympathy for any attempt that might be made to revise the Norwegian constitution, as, for example, by the substitution of an absolute for a suspensive veto, by conferring upon the king the right to dissolve the Storthing and to elect its presidents—in short, to adapt the Norwegian constitution to the liking of his less democratic Swedish subjects.

About this time another important question had to be finally settled by the Storthing, which the king was anxious to oppose at all costs. The Storthings of 1815 and 1818 had already passed a bill for the abolition of nobility, but the king had on both occasions refused his sanction. The Norwegians maintained that the country was too poor consistently to keep up an aristocracy, and that the few counts and barons still to be found in Norway were all Danish and of very recent origin, while the really true and ancient nobility of the country were the Norwegian peasants, descendants of the old jarls and chieftains, who had no desire for titular distinction. According to the constitution, any bill which has been passed by three successively elected Storthings (elections are held every third year) becomes law without the king's sanction. When the third reading of the bill came on, the king did everything in his power to obstruct it, but in spite of his opposition the bill was eventually carried and became law. These conflicts with the king had increased the strained relations which for some time had existed between him and the Storthing; but after the question of the debt to Denmark had been settled, and the king had formally sanctioned the bill for the abolition of nobility, a more conciliatory feeling set in.

In 1822 Count Wedel Jarlsberg retired from the Government. He had become unpopular through his financial policy, and was also at issue with the king on vital matters. In 1821 he had been impeached before the Rigsret (the supreme court of the realm) for having caused the State considerable losses. J. Collett was appointed as his successor to the post of Minister of Finance.

Royal proposals for constitutional revision.

The king had by this time apparently abandoned his plan of a *coup d'état*, for in the following August he submitted to the Storthing several proposals for fundamental changes in the constitution, all of which aimed at removing all that was at variance with a monarchical form of government. The changes, in fact, were the same as he had suggested in his circular note to the Powers, and which he knew would be hailed with approval by his Swedish subjects. It may seem strange that the king, favoured as he was by circumstances, took the constitutional course, when he might easily have gained his end by a *coup d'état;* but although Carl Johan was a man of courage on the battlefield, he seems to have been wanting in *courage civil*, and he doubtless feared that a *coup d'état* might result in unpleasant and humiliating consequences for himself. At the same time he knew that the Great Powers looked upon him with distrustful eyes, and that even in Sweden there were powerful enemies working against him.

When the Storthing met again in 1824 the royal proposals for the constitutional changes came on for discussion. The Storthing adopted a friendly attitude towards the king personally, without, however, showing itself subservient; but the assembly unanimously rejected not only the king's proposals, but also several others by private members for changes in the constitution. The king submitted his proposals again in the following session of the Storthing, and again later on, but they were always unanimously rejected. In 1830 they were discussed for the last time, with the same result. The king's insistence was viewed by the people as a sign of absolutist tendencies, and naturally excited fresh alarm. They felt they would have to be on their guard against all attempts at encroachment and at amalgamation between Norway and Sweden. In the eyes of the people the members of the Opposition in the Storthing were the true champions of the rights and the independence which they had gained in 1814.

The king's absolutist tendencies.

For several years the Norwegians had been celebrating the 17th of May as their day of independence, it being the anniversary of the adoption of the constitution of 1814; but as the tension between the Norwegians and the king increased, the latter began to look upon the celebration in the light of a demonstration directed against himself, and when Collett, the Minister of Finance, was impeached before the supreme court of the realm for having made certain payments without the sanction of the Storthing, he also considered this as an attack upon himself and his royal prerogatives in general. His irritation knew no bounds, and although Collett was acquitted by the supreme court, the king, in order to express his irritation with the Storthing and the action they had taken against one of his ministers, dissolved the National Assembly with every sign of displeasure. The Swedish viceroy at the time, Count Sandels, had tried to convince him that his prejudice against the celebration of the 17th of May was groundless, and for some years the king had made no objection to the celebration. In 1827 it was, however, celebrated in a very marked manner, and later in the same year there was a demonstration against a company of Swedish actors who had been performing a foolish political piece called *The Union*, and this being privately reported to the king and represented to him in as bad a light as possible, he thought that Count Sandels, who had not considered it worth while to report the occurrence, was not fitted for his post, and had him replaced by Count Platen, an upright but narrow-minded statesman, who was looked upon as a mouthpiece of the prevailing opinion in Sweden, where the people considered themselves defrauded of the real union they had hoped for.

Count Platen's first act was to issue a proclamation warning the people against celebrating the day of independence; and in April 1828 the king, against the advice of his ministers, summoned an extraordinary Storthing, in consequence of the judgment of the supreme court and the uncertain basis upon which that judgment seemed to place his royal prerogatives, his intention being to wrest from the Storthing the supremacy it had gained in 1827. He also intended to take steps to prevent the celebration of the 17th of May, and in order to give due emphasis to his proposals he assembled a force of 2000 Norwegian soldiers in the neighbourhood of the capital. The king arrived in Christiania soon after the opening of the extraordinary Storthing. He did not succeed, however, in his attempt to make any constitutional changes, but the Storthing met the king's wishes with regard to the celebration of the 17th of May by deciding not to continue the celebration, and the people all over the country quietly acquiesced. This was all that resulted from the king's great efforts on this occasion; but even this little triumph did not last long. The following year trouble broke out again. The students had decided to celebrate the 17th of May with a festive gathering, which, however, passed off quietly. But it was known that the authorities had made extraordinary preparations, and large masses of the people paraded the streets, out of curiosity, singing and shouting, and gathered finally in the market-place. There was no rioting or disturbance, but the Riot Act was read, and the police and the military eventually dispersed the people and drove them to their homes with sword and musket. This episode has become known as the "Battle of the Market-place," and did much to increase the general ill-feeling against Count Platen, who, it has since been proved, was no friend of Norway, having actually

The "battle of the market-place."

advised the king to try a *coup d'état*. His health eventually broke down from disappointment and vexation at the indignities and abuse heaped upon him. He died in Christiania at the end of the year, and owing to the state of public feeling his post was not filled by a Swede, but remained vacant for several years, the presidency of the Norwegian Government in the meantime being taken by Collett, its oldest member. From this time the day of independence has been celebrated every year with increasing enthusiasm.

By the July Revolution the political situation in Europe became completely changed, and the lessons derived from that great movement reached also to Norway. A new generation had grown up, which was more familiar with the forms of political freedom, and also bolder in adopting them. The representatives of the peasantry, for whom the constitution had paved the way to become the ruling element in political life, were also beginning to distinguish themselves in the National Assembly, where they now had taken up an independent position against the representatives of the official classes, who in 1814 and afterwards had played the leading and most influential part in politics. This party was now under the leadership of the able and gifted Ole Ueland, who remained a member of every Storthing from 1833 to 1869. The Storthing of 1833 was the first of the so-called "peasant Storthings." Hitherto the peasantry had never been represented by more than twenty members, but the elections in 1833 brought their number up to forty-five, nearly half of the total representation. The attention of this new party was especially directed to the finances of the country, in the administration of which they demanded the strictest economy. They often went too far in their zeal, and thereby incurred considerable ridicule, and even the contempt of the official and well-to-do classes, who began to regard the new party with distrustful and hostile feelings.

Increased political power of the peasantry.

About this time the peasant party found a champion in the youthful poet Henrik Wergeland, who threw himself heart and soul into the political questions of the day, and soon became one of the leaders of the "Young Norway" party. He was a republican in politics, and the most zealous upholder of the national independence of Norway and of her full equality with Sweden in the union. He soon became as detested by the "party of intelligence," as the official and well-to-do classes were called, as the party he had joined. In addition to the political struggles of the day, a literary conflict now began, which lasted for many years, and which in violence and intensity has scarcely ever been equalled in the history of the country. A strong opposition to Wergeland and the peasant party was formed by the upper classes under the leadership of another rising poet and writer, Johan Sebastian Welhaven, and other talented men, who wished to retain the literary and linguistic relationship with Denmark, while Wergeland and his party wished to make the separation from Denmark as complete as possible, and in every way to encourage the growth of the national characteristics and feeling among the people. Wergeland had therefore welcomed with joy the increase of the peasant party: he considered the peasantry the real descendants of the old Norsemen, the kernel of the nation, in fact, and with the prophetic foresight of the poet saw the important part they would play in the future political and intellectual life of the country. He devoted much of his time, by writing and other means, to promote the education of the people; but although he was most popular with the working and poorer classes, he was not able to form any political party around him, and at the time of his death he stood almost isolated. He died in 1845, and his opponents became now the leaders in the field of literature, and carried on the work of national reconstruction in a more restrained and quiet manner. The peasant party still continued to exist, but restricted itself principally to the assertion of local interests and the maintenance of strict economy in the budget.

Wergeland; opposed by Welhaven.

The violent agitation that began in 1830 died away, and after Wergeland's death the political life of the country assumed a more quiet and harmonious aspect. The tension between the king and the legislature, however, still continued, and reached its height during the session of 1836, when all the royal proposals for changes in the constitution were laid aside, without even passing through committee, and when various other steps towards upholding the independence of the country were taken. The king, in his displeasure, decided to dissolve the Storthing; but before it dispersed it proceeded to impeach Lövenskiold, one of the ministers, before the supreme court of the realm, for having advised the king to dissolve the Storthing. He was eventually sentenced to pay a fine of 10,000 kroner (about £550), but he retained his post. Collett, another minister who had greatly displeased the king by his conduct, was dismissed; but unity in the Government was brought about by the appointment of Count Wedel Jarlsberg as viceroy of Norway. From this time the relations between the king and the Norwegian people began to improve, whereas in Sweden he was in his later years not a little disliked.

When the king's anger had subsided, he summoned the Storthing to an extraordinary session, when several important bills were passed. Towards the close of the session an address to the king was agreed to, in which the Storthing urged that steps should be taken to place Norway in political respects upon an equal footing with Sweden, especially in the conduct of diplomatic affairs with foreign countries. The same address contained a petition for the use of the national or merchant flag in all waters. According to the constitution, Norway was to have her own merchant flag, and in 1821 the Storthing had passed a resolution that the flag should be scarlet, divided into four by a blue cross with white borders. The king, however, refused his sanction to the resolution, but gave permission to use the flag in waters nearer home; but beyond Cape Finisterre the naval flag, which was really the Swedish flag, with a white cross on a red ground in the upper square, had to be carried. In reply to the Storthing's address the king in 1838 conceded the right to all merchant ships to carry the national flag in all waters. This was hailed with great rejoicings all over the country; but the question of the national flag for general use had yet to be settled, and later on gave rise to long and violent strifes before it was finally settled in accordance with the wishes of the people. With regard to the question raised in the address of the Storthing about the conduct of diplomatic affairs, and other matters concerning the equality of Norway in the union, the king in 1839 appointed a committee of four Norwegians and four Swedes, who were to consider and report upon the questions thus raised. In 1835 a royal decree had ordained that when the Swedish minister of foreign affairs transacted business which concerned the two countries, or Norway only, the Norwegian minister in attendance upon the king at Stockholm should be present; but the Storthing, in its address, declared that it only considered this resolution to be a preparatory step towards a more complete and satisfactory arrangement of this important matter.

The national flag question.

During the sitting of this first "Union Committee," as it was called, the question of a complete revision of the Act of Union was raised by the division of the Norwegian Government in attendance upon the king at Stockholm, but the proposal was not accepted by the Norwegian home Government. The powers of the committee were, however, extended to consider a comprehensive revision of the Act of Union, with the limitation that the fundamental conditions of the union must in no way be interfered with. But before the committee had finished their report the king died (8th March 1844), and was succeeded by his son Oscar I. According to the constitution the Norwegian kings must be crowned in Throndhjem cathedral, but the bishop of Throndhjem was in doubt whether the queen, who was a Catholic, could be crowned, and after the question had become the subject of public discussion, the king decided to forego the coronation both of himself and his queen. The new king soon showed his desire to meet the wishes of the Norwegian people. Thus he decided that in all documents concerning the internal government of the country Norway should stand first where reference was made to the king as sovereign of the two kingdoms. After having received the report of the committee concerning the flag question, he resolved (20th June 1844) that Norway and Sweden should each carry its own national flag as the naval flag, with the mark of union in the upper corner; and it was also decided that the merchant flag of the two kingdoms should bear the same mark of union, and that only ships sailing under these flags could claim the protection of the State. The Union Committee did eventually present a report, in which it was proposed that the two countries should have a foreign minister in common, which the Norwegian Government gave their opinion upon, but which the Swedish Government rejected.

Death of King Carl Johan; succeeded by Oscar I.

The financial and material conditions of the country had now considerably improved, and King Oscar's reign was marked by the carrying out of important legislative work and reforms, especially in local government, of which Norway now possesses one of the most perfect systems. New roads were planned and built all over the country, the first railway was built, steamship routes along the coast were established, lighthouses were erected, and trade and shipping made great progress. The king's reign was not disturbed by any serious conflicts between the two countries, and the relations between the Government and the Storthing were of a harmonious character, both working for the internal development of the country. No change took place in the ministry under the presidency of the Viceroy Lövenskiold upon King Oscar's accession to the throne, but on the death or retirement of some of its members the vacant places were filled by younger and talented men, among whom was Frederik Stang, who in 1845 took over the newly established Ministry of the Interior. During the Schleswig-Holstein rebellion (1848–50) and the Crimean war King Oscar succeeded in maintaining the neutrality of Norway and Sweden, by which Norwegian shipping especially benefited. The abolition of the English Navigation

Acts (1850) was of great importance to Norway, and opened up a great future for its merchant fleet.

In 1826 a treaty had been concluded with Russia, by which the frontier between that country and the adjoining strip of Norwegian territory in the Polar region was definitely delimited; but in spite of this treaty Russia in 1851 demanded that the Russian Lapps on the Norwegian frontier should have the right to fish on the Norwegian coast, and have a portion of the coast on the Varanger fjord allotted to them to settle upon. The Norwegian Government refused to accede to the Russian demands, and serious complications might have ensued if the attention of Russia had not been directed in another direction. While his father had looked to Russia for support, King Oscar was more inclined to secure the Western Powers as his allies, and during the Crimean war (1855) he concluded a treaty with England and France, according to which these countries promised their assistance in the event of any fresh attempts at encroachment on Norwegian or Swedish territory by Russia. In consequence of this treaty the relations between Norway and Sweden and Russia became somewhat strained; but after the peace of Paris (1856) and the accession of Alexander II., whose Government was in favour of a peaceful policy, the Russian ambassador at Stockholm succeeded in bringing about more friendly relations.

Relations with Russia.

In 1855 two commissions, consisting of an equal number of Norwegians and Swedes, were appointed. One of these was to consider a new bill for regulating the commercial relations between the two countries, which was to take the place of an older one of 1827; while the other commission was to prepare a bill for the execution in either country of judicial judgments delivered in the other. The reports of these commissions were laid before and passed by the Swedish Riksdag; but when they came before the Norwegian Storthing they were rejected as unsuitable for Norway, a decision which caused great irritation in Sweden.

Owing to the king's ill-health, his son, Crown Prince Carl, was appointed regent in 1857, and two years later, when King Oscar died, he succeeded to the thrones of the two countries as Carl XV. He was a gifted, genial, and noble personality, and won the hearts of all who came into contact with him. He was also of an artistic nature, and devoted himself to painting, poetry, and music. He had desired to inaugurate his reign by giving the Norwegians a proof of his willingness to acknowledge the claims of Norway, but he did not live to see his wishes in this respect carried out. According to the constitution, the king had the power to appoint a viceroy for Norway, who might be either a Norwegian or Swede. Since 1829 no Swede had held the post, and since 1859 no appointment of a viceroy had been made, the general hope being that the office would be abolished altogether. But the paragraph in the constitution still existed, and the Norwegians naturally wished to have this stamp of "provinciality" obliterated. A proposal for the abolishment of the office of viceroy was laid before the Storthing in 1859, and passed by it. The king, whose sympathies on this question were known, had been appealed to, and had privately promised that he would sanction the proposed change in the constitution; but as soon as the resolution of the Storthing became known in Sweden, a violent outcry arose both in the Swedish press and the Swedish Estates. The latter adopted a resolution declaring that the paragraph relating to the office of viceroy was a necessary condition of the union between the two countries, and could not be altered without the consent of the Swedish executive. Under the pressure that was brought to bear upon the king in Sweden, he eventually refused to sanction the resolution of the Storthing; but he added that he shared the views of his Norwegian counsellors, and would, when "the convenient moment" came, himself propose the abolition of the office of viceroy. This was but a poor consolation for the Norwegian people, who well knew that it was the dominant feeling in Sweden against the equality of Norway in the union which had come out triumphantly on this occasion. When the Storthing received the news of the refusal, it adopted an address to the king (April 1860) which stated that no Norwegian who had any regard for his country and his own honour would take any share in the revision of the Act of Union on any other basis than that of the complete equality of the two kingdoms in the union.

Death of Oscar I.; accession of Carl XV.

Question of Norwegian viceroy.

In the following year the Swedish Government again pressed the demands of the Swedish Estates for a revision of the Act of Union, which this time included the establishment of a union or common parliament for the two countries, on the basis that, according to the population, there should be two Swedish members to every Norwegian. The proposal was sent to the Norwegian Government, which did not seem at all disposed to entertain it; but some dissensions arose with regard to the form in which their reply was to be laid before the king. The more obstinate members of the ministry resigned, and others, of a more pliable nature, were appointed under the presidency of Fredrik Stang, who had already been minister of the interior from 1845 to 1856. The reconstructed Government was, however, in accord with the retiring one, that no proposal for the revision of the Act of Union could then be entertained, as the attitude of Sweden towards the claims of the Norwegians for equality in the union seemed to be the same as in 1859 and 1860, and the question was in consequence to be allowed to rest for the time being. The king, however, advocated the desirability of a revision, but insisted that this would have to be based upon the full equality of both countries.

Swedish proposals for revision of Act of Union.

In 1863 the Storthing assented to the appointment by the king of a Union Committee, the second time that such a committee had been called upon to consider this vexatious question. It was not until 1867 that the report of the committee was made public, but it could not come on for discussion in the Storthing till it met again in 1871. During this period the differences between the two countries were somewhat thrust into the background by the Danish complications in 1863–64, which threatened to draw the two kingdoms into war. King Carl was himself in favour of a defensive alliance with Denmark, but the Norwegian Storthing would only consent to this if an alliance could also be effected with two, or at least one, of the Western Powers. Under the circumstances the king felt himself obliged to withdraw from the proposed alliance with Denmark, as none of the Western Powers showed any sign of assisting the Danes, although they had guaranteed the indivisibility of Denmark.

In 1869 the Storthing passed a resolution by which its sessions from 1871 were made annual instead of triennial according to the constitution of 1814. The first important question which the first yearly Storthing in 1871 had to consider was once more the proposed revision of the Act of Union. The Norwegians had persistently maintained that in any discussion on this question the basis for the negotiations should be (1) the full equality of the two kingdoms, and (2) no extension of the bonds of the union beyond the line originally defined in the Act of 1815, but the draft of the new Act contained terms in which the supremacy of Sweden was presupposed, and which introduced important extensions of the bonds of the union; and, strangely enough, the report of the Union Committee was adopted by the new Stang ministry, and even supported by some of the most influential newspapers and in several of the leading circles of the Norwegian community. The reactionary tendencies, which were hidden under the plausible garb of "Scandinavianism," reasserted themselves, and the official classes saw in this new union a safeguard against the growing liberal and democratic movements in the country. Under these circumstances the "lawyers' party," under the leadership of Johan Sverdrup, who was to play such a prominent part in Norwegian politics, and the "peasant party," led by Sören Jaabæk, a gifted peasant proprietor, who was also destined to become a prominent figure in the political history of the country, formed an intimate alliance, with the object of guarding against any encroachment upon the liberty and independence which the country had secured by the constitution of 1814. This was the foundation of the great national party, which became known as the "Venstre" (the left), and which before long became powerful enough to exert the most decisive influence upon the political affairs of the country. When, therefore, the proposed revision of the Act of Union eventually came before the Storthing of 1871, it was rejected by an overwhelming majority, and this contentious question, which since 1859 from time to time had assumed a most threatening aspect, may now be said to have been finally shelved and disposed of. The position which the Government had taken up on this question helped to open the eyes of the Norwegians to some defects in the constitution, which had proved obstacles to the development and strengthening of the parliamentary system, of which the constitution had laid the foundation, and to the desirability of a harmonious co-operation between the executive and legislative powers of the country, in order that the smaller State might more effectively assert its rights and position in the union in opposition to the greater, which seemed ever intent upon assuming the rôle of the predominant partner in the union. And this gave rise to the great question of the admittance of the ministers to seats in the National Assembly, which came to a crisis in the 'eighties.

Foundation of the Norwegian national party.

In 1872 a private Bill came before the Storthing, proposing that the ministers should be admitted to the Storthing and take part in its proceedings. After a number of stormy debates, the Bill was successfully carried under the leadership of Johan Sverdrup, by a large majority (80 against 29); but the Government, evidently jealous of the growing powers and influence of the new Liberal party in the Storthing, advised the king to refuse his sanction to the Bill, although the Government party itself had several times in the preceding half-century introduced a similar Bill for admitting the ministers to the

Question of admittance of ministers to seats in the Storthing.

Storthing; but at that time the Opposition had looked with suspicion on the presence of the ministers in the National Assembly, lest their superior skill in debate and political experience should turn the scale too readily in favour of Government measures. Now, on the contrary, the Opposition had gained more experience and confidence in its own strength, and no doubt found that the legislative work could better be carried on if the ministers were present to explain and defend their views; but the Government saw in the proposed reform the threatened introduction of full parliamentary government, by which the ministry could not remain in office unless supported by a majority in the Storthing. The king's refusal created great dissatisfaction and irritation both in the Storthing and throughout the country. The relations between the Government and the majority in the Storthing were already considerably strained, and in the refusal the Storthing only saw another ill-timed assertion of governmental authority. Before the Storthing separated the Liberals carried a vote of censure against the Government; but the king declared that the ministers enjoyed his confidence, and that he would uphold his right to appoint and keep what ministers he pleased, and took no further notice of the vote. Two of the ministers, who had advised the ratification of the Bill, resigned, however; and a third minister, who had been in the Government since 1848, resigned also, and retired from public life, foreseeing the storm that was brewing on the political horizon. Numerous public meetings were held all over the country in support of the proposed reform, fully approving of the step the Storthing had taken by proposing the vote of want of confidence. Among the speakers was Johan Sverdrup, who had now become the acknowledged leader of the Liberal party, and who was hailed with great enthusiasm as the champion of the proposed reform.

Death of Carl XV.; accession of Oscar II.

This was the political situation when King Carl died (18th September 1872). He was succeeded by his brother, who ascended the throne as Oscar II. In the following year he gave his sanction to the Bill for the abolition of the office of viceroy, which the Storthing had again passed, and the president of the ministry was afterwards recognized as the prime minister and head of the Government in Christiania. Fredrik Stang, who was the president of the ministry at the time, was the first to fill this office. In the same year Norway celebrated its existence for a thousand years as a kingdom, with great festivities.

Proposals by the Storthing for full popular control.

In 1874 the Government, in order to show the people that they to some extent were willing to meet their wishes with regard to the great question before the country, laid before the Storthing a royal proposition for the admittance of the ministers to the National Assembly. But this was to be accompanied by certain other constitutional changes, such as giving the king the right of dissolving the Storthing at his pleasure and providing fixed pensions for ex-ministers, which they held up as a guarantee against the majority of the assembly misusing its new power. The Liberal party in the meantime received more and more support all over the country for their proposal and for full parliamentary government. Johan Sverdrup well summed up their policy in the following curt sentence: "All power must be gathered in this hall." The Bill which the Government brought in was unanimously rejected by the Storthing, the Conservatives also voting against it, as they considered the guarantees insufficient. The same year, and again in 1877, the Storthing passed the Bill for admitting the ministers to the National Assembly, but in a somewhat different form from that of 1872. On both occasions the king refused his sanction to the Bill.

The king's veto.

The Storthing then resorted to the procedure provided by the constitution to carry out the people's will. In 1880 the Bill was passed for the third time, and on this occasion by the overwhelming majority of 93 out of 113. Three Storthings after three successive elections had now carried the Bill, without any divergent resolution having been adopted in the period between the first and third reading, and according to the constitution the Bill would then become law with or without the king's sanction. It was, however, generally expected that the king and his Government would at length comply with the wishes of the people, but the king on this occasion also refused to sanction the Bill, declaring at the same time that his right to the absolute veto was "above all doubt." A feeling of disappointment and irritation pervaded the whole country, and many even of the Conservatives, both in and out of the Storthing, regretted the king's decision. Johan Sverdrup, the leader of the Liberal party and president of the Storthing, brought, however, the question to a prompt issue by proposing to the Storthing that the Bill, which had been passed three times, should be declared to be the law of the land without the king's sanction. This proposal was carried by a large majority on the 9th of June 1880, but the king and his ministers in reply declared that they would not recognize the validity of the resolution.

Struggle between the king and the Storthing.

From this moment the struggle may be said to have centred itself upon the existence or non-existence of an absolute veto on the part of the crown. The king requested the Faculty of Law at the Christiania University to give its opinion on the question at issue, and with one dissentient the learned doctors upheld the king's right to the absolute veto in questions concerning amendments of the constitution, although they could not find that it was expressly stated in the fundamental law of the country. The ministry also advised the king to claim a veto in questions of supply, which still further increased the ill-feeling in the country against the Government, and the conflict in consequence grew more and more violent.

Elections of 1882.

In the midst of the struggle between the king and the Storthing, the prime minister, Frederik Stang, resigned, and Christian August Selmer became his successor; and this, together with the appointment of another member to the ministry, K. H. Schweigaard, plainly indicated that the conflict with the Storthing was to be continued. In June 1882 the king arrived in Christiania to dissolve the Storthing, and on this occasion delivered a speech from the throne, in which he openly censured the representatives of the people for their attitude in legislative work and on the question of the absolute veto, the speech creating considerable surprise throughout the country. Great preparations were now made by both parties for the impending elections, and public meetings were held during the recess all over the country. Johan Sverdrup and Björnstjerne Björnson, the popular poet and dramatist, were the principal speakers, and called upon the people to support the Storthing in upholding the resolution of the 9th of June, and to rouse themselves to a sense of their political rights. The elections resulted in a great victory for the Liberal party, who returned stronger than ever to the Storthing, the Liberals now numbering 83 and the Conservatives only 31. The ministry, however, showed no sign of yielding or resigning their offices, and when the new Storthing met in February 1883, the Odelsthing (the lower division of the National Assembly) decided upon having the question finally settled by impeaching the whole of the ministry before the Rigsret, or the supreme court of the realm, the last constitutional means by which the Storthing could obtain the dismissal of the ministry, which for years had continued to govern without the confidence or support of the National Assembly. The jurisdiction of the Rigsret is limited to the trial of offences against the State, and there is no appeal against its decisions. The charges against the ministers were for having acted contrary to the interests of the country by advising the king to refuse his sanction—first, to the amendment of the law for admitting the ministers to the Storthing; secondly, to a bill involving a question of supply; and thirdly, to a bill by which the Storthing could appoint additional directors on the State railways.

Impeachment of ministers by the Storthing, 1883.

The ministry sentenced by the Rigsret.

The trial of the eleven ministers of the Selmer cabinet began in May 1883, and lasted over ten months. In the end the Rigsret sentenced the prime minister and seven of his ministers to be deprived of their offices, while three, who had either recommended the king to sanction the Bill for admitting the ministers to the Storthing, or had entered the cabinet at a later date, were heavily fined. The excitement in the country, already considerable before the verdict had been given, rose to feverish anxiety in expectation of what the king would do. The Conservative organs of the country openly advised the king to disregard the judgment of the supreme court, while party feeling everywhere ran high. Rumours of all kinds were afloat, and it was generally believed that the king would attempt a *coup d'état*. Many of the Conservative party in Sweden also encouraged the king to set the judgment aside, and it was even hinted that he might depend upon the Swedish army to assist him in carrying out his policy in Norway. Fortunately the king did not follow this advice, and after some hesitation he issued (11th March) an order in council announcing that the judgment of the supreme court would be carried into effect, and Selmer was then called upon to resign his position as prime minister. The king, however, in his declaration upheld the constitutional prerogative of the crown, which, he maintained, was not impaired by the judgment of the Rigsret. The Conservatives were much disappointed with the king's course of action, but consoled themselves by forcing upon the king the urgent necessity of appointing a new Conservative ministry, which would carry on the policy of the late cabinet. The following month the king, regardless of the large Liberal majority in the Storthing, asked Schweigaard, one of the late ministers, whose punishment consisted in a fine, to form a ministry, and the so-called "April ministry" was then appointed. It tried to adopt the policy of its predecessors in a moderate form, but it met with such opposition from the very first that it sent in its resignation in the following month. Professor Broch, a former minister, next attempted to form a ministry, but without success, and the king

Acquiescence by the king.

was at last compelled to appoint a ministry in accordance with the majority in the Storthing. In June 1883 Johan Sverdrup was asked to form a ministry. He selected for his ministers leading men on the Liberal side in the Storthing, and the first Liberal ministry that Norway had was at length appointed. The Storthing, in order to satisfy the king, passed a new resolution admitting the ministers to the National Assembly, which then received the formal sanction of the king.

First Liberal ministry, 1883.

During the following years a series of important reforms were carried through. Thus in 1887 the jury system in criminal matters was introduced into the country after violent opposition from the Conservatives. A Bill intended to give parishioners greater influence in Church matters, and introduced by Jakob Sverdrup, the minister of education, and a nephew of the prime minister, met, however, with strong opposition, and was eventually rejected by the Storthing, the result being a break-up of the ministry and a disorganization of the Liberal party. In June 1889 the Sverdrup ministry resigned, and a Conservative one was formed by Emil Stang, the leader of the Conservatives in the Storthing, and during the next two years the Storthing passed various useful measures; but the ministry was eventually wrecked on the rock of the great national question which about this time came to the front —that of Norway's share in the transaction of diplomatic affairs. At the time of the union in 1814 nothing had been settled as to how these were to be conducted, but in 1835 a resolution was issued, that when the Swedish foreign minister was transacting diplomatic matters with the king which concerned both countries, or Norway only, the Norwegian minister of state in attendance upon the king at Stockholm should be present. This arrangement has not always proved satisfactory to the Norwegians, especially as the Swedish foreign minister cannot be held responsible to the Norwegian Government or Parliament; but in the meanwhile this state of affairs has been allowed to drift on, and gradually the Swedish foreign minister has come to be looked upon as the foreign minister for Norway also. But this is not sanctioned by any paragraph in the constitution or the Act of Union, neither has it been confirmed by any act of the Storthing, and the Norwegians maintain that Norway has not enjoyed equal rights in the union and equal share in the transaction of diplomatic affairs with Sweden, as, according to the Act of Union, it had a right to demand.

The question of diplomatic representation.

By a change in the Swedish constitution in 1885 the ministerial council, in which diplomatic matters are discussed, came to consist of the Swedish foreign minister and two other members of the cabinet on behalf of Sweden, and of the Norwegian minister at Stockholm on behalf of Norway. The king, wishing to remedy this disparity, proposed that the composition of the council should be determined by an additional paragraph in the Act of Union. The representatives of the Norwegian Government in Stockholm proposed that three members of the cabinet of each country should constitute the ministerial council, to which the Swedish Government were willing to agree, but on the assumption that the minister of foreign affairs should continue to be a Swede as before, which the Norwegians, of course, would not accept. The matter was in consequence shelved, and remained in abeyance for some time, but continued to be discussed in the press and at public meetings.

The Norwegian claim.

At the king's instigation the negotiations with the Swedish Government were resumed at the beginning of 1891, and the Stang ministry succeeded in coming to an agreement with the Swedish Government that a measure should be introduced by which the Norwegians would practically obtain what the Storthing of 1886 had asked for, while the question of the nationality of the minister of foreign affairs was left for settlement in the near future. The Swedish Riksdag, however, rejected the proposal, while the Norwegian Storthing insisted upon "Norway's right, as an independent kingdom, to full equality in the union, and therewith her right to watch over her foreign affairs in a constitutional manner."

The Stang ministry then resigned, and a Liberal ministry, with Steen, the recognized leader of the Liberal party after Sverdrup's withdrawal from politics, as prime minister, was appointed. In the same year the provision in the constitution empowering the king to instal the crown prince as regent in Norway was repealed, and the resolution was sanctioned by the king.

The new ministry had placed the question of a separate minister of foreign affairs for Norway prominently in their programme, but little progress was made during the next few years. Another and more important question for the country, as far as its shipping and commerce are concerned, now came to the front. The Storthing had in 1891 appointed a committee to inquire into the practicability of establishing a separate Norwegian consular service, instead of the existing combination with Sweden, with which the Norwegians maintain they have had reason to be dissatisfied. In 1892 the Storthing, acting upon the committee's report, determined to establish a consular service in accordance with a plan prepared by the department of the interior. The king, no doubt influenced and supported by public opinion in Sweden, which was against the proposed separation of the consular services, refused his sanction, and the Norwegian Government in consequence sent in their resignation, whereupon a complete deadlock ensued. This was terminated by a compromise to the effect that the ministry would return to office on the understanding that the question be postponed by common consent. The following year the Storthing again passed a resolution calling upon the Norwegian Government to proceed with the necessary measures for establishing the proposed consular service for Norway, but the king again refused to take any action in the matter. Upon this the Liberal ministry resigned (May 1893), and the king appointed a Conservative Government, with E. Stang as its chief. Thus matters went on till the end of 1894, when the triennial elections took place, with the result that the majority of the electors declared in favour of national independence on the great question then before the country—that of separate consuls for Norway, and eventually of a separate responsible minister of foreign affairs for the country. The ministry did not at once resign, but waited till the king arrived in Christiania to open the Storthing (January 1895). The king would not accept their resignation there and then, but kept the country for over four months without a responsible Government, during which time the crisis had become more acute than ever. A coalition ministry was at last formed, with Professor Hagerup as prime minister. A new committee, consisting of an equal number of Norwegians and Swedes, was appointed to consider the question of separate diplomatic representation; but after sitting for over two years the committee separated without being able to come to any agreement, having, like the two previous "union committees," proved the impossibility of the two countries coming to an understanding in this important question. While the committee was sitting the disputes concerning the political relations between the two countries were allowed to lie in abeyance.

Question of separate consular service.

The elections in 1897 proved again a great victory for the Liberal party (79 Liberals *v.* 35 Conservatives), and in February 1898 the Hagerup ministry was replaced by a Liberal, once more under the premiership of Steen. Soon afterwards the Bill for the general adoption of the national or "pure" flag, as it was called, was carried for the third time, and became law without the king's sanction. By this act the device or mark of union in the upper corner of the flag was abolished, but is still retained on men-of-war and fortifications. In 1898 universal political suffrage for men was passed by a large majority (75 *v.* 36), while the proposal to include women received the support of only 33 votes. In 1901 universal municipal suffrage was given both to men and women; to the latter, however, with certain limitations. In January 1902 a committee was appointed to consider the consular question, and it was hoped that at last it would be settled. In April 1902 Steen, the prime minister, resigned and retired into private life. He was succeeded by Otto Albert Blehr. (H. L. B.)

III. Literature since 1885.

The political crisis of 1884–85, which produced so remarkable an effect upon the material and social life of Norway, was not without its instant influence upon literature. There had followed to the great generation of the 'sixties, led by Ibsen and Björnson, a race of entirely prosaic writers, of no great talent, much exercised with "problems," disturbed by the theories of Zola and Maupassant, which they failed to comprehend, and ruined for the higher imaginative spheres of work by their obstinately doctrinaire attitude towards life. What strikes us as of high interest in the movement which began in 1885 is, firstly, that it brought back the fine masters of a previous imaginative age; secondly, that it silenced the problem-setters; and thirdly, that it encouraged into eager production a whole generation of new men, realists of a healthier sort, individualists, idealists, and poets. In 1885, then, the field was still held by the three great writers who are the three main names of modern Norse literature — Ibsen, Björnson, and Lie. Henrik Ibsen (born 1828) (*q.v.*) proceeded deliberately with his labours. During the period under review he produced seven dramas, including what many critics hold to be his *chef-d'œuvre*, *The Master Builder*. His tendency was to turn more and more definitely back again towards the poetic and symbolic manner of his youth, and his name has at the same time steadily grown in reputation and influence. The advance of Björnstjerne Björnson (born 1832) (*q.v.*) was not so regular, because it was disturbed by political issues; but he published one of the most remarkable of his novels, *In God's Way*, and various tales and dramas. Moreover, his early peasant tales have once more, after having suffered great neglect, grown to be a force, and Björnson's example has done much to revive an interest in the art of verse, which had entirely died out in Norway in the previous decade. Jonas Lie (born 1833) (*q.v.*), still without a rival as the most popular novelist of Norway, continued to publish his pure, fresh, and eminently characteristic stories. Of these, eight or ten appeared after 1885, among them the most prominent being perhaps *The Commodore's Daughter* and *Dyre Rein.* Lie is not a great creative artist, but he contrived to win the ear of his country by his sincerity, his skill in narrative, and his remarkable power of identifying himself with the peculiarities of Norwegian feeling. His style, colloquial almost to a fault, has neither the charm of Björnson nor the art of some of the latest generation. Ibsen, Björnson, and Lie continue, however, to be the three representative authors of their country, and in their old age they grew to be the objects of extreme reverence and curiosity. Ibsen's mother-in-law, the venerable novelist, Magdalene Thoresen (born 1819), who long resided in Denmark, published nothing new for many years. Of the generation which followed hers, Kristofer Janson (born 1841) survived in 1902. In 1882 he left Norway to settle in America as a Unitarian minister, and from this exile he sent home in 1885 what is perhaps the best of his books, *The Saga of the Prairie.* Janson went back to reside in Norway, and published in 1901 the most successful of his recent productions, *Mediæval Tales.* He writes in dialect, and has essayed lyric and drama, as well as prose fiction. Kristian Gloërsen (born 1838), though still living in 1902, had not written for many years past. Frithiof Foss (1820–1899) had long been silent before his death.

During the transition an author appeared, Alexander Kielland (born 1849), from whom for a time much was expected, and whose writings were treated with exaggerated attention. From 1878 to about 1887 Kielland published in rapid succession a series of novels and short stories, in which he showed himself a rather naïve imitator of Guy de Maupassant. He had no real vocation for letters, however, and civic ambition took the place of literary ardour; Kielland was made burgomaster of Stavanger, and has been heard of no more. A far more important talent of the transitional time was that of Arne Garborg (born 1851). He was brought up under sternly pietistic influences in a remote country parish, the child of peasant parents, in the south-west corner of Norway, and the gloom of these early surroundings has tinged all his writings. The early novels of Garborg were written in the peasant dialect, and for that reason, perhaps, attracted little attention. It was not until 1890 that he addressed the public in ordinary language, in his extraordinary novel, *Tired Men*, which produced a deep sensation. This was an analysis of the passive type of intelligent decadent, the thinking man without a will, who becomes more and more a feature of modern society. Of late Garborg has returned, with violence, to the cultivation of the peasant language, and has taken a foremost part in the *maalstræv.* A novelist of considerable crude force is Amalie Skram, settled in Denmark, who continues to write novels destitute of literary beauty, but excellent in their local colour, dealing with life in Bergen and the west coast. But the most extravagant product of the prosaic period was Hans Jaeger (born 1854), who accepted the naturalistic formulas wholesale, and outdid Zola himself in the harshness of his pictures of life. The suit brought against his preposterous novel, *Kristiania-Bohêmen*, in 1885, was the signal for a reaction, and marks the moment of crisis. An author of more talent, in whom many of the qualities of the "problem" school are still to be discovered, is Knud Hamsun (born 1860), who has been remarkable for his egotism, and for the bitterness of his attacks upon his own fellow-writers and upon the great classic names of literature. He is more pleasantly contemplated in his own novels, which, however, are commonly deformed by a cynical violence and ugliness; Hamsun is seen at his best in the powerful romance called *Hunger* (1888). A writer of a much more pleasing, and in its quiet way of a much more original order, is Hans Aanrud (born 1863), in whom the new influences of sweetness and light first made themselves felt. His humour, applied to the observation of the Östland peasants—Aanrud himself comes from the Gulbrandsdal—is exquisite; he is by far the most amusing of recent Norwegian writers, a race whose fault it is to take life too seriously. His story, *How Our Lord made Hay at Asmund Bergemellum's*, is a little masterpiece. His latest volume is *The Seminarist* (1901). Peter Egge (born 1869) is a young novelist and playwright from Trondhjem, who is steadily coming to the front with very careful studies of types of Norwegian temperament. In his *Jacob and Christopher* (1901) Egge also proved himself a successful writer of comedy. Gunnar Heiberg (born 1857), although older than most of the young generation, has but lately come into prominence. His poetical drama, *The Balcony*, made a sensation in 1894, but ten years earlier his comedy of *Aunt Ulrica* should have awakened anticipation. Heiberg is ardent and sensual, filled with the joy of life; his dialogue is brilliant, but it might be possible to wish that it were made the ornament of less momentary issues. He is an author from whom much is expected. Two young writers of great promise have been removed in the very heyday of success, Gabriel Finne (1866–1899) and Sigbjörn Obstfelder (1866–1900). The last-mentioned was much under the sway of the latest mysticism, and not unbiassed by Maeterlinck. But in two books published in 1897, *The Red Drops* and *The Cross*, he achieved an independent effect, obscure but attractive, and giving promise of something quite new in Norwegian literature. Obstfelder, who died in a hospital in Copenhagen in August 1900, left an important book in MS., *A Priest's Diary* (1901).

Verse was not merely neglected, but absolutely banished from Norwegian literature, during the years that immediately preceded 1885. The credit of restoring it is given to a writer named Sigurd Bödtker, who wrote an extremely naturalistic piece called *Love*, in the manner of Heine. The credit of being the earliest real poet of the new generation belongs, however, without question to Niels Collett Vogt (born 1864), who published a little volume of *Poems* in 1887. In 1891 was printed in a magazine Vilhelm Krag's (born 1871) very remarkable poem called *Fandango*, and shortly afterwards a collection of his lyrics. Vogt and V. Krag continued to be the leading lyrical writers of the period, and although they have many imitators, they cannot be said to have found any rivals. Vilhelm Krag has of late turned to prose fiction, and his novels *Isaac Seehuusen* (1900) and *Isaac Kapergast* (1901) are excellent studies of Westland life. More distinguished as a novelist, however, is his brother, Thomas P. Krag (born 1868), who has published a series of romantic novels, of which *Ada Wilde* (1897) is the most powerful; he has great charm of presentment, but seems unhappily not to be able to escape from a curious monotony of subject and treatment. His short stories are full of delicate charm;

the latest collection of them is *The Happy Corner* (1901). Hans E. Kinck (born 1865) is an accomplished writer of short stories from peasant life, written in dialect. He has published ten volumes, from *The Fairy* (1892) to *Spring Nights* (1901). Bernt Lie is the author of nine or ten popular works of fiction, mainly for the young; the latest of these is *Sister Judith* (1901). Sven Nilssen (born 1864) began to publish sketches and stories in 1894, and is the author of a very successful novel, *The Barque Franciska* (1901). With him may be mentioned the popular dramatist and memoir-writer, John Paulsen (born 1851), author of *The Widow's Son*. Jakob Hilditch (born 1864) has written many stories and sketches of a purely national kind, and is the anonymous author of a most diverting parody of banal provincial journalism, *Tranviksposten* (1900–1). Criticism made some advance in these last years. The leading critics are Carl Nærup (born 1864) and Hjalmar Christensen (born 1869), each of whom has published valuable collections of essays dealing with the aspects of recent Norwegian literature. The sudden death of the leading bibliographer and lexicographer of Norway, Jens Braage Halvorsen (1845–1900), inflicted a blow upon the literary history of his country; his *Dictionary of Norwegian Authors*, 1885–1900—still unhappily incomplete—is one of the most elaborate works of its kind ever undertaken. It is to be finished by Halfdan Koht. Among recent historians of Norway much activity has been shown by Ernst Sars (born 1835) and Yngvar Nielsen (born 1843). In Norwegian systematic theology no one has arisen to take the place of Carl Paul Caspari (1814–1892), or even of Gisle Johnson (1822–1894). The great historian of Northern jurisprudence was L. M. B. Aubert (1838–1896), and in this connexion T. H. Aschehoug (born 1822) must also be mentioned. The leading philosopher of Norway in these years has been the Hegelian Marcus Jakob Monrad (born 1816), whose *Æsthetics* of 1889 is his masterpiece.

The close of 1899 and the beginning of 1900 were occupied by a discussion, which drowned all other interests, and in which every Norwegian author took part, as to the adoption of the *landsmaal*, or composite dialect of the peasants, as the national language in place of the *rigsmaal* or Dano-Norwegian. Political prejudice greatly embittered the controversy, but the proposition that the *landsmaal*, which dates from the exertions of Ivar Aasen (*q.v.*) in 1850, should oust the language in which all the classics of Norway are written, was opposed by almost every philologist and writer in the country, particularly by Björnson and Sophus Bugge (born 1833). On the other side, Arne Garborg's was almost the only name which carried any literary weight. The *maal* has no doubt enriched the literary tongue of the country with many valuable words and turns of expression, but there the advantage of it ends, and it is difficult to feel the slightest sympathy with a movement in favour of suppressing the language in which every one has hitherto expressed himself, in order to adopt an artificial dialect which exists mainly on paper, and which is not the natural speech of any one body of persons throughout the whole of Norway. (E. G.)

Norwich, a city and municipal, county (1888), and parliamentary borough of England, forming a county of itself, situated on the Wensum, a little above its junction with the Yare, in Norfolk, 103 miles from London by rail. "A fine old city, truly, is that, view it from whatever side you will; but it shows best from the east, where the ground, bold and elevated, overlooks the fair and fertile valley in which it stands. . . . At the foot of the heights flows a narrow and deep river, with an antique bridge communicating with a long and narrow suburb, flanked on either side by rich meadows of the brightest green, beyond which spreads the city; the fine old city, perhaps the most curious specimen at present extant of the genuine old English town. Yes, there it spreads from north to south, with its venerable houses, its numerous gardens, its thrice twelve churches, its mighty mound. . . . There is a grey old castle upon the top of that mighty mound; and yonder, rising 300 [215] feet above the soil, from among those noble forest trees behold that old Norman master-work, that cloud-encircled cathedral spire, around which a garrulous army of rooks and choughs continually wheel their flight" (George Borrow, *Lavengro*, chap. xiv.). Very many of the churches were restored, either wholly or in part, during the last sixteen years of the 19th century, *e.g.*, the cathedral in 1892 and 1900; St Peter Mancroft, St Andrew's, St Michael's at Coslany, and its Thorp chapel; St John Maddermarket, St Augustine's, St George's, St James's, St John the Baptist's, St Margaret's, St Martin at Oak, St Mary the Virgin, St Michael's at Plea, St Michael at Thorn. St Thomas's was consecrated in 1888. St Peter at Southgate was taken down in 1887. The Roman Catholic cathedral of St John the Baptist, begun in 1884 from designs by Mr G. G. Scott, occupies a commanding site outside St Giles's Gate. In 1884 the corporation purchased the castle, which had been used as a prison, and—a new gaol having been built on Mousehold Hill—converted it (1894) into picture galleries and rooms for the museum. The more notable public buildings and institutions which have come into existence since 1884 are—the volunteer drill hall, the new barracks on Mousehold Heath, the gaol there, the Blind Asylum and schools, the Norwich and Ely Diocesan Training College, the Soldiers' and Sailors' Institute, the Jenny Lind Infirmary for Sick Children (1900), and the Municipal Technical Institute, amalgamated with the School of Science and Art (1901). The Norfolk and Norwich Library was burnt down in 1899, but was re-erected and opened in 1900. Mousehold Heath has been acquired by the corporation, and laid out as a public recreation ground. Chapel Field Gardens and Castle Gardens are laid out as public recreation grounds. In 1899 the resewering of the city was completed. The numerous and varied industries retain their importance. The municipal and county borough, which is coextensive with the parliamentary borough, and has an area of 7558 acres, is administered by a mayor, 16 aldermen, and 48 councillors. It returns two members to the House of Commons. Population (1891), 100,970; (1901), 111,728. Birth-rate, 29·1 (1899); death-rate, 17·3 (1899).

See Rev. W. HUDSON, *How the City of Norwich grew into Shape* (Norwich, 1897), and other works by the same; also, books quoted under NORFOLK.

Norwich, a city of Connecticut, U.S.A., capital of New London county, on the Thames river, 14 miles above New London, in the south-eastern part of the state. Its plan is very irregular, it has an excellent water-supply, the works of which are owned and operated by the city, and an excellent sewerage system. It has a good harbour and much coastwise commerce, having daily steamers to New York. It is on the New York, New Haven, and Hartford (New England) and the Central Vermont railways. The capital invested in manufactures was, according to the census of 1900, $8,566,437, and the value of the products was $8,388,343. Population (1890), 16,156; (1900), 17,251.

Norwich, a village of New York, U.S.A., capital of Chenango county, in lat. 42° 32′, long. 75° 31′, on the Chenango river and the Delaware, Lackawanna, and Western and the New York, Ontario, and Western railways, at an altitude of 987 feet. It is in a farming and dairying region and contains some manufactures, including the works of the New York, Ontario, and Western Railway. Population (1890), 5212; (1900), 5766.

Norwood, a village of Hamilton county, Ohio, U.S.A., a few miles north-east of Cincinnati, of which it is a suburb. Population (1900), 6480, of whom 718 were foreign-born and 80 negroes.

Nossi Bé, an island and French colony off the north-west coast of Madagascar. It has an area of 130 square miles, and bristles with volcanoes. The climate is similar to that of Mayotte (see COMORO ISLANDS), and the neighbouring island of Nossi Comba serves for a sanatorium. The population, consisting of Sakalavas, increased from 7800 to 9500 between 1888 and 1898. Since 1896 Nossi Bé has been under the authority of the governor of Madagascar. It has an administrator at Hellville (population, 1100), the capital, a port of call for the Messageries steamships from France, and an important centre for the coasting trade along the western shores of Madagascar. There is excellent anchorage at this port, which has a magnificent pier 800 feet long; two important German mercantile houses have been established, and there are twenty factories for sugar and rum. The soil of the island is very fertile, and yields coffee, sesame, the sugar-cane, vanilla, and tobacco. The trade with France in 1898 amounted to only £22,120, of which £16,000 was for imports, but the total trade exceeded £120,000.

Noto, a town and bishop's see of the province of Syracuse, Sicily, Italy, 27 miles south-west of Syracuse on the railway to Licata. It possesses a fine town hall and cathedral, a convict prison, and antiquarian and numismatic collections. It manufactures vegetable fibre, macaroni, and olive oil, quarries limestone, and produces wine. Population (1881), 16,262; (1899), 18,500.

Nottingham, a north midland county of England, bounded on the E. by Lincoln, on the S. by Leicester, on the W. by Derby and York, and on the N. by York.

Area and Population.—In 1891 the area of the ancient (geographical) county was 539,752 acres, and the population 445,823, of whom 214,199 were males and 231,624 females, showing an increase of 54,008 since 1881, an increase at the rate of 12·1 per cent., as compared with an increase at the rate of 17·3 per cent. during the ten years 1871–81. In 1901 the population was 514,537, showing an increase of 68,714, or at the rate of 15·4 per cent. since 1891. In 1901 there were 0·95 persons to an acre and 1·04 acres to a person. The area of the registration county in 1891 was 616,285 acres, and the population 505,311, of whom 245,338 were males and 259,973 females; and in 1901, 596,668. Particulars of the birth-rate, death-rate, and the number of persons married per thousand inhabitants, as well as the illegitimacy-rate per thousand births, are given in the annexed table:—

	1871–80.	1881–90.	1889–98.	1899.
Birth-rate	36·9	36·1	32·5	32·2
Death-rate	21·4	19·6	17·9	18·8
Illegitimacy-rate	64	54	54	48
Marriage-rate	17·8	16·3	16·3	17·6

In 1891 the county contained 1734 persons of Scottish birth, 1454 of Irish birth, and 1295 foreigners. At the same date there were 390 blind persons, 200 deaf and dumb, and 1474 insane.

Administration.—For parliamentary purposes the ancient county is divided into four divisions (Bassetlaw, Newark, Rushcliffe, and Mansfield), each returning one member, and the parliamentary borough of Nottingham, which returns one member for each of its three divisions (West, East, and South). The administrative county embraces the three municipal boroughs of East Retford, Mansfield, and Newark, and the county and municipal borough of Nottingham. There are one court of quarter sessions and seven petty sessional divisions. The boroughs of East Retford, Newark, and Nottingham have separate commissions of the peace, also separate courts of quarter sessions. The administrative county contained 259 and the county borough of Nottingham 9 entire civil parishes in 1891; there were also four parishes which were partly situated in the county and partly in the county borough, and three others which were partly in other administrative counties. Since 1897 the nine parishes and four parts of parishes comprised within the county borough have been constituted one civil parish. The ancient county contains 220 entire ecclesiastical parishes and districts, and parts of six others; it is situated principally in the diocese of Southwell and partly in the diocese of York.

Education.—University College at Nottingham was attended during the session 1899–1900 by 1914 students; the college was opened in 1881. Associated with it is a day training college for schoolmasters and schoolmistresses. At Nottingham there are also the Midland Institution for the blind and a school for deaf-mutes. On 31st August 1900 the county contained 245 elementary schools, namely, 60 board schools and 185 voluntary schools, the latter including 164 National Church of England schools, 8 Wesleyan, 5 Roman Catholic, and 8 "British and other." The average attendance during the year amounted to 42,873, out of a total of 53,066 on the register. The total school board receipts during the year were £188,355, inclusive of £563 earned under the Technical Instruction Act and £2669 under the Agricultural Rates Act.

Agriculture.—Since 1885 there has been an increase in the area of the meadow-lands, but a decrease in the areas sown with corn and devoted to fallows; also an increase in the acreage of permanent grass. The area cultivated by tenants increased from 378,429 acres in 1889 to 385,319 acres in 1895, and to 395,003 acres in 1900; the area cultivated by owners decreased from 76,650 in 1889 to 62,918 acres in 1895, and to 52,686 in 1900.

The following table shows the areas under the different kinds of crops at the periods named:—

Year.	Area in Cultivation.	Area under Corn Crops.	Area under Green Crops.	Area of Bare Fallow.	Area under Permanent Grass.
1880	450,862	149,162	51,834	24,232	...
1885	455,077	135,047	51,781	16,304	190,193
1890	455,739	126,691	49,733	13,366	204,333
1895	448,237	119,794	49,987	9,811	208,531
1900	447,689	123,663	51,115	8,418	209,274

The next table shows the number of the live stock at the periods named:—

Year.	Cows and Heifers.	Other Cattle.	Total Cattle.	Horses.	Sheep.	Pigs.
1880	23,735	53,884	77,619	20,348	258,120	23,026
1885	28,636	59,619	88,255	20,456	229,983	26,605
1890	28,474	53,533	82,007	21,087	231,417	32,333
1895	26,834	54,318	81,152	22,836	221,642	33,649
1900	28,405	57,686	86,091	22,405	196,680	28,295

Industries.—During the year 1897 the number of hands employed in the factories and workshops of the county amounted to 67,556, of whom 9410 were engaged in making machinery, implements, &c., 8986 in the clothing industries, 8955 in lace-making, 6961 in making hosiery, 4396 in bleaching and dyeing, 3299 in the paper and printing trades, 2965 in the cotton and woollen manufacture, 2852 in manufacturing tobacco and cigars, 1772 in the metal industries, 1549 in the wood industries, and 1460 in brewing, &c. Coal is the principal mineral mined, chiefly on the south-west border of the county, near Mansfield, and near Nottingham. In 1900 the output was 8,626,177 tons of coal (valued at £4,708,455), 397,073 tons of clay, 133,610 tons of gravel and sand, 77,492 tons of gypsum, 95,790 tons of limestone, and 6582 tons of sandstone; the total value of all the mineral products being £4,784,322. In the same year 28,009 persons were employed in the mines and quarries.

See J. T. GODFREY. *Notes on the Bibliography of Nottinghamshire.* Ratcliffe-on-Trent, 1891.—J. WARD. *Descriptive Catalogue of Books relating to Nottinghamshire.* Nottingham, 1892.

(J. T. BE.)

Nottingham, a municipal, county, and parliamentary borough of England, officially styled (by letters patent of 7th August 1897) "the City of Nottingham and County of the Same City," with a present area of 10,935 acres; on the Trent, 124 miles from London by rail. Connexion with the London and North-Western line was opened in 1888, and with the Great Central in 1899, the station on the latter railway costing over a million sterling. By the Borough Boundaries Act of 11th June 1887 the parishes or districts of Sneinton, Lenton, Radford, Bulwell, Standard Hill, the Castle, Brewhouse Yard, and parts of Wilford, West Bridgford, and Gedling were incorporated in the municipal borough, which is now administered by a mayor, 16 aldermen, and 48 councillors, and has its own commission of the peace and a separate court of quarter sessions. Of modern churches may be mentioned St Catherine's, in the Perpendicular style, St George's, St Emmanuel's, St Stephen's (1898), and St Bartholomew's, erected in 1899. The following have been restored since about 1875: St Mary's, St James's, St Mark's, and St Peter's. In addition to their cathedral, the Roman Catholics own the church of St Edward's and the Church of Our Lady and St Patrick. Altogether there are over 90 Nonconformist places of worship. In 1899–1900 University College was attended by 1914 students, whilst 16,951 class tickets were issued. There are two technical schools in connexion with the school board. The more notable public buildings are the Guildhall and City Sessions Courts (1887), the post office, and the poor law offices. The county gaol was enlarged in 1894. The Free Library and the Free Museum of Natural History have been housed in the University College buildings since 1881; the former has 13 branches. In 1886 a new cattle market, covering 7 acres, was opened. New corporation and private baths have been built in Gedling Street, and a new wing added to the Midland Institution for the Blind. There is a high school for girls; and in 1882 the Midland Baptist College was transferred to Nottingham. The city is supplied with water from waterworks at Papplewick, Bestwood, Bellevue, Mapperley, and Burton Joyce, and there is a reservoir at Boughton. The principal industries still remain the same as in 1884, but the cycle trade is now largely carried on here and in the locality. The city returns three members to the House of Commons, being divided for parliamentary purposes into the West, East, and South divisions. Population (1891), 213,877; (1901), 239,753. Area, 10,935 acres. Death-rate, 20·0 (1899); birth-rate, 28·8 (1899).

See *Records of the Borough of Nottingham*, 4 vols. (1882–89).

Nouzon, town, arrondissement of Mézières, department of Ardennes, France, 4 miles north of Mézières by rail, picturesquely situated at the confluence of the Gontelle and the Mardreuil with the Meuse. It has numerous foundries and forges turning out all kinds of iron goods. One of the establishments is said to be the largest foundry for malleable metal in France. Steam tramways connect Nouzon with Neufmanil, 6 miles, and Gespunsart, 8 miles distant, where also are important iron-works. Population (1891), 6473; (1901), 7795.

Novaliches, Manuel Pavia y Lacy (1814–1896), 1st Marquis de, Spanish marshal, was born at Granada on 6th July 1814. He was the son of Colonel Pavia, and after a few years at the Jesuit school of Valencia he entered the Royal Artillery Academy at Segovia. In 1833 he became a lieutenant in the guards of Queen Isabella II., and distinguished himself so much during the Carlist war from 1833 to 1840 that he rose to the rank of general of division in the latter year at the early age of twenty-six. He was offered the post of war minister before he reached his thirtieth year. He then began to take part in politics with the Moderate party, who made him war minister in 1847, and sent him to assume the command in Catalonia, where the great severity he displayed in his efforts to put down a Carlist rising was not attended with success. He had been made a senator in 1845, and marquis in 1848. Despite his reluctance, he was sent out to Manila in 1852 as captain-general of the Philippine Islands. In April 1854 he crushed with much sternness a formidable insurrection, shot or hanged all the ringleaders, and carried out many useful reforms after he had pacified the colony. On his return to Spain he married the countess of Santa Isabel, and commanded the reserves in the Peninsula during the war with Morocco. He refused the war portfolio twice offered him by Marshals O'Donnell and Narvaez, and undertook to form a cabinet of Moderates in 1864 that lived but a few days. He volunteered to assist in crushing the insurrection in the streets of Madrid on 22nd June 1866, and when the revolution broke out decisively in September 1868 he accepted the command of Queen Isabella's troops. At their head he was defeated by Marshal Serrano at the bridge of Alcolea 28th September 1868, and was so badly wounded in the face that he was disfigured for life. He kept apart during the revolution, and went to meet King Alphonso XIII. when he landed at Valencia in January 1875. The Restoration made the marquis de Novaliches a senator, and the new king gave him the Golden Fleece. He died in Madrid on 22nd October 1896.

Novara, a town, episcopal see, and capital of the province of the same name, Piedmont, Italy, 31 miles by rail west of Milan. The town possesses a new theatre (1888), a museum of Roman antiquities, a notaries' school, and a technical school; and is adorned by a bronze statue of Garibaldi and an equestrian monument of Victor Emmanuel (1881). There are two schools of the industrial arts. The principal industry is the carding and spinning of silk; there are, further, iron-works and foundries, cotton mills, rice-husking mills, organ factories, dye-works, and printing works. Population (1881), 25,181; (1901), 44,928.

Nova Scotia.—A province of the Dominion of Canada, lying between 43° 25′ and 47° N. and 59° 40′ and 66° 10′ W. The Lower Cambrian formation, which forms an almost continuous belt along the Atlantic coast, where extensive gold-mining operations are carried on, varies in width from 10 to 75 miles and covers an area estimated at 8500 square miles. This belt is interrupted by large masses of intrusive granite, which occupy about 3500 square miles, leaving 5000 square miles of gold-bearing rocks. This part of the province presents a rough, rugged, and sterile appearance, abounding in small lakes and peat bogs. North of this area rocks of Ordovician, Silurian, and Devonian ages occur, which are also interrupted by great masses of felspathic and granitic rocks. These formations are capped in places by the Carboniferous and Permian, including two large areas of productive coal measures in Cumberland and Pictou counties respectively. The Carboniferous area is divided into Carboniferous limestone or gypsiferous series, the Millstone Grit and the Coal Measures. The Cobequid Mountains, rising to a height of about 1050 feet and extending from the Bay of Fundy along the shores of Minas Channel and Basin to the vicinity of Pictou, form the most prominent physical feature of this part of the province. The surface of the greater part is, however, undulating, with fertile uplands and exceedingly rich valleys and marshes. Along the coast of the Bay of Fundy and at Minas Basin and Channel are bright, soft red sandstones of Triassic age associated with masses of contemporaneous trap rich in zeolites. The ridge of trap extending along the coast from Minas Channel to Briar Island is called the North Mountain, and rises about 700 feet high. Besides gold, already referred to, coal, gypsum, grindstones, building stone, and many minerals of economic importance are found in the province. (See Breton, Cape.)

The following statistics relate to the whole province, including Cape Breton.

Climate.—Owing to its insular position, Nova Scotia enjoys a more temperate climate than New Brunswick. The average summer temperature is 65° F. and the winter 25° F. The average rainfall for twenty-seven years (1874–1900) was

38·1 inches, and the snowfall for the same period was 75·4 inches; total precipitation, 45·6 inches.

Game.—Large and small game abound, owing to the strict enforcement of the laws, but the wolf has become extinct.

Area and Population.—The area of the province is about 21,068 square miles, and the population is now (1901) 459,574. Population per square mile, 21·8. The population was 440,572 in 1881; in 1891, 450,396. In 1901 there were 89,106 families; average number per family, 5; number of males, 233,642, and the number of females, 225,932. In 1891 the occupations were thus distributed: agriculture, fishing, and mining, 83,233; domestic and personal service, 23,468; manufactures and mechanical industries, 26,548; professional, 6100; trade and transportation, 18,117; non-productive, 2619. In the census of 1901 the origin of the people is given as follows: English, 162,141; Irish, 55,830; Scottish, 142,207; Welsh, 1199; Dutch, 2941; French, 45,067; German, 38,854; Indians, 1543; negroes, 5984; Swiss, 1004; all other nationalities, 2804. Of the whole population, 457,948 were either born in Canada or are now naturalized citizens.

Constitution and Government.—The provincial executive now consists of three ministers with salaries and six without portfolios, and the members elected to the House of Commons have been reduced from twenty-one to twenty.

Religion.—In 1901 the principal religious denominations and their adherents were as follows: Church of England, 66,067; Church of Rome, 129,578; Presbyterians, 106,319; Methodists, 57,490; Baptists, 83,333; Congregationalists, 2938; Lutherans, 6572; Adventists, 1494; Disciples of Christ, 1412; Salvation Army, 1251.

Education.—In 1901 there were 2387 schools in operation, attended by 98,410 pupils, 91,114 of whom were in the common schools and 7296 in the high schools. There were 2492 teachers, and the total expenditure for public education was $844,762, the cost per pupil in annual enrolment being $8·58, and the cost per pupil daily present on an average $15·75. The following table shows the increase in attendance by decades, the figures giving the average of the summer and winter terms:—

Year.	Teachers.	Pupils.	Total Cost.
1880	1809	76,393	$584,959
1890	2214	85,482	709,312
1900	2557	100,129	887,852

Finance.—The total revenue for the year 1901 was $1,090,230, and the expenditure $1,088,927; the gross debt $3,771,167, and the assets $1,368,655. Succession duties have been imposed on estates above a certain value.

Defence.—The militia consists of an active cavalry, garrison artillery, and infantry force of 307 officers and 3742 non-commissioned officers and men. There are important fortifications at Halifax, where British regiments were formerly stationed, but since 1900 their place has been occupied by Canadian troops.

Minerals and Mining.—There has been a steady increase in the output of gold and coal, which have about doubled since 1882. The mineral production in 1901 was valued at $8,335,000, including gold, 26,057 oz., $546,963; iron ore, 18,169 tons, $46,548; coal, 4,158,068 tons, $6,496,982; gypsum, 170,100 tons, $136,947.

Agriculture.—In common with other provinces of Canada, Nova Scotia has made considerable progress in butter and cheese manufacture. In 1901 there were in operation eight creameries, seven cheese factories, and six factories where both butter and cheese were made, producing 316,180 ℔ of cheese and 266,109 ℔ of butter, valued at $83,761. This is exclusive of large quantities of home-made butter and cheese. Increased attention has been given to the cultivation of small fruits, and also to the shipping of apples to the English market. In 1891 the total occupiers of land were 64,643; of these 60,069 were owners, 4413 tenants, and 161 employés. Total lands occupied, 6,080,695 acres; improved, 1,993,697 acres; under crop, 969,548 acres; in pasture, 994,113 acres; woodland and forest, 4,086,998 acres; garden and orchards, 30,036 acres. The principal crops raised were oats, buckwheat, potatoes, turnips, and other roots. Of animals and their products there were in 1891: horses, 65,047; oxen, 28,424; milch cows, 141,684; other horned cattle, 154,664; sheep, 331,492; swine, 48,048; domestic fowl, 792,184; butter, 9,011,118 ℔; cheese, 589,363 ℔; wool, 1,072,234 ℔.

Fisheries.—Under an Act passed by the Dominion Government $160,000 is annually distributed among the fishermen and fishing vessels; of this amount Nova Scotia received $101,448 in 1900, divided among 525 vessels (22,474 tons) and 5352 men, 6927 boats and 10,645 men. In the same year the total number of vessels employed in the fisheries was 557 (26,064 tons), manned by 5816 men, and 14,766 boats with 19,396 men; 6447 persons were employed in the lobster canneries. The total value of vessels, boats, nets, lobster factories, fish-houses, and all other material used in the fisheries in the whole province was $3,278,623. The total value of the fisheries was $7,809,153: lobsters, $1,898,725; cod, $2,294,160; haddock, $489,668; mackerel, $1,248,626; herring, $376,476; halibut, $163,950; and fish products, $443,298, were the largest items.

Manufactures.—Among the new industries may be mentioned five pulp mills, with a capacity of 100 tons every twenty-four hours; one factory for condensing milk, and works for the manufacture of railway carriages; boot and shoe factory, &c. In 1891 there were engaged in manufactures as follows:—Industrial establishments, 10,496; total capital employed, $19,821,986; hands employed, 34,965; wages paid, $7,240,611; value of raw material, $16,099,229; value of articles produced, $31,043,392.

Commerce.—The volume of trade is shown in the following table:—

	1875.	1885.	1895.	1901.
Exports . .	$6,979,130	$8,894,085	$11,723,534	$12,720,343
Imports . .	11,531,956	8,418,826	9,270,414	12,146,882
Entered for consumption .	10,672,981	8,192,381	8,991,559	12,041,185
Duty . .	1,493,149	1,751,637	1,160,101	2,091,537

In 1901 Nova Scotia shipped to transatlantic ports 136,537,100 superficial feet of deals, &c., and the total value of all the products of the forest exported was $2,367,125 (1899).

Shipping.—The registry books of the Dominion show that in 1900 Nova Scotia owned 2121 sailing vessels and steamers—net tonnage, 226,817; of these 155 were steamers—gross tonnage, 18,243. In the same year 117 vessels and steamers were built—net tonnage, 9416.

Roads and Railroads.—Road-making machines are employed for the improvement of the ordinary highways, and substantial steel bridges are replacing the wooden structures. Besides the main intercolonial railway from Halifax to Amherst, a branch line runs from Truro to Sydney, and another from Oxford Junction to Pictou and Stellarton. The Dominion Atlantic Railway extends from Windsor Junction, near Halifax, to Yarmouth; the Nova Scotia Central Railway from Lunenburg to Middleton on the Dominion Atlantic Railway; and the Dominion Coal Company's railway connects Sydney and Louisburg. There are also several branches connecting the trunk lines with outlying towns and villages. Two lines have been completed—one from Windsor to Truro, and another from Point Tupper to Broad Cove; and two lines are in course of construction—one from Port Hawkesbury to Louisburg, and the other from Halifax to Yarmouth, both along the Atlantic coast. In 1901 there were 943 miles of railway in operation. Telegraph and telephone lines extend all over the province, and there are two cable stations, one at Canso and the other at Sydney.

The *chief cities and towns* are:—Halifax (40,832, 1901), the capital; Yarmouth (6430); Pictou (3235); Stellarton (1422); Westville (2250); New Glasgow (4447); Sydney (9909); North Sydney (4646); Liverpool (1937); Lunenburg (2916); Windsor (3398); Annapolis (1019); Amherst (4963); Antigonish (1526); Shelburne (1300); Dartmouth (4806); Springhill (5178); Truro (5993); Kentville (1731); Digby (1150); Wolfville (1412); Oxford (1266); Baddeck (1000); Port Hood (1500); Glace Bay (6945); Louisburg (1588); Sydney Mines (3191); Parrsboro (2705); Canso (1734); Bridgewater (1816).

Novaya Zemlya. See POLAR REGIONS.

Novelda, a town of Spain, in the province of Alicante, on the right bank of the river Vinalopó, and on the railway from Madrid to Alicante. The population was 9648 in 1887 and 9955 in 1897. The country around is flat and fertile, producing much wine, oil, saffron, aniseed, and cereals. In the town there are tanneries, and manufactures of alcohol, chocolate, and soap. Five miles off are sulphurous and saline springs. The streets are regular, and there are several squares, with a fine town hall and a palace of the marquess de la Romana. To the north are the ruins of the Mola Castillo, where Alvaro de Luna was imprisoned.

Novgorod, a government of north Russia, bounded on the S.W. by Pskoff, on the N.W. by St Petersburg and Olonets, and on the S.E. by Vologda, Yaroslav, and Tver. Area, 47,236 square miles. Its population was, in 1897, 1,392,933, of whom 720,237 were women, and only 84,947 lived in towns. The chief occupation, agriculture, becomes less and less able to satisfy the needs of the population, the average crop of rye being (about 1895) 0·6 quarter per head of population below the real wants; that is, the yield amounted to 703,300 quarters, as against 943,000 quarters in 1860. The yield of the crops in 1894–99 was: rye, 4,135,300 cwts.; oats, 3,847,000; all cereals, 8,514,000 cwts. There were, in 1897, 248,500 horses, 475,000 horned cattle, and 275,000 sheep.

Various trades are on the increase, and about 35,000 people find occupation in them (building, smith-work, fishing, shipbuilding, &c.), as also a variety of domestic industries, giving occupation to about 40,000 families. The industries are, however, slow to develop, the aggregate production of all the factories (mainly distilleries, glass, matches, saw-mills), which employed only 11,850 persons in 1898, hardly reaching £1,000,000. Considerable efforts have been made by the local government to improve both agriculture and education, there being on an average over 52,000 pupils in 1200 schools, as also to organize the medical help in the villages. For this purpose there are 47 hospitals, and over 276,000 persons receive every year free medical advice and help. The chief towns of the eleven districts into which the government is divided are: Novgorod (26,095 inhabitants), the capital of the government, now connected by rail with Chudovo on the St Petersburg to Moscow line (45 miles), and with Staraya Russa, also in regular steam communication down the Volkhov with Novaya Ladoga; Borovichi (9421), Byelozersk (6012), Cherepovets (6916), Demiyansk (1647), Kiriloff (4304), Krestsy (2587), Staraya Russa (15,234), Tikhvin (6631), Ustyuzhna (5109), and Valdai (3525).

Novograd-Volhynsk, a district town of Russia, government of Volhynia, 64 miles north-west of Zhitomir, on the Sluch river. It has iron-works, tanneries, and soap-works, and its fairs are animated. It is a very old town, mentioned in the annals in 1257 under the name of Zwiagel, when it belonged to the Vladimir–Volhynia principality. Later it fell into the hands of Lithuania, and was annexed to Russia in 1793. From 7500 in 1865 its population increased to 16,873 in 1897.

Novorossiysk, a seaport and district town of Caucasia, Russia, in the Chernomorsk or Black Sea government, on a bay of the same name (also named Tsemes), on the north-east coast of the Black Sea. This bay, nearly 3½ miles wide at its entrance, and 5 miles deep from east to west, is exposed to the north-east wind (*bora*), which sweeps down from the mountains with such violence that the town is drenched with the spray of the waves, and in winter the thick layer of ice formed on the rigging of the ships becomes a danger. A mole has been constructed at a cost of about £700,000, to provide protection from the sea. Novorossiysk is connected by a branch railway to Tikhoryetskaya (169 miles) with the main Caucasus line, which crosses the Volga near Tsaritsyn. Since this connexion was established, Novorossiysk has become an important port for the export of corn, over 600,000 tons being exported every year; and since the naphtha wells of Groznyi have been tapped it has also become an entrepôt for the export of naphtha. It is visited annually by about 375 sea-going vessels and about 350 coasting vessels. Large grain elevators have been built, and altogether a new commercial town has grown up. It is, however, unhealthy, on account of malaria. Population (1897), 16,208.

Novouzensk, a district town of Russia, government and 242 miles south-south-west of Samara, on the Uzeñ river. It was founded in the 18th century by Nonconformists, who had much to suffer from Kirghiz and Kalmuck raids, until forts were founded to protect them both at this village and along the whole line to the Volga. In 1897 it had a population of 13,475, and is a centre for the trade with the Kirghiz Steppe. It has four animated fairs. It stands on a branch of the railway which connects Saratoff, on the Volga, with Uralsk, 88 miles south-east of the Urbach junction.

Novozybkoff, a district town of Russia, government and 101 miles north-north-east of Chernigov. It was founded in the 17th century by Nonconformists in the forests of Starodub, and became in the 18th century a centre of Russian Dissent. It is situated on the Bryansk–Gomel railway, 129 miles from the former town, and is the junction for the Novgorod–Syeversk branch. It is surrounded by ponds and marshes, which render it unhealthy. There are several tallow-melting works and tanneries, and it has trade in hemp, hemp-seed oil, cattle, preserved meat, tallow, and leather. Population (1897), 15,480.

Nowgong, a town and district of British India, in the Brahmaputra Valley division of Assam. The town is situated on the Kalang river. Population (1891), 4815; municipal income (1897–98), Rs.11,781. The Government high school had 159 pupils in 1896–97.

The district of Nowgong has an area of 3258 square miles; population (1881), 310,579; (1891), 344,141; (1901), 261,634, showing an increase of 11 per cent. between 1881 and 1891, but a decrease of 24 per cent. between 1891 and 1901; average density, 180 persons per square mile. Classified according to religion, Hindus in 1891 numbered 214,425; Mahommedans, 14,137; hill tribes, 115,044; Christians, 417, of whom 63 were Europeans; "others," 118. The land revenue is Rs.59,49,105, the incidence of assessment being Rs.2 : 8 : 9 per acre; number of police, 162; number of boys at school (1896–97), 5527, being 20·72 per cent. of the male population of school-going age; registered death-rate (1897), 50·4 per thousand. The soil and climate are not so favourable for tea cultivation as in Upper Assam. In 1897 there were 50 gardens, with 12,659 acres under tea, employing 21,397 persons (of whom 7508 had been imported under contract), and yielding just over 4 million ℔, or at the rate of 355 ℔ per acre. The section of the Assam–Bengal railway, now under construction from Gauhati to the hills, passes through part of the district, but not very near Nowgong town; and feeder roads to the stations are being made from the main road that runs parallel to the Kalang river.

Nowgong, a town of India, headquarters of the Bundelkhand agency and a military cantonment, in the native state of Chhatarpur, on the border of the British district of Jhansi. Population (1891), 7492. It has accommodation for a force of all arms. Rajkumar College, founded in 1875 in memory of Lord Mayo, for the education of young chiefs on the model of an English public school, had 17 pupils in 1897–98. There are a high school, a dispensary, and a gaol. The number of police is 50 men. The expenditure on public works in 1897–98 was Rs.1269. It is proposed to connect Nowgong by a branch line with Harpalpur on the East Indian Railway.

Nowo-Radomsk, or Radomsko, a district town of Russian Poland, government and 28 miles by rail south of Piotrków. It has factories for bent-wood furniture, woollens, and cloth, tanneries and saw-mills, and is the centre of a very active trade. Population (1897), 12,407.

Noya, a coast town of Spain, in the province of Corunna, on the left bank of the Rio de Muros y Noya. Population, 9357 in 1887, and 9156 in 1897. Quantities of wheat, hemp, and fruit are produced, and much live stock is reared in the neighbourhood. The local industries include manufactures of paper, soap, preserves, lace, and linen. Noya is a very ancient town, and was of more importance in the Middle Ages than at present. Its estuary and port are only accessible to fishing-boats and coasters. The town was a fief of the dukes of Alba, and many noble families once lived in it. The parish church is a stately Gothic pile. There are several convents, schools, an asylum for old people, a bull-ring, and a theatre.

Nubar Pasha (1825–1899), Egyptian statesman, was born at Smyrna in January 1825, the son of an Armenian merchant named Moghreditch, who had married a relative of Boghos Bey, the influential minister of Mehemet Ali. Boghos had promised to interest himself in the future of his young relative, and at his suggestion he was sent first to Vevey, and then to Toulouse, to be educated by the Jesuits, from whom he acquired a very perfect knowledge of French, and perhaps that singular suppleness and subtlety of character by which he was mainly distinguished. Before he was eighteen he went to Egypt, and after some eighteen months' training as secretary to Boghos, who was then Minister of both Commerce and Foreign Affairs, he was made second secretary to Mehemet Ali, whom he used to read to sleep with Thiers's *Histoire du Consulat et de l'Empire*. In 1845 he became first secretary to Ibrahim Pasha, the heir apparent, and accompanied him on a special mission to Europe, a period to which Nubar always referred with horror, declaring that he was in continual danger of his life, from the paroxysms of rage with which his master was afflicted. Abbas Pasha, who succeeded Ibrahim in 1848, maintained Nubar in the same capacity, and sent him in 1850 to London as his representative to resist the pretensions of the Sultan, who was seeking to evade the conditions of the treaty under which the viceroyalty of Egypt was secured to the family of Mehemet Ali. Here he was so completely successful that he was made a bey; in 1853 he was sent to Vienna on a similar mission, and remained there until the death of Abbas in July 1854. The new viceroy, Said, at once dismissed him from office, but two years afterwards appointed him his chief secretary, and later gave him charge of the important transport service through Egypt to India. Here Nubar was mainly instrumental in the completion of railway communication between Cairo and Suez, and exhibited strong organizing ability combined with readiness of resource. After a second time falling a victim to Said's caprice and being dismissed, he was again sent to Vienna, and returned as principal secretary to Said, a position he held till Said's death in January 1863.

On the accession of Ismail Pasha, Nubar Bey was in the prime of life. He was already on friendly terms with him; he even claimed to have saved his life—at all events, it was a coincidence that the two had together refused to travel by the train the accident to which caused the death of the Prince Ahmed, who would otherwise have succeeded Said. Ismail, himself a more capable man than his immediate predecessors, at once recognized the ability of Nubar, and charged him with a mission to Constantinople, not only to notify his accession, but to smooth the way for the many ambitious projects he already entertained, notably the completion of the Suez Canal, the change in title to that of Khedive, and the change in the order of succession. In the first of these he was completely successful; the Sultan, believing as little as every one else that the canal was anything more than a dream, gave his consent at a price the moderation of which he must afterwards have regretted. The gratified Ismail created Nubar a pasha, and the Sultan himself, persuaded to visit Cairo, confirmed the title so rarely accorded to a Christian. Half the work was, however, yet to be done, and Nubar was sent to Paris to complete the arrangements, and to settle the differences between Egypt and the Canal Company. In what he used to call "an expensive moment of enthusiasm," he left these differences to the arbitration of the Emperor Napoleon III., and cost Egypt four millions sterling. On his return he was made Egypt's first Minister of Public Works, and was distinguished for the energy which he threw into the creation of a new department; but in 1866 he was made Minister of Foreign Affairs, and at once went on a special mission to Constantinople, where he succeeded in the other two projects that had been left in abeyance since his last visit. In June 1867 Ismail was declared Khedive of Egypt, with succession in favour of his eldest son. Great as had been Nubar's successes, they had as yet been gained only over the Sultan. Oriental methods of statecraft he had shown that he understood; in his one negotiation with a European Power he had gained only a Pyrrhic victory, and now he had to undertake a very different task. The antiquated system of "capitulations" which had existed in the Ottoman Empire since the 15th century, had grown in Egypt to be a practical creation of seventeen *imperia in imperio*: seventeen consulates of seventeen different Powers administered seventeen different codes in courts before which alone their subjects were amenable. A plaintiff could only sue a Frenchman in the French court, with appeal to Aix; an Italian in the Italian court, with appeal to Ancona; a Russian in the Russian court, with appeal to Moscow. Had it been limited to the Great Powers, or even to European Powers, it would hardly have been tolerable, but a Brazilian claimed the same rights, and in many cases it was practically an impossibility to contemplate judicial action at all. Nubar's bold design, for which alone he deserves the credit, was to induce these seventeen Powers to consent to abandon their jurisdiction, to substitute mixed International Courts and a uniform code binding on all. That in spite of the jealousies of all the Powers, in spite of the opposition of the Porte, he should have succeeded, places him at once in the first rank of statesmen of his period. Those who have lived to see the European Concert of four or five Powers reduced almost to impotence before China, Turkey, and Greece, can appreciate the genius of the man who, single-handed as the almost unknown representative of a mere vassal state, brought the seventeen chancelleries into line and induced them voluntarily to surrender, without *quid pro quo*, privileges which they had acquired and maintained during five centuries. Nubar's fame might rest upon this alone, and perhaps it was rather by accident than by design—though he always attributed it to his prescience—that the establishment of the mixed courts had consequences far greater than could have been foreseen. Into the codes was inserted the famous article which rendered Ismail "justiciable" before the Tribunals, and it was this article which ultimately caused in 1879 the deposition of Ismail and the substitution of his son Tewfik.

The extravagant administration of Ismail, for which perhaps Nubar can hardly be held wholly responsible, had brought Egypt to the verge of bankruptcy, and Ismail's disregard of the judgments of the Court at last compelled Great Britain and France to interfere (spurred thereto by Bismarck, who perhaps hoped that Egypt might embitter the relations between the two Western Powers). Under pressure, Ismail, who began to regret the establishment of the International Courts, assented to a mixed ministry under Nubar, with Rivers Wilson as Minister of Finance and de Blignières as Minister of Public Works. Nubar, finding himself supported by both Great Britain and France, tried to reduce Ismail to the position of a constitutional monarch, and Ismail, with an astuteness worthy of a better cause, took advantage of a somewhat injudicious disbandment of certain regiments to incite a military rising against the ministry. The Governments of Great Britain and France, instead of supporting the ministry against the Khedive, weakly consented to Nubar's dismissal; but when this was shortly followed by that of Rivers Wilson and de Blignières they realized that the situation was a critical one, and they succeeded in obtaining from the Sultan the deposition of Ismail and the substitution of his son Tewfik as Khedive (1879). Nubar remained out of office until 1884.

In the interval Great Britain had intervened in Egypt —the battle of Tel-el-Kebir had been fought, Arabi had been banished, and Sir Evelyn Baring (afterwards Earl of Cromer) had succeeded Sir Edward Malet. The British Government, under the advice of Baring, insisted on the evacuation of the Sudan, and Sherif having resigned office, the more pliant Nubar was induced to become Premier, and to carry out a policy of which he openly disapproved, but which he considered Egypt was forced to accept under British dictation. At this period he used to say, "I am not here to govern Egypt, but to administer the British government of Egypt. I am simply the greaser of the official wheels." It might have been well if Nubar had confined himself to this modest programme, but it was perhaps hardly to be expected of a man of his ability and restless energy. In justice to him, it must be admitted that some of the tools he was given to work with made his task a difficult one. Sir Benson Maxwell and Mr Clifford Lloyd were zealous but impracticable officials, and when after the suppression of *Le Bosphore Egyptien* Nubar was forced to apologize in person to the French Minister, he may not unnaturally have felt that when he had to bear all the responsibility he ought to be allowed some of the power. Apart from this, however, it must be admitted that the characters of Nubar and Lord Cromer were not formed to run in harness, and it was with no surprise that the public learnt in June 1888 that he had resigned office. The ministry of Riaz Pasha, who succeeded him, lasted for nearly six years, and Nubar returned to office in April 1894. By that time Lord Cromer had more completely grasped the reins of administration as well as of government, and Nubar had realized more clearly the rôle which an Egyptian minister was called on to play: the former was the real ruler of Egypt, and the death of Tewfik in 1890 had necessitated a more open exercise of British authority. In November 1896 Nubar had completed his fifty years of service, and, accepting a pension, retired from office. He lived little more than two years longer, spending his time between Cairo and Paris, where he died in January 1899 at the age of seventy-four. (C. F. M. B.)

Nuevitas, a small land-locked seaport on the north coast of the province of Puerto Principe, Cuba. Many historians assert that this was the site of Columbus's first landing in Cuba. Population (1899), 4228.

Nuevo Leon, a state of Mexico, bounded on the N., N.W., and W. by the state of Coahuila, on the S. and S.W. by San Luis Potosi, and on the E., N.E., and S.E. by Tamaulipas. Area, 24,324 square miles. Population in 1879, 203,284; and in 1900, 326,940. Agriculture has been steadily progressing, rising in value from \$717,450 in 1872 to \$5,000,000 in 1899. The value of the live stock is estimated at \$6,000,000. The mercantile movement is estimated at \$15,000,000 annually. The Mexican National Railway crosses Nuevo Leon from west to north-east, and the Monterey and Gulf of Mexico Railway crosses it from west to south. There are 13 miles of tramways, all starting from Monterey; also fine waggon roads in all directions. The state is divided into 48 municipalities. The capital is Monterey, with 56,326 inhabitants in 1900. The principal towns are Linares (7220), Lampazos (5197), Santiago, Cadereyta, and Garcia.

Number.—1. The most elementary process of thought involves a distinction within an identity—the A and the not-A within the sphere throughout which these terms are intelligible. Again, A may be a generic quality recognizable in different modes, which may be represented by Aa, Ab, Ac, &c. Thus the notions of "one," "two," and the vague "many" are fundamental, and must have impressed themselves on the human mind at a very early period; evidence of this fact is afforded, for instance, by the grammatical distinction of singular, dual, and plural which we find in very ancient languages. A more definite idea of number seems to have been gradually acquired by realizing the equivalence, *quâ* plurality, of different concrete groups, such as the fingers of the right hand and those of the left. This led to the invention of a set of names which in the first instance did not even suggest a numerical system, but denoted certain recognized forms of plurality, just as blue, red, green, &c., denote recognized forms of colour. Eventually the conception of the series of natural numbers became sufficiently clear to lead to a systematic terminology, and the science of arithmetic was thus rendered possible. But it is only in quite recent times that the notion of number has been submitted to a critical analysis; it is, in fact, one of the most characteristic results of modern mathematical research that the term *number* has been made at once more precise and more extensive.

2. *Manifolds.*—Let us assume the possibility of constructing a permanent system of things such that (1) the system includes all objects to which a certain definite quality belongs; (2) no object without this quality belongs to the system; (3) each object of the system is permanently recognizable as the same thing, and as distinct from all other objects of the system. Such a system is called a *manifold;* the separate objects belonging to it are called its *elements.* A manifold may consist of a single element.

It is further assumed to be possible to select, by a definite process, one or more elements of any manifold A at pleasure; these selected elements form another manifold B. If any element of A remains unselected, B is said to be a part of A (in symbols, $B \prec A$); if not, B is identical with A. Every element of A is a part of A. If $B \prec A$, and $C \prec B$, then $C \prec A$.

When a correspondence can be established between two manifolds A and B in such a way that to every element of A corresponds one and only one element of B, and conversely, A and B are said to have the same *power*, or to be *equivalent;* in symbols, $A \backsim B$. If $A \backsim B$ and $B \backsim C$, then $A \backsim C$. It is possible for a manifold to be equivalent to a part of itself; the manifold is then said to be *infinite.*

3. Suppose that when any two elements a, b of a manifold A are taken there can be established, by a definite criterion, one or other of two alternative relations, symbolized by $a<b$ and $a>b$, subject to the following conditions:—(1) If $a>b$, then $b<a$; and if $a<b$, then $b>a$; (2) If $a>b$ and $b>c$, then $a>c$. In this case the criterion is said to arrange the manifold in order. A manifold which can be arranged in order may be called *ordinable.* An ordinable manifold may, in general, by the application of different criteria, be arranged in order in a variety of ways. According as $a<b$ or $a>b$ we shall speak of a as anterior or posterior to b. These terms are chosen merely for convenience, and must not be taken to imply any meaning except what is involved in the definition of the signs $>$ and $<$ for the particular criterion in question. The consideration of a succession of events in time will help to show that the assumptions made are not self-contradictory. A manifold arranged in order by a definite criterion will be called an *ordered* manifold. Let

a, b be any two elements of an ordered manifold, and suppose $a<b$. All the elements c (if any) such that $a<c<b$ are said to fall within the interval (a, b). If an element b, posterior to a, can be found such that no element falls within the interval (a, b), then a is said to be isolated from all subsequent elements, and b is said to be the element next after a. So if $b'<a$, and no element falls within the interval (b', a), then a is isolated from all preceding elements, and b' is the element next before a. For any assigned element a, either, neither, or both of these cases may occur.

4. *The Natural Scale.*—It will be convenient to use the term *progressive manifold*, or simply *progression*, for an ordered manifold in which (1) there is one element anterior to all the rest, and (2) every element a is followed by a definite next element a', so that $a<a'$ and no element falls within the interval (a, a'). The generic idea common to all progressions (which are obviously equivalent) is the scale of natural numbers. Thus a natural number is an element of an ideal manifold defined solely by the conditions (1) and (2) above stated. The essence of the natural scale consists in the arrangement of its elements; if we try to abstract this there is nothing left. Any such scheme as 1, 11, 111, 1111 . . . . or 1, 2, 3, 4 . . . is merely a conventional symbolism by which the natural scale can be suggested to the mind. Any manifold equivalent to the whole or a part of the natural scale is said to be *numerable*. Any element of the natural scale is said to be "the number of" things in the group which consists of itself and all anterior elements, or of any group equivalent thereto. Counting a given set of objects means establishing its equivalence to a set consisting of a natural number and all those preceding it.

The natural scale is an infinite manifold. For each element a may be associated with the next succeeding element a', while the elements a' (symbolized by 2, 3, 4 . . .) form a part of the manifold. Conversely to every element a' corresponds a definite element a.

5. *Arithmetical Operations.*—When the natural scale (N) has once been obtained, it is comparatively easy to define the arithmetical operations of addition, multiplication, and involution, as applied to natural numbers. It can be proved that these operations are free from ambiguity and obey certain formal laws of commutation, &c., which need not be discussed here. Each of the three direct operations leads to an inverse problem which cannot be solved except under certain implied conditions. Let a, b denote any two assigned natural numbers: then it is required to find natural numbers x, y, z such that

$$a=b+x, \quad a=by, \quad a=z^b$$

respectively. The solutions, when they exist, are perfectly definite, and may be denoted by $a-b$, a/b and $\sqrt[b]{a}$; but in order that these symbols may be intelligible it is necessarily implied in the first case that $a>b$, in the second that a is a multiple of b, and in the third that a is a perfect bth power. It is found to be possible, by the construction of certain elements, called respectively *negative*, *fractional*, and *irrational numbers*, and *zero*, to remove all these restrictions.

6. There are certain properties, common to the manifolds with which we have next to deal, analogous to those possessed by the natural scale, and consequently justifying us in applying the term *number* to any one of their elements. They are stated here, once for all, to avoid repetition; the verification, in each case, will be, for the most part, left to the reader. Each of the manifolds in question (A, suppose) is an ordered manifold. If α, β are any two elements of A, they may be combined by two definite operations, represented by + and ×, so as to give two definite elements of A represented by $\alpha+\beta$ and $\alpha\times\beta$ (or $\alpha\beta$); these operations obey the formal laws satisfied by those of addition and multiplication. The manifold A contains one[1] element ι, such that if α is any element of A (ι included), then $\alpha+\iota>\alpha$, and $\alpha\iota=\alpha$. Thus A contains the elements ι, $\iota+\iota$, $\iota+\iota+\iota$, &c., or, as we may write them, ι, 2ι, 3ι, . . . $m\iota$ . . . such that $m\iota+n\iota=(m+n)\iota$ and $m\iota\times n\iota=mn\iota$; also $\iota<2\iota<3\iota$ . . . We may express this by saying that A contains an *image* of the natural scale. The element denoted by ι may be called the *ground element* of A.

7. *Negative Numbers.*—Let any two natural numbers a, b be selected in a definite order a, b (to be distinguished from b, a, in which the order is reversed). In this way we obtain what we shall call a *couple*, or more precisely, if necessary, an *ordered couple* (a, b). These couples may be associated with an ordered manifold according to the following rules:—

Two couples (a, b), (a', b') are said to be equal if $a+b'=a'+b$. In other words (a, b), (a', b') are then taken to be equivalent symbols for the same thing.

If $a+b'>a'+b$, we write $(a, b)>(a', b')$; and if $a+b'<a'+b$, we write $(a, b)<(a', b')$.

The symbols + and × are defined by the formulæ

$$(a, b)+(a', b')=(a+a', b+b')$$
$$(a, b)\times(a', b')=(aa'+bb', ab'+a'b)$$

The manifold thus defined will be denoted by $\bar{N}$; it may be called the scale of relative integers.

If ι denotes (2, 1) or any equivalent couple, $(a, b)+\iota=(a+2, b+1)>(a, b)$ and $(a, b)\times\iota=(2a+b, a+2b)=(a, b)$. Hence ι is the ground element of $\bar{N}$. By definition, $2\iota=\iota+\iota=(4, 2)=(3, 1)$: similarly, we find that $3\iota=2\iota+\iota=(5, 2)=(4, 1)$, and hence by induction $m\iota=(m+1, 1)$. Conversely every element (a, b) in which $a>b$ can be expressed by the symbol $(a-b)\iota$. If $\iota'=(1, 2)$, it may be proved in the same way that $m\iota'=(1, m+1)$, and that every element (a, b) in which $b>a$ can be expressed by the symbol $(b-a)\iota'$.

8. It follows as a formal consequence of the definitions that $\iota+\iota'=(2, 1)+(1, 2)=(3, 3)$. Now couples of the type (a, a) cannot properly be said to be *ordered*: still it is convenient to admit these symbols and associate them all with a definite element of $\bar{N}$ which we call *zero*, and denote by 0. Thus finally $\iota+\iota'=0$, and we can represent $\bar{N}$ by the scheme—

$$\ldots 3\iota', 2\iota', \iota', 0, \iota, 2\iota, 3\iota \ldots$$

in which each element is obtained from the next before it by the addition of ι. With this notation the rules of operation may be written (m, n, denoting natural numbers)—

$$m\iota+n\iota=(m+n)\iota \qquad m\iota'+n\iota'=(m+n)\iota'$$
$$m\iota+n\iota'=(m-n)\iota \text{ if } m>n$$
$$=(n-m)\iota' \quad m<n$$
$$m\iota\times n\iota=mn\iota,\ m\iota'\times n\iota'=mn\iota,\ m\iota\times n\iota'=mn\iota',$$

with the special rules for zero, that if α is any element of $\bar{N}$,

$$\alpha+0=\alpha,\ \alpha\times 0=0.$$

To each element, α, of $\bar{N}$ corresponds a definite element α' such that $\alpha+\alpha'=0$; if $\alpha=0$, then $\alpha'=0$, but in every other case α, α' are different and may be denoted by $m\iota$, $m\iota'$. The natural number m is called the *absolute value* of $m\iota$ and $m\iota'$.

9. If α, β are any two elements of $\bar{N}$, the equation $\xi+\beta=\alpha$ is satisfied by putting $\xi=\alpha+\beta'$. Thus the symbol $\alpha-\beta$ is always interpretable as $\alpha+\beta'$, and we may say that within $\bar{N}$ subtraction is always possible. On

[1] There cannot be more than one such element.

the other hand, α/β is intelligible only if the absolute value of α is a multiple of the absolute value of β.

The manifold $\bar{N}$ has no least element and no greatest element. At the same time it is numerable, as we see, for instance, by associating the elements 0, $a\iota$, $b\iota'$ with the natural numbers 1, $2a$, $2b+1$ respectively, thus—

$$(N)\ 1,\ 2,\ 3,\ 4,\ 5,\ 6,\ \ldots$$
$$(\bar{N})\ 0,\ \iota,\ \iota',\ 2\iota,\ 2\iota',\ 3\iota\ \ldots$$

It is usual to write $+a$ (or simply a) and $-a$ for $a\iota$ and $a\iota'$ respectively; that this should be possible without leading to confusion or ambiguity is certainly remarkable.

10. *Fractional Numbers.*—Starting as before with ordered couples chosen from N, we may form a set of symbols $[a, b]$, and associate them with the elements of an ordered manifold R by the following rules:—

The symbols $[a, b]$, $[a', b']$, are equivalent if $ab' = a'b$.

If $ab' > a'b$ we write $[a, b] > [a', b']$; and if $ab' < a'b$ we write $[a, b] < [a', b']$.

The symbols $+$ and $\times$, as applied to elements of R, are defined by the formulæ

$$[a, b] + [a', b'] = [ab' + a'b,\ bb']$$
$$[a, b] \times [a', b'] = [aa',\ bb'].$$

Symbols of the type $[a, a]$ are admissible. It follows from the definitions that they are all equivalent, and that, if we denote $[1, 1]$ by v, then $[a, b] + v = [a+b, b] > [a, b]$, $[a, b] \times v = [a, b]$. Hence v is the ground element of R.

By definition, $2v = v + v = [2, 1]$; similarly $3v = 2v + v = [3, 1]$, and by induction $mv = [m, 1]$. It also follows that if a is a multiple of b, say mb, the element corresponding to $[a, b]$ may be denoted by the equivalent symbol mv.

11. The manifold R differs in one important respect from N and $\bar{N}$, and from any other ordered manifold in which isolated elements occur. No element of R is isolated either from subsequent or preceding elements: this follows at once from the fact that if $[a, b] = \alpha$ and $[a', b'] = \alpha'$ are the symbols of any two elements of R, the element denoted by $[a+a', b+b']$ falls within the interval (α, α'). On account of this property R is said to be *dense*. Strange as it appears at first sight, R is a numerable manifold—a fact first proved by G. Cantor. To see this, observe that every element of R may be represented by a "reduced" couple $[a, b]$, in which a, b are prime to each other. If $[a, b]$, $[c, d]$ are any two reduced couples, we will say that $[a, b]$ is anterior to $[c, d]$ if either (1) $a+b < c+d$, or (2) $a+b = c+d$, but $a < c$. This gives a criterion by which the elements of R can be arranged in the progression

$[1, 1]$, $[1, 2]$, $[2, 1]$, $[1, 3]$, $[3, 1]$, $[1, 4]$, $[2, 3]$, $[3, 2]$, $[4, 1]$...

which is equivalent to the natural scale.

R agrees with $\bar{N}$ in having no least and no greatest element; for if α denotes any element $[a, b]$, then $[2a-1, 2b] < \alpha$, while $[2a+1, 2b] > \alpha$.

12. The division of one element of R by another is always practicable; for by definition

$$[c, d] \times [ad, bc] = [acd, bcd] = [a, b],$$

and consequently $[a, b] \div [c, d]$ is always interpretable as $[ad, bc]$. As a particular case $[m, 1] \div [n, 1] = [m, n]$, so that every element of R is expressible in one of the forms mv, mv/nv. When m is a multiple of n, $mv/nv = (m/n)v$. It is usual to omit the symbol v altogether, and to represent the element $[m, n]$ by m/n, whether m is a multiple of n or not. This does not lead to any confusion, if it is borne in mind that the symbols 1, 2, 3, &c., when used to represent elements of R, really have a meaning distinct from that assigned to them when they represent elements of N.

13. Within the manifold R subtraction is not always practicable; but this limitation may be removed by constructing a manifold $\bar{R}$ related to R in the same way as $\bar{N}$ to N. This may be done in two ways which lead to equivalent results. We may either form symbols of the type (α, β), where α, β denote elements of R, and apply the formulæ of § 7; or else form symbols of the type $[\alpha, \beta]$, where α, β denote elements of $\bar{N}$, and apply the formulæ of § 10. The final result is that $\bar{R}$ comprises a zero element, 0, a ground element v, an element v' such that $v + v' = 0$, and a set of elements representable by the symbols $(m/n)v$, $(m/n)v'$. In this notation the rules of operation are—

$$\frac{m}{n}v + \frac{m'}{n'}v = \left(\frac{mn' + m'n}{nn'}\right)v, \quad \frac{m}{n}v' + \frac{m'}{n'}v' = \left(\frac{mn' + m'n}{nn'}\right)v';$$

$$\frac{m}{n}v + \frac{m'}{n'}v' = \frac{mn' - m'n}{nn'}v, \text{ or } \frac{m'n - mn'}{nn'}v', \text{ as } mn' > \text{or} < m'n;$$

$$\frac{m}{n}v \times \frac{m'}{n'}v = \frac{mm'}{nn'}v = \frac{m}{n}v' \times \frac{m'}{n'}v', \quad \frac{m}{n}v \times \frac{m'}{n'}v' = \frac{mm'}{nn'}v';$$

$$\frac{m}{n}v \div \frac{m'}{n'}v = \frac{m}{n}v' \div \frac{m'}{n'}v' = \frac{mn'}{m'n}v, \ \frac{m}{n}v \div \frac{m'}{n'}v' = \frac{m}{n}v' \div \frac{m'}{n'}v = \frac{mn'}{m'n}v';$$

$$\alpha - \beta = \alpha + \beta', \text{ where } \beta + \beta' = 0;$$

$$\alpha + 0 = \alpha,\ \alpha \times 0 = 0;$$

α and β denoting any two elements of $\bar{R}$. If $\beta = (m/n)v$, then $\beta' = (m/n)v'$, and if $\beta = (m/n)v'$, then $\beta' = (m/n)v$.

14. When $\bar{R}$ is constructed by means of couples taken from $\bar{N}$, we must put $[m\iota, n\iota] = [m\iota', n\iota'] = (m/n)v$, $[m\iota, n\iota'] = [m\iota', n\iota] = (m/n)v'$, and $[0, \alpha] = 0$, if α is any element of $\bar{N}$ except 0. The symbols $[0, 0]$ and $[\alpha, 0]$ are inadmissible; the first because it satisfies the formal definition of equality with every symbol $[\alpha, \beta]$, and is therefore indeterminate; the second because, according to the rule of addition (§ 10)—

$$[\alpha, 0] + [\iota, \iota] = [\alpha\iota, 0] = [\alpha, 0],$$

which is inconsistent with $\xi + v > \xi$.

In the same way, if 0 denotes the zero element of $\bar{R}$, and ξ any other element, the symbol $0/0$ is indeterminate, and $\xi/0$ inadmissible, because, by the formal rules of operation, $\xi/0 + v = \xi/0$, which conflicts with the definition of the ground element v. It is usual to write $+\frac{m}{n}$ $\left(\text{or simply } \frac{m}{n}\right)$ for $\frac{m}{n}v$, and $-\frac{m}{n}$ for $\frac{m}{n}v'$. Each of these elements is said to have the absolute value m/n. The ultimate ordering criterion of the manifold $\bar{R}$ is that, if ξ, η are any two elements of it, $\xi > \eta$ when $\xi - \eta$ is positive; that is to say, when it can be expressed in the form $(m/n)v$.

15. The manifold $\bar{R}$ is very important, because it is the simplest type of a *domain of rationality*, or *corpus*. An algebraic corpus is a manifold, such that its elements are representable by symbols α, β, &c., which can be combined according to the laws of ordinary algebra; every algebraic expression obtained by combining a finite number of symbols by means of a finite chain of rational operations $(+, -, \times, \div)$, being capable of interpretation as representing a definite element of the manifold, with the single reservation that division by zero is inadmissible. Since, by the laws of algebra, $\alpha - \alpha = 0$, and $\alpha/\alpha = 1$, every algebraic corpus must contain $\bar{R}$, or, more properly, a manifold which is an image of $\bar{R}$.

16. *Irrational Numbers.*—Let α denote any element of $\bar{R}$; then α and all anterior elements form a manifold, A say; the remaining elements form another manifold A', which we shall call complementary to A, and we may write $\bar{R} = A + A'$. Now the essence of this separation of $\bar{R}$ into the parts A and A' may be expressed without any reference to α as follows:—

I. The manifolds A, A' are complementary; that is, their elements, taken together, make up the whole of $\bar{R}$.

II. Every element of A is less than every element of A'.

III. The manifold A' has no first element. (This last condition is artificial, but saves a distinction of cases in what follows.)

Every separation $\bar{R} = A + A'$ which satisfies these conditions is called a *cut*, and will be denoted by (A, A'). We have seen that every rational number α is associated with a definite cut. Conversely, a cut (A, A') in which A has a last element α is perfectly definite, and specifies α without ambiguity. But there are other cuts in which A has no last element. For instance, all the elements (α) of $\bar{R}$ such that either $\alpha \leqslant 0$, or else $\alpha > 0$ and $\alpha^2 < 2$, form a manifold A, while those for which $\alpha > 0$ and $\alpha^2 > 2$ form the complementary manifold A'. This separation is a cut in which A has no last element; because if p/q is any positive element of A, the element $(3p+4q)/(2p+3q)$ exceeds p/q, and also belongs to A. *Every cut (A, A') of this kind is said to define an irrational number.* The justification of this is found in the following propositions:—

(1) A cut is a definite concept, and the *ensemble* of cuts is a manifold according to definition; the generic quality of the manifold being the separation of $\bar{R}$ into two complementary parts, without altering the order of its elements.

(2) The manifold of cuts may be arranged in order by the rule that $(A, A') < (B, B')$ if A is a part of B.

(3) This criterion of arrangement preserves the order of gnitude of all rational numbers.

(4) Cuts may be combined according to the laws of algebra, and, when the cuts so combined are all rational, the results are in agreement with those derived from the rational theory.

As a partial illustration of proposition (4) let (A, A'), (B, B') be any two cuts; and let C' be the manifold whose elements are obtained by forming all the values of $\alpha' + \beta'$, where α' is *any* element of A' and β' is any element of B'. Then if C is the complement of C', it can be proved that (C, C') is a cut; this cut is said to be the sum of (A, A') and (B, B'). The difference, product and quotient of two cuts may be defined in a similar way. If $\mathfrak{n}$ denotes the irrational cut chosen above for purposes of illustration, we shall have $\mathfrak{n}^2 = (C, C')$ where C' comprises all the numbers $\alpha'\beta'$ obtained by multiplying *any* two elements α', β' which are rational and positive, and such that $\alpha'^2 > 2$, $\beta'^2 > 2$. Since $\alpha'^2\beta'^2 > 4$ it follows that $\alpha'\beta'$ is positive and greater than 2; it can be proved conversely that every rational number which is positive and greater than 2 can be expressed in the form $\alpha'\beta'$. Hence $\mathfrak{n}^2 = 2$, so that the cut $\mathfrak{n}$ actually gives a real arithmetical meaning to the positive root of the equation $x^2 - 2 = 0$; in other words, we may say that $\mathfrak{n}$ defines the irrational number $\sqrt{2}$. The theory of cuts provides, in fact, a logical basis for the treatment of all numerical irrationalities, and enables us to justify all arithmetical operations involving the use of such quantities.

17. Since the manifold of cuts ($\mathfrak{N}$ say) has an order of magnitude, we may construct cuts in this manifold. Thus if $\mathfrak{a}$ is any element of $\mathfrak{N}$, and $\mathfrak{A}$ is the manifold which consists of $\mathfrak{a}$ and all anterior elements of $\mathfrak{N}$, we may write $\mathfrak{N} = \mathfrak{A} + \mathfrak{A}'$, and now $(\mathfrak{A}, \mathfrak{A}')$ is a cut in which $\mathfrak{A}$ has a last element $\mathfrak{a}$. It is a remarkable fact that no other kind of cut in $\mathfrak{N}$ is possible; in other words, *every conceivable cut in $\mathfrak{N}$ is defined by one of its own elements.* This fact is expressed by saying that $\mathfrak{N}$ is a *continuous* manifold, and $\mathfrak{N}$ itself is referred to as *the numerical continuum.* The property of continuity must be carefully distinguished from that of density; a continuous manifold is necessarily dense, but a dense manifold is not always continuous. The manifold $\mathfrak{N}$ is not numerable.

18. Another way of treating the theory of irrational numbers is by means of *sequences.* A sequence is an unlimited succession of rational numbers

$$a_1, a_2, a_3 \ldots a_m, a_{m+1} \ldots$$

the elements of which can be assigned by a definite rule of calculation, and such that when any rational number ϵ, however small, has been fixed upon, it is possible to find an integer m, so that for *all* positive integral values of n the absolute value of $a_{m+n} - a_m$ is less than ϵ. Under these conditions the sequence may be taken to represent a definite number, which is, in fact, the limit of a_m when m increases without limit. Every rational number a can be expressed as a sequence in the form $(a, a, a, \ldots)$, but this is only one of an infinite variety of such representations, for instance—

$$1 = (\cdot 9, \cdot 99, \cdot 999, \ldots) = \left(\frac{1}{2}, \frac{3}{4}, \frac{7}{8}, \ldots \frac{2^n - 1}{2^n} \ldots\right)$$

and so on. The essential thing is that we have a mode of representation which can be applied to rational and irrational numbers alike, and provides a very convenient symbolism to express the results of arithmetical operations. Thus the rules for the sum and product of two sequences are given by the formulæ

$$(a_1, a_2, a_3, \ldots) + (b_1, b_2, b_3, \ldots) = (a_1 + b_1, a_2 + b_2, a_3 + b_3 \ldots)$$

$$(a_1, a_2, a_3, \ldots) \times (b_1, b_2, b_3, \ldots) = (a_1 b_1, a_2 b_2, a_3 b_3 \ldots)$$

from which the rules for subtraction and division may be at once inferred. It has been proved that the method of sequences is ultimately equivalent to that of cuts. The advantage of the former lies in its convenient notation, that of the latter in giving a clear definition of an irrational number without having recourse to the notion of a limit.

19. *Transfinite Numbers.*—In the course of his researches in the theory of manifolds, G. Cantor has been led to the construction of the very subtle calculus of transfinite numbers. This has not yet been fully developed, and the terminology is still fluctuating; hence only a very brief account can be attempted here. It has been observed (§ 4) that a manifold which can be "counted" may be associated with an element of the natural scale, which is called "the number of" the elements of the manifold. An infinite manifold cannot be counted in the ordinary sense; but if it is numerable, there is some criterion by which its elements may be represented by the scheme

$$u_1 \quad u_2 \quad u_3 \ldots u_n \ldots$$

or

$$1' \quad 2' \quad 3' \ldots n' \ldots$$

When the elements of a manifold are arranged according to the scheme $1', 2', 3' \ldots$ it may be said to be *similar*, or to be *arranged similarly*, to the natural scale. Now, just as the number 3 may be associated with the succession 1, 2, 3, or with any equivalent manifold similarly arranged, we may invent a new symbol ω, and associate it with the whole of the natural scale, or with any equivalent manifold *similarly arranged.* For convenience we shall call ω the *index* of the natural scale, thus—

$$\omega = \text{ind. } N = \text{ind. } (u_1, u_2, u_3, \ldots)$$

when u_1, u_2, u_3, &c. is any manifold arranged similarly to the natural scale.

20. There is no logical difficulty in constructing a scheme

$$u_1, u_2, u_3 \ldots \mid v_1,$$

where the progression $u_1, u_2, u_3 \ldots$ is immediately followed by an element v_1. Any manifold represented by this scheme is associated with the index $\omega+1$; and in like manner we may form arranged manifolds associated with the indices

$$\omega+2, \omega+3 \ldots \omega+n,$$

where n is any element of N. The scheme

$$u_1, u_2, u_3 \ldots \mid v_1, v_2, v_3 \ldots$$

is associated with $\omega+\omega=\omega 2$; the scheme

$$u_{11}, u_{12}, u_{13} \ldots \mid u_{21}, u_{22}, u_{23} \ldots \mid \ldots \mid u_{n1}, u_{n2} \ldots \mid \ldots$$

with $\omega . \omega$ or ω^2; and so on. Thus we may construct arrangements of manifolds corresponding to any index of the form

$$\phi(\omega)=\omega^n a+\omega^{n-1}b+\ldots+\omega k+l,$$

where $n, a, b, \ldots l$ are any elements of N.

We are thus led to the construction of a scheme of symbols—

$$\begin{array}{ll}
\text{I.} & 1, 2, 3, \ldots n \ldots \\
\text{II.} & \left\{\begin{array}{l}\omega, \omega+1, \ldots \omega+n, \ldots \\ \omega 2, \omega 2+1, \ldots \omega 2+n, \ldots \\ \vdots \\ \omega^2, \omega^2+1, \omega^2+2 \ldots \omega^2+n, \ldots \\ \vdots \\ \phi(\omega), \phi(\omega)+1, \ldots \phi(\omega)+n, \ldots \\ \vdots \end{array}\right. \\
\text{III.} & \left\{\begin{array}{l}\omega^\omega, \omega^\omega+1, \ldots \omega^\omega+n, \ldots \\ \vdots \\ \omega^{\phi(\omega)}, \omega^{\phi(\omega)}+1, \ldots \omega^{\phi(\omega)}+n, \ldots \\ \vdots \end{array}\right.
\end{array}$$

where the first element of any row is supposed to follow immediately all the elements of the row next before it, and other elements of the row are obtained by successive additions of 1. The first elements of the parts of the scheme denoted by I., II., III. &c., are $1, \omega, \omega^\omega$, &c. All the symbols in which ω occurs are called *transfinite ordinal numbers.*

21. The index of a finite manifold is a definite integer, however the manifold may be arranged: we may take this index as a symbol for the power of the manifold. But the index of an infinite ordinable manifold depends upon the way in which its elements are arranged; for instance, ind. $(1', 2', 3', \ldots)=\omega$, but ind. $(1', 3', 5', \ldots \mid 2', 4', 6', \ldots)=\omega 2$. Or, to take another example, the scheme—

$$\begin{array}{l}
1, 3, 5, \ldots (2n-1) \ldots \\
2, 6, 10, \ldots 2(2n-1) \ldots \\
4, 12, 20, \ldots 4(2n-1) \ldots \\
\vdots \quad \vdots \quad \vdots \\
2^m, 2^m.3, 2^m.5, \ldots 2^m(2n-1) \ldots \\
\vdots
\end{array}$$

in which each row is supposed to follow the one before it gives a permutation of any manifold $(u_1, u_2, u_3 \ldots)$ by which the index is changed from ω to ω^2. It may be proved that if M is any numerable manifold, there is a permutation of M for which the index is $\phi(\omega)$, any assigned element of (II.); and that, conversely, if the index of any arranged manifold is $\phi(\omega)$, the manifold is numerable. Thus the power of all manifolds which can be associated with indices of the class (II.) is the same as that of the natural scale; this power is indicated by $\aleph_0$. Since $\aleph_0$ is associated with all manifolds of a particular power, independently of the arrangement of their elements, it is analogous to the integers 1, 2, 3, &c., when used to denote powers of finite manifolds; for this reason it is called "the least transfinite cardinal number."

22. There are manifolds (for instance, $\mathfrak{R}$) which are of higher power than $\aleph_0$; the next higher power $\aleph_1$ belongs to manifolds which can be associated with transfinite indices of the class (III.). It is not unlikely that there is a natural progression of powers $\aleph_0, \aleph_1, \aleph_2$, &c., belonging to manifolds which can be associated with indices of the classes II., III., IV., &c., and that every ordinable manifold may be associated with one and only one of the cardinal numbers $\aleph_i$. It has also been conjectured that $\aleph_1$ is the proper symbol for the power of the numerical continuum; but this still awaits demonstration or disproof. Again, it may be asked whether any meaning can be attached to such a symbol as $\aleph_\omega$, or, more generally, $\aleph_\psi$, where ψ is any ordinal number of the nth class.

23. Transfinite numbers, both ordinal and cardinal, may be combined by operations which are so far analogous to those of ordinary arithmetic that it is convenient to denote them by the same symbols. But the laws of operation are not entirely the same; for instance, $\omega 2$ and 2ω have different meanings: the first has been explained, the second is the index of the scheme $(a_1 b_1 \mid a_2 b_2 \mid a_3 b_3 \mid \ldots \mid a_n b_n \mid \ldots)$ or any similar arrangement

24. *Complex Numbers.*—If a is an assigned number, rational or irrational, and n a natural number, it can be proved that there is an element of $\mathfrak{R}$ satisfying the equation $x^n=a$, except when n is even, and a is negative; in this case the equation is not satisfied by any element of $\mathfrak{R}$. The difficulty is removed by the construction of a manifold of ordered couples $\{x, y\}$ where x, y are any elements of $\mathfrak{R}$: this may be arranged by the criterion that $\{x, y\}<\{x', y'\}$ if $x<x'$, or if $x=x'$ and $y<y'$. The rules of operation are

$$\{x, y\}+\{x', y'\}=\{x+x', y+y'\};$$
$$\{x, y\}\times\{x', y'\}=\{xx'-yy', xy'+x'y\}.$$

Hence the manifold has the ground element $\{1, 0\}$, which we may denote by σ; and, if we write τ for the element $\{0, 1\}$,

$$\tau^2=\{-1, 0\}=-\sigma.$$

Whenever m, n are rational $\{m, n\}=m\sigma+n\tau$, and we are thus justified in writing, if we like, $x\sigma+y\tau$ for $\{x, y\}$ in all circumstances. A further simplification is gained by writing x instead of $x\sigma$, and regarding τ as a symbol which is such that $\tau^2=-1$, but in other respects obeys the ordinary laws of operation. It is usual to write i instead of τ; we thus have a manifold $\mathfrak{Z}$ of complex numbers $x+yi$. In this manifold, which includes an image of $\mathfrak{R}$, not only the four rational operations (excluding division by zero), but also the extraction of roots, may be effected without any restriction. Moreover (as first proved by Gauss and Cauchy), if $a_0, a_1, \ldots a_n$ are any assigned elements of $\mathfrak{Z}$, the equation

$$a_0 z^n+a_1 z^{n-1}+\ldots+a_{n-1}z+a_n=0$$

is always satisfied by precisely n elements of $\mathfrak{Z}$, with a proper convention as to multiple roots. Thus any algebraic function of any finite number of elements of $\mathfrak{Z}$ is also contained in $\mathfrak{Z}$. In this sense $\mathfrak{Z}$ is a closed arithmetical domain, just as $\mathfrak{R}$ is when we restrict ourselves to rational operations. The power of $\mathfrak{Z}$ is the same as that of $\mathfrak{R}$.

25. *Algebraic Numbers.*—As explained in the article NUMBERS, THEORY OF (*Ency. Brit.* vol. xvii. p. 614), Gauss distinguished as *integral* those elements $x+yi$ of $\mathfrak{Z}$ in which x, y are ordinary integers; and Kummer extended Gauss's conception by introducing "complex integers" of the form

$$\psi(\eta)=a\eta+a_1\eta_1+\ldots+a_{e-1}\eta_{e-1},$$

where $\eta, \eta_1, \ldots \eta_{e-1}$ are the Gaussian periods of f terms associated with the roots of the equation $(x^p-1)/(x-1)=0$, p being a prime, and $ef=p-1$. The remarkable fact that an integer $\psi(\eta)$ may be resolvable in more ways than one into the product of irresolvable factors of the same type, appeared to involve the complete failure of the ordinary laws of divisibility so far as these new integers were concerned; but Kummer succeeded in restoring a complete analogy by his invention of ideal numbers.

Kronecker and Dedekind independently generalized the results of Gauss and Kummer, and thus laid the foundations of a perfectly general theory of algebraic numbers, which is one of the most beautiful results of analysis. In the brief outline which follows, Dedekind's notation and point of view will be adopted.

26. If

$$f(\theta)=a_0\theta^n+a_1\theta^{n-1}+\ldots+a_n=0,$$

where $a_0, a_1, \ldots a_n$ are ordinary integers, is an irreducible equation in the domain N (that is, if $f(\theta)$ cannot be resolved into the product of two integral functions with rational integral coefficients), the n roots $\theta, \theta', \theta'' \ldots \theta^{(n-1)}$ are said to form a set of conjugate algebraic numbers of the nth order. If $a_0=1$, the roots are said to form a set of conjugate algebraic *integers*. Every algebraic number can be expressed in the form ω/a_0 where a_0 is a natural number and ω an algebraic integer; in all that follows it will be supposed that $a_0=1$, and consequently θ is integral.

Associated with θ we have a corpus $\Omega=R(\theta)$ consisting of all rational functions of θ with real rational coefficients; and in like manner we have the conjugate corpora $\Omega'=R(\theta')$, $\Omega''=R(\theta'')$ . . . $\Omega^{(n-1)}=R(\theta^{(n-1)})$ associated with $\theta', \theta'' \ldots \theta^{(n-1)}$ respectively. The manifold of integers contained in Ω is denoted by $\mathfrak{o}$.

Every element of Ω can be put into the form

$$\omega=c_0+c_1\theta+\ldots+c_{n-1}\theta^{n-1},$$

where $c_0, c_1, \ldots c_{n-1}$ are real and rational. If the c-s are integral, ω is an integer; but the converse is not necessarily true. It is possible, however, to find a set of integers $\omega_1, \omega_2, \ldots \omega_n$ belonging to Ω, such that every integer in Ω can be uniquely expressed in the form

$$\omega=h_1\omega_1+h_2\omega_2+\ldots+h_n\omega_n,$$

where $h_1, h_2, \ldots h_n$ are real integers, which may be called the *co-ordinates* of ω with respect to the *base* $(\omega_1, \omega_2, \ldots \omega_n)$. The conjugate numbers $\omega_1^{(i)}, \omega_2^{(i)}, \ldots \omega_n^{(i)}$ form a base of the manifold $\mathfrak{o}^{(i)}$, which comprises all the integers in $\Omega^{(i)}$. There exists an infinite number of equivalent bases of $\mathfrak{o}$.

The quantity

$$\Delta(\Omega)=\begin{vmatrix} \omega_1, & \omega_2, & \ldots & \omega_n \\ \omega_1', & \omega_2', & \ldots & \omega_n' \\ \omega_1'', & \omega_2'', & \ldots & \omega_n'' \\ \vdots & & & \\ \omega_1^{(n-1)}, & \omega_2^{(n-1)}, & \ldots & \omega_n^{(n-1)} \end{vmatrix}^2$$

is a rational integer called the *discriminant* of the corpus. Its value is the same whatever base $(\omega_1, \omega_2, \ldots \omega_n)$ is chosen.

If α is any integer in Ω, the product of α and its conjugates is a rational integer called the *norm* of α, and written $N(\alpha)$. Thus—

$$N(\alpha)=\alpha\alpha'\alpha'' \ldots \alpha^{(n-1)}=\alpha\alpha_1,$$

where α_1 is an integer in Ω. It follows from the definition that if α, β are any two integers in Ω, then $N(\alpha\beta)=N(\alpha)N(\beta)$.

27. *Ideals.*—That form of the theory which has been developed by Dedekind is based upon the notion of an *ideal*, which is defined by the following properties:—

(I.) An ideal $\mathfrak{m}$ is a manifold of integers belonging to Ω.

(II.) If μ, μ' are any two elements of $\mathfrak{m}$ (the same or different), then $\mu+\mu'$ and $\mu-\mu'$ are also elements of $\mathfrak{m}$.

(III.) If μ is any element of $\mathfrak{m}$, and ω any element of $\mathfrak{o}$, then $\omega\mu$ is an element of $\mathfrak{m}$.

It is clear that ideals exist: for instance, $\mathfrak{o}$ itself is an ideal. Again, all integers in Ω which are divisible by a given integer α (in $\mathfrak{o}$) form an ideal; this is called a *principal ideal*, and is denoted by $\mathfrak{o}\alpha$. In any ideal $\mathfrak{m}$ a set of elements $\mu_1, \mu_2, \ldots \mu_n$ can always be found, such that every element of $\mathfrak{m}$ is expressible in the form $\Sigma h_i\mu_i$, where h_i is a rational integer. In other words, every ideal has a base (and therefore, of course, an infinite number of bases). If $\mathfrak{a}, \mathfrak{b}$ are any two ideals, and if we form all the products $\alpha\beta$ obtained by multiplying each element of $\mathfrak{a}$ by each element of $\mathfrak{b}$, then these products and sums of such products constitute an ideal which is called the product of $\mathfrak{a}$ and $\mathfrak{b}$ and written $\mathfrak{ab}$. In particular $\mathfrak{oa}=\mathfrak{a}$, $\mathfrak{o}^2=\mathfrak{o}$, $\mathfrak{o}\alpha.\mathfrak{o}\beta=\mathfrak{o}\alpha\beta$. This law of multiplication is commutative and associative. It is clear that every element of $\mathfrak{ab}$ is contained in $\mathfrak{a}$. It can be proved that, conversely, if every element of $\mathfrak{c}$ is contained in $\mathfrak{a}$, there exists an ideal $\mathfrak{b}$ such that $\mathfrak{c}=\mathfrak{ab}$. In particular, if α is any element of $\mathfrak{a}$, there is an ideal $\mathfrak{a}'$ such that $\mathfrak{o}\alpha=\mathfrak{aa}'$. A *prime ideal* is one which has no divisors except itself and $\mathfrak{o}$. It is a fundamental theorem that every ideal can be resolved into the product of a finite number of prime ideals, and that this resolution is unique. It is the decomposition of a principal ideal $\mathfrak{o}\alpha$ into the product of prime ideals that takes the place of the decomposition of an integer into its prime factors in the ordinary theory. It may happen that all the ideals in Ω are principal ideals; in this case every resolution of an ideal into factors corresponds to the resolution of an integer into actual integral factors, and conversely, so that the introduction of ideals is not absolutely necessary. But in every other case the introduction of ideals, or some equivalent notion, is indispensable. When two ideals have been resolved into their prime factors, their greatest common measure and least common multiple are determined by the ordinary rules. Every ideal may be expressed (in an infinite number of ways) as the greatest common measure of two principal ideals.

28. There is a theory of congruences with respect to an ideal modulus. Thus the congruence $\alpha\equiv\beta \pmod{\mathfrak{m}}$ means that $\alpha-\beta$ is an element of $\mathfrak{m}$. With respect to $\mathfrak{m}$, all the integers in Ω may be arranged in a finite number of classes such that any two elements of the same class are congruent, while no two elements of different classes are congruent. The number of these classes is called the *norm* of $\mathfrak{m}$, and written $N(\mathfrak{m})$. The norm of a prime ideal $\mathfrak{p}$ is some power of a real prime; if $N(\mathfrak{p})=p^f$, $\mathfrak{p}$ is said to be a prime ideal of degree f. If $\mathfrak{m}, \mathfrak{n}$ are any two ideals, then $N(\mathfrak{mn})=N(\mathfrak{m})N(\mathfrak{n})$. If $N(\mathfrak{m})=m$, then $m\equiv0 \pmod{\mathfrak{m}}$, and there is an ideal $\mathfrak{m}'$ such that $\mathfrak{o}m=\mathfrak{mm}'$. The norm of a principal ideal $\mathfrak{o}\alpha$ is equal to the absolute value of the norm of α as defined in § 26.

The number of incongruent residues prime to $\mathfrak{m}$ is—

$$\phi(\mathfrak{m})=N(\mathfrak{m})\Pi\left(1-\frac{1}{N(\mathfrak{p})}\right),$$

where the product extends to all prime factors of $\mathfrak{m}$. If ω is any element of $\mathfrak{o}$ which is prime to $\mathfrak{m}$,

$$\omega^{\phi(\mathfrak{m})}\equiv1 \pmod{\mathfrak{m}}.$$

29. *Ideal Classes.*—If $\mathfrak{m}$ is any ideal, another ideal $\mathfrak{n}$ can always be found (for instance, $N(\mathfrak{m})/\mathfrak{m}$) such that $\mathfrak{mn}$ is a principal ideal. Two ideals $\mathfrak{m}, \mathfrak{m}'$ are said to be *equivalent* ($\mathfrak{m}\backsim\mathfrak{m}'$), or to belong to the same class, if an ideal $\mathfrak{n}$ can be found such that $\mathfrak{mn}, \mathfrak{m}'\mathfrak{n}$ are both principal ideals. It can be proved that two ideals each equivalent to a third are equivalent to each other, and that all ideals in $\mathfrak{o}$ may be distributed into a *finite* number, h, of ideal classes. That class which contains all principal ideals is called the principal class, and denoted by O.

If $\mathfrak{a}, \mathfrak{b}$ are any two ideals belonging to the classes A, B, then $\mathfrak{ab}$ belongs to a definite class which depends only upon A, B and may be denoted by AB or BA. Thus the symbols of the classes form an Abelian group of order h, in which O is the unit element. All the known properties of Abelian groups are immediately applicable: thus there is a system of "base classes" $A_1, A_2, \ldots A_k$ such that every class is representable by a symbol $A_1^a . A_2^b . \ldots A_k^l$, and so on. Every class satisfies an equation $A^f = O$, where f is some factor of h. Hence, also, some power of every ideal is a principal ideal. In the case of a quadratic corpus ideal classes correspond to classes of quadratic forms; and the multiplication of ideals or of ideal classes corresponds to the composition of quadratic forms.

30. The discriminant of a corpus enjoys some very remarkable properties. Thus its value is always different from ± 1; there can only be a finite number of corpora of order n which have a given discriminant d; and the rational prime factors of $\Delta(\Omega)$ are precisely those rational primes which are divisible, in Ω, by the square (or some higher power) of a prime ideal.

31. Every element of $\mathfrak{o}$ which is not contained in any other ideal is an *algebraic unit*. If the conjugate corpora $\Omega, \Omega', \ldots \Omega^{(n-1)}$ consist of r_1 real and $2r_2$ imaginary corpora, there is a system of units $\epsilon_1, \epsilon_2 \ldots \epsilon_\mu$, where $\mu = r_1 + r_2 - 1$, such that every unit in Ω is expressible in the form $\epsilon = \rho\, \epsilon_1^a\, \epsilon_2^b \ldots \epsilon_\mu^l$, where ρ is a root of unity contained in Ω and $a, b, \ldots l$ are natural numbers. This theorem is due to Dirichlet.

The norm of a unit is $+1$ or -1; and the determination of all the units contained in a given corpus is in fact the same as the solution of a diophantine equation

$$F(h_1, h_2, \ldots h_n) = \pm 1.$$

For a quadratic corpus the equation is $h_1{}^2 - Dh_2{}^2 = \pm 1$, and the theory of this is complete; but, except for certain special cubic corpora, little has been done towards solving the important problem of assigning a definite process by which, for a given corpus, a system of fundamental units may be calculated. The researches of Jacobi, Hermiti, and Minkowski seem to show that a proper extension of the method of continued fractions is necessary.

32. *Normal Corpora.*—The special properties of a particular corpus Ω are closely connected with its relations to the conjugate corpora $\Omega', \Omega'', \ldots \Omega^{(n-1)}$. The most important case is when each of the conjugate corpora is identical with Ω; the corpus is then said to be *Galoisian* or *normal*. The manifold $R(\theta, \theta', \ldots \theta^{(n-1)})$ of all rational functions of the conjugate numbers $\theta, \theta', \ldots \theta^{(n-1)}$ is a Galoisian corpus; so that every arithmetical corpus of order n is either normal, or is contained in a normal corpus. The roots of an equation $f(\theta) = 0$ which defines a normal corpus are associated with a group of substitutions; if this is Abelian, the corpus is called Abelian; if it is cyclic, the corpus is called cyclic. A cyclotomic corpus is one the elements of which are all expressible as rational functions of roots of unity; in particular the complete cyclotomic corpus C_m is the corpus (of order $\phi(m)$) which consists of all rational functions of a primitive mth root of unity. To Kronecker is due the very remarkable theorem that all Abelian corpora are cyclotomic; in other words, if the roots of a rational equation $f(\theta) = 0$ are connected by a set of relations $\theta_2 = \phi(\theta_1)$, $\theta_3 = \phi(\theta_2) \ldots \theta_n = \phi(\theta_{n-1})$, $\theta_1 = \phi(\theta_n)$, where $\phi(\theta)$ is an integral function of θ with rational coefficients, then all the roots $\theta_1, \theta_2, \ldots \theta_n$ can be expressed as rational integral functions, with rational coefficients, of some root of unity. The first published proof of this was given by H. Weber.

33. It may be observed that in the theory of an arithmetical corpus we are not concerned with the actual values (as complex numbers) of its elements; the symbols are in fact mere *umbræ*, serving as regulators, so to speak, of operations which are actually performed on rational integers. When we have once obtained a base of $\mathfrak{o}$, and have constructed the "multiplication table," expressing the products $\omega_i\omega_j$ as linear functions of $\omega_1, \omega_2, \ldots \omega_n$, every integer in Ω is expressible by an abstract symbol $[h_1, h_2, \ldots h_n]$, where $h_1, h_2, \ldots h_n$ are rational integers (called in § 26 the co-ordinates of the number). Then we have rules for combining these symbols, of the form

$$[h_1, h_2, \ldots h_n] + [k_1, k_2, \ldots k_n] = [h_1 + k_1, h_2 + k_2, \ldots h_n + k_n]$$

$$[h_1, h_2, \ldots h_n] \times [k_1, k_2, \ldots k_n] = [p_1, p_2, \ldots p_n]$$

where $p_1, p_2, \ldots p_n$ are lineo-linear functions of the h-s and k-s. The divisibility of $[h_1, h_2, \ldots h_n]$ by an ideal $\mathfrak{m}$ may be expressed by one or more ordinary linear congruences satisfied by $h_1, h_2, \ldots h_n$. For instance, if $[x, y]$ stands for $x + yi$, the rules of operation are those given in § 24, and if $\mu = a(b + ci)$, where a, b, c are real integers, and b, c are prime to each other, the divisibility of $[x, y]$ by μ is expressed by the congruences

$$bx + cy \equiv 0, \quad cx - by \equiv 0 \quad (\text{mod } a(b^2 + c^2)),$$

which may be replaced by other equivalent conditions. This point of view is indicated by Kummer.

Every linear associative algebra suggests a corresponding arithmetical theory.

34. *Transcendental Numbers.*—The manifold of real algebraic numbers is numerable. Hence immediately follows the proposition (first proved by Liouville) that there are numbers, both real and complex, which cannot be defined by any combination of a finite number of equations with rational integral coefficients. Such numbers are said to be *transcendental*. Hermite first completely proved the transcendent character of e. Lindemann, by a similar method, proved the transcendence of π. Thus it is now finally established that the quadrature of the circle is impossible, not only by rule and compass, but even with the help of any number of algebraic curves of any order when the coefficients in their equations are rational. (See Hermite, "Sur la fonction exponentielle," *C.R.* t. lxxvii. 1873; and Lindemann, "Ueber die Zahl π," *Math. Ann.* xx. 1882.)

35. It is especially noteworthy that the science of arithmetic has now reached a stage where all its definitions, processes, and results are demonstrably independent of any theory of variable or measurable quantities such as those which are postulated in geometry and mathematical physics; even the notion of a limit may be dispensed with, although this idea, as well as that of a variable, is often convenient. For the questions which arise in the application of arithmetic to geometry and analysis the reader is referred to the article on FUNCTIONS OF REAL VARIABLES.

NUMISMATICS.

I. Coins.

Ancient.

SINCE 1870 a very great advance has been made in the study of the coinages of the ancient world, and also of mediæval and more recent times. In the Greek series not only has great progress been made in its geographical classification, but also in ascertaining the chronological sequence of the numerous coinages. This last result has been effected by a careful examination of the principal centres of coinage, by a close study of style and the art displayed, and by a minute inquiry into the various metrical systems of the ancients. The phases of art as illustrated by Greek coins have been defined within certain chronological divisions or periods, the characteristics of which enable the student to group at sight his coins within well-ascertained limits. Whilst this classification by style has been of great service to the chronology of other objects of antiquity, especially of Greek sculpture, gems, &c., it has served to raise ancient coins to a position which their science had not before attained. In Roman numismatics the progress is not so marked, the scope for inquiry being perhaps much more limited. Mommsen's chronological arrangement of the Roman republican series has not been superseded; and no serious attempt has been made to treat the imperial series in a similar manner; but until this is done Roman coins as historical records must lose their chief value. In the mediæval section the early issues of the Merovingians, the Visigoths, the Anglo-Saxons, the feudal princes of France, the early rulers of Germany, and the Latin princes of the East, have all received much attention, and these have thrown much light on a difficult portion of the world's history. The same may also be said of the various Oriental sections, especially in the case of the early coinages of India, of which till recently our knowledge was very vague. The bibliography at the end of this article will give a few of the more important recent works in each branch.

Modern.

Turning to the coinages of the present day, we shall note the more important changes which have occurred since 1870; and it is a singular fact that there are but very few countries in any quarter of the globe which have not made some radical change in this respect.

The United Kingdom.—No fundamental alteration has, however, occurred in the case of the British coinage. The standard of gold and silver has remained unchanged for over two hundred years, and until 1887 the denominations were practically the same as instituted at the great recoinage of 1816. The substitution of a bronze for a copper currency had already taken place in 1860. On the occasion of Queen Victoria's Jubilee in 1887 it was determined to mark the event by a new coinage of gold and silver, and to make the royal portrait more suitable to her Majesty's then age. Two new denominations of five and two pounds were added to the gold series, and the double florin to the silver. For the reverse type of all the gold and of the five-shilling piece, Pistrucci's design of St George and the Dragon was used, and former types of Anne and George IV. were revived for the double florin, florin, half-crown, and sixpence; that of the last was, however, soon abandoned. This new coinage did not meet with general approval, especially as regards the portrait of the Queen, and in consequence a third portrait was adopted for the gold and silver in 1893, new reverse types were prepared for the half-crown, florin, and shilling, and the issue of the double florin was discontinued. The new portrait of the Queen was the work of the sculptor, Mr Thomas Brock, R.A. (Fig. 1), who was careful to avoid the defects which had been somewhat severely criticized in Sir J. Edgar Boehm's design of 1887. The new type for the half-crown, a spade-shaped shield within the garter, was also executed by Mr Brock; and those for the florin and shilling, three shields placed triangularly, were by Sir Edward Poynter. In 1895 a new issue of bronze money was ordered, when the Queen's bust of 1893 was adopted, and a slight alteration made in the reverse type, the representation of a lighthouse and a ship, which had been added to the design in 1860, being eliminated.

Fig. 1.—Sovereign (gold), England: Queen Victoria (obverse by Brock).

The coinage of Edward VII. (Fig. 2) differs but slightly from that of Queen Victoria. The denominations are the same; but on the obverse the head of the king (by Mr G. W. de Saulles, engraver to the Mint) is represented bare, and the title "Britanniarum" is changed to "Britanniarum Omnium Rex," and the reverse of the florin shows Britannia standing on a ship, and that of the shilling the royal crest, the lion on a crown, as on the so-called "lion shillings" of 1826.

Fig. 2.—Sovereign (gold), England: King Edward VII. (obverse by de Saulles.)

France.—On the establishment of the Third Republic in France in 1870, the coinage was continued on the same lines as before, the types only being altered. The silver franc of 5 grammes (78 grains) as ordered in 1793 and confirmed by the Latin Monetary Union of 1865, which included Belgium, Italy, and Switzerland, and subsequently in 1868 Greece, has remained the unit of value. The denominations ordered were, in *gold*, the 100, 50, and 20 francs; in *silver*, the 5, 2, and 1 franc, and 50 and 20 centimes; and in bronze, the 10, 5, 2, and 1 centime. The types adopted were those which had been used previously—thus for the gold that of a genius inscribing the tables of the law, as designed by Augustin Dupré for the reverse of the constitutional coinage of Louis XVI.; for the silver and copper the head of the Republic as executed by Oudiné for the money of 1848. Subsequently, in 1871, the type of the 5 francs was changed for that of Hercules leaning on Liberty and Strength, as made by Dupré for the First Republic. In 1889 the 10 francs in gold was added to the list, having the head of the Republic crowned with corn, the work of Merley for the Republic of 1848; but only a small number of these coins was struck in that year and in 1895. No further alteration was made till after 1895, when, in consequence of suggestions that the types should be modified so as to mark the Third Republic, the artists MM. Chaplain, Roty, and Dupuis were commissioned to execute new designs—the first for the gold, the second for the silver, and the last for the bronze. The types approved were: for the gold 20 francs, the head of the Republic with a Phrygian cap, and the Gallic cock (Fig. 3); for the silver 2 and 1 franc and 50 centimes, the sower sowing with the rising sun, and a laurel wreath (Fig. 4);

and for the bronze, the bust of the Republic wearing a Phrygian cap, and on the reverse France seated amidst clouds, holding a branch and a flag, and accompanied by a genius. These coins were not issued simultaneously—the 50 centimes appearing in 1897, the 2 and 1 franc and 10, 5, 2, and 1 centime in 1898, and the 20 francs in 1899. These new coins all show considerable skill in their designs, and are characteristic of French medallic art of the present time, which has a strong tendency to imitate that of Italy of the 16th century. We cannot help thinking, however, that a mistake has been made in giving in some instances the surface of the coin a "blurred" or "cloudy" appearance, such as a cast medal would have before it was tooled or chased. This is contrary to all precedent in the art of coinage, and as it seems to lend itself to forgery and imitation, it is an open question whether it will meet with general favour.

Fig. 3.—Twenty Francs (gold), France (Chaplain).

Fig. 4.—Two Francs (silver), France (Roty).

Belgium.—Of the other states which formed the Latin Monetary Union, Belgium had already in 1832 adopted the French decimal and bimetallic system, with the franc as the unit of value. Her accession to the Union, therefore, only entailed a slight modification of type and denominations, which latter were the same as in France, except that the only gold coin was the 20 francs, the 25 centimes in silver was not issued, and the pieces of 10 and 5 centimes are now in nickel. The gold and silver coins have for types the head of the king and the royal shield, those in nickel the Belgic lion and mark of value, and those in bronze the royal monogram and the lion holding the tables of the constitution. Some of the silver coins have the inscriptions in Flemish.

Switzerland.—Like Belgium, Switzerland had before her adhesion to the Latin Monetary Union adopted the French system, with the franc of 100 centimes or rappen as the unit of value. The denominations in gold and silver were the same as issued for Belgium, but no gold was struck before 1883. The coins of baser metal were the 20, 10, and 5 centimes in billon, which metal was in 1879 changed for nickel, and in copper the 2 and 1 centime. Certain changes of type have from time to time occurred. The first issue of the 20 francs in 1883 shows the head of the Republic and the shield of the Confederation; but this was changed in 1897 for the head of Helvetia above a range of mountains, and on the reverse a wreath with mark of value. On the silver coins from 1874 Helvetia is represented standing instead of seated, and on the nickel money of 1879 the shield of the Republic is replaced by the head of Helvetia. The mark of value and a wreath form the general reverse type of all the silver, nickel, and copper coins (Fig. 5). Since 1888 a 5-franc piece, similar in type to the 20 francs of 1883, has been issued.

Fig. 5.—Twenty Centimes (nickel), Switzerland.

Italy.—When Italy joined the Latin Monetary Union in 1865, she adopted as the unit of her coinage the lira of 100 centesimi, equal to the franc. The coins were of gold, silver, and bronze, and of the same denominations as those struck in Belgium and Switzerland. In 1894 a nickel coinage of 20 centesimi was ordered. The general type for all the coinage is the head of the king and the royal arms (Fig. 6), but on the reverse of the copper is the mark of value; and the nickel money has on the reverse a crown with a wreath. The coinages of all the small Italian states, including the Papal, have now passed out of currency.

Fig. 6.—Two Lire (silver), Italy.

Greece.—A special stipulation was made, when Greece was enrolled in the Latin Monetary Union in 1868, that all her money should be struck at a French mint. The unit of the coinage is the drachm of 100 lepta, which, like the lira, is equivalent to the franc. The denominations are—in *gold*, the 100, 50, 20, 10, and 5 drachms; in *silver*, the 5, 2, and 1 drachm, and 50 and 20 lepta; and in *bronze*, the 10, 5, 2, and 1 lepton. In 1893 nickel was substituted for bronze, and coins of the value of 20, 10, and 5 lepta were issued in this metal. The types of the coins of Greece are similar to those of Italy.

Germany.—Since 1871 the coinage of the German Empire has been entirely remodelled. By a convention in 1857 between the States of Germany, north and south, and Austria a general coinage of a silver standard was established on the basis of the new pound of 500 grammes as sanctioned by the *Zollverein.* The contracting countries were divided into three sections, North Germany, South Germany, and Austria. From the pound of fine silver of 500 grammes the Northern States struck 30 thalers, Austria 45 florins, and the Southern States $52\frac{1}{2}$ florins; their relation being 1 North German thaler $= 1\frac{1}{2}$ Austrian florins $= 1\frac{3}{4}$ South German florins. The free towns of Hamburg, Lübeck, and Bremen did not join the convention. The first reform in the coinage of the German Empire occurred in 1871, when a new gold money was introduced, which had for its unit the silver mark (a money of account) of 100 pfennigs weighing 5·555 grammes. The new gold pieces were of the value of 10 and 20 marks, called crowns and double crowns, and the fineness was $\frac{9}{10}$ pure to $\frac{1}{10}$ alloy. This new issue necessitated a readjustment of the current values of the various silver coinages in circulation. In 1873 a further step was made by the introduction of an entirely new silver coinage throughout the empire, which was also based on the silver mark, and of a new base metal coinage in nickel and bronze. The silver coins were the 5, 2, and 1 mark and 50 and 20 pfennigs; those in nickel the 10 and 5 pfennigs, and in bronze the 2 and 1 pfennig. The silver coins were, like the gold, $\frac{9}{10}$ fine, so that 90 marks were struck to the pound of pure metal. The gold 5 marks was struck in 1877 and 1878, and the 20 pfennigs in silver was replaced by a coin of the same value in nickel in 1886. The reverse type for all the coins is the imperial eagle, but that of the obverse varies; the gold and silver showing the portrait of the reigning king or prince (Fig. 7), but the mark, and all lesser denominations, the current value. An exception was made in the case of the coinage of the Free Towns struck at Hamburg, which has the arms of the city instead of a portrait. Each state retained its full rights of coinage, and the various mints throughout the empire with their special marks are:—Berlin, A; Hanover, B; Frankfort, C; Munich, D; Dresden (removed since 1877 to Müldner-Hütte), E; Stuttgart, F; Karlsruhe, G; Darmstadt, H; and Hamburg, J. In 1876 a gold standard was proclaimed, and henceforth no person was legally bound to accept in payment more than 20 marks in silver and the value of 1 mark in nickel or bronze.

Fig. 7.—Twenty Marks (gold), Germany.

Austria-Hungary.—After the convention of 1857 with Germany (see above), when Austria based her coinage on the silver standard of the florin, two series were issued—(i.) Vereinsmünzen (money of the union), in *gold*, the crown and half-crown; in *silver*, the double thaler (=3 florins) and thaler; (ii.) Landesmünzen (money of the state), in *gold*, the 4 and 1 ducat; in *silver*, the double florin and florin; in *billon*, the 20, 10, and 5 kreuzers; and in *copper*, the 4, 3, 1, and ½ kreuzer. In 1868 Austria abandoned the convention, but made no change in her money; and in the same year the coinage of Hungary was made uniform with that of the empire, both in standard and denominations. In 1870 the Vereinsmünzen crown and half-crown were discontinued, and their place was taken by 8 and 4 florin pieces which were of the current value of 20 and 10 francs. In 1892 the monetary system of Austria-Hungary was entirely reformed on a gold standard, the unit of account being the crown of 100 hellers. This is a decimal coinage, and the denominations are, in *gold*, the 20 crowns (of 164 from the kilogramme of fine gold), 10 crowns, and ducat (=9 silver crowns 60 hellers); in *silver*, the crown and half-crown; in *nickel*, the 20 and 10 hellers; and in *bronze*, the 2 and 1 heller. The gold ducat was a trade-money (handelsmünze) of the current value of 10 francs, and it displaced the 8 and 4 florin pieces of 1870. The types of the Austrian and Hungarian coins somewhat vary (Fig. 8).

Fig. 8.—Florin (silver), Austria-Hungary.

The Austrian gold coins show the head of the emperor and the two-headed eagle, but those of Hungary a full-length figure of the emperor and the national shield surmounted by the crown of St Stephen held by angels. The silver coins of both series have the head of the emperor and the mark of value under the imperial or royal crown. The nickel and bronze money of Austria displays the imperial eagle on the obverse, whilst that of Hungary has the crown of St Stephen. The legends are respectively in Latin and Magyar.

Spain.—The unit of the Spanish coinage from 1864 to 1868 was the silver escudo of 200 grains divisible into 10 reals. On the dethronement of Isabella in 1868 the provisional government adopted the principles of the Latin Monetary Union and made the peseta the unit of account, this coin being equivalent to the franc. The coins struck during 1869–70 were, in *gold*, the 100 pesetas; in *silver*, the 5, 2, and 1 peseta, and the 50 and 20 centimos; and in *bronze*, the 10, 5, 2, and 1 centimo. The obverse type of each metal varied; on the gold Spain is standing; on the silver she is reclining; and on the bronze she is seated. During his short reign (1870–73) Amadeus I. struck only gold coins of 100 and 25 pesetas and silver of 5 pesetas, and there was practically no money issued during the Republic which followed his abdication. Don Carlos during the insurrection of 1874–75 struck 5 pesetas in silver and 10 and 5 centimos in bronze bearing his portrait and title "Carolus VII." After the restoration of Alphonso XII. the coinage consisted of 25 and 10 pesetas in gold; 5, 2, and 1 peseta and 50 centimos in silver; and 10 and 5 centimos in bronze; and this coinage was continued by his son Alphonso XIII., who, however, in 1887 substituted the 20 pesetas in gold for the 25 pesetas, and in 1897 struck large coins of 100 pesetas. The types show the head of the king on the obverse and the shield with (Fig. 9) or without the pillars of Hercules on the reverse; but in the case of Alphonso XIII. changes have been made in the portrait suitable to his age.

Fig. 9.—Peseta (silver), Spain.

Portugal.—A gold standard was adopted by Portugal in 1854, the unit of value being the milreis of 1000 reis. The coins are, in *gold*, the crown or 10 milreis and the half, fifth, and tenth crown or milreis; in *silver*, the 5, 2, 1, and ½ testoon or 50 reis; and in *bronze*, the 20, 10 and 5 reis. The general type of the gold and silver is the head or bust of the king and the royal shield; but the bronze varies in having on the obverse a shield and on the reverse the mark of value.

Denmark, Sweden, and Norway.—Previous to 1872 in Denmark the unit of value was the silver *rigsbankdaler* of 96 skillings; in Sweden, the *rigsdaler* of 100 öre; and in Norway, the *speciesthaler* of 120 skillings; but in that year a monetary convention was concluded between these countries establishing a decimal coinage, which had for its unit the krone of 100 öre, and of which the standard was gold. The denominations are, in *gold*, the 20, 10, and 5 kroner; in *silver*, the 2 and 1 krone, and 50, 25, and 10 öre; and in *bronze*, the 5, 2, and 1 ör. The gold and silver money of Sweden and Norway to the 50 öre bears the head of the king and the royal shield; the silver of smaller denominations and the bronze, the monogram of the king and the mark of value. In Denmark the gold and silver have the head of the king, and for reverse type, a figure of Denmark, a shield, or the mark of value. The bronze coins are similar to those of Norway and Sweden.

Russia.—The Russian coinage previous to 1885 was based on the silver rouble of 278 grains of pure metal; but during the greater part of the reign of Alexander II. (1855–81) the currency consisted almost entirely of paper money. In 1885 Alexander III. determined to place the coinage on a proper footing, and introduced the rouble of 100 copeks as the unit of account, with a relative value of gold and silver of 1 to 15½. The coins issued were, in *gold*, the imperial of 10 roubles, and the half-imperial; in *silver*, the rouble, and the 50, 25, 20, 15, 10, and 5 copeks; and in *copper*, the 5, 3, 2, 1, ½, and ¼ copek. In 1897 the relative value of gold and silver was advanced to 1 to $23\frac{1}{4}$, thus raising the current value of the imperial to 15 roubles; but no change was made in the weights of the coins, and the silver rouble remained the unit of account. In the same year a piece of 5 roubles, called the one-third imperial, was added to the gold coins. The general types of the gold (Fig. 10) and silver show the head of the emperor and the imperial eagle; and of the copper, the imperial eagle and mark of value.

Fig. 10.—Seven and one half Roubles (gold), Russia.

Georgia, Poland, and Finland.—The separate issues of Georgia and Poland were suppressed in 1833 and 1847 respectively; but Finland in 1878 established a decimal coinage of gold, silver, and bronze on the principles of the Latin Monetary Union, having the *markhaa* (=1 franc) as its unit of value. Russia having since 1899 deprived Finland of her autonomy, her separate coinage will probably disappear.

Turkey.—There has been practically no change in the money of the Ottoman empire since the reforms of Abdul-Medjid in 1844, when the piastre, or 40-para piece, of the current value of $2\frac{1}{4}$d., was made the unit of the coinage, and of which 100 go to the gold medjidieh or pound. The denominations are, in *gold*, the 500, 250, 100, 50, and 25 piastres; in *silver*, the 20, 10, 5, 2, 1, and $\frac{1}{2}$ piastre; and in *copper*, the 40, 20, 10, 5, and 1 para. The type in all metals is, on the obverse, the Sultan's *tughra*, or cipher, and on the reverse, a wreath, and the name of the mint, date, &c.

Balkan States.—Since the dismemberment of the Ottoman empire the kingdoms of Rumania and Servia, and the principality of Bulgaria, have each adopted the decimal system of the Latin Monetary Union. In Rumania the unit of account is the *leu* of 100 *bani*; in Servia, the *dinar* of 100 *paras*; and in Bulgaria, the *lev* of 100 *stotinki*—each of these units being the equivalent of the franc. All these states issue gold and silver money; but the last two have adopted nickel instead of a bronze coinage.

United States.—Turning to the West, we find that in the United States the most important event connected with the coinage has been a change of standard. Previous to 1873 the standard was silver, having for its unit the dollar of $412\frac{1}{2}$ grains of $\frac{9}{10}$ fine; but in that year a gold standard was adopted, the gold dollar of 25·8 grains and $\frac{9}{10}$ fine being the sole unit of value. This change of standard was accompanied by a slight modification of the denominations, which were, in *gold*, the double-eagle, eagle, half, and quarter eagle, three dollars, and dollar; in *silver*, the half and quarter dollar, 20 cents, and dime; in *nickel*, the 5 and 3 cents; and in *bronze*, the cent. In addition to these a silver piece called the "trade dollar" of 420 grains was struck, not for circulation in the States, but for export to China. The following changes have since occurred:—In 1878 the silver dollar of $412\frac{1}{2}$ grains was resumed, and the 20 cents discontinued; in 1887 the issue of the "trade dollar" was suspended; and in 1890 the same fate befell the three dollars and dollar in gold, and the three cents in nickel. The types are—*gold*, head of Liberty and eagle; *silver*, head of Liberty, or Liberty seated, and eagle, except the dime, which has the mark of value; *nickel*, shield (5 cents) and head of Liberty (3 cents); *bronze*, head of an Indian; with reverse types for either metal, the mark of value.

Canada.—The currency for the Dominion of Canada, which includes Nova Scotia, New Brunswick, and British Columbia, is of silver and bronze, based on the system of the United States. The denominations are 50, 25, 20, 10, and 5 cents in silver, and the cent in bronze; and they also have a uniform type of the sovereign's head and mark of value. The same system prevails in Newfoundland, which also issues the double dollar in gold: this is the only gold coin issued in a British colony whose standard is not the same as that of the mother country. There is a separate coinage for Jamaica, but of nickel only, and consisting of the penny, halfpenny, and farthing. Hitherto all the Canadian coins have been struck at the Royal Mint, or by Messrs Heaton of Birmingham, but it is proposed to establish a separate mint at Montreal.

Mexico, &c.—We need not give any detailed account of the coins of Mexico, and of the various states of Central and South America, in nearly all of which there have been radical changes since 1870. Most of them have adopted the decimal system, with a gold, silver, or bi-metallic standard; the unit of value in the gold standard being generally the peso of 3·225 grammes, and in the silver also the peso, but of silver of 20, 25, or 27 grammes.

India.—As to the coins of the East and Far East, we will limit our remarks to the more important countries. In British India the rupee of silver of 150 grains is still the unit of value, but of late years serious steps have been taken to establish a gold currency also, and at present there appears some prospect of this being carried out.

Persia.—In Persia since 1879 a decimal system in conformity with the principles of the Latin Monetary Union has been adopted, having for its unit the *krân* weighing 78 grs, thus being equivalent to the franc, but since reduced to 71 grs. or even less. The denominations are: in *gold*, the 10, 5, 2, 1, $\frac{1}{2}$, and $\frac{1}{4}$ toman (the toman = 10 krâns); in *silver*, the 5, 2, and 1 krân (= 20 shahis), and the 10 and 5 shahis; and in copper, the 4, 2, and 1 shahi (= 2 pals), and the pal.

Japan.—Since 1871 Japan has formed its coinage on the European decimal system in place of the ancient national coins, the *obangs* and *itsibus*, the unit being the *yen* of 100 *sen*. The standard was bi-metallic, and the relation of gold and silver stood at 1–16·17. In 1898 a gold standard was adopted, the issue of the silver yen was suspended, and the weight of the gold money was reduced by one-half. The coins issued since that date are, in *gold*, the 20, 10, and 5 yen; in *silver*, the 50, 20, and 10 sen; in *nickel*, the 5 sen; and in *bronze*, the sen and half-sen. There is one general type for all the silver, nickel, and bronze coins, being the dragon on the obverse and a wreath of flowers with mark of value on the reverse. The gold varies in having flags and flowers on the reverse. On the silver and bronze coins the legends are in English as well as in Japanese.

China.—In 1890 China followed the example of Japan, but only to a limited extent, and instituted a silver coinage having as its unit a dollar of the same value as the United States silver dollar and the Japanese yen. It is calculated in fractions of the *tael*, a money of account of the value of 2s. $11\frac{3}{4}$d. The coins are the dollar, and the 50, 25, 10, and 5 cents, with the Chinese dragon and inscriptions, mint and mark of value in English on the obverse, and on the reverse the mark of value in Chinese and Manchu. They were first struck at Canton and Wei-Chang, but later other mints have been established.

Hong Kong.—The only other Asiatic coinage we shall note is that of Hong Kong, where in 1866 was established a coinage, which was also based on the United States standard, having the silver dollar as its unit. The denominations are the dollar and 50, 20, and 5 cents in silver, and the cent and mill in bronze; and, with the exception of the mill, they all have for type the sovereign's head and the mark of value. In connexion with this coinage there has been issued since 1895 a "trade dollar" for special currency in the Straits Settlements

Fig. 11.—"Trade Dollar" (silver), Hong Kong.

and Hong Kong in lieu of the Mexican dollar, the scarcity of which was a considerable hindrance to trade. This coin, which is struck at the Bombay mint, shows on the obverse Britannia holding a trident and shield, and on the reverse within an ornamental design the denomination in Chinese and Malay (Fig. 11).

Egypt.—Glancing cursorily at the coinage of Africa, it may be noted that since 1885 Egypt has adopted a gold standard with the gold pound of 100 piastres as the unit of account. The piastre is no longer divisible into 40 paras, but into 10 *ochr-el-guerche* or tenths. The types are similar to the Turkish money, and though bearing the legend "struck at Cairo" the coins are really manufactured at some European mint.

Abyssinia.—In Abyssinia since 1893 there has been a silver coinage formed on the basis of the Austrian Maria Theresa dollar. The coins are, in *silver*, the *talari* (= dollar), $\frac{1}{2}$, $\frac{1}{4}$, and $\frac{1}{8}$ *talari*, and in *copper*, the *guerche* and $\frac{1}{2}$ and $\frac{1}{4}$ *guerche*. They show on one side the head of the king, and on the other a lion holding a banner.

Zanzibar.—Zanzibar has also issued a dollar of the fixed value of 2 rupees and 2 annas, and a copper coin called a *pessa* (= 136th dollar).

Sudan.—The African coinages which have attracted exceptional attention are those of the Sudan and the South African Republic. The former dates from 1885, when the Mahdi struck the pound of 100 piastres in gold and the 20 piastres in silver, of the same type as the Egyptian coins, but on the silver piece were placed the words "By order of the Mahdi," but no mint name. His successor, Abdullah, struck pieces of 20, 10, 5, 2, and 1 piastre in silver and 10 paras in copper, but no gold. They bear the name of the mint, Omdurman, and the word *makbul, i.e.*, accepted. At first the silver coins were of 6 parts silver and 2 copper, but in a few years they were so debased that they degenerated into mere pieces of copper washed with silver. The last issue is dated 1897 (A.H. 1315).

Transvaal.—The first attempt at a separate coinage in the Transvaal was in 1874, when President Burgers issued sovereigns or pounds showing his portrait on the obverse and the shield of the Republic on the reverse. They were struck by Messrs Heaton of Birmingham, but as each piece of the current value of 20s. cost 26s. to strike, only £680 worth was issued, and but few of these passed into circulation, being preserved as curiosities. No further attempt was made till 1891, when President Kruger induced the Raad to order a coinage in gold, silver, and bronze after the English standard. The first issue occurred in 1892, and consisted of the pound and half-pound in gold; the crown, half-crown, florin, shilling, sixpence, and threepence in silver; and the penny in bronze. They are all of the same type as the pound of 1874, but with the portrait of President Kruger on the obverse. The first issue of the pound, half-pound, and crown was minted at Berlin, and a curious mistake was made in the arms of the state, the waggon being represented with two shafts instead of with one. This blunder was soon noticed, and a recoinage took place in the same year at Pretoria.

II. Medals.

The art of the medallist developed during the last thirty years of the 19th century beyond most of the other fine arts, consequent on the growing taste of the public and the critics. The medal—as it is understood to-day—enjoys a life entirely independent of the coin on the one hand, and, on the other, of the sculptured medallion, or bas-relief; and its renascence is one of the phenomena in art witnessed by the present generation. It is in France that it has risen to the greatest perfection, as it is in that country most widely appreciated and most effectually supported. Its popularity there is well-nigh universal; it is esteemed for its appropriateness not only for memorials of popular events and of public men, but also for private celebrations of all kinds, and, through religious allusion (communions, fêtes, saints' days, and the like), for the gratification of the pious. Other nations, in a degree far inferior, are producing medallists and medals in number, but none approaches in excellence—in artistic feeling, treatment, and sensitiveness of execution—the artists and the achievements of France. In England, although the Royal Academy seeks to encourage its students to practise the art, the prize it offers commonly induces no competition. The art of the medallist is not properly appreciated or understood, and receives little or no support. The prevailing notion concerning it is that it consists in stamping cheap tokens out of white metal or bronze, on which a design, more or less vulgar, stands out in frosty relief from a dazzling, glittering background. These works, even the majority of military and civic medals, demonstrate how the exquisite art of the Renaissance had been degraded in England—almost without protest or even recognition—so that they are, to a work by Roty or Chaplain, what a nameless daub would be to a picture by Rembrandt or Velasquez.

It is probable that Jacques Wiener (died 1899), of Belgium, was the last of the medallists of note who habitually cut his steel dies entirely with his own hand without assistance, though others in some measure do so still. The fact is that although most modern workers, exclusively medallists, have themselves cut dies, they nowadays take

advantage of the newest methods; and the *graveur en médailles* has become simply a *médailleur.* His knowledge of effect is the same—though the effect sought is different: in earlier times the artist thought chiefly of his *shadows*; nowadays he mainly regards his *planes.* Otherwise his aims are not dissimilar; but he sees no object in pursuing the slow, laborious system that was formerly practised, when he can gain freedom, save time, and increase effect by seizing the advantages offered by recent inventions. At the present day the medallist, after making conscientious studies from life (as if he were about to paint a picture), commonly works out his design in wax, or similar substance, upon a disc of plaster about 12 or 14 inches in diameter. From that advanced model a simple mould, or matrix, is made, and a plaster cast is taken, whereupon the artist can complete his work in the utmost perfection. Then, if a struck medal is required, a steel cast is made, and from that a reduction to the size required for the final work is produced by means of the machine—the *tour à réduire.* It is this machine which has made possible the modern revival, and has revolutionized the taste of designers and public alike. It was invented by Contamin, who based it upon that *tour à portrait* which Houlot produced in 1766, and which helped to fame several engravers now celebrated. This machine was first exhibited in Paris in 1839, and was sold to the Munich Mint; while a similar invention, devised at the same time by the English engraver Hill, was acquired by Wyon for £2000, and was ultimately disposed of to a private mint in Paris. From that city comes the machine, based by the French inventor M. Ledru upon the two already referred to, now in use at the Royal Mint in London. A well-served medallist, therefore, need trouble himself nowadays about little beyond the primary modelling and the final result, correcting with his own hand only the slightest touches—refining, perfecting—but sometimes merely confining himself to giving his directions to the professional engraver.[1]

The great majority of the artistic medals at present in the world (in the great collection of France there is a total of not fewer than 200,000 medals) are cast, not struck. There is in them a charm of surface, of patina, of the metal itself, which the struck medal, with all the added beauties which it allows of delicate finish and exquisite detail, can hardly give. On the other hand, the production of the cast medal is much slower, much more uncertain; and the number of fine copies that can be produced is infinitely smaller. All the early medals were cast, being first modelled in wax, and then cast by the *cire perdue* (waste wax) process, and were usually worked over by the chaser afterwards; indeed, it was not until the beginning of the 16th century that dies, hitherto used only for coins executed in low relief, were employed for larger and bolder work. The medallists of those days always cast in bronze or lead, and only proceeded to use silver and gold as a luxurious taste began to demand the more precious metals. There is little doubt that the material to be preferred is dull silver (*mat* or *sablé*—sand-blasted), as the work, with all its variations of light and shade, can be better seen in the delicate grey of the surface.

The medal, properly considered, is not sculpture. Vasari was happy in his definition when he described the medallic art as the link between sculpture and painting, that is to say, painting in the round with the colour left out. Less severe than sculpture, it need not be less dignified; it is bound down by the conventions of low relief, and by compulsions of composition and design, dependent on shape, from which sculpture, even when the relief is the lowest, is in a great measure free. In the medal, otherwise than in sculpture, elaborate perspective and receding planes are not out of place. The genius of the modern Frenchman rebelled against the rule that commonly governed the medal during the decadence, and has triumphed in his revolt, justifying the practice by his success. The modern medal and the *plaquette* aim at being decorative yet vigorous, reticent and dignified, delicate and tender, graceful and pure; it may be, and often is, all these in turn. Imagination, fancy, symbolism, may always be brought into play, allied to a sense of form and colour, of arrangement and execution. By the demonstration of these qualities the artist is to be differentiated from the skilful, mechanical die-sinker, who spreads over the art the blight of his heavy and insensitive hand and brain. So with portraiture. Accurate likeness of feature as well as character and expression are now to be found in all fine works, such as are seized only by an artist of keenly sensitive temperament. It is thus that he casts the events and the actions of to-day into metallic history, beautifully seen and exquisitely recorded; thus that the figure on the medal is no longer a mere sculpturesque symbol, but a thing of flesh and blood, suave and graceful in composition, and as pleasing in its purely decorative design as imagination can inspire or example suggest. It is thus that the art, while offering easy means of permanent memorial, has afforded to men of restricted means the eagerly seized opportunity of forming small collections of masterpieces of art at a small outlay.

France.—In France the example of Oudiné, coming after that of David d'Angers, did much to revolutionize the spirit animating the modern medallist, but Chapu, by his essentially modern treatment, did more. To Ponscarme (pupil of Oudiné) is chiefly due the idea of rendering *mat* the ground as well as the subject on the medal, the suppression of the raised rim, and the abandonment of the typographic lettering hitherto in vogue, together with the mechanical regularity of its arrangement. Degeorge, with his semi-pictorial treatment, was followed by Daniel Dupuis, whose delicate and playful fancy, almost entirely pictorial, makes us forget alike the material and the die. J. C. Chaplain is unsurpassed as a modeller of noble heads, including those of four presidents of the French Republic—Macmahon, Casimir-Perier, Faure, and Loubet—and his allegorical designs are finely imagined and admirably worked out (see Plate); but L. Oscar Roty (pupil of Ponscarme) is at the head of the whole modern school, not only by virtue of absolute mastery of the technique of his art, but also of his originality of arrangement, of the poetic charm of his symbolism and his allegories, the delicate fancy, the exquisite touch, the chasteness and purity of taste—wedding a modern sentiment to an obvious feeling for the Greek. Though expressly less virile than Chaplain, Roty is never effeminate. To Roty belongs the credit of having first revived the form of the *plaquette,* or rectangular medal, which had been abandoned and forgotten along with many other traditions of the Renaissance (see Plate). Others there are of great talent who do not occupy so high a position. Alphée Dubois, Lagrange, and Borrel must be mentioned among those who are understood to engrave their own dies. Followers are to be found in Mouchon, Lechevrel, Vernon, Henri Dubois, Patey,

[1] The method of preparing the dies, &c., is the same for medals as for coins, save that for larger and heavier work more strokes are required, as in the case of L. Coudray's popular "Orphée"—rather a sculpture-relief than a medal. The dies are capable of a great yield before becoming quite worn out; it is said that no fewer than three million copies were struck of Professor J. Tautenhayn's Austrian jubilee medal of the Emperor Francis Joseph. In France, Thonelier's perfected machine, substituting the lever for the screw, has been in use for coins since 1844; but for the striking of medals the same old-fashioned screw-press is retained which had till then been employed both for coins and medals since the time of Louis XIV. In its present form the machine consists of an iron or bronze frame, of which the upper part is fitted with a hollow screw wherein works an inner screw. This screw, moved by steam or electricity, drives the dies, set in iron collars, so that they strike the blank placed between them. So docile is this powerful machine in the hands of the operator, that it can deliver a strong blow to produce a high relief, or a delicate touch to add the finest finish. In the Paris mint, where the striking of the beautiful modern medals of France is an important undertaking, yielding considerable profits, fourteen screw-presses are at work, and the biggest and most recent machine can strike large medals with comparative ease and rapidity. A hydraulic press of nearly two million pounds pressure is utilized for testing the dies.

Bottée (see Plate)—all sterling artists if not themselves innovators. Medallists of more striking originality but less finish, and of far less elegance, are Michel Cazin, Levillain (who loves as much as Bandinelli to make over-display of his knowledge of muscular anatomy), Charpentier, and their school, who aim at a manner which makes less demand of highly educated artistry such as that of Roty or of Chaplain. It is learned and accomplished in its way, but lumpy in its result; breadth is gained, but refinement and distinction are in a great measure lost. It may be added—in order to give some idea of the industry of the modern medallist, and the encouragement accorded to him—that between 1879 and 1900 M. Roty executed more than 150 pieces, each having an obverse and a reverse.

Austria.—The two leading medallists of the Austrian school are Josef Tautenhayn (see Plate) and Anton Scharff, both highly accomplished, yet neither displaying the highest qualities of taste, ability, and "keeping," which distinguishes the French masters. About 330 pieces have come from the hand of Anton Scharff. Stefan Schwartz, Franz Pawlik, Staniek, Marschall, and J. Tautenhayn, junior, are the only other artists who have risen to eminence.

Germany.—A characteristically florid style is here cultivated, such as lends itself to the elaborate treatment of costume, armorial bearings, and the like; but delicacy, distinction, and the highest excellence in modelling and draughtmanship—qualities which should accompany even the most vigorous or elaborate designs—are lacking in a great degree. Profs. Hildebrand and Kowarzik have wrought some of the most artistic works there produced.

Belgium.—Although sculpture so greatly flourishes in Belgium, medal work shows little promise of rivalling that of France. The influence of the three brothers Wiener (Jacques, Léopold, and Charles)—good medallists of the old school—has not yet been shaken off. The remarkable architectural series by the first named, and the coinage of the second, have little affinity with the spirit of the modern medal. Lemaire has perhaps done as well as any, followed by Paul Dubois, J. Dillens (a follower of the French), G. Devreese, and Vinçotte (see Plate)—whose *plaquette* for the Brussels Exhibition award (1887) is original, but more admirable in design than in finish.

Holland.—In Holland not very much has been done. Patriotism has called forth many medals of the young queen, and the best of them are doubtless those of Bart van Hove and Wortman. Baars is a more virile artist, who follows Chaplain at a distance. Wienecke is interesting for the sake of his early Netherlandic manner; the incongruity is not unpleasant.

Switzerland.—The medal is also popular in Switzerland. Here Bovy is the leader of the French tradition, and Hans Frei of a more national sentiment. The last-named, however, is more remarkable as a revivalist than as an original artist.

Great Britain.—In England only two medallists of repute can be counted who practically confine themselves to their art—G. W. de Saulles, of the Royal Mint, best known by the Diamond Jubilee medal of Queen Victoria and by his medal of Sir Gabriel Stokes, and Frank Bowcher (see Plate) by that of Thomas Huxley. These artists both cut their own dies when necessary. Emil Fuchs, working in England in the manner of the French medallists, but with greater freedom than is the wont of the older school, has produced several examples of the art: the medals commemorative of the South African war and of Queen Victoria (two versions), all of 1900; and many portrait medals and plaquettes of small size have come from the same hand. Besides these, the leading English sculptors have produced medals—Lord Leighton, P.R.A., Sir Edward Poynter, P.R.A., Hamo Thornycroft, R.A., T. Brock, R.A., Onslow Ford, R.A., G. Frampton, A.R.A., and Goscombe John, A.R.A.; but, practising more continually in sculpture, they do not claim rank as medallists, nor have they sought to acquire that class of dexterity which constant habit alone can give. Alphonse Legros, who has cast a certain number of portrait medals, is usually included in the French school.

United States.—Among American medallists Augustus St Gaudens (see Plate) is perhaps the most prominent; but he is not, strictly speaking, a medallist, but a sculptor who can model in the flat.

Nuneaton, a market town in the Nuneaton parliamentary division of Warwickshire, England, 22 miles east by north of Birmingham by rail. Stone is quarried in the neighbourhood, in which are also coal and ironstone mines. Recent buildings include public offices (1897) and free library (1899). The making of drain-pipes, tiles, and blue and red bricks is a considerable industry, besides those for which the town is more generally known. Population of parish (an urban district) (1891), 11,580: of the extended urban district (Nuneaton and Chilvers Coton) (1891), 15,297; (1901), 24,995.

Nupe. See NIGERIA.

Nuremberg, a town of Bavaria, Germany, district of Middle Franconia, on the Pegnitz, a tributary of the Main, and 124 miles by rail north by west of Munich. The town has lost a good deal of its mediæval character through the demolition of large portions of its walls, though considerable sections of them still remain. In 1898 and 1899 more than a dozen outlying communes were incorporated, with a total population of 33,448, namely, Sündersbühl (3871), Erlenstegen (1031), Giebitzenhof-Lichtenhof (5077), Glaishammer (5378), Grossreuth (two communes of 711 and 1363), Kleinreuth (1053), Höfen (1944), Mögeldorf (2414), Schniegling (2263), Schoppershof (2271), Schweinau (2640), Thon (403), and Wetzendorf (3029), thus extending the area of the town from 2805 to 13,700 acres. Amongst modern structures are the new building (1894–96) for the Bavarian Industrial Museum, the new wing (1884–89) of the town hall, Christ's Church in the suburb of Steinbühl, the post office in the Sebald quarter, the market hall in the Rag (*Trödel*) Market, the massive bridge connecting the suburb of St Johannis with the suburb of Gostenhof, the industrial arts school, the monument to Behaim (1890), and three artistic fountains. The Walpurgis chapel, a portion of the Burggravian castle, destroyed in 1420, was restored in 1892. The Germanic National Museum has developed into one of the largest and most important institutions of its kind in all Germany. The most notable of its treasures embrace prehistoric remains, sculptured monuments of the 15th and 16th centuries, a picture gallery containing especially German works of the 15th and 16th centuries, and collections of domestic furniture, dress, plaster casts of sculptured monuments and tombs, instruments of torture, glass and pottery, weapons and armour, musical instruments, scientific and mathematical instruments, industrial models, and so forth. The municipal library now contains 70,000 volumes and 2000 MSS. Amongst the educational and charitable foundations should be mentioned the natural history museum, the Rothermundt collection of antiquities and plaster casts, the municipal archives, a technical, an industrial art, and a commercial school, and blind and deaf and dumb asylums. The ancient linden tree in the castle courtyard died in 1893. There are two parks, the town park and Rosenau. The industries of greatest importance are those concerned with the production of goldsmiths' work (1100 operatives), machinery (2500 operatives), pencils, colours, and brushes (3200), lithography, &c. (1500), mathematical and scientific instruments (1000), and toys (700). Many industrial establishments have moved outside the city, so as to get the advantage of the electric generating works on the river Pegnitz below the town. In 1882, and again in 1896, a large industrial and art exhibition was held at Nuremberg, and in 1885 an international metal exhibition. Nuremberg still remains the chief hop market in the middle of Europe, and also has a large wool market. Population (1890), 142,590; (1900), 261,022.

Nursing.—The development of sick-nursing, which has brought into existence a large, highly-skilled, and organized profession, is one of the most notable features of modern social life. To deal adequately with the subject in all its aspects would require a treatise, which still remains to be written, though Sir Henry Burdett's various publications go far to supply the want. Only the more salient points can be touched upon here.

History.

The evolution of the sick-nurse is mainly due to three very diverse influences—religion, war, and science—to name them in chronological order. It was religion which first induced ladies, in the earlier centuries of Christianity, to take up the care of the sick as a charitable duty distinct from domestic nursing, which is one of the natural functions of women in all ages and among all races. The earliest forerunner of the great sisterhood of nurses of whom we have any record was Fabiola, a patrician Roman lady, who in A.D. 380 founded a hospital in Rome with a convalescent home attached, and devoted herself and her fortune to the care of the sick poor. She had a rival in the Empress Flaccilla, the pious consort of Theodosius I. (A.D. 379–395), who also personally visited the hospitals and attended on the sick. Some sort of hospital, or at least dispensary, system, with medical attendance by public officers, can be traced to a far earlier date in Egypt, India, Greece, and Rome; but that is a different question. Organized nursing does not appear to have formed any part of medical treatment, except in so far as the deacons of the Church attended on the poor, until the 4th century of the Christian era. After that date the employment of women for this purpose must have developed rapidly, for in the reign of Honorius (A.D. 395–423) six hundred women were engaged in the hospitals of Alexandria. These institutions were managed by the clergy, and throughout the Dark and Middle Ages the hospital and nursing systems were connected with religious bodies. Nurses were provided by the male and female monastic orders, an arrangement which still continues in most Roman Catholic countries, though it is gradually being abandoned through the increasing demands of medical science, which have led the hospitals to establish training schools of their own. The names of the oldest foundations which still survive, such as the Hôtel Dieu in Paris, St Thomas's and St Bartholomew's in London, the order of St Augustine, and (in the form of a modern revival) that of St John of Jerusalem, sufficiently indicate the original religious connexion. The order of St Vincent de Paul, founded in 1633 for the express purpose, is still the largest nursing organization in the world. Even in Protestant England, where purely secular training schools have reached their highest development, the generic title of Sister, alike prized by its holders and honoured by the public, remains the popular and professional synonym for head nurse, and perpetuates the old association. Nursing, as a popular or fashionable occupation, is not a modern invention. Sir Henry Burdett quotes an order, dated 30th May 1578, directing the Master and the Prior of the Hôtel Dieu "not to receive henceforth any novices without speaking of it to the company, because there are an excessive number of nuns and novices, who cause great expense to the said Hôtel Dieu." He infers that they suffered from a plethora of nurses, or, as one might say, "a plague of women." In Protestant countries a secular nursing system came in with the Reformation. The staff appointed for St Bartholomew's, on its re-establishment by Henry VIII. in 1544, consisted of a matron and twelve nurses, who were engaged in domestic occupations when off duty. Thus nursing became a menial office and an inferior means of livelihood, adopted by women of the lower orders without any training or special skill; and so it continued down to the middle of the 19th century, when a new movement began which was destined to revolutionize the status of the nurse.

Its distinctive feature was the systematic training of nurses for their vocation. Previously a certain amount of regular instruction had no doubt been given here and there by individual physicians and surgeons; lectures to nurses were delivered in the New York Hospital as early as 1790. But these were isolated efforts. Such skill as nurses possessed was picked up in the wards. No qualifications were required, nor indeed would they have been forthcoming, so low had the calling sunk in public estimation. The credit of inaugurating the new order of things belongs to Germany, and here again the religious influence came into play. The beginning of the modern system dates from the foundation of the institute for training deaconesses at Kaiserswerth by Pastor Fliedner in 1836. It is true that State training schools for male nurses had previously existed in Prussia, the oldest having been founded at Magdeburg in 1799; but the employment of men in hospital wards is a feature of the German system which has not been copied by other advanced countries, and seems to be in process of abandonment in Germany. It is a heritage from the Middle Ages, when the Knights Hospitallers undertook for men the duties discharged in female institutions by the nuns. The male schools therefore stand somewhat apart, though they mark a stage in the evolution of nursing as the earliest regular training establishments. The Kaiserswerth Institute, on the contrary, had a far-reaching and lasting influence, and may fairly claim to be the mother of the modern system. England, in particular, owes much to it, for there Florence Nightingale acquired the practical knowledge which enabled her afterwards to turn her remarkable gift of organization to such brilliant account. The example of Kaiserswerth was soon followed, and not in Germany only. In 1838 the Society of Friends founded a nursing organization in Philadelphia, and in 1840 Mrs Fry, a member of the same community, started the Institution of Nursing Sisters in London. In 1857 the nurses attached to it numbered ninety. They received their practical training at Guy's and St Thomas's Hospitals. On the Continent institutes for nursing deaconesses were founded at Strasburg, Utrecht, Berlin, Breslau, Königsberg, and Carlsruhe between 1842 and 1851. In London a Church of England training institution (St John's House) was opened in 1848. There were three classes—(1) sisters, (2) probationers, (3) nurses. The nursing at King's College Hospital was for many years undertaken by this society, whose members were trained at the hospital.

The training system, thus inaugurated on a semi-religious basis, received a new impetus from the Crimean war, which was further emphasized by the Civil War in America and the subsequent great conflicts on the Continent. There is, of course, a natural connexion between nursing and war, which provides a large supply of surgical cases in need of ministration; and the Crusades, in particular, had raised the care of wounded warriors and toil-worn pilgrims to the level of a pious duty. But the Crimean war had an unprecedented effect on public opinion. This was due to several causes. One of the most important was the publicity given by the press, and notably by *The Times* newspaper, to the details of the campaign. It brought home to every one the realities of warfare and the enormous loss of life through sickness, besides disclosing grossly defective organization. The despatch of Miss Nightingale, with a staff of trained nurses, to superintend the administration of the military hospitals was the direct result, and it formed a new departure which riveted the eyes of the civilized world. The work undertaken and accomplished by this lady was far more important than the mere nursing of sick and wounded soldiers. She had grasped the principles of hygiene, which were then beginning to be understood, and she applied them to the reform of the hospital administration; but the sentimental aspect of the experiment was that which chiefly arrested popular attention. The picture of the delicate lady smoothing the sick soldier's pillow did much to elevate the hospital nurse's calling in public estimation, and in a measure revived the fervour of earlier centuries, though with less lofty motives. The same stimulus was felt in Russia, where ladies also devoted their services to the military hospitals. It would be outside the scope of this article to trace the effect of the movement so begun on the care of the sick and wounded in war. That belongs more properly to the subject of war. It must suffice to say that, while on the popular side the Crimea led to the Red Cross organization, on the official side its lessons have largely been forgotten, especially in relation to the prevention of disease among armies in the field. In civil life it had a marked effect in stimulating the training movement and raising the status of the nurse; but substantial results were only obtained by degrees. It was not until 1860 that the modern hospital school system was definitely inaugurated by the opening of the Nightingale Fund School at St Thomas's Hospital, founded with the money subscribed by the British public in recognition of Miss Nightingale's national services, and worked on principles laid down by her. In the meantime several nursing societies, in addition to those previously mentioned, had been founded in England and elsewhere. Among them the Baden Ladies' Society, founded in 1859 by the Grand Duchess Luise, deserves mention. In the same year the first district nurse began work in Liverpool; and in 1865 the reform of the much-neglected workhouse nursing was inaugurated by Miss Agnes Jones and twelve nurses from St Thomas's, who took up the work in Liverpool. At this time England took a decided lead, which she has never lost. Other countries gradually followed. In Germany the Albert Nursing Society was founded by Queen Carola of Saxony, and the Alice Society by the Grand Duchess Alice of Hesse, both in 1867. In France, where the nursing was comparatively well performed by the religious orders, no change was made until 1877, when a training school was opened in Paris by the municipality, and two others by the Assistance Publique, in connexion with the Salpêtrière and Bicêtre Hospitals. In the United States schools were opened in New York, New Haven, and Boston in 1873. The British colonies, Austria, and other European countries followed some years later.

It remained for the third influence to complete the work begun and to develop systematic nursing to its present dimensions. Since 1880 the increasing demands of medical knowledge have well-nigh revolutionized the craft in the home, the hospital, and the workhouse. A large part of the change may be summed up in the words "scientific cleanliness." It enters into all kinds of nursing, general and special; it is the very life of modern surgery, and it is virtually synonymous with hygiene or sanitation. And scientific cleanliness is quite incompatible with the old style of nurse. There are also other improvements in knowledge, which on the one hand emphasize the importance of good nursing and on the other raise the standard of education, intelligence, skill, and trustworthiness required for its attainment. The outcome of all this has been to raise the dignity of the calling, to induce persons of a superior class to adopt it in increasing numbers, to enlarge the demand for their services, and to multiply the means of educating them. These changes have taken effect in all countries, though in unequal degree. Information is defective with regard to the present state of things in some of them, but full details are available for Great Britain, and some indication of the systems prevailing elsewhere can be given.

Training and organization.

Nursing does not appear to be regulated by law in any country; its organization is voluntary, and even in State or municipal institutions is dependent on the direction of the administration. In Great Britain nearly all the general and special hospitals and many of the poor-law infirmaries offer systematic professional training to nurses. According to Burdett's annual hand-book (*The Nursing Profession*) for 1902, there are 137 such training schools, having over 100 beds. They are thus distributed—England 114, Scotland 13, Ireland 10. Of those in England, 37 are in London and 77 in provincial towns. In addition to these 114 major schools there are about 350 minor ones, consisting of small general hospitals and dispensaries, special hospitals of various kinds, and other institutions. The provisions differ considerably in detail, but in the larger schools the system is uniform in all important respects. Candidates must be between 23 (sometimes 21 or 22) and 35 years of age, and must produce satisfactory evidence of character, education, health, and physique; after a personal interview and one, two, or three months' trial they are admitted for three years' training. During this period they receive regular instruction in theoretical and practical knowledge, and have to pass periodical examinations. At the end of it they are granted certificates and may serve as staff nurses. They pay no premium, and generally receive a salary of £8 to £12 in the first year, rising annually to £30 or £35 as staff nurse, and subsequently to £40 or £50 as sister or head nurse. They live in a home attached to the institution, under a matron, and in the most modern establishments each nurse has a separate bedroom, with common dining and recreation rooms. In addition to these ordinary probationers, many of the large general hospitals take special pupils for short periods of instruction (three or six months), for which they pay a premium (usually 13 guineas a quarter). Their duties in the wards are the same as those of the other probationers. Private nursing staffs are attached to several of the hospitals; they are recruited from the staff nurses and probationers on completion of their course, and supply nurses to private patients. In the special hospitals the training is shorter, being for one or two years. There seems to be a constant tendency to increase the requirements. At St Bartholomew's, St George's, the London Hospital, St Thomas's, and others, probationers must enter for four years, and at St Bartholomew's they have to pass an entrance examination in elementary anatomy, physiology, and other subjects. At all the more important schools the number of applications is many times greater than the vacancies.

In Great Britain trained and certificated nurses generally belong to a society or association. Including the private staffs attached to hospitals, there are over 200 of these bodies; about thirty of them are private concerns, the rest are managed by committees. The most noteworthy of the associations is Queen Victoria's Jubilee Institute for Nurses. It was founded in 1887 with the object of providing skilled nursing for the sick poor in their own homes, and has now 479 branches thus distributed throughout the kingdom—England 236, Wales 62, Scotland 128, Ireland 53. A great many of the provincial nursing associations are affiliated to it. The number of nurses supported by each branch varies from one or two in country parishes to as many as 51 (Manchester). In London there are 20 branches and 110 nurses. The qualifications for a Queen's nurse are as follows: (1) training at an approved general hospital or infirmary for two years; (2) approved training in district nursing for not less than six months, including the nursing of mothers and infants after child-birth; (3) nurses in country districts must in addition have had at least three months' approved training in midwifery. Candidates possessing the first qualification are received on trial for one month, after which they complete their six months' training for the second qualification, at the same time entering into an agreement to serve as district nurse for one or two years at the end of the six months. The salary during training is £12, 10s., and afterwards £30 to £35 a year, with board, lodging, laundry, and uniform. With regard to the earnings of nurses in general, the salaries paid in hospitals have already been mentioned; for private work the scales in force at different institutions vary considerably, according to the other advantages and benefits provided. At some the nurses receive all their own earnings, minus a percentage deducted for the maintenance of the institute; at others they are paid a fixed salary, as a rule from £25 to £30 a year, plus a varying percentage on their earnings or a periodical bonus according to length of service. This is perhaps the commonest system, but some of the best nursing homes give a somewhat higher fixed salary without any percentage. In all these cases the nurses receive in addition board and lodging, laundry, and uniform, or an equivalent allowance. For special cases — infectious, massage, mental, and maternity—nurses on a fixed salary usually receive extra pay. The fees commonly charged by high-class institutions for the services of a trained and certificated nurse are—for ordinary cases £2, 2s. a week, for special cases £2, 12s. 6d. or £3, 3s. a week; but many provincial associations supply nurses for £1, 1s. a week and upwards. The discrepancy between the fees paid by patients and the salaries received by nurses, especially in London, has occasionally excited unfavourable comment, but it is to be remembered that the nurses are maintained when out of work or ill, and have other advantages; many institutions either provide pensions or assist the members of their staff to join the Royal National Pension Fund. This is the most important of several benefit societies now maintained by and for the profession. It offers insurance against sickness and provision for old age. Individual nurses or institutions can belong to it; in many cases a joint system is adopted, the premiums being paid partly by the persons to be benefited, and partly by the societies to which they belong.

To complete this account of the organization in Great Britain a few details with regard to special nursing are added.

Fever.—Regular training on the same plan as in general hospitals is provided in London at the fever hospitals of the Metropolitan Asylums Board (12 in number, with from 360 to 760 beds each), and at a considerable number of provincial institutions.

Insanity.—The Medico-Psychological Association of Great Britain and Ireland holds examinations and grants certificates in mental nursing; candidates must undergo two years' regular training, with instruction by lectures, &c., which may be obtained in a large number of public asylums by arrangement with the Association; one county asylum (Northampton) gives its own certificates after a three years' course.

District Nursing.—In addition to the Queen's nurses, of whom details have been given above, many local associations train their own nurses for this work. *Cottage* and *village* nursing are varieties of the same department; the former is organized on the benefit system, and aims at supplying domestic help and sick-nursing combined in rural districts for an annual subscription of from 2s. to 10s., according to the class in life of the family, and a weekly fee of the same amount during attendance.

Monthly Nursing and Midwifery.—Systematic instruction in these subjects is given at some fifty lying-in institutions in different parts of the kingdom. The usual course for nursing is not less than three months, and for midwifery not less than six months; a premium is required of 12 or 13 guineas for three months, and 25 guineas for six months.

Male Nursing.—Two or three associations in London supply male nurses (fees 2 to 4 guineas a week), but there appears to be only one institution, apart from the military and naval services, at which they are systematically trained—namely, the National Hospital for the Paralysed and Epileptic.

Massage is taught regularly at the hospital just named, and at a few other special hospitals. Competent operators are supplied by the Incorporated Society of Trained Masseuses and, to some extent, by other nursing associations; but this branch of the profession is still imperfectly organized (see MASSAGE).

Children.—A large number of children's hospitals throughout the country give regular training in the nursing of children; they take probationers at a somewhat earlier age than the general schools; the course is usually shorter (one or two years), and the salaries slightly lower.

The State offers employment to nurses in the naval and military hospitals and in the Indian Government service; the salaries are somewhat higher than in civil life, and a pension is attached.

A movement for the legal registration of trained nurses has been started in Great Britain, but the question is full of difficulties. A similar proposal to regulate the position of midwives, who may be said to stand between the medical and nursing professions, was embodied in a Bill which, after being before Parliament for several sessions, was at last carried and passed as law in 1902.

In the more important *British colonies* — Australasia, Canada, and South Africa—there are now a considerable number of hospital schools and other institutions formed and conducted on the English model. Salaries and fees are very much the same in Australia; in Canada and South Africa they are higher.

In the *United States* a similar system prevails in New York, Boston, Brooklyn, Chicago, Baltimore, Philadelphia, New Haven, and many other large towns. The period of training is either two or three years. At the Johns Hopkins School at Baltimore twelve scholarships of $100 and $120 each are awarded annually; graduate nurses are paid $360 (£72) a year. Salaries are altogether much higher in the United States. At the Boston City Hospital graduate nurses receive $420 (£84) a year, and at the Indianapolis City Hospital those on private duty are paid $72 a month, which is equivalent to £172 a year, with board, lodging, laundry, and uniform. This may be taken to indicate the possible earnings of trained nurses working independently, as they usually do in America. The system of belonging to a society and being paid a salary is much less in vogue there than in Great Britain. The fees charged for trained nurses run from $12 to $25 a week, and even more for special cases. Male nurses are trained at the New York City Hospital and at the Grace Hospital, Detroit. In the American schools more attention is paid to the preparation of nurses for private work than in the British (Burdett), and a directory or registry of them is kept in most large towns.

In *Germany*, their original home, both training schools and societies have multiplied and developed. In the year 1887 there were 14,585 trained nurses, of whom 1614 were men. Their organization was as follows:—

	Female.	Male.
Attached to religious institutions . .	10,544	584
Attached to lay institutions . . .	1,465	554
Private	962	476

Nursing by religious orders has since been largely replaced by hospital schools. The period of training appears to be considerably shorter than in Great Britain and America. At many schools it is only one year: the first three months are devoted to house-work, the second three months to theory, and the last six months to practical instruction. Members of the Albert Society of Saxony, however, spend two years in the wards at Dresden, and a third at Leipzig, attending lectures and demonstrations. They are sent out to nurse rich and poor alike, and their pay is very small. Most of the German institutes have pension funds.

In *France* a great deal of the nursing has remained in the hands of religious orders, but there too the hospital school system, inaugurated in 1877, has grown. The schools managed by the Assistance Publique in Paris give a very thorough course of instruction. Lay societies exist in several of the large towns, and provide trained nurses for private cases.

In *Russia* nursing is mainly in the hands of the Red Cross Society, whose members are, however, trained in the hospital schools.

In *Italy*, *Spain*, *Portugal*, and *Belgium* scientific nursing is in a backward state. The old religious system still prevails to a large extent, and, though some of the orders do their work with great devotion, the standard of knowledge and skill is not up to modern requirements. In Spain and Portugal monks still nurse in the male and nuns in the female wards of hospitals, as in the Middle Ages. At San Remo and Rome institutions have been established for providing English trained nurses to private cases.

Austria is also in a very backward state, in spite of the fame of the Vienna cliniques. The Red Cross Society provides a certain amount of trained nursing, and next to it the best-organized work is done by religious orders; but many of the hospitals appear to be still as neglected as were the English ones in 1850. The Brothers of Mercy have charge of most of the men's hospitals, and also carry on a remarkable system of district nursing.

In *Holland* and the *Scandinavian countries* the organization is more modern and fairly adequate.

Taken altogether, the continent of Europe is far behind Great Britain and the United States with regard to sick-nursing both in the home and the hospital. The calling, as such, has not attained the same dignity, and, with some exceptions, is pursued by an inferior class of persons, who are both less capable and less well instructed. But the pressure of modern requirements, particularly in surgery, is being felt even in the most backward quarters, and is compelling gradual improvement.

For full details on this large subject the reader is referred to the numerous text-books and other technical authorities. Only a few general observations can be made here. Many candidates approach the calling with a very imperfect appreciation of its exacting character. The work is not easy or to be taken up lightly. It demands physical strength, sound health, scrupulous cleanliness, good temper, self-control, intelligence, and a strong sense of duty. It embraces many duties—some of them menial and disagreeable—besides the purely medical and surgical functions. This is especially the case with district nursing, which is the highest and most exacting branch of the profession, because it imposes the greatest responsibility with the fewest resources and demands the most varied qualifications, while affording none of the attractions incidental to hospital work or private nursing among the rich. A district nurse should be able to do everything for the patient—which often means mother and child—and for the house: she should be able to cook, do house-work, and manage children, in addition to carrying out the technical details of nursing and applying the principles of hygiene under the most difficult conditions. This may be regarded as the ideal. It is comparatively easy to fulfil routine duties, when every means is at hand and the standing conditions are the most favourable possible; when ventilation, warmth, light, and cleanliness are all provided of the best, and when assistance can be summoned in a moment. To be thrown on your own resources and make the best of adverse conditions is an entirely different matter; it requires a thorough knowledge not of routine, but of principles. It is impossible, therefore, for nurses to be over-educated in the fullest sense of the word; but it is possible for them to be inappropriately educated, and perhaps that is sometimes the case now. Some experienced authorities believe that the third year of hospital training, however valuable or necessary it may be for the hospital career, is no advantage, but rather the contrary, for the general business of nursing; and that during it probationers carry technical knowledge to a point which tends to make them self-opinionated and unfit for the ordinary duties of the sick-room. This opinion is to a certain extent corroborated by not infrequent signs of revolt on the part of the public against the oppressive "airs" of the highly-educated modern nurse, and by the experience of general practitioners, on whom she considers herself competent to sit in judgment. Probably the meaning of it all is that nursing has been elaborated to the inevitable point of specialization, and that a somewhat different preparation is needed for different branches of the art.

Duties and qualifications.

Allusion has been made above to the subject of male nursing. It hardly finds a place in the British civil system, and has been condemned for hospitals in Germany, where it is at its best, by so eminent an authority as Professor Virchow. In the South African campaign it was even suggested that female nurses should replace orderlies at the front. The only valid reason for preferring women to attend men rather than members of their own sex is the difficulty of obtaining a supply of equally well qualified and satisfactory male nurses. But this difficulty need not be permanent, and the assumption is much to be deprecated. It is, indeed, most desirable that men should be nursed by men. The advantages are many and real. For one thing, women do not possess the physical strength which is often required. They cannot lift a heavy man, and ought not to be asked to do it. Their inability to move patients who cannot move themselves often explains the occurrence of bed-sores, which might otherwise have been avoided. Nor can they cope with delirious male patients, who sometimes escape and injure or destroy themselves. Then it is excessively irksome to a sensitive man to be attended by women for various necessary offices. In order to avoid it he will endeavour to do without assistance, and seriously prejudice his chances of recovery. There is no doubt that when men are good nurses they are quite unsurpassed; they possess every qualification for the work, and in a hospital their dress, which raises no dust and makes no sound, is greatly preferable. The writer was much struck by the efficiency of the male nurses in the cholera hospitals at Hamburg in 1892. Strong, quick, deft and clean, skirtless, and with sleeves rolled up, they moved about their work and handled the patients, many of whom were collapsed, as women could not possibly do. The restoration of male nurses on modern lines may be impossible for lack of the right material, but any movement in that direction is to be welcomed. So far as the preference for women is sentimental, it deserves nothing but condemnation. Nursing is not a sentimental, but a serious business. (See also HOSPITALS.)

Nutrition. See PHYSIOLOGY.

Nuwara Eliya, the sanatorium of Ceylon, is a town of about 5000 people, with 1000 additional visitors during the "season." It is situated 6240 feet above sea-level, with the highest mountain in the island, Pedrotallagalla, towering over the plain for 2056 feet more, offering a morning climb to the top, 8296 feet above the sea. Nuwara Eliya is reached from Colombo by rail, eight hours to Nanuoya, and thence less than one hour by coach (to be replaced by light railway). The Hakgalla Botanical Gardens are within an easy drive, and other attractions for visitors are provided. The climate is delightfully dry and cool during the "season" (1st February to 31st May). The average shade temperature for the year is 58°; the rainfall, 95 inches.

Nyasa, the third in size of the great lakes of Central Africa, occupying the southern end of the great rift valley system which traverses the eastern half of the equatorial region from north to south. Extending from 9° 29′ to 14° 25′ S., or through nearly 5° of latitude, the lake measures along its major axis, which is slightly inclined to the west of north, exactly 350 miles, while the greatest breadth, which occurs near the middle of its length, between 11° 30′ and 12° 20′ S., is 45 miles. In the northern and southern thirds of the length the breadth varies generally from 20 to 30 miles, and the total area may be estimated at 11,000 square miles. The lake lies somewhat over 1500 feet above the sea. The sides of the valley in which Nyasa lies, which are somewhat irregular towards its southern end, take a decided character of fault scarps in the northern third, and are continued as such beyond the northern extremity. Apart from the recent alluvium on the immediate shores, the lake lies almost entirely in granite and gneiss formations, broken, however, by a band of horizontally-bedded sandstones, which cuts the axis of the lake in about 10° 30′ S., the flat-topped, terraced form of the latter contrasting strangely with the jagged or rounded outlines of the former. Near the margin, overlying the sandstones, there are beds of limestone with remains of recent molluscs, pointing, like the raised beaches which occur elsewhere, to an upward movement of the coasts. The depth of the lake seems to vary in accordance with the steepness of the shores, increasing from south to north. The greater part of the northern half shows depths of over 200 fathoms, while a maximum of 430 fathoms was obtained by Mr J. E. Moore in 1899, off the high western coast in about 11° 40′ S. A more complete series of soundings, however, since made by Lieut. Rhoades, and published in the *Geographical Journal* in 1902, gives a maximum of 386 fathoms off the same coast in 11° 10′ S.

At the north-western end is a plain of great fertility, traversed by the Kivira, Songwe, and other streams, rising either among the volcanic masses to the north or on the western plateau. Just north of 10°, on the delta of the Rukuru, is the British station of Karonga, the northern port of call for the lake steamers, though with but an open roadstead. Southwards the plain narrows, and in about 10½° S. the sandstone scarp of Mount Waller rises sheer above the indentation of Florence Bay, the high western plateaux continuing to fall steeply to the water in wooded cliffs for more than 80 miles. In this stretch occur the land-locked bays of Ruarwe (11° 5′ S.) and Nkata (11° 36′ S.), and the mouth of the Rukuru (10° 43′ S.), which drains the plateau from south to north. At Cape Chirombo (11° 40′ S.) the coast bends to the west, and soon the plateau escarpments recede, and are separated from the lake along its southern half by an undulating plain of varying width. In 11° 56′ S. is the British station of Bandawe, and in 12° 55′ that of Kota Kota, on a lake-like inlet, forming a sheltered harbour. A little north of the latter the Bua river, coming from a remote source on the upper plateau, enters by a projecting delta. At Domira Bay, in 13° 35′, the coast turns suddenly east, contracting the lake to a comparatively narrow neck, beyond which it runs southwards into two bays separated by a granitoid peninsula, off which lie several small rocky islands. On this peninsula was placed the mission station of Livingstonia, the first to be established on the shores of Nyasa. From the extremity of the eastern bay the Shire makes its exit to the Zambezi. On the eastern side the plateau escarpments keep generally close to the lake, leaving few plains of any extent along its shores. The crest of the eastern watershed runs generally parallel to the coast, which it approaches in places within 20 miles. From the north point to 10° 30′ S. the coast is formed by the unbroken wall of the Livingstone or Kinga range, rising where highest (9° 40′ S.) 6000 feet above the water. On this coast, on a projecting spit of land, is the German station of Langenburg, some 10 miles from the northern extremity. In 10° 30′ the plateau is broken by the valley of the Ruhuhu, the only important stream which enters the lake from the east. The formation is here sandstone, corresponding to that of Mount Waller on the opposite shore. Just north of the Ruhuhu is the German station of Wiedhafen, on an excellent harbour, formerly Amelia Bay. South of the Ruhuhu the wall of mountains recedes somewhat, and the remainder of the eastern shore shows a variation between rocky cliffs, marshy plains of restricted area, and groups of low hills. In 11° 16′ is the deep inlet of Mbampa Bay, offering a sheltered anchorage. South of it the coast forms a wide semicircular bay, generally rock-bound, and ending south in Malo Point (12° 10′ S.), off which are the largest islands the lake possesses, Likoma and Chisamulu, the former measuring about 4 miles by 3. In the southern half the coast is highest in about 13° 10′ S., where the Mapangi hills rise to 3000 feet. Nyasa, reached in 1858 both by Dr Livingstone (from the south) and by the German traveller Roscher (from the east), was explored by the former to about 11°, and to its northern end by Young in 1876. From this date onwards it has been the scene of much civilizing work on the part of British (principally Scottish) missionaries, traders, and Government officials, and, in more recent years, of Germans also. In the political partition of Africa its shores have been divided between Great Britain, Portugal, and Germany, Great Britain holding (within the British Central Africa Protectorate) all the west coast south of the Songwe and the southern extremity of the east coast (south of 13½° S.); Portugal the rest of the east coast south of 11½° S.; and Germany the remainder. A considerable number of British steamers, including two or three gunboats, have been launched on Nyasa, which forms an important link in the water-route from the Zambezi mouth to the heart of the continent. Germany also has a gunboat on the lake. The first detailed survey of its shores was executed by Mr James Stewart (1878–83), but this has been superseded by more recent work, especially that of Lieutenants Rhoades and Phillips. (See *Proc. R.G.S.*, 1883, p. 689; *Geogr. Journal*, xii. p. 580. Also MOORE, *ibid.* x. p. 289). (E. HE.)

Nye, Edgar Wilson (1850–1896), American humorist, was born at Shirley, Me., on 25th August 1850, and after his schoolboy days went to study law in Wyoming, being there called to the bar in 1876. He soon began to contribute humorous articles to the press under the pseudonym of "Bill Nye," and obtained so much success that he devoted himself to writing and lecturing in his own humorous vein. His principal volumes were *Bill Nye and the Boomerang* (1881), *The Forty Liars* (1883), *Bill Nye's Blossom Rock* (1885), and *Remarks* (1886). He died at Asheville, N.C., on 22nd February 1896.

Nykjöbing, a seaport town of Denmark, county of Maribo, on the west shore of the island of Falster, 91 miles south-south-west of Copenhagen by rail. Its church contains a genealogical tree of the Mecklenburg ducal family, with portraits, dating from 1627 or earlier. Here is the house occupied by Peter the Great of Russia in 1716, restored in 1898. The harbour was in 1899 entered by 1184 vessels of 74,381 tons, and cleared by 1199 vessels of 74,217 tons. Exports, bacon and butter; import, coal. Population (1880), 4560; (1890), 6087; (1901), 7345. The area was slightly enlarged in 1900.

Nyköping, a seaport town of Sweden, at the head of an inlet on the east coast, 98 miles south-west of Stockholm by a branch line from the Stockholm–Malmö railway. It is a growing place, with engineering works, cotton and cloth factories, and shipbuilding. Its port and the port of Oxelösund (10 miles south-east), at the mouth of the bay, which is seldom closed in winter, together export considerable quantities of iron and zinc ore (536,250 tons in 1900), timber, oats, and wood-pulp, and import principally coal (over 200,000 tons in 1900), with iron, grain, &c. Population (1880), 4813; (1890), 5978; (1900), 7375.

Oakham, a market town of England, capital of Rutland county, in the fertile vale of Catmos, 90 miles north of London by rail. It is a clean and healthy town, with a school, endowed by Archdeacon Johnson in 1584, reconstituted in 1875 as a first-class modern school for boys, under the same charity, as Uppingham School. The parish church of All Saints has a fine reredos. There are also a Roman Catholic church and various Nonconformist chapels, an agricultural hall, the Oakham Institute (1877), and one surviving hall of the 12th-century Norman castle, now used as a county hall. The town is governed by the county magistrates and its own rural district council. Population of the two civil parishes—Oakham Deanshold with Barleythorpe and Oakham Lordshold (1891), 3542. In 1894 Barleythorpe was formed into a separate parish outside the bounds of the parish of Oakham. Population of Oakham civil parish, without Barleythorpe (1901), 3293.

Oakland, a city of California, U.S.A., capital of Alameda county, on the east side of San Francisco Bay, opposite to and 6 miles distant from the city of San Francisco, of which it is the principal residential suburb, being connected with it by ferries. It has a level site, on which it is laid out with great regularity. It is divided into seven wards, and has a good water-supply; its streets are broad, well shaded, and macadamized. It is a beautiful residential city. It is the terminus of lines of the Southern Pacific Railway, whence passengers are transferred to San Francisco by ferry. Though mainly residential, it has some manufactures. In 1900 it contained 752 manufacturing establishments, with a total capital of $6,364,651. They employed 4012 wage-earners, and the product was valued at $9,174,257. The principal items of production were lumber and foundry and flouring products. It is the seat of California College, a Baptist institution, opened in 1870, which had in 1899 eight instructors and sixty-six students. The assessed valuation of real and personal property in 1900, on a basis of about two-thirds of the full value, was $43,275,381; the net debt was only $484,030, and the rate of taxation was $25.33 per $1000. Population (1890), 48,682; (1900), 66,960, of whom 17,256 were foreign-born and 2172 coloured, including 1026 negroes.

Oaxaca de Juarez, a state of Mexico, bounded on the N. by the states of Puebla and Vera Cruz, on the E. and N.E. by those of Vera Cruz and Chiapas, on the S. by Chiapas and the Pacific, and on the W. and N.W. by Guerrero, with an area of 35,392 square miles. Its coast-line is 530 kilometres long. Its population, 744,000 in 1879, in 1895 was 884,909. It occupies a beautiful and fertile region, watered by a number of rivers; the Sierra Madre Mountains traverse the whole state. The principal agricultural products are cereals, sugar-cane, cotton, coffee, and tobacco, the total yearly yield being estimated at about $15,000,000. Stock-raising represents a capital of $4,000,000. Silver, gold, iron, lead, and coal are abundant, but as yet little exploited. The South Mexican Railway runs from Puebla to Oaxaca on its way to the Guatemalan frontier, with a branch line to Puerto Angel, and the Interoceanic Railway runs from Salina Cruz on the Pacific to Coatzocoalcos on the Gulf. It has two ports open to foreign and coastwise trade, Salina Cruz and Puerto Angel. The capital, OAXACA DE JUAREZ, near the Rio Atoyac, with 32,437 inhabitants, is one of the most beautiful and most famous cities of Mexico, has fine public buildings, an institute of sciences and arts, a model school, a general hospital, a mint, fine public gardens, and tramways. It is also an important industrial and commercial centre. It was founded in 1486 under the name of Huaxyacac. In 1872 it was given its present name. Amongst other towns in the state are Juchitan (10,820), Tehuantepec (9415), Tlaxiaco (8535), Huantla (5924), Zachila (5814), Ojitlan (5583), Tlacolula (5377), Ejutla (5254).

Oban, a seaport and parliamentary burgh—extended 1881—(Ayr group) of Argyllshire, Scotland, on the Firth of Lorn, 92 miles north-west by north of Glasgow by rail. Manufactures of aërated waters and sheep dip have been introduced; and modern erections are the parish church, United Free church, Roman Catholic pro-cathedral, cottage hospital, court house, municipal buildings, and an isolation hospital. A large quay and sea wall have been enlarged. The harbour, which will admit vessels up to 600 tons, is 20 acres in extent, and gives 12 feet of water beside the quay. At one end of the fine bay stands Dunollie Castle, beautifully situated on a rocky knoll. On the hill in the heart of the town are the picturesque ruins of a hydropathic, built on far too gigantic a scale, from which a magnificent view of the Sound of Mull and the mountains of Morven is to be had. William Black, the novelist, had a villa here for many years, and Professor Blackie was a constant visitor until he took umbrage at the railway and the class of buildings that were being erected to meet the growing popularity of the town. Oban is full of hotels, and has been called the "Charing Cross of the Highlands." Some three miles to the north-east are the hoary ruins of Dunstaffnage Castle, with relics of the Spanish Armada, but still more memorable as being the resting-place of the Stone of Destiny, prior to its removal to Scone, whence it was conveyed in 1296 by Edward I. to Westminster Abbey, where it now lies beneath the coronation chair. Population (1891), 4946; (1901), 5374.

Oberammergau, a village of Bavaria, Germany, district of Upper Bavaria, situated amongst the foot-hills of the Alps, 64 miles south-south-west of Munich (of which 57 miles by rail to Oberau), where the famous Passion Play is performed every tenth year (*e.g.*, in 1900). The people make crucifixes, rosaries, &c., and toys. Population, 1400.

Oberlahnstein, a town of Prussia, province of Hesse-Nassau, on the right bank of the Rhine, at the confluence of the Lahn, 4 miles above Coblenz. It still retains parts of its ancient walls and towers, and possesses a former castle of the electors of Mainz, the castle of Lahneck (restored in 1860), and the chapel in which King Wenceslaus was deposed in 1400. In the vicinity are iron, lead, and silver mines. It has a trade in wine, and machine factories and saw-mills. Population (1900), 7969.

Oberleutensdorf (Czech, *Litvinov horni*), a town in the government district of Brüx in Bohemia. In addition to important coal-mines, the chief industries include textiles, cutlery, and leather-making, besides manufactures of toys, furniture, hats, &c. Population (1890) 7502; (1900), 12,928, German.

Oberlin, a village in Russia township, Lorain county, Ohio, U.S.A., in the northern part of the state, and 34 miles distant (by rail) west-south-west from Cleveland. Besides being on the main line of the Lake Shore and Michigan Southern Railway, it is on the Cleveland, Elyria, and Western (electric) Railway, which furnishes connexions not only with the cities of Cleveland and Elyria, but also with the village of Wellington, thus giving access to the Cleveland, Cincinnati, Chicago and St Louis, and the Wheeling and Lake Erie railways. The village is partly paved, and has electric lighting, sewerage, and water-supply systems. Oberlin College, a co-educational institution situated here, had in 1900 (including the theological seminary, the conservatory of music, the preparatory academy, &c.), 84 instructors and 1357 students, of whom 825 were women. The college proper had 34 instructors and 428 students, of whom 231 were women. Population (1890), 4376; (1900), 4082, of whom 261 were foreign-born and 641 negroes.

Oberstein, a town of Prussia, grand-duchy of Oldenburg, in the district of Birkenfeld, and on the river Nahe, 33 miles south-west of Kreuznach. It is famous for the industry of cutting and setting agates and other precious stones, an industry which has been established here since the 16th century. The (Evangelical) parish church is partly hewn out of the solid rock. Population (1885), 5400; including Idar (1895), 14,774; (1900), 16,729.

Oberwesel, a town of Prussia, in the Rhine province, on the left bank of the Rhine, 26 miles by rail south by east of Coblenz, a former free imperial town. It is still partly surrounded with ruinous walls, having conspicuous towers. It has a couple of Gothic churches, one of the 14th century; and above the town are the ruins of the castle of Schönburg. A little lower down the river, on the opposite bank, is the romantic rock of the Lorelei, and immediately opposite the town are the rocks of the Seven Sisters. Population (1900), 2601.

Observatory.—Since 1884 the instrumental equipment of many observatories has been considerably increased, chiefly owing to the rapid rise of astronomical photography. In the following list all important additions are mentioned, and the principal new observatories founded since 1884 are shortly described. In a few cases improved values of the latitude and longitude of older institutions are also given.

[*Abbreviations:* ap., aperture; obs., observatory; o.g., object glass; phot., photographic; refl., reflector; refr., refractor; s.g., silvered glass; vis., visual. Where the names of two makers are given, the first is responsible for the optical, the second for the mechanical part of the instrument.]

Great Britain and Ireland.—*Greenwich.*—Lassell's 2 foot refl., erected 1884; 13 in. phot. refr. with 10 in. vis. o.g. by Grubb; 28 in. refr. by Grubb; 26 in. phot. refr. by Grubb, with the old 12·8 in. refr. as guiding telescope; 9 in. phot. refr. by Grubb, and 30 in. s.g. refl. by Common, the last four being on one stand; 8 in. altazimuth by Simms, erected 1896. The 26 in. and the 9 in. were presented by Sir H. Thompson.

South Kensington.—Solar Physics obs., lat. +51° 29′ 48″·0, long. 0^h 0^m 41^s·5 W. Directed by Sir N. Lockyer. 3 foot refl. by Common; 10 in. refr. by Cooke; 9 in. refr. by Henry, with attachments for phot. and spectroscopic work on the sun and fixed stars.

Oxford.—Radcliffe obs. Mr Barclay's 10 in. refr. erected; 24 in. phot. and 18 in. vis. refr. by Grubb, erected in 1902. University obs. 13 in. phot. refr. by Grubb.

Cambridge.—Mr Newall's 25 in. refr., presented and erected 1891; siderostatic telescope on Grubb's plan, with 12½ in. triple photo-vis. o.g. by Cooke, 1898.

Edinburgh.—New Royal obs. on Blackford Hill, opened 1896, lat. +55° 55′ 28″·0, long. 0^h 12^m 44^s·2 W., contains all the instruments and library of Lord Crawford's obs. and the 2 foot refl. The Calton Hill obs. has been acquired by the city, and a 21 in. refr. erected.

Glasgow.—20 in. s.g. refl. by Grubb, with spectrograph.

Armagh.—10 in. refr. by Grubb, erected 1885.

Mr Common's obs.—5 foot refl., erected 1888; the 3 foot sold.

Rev. T. E. Espin's obs., Tow Law, Darlington.—17 in. refl. by Calver.

Mr F. M'Clean's obs., Rusthall House, Tunbridge Wells.—12 in. phot. refr. by Grubb, with o.g. prism same size.

Dr Isaac Roberts's obs., Crowborough, Sussex.—Lat. +51° 3′ 7″, long. 0^h 0^m 37^s E. Erected 1890, 20 in. s.g. refl. by Grubb (with 7 in. refr.), devoted to photography of nebulæ and clusters.

Stonyhurst College.—15 in. Perry memorial refr. by Grubb.

Mr W. E. Wilson's obs., Streete, Co. Westmeath.—2 foot refl. by Grubb, and other instruments for work on solar physics.

The private observatories of Mr Barclay, Lord Crawford, Mr Knott, Mr Newall, and Colonel Tomline have been discontinued.

France.—*Paris.*—Equatoréal coudé of 10·6 in. ap., erected 1883; 13 in. phot. refr. by Henry, 1885; equat. coudé with 23·6 in. vis. and phot. o.g. by Henry and Gautier, completed 1891.

Juvissy (Seine et Oise).—M. Flammarion's obs. 9½ in. refr. by Bardou.

Meudon, lat. +48° 48′ 18″, long. 0^h 8^m 55^s·6 E. Refr. by Henry and Gautier, with 32 in. vis. and 24·4 in. phot. o.g.; refl. of 39 in. ap. by the same. M. Janssen has established a branch on Mont Blanc for solar and spectroscopic observations.

Besançon, lat. +47° 14′ 59″·0, long. 0^h 23^m 57^s·2 E. Chronometric and meteorological obs., opened 1884. 8 in. refr., 13 in. equat. coudée, 7½ in. transit circle, all by Gautier.

Lyons, lat. +45° 41′ 41″·0, long. 0^h 19^m 8^s·6. 12 in. equat. coudé.

Marseilles.—7½ in. transit circle.

Nice, lat. +43° 43′ 16″·9, long. 0^h 29^m 12^s·2 E. 15 in. refr. and 15 in. equat. coudée, both by Henry and Gautier.

Bordeaux, lat. 44° 50′ 7″·2, long. 0^h 2^m 5^s·5 W. Transit circle of 7 in. ap. by Eichens; 8 in. refr., 14 in. refr. by Merz and Gautier; 13 in. phot. refr. by Henry and Gautier.

Toulouse.—13 in. phot. refr. by Henry and Gautier; transit circle by Gautier; old 13 in. refl. by Foucault. The Brunner refr. is of 9 in. ap.

Germany.—*Bamberg.*—Remeis obs., lat. +49° 53′ 6″·0, long. 0^h 43^m 33^s·7 E. 7 in. heliometer by Repsold; 10 in. refr. by Schröder.

Berlin.—Urania Society for Diffusing Natural Knowledge, lat. +52° 31′ 30″·7, long. 0^h 53^m 27^s·5 E. Opened 1889. 12 in. refr. by Schröder.

Breslau.—Engelmann's 8 in. refr., acquired 1898.

Dresden.—Instruments given to Kasan obs., 1897.

Düsseldorf.—7 in. refr. by Merz and Bamberg.

Göttingen.—6 in. heliometer by Repsold.

Heidelberg.—University obs., lat. +49° 23′ 56″·6, long. 0^h 34^m 48^s E., 1600 feet above the Neckar. Instruments from Karlsruhe, also 6 in. transit circle by Repsold, 8 in. refr. by Merz, 12 in. refr. by Steinheil and Repsold; 16 in. phot. refr. by Brashear and Grubb.

Königsberg.—13 in. refr. by Reinfelder and Repsold.

Leipzig.—6 in. heliometer by Repsold; 12 in. refr. by Reinfelder.

Munich.—6 in. transit circle by Repsold.

Potsdam.—9 in. vis. and 13 in. phot. refr. by Steinheil and by Merz; phot. spectrograph; 31 in. phot. and 19·7 in. vis. refr. by Steinheil and Repsold, erected 1899.

Austria-Hungary.—*Vienna.*—Imp. and R. obs. 14·9 in. equat. coudé by Gautier, presented by Baron A. Rothschild.

Vienna—Ottakring.—Private observatory of M. von Kuffner, lat. +48° 12′ 46″·7, long. 1^h 5^m 11^s·1 E. 10 in. vis. and 6 in. phot. refr. by Steinheil and Repsold; 8 in. heliometer by Repsold; transit circle by same.

Lussinpiccolo (Istria).—Manora private obs., lat. +44° 32′ 11″·0, long. 0^h 57^m 52^s·4 E. 7 in. refr. by Reinfelder.

Kis Kartal.—Private obs. of Baron Podmaniezky, lat. 47° 41′ 54″·8, long. 1^h 18^m 11^s·7 E. 7 in. refr. by Merz and Cooke.

Spain.—*Cadiz.*—13 in. phot. refr. by Henry and Gautier.

Italy.—*Teramo.*—Private obs. of V. Cerulli, lat. +42° 39′ 27″ long. 0^h 54^m 56^s E. 15·5 in. refr. by Cooke.

Padua.—Dembowski's 7 in. refr., erected 1881.

Rome.—Vatican, papal obs., founded 1890, lat. +41° 54′ 4″·8, long. 0^h 49^m 49^s·5 E. 13 in. phot. refr. and 5·5 in. photoheliograph, both by Henry.

Catania, +lat. 37° 30′ 13″·3, long. 1^h 0^m 20^s E. 13 in. refr. by Merz and 13 in. phot. refr. by Henry and Gautier.

Russia.—*St Petersburg.*—University obs., lat. +59° 56′ 32″, long. 2^h 1^m 11^s.4 E., with a branch obs. at Domkino for summer use, lat. +58° 35′ 36″, long. 1^h 59^m 25^s·1 E. 9 in. refr. used for double stars.

Pulkowa.—30 in. refr. by Clark and Repsold. A branch has been established at Odessa, with a 4 in. transit by Freiberg, and 4 in. vertical circle by Repsold.

Helsingfors.—13 in. phot. refr.

Vilna.—Abolished in 1883.

Plonsk.—Discontinued after the owner's death.

Kasan.—New obs. built 1899 (see *Dresden*).

Sweden.—*Upsala.*—13 in. phot. and 14 in. vis. refr. by Steinheil.

Denmark.—*Copenhagen.*—14 in. vis. and 8 in. phot. refr. by Steinheil.

Holland.—*Leyden.*—10·5 in. refr. by Clark and Repsold.

Belgium.—*Brussels.*—New obs., lat. +50° 47′ 53″, long. 0^h 17^m 26^s·9 E.

Liége.—University obs., lat. +50° 37′ 7″, long. 0^h 22^m 15^s·2 E. 10 in. refr. by Cooke; 6 in. transit circle by same.

United States.—*Albany* (N.Y.).—New obs., lat. +42° 39′ 12″·7, long. 4^h 55^m 6^s·8 W. New 12 in. refr. by Brashear.

Cambridge (Mass.).—Harvard University obs., 12 in. horizontal telescope for photometric obs. of faint stars; 11 in. Draper phot. refr.; 8 in. Draper refr. for regular photographs of northern sky several times a year; 15 in. Draper refl. for phot. trails of stars near the pole; phot. transit photometer (see *Arequipa*, S. America).

Charlottesville (Va.).—Leander M'Cormick obs. of University of Virginia, lat. $+38° 2' 1''\cdot2$, long. 5^{h} 14^{m} $5^{s}\cdot2$ W. 26 in. refr. by Clark.

Columbus.—Ohio State University obs. 12 in. refr. by Brashear and Warner & Swasey.

Denver (Col.).—Chamberlin obs., lat. $+39° 40' 36''\cdot4$, long. 6^{h} 59^{m} $47^{s}\cdot6$ W., 5400 feet above sea-level. 20 in. refr. by Fauth.

Echo Mountain, Los Angeles (Cal.).—Lowe obs., 3500 feet above sea-level. 16 in. refr. from Rochester.

Evanston (Ill.).—Dearborn obs., lat. $+42° 3' 33''\cdot4$, long. 5^{h} 50^{m} $42^{s}\cdot3$ W. Removed from Chicago in 1889.

Flagstaff (Arizona).—Lowell obs., 7300 feet above sea-level. 18 in. refr. by Brashear.

Georgetown (D.C.).—12 in. refr. by Clacey and Saegmuller; 9 in. phot. transit instr. by Saegmuller; 6 in. phot. zenith telescope by Brashear.

Haverford (Pa.).—College obs., lat. $+40° 0' 40''\cdot1$, long. 5^{h} 1^{m} $12^{s}\cdot7$ W. 10 in. refr. by Clark.

Mount Hamilton (Cal.).—Lick obs. of University of Cal., opened 1888, lat. $+37° 20' 25''\cdot6$, long. 8^{h} 6^{m} $34^{s}\cdot9$ W. The 36 in. refr. has a 33 in. phot. lens; 6 ins. transit circle by Repsold; 3 foot refl. by Common; 5 in. horiz. photoheliograph.

New Haven (Conn.).—The new obs. is in lat. $+41° 19' 22''\cdot3$, long. 4^{h} 51^{m} $40^{s}\cdot6$ W.

New York.—Columbia University obs., lat. $+40° 45' 23''\cdot1$, long. 4^{h} 55^{m} $53^{s}\cdot6$ W. Contains Rutherfurd's instruments.

Northfield (Minn.).—16 in. refr. by Brashear and Hastings; 4·8 in. transit circle by Repsold.

Philadelphia.—University of Pa. obs., lat. $+39° 57' 7''\cdot5$, long. 5^{h} 0^{m} $38^{s}\cdot5$ W. 18 in. refr., 4 in. transit circle, and 4 in. zenith telescope, all by Brashear and Warner & Swasey.

Poughkeepsie (N.Y.).—Vassar College obs., lat. $+41° 41' 18''$, long. 4^{h} 55^{m} $33^{s}\cdot7$ W. Founded 1865. 12⅜ in. refr. by Fitz and Clark; small transit circle

Rochester (N.Y.).—Discontinued (see *Echo Mountain*).

Washington (D.C.).—New naval obs., opened 1893, lat. $+38° 55' 14''\,0$, long. 5^{h} 8^{m} $15^{s}\cdot8$ W. In addition to the old instruments, there is a 40 foot photoheliograph of 5 in. ap.; 6 in. transit circle built of steel by Warner & Swasey; 5 in. steel altazimuth by same; 12 in. refr.

Washington (D.C.).—Astrophysical obs. of the Smithsonian Institution, lat. $+38° 53' 17''\cdot3$, long. 5^{h} 8^{m} $6^{s}\cdot2$. Siderostat with 20 in. mirror; spectrobolometer, &c

Williams Bay (Wis.).—Yerkes obs. of University of Chicago, lat. $+42° 34' 15''$, long. 5^{h} 54^{m} 14^{s} W. Opened 1897. 40 in. refr. by Clark and Warner & Swasey, also a 12 in. refr., 24 in. refl., 10 in. phot. refr.

Williamstown (Mass.).—The transit circle is in the Field Memorial obs. (1882), lat. $+42° 42' 30''$, long. 4^{h} 52^{m} 50^{s} W.

Mexico.—*Taeubaya.*—National obs., lat. $+19° 24' 17''\cdot5$, long. 6^{h} 36^{m} $46^{s}\cdot5$ W., 7600 feet above sea-level. 15 in. refr. by Grubb; 13 in. phot. refr. by Henry and Gautier.

South America.—*Santiago* (Chile).—13 in. phot. refr. by Henry and Gautier; new transit circle.

Arequipa (Peru).—Branch of Harvard College obs., lat. $-16° 24'$, long. 4^{h} 45^{m} 30^{s} W., 8060 feet above sea-level. 24. in. Bruce refr. by Clark, and 13 in. Boyden telescope for phot. charts and spectra of faint stars; 4 in. transit photometer extends the Harvard photometry to the south pole.

Rio de Janeiro.—13 in. phot. refr. by Henry and Gautier.

La Plata (Argentina), lat. $-34° 54' 30''\cdot3$, long. 3^{h} 51^{m} $37^{s}\cdot0$ W. 8 in. refr., 18 in. equat. coudé, and 13 in. phot. refr. by Henry and Gautier.

Africa.—*Cape of Good Hope.*—7 in. heliometer by Repsold; 13 in. phot. and 10 in. vis. refr. by Grubb; new transit circle by Simms; 24 in. phot. and 18 in. vis. refr. by Grubb (with 24 in. objective prism), presented by Mr F. M'Clean. A phot. survey of the southern heavens has been made with a 6 in. Dallmeyer lens.

Mauritius.—Royal Alfred obs., lat. $-20° 5' 39''$, long. 3^{h} 50^{m} $12^{s}\cdot5$ E. Chiefly meteorological, but solar photos regularly taken.

Algiers.—20 in. refl., equat. coudé, and 13 in. phot. refr. by Henry and Gautier; transit circle.

India.—*Madras.*—New obs. is being built at Kodaikanal, 7700 feet above sea-level.

Poona.—Obs. of College of Science. 16½ in. s.g. refl. by Grubb, with 6 in. refr. by Cooke; spectroscopes, &c., chiefly for solar work.

Dehra Dûn.—Obs. of Indian Survey, lat. $+30° 19' 29''\cdot1$, long. 5^{h} 12^{m} $11^{s}\cdot6$ E. Regular solar phot. work.

Japan.—*Tôkyô.*—University obs., lat. $+35° 39' 17''\cdot5$, long. 9^{h} 18^{m} $58^{s}\cdot0$ E. 5 in. transit circle by Repsold.

Australia.—*Sydney.*—13 in. phot. refr. by Grubb.

Windsor (N.S.W.).—8 in. refr. by Grubb.

Melbourne.—13 in. phot. refr. by Grubb.

Perth (West Australia), lat. $-31° 57' 2''\cdot4$, long. 7^{h} 43^{m} $22^{s}\cdot6$ E. 13 in. phot. and 10 in. vis. refr. by Grubb; 6 in. transit circle by Simms.

AUTHORITIES.—In addition to their *Annals* or *Observations*, the leading national observatories (Greenwich, Paris, Washington, &c.) publish annual reports stating the nature of the work and changes in *personnel* and instruments. Short reports from nearly all British observatories are annually published in the February number of the *Monthly Notices R. Astr. Soc.*, and from most German and some other Continental observatories in the *Vierteljahrsschrift d. astr. Gesellschaft.* Since 1889 much information about American observatories is given in the *Publications of the Astr Soc. of the Pacific.* (J. L. E. D.)

Obstetrics.—Along with Medicine and Surgery, Obstetrics goes to form what has been called the Tripos of the medical profession, because every person desiring to be registered under the Medical Acts must pass a qualifying examination alike in medicine, surgery, and midwifery. Registrates who become general practitioners find that their midwifery cases make up a very large proportion of the patients they visit in their daily round, and in an ordinary practice such patients furnish the most constant contingent to the visiting list. Midwifery stands related both to medicine proper or internal medicine, as it is sometimes called, and to surgery or external medicine; and of registrates who in the larger centres of population specialize and devote themselves to one branch of the profession, whilst physicians seek the fellowship of a college of physicians and the surgeons that of a college of surgeons, obstetricians become fellows sometimes of the one college and sometimes of the other—it may even be of both. At present, in the capitals of the three kingdoms, the greater number of the obstetricians are fellows of the colleges of physicians. When two colleges combine to give a conjoint qualification the examiners in medicine are provided by the Physicians' College, and the examiners in surgery by the Surgeons' College, whilst the examiners in midwifery are provided in equal numbers by each of the two.

The Scope of Obstetrics.—It is required of the candidate for a qualifying pass in midwifery that he show acquaintance with the physiology and pathology of the female. The term Gynecology, which has come to be applied to the study of the diseases of the female generative system, in its primary sense includes all that pertains to women both in health and disease. This was its earliest application; and while the midwifery societies of the 'fifties took the name Obstetrical, younger societies discussing the same range of subjects adopt the wider name Gynecological. But as the obstetrical section of this branch of medicine preceded the gynecological in its development, so it retains its place of primary importance for those who seek to qualify themselves for practice. To become capable practitioners of midwifery they have to study woman as she plays her part in the reproduction of the race. This implies, to begin with, a study of *Emmenology*—the science which concerns itself with the cyclical changes in the female that culminate in a menstrual uterine hæmorrhage. Like other cyclical processes, menstruation is probably regulated from a nervous centre seated, it is generally believed, in this instance in the lumbar part of the spinal cord; but it is dependent for its healthy flow on the healthy condition of the circulation, and is intimately associated with ovulation —the escape of an ovum from a dehiscent ovisac. The appearance of the menstrual discharge is the first indication that the individual is susceptible of impregnation, and so long as it continues to recur the susceptibility remains.

Emmenology, therefore, has to observe the date of the first menstrual flow at from fourteen to sixteen years of age, and the modifying influences of climate, heredity, race, and social status in the development of puberty; the menstrual type, which is most frequently a twenty-eight-day cycle from the commencement of one period to the commencement of the next; the menstrual habit, which expresses the amount and duration of the flow; and at the end of reproductive life, the climacteric period or menopause, with its wide range of possibilities. Obstetricians recognize that, although the appearance of menstruation indicates the possibility of conception, puberty precedes the physiological age of nubility by as much as from seven to ten years. They know that the normal condition for reproduction is a monogamous union of two individuals, man and woman, mutually consenting and openly declaring their desire to form a family, and that a woman is not ripe, physically or psychically, for the great functions of wifehood and motherhood till she has attained the age of at least twenty-one years. There is the possibility of conception at any point in the menstrual cycle, but the period of greatest conception-probability is within a week after the cessation of the flow, so that if marriage be consummated at this date the newly-married wife may find that her next menstrual period fails to appear because the uterus has become the nest for the incubation of a fertilized ovum. The nine months, or, more precisely, the ten menstrual months of utero-gestation, during which the new being keeps growing like a parasite within the womb, test the strength of the pregnant female in every system of her body. This affords a second sphere of interest in the female economy, where obstetricians find occasion for the exercise of all their medical skill. Weaknesses of the brain and nervous system, of the heart, the blood, blood-vessels and blood-glands, of lungs, liver, stomach or kidneys, or even of the bones, that might otherwise have remained latent, come into view during the strain of pregnancy and may be a menace to the life of the mother and her child. During epidemics, as of small-pox or typhoid fever, the gravid woman runs risks from which her non-gravid sister is free; and whilst there are some common diseases that take on features of special danger, there are yet others that arise only during the course of pregnancy. The consideration of the health conditions of pregnancy has respect not only to the woman, but to her unborn infant; not only to individuals, but to the coming race; and in this regard it becomes part of the function of obstetricians to teach communities and even legislators the need of preventing poor women in the last weeks of pregnancy from toiling at their industries in ways that are detrimental to the race. Considerations of this kind would become urgent in a population thinned by war or fatal epidemics.

Tokology—the doctrine of parturition—is the most distinctive sphere of interest for obstetricians, and here their activities bring them into a closer approximation to the work of surgeons. As a science it demands a study of the phenomena of labour, which in their ordered succession are seen to present three distinct stages: one of preparation, during which the uterus dilates sufficiently to allow of the escape of the infant; a second, of progress, during which the infant is expelled; and a third, of the extrusion of the after-birth or placenta. In each of the stages analysis of the phenomena reveals the presence of three elements which are known as the factors of labour, viz., the powers or forces which are engaged in the emptying of the uterus; the passages or canals through which the ovum is driven; and the passenger or body that is being extruded. The mechanism of labour depends on the balance of these factors as they become adjusted to each other in the varying phenomena of the several stages. The diversities that are met with in different labours even of the same woman have led to their being classified into different groups. A natural labour is commonly defined as one where the child presents by the head and the labour is terminated within twenty-four hours. From this it is obvious that no case of labour can be defined at its onset. The relation of the factors may warrant a favourable expectation; but until the labour is completed, and completed within a reasonably safe period, it cannot be classed as natural. The element of time has this importance, that it is found that, apart from all accidents and interferences, the mortality both to mother and child becomes greater the longer the duration of the labour. Hence lingering or tedious labours, in which the child still presents with the head, but is not expelled within twenty-four hours after the onset of labour-pains, are properly grouped in a separate class, although they are terminated without operative interference. In the class of preternatural labours, where the head comes last instead of first, there are two subdivisions, according as the child presents by the breech and feet, or lies transversely as a cross-birth, and has usually to be delivered artificially. Operative or instrumental labours vary according as the procedures adopted are safe in principle to mother and child, such as turning and the application of the midwifery forceps; or as they involve damage to the infant in the various forms of embryotomy; or are more dangerous to the mother, as in the Cæsarean section and symphysiotomy. A final class of labours includes the cases where some complication or anomaly arises and becomes a source of danger, independently of disturbances of the mechanism or of any operative interference. These complex labours are due to complications that may be maternal, such as hæmorrhage and convulsions; or fœtal, such as twins or prolapse of the umbilical cord. To cope with these anomalies an obstetrician requires all the resource of a physician and all the dexterity of a surgeon.

The interest of obstetricians in their patients does not end with the birth of the children, even after natural labours. The puerpera is still a subject of care. The uterus, that during its nine months' evolution had been increasing enormously in all its elements, has in six weeks to undergo an involution that will restore it to its pre-gravid condition. The allied organs share in their measure in the change, all the systems of the body feel the influence, and especially the mammary glands take on their function of providing milk for the nutriment of the new-born infant. A patient with some latent flaw in her constitution may pass the test of pregnancy and labour with success, only to succumb during the puerperium. Of patients who become insane in connexion with child-bearing, a half manifest their mental disorder first during the days or weeks immediately succeeding their confinement, and numbers more whilst they are suckling their infants. A woman may have had an easy labour, and may have been thankful at the time for help from a hand that she did not know to be unclean; three days later germs left by that hand may have so multiplied within her that she is in mortal danger from septicæmia. The management of the puerperal patient requires not only the warding off of deleterious influences, but the watching of the normal processes, because slight deviations in these, undetected and uncorrected now, may become later a source of lifelong invalidism. It remains further to be noted that to obstetricians belong the earliest stages of pediatrics in their care of the new-born child. In some old works practitioners of this branch of the profession are described as ὀμφαλοτόμοι, because their first business was to cut the umbilical cord. The causes of the high death-rate among infants, whether due to ante-natal, intra-natal, or neo-natal conditions, come under their observation. They have charge of the whole wide field of the hygiene, pathology, and therapeutics of infancy.

Historical Sketch.—The origin of midwifery is lost in the mists of human origins. The learned Jean Astruc, who gave a lead to higher critics in their analysis of the Pentateuch by pointing out the presence of Elohistic and Jehovistic elements, exercised his imagination in fancying how the earliest pair comported themselves at the birth of their first child, and especially how the husband would have to learn what to do with the placenta and umbilical cord. His speculations are not in the least illuminative. The Mosaic writings let us see women of some experience and authority by the side of a Rachel dying in labour or a Tamar giving birth to twins, and superintending the easy labours of Hebrew slaves in Egypt. The Ebers Papyrus (1550 B.C.), which Moses may have studied when he grew learned in all the wisdom of the Egyptians, is the oldest known medical production. It contains prescriptions for causing abortion, for promoting labour, for curing displacements of the uterus, &c. But there is no indication as to how labours are to be managed, and with regard to the child there are only auguries given as to whether it will live or die, according, *e.g.*, as its first cry after it is born sounds like *nī* or *bā*.

The story of the rise and progress of midwifery is intimately bound up with the history of medicine in general. The obstetrician, looking for the dawn of his science, turns like his fellow-workers in other medical disciplines to the Hippocratic writings (400 B.C.). Now the father of medicine was not an obstetrician. As with Egyptians and Hebrews, the skilled attendants on women in labour among the Greeks were also women. But since nothing that concerned the ailments of humanity was foreign to Hippocrates, there are indications in the writings that are accounted genuine of his interest in the disorders of females—in their menstrual troubles, in their sterility, in their gestation symptoms, and in their puerperal diseases; his oath forswears the use of abortifacients, and he recommends the use of sternutatories to hasten the expulsion of the after-birth. In the Hippocratic writings that are supposed to be products of his followers, some of these subjects are more fully dealt with; but whilst the physician is sometimes called in to give advice in difficult labours, so that he can describe different kinds of presentation and can speak of the possibility of changing an unfavourable into a favourable lie of the infant, it is usually only with cases where the child is already dead that he has to deal, and then he tells how he has to mutilate and extract it. So these writings furnish us with the earliest account of the accoucheur's armamentarium, and let us see him possessed of a μαχαίριον—a knife or perforator for opening the head; a πίεστρον—a comminutor for breaking up the bones; and a ἐλκυστήρ—an extractor for hooking out the infant. The classical writers of Greece give the same impression as to the primitive stage of obstetrics. Women, like the mother of Socrates, have the charge of parturient women. Where divine aid is sought, goddesses are invoked to facilitate the labour. Gods or men are only called in where graver interference is required, as when Apollo rescued the infant Æsculapius by a Cæsarean section performed on the dying Semele. Some midwives are known to history, and extracts from the writings of one Aspasia are embedded in the works of later authors. In the great medical school of Alexandria, when the science of human anatomy began to take shape, Herophilus rendered a service to obstetrics in giving a truer idea of the anatomy of the female than had previously prevailed; other physicians give evidence of their interest in midwifery and the diseases of women, and some experience was gradually being acquired and transmitted through the profession until we find from Celsus (in the reign of Augustus) that when surgeons were called in to help the attendant woman they could sometimes bring about the delivery, without destroying the infant, by the operation of turning. In the 2nd century Soranus wrote a work on midwifery for the guidance of midwives, in which for the first time the uterus is differentiated from the vagina and instruction is given for the use of a speculum. A contemporary, Moschion, wrote a guide for midwives which, with that of Soranus, may be said to touch the high-water mark of archaic midwifery. It is written in the form of question and answer, was much prized at the time of the Renaissance, and was used as the basis of the first obstetric work that issued from a printing-press. Philumenos wrote a treatise of some value at the same epoch, but it is only known from the free use made of it by subsequent writers, such as Aëtius in the beginning of the 6th century. Like Oribasius, who preserved in his compilation the work of Soranus, Aëtius draws largely on preceding writers. His treatises on female diseases constitute an advance on previous knowledge, but there is no progress in midwifery, though he still makes mention of turning. This operation has disappeared from the pages of Paulus Ægineta, an 8th-century author, the last to treat at length of obstetrics and gynecology ere the night of the Dark Ages settled down on the Roman world, and it is not heard of again till a millennium had passed. During the centuries when the progress of medicine was dependent on the work of the Arabian physicians, the science of obstetrics stood still. We are curious to know what Rhazes and Avicenna in the 9th and 10th centuries have to say on this subject. But they know little but what they have learned from the Greek writers, and they show a great tendency to relapse to the rudest procedures and to have recourse to operative interferences destructive to the child. Interest attaches to the work of Albucasis in the 12th century, in that he is the first to illustrate his pages with figures of the knives, crushers, and extractors that were employed in their gruesome practices, and that he gives the first history of a case of extra-uterine pregnancy.

We come down to the 16th century before we begin to see any indication of the development of obstetrics towards a place among the sciences. Medicine and surgery profited earlier by the intellectual awakenings of the Renaissance and the Reformation. In anatomical theatres and hospital wards associated with universities great anatomists and clinicians began to discard the dogmas of Galen, and to teach their pupils to study the body and its diseases with unprejudiced minds. But the practice of midwifery was still among all people in the hands of women, and when in 1513 Eucharius Roesslin of Frankfort published a work on midwifery, it bore the title *Der Schwangeren Frawen und Hebammen Rosengarten.* Translated into English by Thomas Raynald with the altered title, *The Birth of Mankynd*, it is mainly compiled from Moschion, and the Soranus and Philumenos fragments of Oribasius and Aëtius, and is intended as a guide to pregnant women and their attendant nurses. It was illustrated with fanciful figures of the fœtus *in utero* that were reproduced in other works of later date—as in the *Rosengarten* of Walter Reiff of Strasburg in 1546 and the *Hebammenbuch* of Jacob Rueff of Zurich in 1554, the latter of which appears in English dress as *The Expert Midwife.* The greatest impulse to the progress of midwifery was given in the middle of the 16th century by the famous French surgeon Ambroise Paré, who revived the operation of podalic version, and showed how by means of it surgeons could often rescue the infant even in cases of head presentation, instead of breaking it up and extracting it piecemeal. He was ably seconded by his pupil Guillemeau, who translated his work into Latin, and at a later period himself wrote a treatise on midwifery, an English translation of which was published in 1612 with the title *Child-Birth; or, The Happy Deliverie of Women.* The close of the 16th century is rendered further memorable in the annals of midwifery by the publication of a series of works specially devoted to it. Three sets of compilations, containing extracts from the various writers on obstetrics and gynecology from the time of Hippocrates onwards, were published under the designation of *Gynæcia* or *Gynæciorum*—the first edited by Caspar Wolff of Zurich in 1566, the second by Caspar Bauhin of Basle in 1586, and the third by Israel Spach of Strasburg in 1597. Spach includes in his collection not only Paré's obstetrical chapters, but the Latin translation of the important *Traitte nouveaux de l'hysterotomotokie*, published by the French surgeon Francis Rousset in 1581, which is the first distinct treatise on an obstetric operation, and advocates the performance of Cæsarean section on living women with difficult labours. From this time onwards evidence accumulates of the growing interest of members of the medical profession, and more especially of surgeons, in the practice of midwifery, and after the middle of the 17th century they began to publish the records of their experiences in special treatises. The most important of these writers were French—as Mauriceau, Viardel, Paul Portal, Peu, and Dionis. The work of Mauriceau, which first appeared in 1668, is specially interesting from its having been translated into English in 1672 by Hugh Chamberlen, who in his preface made the then incredible statement that his father, his brothers, and himself had long attained to and practised a way to deliver women in difficult labours without hooks, where other artists used them, and without prejudice to mother or child. Many years had still to elapse before the secret of the Chamberlens leaked out. In the course of this century some women who had large experience in midwifery appeared as authors. Thus in England Jane Sharp in 1671 wrote *The Midwives' Book, or the whole art of Midwifery discovered*; in Germany, Justine Siegemund, in 1690, *Die Chur-Brandenburgische Hoff-Wehemutter*; and earlier and better than either, in France, Louise Bourgeois in 1626 published *Observations sur la Sterilité et Maladies des Femmes.* Perhaps they were beginning to feel that there was some need to assert their power, for it was during this century that parturient ladies began to call in men to attend them in natural labours. According to Astruc, Madame de la Vallière wished her confinement to be kept secret, and Louis XIV., in June 1663, sent for Jules Clement, the court surgeon, to superintend the delivery. This was accomplished successfully. The king gave him the title of accoucheur. Clement afterwards attended the dauphiness and other court ladies, and went thrice to Madrid to assist at the confinement of the queen of Philip IV. Up till this epoch physicians and surgeons had only been summoned to the lying-in room by midwives who found themselves at the end of their resources, to give help in difficult cases where the child was usually dead and the mother often moribund. Now that it began to be a fashion for women in their ordinary confinements to be under the surveillance of a physician, it became possible for men with their scientific training to study the normal phenomena of natural labour, and through the medium of the printing-press to communicate the results of their observation and experience to their professional brethren. Hence the books of the men already referred to, and of others that appeared later, such as the *Traité Complet des Accouchemens* of De la Motte, 1721, which is a storehouse of acute observations and wise discussion of obstetric measures. In other countries than France physicians and surgeons began to take up midwifery as a speciality and not as a subsidiary part of their practice, of which they were somewhat ashamed (Le Bon, one of the writers whose work is found in Bauhin's *Gynæcia*, says, "Hæc ars viros dedecet"), and it was in Holland that a work was produced that has earned for its author the designation of the Father of Modern Midwifery. Heinrich van Deventer, who practised as an obstetrician at The Hague along with his wife (a Vrœdvrow, as he was a Vrœdmeester), published in 1696 a preliminary treatise called *Dageraat* (*Aurora*) *der Vrœdvrowen*, and in 1701 he followed it up by a more complete second volume, of which the Latin edition that came out simultaneously with the Dutch has a title beginning *Operationes Chirurgicæ Novum Lumen Exhibentes Obstetricantibus*. It has the supreme value of being the first work to give a scientific description of the pelvis, and to take some steps towards the development of the mechanism of labour. The "obstetricantes" for whom Deventer wrote are both men and women. In the early part of the 18th century women had still the main and often the sole charge of their parturient sisters; but the practice of having a doctor to superintend or to supersede the midwives kept spreading among the classes who could afford to pay the doctor's fee; and by the time Deventer's treatise was doing its educational work in an English translation, as *The Art of Midwifery Improved*, in 1716, the doctors were getting into their hands the "harmless forceps" with which a living child could be extracted without detriment to the mother, in conditions where formerly her child's life was sacrificed and her own endangered. This life-saving instrument was invented in London, but by a man not of English birth. The Huguenot, William Chamberlen, fled from Paris to escape the St Bartholomew massacres, carrying with him to Southampton his wife, his two sons, and a daughter. William Chamberlen seems to have been a surgeon, and his descendants through four generations had large and lucrative practices in London. The eldest son Peter, who was old enough when he came to England to be able to attest the birth and baptism of a younger brother, is, on good grounds, credited with being the inventor of the forceps, which for a century was kept a secret among brothers, sons, and grandsons. Hugh, indeed, a great-grandson of William, and the translator of Mauriceau, had offered to sell the family secret for 10,000 crowns; but his failure to effect delivery in a test case that Mauriceau put to him led the profession to believe that he was a boastful quack. Palfyn of Ghent, when in Paris in 1723, putting a work on anatomy through the press, laid before the Academy of Science a pair of forceps, which was figured in Heister's surgery in 1724. He has thus the honour of first laying before the profession a midwifery forceps. But his implement was ill-constructed, and never came into general use. Meanwhile the knowledge that the Chamberlens were really possessed of a serviceable instrument must have stimulated other practitioners. Perhaps a colleague with a keen eye may have got sight of it on some occasion, or an intelligent midwife had been able to describe the "tongs" which she had seen one of the family apply. In 1734 Dr Edward Hody published a record of *Cases in Midwifery* that had been written by Mr William Giffard, "surgeon and man-midwife." The dates range from January 1724 to 1731. Amongst the cases are several where he effected the delivery by means of the forceps—"extractor," he calls it—of which a figure is given; and when Edmund Chapman, who practised first at Halstead and afterwards in London, published his *Treatise on the Improvement of Midwifery* in 1733, he speaks of the use of the forceps as "now well known to all the principal men of the profession both in town and country."

In the course of the 18th century the development of midwifery in the hands of medical men made greater strides than in all the preceding ages. The progress was accelerated by the establishment of chairs of midwifery in the universities of various countries, Edinburgh taking the lead in the appointment of a professor in 1726, and Strasburg coming closely after in 1728. In Strasburg the chair had the advantage of being at once associated with a clinical service. Lecturing was carried out, moreover, by men who were devoting themselves as specialists in midwifery and the diseases of women and infants, and were succeeding in developing lying-in institutions for the benefit of poor women in labour that became schools of instruction both for midwifery nurses and for medical students. Two new operations came during this epoch to enhance the powers of the obstetrician, viz., symphysiotomy, first introduced by Sigault in Paris; and the induction of premature labour, first carried out by Macauley in London in circumstances described by Denman in the preface to his *Midwifery*. William Hunter in London, Sir Fielding Ould in Dublin, Röderer in Göttingen, Camper in Amsterdam, Baudelocque in Paris, Saxtorph in Copenhagen, and many other authors contributed to progress by their atlases and their books. But there are three whose names stand out pre-eminently because of the influence they exerted on the whole obstetric world—Levret, Smellie, and Boër. Kilian, in his vidimus of the history of midwifery, calls Levret "one of the greatest masters in the department that ever lived." Of Smellie he says: "Inferior to Levret in nothing, he excels him in much." Boër he characterizes as "the most meritorious and important of German obstetricians." Levret improved the construction of the forceps, and widened the sphere of their applicability; Smellie worked in the same direction, and furnished, moreover, descriptions and illustrations of natural and morbid labours that are of classical value; and Boër first clearly placed pregnancy (which Mauriceau, *e.g.*, had spoken of as "a nine months' disease") and parturition in the category of physiological processes that might be hindered rather than helped by the pragmatical interferences of meddlesome midwives.

Throughout the 19th century midwifery continued to advance, gynecology grew into a special department with an extensive literature, the mechanism of labour developed under the clinical observations of men like Nägele and the study of such frozen sections of cadavera as were made by Braune, the indications for interference became more clear and the methods of interference more simple and safe, and a whole realm of antenatal pathology and teratology was added to the domain of science, while practitioners learned the art of saving premature and delicate infants by the use of the incubator and proper alimentation. Every advance in all the cognate sciences was appreciated and applied for the advancement of obstetrics. But there are two achievements which will make the 19th century for ever memorable in the annals of midwifery—the abolition of the pains of labour and the arrest laid on mortality from the so-called puerperal fever. In February 1847 Sir J. Y. Simpson, choosing a case where he had to deliver by turning, put the patient asleep with ether. Seeing that the uterine contractions continued, though the attendant pain was abolished, he proceeded to administer ether in cases of natural labour, and in November of the same year demonstrated the virtues of chloroform, and so furnished the most serviceable anæsthetic, not only to the obstetrician in the lying-in room, but to the surgeon on the battlefield and to the general practitioner in his everyday work. Ignaz Philipp Semmelweiss, assistant in the maternity hospital of Vienna, was struck and saddened with the appalling mortality that attended the delivery of the women under his care, as many as one (in some months three) out of every ten of the puerperæ being carried out dead. He observed that the mortality was much higher in the wards allotted to the tuition of students than in those set apart for the training of nurses. In the spring of 1847 he saw at the post-mortem examination of a young colleague who had died of a poisoned wound, that the appearances were the same as he had too often had occasion to see at the post-mortem examinations of his puerperæ. He ordered that every student who assisted a woman in her labour must first wash his hands in a disinfectant solution of chloride of lime, and in 1848 already the mortality was less in the students' than it was in the nurses' wards. Thus the first light was shed on the nature of the mischief of which multitudes of puerperal patients perished, and the first intelligent step was taken to lessen the mortality. When, some twenty years later, Lister had applied the bacteriological principles of Pasteur with beneficent results to surgery, obstetricians gladly followed his lead, and the 19th century beheld added to the comfort of anæsthetic midwifery the confidence of midwifery antiseptic and even aseptic.

Ocaña, a town of Spain, in the province of Toledo, on the extreme north of the plateau of Ocaña, near and to the south-east of Aranjuez, with a station on the line from that place to Cuenca. This plateau produces wine, wheat, oil, fruit, mostly sent to Madrid, and in Ocaña there are manufactures of pottery, alcohol, soap, and leather. The town is surrounded by walls in ruinous condition, and there are the remains of an old castle. It has broad regular streets, several squares with arcades, a fine town hall, schools, hospitals, convents, three parish churches, in one of which is the chapel of Our Lady de los Remedios, in which Ferdinand and Isabella were married. Near the town are the ruins of the convent of La Esperanza, which this queen built. Ocaña is the Vicus Cuminarius of the Romans, and was the dower that Abden Aled of Seville gave his daughter Zaida on her marriage with Alfonso VI. In Ocaña several Cortes of the Middle Ages assembled. Near this town, on 19th November 1809, a battle was fought between the Spanish army under Lacy and the French invaders commanded by Joseph Bonaparte and Marshal Soult, who routed the Castilian forces. Population, about 6000.

Occleve (or Hoccleve), **Thomas** (1368?–1450?), ranks, like his more voluminous and better known contemporary Lydgate, among those poets who have a historical rather than intrinsic importance in English literature. Their work rarely if ever rises above mediocrity; in neither is there even any clear evidence of a poetic temperament. They are eclipsed, not only by every poet of the Scottish school, but by more than one of their nameless English successors. Yet they represented for the 15th century the literature of their time, and kept alive, however faintly, the torch handed on to them by their "maister," Chaucer. What is known of Occleve's life has to be gathered mainly from his works. At eighteen or nineteen he obtained a clerkship in the Privy Seal Office, which he retained on and off, in spite of much grumbling, for about thirty-five years. He had hoped for a benefice, but none came; and in 1399 he received instead a small annuity, which was not always paid as regularly as he would have wished. *The Letter to Cupid*, his first poem to which we can affix a date, was translated from the French in 1402, evidently as a sort of antidote to the moral of *Troilus and Cressida*, to some MSS. of which we find it attached. *La Male Regle*, one of his most readable poems, written about 1406, gives some interesting glimpses of his "misruly" youth. His contrition for the past, which has brought him, as he bewails, to poverty of body and purse, seems to have been lasting; and about 1410 he settled down to married life, and to the composition of moral and religious poems, which are interspersed with continual complaints of poverty. His longest work, *De Regimine Principum*, written for Prince Hal shortly before his accession, is a tedious homily on the virtues and vices, with appropriate instances from the usual mediæval sources; but it is relieved by a Proem, about a third of the whole, containing some further reminiscences of London tavern and club life, in the form of a dialogue between the poet and a beggar. On the accession of Henry V. Occleve turned his muse to the service of orthodoxy and the Church, and one of his poems is a remonstrance addressed to Oldcastle, calling upon him to "rise out of the slough of heresy." Then a long illness was followed for a time, as he tells us, by insanity. His *Dialog with a Friend*, written after his recovery, gives a naïve and pathetic picture of the poor poet, now fifty-three, with sight and mind impaired, but with hopes still left of writing a tale he owes his good patron, Humphrey of Gloucester, and of translating a small Latin treatise, "Scite Mori," before he dies. His hopes were fulfilled in his moralized tales of *Jereslaus' Wife* and of *Jonathas*, which with his *Learn to die* belong to his old age. After finally retiring from his Privy Seal clerkship, he was granted in 1424 sustenance for life in the priory of Southwick, Hants, on which, with his former annuity, he appears to have lived on till about the middle of the century. Besides his *De Regimine*, of which there are a number of MSS., his works are comprised in four MS. volumes, of which three have been edited by Dr Furnivall, and the fourth (Ashburnham MS.) is promised by Mr Gollancz, for the Early English Text Society.

The main interest for us in Occleve's poems is that they are characteristic of his time. His Hymns to the Virgin, Balades to patrons, Complaints to the King and the King's Treasurer, versified homilies and moral tales, with warnings to heretics like Oldcastle, are illustrative of the blight that had fallen upon poetry on the death of Chaucer. The nearest approach to the realistic touch of his master is to be found in Occleve's *Male Regle.* But these pictures of 15th-century London are clouded over by the pale cast of contrition, and are without even the occasional flash of humour that lightens up Lydgate's *London Lackpenny.* Yet Occleve has at least the negative virtue of knowing the limits of his powers. Of a modest and even timid nature, he never attempts a flight too high for him. His unassuming downrightness and sincerity of style is in some respects a relief from the colours of rhetoric and trite verbiage with which Lydgate too often wearies his readers. He says simply what he means, and does not affect what he does not feel. A Londoner, to whom the country was evidently a bore, he has not afflicted us with artificial May mornings; and it is doubtful whether a single reference to nature can be found among his poems. He has yet another distinction among his contemporaries: he wrote no allegory. Whether we ascribe it to his lack of "engine," or to the influence of Chaucer when in his later years he had discovered the limitations of this poetic form, we cannot but be grateful to the poet who has spared us. As a metrist Occleve is also modest of his powers. He confesses that

> Fader Chaucer fayn wolde han me taught,
> But I was dul and learned lite or naught;

and it is true that the scansion of his verses seems occasionally to require, in French fashion, an accent on an unstressed syllable. Yet his seven-line (or *rime royale*) and eight-line stanzas, to which he limited himself, are perhaps more frequently reminiscent of Chaucer's rhythm than are those of Lydgate. As for the heroic couplet of *The Legende of Good Women* and *The Canterbury Tales*, it may be questioned whether Chaucer ever succeeded in imparting the secret of its rhythm to any, whether poet or scribe. Lydgate alone had the temerity to attempt it in the doggerel "riding-rime" of the *Troy Book* and the *Story of Thebes.* Then it disappears from our literature, to be rediscovered from the Italian in the next century. (W. S. M.)

Oceanography.—The department of geography which deals with the phenomena of the collected waters of the globe is termed by the Italians *talassografia*, and attempts have been made but without success to introduce the name "Thalassography" in other languages. The term "Hydrography" has been introduced in Sweden; but this is a misleading expression, as at least two different subjects are already designated by that word. In general use Oceanography is the term applied to the study of the oceans and seas, the cognate science of lakes being termed Limnology, and that of rivers Potamology.

The form of the ocean basins, like that of the land, is the concern of physical geography (see GEOGRAPHY).

Seas. Practically, however, the form of the sea-bed is so intimately associated with all the phenomena of the water resting on it that both have to be considered together. The primary division of the hydrosphere into oceans and seas is arbitrary, but in each case some parts of the boundary are natural limits. A sea is a detached or partially detached portion of the hydrosphere of considerable size. Elaborate classifications of seas have been proposed, according to their relations to the open oceans and to the land; but the simplest, that of Sir John Murray, suffices for most purposes. A sea may be (1) entirely surrounded by land (*inland*), like the Caspian; (2) enclosed by land, except for a single entrance (*enclosed*), like the Mediterranean; (3) partly enclosed by land, but with two or more openings (*partially enclosed*), like the North Sea or Caribbean Sea; to which we may add (4) divided from the general mass of the ocean only beneath the surface (*barred off*) like the Norwegian Sea. In a few instances the name sea is given to a part of the ocean distinguished from the rest by physical peculiarities, but not bounded in any part by land, such as the Sargasso Sea.

The largest divisions of the hydrosphere are termed oceans, but it is just as difficult to distinguish an ocean

Oceans. from a sea as it is to distinguish a continent from an island. From the time of the first circumnavigators three great oceans running from north to south have been recognized—the Atlantic, between Europe-Africa and America; the Indian, between Africa and Malaysia-Australia; and the Pacific or South Sea, between Asia-Malaysia-Australia and America. The extent and limits of the oceans to north and south were variously given by different writers, and much confusion resulted. The question of nomenclature was considered by the Royal Geographical Society in 1845, when a committee drew up provisional rules which were never formally adopted, but nevertheless came into current use.[1] They recognized an Arctic and Antarctic Ocean lying wholly within the respective polar circles, and the water area between the north and the south polar circles was divided into the Atlantic, Pacific, and Indian Oceans by the continental coasts and arbitrary meridians. The advance in physical knowledge of the oceans has shown it to be desirable to recognize the great ring of unobstructed water girdling the southern hemisphere, south of the continents, as a natural unit, and it has accordingly become common, if not yet usual, to place the limits of the Atlantic, Indian, and Pacific Oceans at 40° S., and to call all the water south of that parallel the Southern Ocean. The Southern Ocean may be considered to stretch to the edge of the Antarctic ice, or, if preferred, the southern portion, within the Antarctic circle, may retain its old name. From several points of view it is advisable to call the Arctic Ocean a sea, and to view it as an extension of the Atlantic basin. The chief physical differences between oceans and seas are due to the freedom of the former from the influence of land, which dominates the character and the circulation of the water in the latter.

Historically, it may be noticed that the early Greek antithesis between the Mediterranean Sea surrounded by the habitable land, and the Ocean River surrounding the known world, gave place gradually to the idea of an Ocean Sea, in which the various continents formed islands or parts of islands, and the term Ocean Sea only went out of use when the three great divisions of Atlantic, Indian, and Pacific Oceans were recognized. The distribution of depth in the ocean was very vaguely known so long as the question was merely one of scientific curiosity, although ingenious apparatus for ascertaining the depth had been devised by Robert Hooke and Stephen Hales in the 17th century, and the use of the lead in shallow water early became habitual with sailors. When the question of laying submarine telegraph cables gave practical importance to a knowledge of the form and temperature of the sea-bed about 1855, the methods of deep-sea sounding and temperature-taking were rapidly improved, and scientific oceanography may be said to date from that period.

History of oceanography. The development of oceanography up to 1870 may be summarized in a few lines. The speculations of the Greeks and the crude observations of the European navigators of the 15th and 16th centuries led to no definite knowledge beyond the existence of the trade winds and a few facts as to currents and tides. Athanasius Kircher in 1664 made the first generalization as to the circulation of the waters of the ocean, illustrated by a map of the surface currents; but so little was then known of the depth or configuration of the ocean-bed that he freely introduced subterranean channels to account for local currents, and even suggested a great tunnel through the axis of the Earth as a sort of mainspring to actuate the perpetual motion of the surface water. H. B. de Saussure in 1780 made the first fully satisfactory observations of temperature at a great depth by means of slow-change thermometers, and he drew up a fairly comprehensive scheme of oceanic research.[2] Major Rennell (1742–1830) placed the slowly increasing knowledge of ocean currents on a scientific basis, and the numerous Arctic voyagers of the early part of the 19th century made isolated and sometimes important observations. Sir John Ross in 1818, by means of his "deep-sea clamms," was the first to obtain large samples of mud from great depths, and to prove the existence of organic life on the floor of the ocean.

The adaptation of Sixe's self-registering thermometer, for use in deep water by the device of surrounding the bulb by an outer glass sheath partly filled with mercury or alcohol, was first tested in 1857 on board H.M.S. *Cyclops*. This marked an era in oceanographical research. It was, however, the American naval officer M. F. Maury who did most to direct attention to the science of the sea, and his fascinating *Physical Geography of the Sea*, first published in 1856, continues to be one of the most inspiring scientific works, although the theories of oceanic and atmospheric circulation it puts forth have proved untenable. Maury organized oceanic research under the auspices of the United States Hydrographic Office, and this led to the marine services of other countries taking up similar work, which has been carried out with remarkable success by the British Meteorological Office and the German Marine Observatory.

In 1839 the British Association appointed a committee under the direction of Professor Edward Forbes charged with the investigation of the marine fauna of the British seas. The activity of this committee extended over many

[1] See *Geographical Journal*, i. (1893), p. 535.

[2] *Voyages dans les Alpes*, tome iv., Neuchâtel, 1796.

years, and aroused much interest in the bathymetrical distribution of life. Dr W. B. Carpenter took up the study of the physical conditions and the life of the oceans with great enthusiasm, and as a result of his efforts small expeditions were sent out by the British Government on the *Porcupine*, *Lightning*, and *Shearwater*, to different parts of the North Atlantic between 1868 and 1870.

In 1872 the British Government were induced by the Royal Society to send out H.M.S. *Challenger* for a three years' cruise expressly for the purpose of investigating the physical conditions of the ocean and the distribution of marine life. This was an epoch in oceanography, resulting in a vast increase of knowledge and in the progressive improvement of apparatus and methods of research. Since the return of the *Challenger* in 1876 the most important advances of oceanography, in addition to those resulting from the cruises of surveying and telegraph ships, have been due to the Norwegian North Atlantic expedition in the *Vöringen*, 1876–78, the French *Talisman* and *Travailleur* expeditions in the Bay of Biscay, 1880–83, the foundation of the Scottish Marine Station by Sir John Murray in 1884, the Russian voyage of the *Vityaz* in the Pacific in 1886–89, the explorations of the Austro-Hungarian ship *Pola* in the Mediterranean and Red Sea, 1890–98, the voyages of the Prince of Monaco in the North Atlantic since 1885, the researches of Professors Ekman and Pettersson on the Baltic since 1885, drift of the *Fram* in 1893–96, the Danish *Ingolf* expedition in 1896, the cruises of the United States Fish Commission steamers *Blake* and *Albatross* in the Atlantic, Caribbean Sea, and Pacific, 1877–1901, the voyage of the German ship *Valdivia* through the Atlantic, Southern, and Indian Oceans in 1898–99, and that of the Dutch *Siboga* in the Malay Archipelago in 1900.[1]

Methods and Apparatus.—The study of the ocean floor and of the intermediate depths of water has to be carried on under the disadvantage of inaccessibility; all information must be obtained by means of instruments attached to a single line of rope or wire, and sunk far out of sight. Attempts to employ bathometers for measuring depths without the use of a sounding line have been made for over 400 years, but they have hitherto failed in practice, and no efforts to employ two separate lines to work apparatus at a great depth have ever succeeded. The number of ingenious contrivances, and even of successful instruments, for oceanographical work is so great that it is impossible to give details of any special forms in this article; all that can be attempted is to indicate the principles on which the most satisfactory forms are constructed.

Deep-sea sounding.

The simplest operation is that of ascertaining the depths of the water at a given point. For shallow water, down to 100 fathoms, the familiar hand-lead (weighing 7 lb) or the deep-sea lead (weighing 14 lb) and hemp line may be employed without inaccuracy. In very deep water the amount of line which has to be used is sufficient to float the lead unless the latter is made very heavy, and if very heavy the line is apt to break on attempting to heave it in. Many experiments were made by Maury to overcome this difficulty, but some of them gave very wild results, and depths of 10 miles and over were reported in different parts of the ocean. Midshipman Brooke of the U.S. navy invented the principle, already foreshadowed by Cusanus in the 15th century and by Hooke in the 17th, of using a heavy weight so hung on the sounding tube that it was automatically released on striking the bottom and left behind, while the light brass tube containing a sample of the deposit was easily hauled up. This principle has been universally adopted for deep soundings, and is now applied in many forms. An essential feature is the tube for bringing up a specimen of the bottom, as without such proof of its completion no sounding can be accepted. The weights used as a sinker are usually cast-iron segments, which may be built round the sounding rod, and for great depths they weigh 100 lb or more. The next great advance consisted in the substitution of steel wire for hemp rope, thus practically eliminating friction and permitting a great length of line to be stowed in a small space. The disadvantage of wire is that the line is apt to snap when a kink forms, and hence there is a considerably increased risk of loss of instruments. A stranded wire or wire-rope in which a number of very fine wires are twisted together as in a hawser is free from this objection, and can be made very little bulkier than the single steel wire. Various bronzes have been used instead of steel, but while they have the advantage of greater toughness and flexibility, they are very costly. The depth may be measured either by a registering block, *i.e.*, a pulley fitted with a train of index wheels on the principle of a gas-meter, or by a revolution-counter on the drum on which the wire is wound. The indicator shows the depth and the rate at which the line runs out, a sudden increase in the time intervals being the usual sign that the bottom has been reached. The Lucas and other recent sounding machines automatically stop the running out of the wire as soon as the bottom is reached. The wire is usually hauled in by a steam engine, but the experience of the *Valdivia* expedition showed the great advantage of using an electro-motor, especially in polar seas where steam-pipes are apt to be frozen. The instruments usually attached to the sounding line are water-bottles for collecting samples of water, and thermometers for ascertaining its temperature.

Water-bottles ought to be constructed in such a way that they may be filled with water at any given depth and securely closed as soon as filled, so that no interchange can take place between the water inside and outside. They are usually made of brass, and are technically divided into valve, stop-cock, and slip water-bottles.[2] The first class depends on the principle of two valves opening upwards, which remain open while the bottle descends and allow a continuous current of water to pass through the instrument, but when one begins to pull up the water-bottle the valves are closed by the pressure of the water outside, and the sample then inside is brought up. The only form now in use is Sigsbee's "Water-cup," in which the valves are locked after the first few fathoms of ascent by the action of a small screw propeller which rotates freely during the descent. In Wille's water-bottle the receiver is a spiral tube open at both ends during descent, and locked on the ascent by a propeller at each end. The stop-cock water-bottle as used on board the *Challenger* has the form of a long brass tube closed by a very large stop-cock at each end. This was sent down open, and water passed freely through, but when one commenced to pull it up the resistance of the external water acting on a hinged pressure-plate actuated a lever working on both stop-cocks and closed them simultaneously, shutting in the water which it then contained. A modification of this instrument has been introduced by its inventor, Mr J. Y. Buchanan, by which the stop-cocks may be closed by a weight slid down the line, and thus secured more definitely at any particular depth. The drawback to all these forms is that they collect a mixture of the water from a considerable range of depth, and are thus quite unsuited for use where layers of different salinity are superimposed, or in shallow water. Slip water-bottles are more satisfactory in this and in other ways. The best forms consist of a metal cylinder open at both ends and of uniform diameter throughout, hung so that the water can pass freely through, and capable of being detached at any given depth so as to fall against a fixed base and be closed by a top plate, all three parts becoming automatically united. On the *Challenger* the cylinders of the slip water-bottles were very heavy, with finely ground surfaces, which rested upon correspondingly ground fixed portions of cones. In more recent forms, such as Mill's for shallow water and Pettersson's for deep water, the cylinder is locked against indiarubber discs covering the fixed metal plates. The mechanism for releasing the cylinder is usually actuated by a weight slipped along the line which depresses a lever or spring by its impact; or else by a small screw propeller which revolves freely during the descent, but on being drawn upwards engages with a bolt, and in a certain number of turns, corresponding to a definite vertical distance, sets free the cylinder. The use of a propeller can be justified in deep water alone, and there only in default of more serviceable gear. The grand difficulty in the use of all apparatus which must act at a great distance from the observer and out of his sight is to know whether the action has or has not taken place at the proper position. In shallow water the closing of the water-bottle can be distinctly felt on the line, and it would be very desirable if some method could be found for detecting the impact through a wire at the greatest depth.

Deep-sea thermometers.

The most important physical observation in the deep sea is that of temperature, the problem here being to devise a thermometer which shall bring to the surface a record of the actual temperature at a given depth. One of the most satisfactory, though by far the slowest, of the methods is the use of a slow-action thermometer, *i.e.*, an ordinary thermometer, the bulb of which is embedded in a relatively large mass of badly-conducting material—wax, as originally used by de Saussure in the Mediterranean in 1780; gutta-percha and ebonite, as employed by the German observers on the North Sea and Baltic a century later. This thermometer, to be really satisfactory in its working, should be left immersed at the depth from which a

[1] For a historical summary of oceanography see Sir John Murray, "Summary of Scientific Results," First Part, in the "*Challenger*" *Reports*, London, 1895.

[2] For early forms see H. R. Mill, "On Water-bottles," *Proc. Roy. Soc. Edinburgh*, xiii. (1885), p. 539.

reading is desired for several hours, and its bulb will retain that temperature long enough to allow it to be hauled up and read in the air. An elegant and quick-working adaptation of this principle is found in the Pettersson-Nansen insulating water-bottle as worked out in 1900. This is a slip water-bottle, the cylinder of which is made up of a number of concentric metal tubes, so that when the instrument closes it shuts in a series of entirely separated concentric layers of water, each of which must have its temperature changed in turn before any effect can be produced on the water in the central tube, in the middle of which the bulb of a sensitive thermometer is placed, the stem projecting through the lid. Experiment has shown that in cool climates the central core of water does not change one-hundredth of a degree for many minutes after the water-bottle has been exposed to the temperature of the air, and in the opinion of Professor Nansen this is by far the most accurate method of obtaining deep-sea temperature.[1]

The method hitherto most frequently used is to employ a registering maximum and minimum thermometer on the Miller-Casella modification of Sixe's pattern. When made of a large size with an arbitrary scale of millimetres engraved on the glass, as suggested by Mr J. Y. Buchanan, this thermometer may give the extreme temperatures during the period of its immersion with considerable accuracy. The bulb has to be protected from pressure by an outer bulb partially filled with liquid, and the steel indexes (which are set by means of a magnet) have to be provided with springs which will enable them to hold their position in spite of the tremor of the line in heaving in. The drawback to all maximum and minimum thermometers is that the temperature at a given depth can only be deduced from a series of other temperatures, and in some possible distributions of warmth cannot be ascertained at all.

Outflow thermometers of an elaborate form were used by Aimé as long ago as 1840, but Negretti and Zambra's deep-sea thermometer, which was perfected after the return of the *Challenger*, was the first to give satisfactory results with simple working. Its essential feature is that after the thermometer has attained the temperature of its surroundings it is turned over (see THERMOMETER), the column of mercury outside the bulb breaks off at a little constriction of the tube, and runs down into the inverted upper end, which is graduated so as to be read in that position. The inversion is secured either by means of a screw propeller, as in Magnaghi's frame, or preferably, when the depth permits, by means of a lever worked by a weight slipped down the line, as in the frames devised by Rung, Mill, the Prince of Monaco, and others. The worst drawback to the Negretti and Zambra thermometer is that in deep water the vibration of the wire line in heaving in is apt to shake little jets of mercury out of the overflow reservoir outside the bulb into the tube, and so to make the readings too high. This difficulty has been overcome by Herr Martin Knudsen, who employed on the *Ingolf* expedition a thermometer the bulb of which lies parallel with the stem, and when the instrument is inverted, rests with its orifice upwards instead of downwards; hence it is impossible for any amount of shaking to pass mercury from the bulb to the tube after inversion. The importance of protecting the whole thermometer from pressure, and not merely the bulb, is now recognized, and the Negretti and Zambra and Knudsen thermometers are entirely enclosed in a strong sealed glass tube. The pressure below the surface may be roughly estimated as one ton per square inch for every 1000 fathoms of depth.

Electrical methods of registering deep-sea temperature have frequently been tried and abandoned, but the platinum resistance thermometers of Professor Callender appear likely to lead to good results at sea, as they have been found practicable in the deep lakes of America. Resistance thermometers were experimented with by Knudsen in 1900 in conjunction with an electrical apparatus for finding the salinity by the resistance of the water *in situ*, the balancing of the resistances being effected by the use of a telephone instead of a galvanometer.[2] The resulting curves, both for temperature and salinity in shallow water, appear to show that the method is of value.

In discussing thermal (as distinct from temperature) changes in water, Mr Buchanan has pointed out the convenience of reckoning by the fathom-degree or metre-degree, both units being practically the same, if the Fahrenheit scale is used with the fathom and the centigrade scale with the metre, since a fathom exceeds a metre in the same ratio as a centigrade degree exceeds a Fahrenheit degree.

The physical or chemical examination of sea-water can only be completely carried out in a laboratory on shore when results of the highest precision or complete analyses are required; but much work may be done on board ship. The density of sea-water is usually expressed as specific gravity, or the ratio to the density of pure water, which is taken as unity. The temperature of both is taken as 0° C. in pyknometer observations, on account of the convenience of making direct measurements at that temperature. But in hydrometer work it is more convenient to take as the standard some temperature near the ordinary temperature of the air, either 60° Fahr. (15·6° C.) or 17·5° C. being usually chosen. The comparison may be made either with pure water at the same temperature, or at its temperature of maximum density, *i.e.*, 4° C. It is necessary, therefore, to state the exact meaning of specific gravity in every case. This is usually expressed in the form $S\frac{t}{T}$, where t is the standard temperature of the sea-water sample, and T that of the pure water with which it is compared. The *Challenger* specific gravities are published in the form $S\frac{15{\cdot}6^\circ\,C.}{4^\circ\,C.}$, and those of most of the later Continental expeditions as $S\frac{17{\cdot}5^\circ\,C.}{17{\cdot}5^\circ\,C.}$ Any of these forms can be converted into the others by calculation. The salinity can always be expressed without ambiguity by the amount of chlorine or of total salts, the latter being preferable, and the most convenient form of expression being in parts per mille. It is very desirable that this datum should be given in all statements of results, by whatever method they are obtained. The chemical study of sea-water at sea is practically confined to the volumetric estimation of chlorine and of alkalinity and the collection of dissolved gases, the analysis of the gases and determination of the sulphates or other constituents in the water sample being made in a laboratory on shore. The direct determination of total salts is rendered troublesome by the decomposition of the magnesium salts on evaporation, and the variations in the composition of the salts are usually so slight that extraordinary precautions must be taken in order to detect the differences. The salts of sea-water taken from enclosed seas or near the mouths of rivers do, however, show some variability in composition. The object of determining the alkalinity is that it gives a measure of the carbonic acid in actual combination with a base as normal carbonate, the alkaline reaction of sea-water being due to the carbonates it contains. When kept in glass bottles sea-water is apt to change in alkalinity on account of chemical action on the glass. The extraction of gases from sea-water on board ship, and the sealing of the samples in tubes, is a troublesome and somewhat delicate operation. If a sample of sea-water is preserved in a stoppered bottle its gaseous contents are sure to undergo change in consequence of changes of temperature, while even if the sample be sealed up in a clean glass tube the dissolved gases are altered in nature and amount by the decomposition of the minute plant and animal organisms which the water contained. By Pettersson's method two specimens of each sample of sea-water, brought up by his insulating water-bottle without change of temperature, are taken in glass tubes which have been previously coated internally with mercuric chloride (corrosive sublimate), exhausted of air, and sealed. The tip of the tube is broken off in the water-bottle, and when filled the tube is again sealed up; the corrosive sublimate kills all the organisms and prevents their decomposition, and the sample keeps unchanged. One tube is used for determining the absorbed oxygen and nitrogen, the other for the carbon dioxide. The substantial uniformity of the composition of the salts of ocean-water makes it possible to determine the salinity (*i.e.*, the proportion of total salts to the mass of water) quite accurately by determining any one of the chemical constituents. That selected is always the total halogen estimated as chlorine.

Physical and chemical study of sea-water.

The relations of salinity to density at constant temperature and of density to temperature at constant salinity have been worked out with great accuracy by Professors Thorpe and Rücker, Professor Dittmar, Herr Martin Knudsen, and others. The problem of finding both density and salinity may thus be solved by measuring directly either the density or the total halogen. If p stands for the salinity expressed in parts per thousand by weight (*i.e.*, 1 gram of total salts in 1 kilogram of sea-water), $S\frac{t}{T}$ for specific gravity at temperature t° compared with pure water at temperature T°, and χ the chlorine (total halogen) in grams per kilogram of sea-water, the relation between chlorine and salinity is usually given as—

Relation of density, salinity, and chlorine.

$$p = 1{\cdot}83\,\chi - 0{\cdot}0012\,\chi^2,$$

but Knudsen finds the simpler formula $p = 0{\cdot}03 + 1{\cdot}81\,\chi$ to give excellent results. The relation between salinity and specific gravity is—

$$\sigma\left(S\frac{t}{T} - 1\right)$$

where σ is the salinity constant. In the case of $S\frac{17{\cdot}5^\circ\,C.}{17{\cdot}5^\circ\,C.}$, $\sigma = 1300$; but for $S\frac{15{\cdot}6^\circ\,C.}{4^\circ\,C.}$ the value of σ varies with the value of S, being 1410 for $S\frac{15{\cdot}6^\circ}{4^\circ} = 1{\cdot}010$ and 1340 for $S\frac{15{\cdot}6^\circ}{4^\circ} = 1{\cdot}028$.

[2] *Beretning fra Kommissionen for videnskabelig Undersogelse af Danske Farvande*, vol. ii. part 3. Copenhagen, 1900.

The determination of chlorine is simple, accurate, and direct, and can easily be carried out by titration on board ship, the standard solutions being previously prepared on shore. The measurement of density or specific gravity demands more attention. The only method admitting of the highest accuracy is weighing on a delicate balance a measured portion of distilled water at a constant temperature (usually 0° C.) in a glass tube known as a pyknometer, and again weighing the same tube filled to the same point with the sample of sea-water at the same standard temperature. This is an operation requiring skill and care, and as it must be conducted in a laboratory on shore, the samples require to be secured in such a manner as to prevent any change occurring in the salinity.

The use of hydrometers or areometers is much more simple, and they are as sensitive as the pyknometer, though not so trustworthy. They have the immense advantage of not requiring a rigid table, and thus being capable of employment at sea in moderate weather. The usual form of instrument consists of a cylindrical glass body of considerable size, terminating above in a narrow glass stem, immersed in a sample which comes within the range of salinity for which the instrument is adapted. The scale is usually graduated so as to enable specific gravity to be read directly, the temperature of the water being ascertained at the same time, and the reading reduced to a standard temperature by reference to a table of corrections. Mr J. Y. Buchanan introduced an extremely sensitive and accurate form on the voyage of the *Challenger*, and has since greatly improved it.[1] The stem contains a scale divided into millimetres, and the specific gravity is obtained by the use of tables. The instrument is absolute, inasmuch as its weight is determined beforehand, and several accurately weighed coils of wire are provided which can be used to increase the weight of the whole instrument by small increments in such a way that a series of half a dozen readings may be made at different parts of the scale in a few minutes. The volume of the body of the hydrometer and of each millimetre of the stem may be previously ascertained by experiment in distilled water, and its expansion with temperature determined in the same way. Thus each reading gives the volume of the instrument immersed, and the total weight of that volume of the water under examination. The temperature correction can be much simplified by using the hydrometer in distilled water at the temperature of the air before placing it in the sample of sea-water at the same temperature, and thus comparing directly the weight of equal volumes of sea-water and pure water. By this process the chief difficulty in the use of the hydrometer—the effect of surface tension—is eliminated if the surface of the sea-water and pure water be equally clean. Many oceanographers, however, using direct-reading hydrometers, have found the uncertainty due to the variations of surface-tension so serious as greatly to detract from the value of the instrument.

Hydrometers.

The total-immersion hydrometer is sometimes used to evade surface tension: it is a cylinder with a very short stem, which is loaded by the addition of coils of wire until it just sinks in the water, the final adjustment being made either by titration with sea-water and distilled water, as in Pisati's method of 1890, or more elegantly, as in Nansen's method of 1900, by varying the temperature of the water in the jar by a fraction of a degree, so as to fix the exact temperature at which the immersed hydrometer and the water have the same density.[2] Experiments have been made with the refractometer to measure the specific gravity of sea-water by the refractive index, which is a function of the density. The method has the advantages of being independent of the motion of the ship, and requiring only a minute quantity of water as a sample. Electrical resistance has also been utilized; in Tornøe's method, as tested on the *Fram*, the resistance of a small sample was observed, and the instrument calibrated by experiment on standard solutions; in Knudsen's method the variations in resistance due to salinity are measured *in situ*, and, if this is found practicable in deep water, it will constitute an immense advance in oceanography.

Transparency and colour.

The transparency of sea-water is usually measured by sinking a white enamelled disc, and noting the depth at which it ceases to be visible. The test is a rough one, the depth of visibility depending not only on the transparency but also on the amount of sunlight and the powers of vision of the observer. The colour of sea-water as seen on looking through the depth of a fathom or so at a white disc may be measured with a considerable degree of approximation by the use of Forel's xanthometer. Assuming that the water of lakes varies from pure blue to clear green, Professor Forel constructed a scale of which the extremes were solutions of copper sulphate in ammonia for blue, and of neutral potassium chromate for yellow, the intermediate tints being supplied by mixtures of the two in definite proportions. Dr W. Ule, with the advice of Professor von Drygalski, introduced a brownish tint (a solution of cobalt sulphate) in order to measure the gradations which actually occur in the ocean.[3]

Measurement of currents.

The measurement of ocean currents has been attempted in many ways, none of which can be looked upon as wholly satisfactory, especially in deep water and in the open sea. Rapid surface currents, exceeding say 1 mile per hour in velocity, may be easily measured by watching the drift of a buoy from an anchored ship or mark. It is difficult, however, to anchor even a small vessel in water exceeding a few hundred fathoms in depth. Under-currents are much more difficult to investigate. Their direction can usually be ascertained by the use of a current drag, exposing two large surfaces at right angles to each other and both in a vertical plane. This, when sunk to the proper depth and attached by a line to a float offering a very small surface, will show, with reference to a fixed mark, a certain approximation to the movement of the layer in which the drag is immersed.[4] A more sensitive arrangement is a light drag hung by a wire from a spar projecting over a boat which is kept by the use of the oars in such a position that the wire remains parallel with a plumb-line hung from the end of the same spar. When this is done, the boat moves on the surface in the direction towards which the water of the undercurrent flows and at the same rate.

Much attention has been devoted to the construction of current gauges intended to record the directions and velocities of currents at great depths by rotating vanes, meter-wheels, and other mechanical devices; but the results have not as yet rewarded the labour and ingenuity expended.

The slow-moving currents which carry out most of the superficial circulation of the oceans may be roughly measured in calm weather by the difference between the observed and calculated positions of a vessel, and, in certain circumstances, by the use of floats. Floats are only of great value for determining the speed of currents in the case of oceans the coasts of which are thickly peopled by an intelligent population, and at the present time the North Atlantic alone can be profitably investigated in this way.

For merely testing the direction of currents, without estimating their rate, floats are always useful, and Mr H. C. Russell has shown that much information of the drifts even in the Southern Ocean may be thus obtained. It is essential that a current float should be submerged so as to present as little surface as possible for wind to catch; it should be strong enough not to be damaged when thrown on shore, and sufficiently conspicuous to attract the attention of a passer-by. The experiment of using glass balls of specific gravity a little greater than that of sea-water, to roll along the bottom, in places like the North Sea, where they might be recovered by trawlers, and thus to trace the movements of the deepest layers of shallow seas, has not as yet been fairly tried. The interpretation of current-floats is really satisfactory only when many have been launched simultaneously, or in close succession, along definite lines. Then the first to be found sets a minimum velocity for the current, and the direction of the current may be inferred by laying down on a map the line joining the launching place and the point at which the float nearest to it was found, drawing the course of the next nearest parallel to the first so far as it goes, then straight to its destination, and so with the rest. Treated thus, the "bottle charts" of the North Atlantic give an excellent idea of the superficial circulation of the waters.[5]

Accidental floats, like derelicts or logs, and natural floats such as icebergs and volcanic ashes, often map out the main lines of a current very clearly; and the plankton, or drifting organisms, may also be looked upon as ear-marking definite bodies of water. In the same way, temperature, salinity, and gas-contents are of value in suggesting, and sometimes in demonstrating, the place of origin of the sea-water under examination.

Biological observations.

The apparatus for scientific biological research at sea has been for the most part developed from that used in fishing. The dredge and trawl differ little from those of the oyster-boat and the trawling smack. The Prince of Monaco has introduced a sort of gigantic lobster pot, with the happiest effect in very deep water. The continuous study of plankton on a voyage is usually carried out by straining the sea-water as it is pumped on board for the use of the condensers or to fill tanks. The tow-net, however, a strong silken or canvas bag drawn after the ship to capture the drifting organisms, is purely scientific in its origin. The surface tow-net has been developed into a series of ingenious devices for obtaining specimens from any depth, or even just skimming the mud of the bottom, without catching anything from an intermediate position.

Results of Oceanographical Study (see also the articles on the different oceans).—On account of the small number and irregular distribution of deep-sea soundings, except in the North Atlantic, it is impossible to generalize with any confidence as to the form of the ocean hollows. It is, however, known that the relief of the ocean floor is almost always more gentle and less varied than that of the land. Being protected by the water from the rapid sub-aërial erosion which sharpens the features of the land, and subjected to the regular accumulation of deposits, the whole ocean floor has assumed some approach to uniformity. The continental slopes and the elevations from which some islands rise are, however, often as steep as land slopes. The general arrangement of depths is unsymmetrical; as a rule, the deepest depressions occur near the margins of the oceans, while the greater and more continuous elevations of the sea-bed occur near the centre, and are usually marked on the surface by islands which rise from them. The average depth of the oceans, as calculated by Karstens in 1894,[1] disregarding the shallow seas, is 2170 fathoms, but the actual average depth is probably somewhat greater. Depressions exceeding 3000 fathoms in depth occur in four places in the Atlantic, near the continental slopes; in the angle between the Sunda Islands and Australia, in the Indian Ocean; and in the centre and north-west of the Pacific. The only extensive area over 4000 fathoms in depth is a narrow trough in the north-west Pacific along the oceanic slope of Japan and the Kurile Islands. Individual soundings exceeding 5000 fathoms have been obtained in various parts of the Pacific, the deepest on record being 5269 fathoms at a point east of the Ladrones. A sounding of over 4000 fathoms reported by Sir James Ross in the Southern Ocean, south of the Atlantic, has never been verified, and a definite object of the Scottish Antarctic expedition (1902) was to test the existence of a great depression in that region. The distance of the remotest part of the ocean (as deduced by Rohrbach) from the nearest continental land exceeds 3000 miles only in the South Pacific in 20° S., 130° W.; but if islands be taken into account, De Windt shows that no part of the ocean is more than 1300 miles from land, the remotest spots occurring in the centre of the North Atlantic, at 25° N., 43° W., and at three points in the eastern Pacific, respectively 15° N., 135° W.; 8° S., 115° W; and 45° S., 106° W.[2]

Ocean basins.

The question of sea-level is involved in the comparison of depths, for in all calculations of vertical relief, either above or below the surface, the surface of the ocean is assumed to be uniform. The attraction of the elevated portions of the lithosphere, granted that the whole crust were of uniform density, should cause a rise of the level of the sea along the shores. The survey of India demonstrated that the sea-surface was 300 feet farther from the centre of the Earth at the head of the Arabian Sea than at Ceylon, presumably in consequence of the gravitational attraction of the Himalayan range. Geodetic operations of the necessary delicacy to measure such differences of absolute level have been made as yet in few parts of the Earth, and the problem of the true form of the geoid remains to the future. Minor variations in level between enclosed seas or gulfs and the open ocean may be due to the set of the tidal streams, the excess of rainfall or evaporation in particular areas, the melting or the formation of sea ice, or to the direction and force of the prevailing winds. (For the movements of the ocean due to the differential gravitational attraction of external bodies in the solar system, see TIDES.)

Sea-level.

The salinity of the water of the oceans, as mapped by Mr J. Y. Buchanan, Dr A. Buchan, and others, shows a general banded arrangement. In the far north and the far south, bordering the polar ice, the surface water is comparatively fresh. Two zones of maximum salinity occupy the trade-wind regions and are crossed by the tropics, while a belt of low salinity lies a little north of the equator. The average salinity of the whole surface of the oceans is about 35·0 per mille, the areas of high salinity in the tropics reach about 37·0 per mille as a maximum, and near the edge of the ice the salinity is only about 33·0. Enclosed seas in dry regions, like the Red Sea and Mediterranean, may have a salinity approaching 40·0, while seas in a rainy climate, or those fed by many rivers, such as the Baltic, may have an average salinity under 30·0. The high salinity of the trade-wind areas is due to the rapid evaporation from the surface; while the check to evaporation, perhaps as much as the heavier precipitation of the calms, accounts for their lower salinity. The deeper water of the ocean is usually somewhat fresher than that on the surface, although, on account of lower temperature, it is, at equal pressures, actually denser.

Salinity of the oceans.

The salts of average ocean water differ greatly from those of any "fresh" water, and the composition is practically constant so far as regards the open ocean, the following table (from Dittmar) representing a probable grouping of the salts in the proportion in which their constituents occur.

Composition of Ocean Salts.

Sodium chloride	77·8
Magnesium chloride	10·8
Magnesium sulphate	4·3
Calcium sulphate	4·1
Potassium sulphate	2·5
Magnesium carbonate	0·3
Magnesium bromide	0·2
Total	100·0

A complex solution of this nature exercises a certain amount of chemical action on the substances exposed to it, and is also acted upon in various ways by the life-processes and the decomposition of organisms. The salts of average river water contain over 50 per cent. of calcium and magnesium carbonates, and 10 per cent. of free silica, with only about 2 per cent. of sodium chloride, thus differing very greatly from those of the sea. There has been much speculation as to whether the salts of the ocean are the result of the action of the hot water which first condensed on the surface of the cooling Earth, or the product of the concentration of river water, changed by chemical and vital processes. On the latter assumption, the present salinity of the ocean has been taken by Professor Joly as a measure of the age of the Earth. In ocean water the only distinct local variation of saline composition is a very slight increase in the proportion of dissolved carbonates and calcium salts with increase of depth; but in the water which is contained in the muds, oozes, and clays of the ocean floor there is a remarkable difference. Sir John Murray and Mr Irvine have shown that the sea-water mixed with the blue muds, the typical shallow water terrigenous deposit, is not only of higher salinity than the overlying water, but contains a much smaller proportion of sulphates and thus a relatively higher proportion of chlorides. The chemical action of the iron in the mud reduces sulphates producing ultimately ferrous sulphide, to which the dark colour of the mud is due. When iron is deficient to take up the reduced sulphur, sulphuretted hydrogen is produced, as in the deep water of the Black Sea, where this gas occurs in a proportion as high as 6·55 cubic centimetres per litre of water.[3] Researches have shown that the presence of bacteria in the mud may be a necessary accompaniment, and possibly the cause of this chemical action.

The chemical action of the salts of sea-water on the organic matter of deposits produces decompositions which lead in some cases to the formation of petroleum. Chemical precipitation appears to cover the floor of the sea in some places with a deposit in the form of a stony crust, the physical action of which by the diffusion through it of the different salts is held by Dr Natterer of the Austrian *Pola* expedition to exercise a considerable influence on the chemical processes which occur in the deep sea.

Sea-water in contact with the air absorbs oxygen and nitrogen in an amount dependent on the temperature and salinity of the water, the solubility of the gases and the proportion in which they occur in the atmosphere. Fully aërated normal ocean water at 32° Fahr. contains 8·2 c.c. of oxygen and 15·6 c.c. of nitrogen per litre, the amount absorbed diminishing as the temperature rises: thus at 70° Fahr. only 5·2 c.c. of oxygen and 10·0 of nitrogen are absorbed. It will be observed that on account of the greater solubility of oxygen the dissolved air in sea-water contains one-third of its volume of that gas, instead of only one-fifth, which is the proportion in the atmosphere. The action of living organisms in the water alters the proportion of oxygen and carbon dioxide, while that of nitrogen remains practically unchanged, and is proportional to the temperature at which the atmospheric gases had been absorbed at the surface. Hence when the nitrogen extracted from a sample of water has been estimated it is possible to tell the temperature which the water possessed when at the surface, and the amount of oxygen it originally contained. Herr Martin Knudsen has shown in the *Ingolf* expedition that wherever vegetable plankton (diatoms, &c.) is abundant the absorbed gases contain more oxygen than should normally be associated with the nitrogen, while where animal plankton prevails there is a deficit of oxygen and a larger quantity of carbonic acid. He has even been able to detect a distinct difference between the amount of oxygen in solution in sea-water by day and by night when diatoms are present. The extreme variability of the dissolved gases in the presence of living organisms explains many of the discrepancies in the earlier observations which were formerly very puzzling. The fact that no sample of ocean water, even from the greatest depth, has ever been found entirely without absorbed oxygen proves that the whole mass of water in the ocean is subject to a general circulatory movement. In deep enclosed seas, on the other hand, of which the Black Sea is the best example, the absorbed oxygen disappears and carbonic acid and sulphuretted hydrogen take its place. In such conditions the deep water is incapable of supporting life.

Absorbed gases in sea-water.

Carbonic acid in sea-water is troublesome to estimate because it rarely exists as a free gas; unless the proportion is very large it forms a bicarbonate with the normal carbonates which give to sea-water its alkaline reaction. The amount of carbonic acid present as normal carbonate is given by the alkalinity determination, and the total carbonic acid may be determined very accurately by Pettersson's method of boiling acidified sea-water under greatly reduced pressure. The amount of carbonic acid absorbed by sea-water from the air must always be very small; but the respiration of organisms may, in places, convert almost all the absorbed oxygen into carbon dioxide.

Carbon dioxide in sea-water.

Ammonia salts occur in a small and varying proportion in sea-water, as a result of the decomposition of organic matter, and they appear to play an important part in the secretion of calcium carbonate by marine organisms. The combined carbonic acid in sea-water, even if all associated with lime, would only allow a very small proportion of the total salts to exist in the form of calcium carbonate, while the amount of calcium carbonate withdrawn from the water by living organisms is relatively large. It has been shown, however, that ammonium carbonate generated from the waste products of animal life causes a precipitation of calcium carbonate from the sulphate or other salts of calcium present in sea-water, and this is probably the source of the immense quantities of calcareous matter accumulated as oceanic deposits or coral reefs.[1]

The classification of marine deposits generally accepted was arrived at by Sir John Murray and Professor Renard as the result of studying all the specimens brought back by the deep-sea expeditions of all nations up to the completion of the volume of the "*Challenger*" *Reports* dealing with the subject in 1891. The system of classification is twofold, according to origin and according to the depth of water.

Marine deposits.

Classification of Marine Deposits.

1. Deep Sea Deposits (*beyond 100 fathoms*).	Red Clay Radiolarian Ooze Diatom Ooze Globigerina Ooze Pteropod Ooze	I. PELAGIC DEPOSITS.—*Formed in deep water remote from land.*
	Blue Mud Red Mud Green Mud Volcanic Mud Coral Mud	II. TERRIGENOUS DEPOSITS.—*Formed in deep and shallow water close to land.*
2. Shallow Water Deposits (*in less than 100 fathoms*).	Sands, Gravels, Muds, &c.	
3. Littoral Deposits (*between high and low water marks*).	Sands, Gravels, Muds, &c.	

[1] R. Irvine and G. S. Woodhead in *Proc. Roy. Soc. Edinburgh*, xv. (1888), p. 308.

Estimated Area covered by Marine Deposits, &c. (Murray, 1889).

	Deposit.	Estimated Area in Sq. Miles.	Mean Depth, Fathoms.	Mean per cent. of $CaCO_3$.
Pelagic	Red Clay	50,290,000	2730	6·70
	Radiolarian Ooze	2,790,000	2890	4·01
	Diatom Ooze	10,420,000	1480	22·96
	Globigerina Ooze	47,750,000	2000	64·53
	Pteropod Ooze	900,000	1120	79·26
Terrigenous	Coral Sands and Muds	3,200,000	710	86·41
	Other Terrigenous Deposits, blue muds, &c.	27,900,000	1020	19·20

In the tropical oceans far from land, where the depth is less than 600 fathoms the typical pteropod ooze formed by the accumulation of the dead shells of molluscs, foraminifera, and other organisms which live at the surface may contain as much as 90 per cent. of calcium carbonate. With precisely the same surface conditions and with equal abundance of the same organisms in the water the deposits at a depth of about 2000 fathoms have only about 60 per cent. of calcium carbonate; the pteropod shells have disappeared, and the deposit is a globigerina ooze composed mainly of foraminifera. If the depth is 2400 fathoms, the proportion of calcium carbonate is reduced to 30 per cent., and at 2600 fathoms to 10 per cent., while in deeper water it is rare to find anything more than a trace of calcium carbonate in the deposit. This gradual elimination of calcium carbonate with depth points to solution by the sea-water under pressure, and perhaps in presence of carbonic acid due to decomposition of the organic matter in the shells. The slight increase of dissolved calcium salts in water from great depths tends to confirm this deduction. As the foraminiferal remains diminish, the residual deposit is named Radiolarian or Diatom ooze, if the skeletons or spicules of one or other of these silicious organisms are conspicuous, or Red clay if they are practically absent.

Pelagic deposits.

Red clay is the most remarkable as well as the most widespread of all deposits. It is made up partly of the disintegrated fragments of volcanic rocks, such as pumice, partly of the non-calcareous remnants of marine organisms which had lived on the surface, and partly of the teeth of sharks, and the ear-bones of whales, very often crusted over with, or even embedded in, masses of iron and manganese oxides which have been formed by the decomposition of the volcanic rock fragments. Crystals of zeolites, evidently produced *in situ*, are frequently found in the Red clay, and particles of meteoritic iron are also found in considerable quantity. The chemical changes which take place in deep-sea deposits are still very imperfectly known, but it is certain that the Red clay increases in thickness at an excessively slow rate. It is not to be supposed that the remains of more sharks or whales, or more meteorites fall to the ocean floor in the Red clay areas than in other places, but it is evident that if these remnants have been uniformly distributed over the oceans, the more rapid accumulation of the other deposits has covered them up, and they only remain unburied in the Red clay. Sir John Murray believes that not more than a few feet of Red clay have accumulated in the deepest depressions since the close of the Tertiary period, many of the sharks' teeth belonging to fossil species. The existence of this deposit is the main argument for the theory of the permanence of the oceanic and continental areas. Since no rock similar to Red clay has been found in any geological formation, it appears improbable that any part of the present land was ever an ocean floor in the abysmal area.

Red clay.

Terrigenous deposits pass from the stones and rough pebbles of the beach to shingle and sand between tide marks, and to fine mud on the outer margin of the continental shelf. The finer deposits are classified as sands or muds according to the size of the particles composing them. The composition of the deposits depends mainly on the nature of the rocks from which they are derived; thus, oceanic islands, if of coral, are surrounded by coral sands and muds, and if volcanic, by volcanic sands and muds. Off continental shores beyond the continental shelf, blue, green, or red

Terrigenous deposits.

muds are found, the colour of green mud being due to the formation of the secondary mineral glauconite on the grains of rock. Phosphatic nodules are also formed in the same positions by secondary decomposition. The blue and red muds owe their colour to the less or greater degree of oxidation of the iron they contain.

Distribution of deposits.

The distribution of the various kinds of deposit over the ocean floor has been provisionally mapped by Sir John Murray.[1] A belt of sea-bed averaging 200 miles in width around the land is occupied by terrigenous deposits, which are the only deposits found in seas. Only in exceptional cases, *e.g.*, where a great river carries its muddy water several hundred miles out to sea, or where a current floats icebergs laden with mud and boulders far from land, or where a prevailing off-shore wind bears desert dust half across an ocean, is this limit exceeded. Diatom ooze appears to be characteristic of the Southern Ocean, where it probably forms a ring north of the belt of terrigenous deposits which encircles the Antarctic ice. It is always most abundant under relatively fresh and cold water. The moderate depths of the temperate and tropical oceans, down to say 2000 fathoms, are typically covered with globigerina ooze, which closely resembles chalk in its composition, and may be said to be the characteristic deposit of the North Atlantic. Below the depth of 2500 fathoms Red clay prevails, its occurrence being clearly a function of depth, and in places the admixture of a small proportion of radiolarian spicules gives to it the name of Radiolarian ooze. Red clay is the typical deposit in the Indian and Pacific Oceans.

Temperature of sea-water.

The water of the ocean has a somewhat lower specific heat than pure water, Professor Thoulet having determined the specific heat of sea-water of salinity 35·0 per mille as 0·935, if that of pure water is 1·000. In other words, while 100 units of heat are required to raise the temperature of 100 lb of fresh water by 1°, only 93·5 units of heat are required to raise the same weight of sea-water through the same range. The thermal conductivity of sea-water is somewhat greater than that of fresh water; hence the sea heats and cools throughout its mass by conduction more rapidly than an equal mass of fresh water would do in like conditions. It must be remembered, however, that the difference is small, and that when compared with the difference between the thermal capacity and conductivity of water and of rocks or soil it is inappreciable. The greatest difference between fresh water and sea-water with regard to the action of heat is that, whereas fresh water on cooling contracts until 39° Fahr. is reached, and then expands until it freezes at 32°, sea-water contracts steadily until it freezes at a temperature of about 26° Fahr. for normal ocean water. There is thus no temperature at which water of uniform salinity becomes less dense as it cools.

Apparently neither the light nor the heat-rays of the sun penetrate deeper than 100 fathoms, so that changes due to heating and cooling by radiation are confined to the surface layers, the great mass of ocean water changing its temperature only by the very slow and almost imperceptible process of conduction or by the direct mixture by convection or mechanical agitation of bodies of water of differing temperature.

The surface water of the ocean has a very slight diurnal range of temperature at any point, the difference between the daily maximum and minimum not probably exceeding 1° Fahr. The *Challenger* found the extreme daily range for the North Atlantic to be only 0·8° Fahr., while that of the air resting upon it was 3·2°. Dr Schott, on a long voyage on a sailing ship through the Atlantic, Indian, and West Pacific Oceans, found the daily range of surface temperature in the tropics to be about 1·6° Fahr., while in temperate latitudes it was from 0·5° to 0·7° Fahr., his results thus confirming those of the *Challenger*. He also observed that the daily range was much reduced by strong winds and a cloudy sky.[2] The coldest sea-water known is that in the Arctic and Antarctic regions, which may sink as low as 26° Fahr. when freezing; the warmest is in the Red Sea and Persian Gulf, where maxima have been recorded as high as 96° Fahr.

The ocean surface is divided into zones of temperature roughly parallel to the equator, though on account of wind and currents the arrangement in some places is very irregular. The tropical zone has a high surface temperature (for the most part over 80° Fahr.), and an extreme range between the absolute annual maximum and minimum of less than 10°. It practically coincides with the belt in which reef-building corals can live. To the north and south the mean annual temperature falls off rapidly, and the annual range increases; until in the two circumpolar zones the average surface temperature is below 40° Fahr., and the extreme annual range is again slight (under 10°), on account of the low maximum.[3] The effect of great range of temperature on water of uniform salinity is to set up convection currents at the period of annual minimum, whereby the surface water, becoming denser than the lower layers in consequence of fall of temperature, sinks and so cools and aërates the mass of the ocean. When the surface water is much fresher than that of the lower layers no degree of cold will cause it to sink, unless sea-ice forms in such quantity that the exclusion of most of the salt causes an increase of salinity, and thus of density, in the unfrozen portion, which will then sink and produce a very low temperature in the lower layers. The action of heat also, which in fresh water ensures the continuance of the upper layers at the surface, produces a concentration of sea-water by evaporation, and thus an increase of density, which may lead to a mixture with the lower layers, as in the Red Sea. It may be noted, however, that evaporation proceeds more slowly from the surface of salt than of fresh water.

While the annual range at 50 fathoms at any one spot rarely exceeds 2° Fahr., and at 100 fathoms is inappreciable, different parts of the ocean at the same depth may differ in temperature to the extent of :—

Surface	100 fathoms	500 fathoms	1000 fathoms	1500 fathoms
70°	42°	20°	11°	8°

It is evident, from the rapidity with which temperature diminishes from the surface downwards in the upper layers, and the slowness with which the diminution continues in deeper water, that the ocean is a great mass of cold water, on the surface of which, in the extra-polar regions, a thin layer of warm water floats.

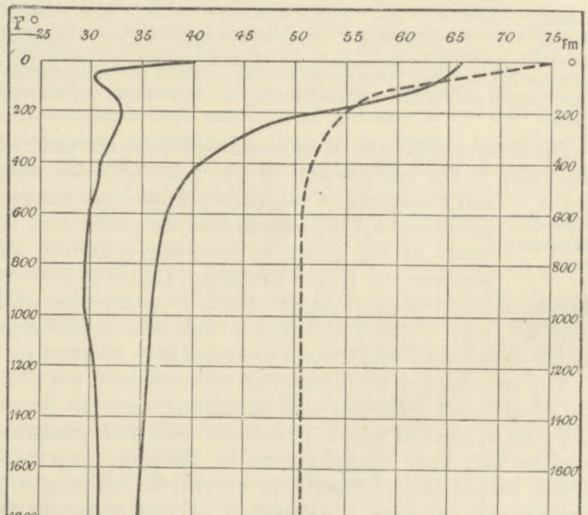

Diagram illustrating Distribution of Sea Temperature.

The normal vertical distribution of temperature is illustrated in curve A in the above diagram, which represents a sounding in the South Atlantic. Curve B shows the typical distribution of temperature in an enclosed sea (in this case the Sulu Sea), where from the level of the barrier to the bottom the temperature is

[1] "*Challenger*" *Reports—Deep-Sea Deposits.*

[2] *Petermanns Mitteilungen, Ergänzungsheft*, No. 109 (1894).

[3] Sir John Murray, "Annual Range of Temperature in the Surface Waters of the Ocean," *Geog. Journ.* xii. (1898), 113-134.

uniform. Curve C shows a typical summer polar curve where layers of water of different temperatures are superimposed. Sir John Murray calculates that no less than 80 per cent. of the mass of the ocean has a mean temperature below 40° Fahr.

The temperature of the floor of the ocean beyond the continental shelf, *i.e.*, about 90 per cent. of the whole oceanic area, is strikingly uniform. Water above 40° occupies only a narrow strip along the continental slope, and fills up the basins of the Red Sea and Mediterranean. Water at temperatures from 40° to 35° covers the whole floor of the North Atlantic south of the Wyville Thomson Ridge, and most of the Pacific, while water from 35° to 30° covers the floor of the whole Southern Ocean, the Indian Ocean, the South Atlantic and some small areas in the Pacific, the relations of which to each other have not yet been clearly made out. Water below 30° is found in the Arctic basin and in the Antarctic seas.[1]

The study of the bottom temperature shows that the main cooling agency in the hydrosphere is the melting of ice in the Antarctic area, for the oceans most open to the Antarctic are the coldest. Thus the Indian Ocean and the South Atlantic have a bottom temperature 2° lower than the North Atlantic, and about 1° lower than the Pacific. Sir John Murray points out that 92 per cent. of the ocean floor, but only 16 per cent. of the surface, have a temperature under 40° Fahr., and he shows how the deposits now being laid down contain mixed together the remains of forms of animal life which flourished in water at 90° and at 35° Fahr., a fact which has very important geological bearings.

The areas occupied by surface water at different temperatures may be given as follows :—

	Mean Annual Surface.		Bottom.	
	Square miles.	Per cent.	Square miles.	Per cent.
Area from 80°–90° F.	30,100,000	21·94	...	...
,, 70°–80° F.	38,200,000	27·84	...	...
,, 60°–70° F.	18,800,000	13·70	4,360,000	3·18
,, 50°–60° F.	13,400,000	9·77	2,710,000	1·97
,, 40°–50° F.	14,900,000	10·86	3,470,000	2·53
,, 35°–40° F. } ,, 30°–35° F. }	14,400,000	10·50	67,060,000 55,760,000	48·88 40·64
,, under 30° F.	7,400,000	5·39	3,840,000	2·80
Total .	137,200,000	100·00	137,200,000	100·00

In shallow seas, especially where there is a complex configuration and tidal currents, the form of the ground completely dominates the seasonal thermal changes in the water, which become extremely complicated and differ entirely from the conditions in the open ocean.[2]

Oceanic circulation. The facts which have been mentioned as to the practical constancy in the composition of the salts of ocean water and the nature of the absorbed gases are accepted by almost all oceanographers as proof that the water of the ocean is everywhere moving and nowhere at rest. Professor Thoulet, however, maintains that the great depths of the ocean are practically stagnant, any circulation being a molecular transference which is chemical rather than mechanical in its nature.

The movements producing the circulation of the ocean are of different velocities and directions, and are due to different causes, of which sometimes one and sometimes another has been considered to be the most important. Much weight was formerly given to the difference of temperature producing expansion of the water in the tropics as compared with the polar area, and thus initiating a difference of level which caused the surface currents to run on the whole from the equator towards the poles. Calculations have shown, however, that on account of the thinness of the heated layer the total thermal increase of level in the tropics must be very slight indeed, and quite insufficient to produce any sensible flow of water. Other theorists have pointed to the reduction of level in the heated areas in consequence of evaporation as sufficient to cause an indraught of the surrounding waters on the surface, especially from places where the level is raised by heavy rain. This undoubtedly must produce some effect even in the open ocean, and is a chief cause of the circulation of many enclosed seas. The Red Sea and the Mediterranean appear to owe their circulation almost entirely to evaporation, and the Baltic very largely to dilution. The melting of ice in the polar seas must have a considerable effect in raising the level of the surface by the liberation of fresh water, not on the surface only, but at the depth, sometimes over 100 fathoms, at which the bottoms of the icebergs float. The escape of the fresh water thus set free causes an up-welling round the bergs and a general outflow from the edge of the ice. Professor Otto Pettersson believes that this action is sufficient to set in motion the whole machinery of oceanic circulation, which thus would start from the edge of the polar ice towards the equator, the poleward-flowing currents being of secondary origin and serving to restore equilibrium.[3] It has been suggested by others that the originating cause of ocean currents is essentially tidal; but since the voyage of the *Challenger* most oceanographers have looked on the prevailing winds as the main cause of oceanic circulation, both horizontal and vertical. The suggestion of wind as the motive power of currents is old, the remarkable coincidence of direction in winds and currents having been appreciated by navigators at an early period. It is difficult to devise any crucial observation which should decide the truth of any one theory as against the others, since the currents of the ocean are all parts of a complete circulation, the impelling force for which may be applied at any part of the system with similar effect. It seems probable indeed that many causes, direct and indirect, conspire to produce the final result; wind and difference of density due to evaporation, rain, temperature, ice-formation, and ice-melting, all pushing or pulling to produce movement in the same direction.

Zöppritz has proved theoretically that the friction of moving air on the surface of the water at rest is sufficient to move forward the upper layer and to increase its velocity to nearly that of the air. The internal friction of water is sufficient to pass on the movement to deeper and deeper layers, although very slowly, the calculation being that with a uniformly acting wind it would require more than a month before water at the depth of one metre was travelling as fast as that at the surface.

It has been proved by experiment that whenever a current of water is set in motion by any cause it exercises a complex influence on the surrounding water, dragging some of it forward in the same direction and impressing on another part a movement, either on the surface or in some deeper layer, in the opposite direction. These deep reaction-currents are especially noticeable where rivers enter the sea or where strong surface currents run through narrow straits.[4]

A condition which may produce feeble currents not due directly to wind but to the cause of wind—unequal distribution of atmosphere pressure—is known as a seiche. This is most easily observed in lakes or bodies of water not affected by tide, and consists of a surge of the water too slow, gradual, and flat to be called a wave, constituting a rising at one place where the atmospheric pressure is low and a falling at another where it is high. When it is remembered that the pressure of an inch of

[4] The literature of the theory of oceanic currents is too voluminous to summarize here. It will be found excellently treated in Boguslawski and Krümmel's *Ozeanographie*, vol. ii. chaps. iii. and iv., and continued in the annual volumes of Wagner's *Geographisches Jahrbuch* since 1888.

mercury is equal to that of a foot of water, and that temporary differences of barometric pressure considerably exceeding one inch of mercury between places much less than a hundred miles apart are not uncommon, the small and fugitive irregularities of the sea-surface and their associated temporary currents due to this cause can be understood.

The direct action of wind on moving water is modified by the influence of the land, the movements due to wind which may occur even in the open sea being intensified under the guiding influence of land-slopes. An off-shore wind has the effect of driving the surface water out to sea, raising the level at some place to leeward and necessitating an upwelling of the deeper layers along the land. A steady off-shore wind thus causes a constant upwelling of deep, and consequently comparatively cold, water near shore.[1] This fact and the similar effect produced by shoals which rise nearly to sea-level has been known to sailors for more than a century, and the thermometer was suggested as a guide to warn the mariner of shallow water as early as 1799.[2] An on-shore wind, on the other hand, drives in the surface-water, skimmed from a considerable extent of ocean, against the shore, raising the level of the sea near the land, and so causing a return movement. This takes place either in the deeper layers, or, if the wind acts only along a narrow path, a counter-current will escape on the surface on one or both sides of the direct current. The result is that off a lee-shore the water has a higher temperature at great depths than in the open sea. In consequence of this action, physical similarities in the configuration of the ocean basins lead to similarities in the movements of the water, which in all are closely related to the prevailing winds. Where the trade-winds blow off the land, as on the north-west and south-west coasts of Africa and of South America and the north-west of Australia, cold currents are found, welling up from below, those in the south probably reinforced by branches of the Antarctic surface drift. In the North Indian Ocean and in other places where the direction of the winds changes twice a year, the currents show a similar change and are known as monsoon currents.[3]

By whatever cause the water of the ocean is set in motion, and in whatever direction it may flow, a force arising from the Earth's rotation causes the current or drift to deviate from a straight line towards the right in the northern hemisphere and towards the left in the southern. In the northern oceans the direction of the coastlines conspires with this deviation to give to the whole of the water a general horizontal circulation in the same direction as the hands of a watch, a fact which has been very clearly proved in the North Atlantic, and is distinctly suggested in the North Pacific. In the South Atlantic, the South Indian Ocean, and the South Pacific a similar horizontal circulation, but in the direction opposite to that of the hands of a watch, as is required by Ferrell's Law of Deviation, has been partially made out.

Nature of currents. When a current-chart which is not generalized but compiled from actual observations, such as those of the British Admiralty, is attentively examined, it will be seen that the arrows indicating the directions of the observed movements are not parallel to each other, but frequently present the appearance of small eddies or divergent streams. Yet, on viewing the chart more generally, certain main directions will be noticed to recur so frequently as to make it possible to assign a definite resultant direction to considerable bands of water. It is usual to distinguish between *currents*, which are comparatively rapid, fairly definite in their boundaries, uniform and permanent in direction even during temporary changes of wind, and *drifts*, which are less defined movements of the water, less certain in direction and velocity, and liable to alter with every prolonged change of wind. But notwithstanding these differences, drifts and currents are part of one system of general oceanic movement, and they must be considered as supplementary and not contrasted. They can never be fully studied by observations of horizontal movement at the surface alone, for the movements of the surface are only the visible portion of the great system of circulation in three dimensions of the mass of the ocean. So little is known of the movements of the deeper layers that the complete system of circulation can only be divined as yet by the use of theoretical reasoning supported in part by facts of observation. The evidence points to the Southern Ocean as the great meeting- and mixing-place of the waters of the world, and it is there, between 40° S. and the Antarctic ice, that the want of systematic observations at all depths taken by exact modern methods is most seriously felt.

An ingenious system of representing the dynamical conditions determining marine circulation by means of sections has been put forward by Bjerknes and Sandström. The sections combine isotherms and isohalines into curves of equal density *in situ*, the corresponding surfaces of equal density serving to indicate the direction and strength of the movement of the water, as isobaric surfaces indicate the direction and strength of the movements of the air.

Interaction of ocean and air. The importance of the ocean in the economy of the world is perhaps greatest as a regulator of climate, and recent researches indicate that the relation between the atmosphere and hydrosphere is much more intimate and sympathetic than was formerly supposed. The general contrast of the maritime and continental climate is too well known to require emphasizing, but it is useful to remember that the influence of prevailing winds from the sea may carry a maritime climate far inland over level country, as in the North German plain, while prevailing winds from the land may carry a continental climate to islands across narrow seas, as in Japan and the Kurile group in winter. The researches of Mohn, O. Pettersson, and H. N. Dickson have shown that the distribution of sea temperature has a direct relation to the distribution of atmospheric pressure and to the resulting types of weather. The ocean surface not only affords a fair field for the development of unobstructed atmospheric circulation, but helps to fix the position of the great low and high pressure areas, on the margins of which the moving cyclones which dictate the weather of temperate latitudes are generally initiated. The subject is a promising one for future research, and it seems a hopeful direction in which to look for a guide as to the prediction of weather some considerable time in advance.

The practical importance of exact oceanographical research lies in its applications to practical meteorology, to the art of navigation, to the placing of submarine cables, and most directly to fisheries. With regard to the latter, an international council of the nations surrounding the North and Baltic Seas, which was inaugurated at Copenhagen in 1902 after preliminary conferences at Stockholm in 1899 and at Christiania in 1901, formed comprehensive plans for co-operation in the systematic study of the North-West Atlantic and its neighbouring seas at all seasons, with the object of definitely testing the assertions as to the practical value of the study.

Ochakoff, a fortified town of Russia, government of Kherson, district of Odessa, 41 miles east-north-east of Odessa, on a cape of the Black Sea, at the entrance to the estuary of the Dnieper. Its population was 10,784 in 1897. The port is visited chiefly by coasting vessels (about 250, 6500 tons) for the export of grain to Odessa. It has large brickworks, a steam flour-mill, and a few small factories. Strong fortifications have been built between Ochakoff and the Kinburn promontory, to protect the entrance to the Dnieper.

Ochakoff stands on the site of the old Miletan colony Olvia and of the Greek colony Alektor. The fortress of Kara-kerman or Ozu-kaleh was built on this spot by the khan of Crimea, Mengli-ghirei, in 1492. At a later date it became the centre of a Turkish province which included Ajiber (Ovidiopol), Haji-bei (Odessa), and Dubossary, as well as about 150 villages. Moscow, Poland, and the Zaporogue Cossacks, and later the Ukrainian Hetmans, often attacked it. Russia, regarding it as the main obstacle to the possession of the Black Sea littoral, besieged it in 1737, when it was captured by Minich; but next year it was abandoned, and restored in 1739 to Turkey. The second siege was begun in 1788, and lasted six months, until the fortress was stormed and taken, after a terrible loss of life. By the peace of 1791 it became Russian.

Oconto, a city of Wisconsin, U.S.A., capital of Oconto county, on the shore of Green Bay and on the Chicago and North-Western and the Chicago, Milwaukee, and St Paul railways, in the eastern part of the state, at an altitude of 593 feet. It is in a lumber region, and contains saw and planing mills, and has a large lumber trade. Population (1880), 4171; (1890), 5219; (1900), 5646, of whom 1544 were foreign-born.

Odenkirchen, a town of Prussia, in the Rhine province, 21 miles by rail south-west of Düsseldorf. It has linen, cotton, silk, woollen, dyeing, tanning, and other industries. There is also an agricultural school. Population (1885), 10,161; (1900), 14,745.

Odense, a seaport town and bishop's see of Denmark, the principal town on the island of Fünen, near the north coast. A canal, 4 miles long and 15½ to 21 feet deep, gives access to the town from Odense Fjord. Modern buildings include the town hall (Italian Gothic, 1880–83); the museum (built 1883–85, extended in 1897), with valuable collections of antiquities of the Stone Age, coins and medals, paintings, minerals, &c.; the Renaissance provincial archives (1892–93); and the cathedral school (1892–94). In the industrial quarter, Albani, are tanneries, breweries, distilleries, tobacco factories, iron-foundries and machine-shops, and the Mechanics' Institute (1890). In 1899 the port was entered by 876 vessels of 95,999 tons, and cleared by 949 vessels of 114,820 tons, the exports being mostly agricultural produce (bacon, butter, eggs), and the imports iron, groceries, petroleum, coal, yarn, and timber. Population (1880), 20,804; (1890), 30,268; (1901), 40,138, the boundaries having been several times extended between 1882 and 1901.

Odenwald, a wooded mountainous region of Germany, almost entirely in the grand-duchy of Hesse-Darmstadt, with small portions in Bavaria and Baden. It stretches between the Neckar and the Main, and is some 50 miles long by 20 to 30 broad. Its highest elevation is the hill of Katzenbuckel, 2057 feet, overlooking Eberbach on the Neckar. The western part, which rises steeply from the Rhine valley above the Bergstrasse (which connects Darmstadt and Heidelberg), is composed principally of crystalline slates and primary rocks; the eastern portions of New Red Sandstone. The wooded heights overlooking the Bergstrasse are studded with castles and mediæval ruins; and other ruined castles and sites are associated with some of the most memorable adventures of German tradition, *e.g.*, Rodenstein, the reputed home of the Wild Huntsman, and near Grasellenbach, the spot where Siegfried of the *Nibelungenlied* is said to have been slain by Hagen.

Oder, one of the chief rivers of Germany. The navigability of this, as of the other North German rivers, has been very greatly improved since 1875; nevertheless it still shows a strong tendency to choke itself with sand in certain places. The alterations consist principally of three systems of works:—(1) The canalization of the main stream (4 miles) at Breslau, and from the confluence of the Neisse of Glatz up to the mouth of the Klodnitz canal, a distance of over 50 miles, the two costing nearly £1,100,000. These engineering works were completed in 1896. (2) In 1887–91 the Oder-Spree canal was made to connect the two rivers named. The canal leaves the Oder at Fürstenburg (132 miles above its mouth) at an altitude of 93 feet, and after 15 miles enters the Friedrich-Wilhelm canal (134 feet). After coinciding with this for

7 miles, it makes another cut of 5 miles to the Spree at Fürstenwalde (126 feet). Then it follows the Spree for 12 miles, and at Gross Tränke (121 feet) passes out and goes to Lake Seddin (106 feet), 15 miles. Depth throughout, $8\frac{1}{4}$ feet; width, 60 to 90 feet; cost, £630,000. (3) The deepening and regulation of the mouth and lower course of the stream, consisting of the Kaiserfahrt, 3 miles long, affording a waterway between the Stettin Haff and the river Swine for the largest ocean-going vessels; a new cut, $4\frac{1}{4}$ miles long, from Woitzig on the Stettin Haff to Mellin Island; the Parnitz–Dunzig and Dunzig–Oder canals, together 1 mile long, constituting the immediate approach to Stettin. Vessels drawing 24 feet are now able to go right up to Stettin. A project has been mooted for connecting Stettin *viâ* the Oder and canals (to be constructed) with Berlin. Including the older canals (Finow, &c.), there are altogether 361 miles of canal and canalized river in the Oder basin, and in addition $93\frac{1}{2}$ miles connect it with the Elbe. The stream has a total length of 560 miles, of which 480 miles are navigable for boats, though above Glogau the depth does not exceed 3 feet. The drainage basin has an area of 43,300 square miles. Between the source and Breslau the total fall amounts to 1342 feet, between Frankfort and the sea only 66 feet. Altogether a total of 3,640,400 tons of merchandise pass through Breslau (up and down together) on the Oder in the year. There is valuable fishing in the lower part of the river, near Stettin.

For minor canalizations, see the official work, *Der Oderstrom*, &c., 3 vols. (Berlin, 1896); and consult also A. PENCK, "Der Oderstrom," in *Geog. Zeitschrift* (1899), pp. 19–47 and 84–94; HEUBACH, *Die Verkehrsentwickelung auf den Wasserstrassen und Eisenbahnen des Elbe–Oder Gebietes in dem Zeitraum von 1882–1895* (Berlin, 1898); and LEONHARD, *Der Stromlauf d. mittleren Oder* (Breslau, 1893).

Odessa, the chief city and seaport of Russia on the Black Sea. Its population, which increased from 225,000 in 1884 to 405,041 in 1897, is very varied, and out of a population of 340,526 in 1892, in the Odessa township (which includes the suburbs), there were 188,082 Russians, 112,235 Jews, 13,462 Poles, 8897 Germans, 5272 Greeks, 1129 French, and 11,449 of different nationalities. The industrial development has been rather slow, there being in the township only 261 factories, employing 12,000 workers, and showing a yearly return of about £2,600,000, steam flour-mills, sugar refineries, iron and mechanical works, factories of jute sacks, colour and varnish, soap, candle, confectionery, and chemical works being the chief. Commercially the city is now the chief seaport of Russia for exports, which in favourable years are twice as high as those of St Petersburg, while as regards the value of the imports it is second only to the northern capital. The total returns amount to nearly 150,000,000 roubles a year, representing about one-eighth of the entire Russian foreign trade, and 14 per cent. if the coast trade be included as well. The total exports are valued at £10,820,700 yearly (£11,000,000 including the transit trade), and the imports at £3,825,400; *i.e.*, about 9 per cent. of all the imports to Russia. Grain, and especially wheat, is the chief article of export (1,990,000 tons, £7,000,000, in 1895; wheat alone, £3,900,000). The chief customer for the exports is Great Britain; then follow Holland, Germany, France, Belgium, Denmark, Italy, and Scandinavia. Refined sugar (£850,000) comes next, and then seed, fish, raw wool, iron and iron goods, cottons (£200,000), small arms, furniture, tobacco, spirits, wooden wares, &c. These articles are exported to east Siberia, Turkey, Great Britain, France, Rumania, and so on. The chief imports are raw cotton, ships, iron, olive oil, fruit, tea, agricultural machinery, coal, chemicals, &c. The port was visited in 1895 by 1207 steamers (1,798,000 tons) and 70 sailing vessels (18,150 tons); and in the coasting trade by 1930 steamers (1,047,000 tons) and 2167 sailing vessels (120,000 tons). A new and spacious harbour, especially for the naphtha trade, was built in 1894–1900. Regular steam navigation is maintained with the Mediterranean and Baltic ports by a fleet of 75 steamers, with the Far East by 10 steamers, and with the Black Sea ports by a number of smaller steamers. The town has been provided with a costly system of drainage, electric light in the ports, a beautiful new theatre, a monument to Pushkin, and a number of schools, technical and general.

Oels, a town of Prussia, province of Silesia, 20 miles east-north-east of Breslau by rail. The castle was restored in 1894. In 1884 the extinction of the ducal line of Brunswick caused the principality of Oels to lapse to the Prussian Crown. Population (1885), 10,276; (1900), 10,580.

Oelsnitz, a town of Germany, on the Weisse Elster, 26 miles by rail south-south-west of the town and in the circle of Zwickau, kingdom of Saxony The making of Axminster carpets (one firm employing 1000 workmen), corsets, worsteds, curtains, ticks, and table-covers, jute-weaving and printing, are carried on. Population (1890), 9426; (1900), 13,606.

Oelwein, a city of Fayette county, Iowa, U.S.A., in the north-eastern part of the state, at the intersection of the Burlington, Cedar Rapids, and Northern, and the Chicago Great Western railways, a railway junction and shipping point of some importance. Population (1890), 830; (1900), 5142, of whom 789 were foreign-born.

Offenburg, a town of Germany, grand-duchy of Baden, 27 miles by rail south by west of Baden, on the river Kinzig. It has three churches; a memorial fountain to Lorenz Oken (1779–1851), who was born at Bohlsbach close by; a statue of Francis Drake (1853), as the alleged introducer of the potato into Europe; a commercial and a technical school; and manufactures of cottons, hats, cigars, machinery, glass, &c. Population (1885), 7765; (1895), 9727; (1900), 13,669.

Offenburg was founded towards the end of the 12th century, and early in the 13th became an imperial town, and so continued down to 1351. It again occupied the same status from the middle of the 16th century to the year 1802, when it was transferred to Baden.

Ogden, a city of Weber county, Utah, U.S.A., at the junction of the Weber and Ogden rivers, near the shores of Great Salt Lake, in the northern part of the state, at an altitude of 4310 feet. Its site slopes gently from the Wasatch Mountains on the east towards the lake, and its plan is perfectly regular, with broad, well-shaded streets, and a good water supply. Four railways, the Oregon Short Line, the Rio Grande Western, the Southern Pacific, and the Union Pacific, have termini at this point, making it the most important railway centre in the state and, next to Salt Lake, the largest city. Population (1890), 14,889; (1900), 16,313, of whom 3302 were foreign-born and 133 coloured, including 43 negroes.

Ogdensburg, a city of St Lawrence county, New York, U.S.A., on the St Lawrence river, at the mouth of the Oswegatchie, in the northern part of the state, at an altitude of 248 feet. The city has a regular plan, is divided into four wards, has broad, well-shaded streets, few of which are paved, and a good water supply by the Holly pumping system. Its harbour is fair, and it has considerable commerce on the Great Lakes. It has two railways, the New York Central and Hudson River and the Rutland. Population (1890), 11,662; (1900), 12,633, of whom 3222 were foreign-born.

Ogowe, one of the largest of the African rivers of the second class, rising in 3° S. in the zone of West African highlands sometimes known as the Cristal range, and flowing north-west and west to the Atlantic Ocean a little south of the Equator. Its course, which may be estimated at 700 miles, lies wholly within the territory of French Congo. Its upper basin, between 2° and 3° S., is still imperfectly known, but from 2° to its mouth it has been fully explored by French travellers. In spite of its considerable size, the river is of comparatively little use for navigation, as rapids constantly occur as it descends the successive steps of the interior tablelands. The principal obstructions are the falls of Dume, in 13° E.; Bunji, in 12° 35′; Chengwe, in 12° 16′; Bowe, in 11° 53′; and the rapids formed in the passes by which it breaks through the outer chains of the mountainous zone, between 10¾° and 11¾° E. It has a large number of tributaries, especially in its upper course, but of these few are navigable. The most important are the Lolo, which joins on the south bank in 12° 20′ E., and the Ivindo, from the north, a few miles lower down. The latter—explored in 1899 by Fourneau, and in 1901 by Lesieur—has proved to be a large stream, though obstructed by rapids in its lower course. It is even said to contain more water than the upper Ogowe. Below the Ivindo the largest tributaries are the Ofowe, 400 yards wide at its mouth (11° 47′ E.), but unnavigable except in the rains, and the Ngunye, the largest southern tributary, navigable for 60 miles to the Samba or Eugénie Falls.

Ohio, the fourth of the states of the American Union in population, bounded on the N. by Michigan and Lake Erie, on the E. by Pennsylvania and West Virginia, on the S. by West Virginia and Kentucky, and on the W. by Indiana.

Population.—The total population rose from 3,198,062 in 1880 to 3,672,316 in 1890, and to 4,157,545 in 1900. The percentage of increase for the decade ending in 1900 was 13·2, as compared with 14·8 for the ten years before. Between 1880 and 1890 the percentage of persons of foreign birth remained unchanged. Of the foreigners, numbering 459,293 in 1890, 50,947 were born in England, 70,127 in Ireland, 23,180 in Scotland and Wales, and 235,668 in Germany; and there was also a decided increase in the number of Italians, Russians, Hungarians, and Bohemians, this tendency being accentuated after 1890. The total land surface of Ohio is approximately 40,760 square miles, and the density of the population was therefore 102·0 in 1900, as compared with 90·1 in 1890. In 1900 the native-born numbered 3,698,811 and the foreign-born 458,734, the latter showing a slight decrease for the decade. At the same date there were 96,901 negroes in the state. There were, in 1900, 143 incorporated places with a population of 2000 or over: of these 72 had a population of less than 5000; 43 had more than 5000 but less than 10,000; 19 had more than 10,000 but less than 25,000; and 9 had more than 25,000, namely, Cleveland, 381,768 (increase since 1890, 120,415); Cincinnati, 325,902 (increase, 28,994); Toledo, 131,422 (increase, 50,388); Columbus, 125,560 (increase, 37,410); Dayton, 85,333; Youngstown, 44,885; Akron, 42,728; Springfield, 38,253; Canton, 30,667. The urban population in 1900 was 38·5 of the total population, as compared with 31·6 in 1890. Prosecutions for crimes against the person have not increased since 1882, but prosecutions for crimes against property have increased slightly from 2049 to 2210, the latter including 2560 individuals. In the five years from 1882 to 1886 the divorces equalled $5\frac{9}{10}$ per cent. of the marriages, while in the five years from 1896 to 1900 they constituted 9 per cent. of the marriages. Because of its situation with water routes to all ports of the Mississippi valley and of the Great Lakes, its manufactures and commerce have outstripped its agricultural interests in development. Between 1880 and 1890 the number of farmers increased from 260,520 to 275,221, while the number of persons engaged in trade and transportation increased from 101,445 to 180,978, and those engaged in manufacturing and the mechanical arts from 204,787 to 273,650. Moreover, the percentage of the urban population to the total population increased in the same time from 23·3 to 31·6. And the rate of increase in the six principal lake towns, Cleveland, Toledo, Sandusky, Lorain, Conneaut, and Ashtabula, was 61 per cent., although the rate for the total population was only 14 per cent.

Agriculture.—During the years from 1882 to 1899 the agricultural interests grew slowly but steadily. Cultivated land increased from 9,388,018 acres to 10,239,866. Pasture land remained about the same, while woodland decreased from 4,208,247 acres to 2,817,599. The average production of wheat in the five years from 1882 to 1886 inclusive was 33,504,000 bushels, and from 1895 to 1899 inclusive, 33,700,000. Of shelled corn the yield for the same periods amounted to 88,733,000 bushels and 155,124,000. There was an increase in the corn acreage, but no substantial increase in the acreage of wheat. In 1882 the orchards covered 388,574 acres; in 1899, 359,256. The crop showed great fluctuations from year to year, but no decided tendency to increase or to diminish. The acreage of vineyards, situated principally along the lake shore, increased; and the product rose from 11,678,545 lb of grapes in 1882 to 31,127,743 lb in 1889. The number of horses and cattle fell off about one-fourth. Certain dairy products, eggs and milk, were increased, while there was a decrease in the production of butter and cheese. The wool clip fell off decidedly through the whole period, rallying slightly in 1898 and 1899, and was apparently little affected by changes in the tariff. In 1882 the amount was 23,629,424 lb; in 1890, 18,629,961; and in 1899, 13,017,052.

The following table shows the growth of manufactures in recent years:—

	1880.	890.	1900.	Percentage of Increase, 1890–1900.
Number of establishments . . .	20,699	28,673	32,398	13·0
Capital . . .	$188,939,614	$402,793,019	$605,792,266	50·4
Wage-earners, average number . . .	183,609	292,982	345,869	18·1
Value of product .	$348,298,390	$641,688,064	$832,438,113	29·7

The leading industries were iron and steel, the value of the products of which increased from $65,206,828 in 1890 to $138,935,256 in 1900; foundry and machine shops, with products valued in 1900 at $72,399,632; flouring and grist-mills, $37,390,367; liquors, $31,771,591; and lumber and timber, $20,790,854. In the value of its manufactures Ohio ranks as fifth among the states.

Minerals.—The mining of iron ore has been almost abandoned, the product falling from 276,286 tons in 1884 to 52,266 in 1900; while the product of bituminous coal has risen from 9,450,000 tons in 1882 to 11,788,859 tons in 1890, and to 12,448,822 in 1897. In 1884 natural gas was discovered at a deeper level than that at which it had been believed to exist. In January 1886 a well was drilled at Findlay to a depth of 1144 feet. For a time the daily yield was 12,080,000 cubic feet. Findlay soon had a daily product of 25,000,000 feet. These discoveries led to others in various parts of the state and of neighbouring states, but the supply was wastefully used, so that after a time it became uncertain, and its commercial value decreased.

Railways and Transportation.—The natural highways afforded by Lake Erie and the Ohio river are supplemented by systems of canals and of railways. With the development of the railways, the receipts from the canals have fallen off, so that there has long been an annual deficit; yet the General Assembly has maintained the canals, wisely seeing in them a means of keeping rates of transportation from becoming oppressive. The mileage of railways, including main line, second line, branches, and side tracks, in 1882 was 8311; in 1890, 10,504; and in 1898, 13,289. The valuation of railways for taxation increased 18 millions during the same period. The receipts for 1898 were $68,764,938, and the expenditures $49,062,218. There has been a decided tendency towards consolidation. Such through lines as the Lake Shore and Michigan Southern, the Pennsylvania, the Erie, the Baltimore and Ohio, and the Cleveland, Columbus, Cincinnati, and St Louis have acquired control by purchase or by lease of many of the minor lines. So far has this movement for consolidation gone that the Lake Shore and Michigan Southern and the Baltimore and Ohio have passed under the control of other and larger railway companies.

Banks.—The national banks increased from 189 in 1882, with a capital of $31,464,000, to 228 in 1890, with a capital of $39,592,719, and to 268 in 1900, with a capital of $45,380,670. The state banks and banking associations grew even more rapidly, from 30 in 1882 to 181 in 1900, with a capital of $14,895,532.

Finances.—From 1882 to 1900 the valuation increased from $1,634,910,734 to $1,834,053,228. The state tax remained about the same, while the local taxation increased 5 millions. The net receipts of the state treasury for 1900 were $5,222,355, and the disbursements $5,104,769. The funded debt on 15th November 1900 was $701,665. In 1882 it was $4,901,665. More than half of this debt became due in 1886, and was refunded at 3 per cent., a reduction of one-half in the rate of interest. The local debts increased from $45,766,551 in 1882 to $62,992,957 in 1890 and $96,193,514 in 1899.

Education.—The number of children of school age rose from 1,081,321 in 1882 to 1,226,366 in 1900. Of these 829,160 were enrolled, and 616,365 in daily attendance. The number of teachers employed was 26,017. The receipts amounted to $14,426,858, and the expenditures to $14,266,973. There were, in 1882, 25 colleges granting a degree; in 1890, 30; in 1900, 32. The number of instructors increased from 222 to 1031. Of the 222 instructors in 1882, 27 per cent. were in four institutions, *i.e.*, Oberlin College, Ohio State, Ohio Wesleyan, and Western Reserve universities; but of the 1031 instructors in 1900, 47 per cent. were in these institutions. In 1898 the total property reported was $14,716,782; the income, $1,242,135; and the expenditures, exclusive of permanent improvements, $902,714. In nearly all the colleges men and women are admitted, but the co-educational system was abandoned by Adelbert College, of Western Reserve University, formerly Western Reserve College at Hudson, and a separate college for women was organized as a department of the university. In 1890 the total number of students in universities and colleges was 3963, of whom 1163 were women; in 1898 it was 5530, of whom 1582 were women.

Churches.—The organized churches in 1890 numbered 9345. The Catholics were the leading denomination, with 336,114 communicants in 586 churches, and a property of $7,395,640; although the Methodists, with a smaller number of communicants (272,737), had 2798 churches and a property of $9,600,820. In number of communicants and in property the Presbyterians come third, but they have fewer churches than the Baptists. The Episcopalians, though seventh in number of communicants and ninth in number of churches, are fifth in property

Public Institutions.—There are 17 charitable institutions, maintained by the state at an expense of $3,085,880. They include 8 hospitals for the insane, 2 asylums for juvenile offenders, 1 reformatory, 5 educational and benevolent institutions, and the penitentiary.

Legislation.—Legislation regulating or taxing the liquor traffic has been difficult, owing to a section in the constitution which forbids the granting of licences for the sale of liquors. After some futile attempts at legal control, the Dow tax law was passed in 1886, and successfully defended in the courts as a tax and not a licence. The organization of the state government, with a General Assembly uncontrolled by executive veto and with an independent executive, has been unchanged, except that circuit courts have been substituted for the district courts, and that the constitutional provision for biennial sessions of the General Assembly, after remaining a dead letter since 1851, was in 1894 carried out by the passing of an appropriation bill covering the expenses of two years and by an adjournment *sine die.* The election laws were changed by introducing the Australian ballot system in 1891, and by granting in 1894 the suffrage to women for the election of school officials. The results of the last measure have been unsatisfactory, even to its advocates.

Politics.—Since 1882 the Republicans have uniformly been successful, except in the elections for governor in 1883 and 1889; in the latter year their failure was attributed to personal rather than political reasons. The Prohibitionist party gradually lost strength, and was finally disorganized by the famous struggle between the Republicans and Democrats in 1896. It polled only one-fourth of its average vote at that election, and rallied only slightly in 1897 and 1898, to fall back again in 1899. In the Presidential election of 1884, 784,610 votes were cast as follows:—Republican, 400,082; Democratic, 368,280; Prohibitionist, 11,069; Greenback, 5179. In the election of 1888, 840,361 votes were cast as follows:—Republican, 416,054; Democratic, 396,455; Prohibitionist, 24,356; Union Labour, 3496. In the election of 1892, 850,164 votes were cast as follows:—Republican, 405,187; Democratic, 404,115; People's Party, 14,850; Prohibitionist, 26,012. In 1896, 1,014,295 votes were cast as follows:—Republican, 525,991; Democratic, 474,882; People's, 2615; Prohibitionist, 5068; National Party, 2716; Social Labour, 1165; National Democrat, 1858. In 1900, 1,040,073 votes were cast as follows:—Republican, 543,918; Democratic, 474,882; Union Reform, 4284; Prohibitionist, 10,203; Social Labour, 1688; People's, 251; Social Democrat, 4847.

Ohio River, the largest eastern branch of the Mississippi river, U.S.A., formed by two main forks, the Allegheny river, which rises in southern New York, and the Monongahela, rising in West Virginia. These two streams join at Pittsburg. Its general course from Pittsburg to its mouth at Cairo is south-west, although in detail it flows in nearly every direction except eastwards. Its length is 963 miles. It is navigable throughout, with the exception of the falls at Louisville, which are overcome by means of a canal and lock. Its drainage basin comprises 201,720 square miles, including parts of New York and Pennsylvania, nearly all of West Virginia and part of Virginia, most of Ohio and Indiana, and a large part of Illinois, all of Kentucky, nearly all of Tennessee, and parts of North Carolina, Alabama, and Mississippi. Besides its parent streams, the Allegheny and Monongahela, the Ohio has numerous large branches. On the north it receives the waters of the Muskingum, Scioto, Miami, and Wabash rivers, and on the south those of the Kanawha, Big Sandy, Kentucky, Green, Cumberland, and Tennessee rivers. The Ohio drains the western slope of the Cumberland–Allegheny plateau from New York south to Alabama, and also most of the east side of the Mississippi valley. Several large cities are on its banks, among them Pittsburg, Cincinnati, and Louisville. For a century the Ohio has been one of the great highways of internal commerce, and even now, in spite of the competition of the railways, its waters are laden with boats which transport the heavier and bulkier articles of freight, such as coal and lumber.

Ohlau, a town of Prussia, province of Silesia, 16 miles by rail south-east of Breslau, on the left bank of the Oder. It is the centre of a tobacco-growing district and has manufactures of cigars, machinery, white lead, beer, &c. In the 17th and 18th centuries it was often the residence of the dukes of Brieg and of the Sobieskis. Population (1885), 8575; (1900), 9235.

Ohligs, a town of Prussia, in the Rhine province, 17 miles by rail north of Cologne. It is an industrial place, manufacturing cutlery, hardware, silks, and bricks, and possessing iron-foundries and flour-mills. Down to 1891 it was known as Merscheid. Population (1885), 12,646; (1900), 20,682.

Ohrdruf, a town of Germany, duchy of Saxe-Coburg-Gotha, 11 miles by rail south by east of Gotha. It has manufactures of porcelain, paper, copper goods, small wares (buttons, &c.). It has a castle, a couple of churches, and a technical school. Close by is the summer resort of Luisenthal. Population (1900), 6295.

Oil City, a city of Venango county, Pennsylvania, U.S.A., on the Allegheny river, at the mouth of Oil Creek, in the north-western part of the state, at an altitude of 1005 feet. It is in the centre of the Pennsylvania oil region, and owes its existence to the development of the petroleum industry. It contains petroleum refineries, and its manufactures are in great part related to the production and refining of oil. It is at the intersection of four railways, the Allegheny Valley, the Erie, the Lake Shore and Michigan Southern, and the Western New York and Pennsylvania. Population (1890), 10,932; (1900), 13,264—2001 foreign-born and 184 negroes.

Oil Engines. See Engines, 3.

Oise, a department of northern France, traversed by the Oise.

Area, 2272 square miles. The population, 404,555 in 1881, was 405,642 in 1901. Births in 1899, 8933, of which 861 were illegitimate; deaths, 9387; marriages, 3174. The schools in 1896 numbered 1134, with 57,000 pupils, and 4 per cent. of the population was illiterate. Out of 1,417,780 acres cultivated in 1896, 948,480 were plough-land, 32,110 gardens, and the rest grass and woodland. The wheat produce of 1899 returned the value of £1,640,000; rye, £120,000; oats, £1,005,000; mangold-wurzel, £208,000; potatoes, £260,000; beetroot, £1,280,000; apples, £52,000. Oise owned in 1899, 48,990 horses, 126,180 cattle, 354,500 sheep, and 35,280 pigs. With the exception of building-stone, the department raised (1898) only 8300 metric tons of peat; but the industry in metals yielded, in 1898, 17,000 tons of iron and 41,000 tons of steel, of a total value of nearly £400,000. Oise ranks fifth among the departments for the production of sugar—1,400,000 cwts. in 1899—while its alcoholic production in the same year amounted to 1,760,000 gallons. These, with tapestry, are the principal industries. Beauvais, the capital, had in 1901, 20,300 inhabitants.

Okehampton, a municipal borough, parish, and market town in the Tavistock parliamentary division of Devonshire, England, on the East and West Okement rivers, 22 miles west by north of Exeter by rail. Its earliest charter dates from 1623. In 1885 the electric light was adopted by the town, a complete scheme of drainage was carried out in 1886–87, and the market premises were rebuilt in 1900. The curfew bell is still tolled here. Population (1891), 1879; (1901), 2568.

Oki, a group of islands belonging to Japan, lying due north of the province of Izumo, at the intersection of 36° N. and 133° E. The group consists of one large island called Dôgo, and three smaller isles—Chiburi-shima, Nishi-no-shima, and Naka-shima—which are collectively known as Dôzen. These four islands have a coast-line of 182 miles, an area of 130 square miles, and a population of 62,759. The island of Dôgo has two high peaks, Daimanji-mine (2185 feet) and Omine-yama (2128 feet). The chief town is Saigo in Dôgo, distant about 40 miles from the port of Sakai in Izumo. The name Oki-no-shima signifies "islands in the offing," and the place is celebrated in Japanese history not only because the possession of the islands was much disputed in feudal days, but also because an ex-emperor and an emperor were banished thither by the Hôjô regents in the 13th century. Great quantities of cuttle-fish are taken at the archipelago.

Oklahoma, a territory lying in the south central part of the United States, organized under an Act of Congress, passed 2nd May 1890. It was formed from the western part of Indian Territory, and included all that part of it not occupied by the Five Civilized Tribes, and the Indian tribes within the Quapaw Agency, except the Cherokee outlet lands. The Cherokee outlet and "No Man's Land" were added by proclamation of the President in September 1893. Lying between 34° and 37° N. and 96° and 103° W., it is bounded on the N. by Colorado and Kansas, on the E. by Indian Territory, on the S. by Texas, and on the W. by Texas and New Mexico. There are contained within its boundaries 39,030 square miles, of which 4600 square miles are reserved. Geologically it is divided into regions of mountains, prairie plains, and great plains. The group or range, in the southern part, known as the Wichita Mountains, is of granitic formation, and rises through Silurian limestones and red beds to an altitude of about 2700 feet above the sea-level. The prairie plains in the north-east are a continuation of the residual soils of the Carboniferous prairies to the east, extending westwards to about 97° 30′ W., marked by red sandy clays, or red beds, and further characterized by great deposits of gypsum and salt. Here and there over the prairies are areas of Cretaceous formation, the sandy beds of which are covered with oak timber ("Cross timbers"). The great plains in Oklahoma are eastern breaks of the Great Plains plateau to the west, making a ragged line through the western part, with sandy tongue-like divides between the streams. Soils and rocks are sandstone, gravel, and marl, and there are great salt deposits in the north-western corner along Beaver Creek.

Geography.—There is very little relief to the surface, which is generally flat or rolling prairie, with the single exception of the isolated Wichita Mountains, situated in the middle southern portion. The principal rivers, which are the characteristic broad shallow streams of the semi-arid west, flowing through wide valleys, are the Arkansas, Cimarron, North Fork of Canadian, Washita, North Fork of Red, and Red rivers. The extreme western portion is a semi-arid, treeless plain, while the extreme eastern part is wooded by the belt of forest known as the "Cross timbers"; between lie fertile prairies and valleys partly wooded and principally along streams. The forest is composed largely of varieties of oak on the higher ground, with ash, elm, and cottonwood by the rivers in the valleys. The climate is about the same as Arkansas and Tennessee, except that it is less humid, the mean annual rainfall being about 32 inches in the eastern part of the Territory and about 20 inches in the western. Among the wild animals and birds are deer, antelope, wolf, coyote, fox, prairie dog, rabbit, squirrel, turkey, prairie chicken, quail, hawk, and buzzard.

History.—For a number of years before the opening of this country, public lands in adjoining territory had been so over-populated that many illegal attempts were made by covetous squatters to obtain possession. When finally the lands had been purchased of the Indians by the Government, and thrown open to settlement, the rush to secure homesteads and town lots was unprecedented, there being five or six persons for every available claim, and innumerable contests arose in consequence. Probably no agricultural country was ever settled with such rapidity. Towns were started without a single inhabitant in the morning and by night contained a population of five thousand, housed in tents or without shelter. Railways already built facilitated this rapid growth by landing building material and supplies without delay. "No Man's Land," the extreme western strip of land, was for many years unattached to any state or territory, and designated on the maps as "Public Land." Greer county, in the south-western corner, was disputed territory for many years, the state of Texas claiming that the North Fork of the Red river was the main stream, and therefore the boundary line. A decision of the United States Supreme Court was against this claim and it remains attached to Oklahoma.

Products.—The eastern and middle parts are agricultural lands, the richest soil being in the bottom lands of the broad river valleys, devoted to the cultivation of various farm products, the most important of which are wheat, oats, cotton, and corn. Indian corn, castor beans, melons, pea-nuts, alfalfa, and many fruits and vegetables are raised. The rainfall is occasionally much below the average, when failures result, but with normal conditions the soil produces luxuriantly. The western part is a grazing land, affording pasturage for cattle in large numbers. Horses, sheep, and swine are also raised. No trustworthy statistics have been gathered since the settlement of the country in regard to farm products or domestic animals, but from the best obtainable data it is estimated that during 1901 25,000,000 bushels of wheat, 60,000,000 bushels of corn, and 140,000 bales of cotton were raised, and that 36,235 horses, 52,580 mules, 617,750 cattle, 42,000 sheep, and 277,289 hogs were owned in the Territory.

Population.—The population in 1900 was 398,331, as compared with 61,834 in 1890; 214,359 were males and 183,972 were females; 382,651 were native and 15,680 were foreign-born; 367,524 were whites, 18,831 were negro, 11,945 were Indians, and 31 were Chinese. The population materially increased in 1901 by the opening to settlement of the Kiowa and Comanche Indian Reservation. The average number of persons to the square mile was 10·3, as compared with 1·6 in 1890. There were fifty incorporated cities and towns in 1900, but of these only two had a population of over 4000, namely, Oklahoma city with 10,037, and Guthrie (the capital) with 10,006 inhabitants. There are 700 churches and 2000 public schools, several normal schools, and an agricultural college, the school attendance being 110,000. One thousand and seventy-five miles of railway had been built at the beginning of 1901, four trunk lines extending across the Territory. There are about 12,000 Indians upon the several reservations and allotted lands set apart for their use, representing members of the following tribes: Kiowa, Comanche, Apache, Wichita, Cheyenne, Arapaho, Sac and Fox, Ponca, Pawnee, Caddo, Delaware, Kansas, Osage, and Shawnee. Some of the tribes are dependent upon the Government for support, while others are self-sustaining. Several Government schools are maintained, attended by 2000 Indian children. Many acres of their land are leased for grazing purposes, but some of it is used by the Indians themselves for agriculture and grazing. There is a military post at Fort Sill and also at Fort Reno. About 400 Apache Indians, prisoners of war, are held on a small reservation near Fort Sill, where they are slowly becoming civilized, and are taught farming and cattle-raising.

There has been a remarkable increase in the manufactures and mechanical industries since 1890, an increase even more striking than the increase in population (544·2 per cent.), and exceeding that of any other state or territory. Compared with older localities, the amount of manufacturing is still insignificant. A notable product is the manufacture of cotton-seed oil, which has grown with the rapid development of the cotton crop. The accompanying table is a comparative summary of the manufacturing and mechanical industries of the Territory for 1890 and 1900. (C. H. F.)

	1890.	1900.	Per cent. of Increase.
Number of establishments	72	870	1,108·3
Capital	$95,519	$3,352,064	3,409·3
Wage - earners, average number . . .	147	2,054	1,297·3
Total wages . . .	$52,326	$807,826	1,443·8
Miscellaneous expenses .	$21,970	$246,081	1,020·1
Cost of materials used .	$56,518	$4,449,944	7,773·5
Value of products, including custom work and repairing . . .	$180,445	$7,083,938	3,825·8

Oklahoma, a city of Oklahoma Territory, U.S.A., capital of Oklahoma county, on the north fork of the Canadian river and on the Atchison, Topeka, and Santa Fé, the Choctaw, Oklahoma, and Gulf, and the St Louis and San Francisco railways, in the south-eastern portion of the territory, at an altitude of 1195 feet. The city is regularly laid out on a level site, has considerable trade in cotton, and contains cotton gins and flour and other mills or factories. It was settled in 1889. Population (1890), 4151; (1900), 10,037, of whom 571 were foreign-born and 1219 negroes.

Okuma (Shigenobu), Count (1837——), Japanese statesman, was born in the province of Hizen in the year 1837. His father was an officer in the artillery, and during his early years his education consisted mainly of the study of Chinese literature. Happily for him, however, he was able to acquire in his youth a knowledge of English and Dutch, and by the help of some missionaries he succeeded in obtaining books in those languages on both scientific and political subjects. These works effected a complete revolution in his mind. He had been designed by his parents for the military profession, but the new light which now broke in upon him determined him to devote his entire energies to the abolition of the existing feudal system and to the establishment of a constitutional government. With impetuous zeal he urged his views on his countrymen, and though he took no active part in the revolution of 1868, the effect of his opinions exercised no slight weight in the struggle. Already he was a marked man, and no sooner was the Government reorganized, with the Mikado as the sole wielder of power, than he was appointed chief assistant in the department of Foreign Affairs. In the following year he succeeded to the post of secretary of the joint departments of the Interior and of Finance, and for the next fourteen years he devoted himself wholly to politics. In 1870 he was made a councillor of state, and a few months later he accepted the office of president of the commission which represented the Japanese Government at the Vienna Exhibition. In 1872 he was again appointed minister of finance, and when the expedition under General Saigô was sent to Formosa (1874) to chastise the natives of that island for the murder of some shipwrecked fishermen, he was nominated president of the commission appointed to supervise the campaign. Throughout his political career Count Okuma was a leader of the progressive party, and with indefatigable energy he in 1887 advocated the revision of the treaties. By one of those waves of popular feeling to which the Japanese people are peculiarly liable, the nation which had supported him up to a certain point suddenly veered round and opposed him with heated violence. So strong was the feeling against him that on one occasion a would-be assassin threw at him a dynamite shell, which blew off one of his legs. During the whole of his public life he recognized the necessity of promoting education. When he resigned office in the early 'eighties he established the Semmon Gako, or school for special studies, at the cost of the 30,000 yen which had been voted him when he received the title of count, and subsequently he was instrumental in founding other schools and colleges. He was a consistent advocate for the higher education of women, and did much to elevate the position of his countrywomen in the social scale. In 1896 he joined the Matsukata cabinet, and resigned in the following year in consequence of intrigues which produced an estrangement between him and the prime minister. On the retirement of Marquis Ito in 1898 he again took office, combining the duties of premier with those of minister of foreign affairs. But dissensions having arisen in the cabinet, he resigned a few months later, and retired into private life, cultivating his beautiful garden at Waseda near Tôkyô.

Öland, an island of Sweden, lying off the east coast, from which it is separated by Calmar Sound. The principal products are cattle, game, fish, cement, lime, and building stone. The town of Borgholm (population, 926 in 1900) has now a certain repute as a seaside resort. Population of island (1900), 30,408, scarcely more than in the middle of the 19th century.

Old-Age Pensions.—The organization of annuities for the poor by the State was proposed in the 18th century—*e.g.*, by Francis Maseres, cursitor baron of the Exchequer, in 1772, and by Mr Mark Rolle, M.P., in 1787. Suggestions for subsidizing friendly societies have also been frequent—*e.g.*, by T. Paine in 1795, tentatively in Sturges Bourne's Report on the Poor Laws, 1817, and by Lord Lansdowne in 1837. The subject has been revived in the present day. Many persons unfortunately become destitute in old age, and it has been tacitly assumed by advocates of State pensions that destitution in old age is entitled to greater public sympathy, and that it can advantageously be dealt with in a manner more liberal, than the destitution of widows, orphans, and persons prematurely stricken with permanent illness. No such plea, however, was originally put forward by Canon Blackley, the reviver of the controversy towards the close of the 19th century. His plan assumed the ability of the great mass of the population to provide for themselves. He proposed, therefore, to compel every one to insure with a State department against sickness and old age, and essentially his scheme was one for the relief of the ratepayers and a more equitable readjustment of the poor-rate. The terms provisionally put forward by him required that every one in youth should pay £10, in return for which the State was to grant 8s. a week sick allowance and 4s. pension after seventy. These proposals were submitted to the Select Committee on National Provident Insurance, 1885–1887. This body reported unfavourably, more especially on the sick insurance part of the scheme, but the idea of old-age pension survived, and was taken up by the National Provident League, of which Mr (afterwards Sir) J. Rankin, M.P., was chairman. The subject was discussed in the constituencies and expectation was aroused. An unofficial parliamentary committee was formed, with Mr Chamberlain as chairman. This committee published proposals in March 1892, which show a very interesting change of attitude on the part of the promoters. Compulsion, which at the earlier period had found favour with Canon Blackley, Sir J. Rankin, and even Mr Chamberlain, was no longer urged. The annuitant was no longer required to pay a premium adequate to the benefits promised, as in Canon Blackley's proposal. The benefit was no longer a pure annuity, but premiums were, in certain cases, returnable, and allowances were provided for widows, children (if any), and for the next of kin. Canon Blackley's professed object was to supersede the friendly societies, which, he alleged, were more or less insolvent; a proposal was now introduced to double every half-crown of pension derived by members from their friendly societies. Several alternative schemes were put forward, but the figures were only provisional, and it is enough to say that the principle suggested was to double, by subsidy from public funds, the value of the contribution made by the annuitant himself. Adverse criticism has been directed against these voluntary and contributory schemes, not only by those who are entirely opposed to State intervention, but by an influential section of those who favour that principle. Of these, Mr Charles Booth has been the most prominent spokesman. There is only one point of agreement between these two schools. They both assume, not only what all admit, that the destitution of old age is entitled to sympathy, but that it is entitled to a special treatment not accorded to other forms of destitution. Mr Chamberlain's scheme proposes State assistance, on condition that the annuitant voluntarily contributes one-half the requisite amount. Mr Booth points out that this condition will not be fulfilled by the class from which pauperism is drawn. Unless the pension is gratuitous, this class either would not or could not profit by it. Accordingly Mr Booth has proposed that there shall be a general endowment of old age, *i.e.*, as originally proposed, 5s. a week to every one at the age of sixty-five. The details have been varied, but the principle is the same. This proposal involves an expenditure of £18,000,000 for England and Wales and £24,000,000 for the United Kingdom, exclusive of the cost of administration. So large an expenditure has been felt to be a difficulty, and proposals have been made to limit the gratuity either to a special class, *e.g.*, persons with an income of less than 10s. weekly or to members of a friendly society, or to those who require it and are of good character. Mr Booth, however, considers universality to be of the essence of his scheme. The difficulty of drawing a line between those who are, and those who are not, entitled to such assistance seems to him insuperable; and to limit the endowment to those who plead destitution is to reduce the system to a form of poor-law relief, which *ex hypothesi* is supposed to be unsatisfactory. Mr Booth throughout has been anxious to append to his scheme the further condition, that, on its adoption, out-door poor-law relief shall be discontinued. How far this is accepted by those who act with him is not clear. While Mr Booth has severely criticized the weak points of the contributory and voluntary schemes, their most influential advocate, Mr Chamberlain, has not spared Mr Booth's proposals. Speaking at Highbury, for instance, on 24th May 1899, he described Mr Booth's universal scheme as "a gigantic system of out-door relief for every one, good and bad, thrifty and unthrifty, the waster, drunkard, and idler, as well as the industrious," and very forcibly stated his inability to support it.

Notwithstanding these differences of opinion, the advocacy of these gentlemen has raised considerable expectation, and the subject has been referred to a succession of commissions and committees, but without any practical result. In 1893 Mr Gladstone's Government was pressed to declare a policy, and sought refuge in a royal commission (Lord Aberdare, chairman). A majority report, adverse to the principle of State pensions, was issued in 1895. A minority report, signed by Mr Chamberlain and others, dissented, mainly on the ground that public expectation would be disappointed, if nothing was done. In 1896 Lord Salisbury appointed a committee "of experts" (Lord Rothschild, chairman) to report on schemes submitted, and, if necessary, to devise a scheme. The committee were unable to recommend any of the schemes submitted, and added that, "we ourselves are unable, after repeated attempts, to devise any proposal free from grave inherent disadvantages." This second condemnation was not considered conclusive, and a select committee of the House of Commons (Mr Chaplin, chairman) was appointed to consider the condition of "the aged deserving poor." After an ineffectual attempt by Mr Chaplin to induce the committee to drop the pension idea, and to consider the provision made for the aged by the poor law, the committee somewhat hastily promulgated a scheme of gratuitous pensions for persons possessing certain qualifications. Of these the following were the most important:—age of sixty-five; no conviction for crime; no poor-law relief, "unless under exceptional circumstances," within twenty years; non-possession of income of 10s. a week; proved industry, or proved exercise of reasonable providence by some definite mode of thrift. The committee refrained from explaining the machinery and from estimating the cost, and suggested that this last problem should be submitted to yet another committee.

Accordingly a departmental committee (chairman, Sir E. Hamilton) was appointed, which reported in January 1900. The estimated cost of the above plan was, by this committee, calculated at £10,300,000 in 1901, rising to £15,650,000 in 1921. Mr Chaplin had publicly suggested that £2,000,000, the proceeds of a 1s. duty on corn, would go a long way to meet the needs of the case—a conjecture which was obviously far too sanguine. These unfavourable reports appear to have discouraged the more responsible advocates of State pensions. Mr Chamberlain appealed to the friendly societies to formulate a plan, an invitation which they showed no disposition to accept. Efforts continued to be made to press forward Mr Booth's universal endowment scheme or some modification of it. To this Mr Chamberlain declared his hostility. And here up to 1902 the matter rested.

The scheme throughout has been strongly opposed by the school of poor-law reformers generally identified with the London Charity Organization Society. Mr Booth's universal proposal they consider impracticable, and unnecessary to a large extent; and, where necessary, not to be distinguished in its moral and economic effects from poor-law relief. They object also to State-assisted pensions, on the ground that they attempt to popularize a form of investment which probably is not the best use of a poor man's savings. The leaders of the great friendly society movement have also, with few exceptions, opposed or stood aloof from the proposal. Their aim is the absolute independence of their members. The offer of gratuity to their own associations, though very tempting, has been rejected partly on grounds of principle, and also from the belief that State aid would mean more State supervision and ultimately State management.

The movement in favour of State aid to provision for old age has been largely due to the example of Germany. The German system (which for old age dates from 1891) is compulsory and contributory. The element of compulsion was very early deemed unsuitable for the United Kingdom, and the precedent of Germany, therefore, no longer applies. One half of the premium payable is there paid by the labourer, the other half by the employer. The State adds a subvention to the allowances paid to the annuitant. (See *The German Law of Insurance against Invalidity and Old Age*, by T. E. Young, actuary of the Commercial Union Assurance Company, 1891.) A well-informed article by Mr H. W. Wolff in the *Charity Organization Review*, December 1899, describes another phase of the question. He points out that the law is unpopular both with the workmen and the employer, and that the financial difficulty of employing the insurance fund is considerable and progressive. Continuous pressure seems to be exerted in favour of raising the amount of pension and of relaxing the conditions of contributory thrift. The Government, much against its will, is being pushed away from the endowment of thrift, which has been its ideal, towards the mere endowment of old age, which it has always condemned.

The Danish system of old-age pensions differs entirely from the above. It has been disavowed and condemned by Dr Bödeker, the late President of the German State Insurance Department, as a mere extension of out-door relief, as an endowment, and therefore an encouragement not of thrift but of need. The Danish system has been described by Mr A. W. Flux in a pamphlet reprinted from the *Yale Review*, February 1899, and by Mr J. S. Davy of the Local Government Board in evidence given to the Select Committee on the Aged Deserving Poor, 1899. By the law of 1891, the burden of maintaining the aged is in part transferred from the local to the national taxes, and relief from this latter source is called a pension. The committee remark on the Danish plan, "It is difficult to see what substantial difference there is in practice between the pensions in Denmark and the out-relief given in this country [Great Britain] to the deserving poor, except that in Denmark such relief can be claimed as a matter of right, and conveys no civil disqualification." The grant of a pension, though it can be claimed as a right, can be refused, if the applicant is of bad character, has been in receipt of poor-law relief within ten years, or if from other sources he has enough to maintain him. The allowance given, it is stated, like the British system of out-door relief, tends to be inadequate, for it is assumed that applicants as a rule do not fully disclose their resources. As might be expected, the change of incidence of the burden, though it has decreased the demand on the local rates, has increased expenditure by a more than commensurate addition to the central taxes. The idea that, while to be a recipient of poor-law relief is derogatory from the part of a good citizen, the dependency of a pensioner is an honourable status, has gained some sort of currency. Accordingly, promises to extend the scope and amenity of pension-endowment, a form of dependency that is not injurious, are put forward in the rivalry of party politics.

New Zealand.—In 1898 a Bill, introduced by the Rt. Hon. R. J. Seddon, premier, became law which provided for the payment of an old-age pension out of the consolidated fund (revenue of the general government) to persons duly qualified, without contribution by the beneficiaries. The claimants must be 65 years of age, resident in the colony, and have so resided for 25 years. They must be free from conviction for lesser legal offences for 12 years, and for more serious breaches of the law for 25 years, previous to the application. They must be of good moral character and have a record of sobriety and respectability for five years. Their yearly income must not exceed £52, and they must not be owners of property exceeding in value £270. Aliens, aborigines, Chinese, and Asiatics are excluded. The pensions are for £18 per annum, but for each £1 of yearly income over and above £34, and also for each £15 of capital over and above £50, £1 is deducted from the amount of the pension. Applications have to be made to the deputy registrars of one of 72 districts into which the colony is for this purpose divided. The claim is then recorded and submitted to a stipendiary magistrate, before whom the claimant has to prove his qualifications and submit to cross-examination. If the claim is admitted, a certificate is issued to the deputy registrar and in due course handed to the claimant. Payment is made through the local post-office as desired by the pensioner. The Act came into force 1st November 1898. Up to March 1899, 7487 pensions had been granted, amounting to a liability of £128,082 per annum. The average pension was £17, 2s. See *New Zealand Official Year Book* for 1899. In March 1900 the number of pensions was 11,285, and the cost £193,718. The Act was avowedly experimental, and only provided for payments out of revenue until the close of the second session of the next parliament. The cost considerably exceeded the estimate of £100,000 per annum which was originally put forward. The authors of the measure maintain that it is a great success, while others point to the invidious character of the cross-examination required in proving the necessary degree of poverty, and allege that the arrangement penalizes the thrifty members of the poorer class, and is a direct incentive to transfer of property, of a more or less fraudulent character, between members of a family. It is too early as yet to pronounce an authoritative verdict on the facts.

Victoria.—By the Old Age Pensions Act, 1900, £75,000 was appropriated for the purpose or paying a pension of not more than 10s. per week to any person who fulfilled the necessary conditions, of which the following were the principal:—The pensioner must be 65 years of age or permanently disabled, must fill up a declaration that he has lived twenty years in the state; has not been convicted of drunkenness, wife-desertion, &c.; that his weekly income and his property do not exceed a given sum (the regulation of this and other details is intrusted to the Governor in Council). Further sums have since been appropriated to the purposes of the Act, but it is not yet possible to say how far the Act is regarded as a success.

Oldbury, a township and parish in the northern parliamentary division of Worcestershire, England, 5 miles west of Birmingham by rail. It is controlled, together with Langley and Warley, by an urban district council. Public buildings erected in 1891 contain its various offices. Population (1891), 22,697; (1901), 25,191.

Old Calabar. See NIGERIA.

Old Catholics.—Since 1878 there is little to record about Old Catholicism. Its position has disappointed the expectation of its friends and of its enemies. It has neither advanced rapidly, as the former had hoped, nor retrograded, as the latter have frequently predicted it would do. In Germany there are 90 congregations, served by 60 priests, and the number of adherents is estimated at about 60,000. In Switzerland there are 40 parishes (of which only one, that at Lucerne, is in the Roman Catholic cantons), 58 clergy, and about 50,000 adherents. In Austria, where very considerable accessions have been received since the *Los von Rom* movement commenced in 1899, there are 8 priests, 12 churches (besides three more in course of erection), and about 15,000 adherents. In Holland, where the Old Catholic Church has existed independently of the Papacy for nearly two centuries, an addition has taken place in the number of adherents which is very gratifying to the authorities of that Church. There are 3 bishops, 27 congregations, and 8030 adherents. France possesses but one congregation, in Paris, where it has built for itself a church. It is now under the supervision of the Old Catholic archbishops of Utrecht. In Italy a branch of the Old Catholic communion was established in 1881 by Count Enrico di Campello, a former canon of St Peter's at Rome. A church was opened in Rome by Monsignor Savarese and Count Campello, under the supervision of the bishop of Long Island in the United States, who undertook the superintendence of the congregation in accordance with the regulations laid down by the Lambeth conference. But dissensions arose between the two men. The church in Rome was closed; Savarese returned to the Roman Church; and Campello commenced a reform work in the rural districts of Umbria, under the episcopal guidance of the bishop of Salisbury. This was in 1885. In 1900 Campello returned to Rome, and once more opened a church there. In 1902 Count Campello retired from active participation in the work, on account of age and bodily infirmity; and his place at the head of it was taken by the Rev. Professor Cicchitti of Milan. In 1902 there were six priests, who are either in Roman or Old Catholic orders. No statistics have been issued, but there are thirteen congregations. Old Catholicism has spread to America. The Polish Romanists there, in 1899, complained of the rule of Irish bishops; elected a bishop of their own, Herr Anton Kozlowski; presented him to the Old Catholic bishops in Europe for consecration; and he presides over seven congregations in Chicago and the neighbourhood. The Austrian and Italian churches possess no bishops, and the Austrian Government refuses to allow the Old Catholic bishops of other countries to perform their functions in Austria. In 1878 a question arose which threatened the existence of Old Catholicism. The Swiss and German laity insisted that their clergy should be free to marry. The Dutch church protested, and threatened excommunication. Döllinger strongly disapproved of the step. But though it checked adhesions from Romanism, the difference has been accommodated. Every Old Catholic congregation has its choral union, its poor relief, and its mutual improvement society. Theological faculties exist at Bonn and Bern, and at the former a residential college for theological students was established by Bishop Reinkens. Old Catholicism has eight organs in the public press—two in Italy, two in Switzerland, and one each in Holland, Germany, Austria, and France. It has built several churches, of which that at Karlsruhe is the most imposing. It has held reunion conferences at Lucerne in 1892, at Rotterdam in 1894, and at Vienna in 1897. At these, members of the various episcopal bodies have been welcomed. It has also established a quarterly publication, the *Revue Internationale de Théologie*, which has admitted articles in French, German, and English, contributed not merely by Old Catholics, but by members of the Anglican, Russian, Greek, and Slavonic churches. Old Catholic theologians have been very active since 1878, and the work of Döllinger and Reusch on the Jesuits and the history of the Roman Church by Professor Langen have attained a European reputation.

The only history of Old Catholicism is that published at Giessen in 1887 by the celebrated canonist Von Schulte. (J. J. L*.)

Oldenburg, a grand-duchy of Germany, with an area of 2479 square miles, and population (1885), 341,525; (1900), 398,499, thus distributed—duchy of Oldenburg, 317,842; principality of Lübeck, 37,337; principality of Birkenfeld, 43,320. Of the total in 1900, 197,954 were males and 200,545 females. The density is 160 inhabitants to the square mile. In 1895, 26·6 per cent. of the population were classified as urban, and 73·4 per cent. as rural. The number of emigrants decreased from 1296 in 1892 to 255 in 1900. Classified according to religion in 1895, 289,620 of the people (77·5 per cent.) were Protestants, 81,492 (21·8 per cent.) Roman Catholics, and there were 1430 Jews. In 1897 there were 157 secondary schools for boys, 21 for girls, 13 theological seminaries, a school of navigation, &c. About one-half of the population are engaged in agriculture and pastoral pursuits, the crops principally grown being hay, potatoes, oats, wheat, and barley. The farms are mostly under 25 acres. In 1900 the live stock numbered 264,885 cattle, 210,808 pigs, 112,064 sheep, and 41,849 horses. The breweries in 1899 produced 4,796,000 gallons of beer. There were 334 miles of railway in 1899, all, except 25 miles, under State control. The mercantile fleet, which belongs to the ports of Oldenburg, Elsfleth, and Brake, consisted in 1900 of 150 sea-going vessels of 77,467 tons. The public revenue for the entire grand-duchy in 1900 amounted to £390,650, and the expenditure to £478,700. In 1900 the public debt was £2,793,200; and in 1901 the contribution to the imperial treasury, £202,030.

Oldenburg, a town of Germany, capital of the grand-duchy of Oldenburg, on the Hunte, 27 miles by rail west of Bremen. The more important modern buildings are the town hall (1885–87); a west wing (1894–99) to the castle, with frescoes by Fitger; the antiquarian museum

(1876–79); the palace of the heir-apparent (1896); the theatre (1891), rebuilt after a fire; the provincial bank (1896); and the Peace church (1893–94). The grand-ducal palace has been adorned with pictures by modern German artists (Gode, Mackart, Böcklin, Siemiradzki, &c.). Additional pictures by these and other modern painters (*e.g.*, Tischbein) have been collected in the castle. The church of St Lambert was restored in 1874–86. The town possesses, further, an industrial museum, a memorial of the war of 1870–71, a military school, and a teachers' seminary. There is an important horse fair. Population (1885), 19,937; (1900), 26,635.

Old Forge, a borough of Lackawanna county, Pennsylvania, U.S.A. It is in the anthracite coal region, in the north-eastern part of the state, and its industries are mainly devoted to handling and shipping coal. Population (1900), 5630, of whom 2494 were foreign-born.

Oldham, a municipal, county (1888), and parliamentary borough and market town of Lancashire, England, on the Medlock, 200 miles by rail from London. The municipal technical school has been taken over by the corporation. Modern buildings include an Established church, Hulme Grammar School (1895), a free library, art gallery and museum, and the county court. The infirmary was enlarged in 1889. There are 2 daily newspapers. The factories number about 230, and the spindles over 13,000,000. The consumption of cotton is about one-fifth of the total importation into the United Kingdom. In 1891 there were 14,691 males and 20,170 females employed in the manufacture of cotton goods; 1735 males as fitters and turners (engine and machine); 544 persons in the iron and steel manufacture. Area of municipal borough, 4730 acres. Population (1881), 111,343; (1891), 131,463; (1901), 137,238.

Old Town, a city of Penobscot county, Maine, U.S.A., on the west bank of the Penobscot river, and on the Maine Central and the Bangor and Aroostook railways, at an altitude of 95 feet. It is known as the home of a remnant of the Penobscot tribe of Indians, and as one of the termini of the second railway constructed in the country, running thence to Bangor, and built in 1836. Population (1880), 3395; (1890), 5312; (1900), 5763, of whom 1247 were foreign-born.

Olean, a city of Cattaraugus county, New York, U.S.A., on the north bank of the Allegheny river, in the south-western part of the state, at an altitude of 1437 feet. Its site is in the level valley and its plan is regular. It is on three railways, the Erie, the Pittsburg, Shawmut, and Northern, and the Western New York and Pennsylvania. It is in the midst of the oil and natural gas region, and the surrounding country is diversified with oil tanks and derricks. It contains large refineries and storage tanks, and is the eastern terminus of the Ohio pipe line and the western terminus of a pipe line to the seaboard. Population (1880), 3036; (1890), 7358; (1900), 9462, of whom 1514 were foreign-born and 122 negroes.

Olhão, a town of Portugal, district Faro, 5 miles east of Faro, on the coast. Its people are good seamen, and employ themselves in fishing. Population (1900), 9993.

Oliphant, Laurence (1829–1888), English author, son of Anthony Oliphant, a member of a family of ancient descent but moderate fortune, long settled in central Scotland, was born at Cape Town in 1829. His father was then Attorney-General in Cape Colony, but was soon transferred as Chief Justice to Ceylon. The boy's education was of the most desultory kind. Far the least useless portion of it belonged to the years 1848 and 1849, when he accompanied his parents on a tour on the continent of Europe. In 1851 he accompanied Jung Bahadur from Colombo to Nepaul. He passed an agreeable time there, and saw enough that was new to enable him to write his first book, *A Journey to Khatmandu* (1852). From Nepaul he returned to Ceylon and thence to England, dallied a little with the English bar, so far at least as to eat dinners at Lincoln's Inn, and then with the Scottish bar, so far at least as to pass an examination in Roman law. He was more happily inspired when he threw over his legal studies and went to travel in Russia. The outcome of that tour was his book on *The Russian Shores of the Black Sea* (1853). Between 1853 and 1861 he was successively secretary to Lord Elgin during the negotiation of the Canada Reciprocity Treaty at Washington, the companion of the duke of Newcastle on a visit to the Circassian coast during the Crimean war, and Lord Elgin's private secretary on his expedition to China. Each of these experiences produced a pleasant book of travel. In 1861 he was appointed First Secretary in Japan, and might have made a successful diplomatic career if it had not been interrupted, almost at the outset, by a night attack on the Legation, in which he nearly lost his life. It seems probable that he never properly recovered from this affair. He returned to England and resigned the service, and was elected to Parliament in 1865 for the Stirling Burghs. Oliphant did not show any conspicuous parliamentary ability, but made a great success by his vivacious and witty novel, *Piccadilly* (1870). He fell, however, under the influence of the spiritualist prophet Thomas Lake Harris, who was at the head of a small community at Brocton on Lake Erie. This man obtained so strange an ascendancy over Oliphant that the latter left Parliament in 1868, followed him to Brocton, and lived there the life of a farm labourer, in obedience to the imperious will of his spiritual guide. The cause of this painful and grotesque aberration has never been made quite clear. It was part of the Brocton régime that members of the Community should be allowed to return into the world from time to time, to make money for its advantage. After three years this was permitted to Oliphant, who, when once more in Europe, acted as correspondent of *The Times* during the Franco-German war, and spent afterwards several years at Paris in the service of that journal. There he met Miss Alice le Strange, whom he married. In 1873 he went back to Brocton, taking with him his wife and mother. During the years which followed he continued to be employed in the service of the Community and its head, but on work very different from that with which he had been occupied on his first sojourn. His new work was chiefly financial, and took him much to New York and a good deal to England. As late as December 1878 he continued to believe that Harris was an incarnation of the Deity. By that time, however, his mind was occupied with a large project of colonization in Palestine, and he made in 1879 an extensive journey in that country, going also to Constantinople, in the vain hope of obtaining a lease of the northern half of the Holy Land with a view to settle large numbers of Jews there. This he conceived would be an easy task from a financial point of view, as there were so many persons in England and America "anxious to fulfil the prophecies, and bring about the end of the world." He landed once more in England without having accomplished anything definite; but his wife, who had been banished from him for years and had been living in California, was allowed to rejoin him, and they went to Egypt together. In 1881 he crossed again to America. It was on this visit that he became utterly disgusted with Harris, and escaped finally from the long and squalid tyranny under which he and his had suffered. He was at first a little afraid that his wife would not follow him in his renunciation of "the prophet," but this was not the case, and they settled themselves very agreeably, with one house in the midst of the German community at Haïfa, and another about twelve miles off at Dalieh on Mount Carmel. It was at Haïfa in 1884 that they wrote together the strange book called *Sympneumata*, and in the next year Oliphant produced there his novel *Masollam*, which may be taken to contain its author's latest views with regard to the personage whom he long considered as "a new Avatar." One of his cleverest works, *Altiora Peto*, had been published in 1883. In 1886 an attack of fever, caught on the shores of the Lake of Tiberias, resulted in the death of his wife, whose constitution had been undermined by the hardships of her American life. He was persuaded that after death he was in much closer relation with her than when she was still alive, and conceived that it was under her influence that he wrote the book to which he gave the name of *Scientific Religion*. In November 1887 he went to England to publish that book. By the Whitsuntide of 1888 he had completed it and started for America. There he determined to marry again, his second wife being a granddaughter of Robert Owen the Socialist. They were married at Malvern, and meant to have gone to Haïfa, but Oliphant was taken very ill at Twickenham, and died on 23rd December 1888. Although a very clever man and a delightful companion, full of high aspiration and noble feeling, Oliphant was only partially sane. In any case, his education was ludicrously inappropriate for a man who aspired to be an authority on religion and philosophy. He had gone through no philosophical discipline in his early life, and knew next to nothing of the subjects with regard to which he imagined it was in his power to pour a flood of new light upon the world. His shortcomings and eccentricities, however, did not prevent his being a brilliant writer and talker, and a notable figure in the world in which he happened to move.

See also *Memoir of the Life of Laurence Oliphant and of Alice Oliphant his Wife*, by MARGARET OLIPHANT. (M. G. D.)

Oliphant, Margaret Oliphant Wilson (1828–1897), novelist and historical writer, was born at Wallyford, near Musselburgh, Midlothian, in 1828. Her childhood was spent at Lasswade (near Dalkeith), Glasgow, and Liverpool. As a girl she constantly occupied herself with literary experiments, and in 1849 published her first novel, *Passages in the Life of Mrs Margaret Maitland*, which had some success. This she followed up in 1851 with *Caleb Field*, and in the same year met Major Blackwood in Edinburgh, and was invited by him to contribute to the famous *Blackwood's Magazine*. The connexion thus early commenced lasted during her whole lifetime, and she contributed considerably more than 100 articles to its pages. In May 1852 she married her cousin, Frank Oliphant, at Birkenhead, and settled at Harrington Square, in London. Her husband was an artist, of very delicate health, and two of their children died in infancy, while the father himself developed alarming symptoms of consumption. For the sake of his health they moved in January 1859 to Florence, and thence to Rome, where Frank Oliphant died. His wife, left almost entirely without resources, returned to England and took up the burden of supporting her three children by her own literary activity. She had now become a popular writer, and worked with amazing industry to sustain her position. Unfortunately, her home life was full of sorrow and disappointment. In January 1864 her only daughter died in Rome, and was buried in her father's grave. Her brother was shortly afterwards involved in financial ruin, and Mrs Oliphant offered a home to him and his children, and added their support to her already heavy responsibilities. In November 1865 she settled at Windsor, which remained her home for the rest of her life, and for more than thirty years she pursued a varied literary career with courage scarcely broken by a series of the gravest troubles. Her son Cyril died in 1890, and Frank, the youngest, in 1894. With the last of her children lost to her, she had but little further interest in life. Her health steadily declined, and she died at Wimbledon, 25th June 1897. Her life had been one long sacrifice to others, and she had enjoyed a very small share of happiness or peace.

In the course of her long struggle with circumstances, Mrs Oliphant produced more than 120 separate works, including novels, books of travel and description, histories, and volumes of literary criticism. Among the best known of her works of fiction are *Adam Graeme* (1852), *Magdalen Hepburn* (1854), *Lilliesleaf* (1855), *The Laird of Norlaw* (1858), *The Chronicles of Carlingford*, which, originally appearing in *Blackwood's Magazine*, did much to widen her reputation (1861–64), *Salem Chapel* (1863), *Madonna Mary* (1867), *Squire Arden* (1871), *He that will not when he may* (1880), *Hester* (1883), *Kirsteen* (1890), and *The Marriage of Elinor* (1892). Her friends often regretted that she did not work more slowly, and so give full play to her faculties; but it is probable that she was one of those who do best what they do quickly, and who must work at high pressure to succeed at all. Her inventive faculty was fertile and vigorous; she had humour and sympathy, but no depth of insight; she saw superficial details with great accuracy and complexity, but she was no philosopher. Her fiction was of the class that entertains the imagination and touches the emotion without appeal to the more strenuous activities of the brain. In other fields of literary work she was industrious, but unequal. Her biographies of *Edward Irving* (1862) and *Laurence Oliphant* (1891), together with her life of Sheridan in the "English Men of Letters" (1883), have vivacity and a sympathetic touch, but are not important contributions to the biographical library. She also wrote historical and critical works of considerable variety, including *Historical Sketches of the Reign of George II.* (1869), *The Makers of Florence* (1876), *A Literary History of England from 1790 to 1825* (1882), *The Makers of Venice* (1887), *Royal Edinburgh* (1890), *Jerusalem* (1891), and *The Makers of Modern Rome* (1895), while at the time of her death she was still occupied upon *Annals of a Publishing House*, a record of the progress and achievement of the firm of Blackwood, with which she had been so long and honourably connected. Many of these works show to great advantage her singular power of assimilation and arrangement; they are compilations of much charm and effect. But they rarely add anything to what is already known of the subject, and are rather exercises in agreeable presentation than storehouses of research and discovery. She wrote easily, and with a free, unaffected style, but she had little care for niceties of expression, and was herself in the habit of declaring that she had never consciously sought for literary form or finish. It was this natural facility and nonchalance that deprived her work of the highest qualities of distinction, and will probably prevent it from surviving the work of some of her less popular contemporaries. (A. WA.)

Oliva, a town of Spain, in the province of Valencia, near the sea, on the railway from Carcagente to Alicante. The population was 8779 in 1887, and 7949 in 1897. It is a port for small coasting vessels. There are no important local industries, and only some trade in agricultural products, especially wine, rice, raisins, oils. There are two parish churches, and a palace of the dukes of Gandia.

Olivenza, a town of Spain, in the province of and south of the town of Badajoz, near the left bank of the river Olivenza. The local industries include the making of porcelain, leather, and hats, besides flour-mills. It was a fortified town down to 1857, when walls and bastions were razed and the stone given to the people. There are two parish churches, Santa Maria del Castillo of the 13th century and restored in the 16th, and Santa Maria Magdalena of the 16th century, with three naves and a high altar of pluteresque style. Olivenza has good promenades, a theatre, a bull-ring, hospitals, barracks. This town, so near the frontier, has played an important part in the wars between Spain and Portugal, remaining from 1688 to 1801 in the hands of the latter. Population, about 8200.

Ollivier, Olivier Émile (1825——), French statesman, was born at Marseilles on 2nd July 1825. From his father, Démosthène Ollivier, a prominent member of the Assembly of 1848, he inherited pronounced republican opinions. He had just been called to the bar at Paris when the revolution broke out, and though only twenty-three years old, was appointed, through his father's influence with Ledru-Rollin, commissary-general of the Republic in his native department of the Bouches-du-Rhône. His vigour in repressing a Socialist outbreak at Marseilles caused him to be confirmed in his functions by Cavagnari with the title of prefect; but his administration roused much adverse criticism, and he was removed to the prefecture of the Haute-Marne, which he resigned in January 1849. When he resumed his practice at the bar, his great abilities, and especially his fervid and remarkably lucid oratory, rapidly brought him into the front rank. At the general election of 1857 he was returned for the 3rd *circonscription* of the Seine as a representative of the constitutional Opposition. He did not refuse, like some other Republicans who were returned at the same election, to take the oath of allegiance to the emperor; he felt that, setting aside an appeal to arms, which he abhorred, the Opposition could win liberty for the nation only by making use of such powers as the constitution permitted. Together with Darimon, Jules Favre, Hénon, and Picard, he formed the group known as *les Cinq*. Their unanswerable attacks forced the Government to make concessions to public opinion. The decree of 24th November 1860 was a first step towards an effective parliamentary government. Most of the Opposition regarded it as ludicrously inadequate. Ollivier, so recently as 30th December 1859, had appeared as counsel for M. Vacherot, on his trial for the publication of *La Démocratie*, and had attacked the Government in terms which caused him to be debarred from pleading for three months. But he now electrified the House by an eloquent speech in which he thanked the emperor for this first instalment of reform, and promised his support to further steps in the same direction. The divergence between him and the Irreconcilables, led by Jules Favre, widened in ensuing sessions till he stood alone. But one of the traits of his character was a self-reliance amounting to obstinacy. He brought Morny round to his views, and through him worked upon the emperor. The session of 1866 saw the formation of a "third party," to which M. Ollivier attached himself. Napoleon, seeing himself forced to yield, tried to enlist the honesty and ability of M. Ollivier in his service. An outward mark of M. Ollivier's adherence to the emperor was given by his acceptance of the post of arbitrator on the Suez Canal question. He had in July 1865 been appointed by the Egyptian Government as their representative in Paris in this matter—a post that necessitated his retirement from the bar. The negotiations begun by Morny were continued by his successor in the presidency of the Chamber, Walewski, a convinced supporter of Liberal measures. On 31st December 1866 he offered M. Ollivier, in the emperor's name, the ministry of Public Instruction, with the function of representing the general policy of the Government in the Chamber. M. Ollivier laid down a number of conditions, of which the most important were a policy of peace, involving the abandonment of the military law; the presence of the ministers in the Chamber; a law granting liberty of the press; and the abandonment of official candidatures. To these reforms he considered himself pledged. In an audience granted him on 10th January, he believed himself to have converted the emperor to his views; but the reactionary counsels of Rouher prevailed. The emperor's letter of 19th January 1867, announcing the new reforms, did not satisfy M. Ollivier's demands, and such reforms as were granted were executed in a grudging spirit. He therefore broke off negotiations with the emperor. His views were explained in his *Démocratie et Liberté* (1867) and, above all, in his *19 Janvier*, a defence of his political career, addressed to his constituents on the eve of the general election of 1869. In this he declared that the models he endeavoured to copy were Mirabeau and Benjamin Constant. At length, on 27th December 1869, the emperor entrusted him with the formation of a constitutional cabinet, in which were included several members of the Moderate Left, and in which M. Ollivier himself took the ministry of Justice. The cabinet was completed on 2nd January 1870. Though the constitution did not recognize the office of premier, M. Ollivier was the guiding spirit of the ministry in council and its chief spokesman in debate. But he fell upon troubled times. On 10th January Victor Noir was shot by Prince Pierre Bonaparte. M. Ollivier tried with great skill to satisfy the public indignation without compromising the position of the dynasty, but the passions aroused by this unfortunate event showed how the difficulties of his task had increased in the three years since he had first refused to accept office. That refusal he never ceased to regret. Nevertheless, he laid numerous reforms before the Chamber. He ordered the prefects to refrain from applying official influence at the elections, and the magistrates to administer justice without regard to politics. By Rouher's advice, the nation was asked to declare by a plebiscite whether it approved the new "Liberal Empire." The three most distinguished members of the left, Buffet, Daru, and Talhouët, resigned office rather than consent to this measure. Among their successors was Gramont, who was soon to prove M. Ollivier's evil genius. The people were told that a vote in the affirmative would be a vote for peace, and the prefects, in spite of M. Ollivier's instructions, exhausted the resources of official pressure. He himself, though at first reluctant to accede to the plebiscite, hailed its result as a "French Sadowa." The lapse of years had turned the once violent Republican into a very cautious Liberal, animated by a strong regard for the emperor, to whom he had promised "a happy old age." All his plans were suddenly disconcerted by the candidature of Leopold of Hohenzollern for the throne of Spain. The Ollivier government, not content with securing the withdrawal of the candidature, required the king of Prussia to guarantee that it should never be repeated. M. Ollivier, hitherto the strenuous advocate of peace, allowed himself to be won over by the war party. On 15th July he declared to the Chamber that the Prussian Government had addressed a despatch to the foreign Powers, announcing that the king had affronted the French ambassador. Thiers and his followers in vain pointed out that no such despatch existed, and that the ambassador had not considered himself insulted. M. Ollivier obtained a war vote of 500 million francs, and used the fatal words that he accepted the responsibility for the war "with a light heart." He went on to explain that this war was forced upon France by the requirements of honour, and was not sought by the ministry. But the phrase remained when its explanation was forgotten. The country turned savagely upon the authors of its disasters. M. Ollivier convoked the Chamber for the 9th August, when a large majority declared the Government incapable of providing for the safety of the country. In apportioning the blame for the disasters of 1870, it must be remembered that M. Ollivier was deceived, both by the Foreign Minister, Gramont, who misled him as to the attitude of Austria and the South German states, and whose rash and ignorant diplomacy hastened the crisis, and by the Minister of War, Lebœuf, who declared that the army was ready "down to the last button on its gaiters." But had M. Ollivier been as clear-sighted as Thiers, had he adhered at this crisis to that policy of peace with which he entered office, he could have averted war by the threat of resignation. He committed the fault against which he had in 1867 warned the emperor, of "entering, in company with an exhausted Austria, upon a new Seven Years' War, in which this time we should find Russia on the side of Prussia, without being sure of carrying Italy with us." After his fall he quitted France, and did not return till 1873. His subsequent attempts to enter parliament were unsuccessful, but he carried on an active political campaign in the *Estafette.* In 1885 he declared himself not anti-Republican but anti-Radical. Debarred from public life at forty-five by his one fatal mistake, he expressed his views in a series of books, the most important of which are *Principes et conduite* (1875), *Solutions politiques et sociales* (1893), and *L'Empire Libéral* (1895, &c.). His support of the decrees of 1880 against the religious Congregations involved him in a bitter controversy with the section of the Bonapartists represented by M. Paul de Cassagnac. Besides his political writings on this subject he published in 1885 a *Nouveau Manuel de Droit Ecclésiastique Français.* He was elected a member of the French Academy in April 1870. His formal reception was to have taken place in 1873, but owing to his refusal to omit certain political references from his inaugural speech, was indefinitely postponed.

Olmsted, Frederick Law (1822–——), American author and landscape architect, was born at Hartford, Conn., 26th April 1822. In 1840 he shipped as seaman for the East Indies and China. In 1845–46 he studied agricultural science and engineering at Yale College, after which he became a practical farmer for several years. In 1850 he made a pedestrian tour in Great Britain and the continent of Europe, and in 1852–1853 made a horseback trip through the southern and south-western United States. His observations on these travels were published in his books: *Walks and Talks of an American Farmer in England*, *Journey in the Seaboard Slave States*, *Journey through Texas*, and *Journey in the Back Country.* The last three volumes, printed also in England in two volumes with the title *The Cotton Kingdom*, had great influence in the discussion on American slavery preceding the Civil War. Some years after these journeys, Mr Olmsted again visited Italy, France, and Germany, making a special study of parks and rural arts. In 1856 he, with Calvert Vaux, prepared the accepted plans for the improvement of Central Park in New York City. In 1864–65, as chairman of a California State Commission, he directed the survey and preservation of the big-tree reservations of the Yosemite Valley. In 1866 he was again engaged with Mr Vaux in planning and superintending the improvements of Prospect Park in Brooklyn, N.Y. After this he was engaged in most of the important works of park improvement in the United States. Special mention may be made of the Buffalo, N.Y., parks, the Mount Royal Park at Montreal, the Capitol Grounds at Washington, the grounds of Leland Stanford Jr. University in California, the Vanderbilt estate at Biltmore, N.C., the system of parks and parkways in Boston, and the landscape improvements for the World's Fair at Chicago. In 1893 he received honorary degrees from Harvard and Yale Universities.

Olmütz, the second city and the ecclesiastical metropolis of Moravia, Austria. Population (1890), 19,761; (1900), 21,933, including garrison of 3632 men (estimated at 67 per cent. German, 33 per cent. Czech; 92·5 per cent. Catholic, 6·5 per cent. Jewish, and 1 per cent. Protestant). The fortifications were removed in 1886 and their place is occupied by a town park, gardens, and promenades. The modern public buildings include an industrial museum, a German upper *real*-school, and a Czech gymnasium. The industries include brewing and distilling and the manufactures of malt, sugar, starch, &c.

Olney, a city of Illinois, U.S.A., capital of Richland county, situated at the intersection of the Baltimore and Ohio South-Western, the Illinois Central, and the Indiana, Decatur, and Western railways, in the south-eastern part of the state, at an altitude of 481 feet. It has a level site and regular plan, and derives its chief importance from the fact that it is the point of intersection of railway lines. Population (1880), 3512; (1890), 3831; (1900), 4260, of whom 235 were foreign-born.

Olney, Richard (1835–——), American statesman, was born at Oxford, Mass., 15th September 1835. Educated at Brown University and the Harvard Law School, he attained a high position at the Massachusetts bar, but was not known in public life till, in 1893, President Cleveland induced him to enter his cabinet as Attorney-General. Upon the death of Secretary Gresham, Mr Olney succeeded him as Secretary of State, 10th June 1895. He conducted the correspondence with the British Government concerning the boundary dispute with Venezuela, and excited general comment by the vigour with which he sustained the right of the United States to intervene, and by the wide interpretation which he put upon the Monroe Doctrine. At the expiration of President Cleveland's term he resumed his law practice.

Olonets, a government of northern Russia, having Finland on the W., and the governments of Archangel on the N.E., Vologda on the E., and Novgorod and St Petersburg on the S. Its area covers 57,439 square miles. Its population was 321,250 in 1881, and 366,715 in 1897, of whom 193,001 were women (111 women to 100 men), and 24,412 lived in towns. Agriculture is still insufficient for the population, the crops in 1894–99 being: rye, 888,700 cwt.; oats, 847,000; and all cereals, 2,029,000 cwt. There were in 1895, 63,520 horses, 133,300 horned cattle, and 102,300 swine. Industries are still in their infancy (aggregate returns, £2,840,000, chiefly saw-mills). Olonets is divided into seven districts, of which the chief towns and their populations in 1897 were: Petrozavodsk, capital of the government (12,521 inhabitants), Kargopol (2952), Lodeinoye Pole (4500), Olonets (1303), Povyenets (1409), Pudozh (1469), and Vytegra (4501).

Oltenitza, a small town in Rumania, in the district of Ilfov (Bucharest), on the left bank of the Danube.

It is the ancient Constantiola, which was the seat of the first bishopric established in Dacia. In the Crimean war the Turks forced the river at this point and inflicted heavy losses on the Russians. Population, about 5500.

Olympia, a city of Washington, U.S.A., capital of Thurston county and of the state, at the head of Hood canal, an arm of Puget Sound, in the western part of the state. It has a level site and a regular plan, with broad streets. It has good water-supply and sewerage systems, and is the terminus of two branches of the Northern Pacific Railway and of two other short railways. It is in the great forest region of western Washington, and its principal industry is in lumber. It has several large mills and considerable trade by steamer on the Sound, and by rail, in lumber, fish, and oysters. Population (1880), 1232; (1890), 4698; (1900), 4082, of whom 591 were foreign-born.

Omaha, the largest city in Nebraska, U.S.A., on the west bank of the Missouri river, about 20 miles above the mouth of the Platte, occupying an elongated plateau skirted on three sides by undulating hills on which the residential districts are distributed, 962 feet above sea-level. Within the corporate boundaries are included 24 square miles. Its rectilinear street plan gives numbered streets north and south, and named streets east and west. Three bridges (two railway bridges and one waggon bridge —the last traversed by electric cars) span the Missouri, connecting Omaha and Council Bluffs, Ia. Its electric street railway system has 65 miles of trackage. The city was laid out in 1854. Population (1880), 30,518; (1890), 140,452; (1900), 102,555, exclusive of South Omaha. The smaller figures for the last decade are almost wholly due to a padding of the previous census, although growth was affected somewhat by the drought and crop failures of 1893 and 1894 in the agricultural territory, upon which the city is largely dependent. The death-rate in 1900 was 13·5. In 1901 there were 38 schools with 419 teachers, and an average daily attendance of 14,845. The annual expense of maintenance was $544,058, of which $202,624 is from direct taxes. The school district debt (1900, $835,000) and municipal debt (1900, $4,776,800) represent investment in school-houses, public buildings, pavements, drainage, and parks. The electric lighting plant, gas, and water-works are owned by private corporations. As a trade and distribution centre Omaha ranks high. Originally the eastern terminus of the first trans-continental railway (Union Pacific) it now has fourteen different railways radiating in all directions, five of which constitute trunk lines between the Missouri and the Great Lakes. There are 100 wholesale establishments and 175 manufacturing institutions; notable among these are the silver and lead smelting and refining works, employing 600 men, extensive car and locomotive construction and repair works, white-lead works, linseed-oil mill, six breweries, distillery, and bag factories. As a live-stock market South Omaha (founded in 1887, but still a distinct municipal corporation, although immediately adjoining) ranks next to Chicago and Kansas City. Receipts for 1901: cattle, 818,003; hogs, 2,414,052; sheep, 1,314,841. The seven national banks at Omaha held (March 1902) $25,837,653 in deposits, with $3,050,000 aggregate capital. The bank clearings for 1901 aggregated $329,043,688. Omaha is the headquarters of the military department of the Missouri, with military posts at Fort Omaha (immediately north) and at Fort Crook (10 miles south). An interesting example of local enterprise was the Trans-Mississippi Exposition, 1898, illustrating the progress and resources of the states west of the Mississippi. It represented an investment of $2,000,000. Although begun in time of discouraging financial depression, and held during the war with Spain, over 2,600,000 people attended it, and 90 per cent. of their subscriptions were returned in dividends to stockholders. (V. R.)

Oman, a kingdom occupying the south-eastern coast districts of Arabia, its southern limits being a little to the west of the meridian of 55° E. long., and the boundary on the north the southern borders of El Hasa. Oman and Hasa between them occupy the eastern coast districts of Arabia to the head of the Persian Gulf. The Oman–Hasa boundary has been usually drawn north of the promontory of Katar. This is, however, incorrect. In 1870 Katar was under Wahabi rule, but in the year 1871 Turkish assistance was requested to aid the settlement of a family quarrel between certain Wahabi chiefs, and the Turks thus obtained a footing in Katar, which they have retained ever since. Turkish occupation (now firmly established throughout El Hasa) includes Katif (the ancient Gerrha) and El Bidia on the coast of Katar. But the pearl fisheries of Katar are still under the protection of the chiefs of Bahrein, who are themselves under British suzerainty. In 1895 the chief of Katar (Sheikh Jasim ben Thani), instigated by the Turks, attacked Sheikh Isa of Bahrein, but his fleet of dhows was destroyed by a British gunboat, and Bahrein (like Zanzibar) has since been detached from Oman and placed directly under British protection.

Physiography.—Oman is a mountainous district dominated by a range called Jebel Akhdar (or the Green Mountain), which is 6000 feet in altitude, and is flanked by minor ranges running approximately parallel to the coast, and shutting off the harbours from the interior. They enclose long lateral valleys, some of which are fertile and highly cultivated, and traversed by narrow precipitous gorges at intervals, which form the only means of access to the interior from the sea. Beyond the mountains which flank the cultivated valleys of Semail and Tyin, to the west, there stretches the great Rhoba el Khali, or Dehna, the central desert of southern Arabia, which reaches across the continent to the borders of Yemen, isolating the province on the landward side just as the rugged mountain barriers shut it off from the sea. The wadis (or valleys) of Oman (like the wadis of Arabia generally) are merely torrential channels, dry for the greater part of the year. Water is obtained from wells and springs in sufficient quantity to supply an extensive system of irrigation.

Harbours and Roads.—The only good harbour on the coast is that of Muskat, the capital of the kingdom, which, however, is not directly connected with the interior by any mountain route. The little port of Matrah, immediately contiguous to Muskat, offers the only opportunity for penetrating into the interior by the wadi Kahza, a rough pass which is held for the Sultan or Imam of Muskat by the Rehbiyin chief. In 1883, owing to the treachery of this chief, Muskat was besieged by a rebel army, and disaster was only averted by the guns of H.M.S. *Philomel.* About 50 miles south of Muskat the port of Kuryat is again connected with the inland valleys by the wadi Hail, leading to the gorges of the wadi Thaika or "Devil's Gap." Both routes give access to the wadi Tyin, which, enclosed between the mountain of El Beideh and Hallowi (from 2000 to 3000 feet high), is the garden of Oman. Fifty miles to the north-west of Muskat this interior region may again be reached by the transverse valley of Semail, leading into the wadi Munsab, and from thence to Tyin. This is generally reckoned the easiest line for travellers. But all routes are difficult, winding between granite and limestone rocks, and abounding in narrow defiles and rugged torrent beds. Vegetation is, however, tolerably abundant—tamarisks, oleanders, kafas, euphorbias, the milk bush, rhamnus, and acacias being the most common and most characteristic forms of vegetable life, and pools of water are frequent. The rich oasis of Tyin contains many villages embosomed in palm groves and surrounded with orchards and fields.

Cultivation.—In addition to cereals and vegetables, the cultivation of fruit is abundant throughout the valley. After the date, vines, peaches, apricots, oranges, mangoes, melons, and mulberries find special favour with the Rehbiyin, who exhibit all the skill and perseverance of the Arab agriculturist of Yemen, and cultivate everything that the soil is capable of producing.

The present Sultan, a descendant of those Yemenite Imams who consolidated Arab power in Zanzibar and on the East African coast, and raised Oman to its position as the most powerful state in Arabia during the first half of the 19th century, resides at Muskat, where his palace directly faces the harbour, not far from the British residency. The little port of Gwadur, on the Makran coast of the Arabian Sea, a station of the Persian Gulf telegraph system, is still a dependency of Oman.

See Colonel MILES. *Geographical Journal*, vol. vii., 1896.—Commander I. N. STEPPE. *Geographical Journal*, 1899.

(T. H. H*.)

Omdurman. See SUDAN, ANGLO-EGYPTIAN.

Omsk, a town of Russia, capital of the province of Akmolinsk, formerly capital of western Siberia, now capital of the General-Governorship of the Steppes. It is the seat of administration of Siberian Cossacks, and see of the bishop of Omsk. It is situated on the right bank of the Irtysh, at its junction with the Om, in an altitude of 260 feet, on the main Siberian trunk railway, 1013 miles by rail from Samara (the Volga), and 1624 miles from Moscow. It is also the meeting-place of the highways to middle Russia, Orenburg, East Siberia, and Turkestan. Steamers ply down the Irtysh and the Ob, and up the former to the Altai towns and Lake Zaisan. The climate is dry and relatively temperate, but marked by violent snow- and sand-storms. The average temperatures are, for the year, 31° F.; for January, 5°; for July, 68°; the annual rainfall is 12·4 inches. It is poorly built. Its population, from 31,000 in 1881, has grown to 37,470 in 1897; this figure seems, however, to be incomplete, as in 1895 it was 43,226, of whom 8468 were military. Its industries remain unimportant (steam saw-mill, tanneries) and show a yearly return of only £50,000; but the trade, especially since the construction of the railway, is growing, Omsk becoming a depot for goods imported from Europe for the neighbouring provinces. The two yearly fairs show an aggregate return of about £100,000. It has a society for education, which organizes schools, kindergartens, libraries, and lectures for the people. There are a corps of cadets, two gymnasia for boys and for girls, and various lower schools, besides medical, dramatic, and musical societies, and also the West Siberian section of the Russian Geographical Society.

Onega, a lake of northern Russia, with an area of 3765 square miles. Its altitude, which was formerly supposed to be 236 feet, is only 125 feet. It appears from the works of the hydrographical expedition, completed in 1895 (*Izvestia* of the Russ. Geogr. Soc. 1895), that the depth of the lake had been greatly exaggerated. The greatest depths, of from 53 to 68 fathoms, are at the entrance to the double bay, Lizhemsk and Unitsk, which projects westwards in the west of the Zaonezhie peninsula. On the continuation of this line, several spots are found where the depth exceeds 40 fathoms. In the middle of the lake the depth is from 20 to 47 fathoms, and less than 20 fathoms in the south. The lake is 145 miles long, with an average breadth of 50 miles.

Oneida, a village of Madison county, New York, U.S.A., on Oneida Creek, 6 miles from Oneida Lake, at an altitude of 440 feet. The site is level, but the plan of the city irregular. It has two railways, the New York Central and Hudson River, and the New York, Ontario, and Western. Population (1880), 1649; (1890), 6083; (1900), 6364, of whom 784 were foreign-born and 82 negroes.

Oneonta, a village of Otsego county, New York, U.S.A., on Susquehanna river and on the Delaware and Hudson and the Ulster and Delaware railways, at an altitude of 1083 feet. It contains the car works of the railway, saw and planing mills, and other manufactories, together with grain elevators. One of the state normal schools is located here. Population (1880), 3002; (1890), 6272; (1900), 7147, of whom 456 were foreign-born.

Ongole, a town of British India, in the Nellore district of Madras, situated on the East Coast Railway, 181 miles north of Madras. Population (1891), 10,832; municipal income (1897–98), Rs.13,310. There are a college managed by the American Baptist mission, a high school with 330 pupils, a Government training school, a printing-press, and a reading-room.

Onitsha. See NIGERIA.

Ontario, a province of Canada, bounded on the E. and N.E. by Quebec and the Ottawa river, on the S. and S.E. by the St Lawrence and the Great Lakes, on the W. by Manitoba, and on the N. by James Bay and the Albany and English rivers. The south-eastern and south-western portions of the province are occupied by the great plain of Canada, and are underlain by rocks of Cambro-Silurian, Silurian, and Devonian age. The south-eastern tract lies in the angle between the Ottawa and St Lawrence, includes an area of 4500 square miles, and has an elevation of 100 to 400 feet above the sea. The south-western is divided into two tracts, the first lying to the north and east of the Niagara escarpment, with an area of 9000 square miles, and an altitude of 400 to 1000 feet; and the second, the tract to the south and west of the Niagara escarpment, has an area of 15,700 square miles, and an elevation of 600 to 1500 feet. In the last of these petroleum, natural gas, salt, and gypsum are important products, but in the others no minerals, with the exception of building materials, are found. The country to the north of the great plain is occupied by rocks of Archæan age, which form, in a general way, a great plateau or table-land. Its average elevation increases from about 1000 feet in the vicinity of the Ottawa river to about 1500 feet to the north of Lake Superior. It is everywhere studded with lakes, with intervening hills wooded to their summits. Minerals of economic value are almost entirely confined to the bands of Huronian rocks, and include mica, apatite, marble, graphite, and iron.

Rivers and lakes.

Both the St Lawrence and its principal tributary the Ottawa receive many affluents from the province. The Trent and Moira fall into Lake Ontario, the Grand into Lake Erie, the Thames into Lake St Clair, the Severn, Muskoka, Maganatawan, French, Wahnapitai, and Mississauga into Lake Huron, and the Michipicoten, Pic, Nipigon, Kaministikwia, and Pigeon into Lake Superior. Beyond the Height-of-Land the Winnipeg and English rivers flow westward to Lake Winnipeg, and the Albany, Kenogami, and the Moose with its affluents, the Mattagami and Abitibi, empty into James Bay. The principal lakes are: Lake Simcoe, with an area of 300 square miles, and an elevation of 720 feet above the sea; Nipissing, at an elevation of 642 feet; Nipigon, 852; Mille Lacs, 1496; Shebandowan, 1473; Rainy, 1109; St Joseph, 1172; Seul, 1150; and Lake of the Woods, 1060. The principal islands are Wolfe, Howe, and Amherst, at the foot of Lake Ontario; Manitoulin, Cockburn, and St Joseph in Lake Huron, and Michipicoten and St Ignace in Lake Superior.

Climate.

The climate is very diversified; in the south-western portion the winters are not severe, and the summers, owing to the tempering influence of the Great Lakes, are not oppressively hot; in the Ottawa and St Lawrence valleys the winters are moderately cold, but bracing and exhilarating; to the north and north-west of Lake Superior the winters are long and cold, and at times extremely low temperatures are registered. The normal temperatures for three points in the south-western, eastern, and north-western portions are given below:—

	Toronto.	Ottawa.	Port Arthur.
December, January, and February	23·7	13·3	7·3
March, April, and May	40·6	38·5	31·1
June, July, and August	65·4	67·4	58·9
September, October, and November	47·0	44·8	38·5
	in.	in.	
Average annual precipitation	33·944	32·650	23·580

The area included within the limits of the province is 222,000 square miles. The northern and western boundaries, as defined by arbitrators in 1878, were the Albany and English rivers, and a meridian line from the north-west angle of the Lake of the Woods, respectively. This decision, on appeal to the Imperial Privy Council, was upheld, and was finally confirmed by an Act of the Imperial Parliament in 1889. The following table shows the population classified by townships, towns and villages, and cities :—

Area and population.

	1881.	1891.	1901.
Townships . .	1,346,623	1,283,281	1,247,190
Towns and villages	323,188	432,912	935,752
Cities . . .	257,111	398,128	
	1,926,922	2,114,321	2,182,942

The principal cities and towns, with their respective populations in 1901, were:—Toronto, the provincial capital, 208,040 ; Ottawa, the capital of Canada, 59,928 ; Hamilton, 52,634 ; London, 37,981 ; Kingston, 17,961 ; Brantford, 16,619 ; Windsor, 12,153 ; Guelph, 11,496; St Thomas, 11,485 ; Peterborough, 11,239; Stratford, 9959 ; St Catharine's, 9946 ; Berlin, 9747 ; Belleville, 9117 ; Chatham, 9068 ; Brockville, 8940 ; Woodstock, 8833 ; Owen Sound, 8776 ; Sarnia, 8176 ; Galt, 7866 ; Sault Ste Marie, 7169 ; Lindsay, 7003 ; Cornwall, 6704 ; Barrie, 5949 ; Collingwood, 5755 ; Rat Portage, 5202 ; Pembroke, 5156 ; Smith's Falls, 5155. In 1901 the urban population was 935,752, and the rural 1,247,190. Density, 9·8 inhabitants to the square mile. In 1901 there were 1,096,641 males and 1,086,306 females. Indians, 19,597 ; and half-breeds, 5100. Classified according to place of birth, the principal nationalities in 1901 were as follows :—Canada, 1,858,788 ; England and Wales, 121,506 ; Ireland, 68,093 ; Scotland, 49,881 ; other British possessions, 2913 ; United States, 44,175 ; Germany, 18,699 ; Scandinavia, 2005 ; Italy, 3283 ; France, 1254 ; other countries, 12,350. In 1891 there were 341,714 persons engaged in agricultural pursuits ; fishermen, 1421 ; mining, 1666 ; domestic and personal service, 109,328 ; manufactures and mechanical industries, 158,831 ; professional, 30,101 ; trade and transportation, 87,174 ; and non-productive, 20,053. The following table gives vital statistics for the period 1878–1900 :—

	1878.	1888.	1900.
Births . . .	40,236	46,953	46,127
Marriages . .	12,729	14,551	17,104
Deaths . .	17,808	23,734	29,494
Still-born . .	334	(not	578
,, ,, . .	0·8 %	classified)	1·3 %
Illegitimate births	575	618	800
,, ,,	1·4 %	1·3 %	1·7 %

The executive power consists of a lieutenant-governor, appointed for five years, assisted by an executive council of eight ministers with portfolios, who have seats in the local legislature or House of Assembly. The latter consists of ninety-eight members.

Administration.

Classified according to religion, the principal denominations in 1901 were as follows :— Methodists, 666,360 ; Presbyterians, 477,383 ; Episcopalians, 367,940 ; Roman Catholics, 390,355 ; Baptists, 116,180 ; Lutherans, 48,016 ; Congregationalists, 15,285 ; Salvation Army, 6479 ; Disciples of Christ, 10,123 ; Quakers, 3648 ; Brethren, 6416 ; Jews, 5336.

Religion.

In 1900 there were 5655 public elementary schools, taught by 9440 teachers, of whom 2630 were men and 6810 women ; Roman Catholic separate schools, 355 ; Protestant separate schools, 7 ; secondary public schools, 131 (including 38 collegiate institutes), taught by 573 teachers ; and 120 kindergartens, taught by 250 teachers. The pupils enrolled in the public elementary schools of all kinds numbered 420,097, with an average attendance of 237,306 ; pupils in Roman Catholic separate schools, 42,397, with an average attendance of 25,875 ; Protestant separate schools, 416 pupils, and average attendance 238. Total amount expended on public schools during the year, $4,228,532, and on high schools, $718,601. For the professional training of teachers there are (1) county model schools, fifty-five in number ; (2) three normal schools, and (3) one normal college ; their non-professional training is obtained in the secondary schools and universities. There is an agricultural college at Guelph, and at Belleville and Brantford there are institutes for the education of the dumb and the blind. Of the six universities in the province only one, the University of Toronto, is a State institution. The others are Victoria (now "federated" with Toronto), Queens of Kingston, Trinity and McMaster of Toronto, Western of London, and the University of Ottawa.

Education.

There is no direct taxation, except a special tax on insurance, loan, and railway companies doing business in the province, the revenue being derived from the sale of Crown lands, timber, and minerals, liquor licences, and other fees, supplemented by a subsidy from the Dominion Government. The principal items of revenue and expenditure for the year 1901 are tabulated below :—

Finance.

Revenue.		Expenditure.	
Dominion subsidy	$1,116,873	Civil government	$281,136
Specific grant from Dominion Government . . .	80,000	Legislation . .	134,139
Interest . .	189,175	Justice, administration of . .	416,043
Crown lands . .	1,634,724	Education . .	782,193
Licences . .	376,373	Agriculture . .	209,859
Succession duties .	366,582	Hospitals and charities . .	192,280
Provincial tax .	237,507	Public institutions	833,164
Miscellaneous .	464,810	Miscellaneous .	1,190,020
	$4,466,044		$4,038,834

In December 1901 the province had—cash on hand, $1,468,493 ; funds in hands of Dominion Government, $6,212,497 ; and direct investments, $220,898—in all, $7,901,888 : liabilities, $5,330,596, leaving a cash surplus of $2,571,292. In 1898 the total receipts of all the municipalities were $30,921,578 ; disbursements, $29,071,839 ; assets, $61,926,795 ; liabilities, $61,390,107 ; and bonded debt, $54,506,372. In 1899 the total assessment of the townships was $450,952,948 ; towns and villages, $125,982,155 ; cities, $239,825,370 ; and grand total, $816,760,473. The taxes for the same year were: townships, $4,621,803 ; towns and villages, $2,691,534 ; cities, $5,221,947 ; and total, $12,535,284.

The mineral resources, though important, are largely undeveloped, owing to the concentration of the greater part of the population in the fertile Palæozoic tract of the province, where, with the exception of building materials, salt, petroleum, and natural gas, no minerals of economic value are found. Gold has been found along the whole length of the northern Archæan border of the province, but the richest and most numerous discoveries have been made in the country between Thunder Bay, on the north shore of Lake Superior, and the western boundary. Mining on a small scale is also carried on in Hastings county. The most important silver mine is that of Silver Islet, the total production of which between 1870 and 1884 amounted to $3,250,000. A number of silver mines yielding rich ores have been worked in the Thunder Bay district. The nickel deposits of the Sudbury region are, with the possible exception of New Caledonia, the richest in the world. Practically the whole of the copper produced in the province is obtained as a by-product of the nickel, the Bruce mines on the north shore of Lake Superior having ceased producing in 1876. There are also extensive deposits at Parry Sound, now under development, on Michipicoten island and the north shore of Lake Superior. The production of iron was till recently confined to a few mines in Hastings and Frontenac counties, and near Michipicoten. There are also immense deposits of magnetite and hematite in the country between Port Arthur and Rainy Lake, but lack of railways and cheap fuel has prevented their development. Natural gas is produced in the Welland and Essex gas-fields, the greater portion of which is exported to Buffalo and Detroit.

Minerals.

The mineral production for 1901 was as follows :—

	Quantity.	Value.
Copper	8,695,831 lb	$1,401,507
Gold	...	244,837

		$14,167,947

Ontario is pre-eminently an agricultural country, as (1) about 67 per cent. of its inhabitants are engaged in agricultural pursuits, and (2) the amount invested in lands, buildings, implements, and stock—$974,814,931—is two and a half times that invested in the manufactures of the whole Dominion. The statistics of farm lands, as taken by the municipal assessors, are given in the following table :—

Agriculture.

	1883.	1893.	1900.
	Acres.	Acres.	Acres.
Land under crop	7,542,623	8,054,612	8,794,953
Pasture . . .	...	2,682,180	2,694,600
Orchards and gardens	2,996,934	1,394,772	350,098
Fallow land, &c. .	...	...	1,457,555
Total cleared land .	10,539,557	12,131,564	13,297,206
Swamp and waste land . . .	2,093,173	2,694,487	3,143,535
Woodland . .	8,825,337	8,133,229	7,127,363
Total assessed .	21,458,067	22,959,280	23,568,104

The following table gives statistics of the principal field crops :—

	1889.		1900.	
	Product.	Value.	Product.	Value.
	Bush.	$	Bush.	$
Wheat .	20,261,162	17,556,065	30,310,070	20,202,230
Barley .	16,235,295	7,992,105	16,909,751	6,577,893
Oats . .	64,346,301	19,625,622	89,693,327	23,768,732
Rye and buckwheat	3,361,576	1,474,880	4,231,896	1,962,505
Pease and beans .	13,881,130	7,995,833	14,878,571	8,845,143
Potatoes .	14,355,529	6,531,766	21,476,439	5,605,351
Other roots	48,071,545	6,533,265	87,528,043	8,344,962
Corn, husking . .	...	...	27,093,561	8,588,659
Corn, fodder	...	...	...	4,295,064

All field crops :—

	Acres in Crop.	Market Value of Crop.	Market Value per Acre.
1889	7,758,583	$106,500,799	$14·37
1894	8,227,153	94,055,392	11·45
1900	8,794,953	114,758,761	13·05

In 1900 there were in the province 617,309 horses, valued at $46,916,999; cattle, 2,429,330, value $56,320,810; sheep, 1,797,213, value $7,711,496; hogs, 1,771,641, value $9,598,153; poultry, 9,541,241, value $2,727,363. Total value of live stock sold or slaughtered during the year, $41,642,617; wool clip, 5,805,921 ℔, value $894,112. There were, in 1883, 635 cheese factories producing 53,513,032 ℔ of cheese, valued at $5,589,339, and in 1900, 1173 factories producing 127,789,543 ℔, value $13,023,025. In 1893 74 creameries produced 2,707,570 ℔ butter, value $574,156, and in 1900, 308 creameries produced 9,041,468 ℔, value $1,819,290. Value of farm land in 1900, $574,727,610; buildings, $219,488,370; implements, $57,324,130; and live stock, $123,274,821; total, $974,814,931.

Fisheries. The principal fishes, in the order of their relative commercial importance, are trout, whitefish, herring, pickerel, sturgeon, &c. —all fresh-water fish. In 1900 the value of the catch was $1,333,294; vessels, boats and outfit, $789,042; and exports, $381,045.

Timber. The northern portion of the province possesses immense timber resources, and beyond the Height-of-Land a great spruce forest extends to the shores of Hudson Bay. White pine is still the most important as regards value and commercial importance, but the great and increasing demand for spruce for paper-making makes it one of the most valuable assets of the province. Other valuable timber trees are oak, elm, walnut, hemlock, basswood, cherry, and butternut. The cut of logs in 1899 aggregated 875,000,000 feet.

Manufactures. The following table gives statistics of the principal manufactures in 1891 :—

	Number of Establishments.	Number of Employés.	Value of Product.
Flour and grist mills .	1078	3453	$36,558,320
Saw-mills . . .	1895	23,851	26,987,259
Foundries . . .	337	6198	7,803,152
Leather manufactures	3234	6262	7,446,540
Agricultural implements . . .	130	4029	6,927,887
Carriage works . .	1561	5096	5,906,679
Woollen mills . .	303	5191	5,873,685
Distilleries and breweries . . .	89	1435	5,673,474

In 1891 there were 32,151 industrial establishments with a total fixed capital of $81,551,232; working capital, $94,420,789; employing 164,326 persons; paying in wages $49,733,359 per annum; using raw material valued at $128,142,371, and with a product of value $239,781,926.

Commerce. The following table gives statistics of exports, imports, and duty collected for the period 1874–1900 at the custom-houses within the province, but a large amount of the merchandise entered inwards and outwards at the port of Montreal should properly be credited to Ontario :—

	Exports.	Imports.	Duty.
1874	$25,157,087	$49,443,977	$4,371,625
1884	26,891,017	41,967,215	6,979,026
1894	32,726,074	42,025,638	7,475,142
1900	56,116,756	71,258,544	10,763,214

Shipping. In 1901 there were 1647 vessels with a tonnage of 145,981 on the registry books of the province. In the year ending 30th June 1898, 31,983 vessels with an aggregate tonnage of 11,257,361 were entered and cleared at the ports of the province.

Railways. Ontario had, in 1901, 6605 miles of steam railway, and 36·1 per cent. of the railway mileage of the Dominion. The principal systems are the Grand Trunk, Canadian Pacific, Canada Atlantic, and Michigan Central. There are 24 electric railways with nearly 400 miles of track, 480 motor cars, an aggregate of over 30,000 horse-power, and a capital investment of upwards of $10,000,000. The principal suburban roads are the Hamilton, Grimsby, and Beamsville, Hamilton Radial, Niagara Falls Park and River, Galt, Preston and Hespeler, and Metropolitan.

Canals. The St Lawrence canal system overcomes the difference of elevation—222 feet—between the river at Montreal and Lake Ontario, and consists of six canals: Lachine, $8\frac{1}{2}$ miles; Soulanges, 14; Cornwall, $11\frac{1}{2}$; Farrens Point, $\frac{3}{4}$; Morrisburg, $3\frac{7}{10}$; and Galops, $7\frac{6}{10}$ miles. The Welland canal is $26\frac{3}{4}$ miles long; has 25 lift-locks to overcome the difference of elevation—327 feet—between Lakes Ontario and Erie. The locks of the Welland and St Lawrence systems are 270 feet long, 45 feet wide, and have a depth at low water of 14 feet on the sills. The Sault Ste Marie canal, $1\frac{1}{10}$ mile long, with 1 lock 900 feet long, 60 wide, and with a depth of $20\frac{1}{4}$ feet on the sill, overcomes the fall of $18\frac{1}{10}$ feet at the foot of Lake Superior. The Ste Anne canal, $\frac{1}{8}$ mile, Corillon, $\frac{3}{8}$ mile, and Grenville, $5\frac{3}{4}$ miles, render the Ottawa river between its confluence with the St Lawrence and Ottawa city navigable for vessels of 9 feet draught. The Rideau canal system connects the Ottawa river, at the city of the same name, with Lake Ontario at Kingston, and has a navigation depth of $4\frac{1}{2}$ feet. The Trent Valley canal, when completed, will give a direct route from the Bay of Quinte, Lake Ontario, to the south end of Georgian Bay for vessels of $7\frac{1}{2}$ feet draught. The total amount expended on the works and maintenance (chargeable to capital) of the above canals to 30th June 1901 was $79,997,403. In addition, nearly $17,000,000 has been expended from income, making a total expenditure of $97,000,000. (J. WH*.)

Ontario, Lake. See ST LAWRENCE.

Onteniente, a town of Spain, in the province of Valencia, to the west of Albaida, on a hill on the right bank of the river Clariano. The population was 11,165 in 1887, and 11,078 in 1897. The town is well built, with broad streets and a parish church that is remarkable for a lofty square tower. There is a large new suburb outside the old town, which was a walled city in days gone by; some vestiges of the ramparts still remain. The local industries are manufactures of woollen and linen stuffs, alcohol, paper, and furniture, and there is an active trade in the agricultural products of the surrounding districts.

Oporto, the second city of Portugal, an episcopal see and seaport, and capital of the district of Oporto, on the right bank of the Douro, 3 miles above its mouth. With the view of avoiding the bar at the mouth of the river, on which the depth of water varies between 16 and 19 feet, an artificial port has been made at Leixões, on the coast, $2\frac{1}{2}$ miles north of the Douro. In 1900 the port was entered and cleared by 1797 vessels of 777,557 tons (Oporto), and 968 vessels of 1,044,223 tons (Leixões), or in all 2765 vessels of 1,821,780 tons, but a portion of the shipping is counted twice over, that is, in both ports. The total trade is valued at about five millions sterling, of which about three and a half millions represent imports. The principal exports are timber, stone, onions, cork, salt, wool, and port wine. The last-named goes principally to Great Britain, Brazil, and Hamburg, and Norway and Sweden. The combined port possesses a fishing fleet of some 360 vessels, manned by about 1600 men and boys, who catch fish to the annual aggregate value of £50,000 to £100,000. A third of the population are engaged in manufacturing industry, the chief objects of which are leather, tobacco, spirits, woollens, cottons, silk, hats, preserved foods, beer, aërated waters, soap, pottery, corks, and gold and silver filigree work. The Douro is crossed by a fine bridge, built in 1877, and measuring 1158 feet in length; the central arch has a span of 525 feet. Amongst the public buildings should be mentioned the exchange (which cost £133,500), the royal palace of Torre da Marca, and the crystal palace (350 feet long by 48 feet wide), used for exhibitions. The educational institutions embrace a medical college, polytechnic academy, industrial institute, academy of the fine arts, seminary, lyceum of secondary education, two normal schools, trade schools, and a naval training school. There are also a meteorological observatory and the commercial athenæum. Population (1890), 138,860; (1900), 172,421. Area, $13\frac{1}{2}$ square miles.

The district of Oporto has an area of 885 square miles, and population (1900), 601,688, giving 680 inhabitants to the square mile, and consequently the most densely peopled district in the kingdom. The soil is very fertile, and intensely cultivated, except on certain of the higher parts and along the low-lying sandy coast. A large proportion of the surface is covered with wood. The vine is the chief object of cultivation; in 1892 it covered 39,400 acres, the yield being 7,656,000 gallons of wine, valued at £240,000. During the four years 1896–99 inclusive an average of 4,208,200 gallons of port wine produced in this district was exported to the United Kingdom. The districts formerly ravaged by the phylloxera and other diseases are being gradually replanted with vines, though the port wine industry as a whole cannot be said to be in a flourishing condition. In respect of the value of its live stock, especially cattle and pigs, this district ranks as the first in the kingdom. Coal, antimony, and gold are mined, with a little iron and lead, the average yield annually being 7500 tons, valued at £26,900. Slates are quarried, and granite is plentiful. It is estimated that 82,000 persons are employed in industrial pursuits; in addition to the branches mentioned under the city of Oporto (above) and Villa Nova de Gaia, cottons and woollens are manufactured at Vallongo and Santo Thyrso, and at Amarante.

Oppeln, a town of Prussia, province of Silesia, 51 miles by rail south-east of Breslau, on the Oder. The sole surviving fragment, a tower, of the former ducal palace was incorporated in a new gymnasium (school) in 1898. A new Jewish synagogue was built in 1897. There is also a statue to the Emperor William I. (1891). Oppeln is the seat of the provincial administration of Upper Silesia. Population (1885), 15,975; (1895), 23,017; (1900), 30,115.

Oppert, Julius (1825–——), Assyriologist, was born at Hamburg of Jewish parents on the 9th of July 1825. After studying at Heidelberg, Bonn, and Berlin, he graduated at Kiel in 1847, and in the following year went to France, where he became professor of German at Laval. His leisure was given to Oriental studies, in which he had made great progress in Germany, and in 1854 he joined M. Fresnel's archæological expedition to Mesopotamia. On his return he occupied himself in digesting the results of the expedition in so far as they concerned cuneiform inscriptions, and published an important work upon them in 1864. In 1857 he was appointed professor of Sanscrit in the school of languages connected with the National Library, and in this capacity produced a Sanscrit grammar; but his attention has been chiefly given to Assyrian and cognate subjects, and he has been especially prominent in establishing the Turanian character of the language originally spoken in Assyria. In 1865 he published a history of Assyria and Chaldæa in the light of the results of the different exploring expeditions. At a later period he devoted much attention to the language and antiquities of ancient Media, writing *Le Peuple et la Langue des Mèdes* (1879). He has published a very considerable number of separate memoirs upon Assyrian mythology, jurisprudence, and other subjects connected with the ancient civilizations of the East.

Oran, the second port of Algeria, capital of the department, on the Gulf of Oran, between Cape Aiguille on the east and Cape Falcon on the west, 260 miles by rail west-south-west of Algiers, 220 miles east of Gibraltar. Owing to the fact that it is the Mediterranean port in the most direct line with Timbuktu and the Niger, it has experienced a large development. Among fine new edifices are the hôtel de ville, the prefecture, the bank, and the hôtel des postes. Since 1878 there has been an archæological and geological society, which holds the foremost rank in Algeria. Oran has a considerable trade in wines, cereals, oils, and wools. The harbour has been so much improved that ships which formerly stopped at the harbour formed by the promontory of Mers el Kebir, about 3 miles to the west, now enter the port. A pier, three lighthouses, and a breakwater all greatly assist commerce and navigation. Oran owes its importance as a seaport to its proximity to Spain, being only eight hours' distance (about 140 miles) from Carthagena and Almeria. The tonnage, 650,000 in 1875, mounted to 1,231,000 in 1884, 2,064,000 in 1895, and 2,310,000 in 1898. The population in 1886 was 67,681, of whom 13,853 were French; in 1896 it was 80,211, of whom 24,038 were French; and in 1900 it was 85,081, of whom 25,088 were French. The foreign element, chiefly Spaniards, exceeds 34,000.

Orange, chief town of arrondissement, department of Vaucluse, France, 17 miles north of Avignon, on the railway from Paris to Marseilles. The ancient Roman theatre has been restored (1897) and now serves as a National Theatre; the hôtel de ville, erected in the 17th century, was restored in 1888. Amongst modern erections are a colossal statue of the Virgin on the hill above the theatre, and a monument to the soldiers who fell in the war of 1870–71. Population (1881), 6118; (1891), 6099; (1901), 9705.

Orange, a town of Australia, New South Wales, in the counties of Wellington and Bathurst, 192 miles by rail west of Sydney. It lies in a fruit and wheat producing district, in which gold, copper, and silver also abound. Its suburb, East Orange, in the county of Bathurst, is a separate municipality. The mean rainfall (16 years) is 35·84 inches. Population (1901), including East Orange, 6331.

Orange, a city of Essex county, New Jersey, U.S.A., situated at the undulating base of the Watchung Mountain, in the north-eastern part of the state, at an altitude of 187 feet. Two railways—the Delaware, Lackawanna and Western, and the Erie—connect it with New York, 16 miles distant, of which it is a residential suburb. It is also connected with neighbouring cities by trolley lines. It is irregularly laid out, even in the closely-built portions. It has an excellent water-supply and sewer system, and is divided into five wards. Population (1890), 18,844; (1900), 24,141, of whom 6598 were foreign-born and 1903 negroes.

Orange River Colony, a division of South Africa, known as the Orange Free State from 1854 to 1900, situated between 27° and 31° S. and 24° 20′ and

29° 40′ E. It reverted to the position of a British colony as the result of the Boer war, the capital, Bloemfontein, being occupied by the British on 28th February 1900. Under the Boer rule the country had made considerable material progress and reached a fair standard of general comfort, although the population showed but a relatively small increase of from 133,000 in 1880 to 208,000 (78,000 whites and 130,000 natives) in 1890. But this is no doubt partly to be explained by the considerable loss of territory under the Keate award in 1871, when the Kimberley diamond fields, with Griqualand West, were assigned to Great Britain. The economic prosperity of the land is indicated by the rapid development of its agricultural resources, of railway and mining enterprise, of its exports and its sound financial condition before the outbreak of hostilities. The revenue rose from £310,000 in 1892 to £800,000 in 1898, including £408,000 from the railways, which have now a total length of nearly 400 miles, and afford direct communication southwards across the Orange with Cape Town, Port Elizabeth, and East London, and northwards across the Vaal with Pretoria. The total imports (general merchandise of all kinds) advanced from £900,000 in 1895 to £1,192,000 in 1898, while in the latter year the exports (wool, hides, corn, diamonds) exceeded £2,000,000. Much coal continues to be gained from the extensive Kroonstad deposits, while the yield of diamonds in the Fauresmith district, near the Kimberley fields, rose from 99,225 carats, valued at £224,000, in 1890, to 307,000 carats, valued at £1,508,000, in 1898. The area of cultivated lands is encroaching on the pastures, especially in the fertile tracts along the banks of the Caledon river, and in the sheltered and well-watered upland valleys to the north-east of Thaba N'chu. At present the agricultural holdings considerably exceed 10,000, with a total of about 30,000,000 acres, of which 256,600 were under tillage in 1890. In the same year the live stock comprised 890,000 horned cattle, 250,000 horses, and 6,620,000 merino and fat-tailed sheep. Former reports of the dry and salubrious nature of the climate have been fully confirmed, and there can be no doubt that, with the development of irrigation works, vast tracts might be rendered suitable for European settlers. Besides the capital, there are several townships, villages, and other centres of population, which present some interest as markets for farm produce, or for their strategic position and historic associations. Subjoined are the most important arranged in alphabetical order :—

Albertina, a railway station on the line (60 miles long) running from Ladysmith in Natal to Harrismith, not far from Van Reenens Pass.

Bethanie, a railway station on the main line from Bloemfontein to Springfontein junction, founded by the French missionaries amongst the Basutos, who formerly occupied this district.

Bethlehem, a market on the Zand river, 56 miles west of Harrismith, and 83 miles east of Smaldeel railway station.

Bethulie, a station at the head of the railway bridge which here crosses the Orange river just below the Caledon confluence ; occupied by the British, 28th February 1900.

Boshof, a township near the west frontier, a few miles north-east of Kimberley ; here fell the leader of the "European Legion," Colonel de Villebois-Marcuil, 5th April 1900.

Brandford, an important railway station on the main line from Bloemfontein to Pretoria ; occupied by the British, 5th May 1900.

Edenburg, railway station on the main line between Bloemfontein and Springfontein, south of the Riet river.

Fauresmith, a township in the south-western district, at the junction of several roads, and close to the Jagersfontein diamond mines, the most productive in the colony. Here was found the largest African stone, weighing 500 carats uncut, but of imperfect quality.

Harrismith, a town near the eastern frontier, present terminus of the railway which runs from Ladysmith, on the Durban–Pretoria line, through Van Reenens Pass, and is to be continued to Kroonstad on the Bloemfontein–Pretoria line. Harrismith, which is distant 20 miles from Van Reenens Pass, lies in the valley of the Wilge tributary of the Vaal, and is the most important place in the eastern part of the colony.

Jacobsdal, a market in the south-western district, close to the "Griqualand frontier," on the right bank of the Riet river ; occupied by the British, 16th February 1900.

Kroonstad, a town and railway station on the Bloemfontein–Pretoria line, 127 miles from the former place, and 86 miles from the Vaal river ; was chosen by President Steyn as his capital after the fall of Bloemfontein, but was occupied by the British on 12th May 1900 ; is the centre of the chief coal-mining industry in the colony.

Ladybrand, a thriving agricultural town on the right bank of the Caledon, near Maseru in Basutoland.

Lindley, a market on the Valsch tributary of the Vaal, east of Kroonstad.

Paardeberg, a post on the right bank of the Modder, 30 miles south-east of Kimberley ; here the Boer leader, Cronje, surrendered with over 4000 men, 27th February 1900.

Philippolis, a town near the Orange river, south of Fauresmith ; occupied by the British, 23rd March 1900.

Rouxville, a flourishing agricultural station near the Orange river at Aliwal North, above the Caledon confluence ; occupied by the British, 19th March 1900.

Senekal, a market on the Bloemspruit, south-east of Kroonstad ; occupied by the British, 25th May 1900.

Smaldeel, a railway station on the main line, 63 miles north of Bloemfontein ; headquarters of General Roberts, 6th May 1900.

Smithfield, a large market on the Lower Caledon, 50 miles above its confluence with the Orange.

Springfontein, a railway station at the junction of the two main lines from Cape Town and Port Elizabeth.

Thaba N'chu, a station in the hilly eastern district near Ladybrand, former capital of the petty Barolong State, which was deprived of its autonomy by the Orange Free State in 1884.

Wepener, a station on the Lower Caledon, occupied, 29th March 1900, by the British, who successfully held the place against a greatly superior Boer force, 9th–24th April 1900.

Winburg, a large market connected by a short branch with the Smaldeel station on the Bloemfontein–Pretoria main line.

(A. H. K.)

History.—In 1853 a convention was entered into between representatives of the Free State and the British Government for transferring the government of the Orange River sovereignty to representatives delegated by the inhabitants to receive it. By means of this transfer the Imperial Government established the future independence of the country, and further stated that the British Government had no alliance whatever with any native chiefs or tribes to the north of the Orange river, with the exception of the Griqua chief, Adam Kok. It was also stipulated that the Orange River government should, as hitherto, permit no slavery or trade in slaves in their territory north of the Orange river. At the time of this transfer some Boers, leading residents of the Free State, protested against the abandonment, but the duke of Newcastle, who was then British colonial secretary, stated that, in his opinion, Imperial authority had already been extended too far in South Africa. He therefore could not entertain the request made to him to retain the administration of the country.

The new state of things had only been one year in existence when the Free State government found themselves victims to an intrigue of Messrs Pretorius and Kruger, within the Transvaal, to bring about, by force if necessary, a confederation between the two countries. In the first instance, peaceful overtures were made, but the Free Staters declined to accept the proposal. Thereupon Pretorius, aided by Paul Kruger, organized and conducted a raid into the Free State territory, in the hope of overawing the Free State government, and compelling it to fall in with the views of the minority of the Free Staters, who were co-operating with Pretorius. On learning of the invasion, Boshof, President of the Free State, proclaimed martial law throughout the country, and called out his burghers. The majority of the burghers rallied to his support, and in a very short time a formidable force was got together to oppose the invaders. On the 25th of May

1854 the two opposing forces faced one another on the banks of the Rhenoster. President Boshof not only managed to get together a considerable force within the Free State, but he received an offer of support from General Schoeman, the Transvaal leader in the Zoutpansberg district. Pretorius and Kruger, when they learnt what had occurred, realized that they would have to sustain attack from both north and south, and abandoned their enterprise (see TRANSVAAL). Before leaving, a treaty was signed, which amounted to an apology on the part of Pretorius. Several of the malcontents in the Free State, who had joined the Transvaal party, returned with them over the Vaal river, and permanently settled in the Transvaal. Other Free Staters who had been guilty of high treason were arrested and punished.

In 1858 the Volksraad of the Free State were so tired of the responsibilities of independence, that they passed a resolution in favour of a confederation in some shape or form with the Cape Colony. This proposition received the strong support of Sir George Grey, at that time governor of Cape Colony, but his view did not commend itself to the home authorities, and was not adopted.

From the date of their first settlement in the Orange River territories, the Boers were continually at feud with their Basuto neighbours on the eastern border (see BASUTOLAND). In 1866 they organized a powerful expedition, and attacked Moshesh. The expedition was successful, Moshesh was defeated, and a treaty was arrived at, by which he gave up possession of a portion of Basutoland, and acknowledged himself the subject of the Free State. This treaty did not, however, by any means terminate the strife; a period of feud continued, in the course of which Moshesh and his followers were reduced to very dire straits. They appealed to Great Britain for assistance, and in 1869 a treaty was agreed to between the High Commissioner and the Orange Free State, defining the borders between the Orange Free State and Basutoland. All the fertile tract of country lying to the north of the Orange river and west of the Caledon, originally a part of Basutoland, was ceded to the Free State. This tract of country, some hundred miles long and nearly thirty wide, is a fertile stretch of agricultural land on the lower slopes of the Maluti Mountains. It lies at an altitude of nearly 6000 feet, and is well watered by the Caledon and its tributaries. It has ever since been known as the Conquered Territory, and it forms to-day one of the richest corn-growing districts in South Africa.

The Basutoland difficulties were no sooner arranged than the Free Staters found themselves confronted with a serious difficulty on their western border. In the years 1870–71 a large number of diggers had settled on the diamond fields, which were situated on the boundary between the Griqua chief Waterboer and the Free State. At the time both the Free State and Waterboer claimed the district, and the Free State established a temporary government over the diamond fields, but the administration of this body was satisfactory neither to the Free State nor to the diggers. At this juncture Waterboer offered to place the territory under the administration of Queen Victoria. The offer was accepted, and on 27th October 1870 the district was proclaimed, under the name of Griqualand West, British territory. To criticize the grounds on which Waterboer's claims were based is difficult. But whatever the justice of the decision to annex may have been, it is certain that President Brand contended at the time that Waterboer's title was a bad one. The matter involved much correspondence and no little irritation between the British Government and the Free State until 1876. It was then finally disposed of by Lord Carnarvon, who granted to the Free State £90,000 in compensation for any possible harm or wrong which the Free State might have sustained from the annexation. In making this concession, it is right to state that Lord Carnarvon, having gone into the question, declined to acknowledge any validity in the Free State claim to the territory in question. One thing at least is certain with regard to the diamond fields—they were the means of restoring the credit and prosperity of the Free State. In the opinion, moreover, of Dr Theal, who has written the history of the Boer Republics and has been a consistent supporter of the Boers, the annexation of Griqualand West was probably in the best interests of the Free State. Fortunately at the time the Free State had an enlightened and liberal-minded ruler in President Brand, who avoided collisions and encouraged amicable relations with the British authorities.

In spite of the troubles on her borders, the Free State, under Brand's beneficent and tactful guidance, made progress in various directions. Villages sprang up, roads were constructed, and a postal service was established. Tea-planting was encouraged by the government. At the same time the Free State Boers, like their Transvaal neighbours, had drifted into financial straits. A paper currency had been instituted, and the notes—currently known as "bluebacks"—soon dropped to less than half their nominal value. Commerce was largely carried on by barter, and many cases of bankruptcy occurred in the State. But as British annexation in 1877 saved the Transvaal from bankruptcy, so did the influx of British and other immigrants to the diamond fields, in the early 'seventies, restore public credit and individual prosperity to the Boers of the Free State. The diamond fields offered a ready market for stock and other agricultural produce. Money flowed into the pockets of the farmers. Public credit was restored. "Bluebacks" recovered par value, and were duly called in and redeemed by the government. At a later date valuable diamond mines were discovered within the Free State, of which the one at Jagersfontein is the richest. Capital from Kimberley and London was soon provided with which to work them. The relations between the diggers and the Free State Boers, after the question of the boundary was once settled, remained perfectly amicable down to the outbreak of the Boer war in 1899. In 1880, when a rising of the Boers in the Transvaal against Sir Owen Lanyon was threatening, President Brand showed every desire to avert the conflict. He suggested to the authorities at Cape Town that Sir Henry De Villiers, Chief Justice of Cape Colony, should be sent into the Transvaal to endeavour to gauge the true state of affairs in that country. This suggestion was not acted upon, but when, in 1881, the Boers in the Transvaal broke out into open rebellion and war followed, Brand declined to take any part in the struggle. At a later date he urged that peace should be brought about, and expressed his friendly sentiments towards the British Government. In spite of the neutral attitude taken by Brand during this period, there can be no question that a certain number of the Free State Boers, living in the northern part of the Free State, went to the Transvaal and joined their brethren then in arms against the British Government. In 1888 Sir John Brand died. He had been President of the country since 1863, and in him the Boers, not only in the Free State but in the whole of South Africa, lost one of the most enlightened and most upright rulers and leaders they have ever had. Brand had always realized the liberal character of the British Government in South Africa, and while differences from time to time did occur between him and the representatives of Queen Victoria, he nevertheless in the main accepted the broad lines of British policy, and supported them. Throughout his long official career he remained on cordial terms of friendship with Great Britain.

In 1889 an agreement was come to between the Free State and the Cape Colony government, whereby the latter were empowered to extend, at their own cost, their railway system to Bloemfontein. The Free State retained the right to purchase this extension at cost, a right which they exercised within the course of a few years. In the same year Mr Reitz was elected President of the Free State. His accession to the Presidency marked the commencement of a new and disastrous line of policy in the public affairs of the country. Mr Reitz had no sooner got into office than a meeting was arranged with President Kruger, at which various terms of the agreement dealing with the railways, terms of a treaty of amity and commerce, and what was called a political treaty, were discussed and decided upon. The political treaty referred in general terms to a federal union between the two states, and bound each of them to help the other, whenever the independence of either should be assailed or threatened from without, unless the state so called upon for assistance should be able to show the injustice of the cause of quarrel in which the other state had engaged. In 1889 the Free State, having accepted the assistance of the Cape government in constructing its railway, entered into a Customs Union Convention with them. The convention was the outcome of a conference held at Cape Town in the previous year, at which delegates from Natal, the Free State, and the Colony attended. Natal at this time had not seen its way to entering the Customs Union, but did so at a later date. In 1895 the Free State Volksraad passed a resolution, in which they declared their readiness to entertain a proposition from the Transvaal in favour of some form of federal union. In the same year President Reitz retired from the presidency of the Free State on the ground of ill-health, and was succeeded by Judge Steyn. In 1896 President Steyn visited Pretoria, where he received quite an ovation as the future probable President of the two Republics. A further offensive and defensive alliance between the two Republics was then entered into, under which the Free State took up arms on the outbreak of hostilities with the Transvaal in 1899.

In 1897 President Kruger, being bent on still further cementing the union with the Free State, himself visited Bloemfontein. It was on this occasion that President Kruger, referring to the London Convention, spoke of Queen Victoria as a "kwaaje Frau," an expression which caused a good deal of offence in England at the time, but which, to any one familiar with the homely phraseology of the Boers, obviously was not meant by President Kruger as insulting. In order to understand the attitude which the Free State took at this time in relation to the Transvaal, it is necessary to review the history of Mr Reitz from an earlier date. Previous to his becoming President of the Free State he had acted as its Chief Justice, and still earlier in life had practised as an advocate in Cape Colony. In 1881 Mr Reitz had, in conjunction with his successor President Steyn, come under the influence of a clever German named Borckenhagen, the editor of the *Bloemfontein Express*. These three men were principally responsible for the formation of the Afrikander Bond (see CAPE COLONY). From 1881 onwards there is no doubt that they cherished the one idea of an independent South Africa, in which a monopoly of independence was to be held by the Boers. Brand during his lifetime had been far too sagacious to be led away by this pseudo-nationalist dream. He did his utmost to discountenance the Bond when it was started by Mr Reitz and Mr Borckenhagen, inasmuch as he saw full well that it was calculated to cause mischief in the future. At the same time his policy was guided by a sincere patriotism, which looked to the true prosperity of the Free State as well as to that of the whole of South Africa. It was only after his death that the fatal development of an exclusively Dutch policy arose in the Free State. From his death may be dated the disastrous line of policy which led to the extinction of the state as a republic. The one prominent member of the Volksraad who inherited the traditions and enlightened views of President Brand with regard to the future of the Free State was Mr G. J. Fraser. Mr Fraser was the son of a Presbyterian minister, who had acted as a minister in the Dutch Reformed Church since the middle of the century. He grew up in the country of his father's adoption, and he consistently warned the Free State of the inevitable result which must follow their mischievous policy in being led by the Transvaal. His protests, however, were vain, and the mass of Boers in the Free State, deluded by a belief in Great Britain's weakness, paid no heed to his remonstrances. Mr Fraser lived to see the fulfilment of these prophecies. After the British occupation of Bloemfontein he cast in his lot with the Imperial Government, realizing that it had fought for those very principles which President Brand and he had laboured for in bygone years.

The economic progress of the Free State, which began with the discovery of the diamond fields, has been redoubled since the construction of the railway through its territory to Johannesburg, thus fully justifying the forward commercial policy adopted in the teeth of Transvaal opposition. In illustration of this we have only to cite the fact that, in 1898–99, out of a total revenue of about £650,000, £325,000, or more than half, represented the earnings of the railway.

On entering Bloemfontein in 1900 the British obtained possession of certain state papers which contained records of negotiations between the Transvaal and the Orange Free State. The evidence contained in these state records so clearly marks the difference between the policy of Mr Kruger and the pacific, commercial policy of President Brand and his followers, that the documents call for careful consideration. From these papers it was found that, in 1887, two secret conferences had taken place between the Republics, dealing with various political and economical questions. At the first of these conferences, held in Pretoria, there were present President Kruger, with his state secretary and state attorney, Messrs Bok and Leyds, and a commission of the Transvaal Volksraad, consisting of Messrs Wolmarans, Klopper, Taljaard, Lombard, and Spies. On the other side the deputation from the Free State Volksraad was composed of Messrs Fraser, Klynveld, and Myburgh.

An interesting account of this interview was given by a correspondent of *The Times* on 24th May 1900. The account was evidently compiled after a careful study of the papers, and the correspondent states that pre-eminent at that conference, and practically leading it, stood President Kruger, knowing exactly what he wanted, "indifferent to argument, returning again and again to the same point, however often it was refuted; incapable of conviction, though ready as a last resort to lower his demands step by step, and claim that he had made a great concession"—in fact, the same Kruger, as twelve years later at Bloemfontein, only here not on the defensive against a superior intellect and a will as strong as his own (both of which he met in Sir Alfred Milner), but active, persuasive, impassioned, appealing to men more capable of being brought under his influence. On the Free State side was Mr Fraser, resolutely endeavouring to carry out the traditions of Brand's policy.

The objects of the Free State deputies at this conference were apparently straightforward. They were to arrange a general treaty of amity and commerce which would knit the states more closely together, and to come to some agreement with reference to the scheme for building a railway across the Free State from the Cape, to connect with a further extension in the Transvaal to Pretoria. Another proposition of the deputation, which they urged upon the Transvaal, was that of joining the South African Customs Union. Both of these suggestions were strongly disapproved of by Mr Kruger, inasmuch as they obviously meant knitting South Africa together with the British possessions, instead of merely bringing the Free State into completer dependence on the Transvaal. From the minutes of this conference it is clear that the two deputations were practically at cross purposes. In the minds of President Kruger and his immediate followers one idea was dominant, that of ousting and keeping out at all costs British influence and interests in every shape or form. On the part of the Free State, on the other hand, there was obviously a genuine desire to further the best interests of the state, together with the general prosperity of the whole of South Africa. In President Kruger's eyes British trade meant ruin; he desired to keep it out of the Republic at all costs, and he begged the Free State to delay the construction of their railway until the Delagoa Bay line was completed. He said, "Delagoa is a life or death question for us. Help us: if you hook on to the Colony you cut our throat. . . . How can our state exist without the Delagoa railway? Keep free." With regard to the Customs Union President Kruger was equally emphatic; he begged the Free State to steer clear of it. "Customs Unions," he said, "are made between equal states with equal access to harbours. We are striving to settle the question of our own harbour peacefully. The English will only use their position to swindle the Transvaal of its proper receipts." In response, Mr Fraser remarked that a harbour requires forts, soldiers, ships, and sailors to man them, or else it would be at the mercy of the first gunboat that happened to assail it. President Kruger replied that once the Transvaal had a harbour foreign Powers would intervene. Mr Wolmarans was as emphatic as President Kruger. "Wait a few years. . . . You know our secret policy. We cannot treat the Colony as we would treat you. The Colony would destroy us. It is not the Dutch there we are fighting against. Time shall show what we mean to do with them; for the present we must keep them off." This last sentence probably refers to an intrigue with certain Dutchmen in the Cape Colony. If it did not refer to an actual intrigue, the least it could have meant was the intention to intrigue when occasion arose.

The result of this conference was a secret session of the Transvaal Volksraad and the proposition of a secret treaty with the Free State, by which each state should bind itself not to build railways to its frontier without the consent of the other, the eastern and northern frontiers of the Transvaal being excepted. The railway from Pretoria to Bloemfontein was to be proceeded with; neither party was to enter the Customs Union without the consent of the other. The Transvaal was to pay £20,000 annually to the Free State for loss incurred for not having the railway to Cape Colony. Such a treaty as the one proposed would simply have enslaved the Free State to the Transvaal. It was rejected by the Free State Volksraad in due course, but President Kruger, not content with this resolution, determined on a still more active measure, and proceeded with Dr Leyds to interview President Brand at Bloemfontein. A series of meetings took place in October of the same year (1887). President Kruger had come to Bloemfontein nominally with the intention of discussing railway and commercial matters, and also of promoting closer union between the two Republics. President Brand, therefore, opened the proceedings by proposing a treaty of friendship and free trade between the two Republics, in which a number of useful and thoroughly practical provisions occurred. President Kruger, however, soon brushed these propositions aside, and responded by stating that, in consideration of the common enemy and the dangers which threatened the Republic, an offensive and defensive alliance must be preliminary to any closer union. To this Brand rejoined that, as far as the offensive was concerned, he did not desire to be a party to attacking any one, and as for the defensive, where was the pressing danger of the enemy which Kruger feared? The Free State was on terms of friendship with its neighbours, nor (added Brand) would the Transvaal have need for such an alliance as the one proposed if its policy would only remain peaceful and conciliatory. At a later date in the conference (see TRANSVAAL) President Brand apparently changed his policy, and himself drafted a constitution resembling that of the United States. This constitution appears to have been modelled on terms a great deal too liberal and enlightened to please Mr Kruger, whose one idea was to have at his command the armed forces of the Free State when he should require them, and who pressed for an offensive and defensive alliance. Brand refused to allow the Free State to be committed to a suicidal treaty, or dragged into any wild policy which the Transvaal might deem it expedient to adopt. The result of the whole conference was that Kruger returned to Pretoria completely baffled, and for a time the Free State was saved from being a party to the fatal policy into which others subsequently drew it. Independent power of action was retained by Brand for the Free State in both the railway and Customs Union questions.

After Sir John Brand's death, as already stated, Mr Reitz became President, and consistently followed out that policy which, as one of the founders of the Bond, he had endeavoured to inaugurate throughout Dutch South Africa. A series of agreements and measures in the Volksraad gradually subordinated those true Free State interests which Brand had always protected to the mistaken ambition and narrow views of the Transvaal. Mr Fraser in vain tried to stem the tide of Krugerism within the Free State, but the extent to which it had travelled after Brand's death was evidenced by the election for President in February 1896, when Mr Steyn was elected against Mr Fraser by forty-one votes to nineteen. That this election should have taken place immediately after the Jameson Raid probably increased President Steyn's majority. At the same time the history of the state after Brand's death renders it probable that Mr Fraser's defeat was only a question of degree. Mr Fraser continued, down to the outbreak of the war of 1899, consistently to denounce the policy on which the Free State had embarked, warning his countrymen continually that this policy could have but one end—the loss of their independence. Underlying the state policy there was undoubtedly the belief, if not with President Steyn himself, at least with his followers, that the two Republics combined would be more than a match for the power of Great Britain should hostilities eventually occur.

In December 1897 the Free State revised its constitution in reference to the franchise law, and the process of naturalization was reduced from five to three years. The oath of allegiance to the state was alone required, and no renunciation of nationality was insisted upon. In 1898 the Free State also acquiesced in the fresh convention arranged with regard to the Customs Union between the Cape Colony, Basutoland, and the Bechuanaland Protectorate. These measures suggest that already a slight reaction against the extreme policy of President Kruger had set in. But events were moving rapidly in the Transvaal, and matters had proceeded too far for the

Free State to turn back. In 1899 President Steyn suggested the conference at Bloemfontein between President Kruger and Sir Alfred Milner, but this act, if it expressed at all a genuine desire for reconciliation, was too late. President Kruger had got the Free State ensnared in his meshes. The Free Staters were bound practically hand and foot, under the offensive and defensive alliance, in case hostilities arose with Great Britain, either to denounce the policy to which they had so unwisely been secretly party, or to throw in their lot with the Transvaal. War occurred, and they accepted the inevitable consequence. In September 1899 Sir Alfred Milner sent a despatch to President Steyn, informing him that the exigencies of the situation demanded that he should take some steps to protect his line of communications, and that he was stationing a force near the Orange Free State frontier. Sir Alfred Milner at the same time expressed the hope that the difference between the British Government and the Transvaal might still be adjusted, but if this hope were disappointed, he should look to the Free State to preserve strict neutrality, in which case the integrity of their territory would in all circumstances be respected. In similar circumstances Sir John Brand had remained neutral in 1881, but he was unfettered by any treaty with the Transvaal. For President Steyn and the Free State of 1899, in the light of the negotiations we have recorded, neutrality was impossible. Before war had actually broken out the Free State began to expel British subjects, and the very first act of war was committed by Free State Boers, who, on 11th October, seized a train upon the border belonging to Natal (see also STEYN and SOUTH AFRICA).

Orbetello, a town and bishop's see of the province of Grosseto, Tuscany, Italy, 24 miles south by east of Grosseto. It is situated on an artificial causeway, which connects the mainland with the peninsula of Monte Argentario. The town still has the bastions which the Spaniards built during the period (1557–1713) when they were masters of this corner of Italy, and possesses a cathedral and an Etruscan museum. There is a large convict prison, with which is connected another at Porto Ercole, on the east side of the peninsula. The mother-house of the Passionist order crowns an eminence of Monte Argentario. The salt-water lagoon (11 square miles in extent), in the middle of which the town stands, abounds in white fish, soles, and eels. Population (1881), 4449; (1899), about 3800.

Orchardson, William Quiller (1835–——), British painter, was born in Edinburgh, where his father was engaged in business, in 1835. "Orchardson" is a variation of "Urquhartson," the name of a Highland sept settled on Loch Ness, from which the painter is descended. At the age of fifteen he was sent to the Trustees' Academy, then under the mastership of Robert Scott Lauder, where he had as fellow-students most of those who afterwards shed lustre on the Scottish school of the second half of the 19th century. As a student he was not especially precocious or industrious, but his work was distinguished by a peculiar reserve, by an unusual determination that his hand should be subdued to his eye, with the result that his early things reach their own ideal as surely as those of his maturity. By the time he was twenty, Orchardson had mastered the essentials of his art, and had produced at least one picture which might be accepted as representative, a portrait of Mr John Hutchison, the sculptor. For seven years after this he worked in Edinburgh, some of his attention being given to "black and white," his practice in which had been partly acquired at a sketch club which included among its members Mr Hugh Cameron, Mr Peter Graham, Mr George Hay, Mr M'Taggart, Mr John Hutchison, and others. In 1862 he came to London, and established himself in 37 Fitzroy Square, where he was joined twelve months later by his friend John Pettie. The same house was afterwards inhabited by Ford Madox Brown.

The English public was not immediately attracted by Orchardson's work. It was too quiet to compel attention at the Royal Academy, and Pettie, Orchardson's junior by four years, stepped before him for a time, and became the most readily accepted member of the school. Orchardson confined himself to the simplest themes and designs, to the most reticent schemes of colour. Among his best pictures during the first eighteen years after his migration to London were "The Challenge," "Christopher Sly," "Queen of the Swords," "Conditional Neutrality," "Hard Hit"—perhaps the best of all—and portraits of Mr Charles Moxon, his father-in-law, and of his own wife. In all these good judgment and a refined imagination were united to a restrained but consummate technical dexterity. During these same years he made a few drawings on wood, turning to account his early facility in this mode. The period between 1862 and 1880 was one of quiet ambitions, of a characteristic *insouciance*, of life accepted as a thing of many-balanced interests rather than as a matter of *sturm und drang*. In 1865 Pettie married, and the Fitzroy Square *ménage* was broken up. In 1868 Orchardson was elected A.R.A. In 1870 he spent the summer in Venice, travelling home in the early autumn through a France over-run by the German armies. In 1873 he married Miss Helen Moxon, and in 1877 he was elected to the full membership of the Royal Academy. In this same year he finished building a house at Westgate-on-Sea, with an open tennis-court and a studio in the garden.

Orchardson's wider popularity dates from 1881. To that year's Academy he sent the large "On Board the *Bellerophon*," which now hangs in the Tate Gallery. Its success with the public was great and instantaneous, and for ten or twelve years Orchardson's work was more eagerly looked for at the Academy than that of any one else. He followed up the "Bellerophon" with the still finer "Voltaire" (see PLATE) now in the Kunsthalle at Hamburg. Technically, the "Voltaire" is, perhaps, his high-water mark. Fine both in design and colour, it is carried out with a supple dexterity of hand which has scarcely been equalled in the British school since the death of Gainsborough. The subject is not entirely happy, for it does not explain itself, but requires a previous knowledge on the part of the spectator of how Voltaire was beaten by the servants of the Chevalier de Rohan-Cabot, and how the duc de Sully failed to avenge his guest. The painter was attracted by the opportunity it gave for effective opposition of character, line, colour, and movement. The "Voltaire" was at the Academy of 1883; it was followed, in 1884, by the "Mariage de Convenance," perhaps the most popular of all Orchardson's pictures; in 1885, by "The Salon of Madame Récamier"; in 1886, by "After," the sequel to the "Mariage de Convenance," and "A Tender Chord," one of his most exquisite productions; in 1887, by "The First Cloud"; in 1888, by "Her Mother's Voice"; and in 1889, by "The Young Duke," a canvas on which he returned to much the same pictorial scheme as that of the "Voltaire." Subsequently he exhibited a series of pictures in which fine pictorial use was made of the furniture and costumes of the early years of the 19th century, the subjects, as a

"VOLTAIRE." By W. Q. ORCHARDSON, R.A.

rule, being only just enough to suggest a title: "An Enigma," "A Social Eddy," "Reflections," "If music be the food of love, play on!" "Music, when sweet voices die, vibrates on the memory," "Her First Dance,"—in these opportunities are made to introduce old harpsichords, spinets, early pianofortes, Empire chairs, sofas, and tables, Aubusson carpets, long-waisted gowns, delicate in material and primitive in ornament. Between such things and Orchardson's methods as a painter the sympathy is close, so that the best among them, "A Tender Chord," for instance, or "Music, when sweet voices die," have a rare distinction.

As a portrait-painter Orchardson must be placed in the first class. His portraits are not numerous, but among them are a few which rise to the highest level reached by modern art. "Master Baby," a picture, connecting subject-painting with portraiture, is a masterpiece of design, colour, and broad execution. "Mrs Joseph," "Mrs Ralli," "Sir Andrew Walker, Bart.," "Charles Moxon, Esq.," "Mrs Orchardson," "Conditional Neutrality" (a portrait of Mr Orchardson's eldest son as a boy of six), "Lord Rookwood," "The Provost of Aberdeen," and, above all, "Sir Walter Gilbey, Bart.," would all deserve a place in any list of the best portraits of the 19th century. In this branch of art the "Sir Walter Gilbey" may fairly be called the painter's masterpiece, although the sumptuous full-length of the Scottish Provost, in his robes, runs it closely. The scheme of colour is reticent; had the picture been exhibited after 1900 the colour would have been called khaki; the design is simple, uniting nature to art with a rare felicity; and the likeness has been found satisfactory by the sitter's friends. The most important commission ever received by Mr Orchardson as a portrait-painter was that for a group of Queen Victoria, with her son (afterwards King Edward VII.), grandson, and great-grandson, to be painted on one canvas for the Royal Agricultural Society. The painter hit upon a happy notion for the bringing of the four figures together, and as time goes on and the picture slowly turns into history, its merit is likely to be better appreciated.

Orchardson's method is that of one who works under a creative, decorative, and subjective impulse, rather than under one derived from a wish to observe and record. His affiliation is with Watteau and Gainsborough, rather than with those who would base all pictorial art on a keen eye for actuality and "value." Among French painters his pictures have excited particular admiration.

Orchha, or URCHHA (also called TEHRI), a native state of Central India, in the Bundelkhand Agency. Area, about 2000 square miles; population (1881), 311,515; (1891), 333,020, showing an increase of 7 per cent. Estimated gross revenue, Rs.9,00,000; no tribute. The town of Orchha, the former capital, is on the river Betwa, not far from Jhansi. It contains an imposing fort, with a palace. The town of Tehri, where the chief now resides, is about 40 miles south of Orchha. Population (1881), 18,344; (1891), 17,610. It contains the fort of Tikamgarh, by which name the town is sometimes called.

Orders of Knighthood.—The article KNIGHTHOOD in the ninth edition of this work, in the course of a general historical sketch of the origin and institution of orders of chivalry, describes in some detail the leading British, and refers incidentally to certain of the more illustrious foreign, orders.

When orders ceased to be fraternities, and became more and more marks of favour and a means of recognizing meritorious services to the Crown and country, the term "orders" became loosely applied to the insignia and decorations themselves. Thus "orders," irrespective of the title or other specific designation they confer, fall in Great Britain generally into three main categories, according as the recipients are made "Knights Grand Cross" (having for their outward adornment a cross or star and ribbon, worn over the shoulder), "Knights Commanders" (with a star or other badge, but with the ribbon worn round the neck), and "Companions" (who have a badge only, but no star). In some orders the classes are more numerous, as in the Royal Victorian, for instance (*vide infra*), which has 5, numerous foreign orders a like number, some 6, while the Chinese "Dragon" boasts no less than 11 degrees.

Orders may, again, be grouped according as they are (1) PRIME ORDERS OF CHRISTENDOM, conferred upon an exclusive class only. Here belong, *inter alia*, the well-known orders of the *Garter* (England), *Golden Fleece* (Austria and Spain), *Annunciata* (Italy), *Black Eagle* (Prussia), *St Andrew* (Russia), *Elephant* (Denmark), and *Seraphin* (Sweden). Of these the first three only, which are usually held to rank *inter se* in the order given, are historically identified with chivalry. (2) FAMILY ORDERS, bestowed upon members of the royal or princely class, or upon humbler individuals according to classes, in respect of "personal" services rendered to the family. To this category belong such orders as the Royal Victorian and the Hohenzollern (Prussia). (3) ORDERS OF MERIT, whether military, civil, or joint orders. Such have, as a rule, at least three, oftener five, classes, and here belong such as the *Order of the Bath* (England), *Red Eagle* (Prussia), *Legion of Honour* (France). There are also certain orders, such as the recently-instituted *Order of Merit* (England), and the *Pour le mérite* (Prussia), which have but one class, all members being on an equality of rank within the order.

Of the seven British orders of knighthood which existed in 1883, three—the Garter, the Thistle, and the St Patrick—still remain within their former limits, while the Bath, the St Michael and St George, the Star of India, and the Indian Empire have been all exceeded, and the last named enlarged.

Until recently Great Britain had, practically, but one order for the recognition of civil merit in the home country, that of the *Bath*—the *Garter*, *Thistle*, and *St Patrick* being confined to nobles, the *St Michael and St George* generally to colonial dignitaries and officials, the *Star of India* and the *Indian Empire* to princes and officials connected with that country. The closing years of the reign of Queen Victoria and the first two of the reign of King Edward VII. saw the institution of several British orders, the leading characteristic of which may be said to consist in a tendency to recognize merit without conferring knighthood; that is, that while the designation in the form of letters to be appended to the name of the recipient denotes membership of the order, the style or appellation of knight is absent.

The Most Eminent Order of the Indian Empire, which from its institution down to 1887 consisted of one class only—Companions—was, however, on the occasion of the Queen's Jubilee enlarged by the addition of the two higher classes of knights, viz., *Knights Grand Commanders* (G.C.I.E.) and *Knights Commanders* (K.C.I.E.), yet these two classes are less regarded as orders of merit than as conferring a certain social precedence.

The *Royal Victorian Order* was instituted by Queen Victoria on the 25th April 1896, and conferred for personal services rendered to her late Majesty and her successors on the throne. It consists of a sovereign, chancellor, secretary, and five classes — knights grand commanders (G.C.V.O.), knights commanders (K.C.V.O.), commanders (C.V.O.), and members of the fourth and fifth classes (M.V.O.), the distinction between these last divisions lying in the badge and in the precedence enjoyed by the members. The knights of this order rank in their respective classes immediately after those of the *Indian Empire*, and its numbers are unlimited. The precedence enjoyed by its commanders tends to support the view above expressed that membership of an order shall, as denoting inclusion in a select brotherhood or fraternity, be held more in honour than heretofore, and knighthood regarded more as an incident than an essential.

To the class of orders without the titular appellation "knight" belong (1) the newly-created *Order of Merit*, founded by King Edward VII. on the occasion of his coronation, fixed for 26th June 1902, but, owing to the King's serious illness, postponed to 9th August. The order is founded on the lines of the Prussian *Ordre pour le mérite* (*q.v. infra*), yet more comprehensive, including those who have gained distinction in the military and naval services of the Empire, and such as have made themselves a great name in the fields of science, art, and literature. The number of British members has been fixed at twenty-four, with the addition of such foreign persons as the Sovereign shall appoint. The nature of the order may be seen from the names of the recipients:—Earl Roberts, Viscount Wolseley, Viscount Kitchener, Sir Henry Keppel, Sir Edward Seymour, Lord Lister, Lord Rayleigh, Lord Kelvin, Mr John Morley, Mr Lecky, Mr G. F. Watts, and Sir William Huggins. (2) The *Imperial Service Order* was likewise instituted on 26th June 1902, to commemorate King Edward's coronation, and is specially designed as a recognition of faithful and meritorious services rendered to the British Crown by members of the Civil Service in various parts of the Empire, and is to consist of companions only. The numbers are limited to 425, of whom 250 belong to the home and 175 to the civil services of the colonies and protectorates. The members of the order have the distinction of adding the letters I.S.O. after their names. (3) The *Distinguished Service Order*, an order of military merit, was founded on the 6th of September 1886 by Queen Victoria, its objects being to recognize the special services of officers in the army and navy. Its numbers are unlimited, and its designation the letters D.S.O. It consists of one class only, who take precedence immediately after the 4th class of the Royal Victorian Order.

In addition to the above, there are two British orders confined to ladies. The *Royal Order of Victoria and Albert*, which was instituted in 1862, is a purely court distinction. It consists of four classes, and it has as designation the letters V.A. The *Imperial Order of the Crown of India* is conferred for like purposes as the order of the Indian Empire. Its primary object is to recognize the services of ladies connected with the Court of India. The letters C.I. are its designation.

Among decorations which are constantly seen, and are not "orders," may be mentioned the *Victoria Cross* for conspicuous bravery in battle, having as its designation the letters V.C.; the *Royal Red Cross*, instituted in 1883 for the purpose of rewarding services rendered in nursing the sick and wounded of the army and navy. It is confined to ladies, whether subjects or foreigners. The *Volunteer Officers' Decoration*, in recognition of twenty years' service as officers of the volunteer force; the *Kaisar i Hind Medal* for public services in India, consisting of two classes; the naval *Conspicuous Service Cross*, established 15th June 1901; and the *Albert Medal* for saving life, consisting of two classes.

The order of *St John of Jerusalem* (or *Knights of Malta*), closely allied to, if not actually identical with, the Teutonic orders of Austria, the Netherlands, and Prussia (*vide infra*), was instituted in 1048 as an order of knighthood in the Hospital of St John at Jerusalem. The fraternity emigrating in 1309 to Rhodes became known as that of the "Knights of Rhodes," and was in 1330 divided into eight languages, England taking sixth place. In 1530 it established itself at Malta, whence the name "Knights of Malta" (a Maltese cross being still the badge). During the ensuing centuries it decayed in importance, and, on the death of the Grand Master Fra Thomasi de Cortone in 1805, virtually ceased to exist. It was, however, revived in 1879, and the parent stem now flourishes in Malta. A branch became established in England at the Priory of St John, Clerkenwell, its present habitation, about the year 1100, as a charitable brotherhood for the relief of necessitous pilgrims to the Holy Land; and the main object of its institution was pursued under various forms until 1830, when it was revised for the purpose of performing charitable and ambulance work. Originally a Catholic order, in 1888 a royal charter of incorporation was granted, and it now, although not conferring any style like a rank or distinction, exists as a properly-constituted order. The sovereign head and patron of this order is the King; the present Grand Prior is the prince of Wales; Bailiff of Egle, duke of Connaught. It has executive officers, knights of justice (and honorary), ladies of justice (and honorary), chaplain, knights of grace, ladies of grace, and equerries. Its badges—a Maltese cross and medal (according to the classes)—may be worn in England.

The following is a list of the better-known foreign orders:—

Austria-Hungary.—(1) The order of the *Golden Fleece*, above referred to, consists of 1 class only, and was instituted in 1429 by Philip the Good, duke of Burgundy, its statutes dating from the following year. It is common to Austria and Spain, and is conferred only upon members of sovereign houses and the highest nobles in the two countries. (2) The royal Hungarian order of *St Stephen*, instituted in 1764 by the Empress Maria Theresa, consists of the Grand Master (the sovereign), twenty knights grand cross, thirty knights commanders, and fifty knights. The ribbon is crimson with two green stripes. (3) The Austrian *Iron Cross*, founded by Napoleon I. as king of Italy in 1805, consisting of 3 classes, and conferred for personal merit. (4) The *Teutonic Order of Chivalry*, founded, it is said, in 1190 by Duke Frederick de Souabe, abolished by Napoleon in 1809, was revived in 1834. It is akin to the British order of St John of Jerusalem, and is conferred upon Roman Catholics (gentlemen and ladies) who devote themselves to the interests of the ambulance service. (5) The order of the *Starry Cross*, limited to high-born ladies, was instituted in 1668 by Eleanor, widow of the Emperor Ferdinand III., in perpetual commemoration of the discovery of a piece of the true cross.

Besides those enumerated, there are several orders given for personal merit, such as the military orders of *Maria Theresa*, *Elizabeth Theresa*, and the *Leopold*.

Belgium.—*Order of Leopold*, of 5 classes, instituted by King Leopold I. in 1832 for civil and military merit. The civil *Iron Cross*, instituted in 1867, and the military cross (2 classes) dating from 1885. There are also 4 orders connected with the Congo State, instituted by Leopold II., viz., the *African Star* (6 classes), the *Royal Lion* (6 classes), the *Congo Star*, and the *Order of the Crown.*

Bulgaria.—The principal order is that of *St Alexander*, instituted in 1881, of 6 classes.

China.—The order of the *Double Dragon*, originally founded in 1862 as that of the *Imperial Dragon*, to reward the services of foreigners in Chinese service, was reorganized in 1882 and has 5 classes, the first 3 being each again subdivided into 3 grades.

Denmark.—(1) The *Order of the Elephant*, said to have been instituted in 1464 by King Christian I., and remodelled in 1693 by Christian V., has only 1 class of about 30 knights, in addition to princes of royal descent. Its distinguishing ribbon is watered light blue. (2) The *Dannebrog*, an order of merit in 5 classes, said to have been founded in 1219 by Waldemar II., was remodelled in 1693, and again in 1808. Its distinguishing ribbon is white with red edging.

France.—The *Legion of Honour*, instituted in 1802 by Bonaparte, first consul, was enlarged and its statutes modified in 1816 and 1852, and is, apart from some military decorations and a few colonial orders belonging to vassal states, such as Annam, Cambodge, Porto-Novo, &c., the only order now conferred in France. There are 5 classes, and the ribbon is crimson.

Germany.—All German sovereign states have orders in the sense of decorations or badges bestowed for civil or military merit, but certain of the principal countries possess orders which are held in great esteem, viz. :—

1. *Anhalt.*—The order of *Albert the Bear*, instituted in 1836, but possibly, as is claimed for it, dating back to the Crusades, and lately revised, has 5 classes.

2. *Baden* has 3 illustrious orders : *Order of Fidelity*, instituted 1715 by the Margrave Charles William ; the military order of Charles Frederick (3 classes), founded in 1807 ; and that of the *Zähringen Lion* (5 classes), founded in 1812, of which, however, the original first class has since 1877 been instituted as a special order of 4 classes under the name of Berthold I.

3. *Bavaria* has the high order of *St Hubert* (founded in 1444 by Gerhard V.), limited to members of the Royal House of Bavaria and to foreign sovereigns and to nobles ; ribbon red, watered, with green edging. The *St George*, instituted during the Crusades in the Holy Land, later revised by Maximilian I. at the end of the 15th century, but revised by the Elector Charles Albert in 1729, is confined to Roman Catholics and to such as have no other order. In addition to the military *Order of Maximilian Joseph* (3 classes), and the 4 illustrious ladies' orders of *Theresa* (1827), *St Elizabeth* (1766), *St Anne of Munich* (1784), and *St Anne of Würzburg* (1803), Bavaria possesses several minor orders and decorations for military and civil merit.

4. *Brunswick.*—*Henry the Lion* (founded in 1834 by the Duke William) has 5 classes, in addition to a cross of merit of 2 grades.

5. *Hanover.*—The *Order of St George* (1 class only) was instituted in 1839 by King Ernest August I., as the family order of the House of Hanover ; the *Royal Guelphic Order* (3 classes) was founded in 1815 by George, Prince Regent, and afterwards King George IV. of Great Britain ; the order of *Ernest Augustus*, instituted by King George V., 1865. These orders have not been conferred since 1866, when Hanover ceased to be a kingdom, and the *Royal Guelphic Order*, which from its institution is more English than Hanoverian, not since the death of King William IV. in 1837. The sole surviving British Knight Grand Cross (G.C.H.) is his Royal Highness Field-Marshal the duke of Cambridge.

6. *Hesse-Darmstadt*, grand-duchy, has 2 grand orders, the *Golden Lion* (instituted 1790), consisting of 1 class only, and the *Order of Louis* (1807), of 5 classes. The first named is, with few exceptions, conferred only upon such as are members of the grand-ducal house of Hesse-Darmstadt and the electoral house of Hesse-Cassel, which ceased to be a reigning house in 1866.

7. *Mecklenburg* (Schwerin and Strelitz).—These grand-duchies jointly possess 1 order, that of the *Wendish Crown*, founded in 1864 by the Grand Dukes Frederick Francis and Frederick William. It consists of 3 classes, a cross of merit, and a grand cross of the first class for ladies of Schwerin.

8. *Oldenburg.*—*Order of Merit*, of two divisions, each of which has 5 classes, conferred for distinction in art and science.

9. *Prussia* has 5 principal orders—the *Black Eagle*, founded in 1701 by the Elector Frederick I. to commemorate his connexion as king of Prussia ; it is bestowed only upon such as are of royal lineage and upon high officers of state. It is limited to knights, exclusive of princes, and confers the title "von" of hereditary nobility ; the ribbon is orange. *Order of the Red Eagle*, instituted in 1705 by George William, hereditary prince of Brandenburg-Bayreuth, was reorganized in 1712, 1810, and lastly in 1861, and, consisting of 5 classes, is given for civil and military merit. *Order of the Crown* (4 classes), founded in 1861 by King William I., is conferred for merit on the field of battle. *Order of Merit*, military and civil, originally founded by the Elector Frederick in 1667, was remodelled in 1740 by Frederick II., under the title of *Ordre pour le mérite*, and in 1842 Frederick William IV. added a special civil class for merit in arts and sciences. This order has always been highly prized, and it is worthy of note that it is the only distinction which Thomas Carlyle would accept. The family *Order of the House of Hohenzollern* (instituted 1851) ; the *Johanniter Order* or *Order of St John of Jerusalem* (*vide supra*), instituted in 1812, a revival of the old order of the Hospitallers. Of ladies' orders Prussia has that of *Louise* (instituted 1814), of 2 classes.

10. *Saxony, Kingdom of.*—The *Order of the Crown of Rue* (*Rauten-Krone*), founded in 1807 by King Frederick Augustus. It has but one class ; ribbon watered green. The military *Order of St Henry*, for valour on the field, founded 1736, has 4 classes. The *Albert Order* (*Albrecht Orden*), founded 1850, originally instituted as a distinction for merit in arts and sciences, has been enlarged by the addition of a military class. The *Order of Sidonia* (instituted 1870 for services during the war) is conferred on ladies.

11. *Saxon Duchies*, including Saxe-Altenburg, Saxe-Coburg-Gotha, and Saxe-Meiningen, have in common a general order of merit in 4 classes : that of *Ernest*, founded 1690 by Duke Frederick I.

12. *Saxe-Weimar* has as its principal order that of the *White Falcon* (founded 1732), which is by its statutes confined to twenty-four illustrious personages in the civil and military service.

13. *Würtemberg.*—The *Order of the Crown of Würtemberg*, instituted in 1818 by King William I., has been frequently remodelled, and now consists of 5 classes.

Greece.—The *Order of the Redeemer*, founded in 1829 by the fourth General Assembly of the Greeks at Argos, and modified and enlarged by King Otho in 1833, consists of 5 classes, and is a general order of merit.

Holland.—The *Order of the Netherlands Lion* (instituted 1815), to reward civil merit, consists of 3 classes ; the *Order of William* (instituted 1815) for military merit ; and the family order of the House of Nassau, the *Golden Lion* (instituted 1858). The *Teutonic Order* (*Ballei Utrecht* ; see also under Austria) was established in the Netherlands by the States-General in 1580 ; abolished by Napoleon I. in 1809, it was revived by King William I. after Waterloo. It has 3 classes.

Italy.—The *Order of the Annunciata*, said to have been founded in 1355 by Amadeus VI. of Savoy, frequently modified, last in 1809, when the number of knights, exclusive of foreign recipients, was limited to twenty, consists of 1 class only. *St Maurice and Lazarus*, instituted in 1434, when the "Lazarus," supposed to have been founded in the Holy Land in 1000, was merged into the later creation, consists of 5 classes, and is bestowed for meritorious services in all capacities rendered to the state. The numbers are unlimited. The *Military and Civil Orders of Savoy*, the former of 4 classes, instituted in 1815, and the latter instituted in 1831, of 1 class only, and limited to sixty knights "who have deserved well of their sovereign and their country." The *Crown of Italy*, founded in 1831 to commemorate the incorporation of Venetia, has 5 classes, and its numbers are practically unlimited.

Japan.—The *Sublime Order of the Chrysanthemum*, of 1 class only, and practically limited to sovereigns and members of reigning houses, was founded in 1876 by the Emperor Mutsu-Hito. The *Eastern Sun* (instituted in 1875), for civil and military merit, has 8 classes ; the *Order of the Crown* (instituted 1888), 5 classes for ladies.

Luxemburg.—The *Golden Lion* (see Holland), the civil and military order of Adolphus of Nassau (instituted 1858), has 4 classes ; to it is attached a special cross of merit for arts and sciences, of 2 classes ; the *Oaken Crown* (instituted in 1841), remodelled in 1858, and consisting of 5 classes ; it is conferred as a general order of merit.

Monaco.—The *Order of St Charles*, of 6 classes, founded by Prince Charles III. in 1863.

Montenegro.—*St Peter* (instituted 1852), 1 class only, for members of the princely family ; *Danilo* (1855), for merit, of 5 classes.

Papal.—Of the seven orders bestowed by the Pope, two stand out pre-eminent in respect of antiquity of foundation and general estimation : that of the *Holy Sepulchre* ranks with that of *St John of Jerusalem* (*q.v.*), being instituted almost simultaneously with that order and for like objects. It derives its name from the fact that investitures took place in the Holy Land. Supposed to date from 1099, it was revived by Benedict XIV. in 1746, and remodelled by Pius IX. in 1868. It has 3 classes. *Order of Christ*, instituted in 1318 by St Denis to replace on its abolition the order of Knights Templars. It has 1 class, and is conferred also by Portugal, the limitation there being to such only as are of noble lineage. The Holy See also has the orders of *Pius IX.* (instituted 1847), of 2 classes ; *St Gregory the Great* (instituted 1831), 4 classes ; and *St Sylvester*, of 2 classes (instituted 1559), conferred for services to the Roman Catholic Church.

Persia.—Order of the *Sun and the Lion*, instituted in 1808 by the Shah Fatu Ali for merit, has 5 classes. Order of the *Nichane-Aftab* for ladies, instituted in 1873 by Nassir-ed-Din. There is also a medal (in 4 classes) for science and art.

Portugal.—*Order of Christ* (see preceding notice under *Papal*) ; the military order of *St Benedict of Aviz*, founded in 1158 under the designation of the *Order of Calatrava*, was transferred to Aviz in 1187, and changed in 1789 into an order of military and civil merit, with 3 classes ; *St James of the Sword*, jointly with Spain, where it was founded in 1175, since 1862 has 5 classes, and is conferred for science, literature, and art ; *Tower and the Sword*, for merit, with 5 classes (since being remodelled in 1832), was instituted by Alphonso V. in 1450 ; *St Isabella*, a ladies' order, was founded in 1801.

Rumania.—The orders in this country are of recent foundation, and are two in number : *Order of the Star* (instituted 1877), for civil and military merit, has 5 classes ; *Order of the Crown of Rumania*, founded in 1881, also of 5 classes.

Russia.—The *St Andrew*, founded in 1698, by the Tsar Peter I., is the highest order, and admission to it confers also membership of the orders of *St Anne*, *Alexander Newsky*, and the (whilom) order of *St Stanislas of Poland*. These Russian orders likewise bestow a patent of hereditary nobility. The order of *St Andrew* is of 1 class only, the ribbon sky blue, watered ; *St Anne*, founded in 1735 by Charles Frederick, duke of Schleswig-Holstein Gottorp, was in 1797 made a Russian order by the Emperor Paul, and has 3 classes; *Alexander Newsky* is of 1 class only, and was founded by the Empress Catharine in 1725; the order of *St Stanislas* (of Poland), instituted in 1765 by King Stanislas II., revived by the Emperor Alexander in 1815 as a Russian order, has 4 classes. The *White Eagle*, also originally of Poland, where it is supposed to have been founded in 1325, was in 1831 revived as a Russian order. It has 1 class only. There are also the orders of *St Catharine* (instituted 1714) for ladies, and the *St Vladimir* for bravery, in addition to minor orders, medals, &c.

Servia.—Orders of *St Lazarus*, worn only by the king; *White Eagle* (5 classes), founded in 1883 by King Milan I.; *Takovo*, for distinguished services in the cause of Servian independence, founded 1865 by Prince Michel Obrenovitch IV. (5 classes); *St Sava*, bestowed for literature, art, and science, instituted 1883, has 5 classes; *Miloch the Great*, instituted by King Alexander I. for distinguished services.

Siam.—The *Star of the Nine Precious Stones*, exclusively conferred upon Buddhists, founded in 1869; the *White Elephant*, instituted in 1861, consists of 5 classes. In addition to these two chief orders there are the *Maha Chakri*, of 2 classes, instituted 1884, and conferred only on personages of princely rank; the *Mongut-Siam*, of 5 classes, instituted 1869; the order of *Chulachonclao*, of 3 classes, conferred only on natives, and a medal, 2 classes, founded 1887, for art and science.

Spain.—The *Golden Fleece* (*vide* Austria-Hungary, *supra*); the *Order of Calatrava*, founded in 1158 by King Sancho III. to commemorate the recovery of that town from the Moors, and confirmed in 1164 by Pope Alexander III., is an essentially military order; that of *Alcantara*, founded in 1156 by the brothers Don Suero and Gomez Fernando Barricutes under the name of order of *St Julian*, was confirmed in 1177 by Pope Alexander, and on the capture of the town of that name in 1213 became known as that of Alcantara. *St James of the Sword*, or *Compostella*, was instituted in 1175 to commemorate the finding at Compostella of the bones of the patron saint of Spain. It is purely military. The grandmastership of these last three orders was vested in the Crown of Spain by Charles V. in 1523. In addition to the above and the military order of *Malta*, or *John the Baptist* (*vide supra*, order of St John of Jerusalem), Spain has the orders of *St Ferdinand* (instituted 1811 by the Cortes); *Notre Dame de Montesa* (instituted 1319 by James II., king of Aragon), purely military; *St Herménégilde* (instituted 1814), military; the royal order of *Isabella the Catholic*, 3 classes (instituted 1815 by King Ferdinand VII.); *Isabella II.* (instituted 1833); the *Illustrious Order of Charles III.*, 4 classes (instituted 1771); three naval and military orders of merit; the ladies' order, *Maria-Louise* (instituted 1792), for noble ladies; and the order of *Bienfaisance*, for distinguished and humane services, in 3 classes.

Sweden.—*Order of the Seraphim* (blue ribbon), said to have been founded in 1285, and reinstituted in 1748, consists of 1 class, and is limited to twenty-four Swedish and eight foreign members. *Order of the Sword* (yellow ribbon), instituted in 1522 by Gustavus Wasa, and remodelled, the last time in 1814, has 6 classes; order of the *Pole Star* (black ribbon), has now 4 classes, and was founded in 1748 and remodelled in 1844; the *Order of Wasa* (green ribbon), instituted in 1772, has 6 classes; *Charles XIII.*, for Freemasons of the higher ranks, has a red ribbon.

Norway.—Order of *St Olaf*, founded in 1847, has 5 classes, and is a general order of merit.

Turkey.—*Nichan-i-Iontiaz*, an order of merit, of 1 class only, instituted in 1879 by Abdul Hamid II.; *Nichan-i-Iftikhar*, or *Order of Glory*, instituted in 1831 by the Sultan Mahmoud II.; the Imperial Order of the *Osmanie*, instituted in 1862 by Sultan Abdul Aziz, has (since 1867) 4 classes; the *Medjidie*, founded in 1851, has 5 classes, and is largely bestowed, the lowest class consisting of more than 6000 members, irrespective of foreigners; order of *Hanédani-al-Osman*, of 1 class only, instituted in 1895, and conferred solely on Turkish princes; the ladies' order of *Nichan-i-Chéfakat* (instituted in 1878) has 3 classes.

The writer is much indebted to Sir Albert W. Woods, K.C.B., Garter King of Arms, for kind assistance in the portion of the article affecting the British Empire. In compiling the list of foreign orders the *Almanach de Gotha* has been largely utilized.

(P. A. A.)

ORDNANCE.

I. Naval Gunnery (British).

The ordnance carried in recent British warships ranges from the 12-inch 46-ton gun forming the armament of the turrets of the *Majestic* class of battleship to the rifle-calibre Maxims carried by all ships for the armament of their boats and as field guns. The heaviest gun actually afloat in the British navy is the 16·25-inch B.L. gun of 111 tons, two of which are mounted in the *Benbow* and two in the *Sanspareil.* Though in themselves efficient weapons, the great weight of these guns limited the number carried in any ship to two, and owing to the undesirability of risking so large a proportion of the armament if an accident occurred to one of these guns, the type has not been, and is not likely to be, repeated. The next gun in point of weight is the 16-inch M.L. 80-ton gun, of which four are mounted in the *Inflexible;* this gun was the last development of the obsolete muzzle-loading principle. The 13·5-inch B.L. 67-ton gun forms the turret or barbette armament of many of the battleships which, if not quite in the first rank in view of the very rapid development of battleship construction in recent years, are at any rate worthy of a place in the line of battle in the most powerful squadron afloat. These guns form the barbette armament of the six battleships of the *Royal Sovereign* class, and are mounted in the turrets of the *Hood*, *Nile*, and *Trafalgar.* In the *Majestic* class and subsequent classes of battleships the 12-inch 46-ton gun has been substituted for the 13·5-inch gun.

As compared with the 13·5-inch gun, the 12-inch offers the following advantages:—

1. *Reduced Weight.*—This must always be a most important consideration governing the choice of guns for the sea service. Not only is the weight of the gun itself a matter of importance, but a lighter gun will admit of lighter loading appliances and mounting; a smaller area of armour will be required for its protection, and its ammunition will be lighter. The saving of weight in the armament can then be devoted to improved armour protection, increased supply of ammunition, or to increased strength of hull or weight of propelling machinery.

2. *Improved Facility of Working.*—It is obviously an advantage that as much as possible of the working of the gun should be performed by manual labour, provided that the rapidity of fire is not diminished, and that those operations for the performance of which hydraulic or other power is employed should be capable of being performed, in the event of the failure of such power, by manual labour. In practice the breech of the 12-inch gun is always opened and closed by hand, while every other operation in loading and firing the gun can be similarly performed in case of breakdown of the hydraulic arrangements. In the case of the 13·5-inch guns, though the operations of opening and closing the breech and of loading can be performed by hand, the means of doing so are exceedingly inconvenient and involve considerable reduction in the rate of fire, while for the other operations of elevating the gun, running it in and out, and training the turret, the gun is entirely dependent on hydraulic power. In the British navy hydraulic power is universally used for the manipulation of the heaviest guns, though in several foreign navies electricity is preferred. The chief advantages of hydraulic power are noiselessness, and facility in locating the cause of a failure.

3. *Increased Rapidity of Fire.*—Improvements in the form of mounting, the reduced weight of the projectile, and the substitution of a cordite charge for the heavier powder charge, have diminished the time required to load and fire a round from 2 min. 30 secs. to about 1 minute.

4. *Improved Ballistics.*—The advance in the sciences of gun construction and of explosives has enabled the ballistic power to be so increased that the penetrative power of the 12-inch gun is slightly greater than that of the 13·5-inch, in spite of the reduction in the weight of the projectile.

5. The possibility of *loading* the guns *in any position* of the turret. To load the 13·5-inch guns it was necessary to train the turret (or barbette) to a fixed position, in which the hydraulic rammers, which were entirely outside the turret, could ram the projectile and charge into the gun. The arrangements for this "fixed loading position" are found in the earlier ships of the *Majestic* class, but are accompanied by arrangements for loading

the guns in any position of the turret by means of hydraulic rammers. In addition to the gain in rapidity of loading, the guns can be kept continually pointed in the direction of the enemy, and will thus expose the smallest possible target to his fire. Fig. 1, which has been kindly supplied by Sir W. G. Armstrong, Whitworth and Co., shows a 12-inch gun with its mounting and loading arrangements as fitted in the *Canopus* class of battleships.

Authorities differ as to whether the armoured structure shown in Fig. 1 is more properly designated a "turret" or a "barbette." A turret is essentially a circular armoured structure which protects the breech portion of the guns and revolves with them, and in which elliptical ports are cut, through which the guns pass; while the armour of a barbette is fixed, the whole of the gun when in its firing position being above it and unprotected, the barbette armour protecting the loading and other machinery only. The turret system involved a much greater weight of armour and, as this weight could not be carried high up in the ship, a less height of the guns above the water-line, and consequently increased difficulty in fighting them in a heavy sea. It was considered that these disadvantages were too great a price to pay

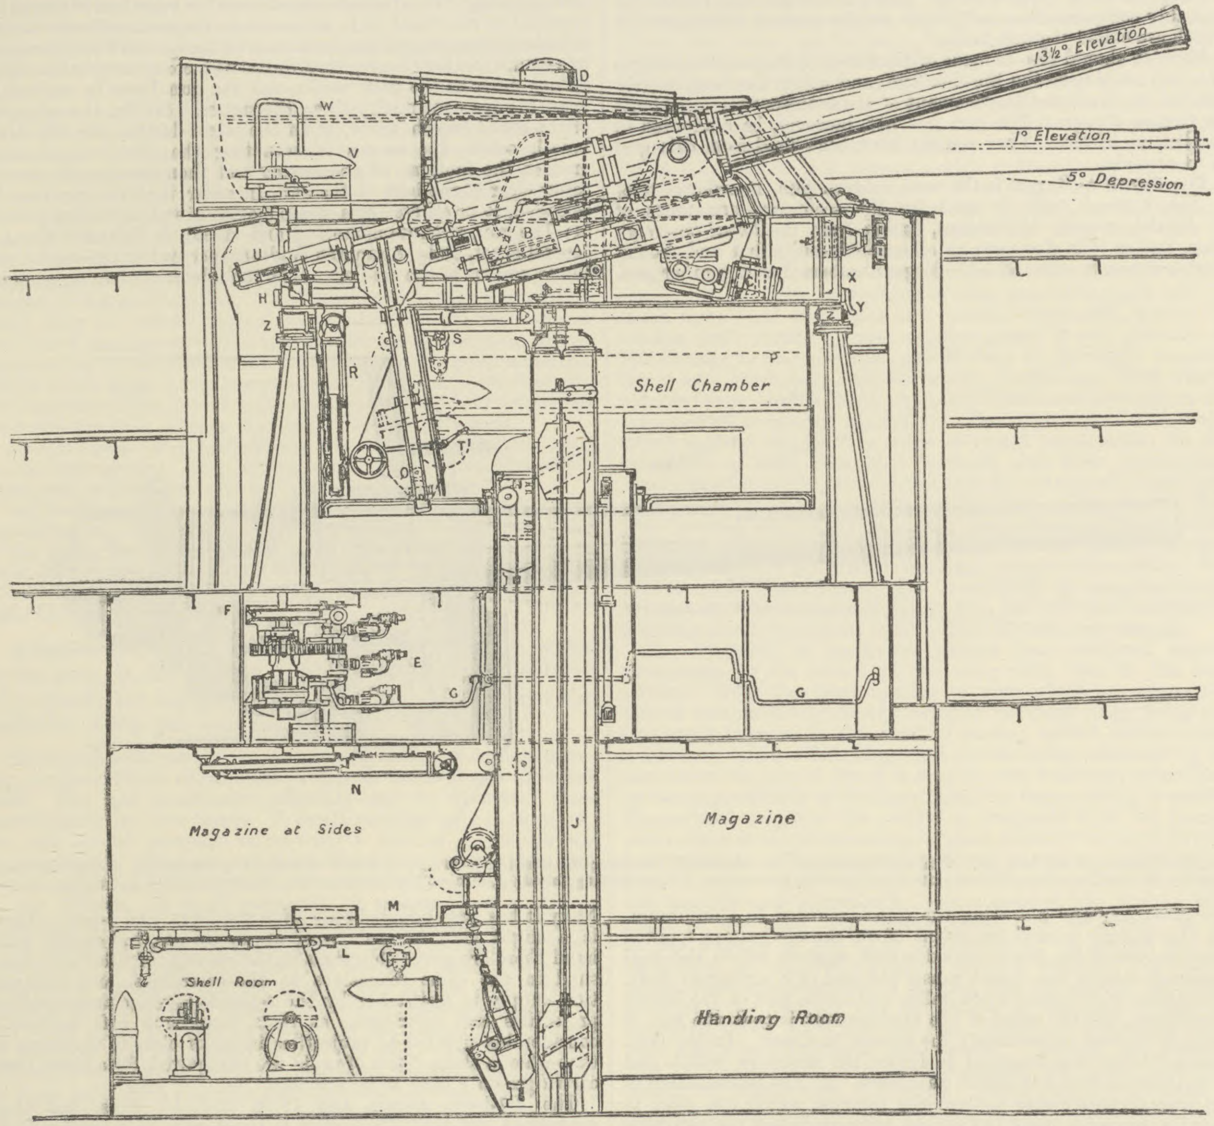

FIG. 1.—Diagram of a 12-inch Gun, with Mounting and Loading Arrangements. A, Slide; B, recoil cylinder; C, elevating cylinder; D, sighting hood; E, hydraulic turning engine; F, brake on turning shaft; G, winch handles for turning by hand-power; H, training rack; J, ammunition trunk; K, cartridge hoist; L, hydraulic and hand arrangements for lifting shell in shell-room; M, platform for working hand-winch for shell hoist; N, hydraulic cylinder and ram for raising shell to shell chamber; P, shell chamber; Q, loading-hoist; R, hydraulic cylinder and ram for working loading-hoist; S, travelling crane; T, hand-winch for working loading-hoist; U, hydraulic rammer; V, hand-loading arrangement; W, hand-loading chamber; X, securing bolt; Y, buffer stop; Z, Z, rollers.

for the protection of the breech portion only of the guns, and the barbette system has therefore been almost universally adopted in British naval construction since 1890. In the *Majestic* class and subsequent battleships, while the guns are entirely above the thick fixed armour, they are protected by a shield revolving with them, and the thickness of this shield, which varies from 10½ inches in front to 4 inches in rear, is such that it is a moot point whether it is justifiable or not to designate it a "turret."

The 12-inch gun shown in Fig. 1, known as Mark VIII., forms the main armament of all the most recent British battleships. The 12-inch Mark IX., which embodies certain improvements in breech mechanism and ballistics, is mounted in the *Formidable* and her sisters.

The modern gun next in size to the 12-inch is the 10-inch, weighing 29 tons. It was adopted for the "main armament" of three battleships only, the *Renown*, *Barfleur*, and *Centurion*, and is worked entirely by hand, the barbettes in which the guns are mounted (in pairs) being trained by steam. The 10-inch gun has also been used in the re-armament of the *Thunderer* and *Devastation*, which originally had M.L. guns in their turrets; but no more are being made.

The object of the main armament of battleships, generally speaking, is to pierce the heavy armour of the enemy, and to inflict damage on his *matériel* by the explosion of heavy shell. The object of the secondary armament, composed in all British modern battleships of 6-inch Q.F. guns, is to demoralize the enemy by a rapid and continuous shell fire.

Modern first-class cruisers have in some cases a couple of 9·2-inch guns mounted forward and aft, and capable of training from right ahead and right astern respectively through an arc of about 120° on either side. These guns are known usually as "chase guns" and their objects are, in the first place, to enable the cruiser to deliver a very heavy blow when chasing or being chased, with accuracy at long ranges, and secondly, to pierce the armour of battleships or armoured cruisers and to inflict serious damage on their *matériel* by the explosion of heavy shell.

The 9·2-inch guns are worked entirely by hand, with the exception that the turn-tables on which they are mounted are in some cases turned by electricity. In the British navy they are not known as "quick-firing" guns, although their rate of fire probably compares favourably with similar guns in foreign navies which are called "quick-firing."

Mention should also be made of the 8-inch Q.F. gun, the designs of which are due to the Elswick firm, and which has been largely utilized by them in the armament of the cruisers they have built for foreign Powers. The gun has not, however, been adopted in the British service. Four rounds have been fired from this gun in 64 seconds.

The 6-inch Q.F. gun is the next modern gun, in order of size, to the 9·2-inch, and is used for the secondary armament of all British modern battleships, dating from the *Royal Sovereign* class, and as it is also used in all recently-built first and second class cruisers, it exists afloat in larger numbers than any other gun. It is also the largest gun whose projectiles, each weighing 100 ℔, can be loaded into the gun by manual labour without the aid of mechanical appliances, and it is consequently the largest gun to which the "quick-firing" principle, properly so called, can be applied.

Comparing the 6-inch Q.F. gun, whose normal rate of aimed fire may be taken as about a round every 15 seconds, with its immediate predecessor, the so-called "6-inch B.L." gun, firing at an average rate of about a round every 45 seconds, there are the following differences of principle in the gun, mounting, and ammunition. (1) The charge is contained in a brass cylinder, instead of a silk cloth bag. This renders unnecessary the operation of sponging, required in the 6-inch B.L. to ensure no fragments of smouldering silk cloth remaining in the chamber after firing. (2) The gun recoils in a cradle to which the sights are attached, consequently the sights do not move as the gun recoils, and the gun layer is enabled to keep his eye continually along the sights. (3) By the adoption of the coned breech screw, or in the latest designs the "Welin" breech screw, the means of actuating the breech mechanism enables the motions of unscrewing and then turning the breech screw clear of the bore of the gun, in order that the gun may be reloaded, to be effected by a single motion of an "actuating lever." (4) The gun, with its mounting and shield, is balanced about a central pivot, and the gun and cradle are accurately balanced about the trunnions of the cradle, so that the labour of training the gun

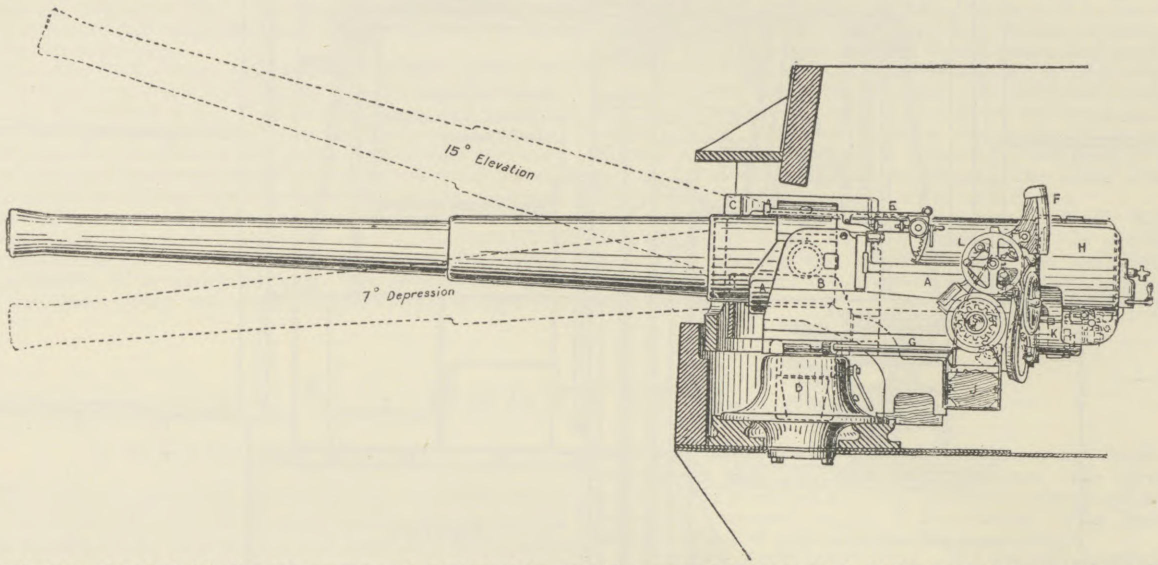

Fig. 2.—Diagram of a 6-inch Q.F. Gun and Mounting. A, Bracket of carriage; B, trunnion bearing; C, 3-inch shield; D, pivot piece; E, bar and drum sight; F, shoulder-piece; G, web-plate for supporting battery box; H, protecting shield; J, electric firing battery box; K, breech ring; L, training wheel.

and mounting and elevating the gun is reduced to a minimum. (5) The charge is fired by means of an electric primer screwed into the base of the brass cartridge case, against which the final motion of closing the breech causes the end of a striker to butt. The striker is insulated electrically, and forms part of the breech mechanism, and the effect of the arrangement is that the gun is ready to be fired immediately the breech is closed. In the B.L. guns a "tube" was required to ignite the cartridge, which had to be inserted after the breech was closed. (6) The introduction of the brass cartridge case enables the rammer, which was used to push the projectile home to its place, to be abolished, the cartridge itself doing this duty.

The features above described differentiate the Q.F. from the B.L. gun, although all of them are not necessarily applied in any particular gun and mounting. Thus in the latest type of 6-inch gun (known as the Mark VII.), which is mounted in the *Formidable* and her sisters, the cartridge case is not employed, the charge being contained in a silk cloth bag. Thus a sponge has to be employed, and a tube has to be used, which is, however, inserted with the breech open, so that its use does not entail delay. Fig. 2 shows a 6-inch Q.F. gun and mounting, as fitted to the *Canopus* class of battleships.

Naval nomenclature divides the Q.F. guns into two classes, the "heavy" and the "light." The "heavy Q.F." guns include the 6-inch, 4·7-inch, and 4-inch guns, the "light Q.F." guns, the 12-prs., 6-prs., and 3-prs. In connexion with smaller guns than the 6-inch, the question of "simultaneous" *versus* "separate" loading arises. In simultaneous loading, the projectile is secured into the mouth of the cartridge case, and cartridge and projectile are entered together, one operation being thus saved as against separate loading, in which cartridge and projectile are entered separately. Some foreign navies employ simultaneous loading with the 4·7-inch and all smaller Q.F. guns, but in the Royal Navy it has been adopted only with the 6-prs. and 3-prs. There is a slight gain in rapidity of fire by its use, but on the other hand there are grave objections to the stowage of filled and fuzed shell in the same magazines as the cartridges, and ammunition supply is facilitated by the separate stowage and supply of projectiles and cartridges, as it is considered safe to keep a considerable number of projectiles in racks close to the guns, so that when a sharp burst of rapid fire is required for a short time, cartridges only have to be provided.

The 4·7-inch, 4-inch, and 12-pr. (3-inch) guns, and their mountings, are generally similar to the 6-inch, on a smaller scale. The 4·7-inch Q.F. gun is largely used in the armament of second and third class cruisers of modern types, while the 4-inch gun is used in third-class cruisers.

The general introduction of the heavy Q.F. gun may be said to date from 1890. There were at that time large numbers of 6-inch B.L. guns in the service, and although after that date no new ships were armed with this gun, it was not feasible to re-arm with the Q.F. gun the ships designed for the B.L. gun. In addition to its greatly increased length, the change of mounting would have entailed great constructive alterations and considerable expense. The 6-inch B.L. guns have, however, been considerably altered with a view to improving their rapidity of fire. Practically all 6-inch B.L. guns now afloat have been so altered, and they are known as "Quick-Firing Converted," or Q.F.C. guns.

In the British navy modern guns of calibres below that of 4 inches are designated in accordance with the weight of the projectile they fire. There are three modern guns of under 4-inch calibre, the 12-pr., 6-pr., and 3-pr., and they are all light Q.F. guns. The principal duty of the light Q.F. gun in modern ship armaments is the repelling of torpedo-boat attack. They might also be used in a ship action for the attack of unprotected or partially protected guns' crews and for the destruction of unprotected parts of the hull and superstructure of the enemy by shell-fire. Opinions are, however, divided as to whether their effect in a ship action would be sufficient to warrant the exposure of their crews, as owing to the number of the guns, they are necessarily mounted in unprotected positions, and are protected only by shields. The 6-pr. was introduced about 1880 for defence against torpedo-boat attack, the 3-pr. being introduced at the same time as a lighter gun for the same purpose, capable of being more conveniently mounted in the tops, boats, and parts of the superstructure not sufficiently strong to withstand the effects of the recoil of the 6-prs. The rate of aimed fire with these guns is from ten to fifteen rounds per minute.

About 1893 the increase in size of torpedo-boats and the advent of the destroyer gave rise to a demand for a heavier projectile than that of the 6-pr. gun to ensure their disablement. The 12-pr. gun was therefore introduced for that purpose, and has taken the place of the 6-pr. in all ships built since that date. No 6-prs. are now being made except for the armament of destroyers, but the 3-pr. is retained for the armament of the fighting tops and of boats, and also for torpedo-boats. The mounting, breech mechanism, and loading and firing arrangements of the 12-pr. are generally similar to those of the 6-inch and other Q.F. guns. There are two 12-prs. in the service, known as the 12-cwt. and 8-cwt. guns. They are generally similar, except in length and in weight of charge of cordite. The 12-cwt. gun is that mounted on board ship for defence against torpedo-boat attack, while one or two 8-cwt. guns are carried in each ship for use as field guns, and as armament of the 42-feet launches, the largest pulling-boats carried. These 8-cwt. guns, whose energy of recoil is of course considerably less than that of the 12-cwt. guns, are also provided with mountings on board the ship, whence they can be used as ship guns.

Machine guns for naval purposes do not differ from those used in the land service. They are supplied to ships primarily for the armament of the boats, and for landing as field guns.

All double-banked pulling-boats and steam-boats are fitted with arrangements for mounting one or two guns, according to the size of the boat; the object of the boat armaments being for use in river operations or as guard boats, and for covering a landing. Three descriptions of gun are used, the 12-pr. 8-cwt. and 3-pr. light Q.F. guns, and the Maxim gun.

Ammunition.—Five descriptions of projectile are in use in the navy, in all cases the weights of the different natures of projectile for any gun being the same, in order that the ballistics of the gun may not vary.

These projectiles are the armour-piercing shot, and armour-piercing, common (filled either with powder or lyddite) and shrapnel shell. The last-mentioned projectile may be dismissed from consideration in a few words. A small quantity only is supplied, for such special purposes as covering a landing, or for use in a bombardment. Shrapnel would not be used in a ship action, and none is supplied for the most modern guns of large calibre, such as the 12-inch. A small proportion of armour-piercing shot is supplied to ships for all guns of 6-inch and larger calibres. As their name implies, they are designed with a view to piercing the thick armour of the enemy, which protects her most vulnerable parts, such as her water-line and her engines and boilers. An armour-piercing shot striking a lightly armoured or unarmoured part of the enemy's side will do a comparatively small amount of damage, as its effect will be limited to its own path. Taking into consideration the extreme difficulty of striking the exact point aimed at when both one's own ship and the enemy are moving rapidly, and both the bearing and the range are quickly changing, it is not generally considered that the chance of injuring a vital part of the enemy is compensated for by the small amount of damage which would be done if another part of her were struck. By far the larger proportion of the projectiles carried on board ship is composed of common shell, which may be looked upon as the projectiles, *par excellence*, of naval artillery. The design of a common shell provides for the maximum weight of bursting charge consistent with the walls of the shell being sufficiently strong to withstand the shock of discharge and the pressures in the bore of the gun. All the common shell constructed of recent years have pointed heads, and in the case of powder-filled shells are ignited by means of a percussion fuze screwed into the base of the shell. Shells filled with lyddite have their fuse in the nose of the shell, which is of course not pointed, as there appears to be a slight risk of a premature burst of the shell occurring with a base fuze, and this risk cannot be accepted in the case of lyddite shell. Common shells, whether filled with powder or lyddite, are only effective against very thin armour, or against the unarmoured portions of a ship's structure. A common shell, generally speaking, is capable of penetrating a thickness of mild steel armour equal to about $\frac{1}{3}$ of its calibre before bursting, and if it penetrates the ship's side, will burst from 4 to 10 feet in rear of it. An effective shell should on bursting break up into a number of fragments which will be projected with great velocity in all directions, and it will probably set fire to any inflammable material in its vicinity.

The effect of common shell was shown in the battles of the Yalu and of Santiago. In the former case the Chinese ships, with the exception of the two battleships, were wrecked by common-shell fire; their guns were disabled, communications to the engine-rooms shot away, and *personnel* destroyed, and eventually the water-lines suffered so much that the ships sank, although intact below the protective deck. The Chinese ships were, as a rule, not provided with common shell, but one such shell bursting in the 4·7-inch gun battery of the *Matsushima* disabled three guns, exploded a quantity of 4·7-inch cartridges, and killed or wounded some seventy officers and men. At Santiago, although their water-line belts saved the Spanish ships from sinking, the ships were set on fire by the American shells; and as the fire-mains were shot away, the fires could not be put out, and the ships had to be run ashore, after suffering enormous loss among the crews of their unprotected guns.

Comparing the effects of the lyddite and powder-filled common shells—the former will detonate with extraordinary rapidity on striking even a $\frac{1}{2}$-inch steel plate. If a lyddite shell strikes thin armour, its effect will probably be only a splash on the armour, as the detonation takes place before the shell has time to penetrate. If the shell strikes an unarmoured side, it will make a very large hole, and its effect inside the ship, though violent enough to pulverize everything in close proximity to it, will be much more local than that of a powder-filled shell, and as the lyddite shell breaks up into smaller pieces, it will probably do less damage to material than will be done by the larger pieces of the powder-filled shell. On the whole, the greatest effect will be obtained from lyddite shells when they strike and detonate on the funnel or other casings amidships. The large area of 4-inch and 6-inch armour employed in ships of recent construction for the protection of their secondary batteries and their ammunition supply has led to the introduction into the service of a third type of shell, known as the armour-piercing shell. This shell is filled with powder, and differs only from the common shell in that its walls are thicker and consequently its bursting charge smaller, generally about 5 per cent. of the total weight of the shell. The shell is made with a special view to carrying its bursting charge through the thin armour of the enemy, and will penetrate before bursting about two-thirds of its calibre of mild steel armour.

The adoption of smokeless powder has conferred greater advantages on the attack in the navy even than in the land service. With the large number of guns which are necessarily carried comparatively closely together on board ship, firing was frequently impeded by the clouds of smoke; indeed, under certain conditions, such as a following wind, the advantage conferred by the increase in the rate of fire of Q.F. guns was well-nigh neutralized by the impossibility of distinguishing the target owing to smoke. The reduced weight of the cordite as compared with the powder ammunition is also an advantage of great value in the naval service.

Armaments.—The gun armament of a modern battleship is divided into four classes, known as the main, secondary, auxiliary, and machine-gun armaments. Some account has already been given of the guns constituting these four divisions: as far as the number of the guns is concerned, we appear in the battleships of the British navy to have reached a point at which there is a consensus of opinion that the general principles governing the number and disposition of the guns cannot be improved upon, since the four last classes of battleships built vary but very slightly in this respect. Taking the *Canopus* (Fig. 3) as a typical ship for description, her main armament consists of four 12-inch B.L. guns. These guns are mounted in pairs in turrets on the quarter-deck and forecastle, each turret having a total arc of training of 240°, the fore turret training from ahead through 120° in either direction, and the after turret from astern through 120° in either direction. This principle of mounting the heavy guns, which has for many years been that adopted in the British navy, has the advantages that while the ahead and astern fire is carried out over parts of the ship which would be unoccupied in action, and while the remainder of the armament would in no way be interfered with, it enables the whole of the four heaviest guns to be in action at the same time through an arc of 120°, namely 30° before and abaft either beam. It is open to the disadvantage, which is, however, more apparent than real, that two of these guns only can be brought to bear ahead or astern. An alternative plan, which has been largely adopted in the French and other navies, for mounting the guns of the main armament is to have one gun only on the forecastle and one on the quarter-deck, the other two being mounted amidships, one on either side, with arcs of training of 180°, namely, from ahead to astern. In theory this plan enables three guns to fire ahead and three astern, but in practice it is probable that so much damage would be caused to the superstructure, and the guns of the secondary armament would be so much interfered with if the 'midship guns were fired on or close to the middle line, that the advantage is a very doubtful one. The disadvantage that only three guns can be brought to bear on or about either beam is undoubtedly a grave one.

The secondary armament, in the *Canopus* as in all the most modern British battleships, consists of twelve 6-inch Q.F. guns (Fig. 2). Four of these guns are mounted on the main deck and two on the upper deck, on each side. Each gun has an arc of training of 120°. The foremost upper-deck and the foremost main-deck gun on each side train from ahead to 30° abaft the beam, and the after upper-deck and after main-deck guns from astern to 30° before the beam, while the two middle guns on each side train from 60° before to 60° abaft the beam. Thus all the guns of the secondary armament can be brought to bear on or about the beam bearing, while four guns can train ahead and four astern. Each gun is isolated in a separate casemate, protected in front by 6-inch and in rear by 2-inch armour, a system by which the maximum protection from shell-fire is obtained, and the disposition of the casemates is such that the fire of one gun cannot interfere appreciably with the crews of adjacent guns. This point is one to which special attention has been paid in British ships, but the same cannot be said for many foreign battleships, in which the attempt to provide for a heavy bow and stern fire has led to a probability of considerable interference between adjacent guns.

The auxiliary armament of the *Canopus* consists of ten 12-pr. Q.F. guns, four of which are mounted on the main deck and six on the upper deck. These guns are primarily intended to repel attacks by torpedo-boats, and are unprotected except by shields. It is doubtful whether they would even be manned in a ship action, as their crews would be exposed to almost certain destruction, and they could exert no very great influence on the result of the action. In addition to the 12-pr. guns, three 3-pr. Q.F. guns are mounted in each of the fighting tops, on carriages which admit of being traversed throughout the circumference of the top. These guns also are of great value for repelling a torpedo-boat attack, and are used also for the armament of the larger boats. The machine-gun armament, consisting of eight rifle-calibre Maxims, is disposed as conveniently as possible about the bridges and superstructure. The guns are intended principally for the armament of boats, and it is highly improbable that they would be manned in a ship action. Fig. 3 shows the position of the main and secondary armaments in the *Canopus* with their arcs of training.

The armaments of first, second, and third class cruisers resemble generally in principle those of battleships. The first-class cruisers carry in some cases a 9·2-inch gun at either end as their main armament, and in all cases their secondary armament is similarly disposed and protected to that of a battleship. The *Europa* class, however, carry no guns heavier than the 6-inch, the 9·2-inch guns being replaced by two pairs of 6-inch guns on the forecastle and quarter-deck respectively. These guns are protected by shields only, which are open in rear, and are

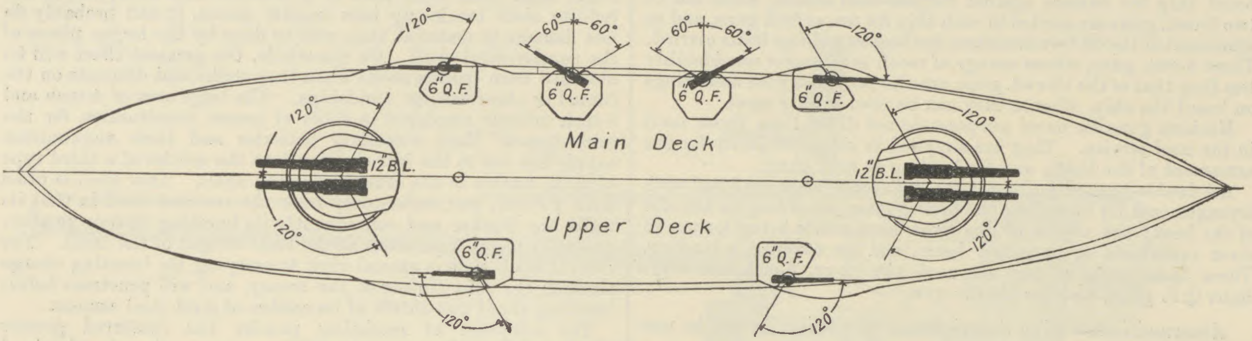

Fig. 3.—Plan of Gun Decks of H.M.S. *Canopus*

undoubtedly extremely vulnerable; it is, further, questionable whether a ship of the size of the *Europa*, which could not decline action with any foreign cruiser, would not fight at a considerable disadvantage, having no gun of greater armour-piercing power than the 6-inch. The same remark applies to the somewhat smaller *Kent* class, but their 6-inch guns on the forecastle and quarter-deck are mounted in pairs in small turrets, and so are better protected. Recent second-class cruisers carry an armament of 6-inch and 4·7-inch guns. The latest and largest, *i.e.*, the *Hermes* class, carry eleven 6-inch guns, while the *Apollo* class, which are some 2000 tons smaller, carry a 6-inch on the poop and forecastle and three 4·7-inch guns on each side. All the guns of the second-class cruisers are on the upper deck, and are protected only by shields. Third-class cruisers, the class being known as the P class, from the initial letter of their name, carry 4·7-inch and 4-inch guns. The armament of torpedo-boat destroyers consists of a 12-pr. on the conning platform forward and five 6-prs. The small armament of the modern British cruisers has excited much controversy; many foreign cruisers, and notably some built at Elswick for the Japanese and Chilian Governments, carry a much greater weight of armament on the same or a smaller displacement. Thus the Japanese *Asama* and *Tokiwa*, of 9700 tons, carry an armament of four 8-inch and fourteen 6-inch guns; whilst the British *Drake* class, of approximately the same displacement (9800), carry fourteen 6-inch guns only.

Organization.—The organization of a large ship for action is necessarily highly elaborate; the complement is based upon it, and each man borne upon the books, whatever duty he may perform in the internal economy of the ship, has his station and duty in action allotted to him.

The most important duty is, of course, that of manning the guns. Taking the *Canopus* again as a typical battleship, we find that twenty-two men are required as the "turret's crew" to man each pair of 12-inch guns. Of these three the captain of the turret and the captains of the two guns are men specially selected for general smartness and aptitude, and as being quick and accurate shots; a certain number more are seamen gunners trained in one of the gunnery schools at Portsmouth, Devonport, or Sheerness; these men are required for the responsible duties of working the hydraulic levers other than those for training the turret and elevating the guns; while the remainder of the turret's crew are usually younger men who have received only such gunnery training as can be given on board their own ship, and are called "trained men." The 6-inch guns are each manned by a crew of eight men, one of whom has been specially selected or trained and is known as the "captain of the gun," while the remainder of the gun's crew consists partly of seamen gunners, who perform the more important duties at the gun, and any one of whom is prepared to take the captain of the gun's place in case of necessity, and of "trained men." The 12-prs. have each a crew of four men, the 3-prs. of three, and the Maxims of two, one of whom at each gun is always a seaman gunner. A proportion of the guns, generally four 6-inch and four 12-prs., is allotted to the Royal Marines, who receive a training in naval gunnery similar to that given to the seamen, the Royal Marine Artillery corresponding in this respect to the seamen gunners, and the Royal Marine Light Infantry all being trained men.

The guns are of course dependent for their efficiency on the arrangements for the supply of ammunition to them, and the greater rate of fire possessed by modern guns of all calibres has caused increased attention to be given to this point. As far as organization of the *personnel* is concerned, no difficulties are presented by the supply to the 12-inch guns, each pair of which is provided with its own magazine and shell-room, which are manned by some twenty-five men to each pair of guns. The arrangements for the supply of 6-inch and 12-pr. ammunition are briefly as follows, the important principle to be borne in mind being that while the supply must be rapid enough to conform to the rate of fire of the guns, no accumulation of ammunition can be permitted, on account of the danger of its ignition by bursting shell. At the fore and after ends of the spaces devoted to the engines and boilers, and immediately below the protective deck, is a space usually known as the "cross-passage." Into this space the hatches open from the 6-inch and 12-pr. magazines and shell-rooms, which are situated below the cross-passages. The cross-passages are connected on each side of the ship by a long passage cut out of the coal bunkers or out of the engine- or boiler-rooms, from which a direct supply of ammunition to each 6-inch gun is arranged by means of an endless rope whip passing from the casemate in which the gun is mounted through a vertical armoured tube into the ammunition passage. The supply to the 12-pr. guns is similarly arranged, but the whips are not protected by armour, and each hoist has usually to serve for a pair of guns. The 6-inch shells having been removed from their racks in the shell-rooms and the cartridges from their boxes in the magazines, are placed in bags fitted with rope beckets for hooking to the whips. They are then hoisted by endless whips into the cross-passages, carried to the bottoms of the ammunition tubes, and thence whipped up as required by the guns. It will be seen that a considerable number of men are required for these operations, all of which are performed by hand, and in the *Canopus* class some eighty men are actually required for the 6-inch ammunition supply and another eighty men for the 12-pr. The supply of 3-pr. and Maxim ammunition is not of such importance. A considerable quantity of 3-pr. ammunition is arranged to be stowed in the tops, and would be placed there before going into action, and the Maxims, as has already been observed, would probably not be manned in a ship action. The torpedo-tubes, of which the latest British ships carry four only, all of which are submerged, are manned by crews consisting principally of highly-trained "S.G.T.'s" or seamen gunner torpedo-men.

In addition to the crews for guns and torpedo-tubes, and to the men employed in the supply of ammunition in action, men are required for the following duties: buglers, messengers, men to attend voice-tubes and to man steering-wheels, fire brigade (consisting of the carpenters and shipwrights and a portion of the stokers), men to transport and attend the wounded, and armourers.

It is not easy to foresee the future developments of naval gunnery; generally speaking, the tendencies are towards lighter but more powerful guns with increased rates of fire, using bare charges and firing shell of increased armour-piercing capability; better protection for guns and their crews and for ammunition supply; constructive improvements having for their object the acceleration of the ammunition supply, and more careful selection of and higher training for captains of guns and gunnery ratings generally. (S. FR.)

II. ARMY (BRITISH). (*a*) GUNS.

The controversy of M.L. *versus* B.L. guns, carried on for several years prior to 1880, was finally settled in favour of the B.L. gun. The necessity for a very long gun in order to develop the high power required in modern ordnance was one of the main factors in the case.

The following table gives the various descriptions of B.L. ordnance in the service and their use, exclusive of those purely naval and dealt with under "Naval Gunnery":—

Description.	Weight.	Muzzle Velocity. f.s.	Maximum Range by Range Table. yards.	Use and Remarks.
	lb.			
2·5 inch	400	1440	4,000	Jointed or screw guns for mountain artillery.
10-pr.	418	1289	6,000	
	cwts.			
12-pr.	6	1585	6,000	R.H.A. batteries: light short gun for mobility.
15 ,,	7½	1581	6,000	R.F.A. batteries: as powerful as possible without loss of mobility.
30 ,,	20	1621	6,300	Heavy Indian field batteries.
4-in.	26	1900	7,700	Siege train and guns of position.
5 ,,	40	1750	8,700	
	tons.			
6 ,, (up to Mark VI.)	5	1960	10,000	Guns of 6-in. and upwards are employed for coast batteries. The latest marks of 6-in. and 9·2-in. are new types, of great length, with high muzzle velocity.
6 ,, (Mark VII.)	7·4	2456	12,000	
8 ,,	13	2000	8,000	
9·2 ,, (up to Mark VII.)	22	2065	10,000	
9·2 ,, (Marks IX. & X.)	27	2601	13,800	
10 ,,	29	2040	11,500	
12 ,, (up to Mark VII)	46	1914	8,000

The howitzers are short pieces, and of large calibre compared to their weight, to enable them to fire a shell containing a large quantity of explosive. As they use charges of various weights in order to obtain any angle of descent for the shell, no muzzle velocity is given in the table.

Q.F. Guns.—About the year 1881 it was found that a more rapid rate of fire than could be obtained by means of the B.L. guns of that day was necessary. This was due to various causes, such as increased speed of torpedo-boats and the necessity for attacking the unarmoured or lightly armoured portions of ships with a heavy shell fire, &c. This high rate of fire was obtained by the introduction of guns known as Q.F. (quick-firing), in which some of the main features were—(1) Rapid means of opening the breech; (2) the charge being contained in a brass case with its own means of ignition, and in the lighter descriptions in one with the shell; (3) the mounting being adapted for the rapid service of the gun. Until the year 1898 guns of this type, up to and inclusive of 6-inch calibre, continued to be made. Except with the 3- and 6-prs., percussion firing was by no means rapid. In endeavouring to overcome this difficulty and to produce a more powerful gun than the then existing 6-inch Q.F., it was found that, at any rate for certain calibres, a B.L. gun could be produced which could be fired quite as rapidly as the corresponding Q.F., and was free from the disadvantage mentioned above. The main features which cause this gun to be classified as B.L. are: (1) The charge is bare (not in a brass case); (2) the system of obturation and firing is similar to that of other B.L. guns, viz., pad obturator, and lock and tubes for firing. Only in mounting and style of opening the breech does it resemble the Q.F. type. A Q.F. gun may now therefore be defined as one which employs "case ammunition," the nomenclature being entirely unconnected with the rate of fire.

Q.F. Guns in the Land Service.

Construction.—When B.L. guns were first introduced their construction was very similar to that of the later R.M.L. guns—that is, they consisted of an inner tube of steel supported by one or more coils of wrought iron. At this date the manufacture of steel had not arrived at the state of perfection to which it has now attained, and

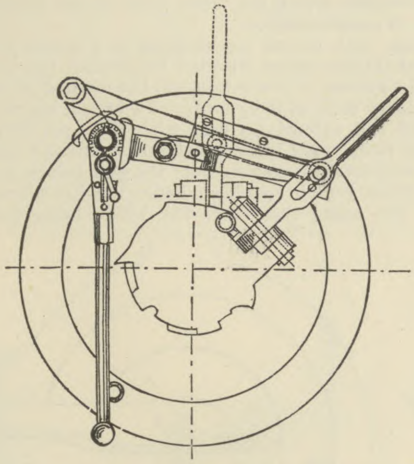

FIG. 8.—Apparatus for turning Breech Screw.

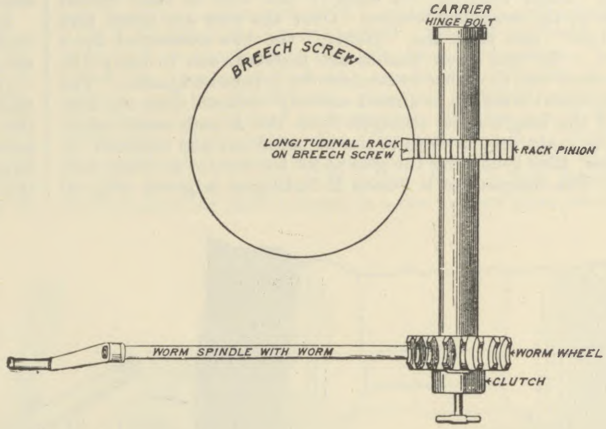

FIG. 9.—Apparatus for withdrawing and swinging Breech Screw of Heavy Gun.

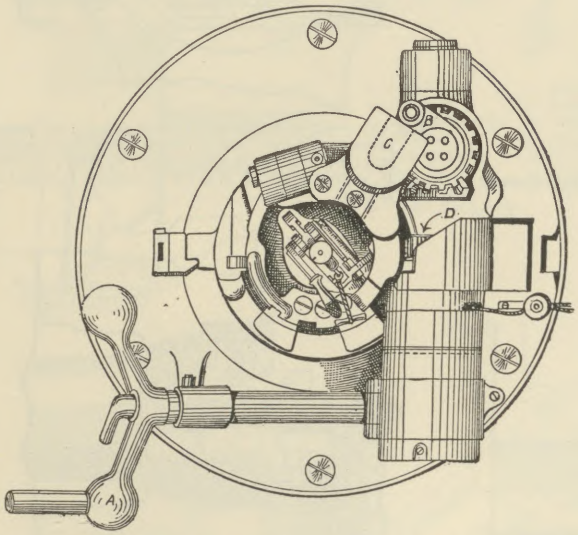

FIG. 10.—Diagram of the Breech Mechanism of 9·2-inch B.L. Gun, Mark IX.

consequently for gun construction its use was limited; but as the manufacture improved it gradually replaced wrought iron, and in the majority of the B.L. guns is the only material used. In the earlier classes, in which the guns are composed of steel hoops and tubes, the building up is on the same lines as with R.M.L. guns; that is, the outer parts are shrunk on, and so placed in a state of initial tension, while the inner tubes are correspondingly compressed.

During the last few years, however, the "wire system of construction" has been applied to many guns. The wire, the section of which is ·06 inch thick and ·25 inch wide, merely takes the place of some of the intermediate tubes, and is wound on in successive layers, of which there are a considerable number. As the tension can be varied at every layer if necessary, the gun is, as it were, one made up with an enormous number of outside hoops all put on at a different shrinkage: in this way full advantage can be taken of the strength of the material; in a thick hoop, shrunk on, it is impossible to do so. Other advantages are: (1) that the material can be tested all over; (2) that a flaw cannot spread; (3) that for a less external diameter than formerly a gun of equal strength can be obtained; (4) that the material in itself is stronger than steel in the mass. Although thus giving great circumferential strength to a gun, it gives little or none longitudinally; this has to be obtained by means of tubes either under or over the wire, or by a combination of the two.

Fig. 1 shows the construction of one of the latest B.L. guns

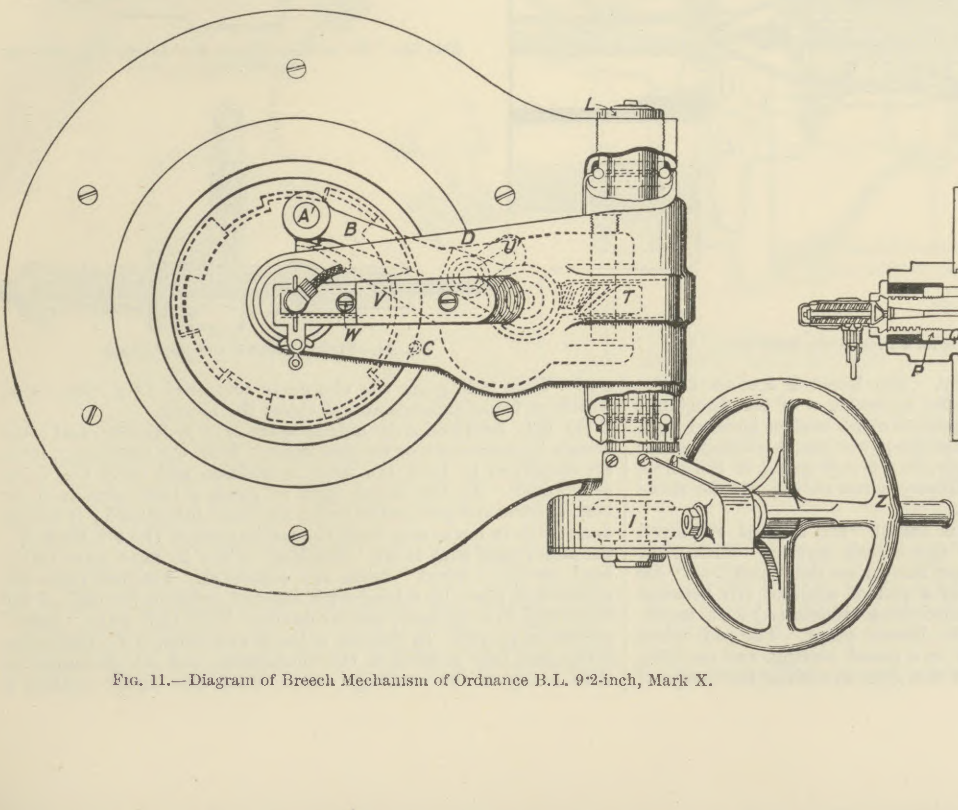

FIG. 11.—Diagram of Breech Mechanism of Ordnance B.L. 9·2-inch, Mark X.

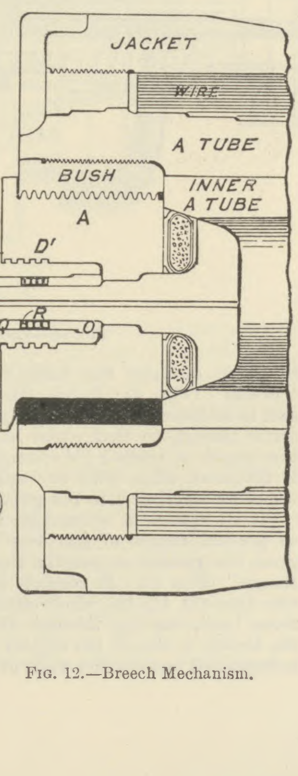

FIG. 12.—Breech Mechanism.

used in both land and naval services. It consists of an "inner A tube," fitted into an "A tube"; the wire is then wound on these at the necessary tension. Over the wire are fitted first a "B tube" and then the "jacket," the two connected by a shoulder. In rear screw bushes are inserted, one to carry the breech screw and the other to connect the A tube and jacket. The circumferential strength is almost entirely obtained from the wire coil, and the longitudinal strength from the A and outer tubes. When the inner tube is worn it can be bored out and replaced by a new one, thus rendering the gun as fit for service as when first issued. The diagram of a 9-inch R.M.L. gun is given (Fig. 2) to show the revolution which has taken place in gun construction since the time of muzzle-loaders.

Before dealing with breech mechanisms as a whole, it will be well to consider (1) the means adopted for closing the breech of the gun, (2) the system of obturation, (3) the method of firing.

(1) The ordinary method is by means of a breech screw. That first introduced and extensively used with B.L. guns is (Fig. 3) the cylindrical block with interrupted screw thread: this type necessitates a withdrawing motion from the gun before it can be swung clear of the breech opening; hence the introduction for Q.F. guns of the coned type (Fig. 23), which being cut away

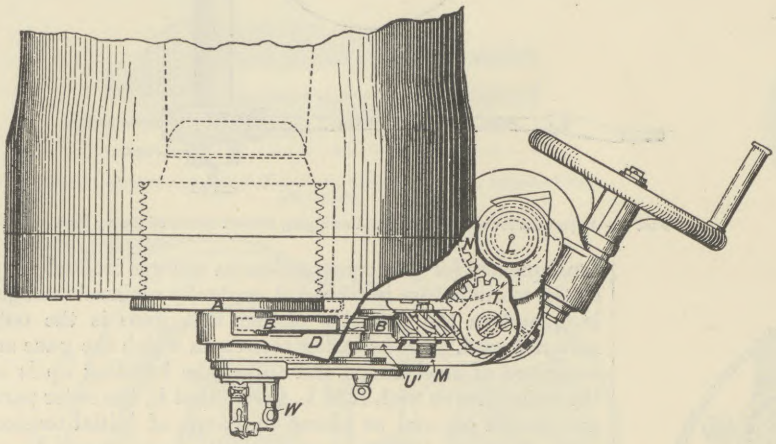

Fig. 13.—Diagram of Breech Mechanism of Ordnance B.L. 9·2-inch, Mark X. Part of carrier frame and gun removed to show gearing of pinion and links.

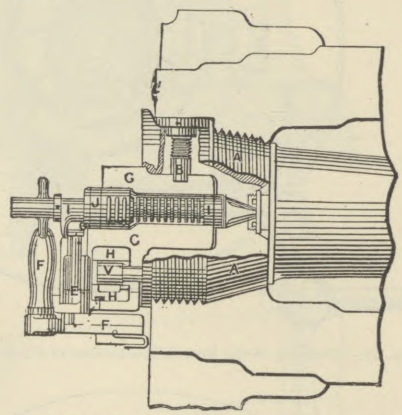

Fig. 23.—"B" or Single Motion Mechanism. (For lettering see Fig. 22.)

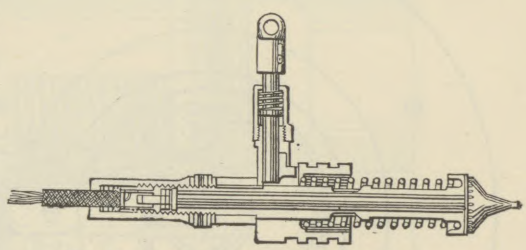

Fig. 24.—Striker (electric and percussion).

in front, obviates the difficulty. The latest is known as the "Welin" (Fig. 4): it has all the advantages of the foregoing, and in addition a much larger portion of its surface covered with screw thread, so that equal holding power can be obtained for less length of screw; for example, in a 6-inch gun ⅔ of the screw is threaded, while with the ordinary screw only ½ can be made use of for holding it in the gun.

(2) By system of obturation is meant "the method employed to prevent escape of gas over the breech screw." With B.L. guns the system is usually that known as the "pad" or "De Bange" (Fig. 5). It consists of a pad of asbestos (B) between two discs (D, C), the whole carried on a spindle (A) with mushroom head, passing through the breech screw. The pad, when the breech is closed, fits tightly on a coned seating, and on firing is expanded against the walls of the gun, so sealing the escape of gas. With Q.F. guns the charge is contained in a brass case, which on firing expands and so closes the breech.

(3) B.L. field and siege ordnance are fired by friction, and other classes by percussion or electric tubes. With the two latter, locks are employed to keep the tube in position and carry the firing mechanism. In the latest type of guns, a lock, combined for both electric and percussion firing, has been introduced; it will be dealt with in connexion with the mechanism of the 9·2 Mark X.; the tubes used with it are "wireless," while in most guns in the land service "wired" tubes are employed. Friction tubes are retained in place by a head with bayonet joint on the end of the vent (Fig. 7) or by some similar device. With Q.F. guns "locks" are not employed. In the case of the 3- and 6-prs. Q.F., percussion firing gear only is fitted to the mechanism, and acts in connexion with a cap in the cartridge case. With the higher calibres a

"striker" is used; it can be adapted for either "electric" or "percussion" firing in connexion with either a "primer" or "tube" in the case (Fig. 24).

Turning now to the breech mechanisms themselves, that of the 15-pr. Mark I. field gun (Figs. 6, 7) is simple and effective, though not so rapid in action as that of the latest pattern Mark IV., which is classed as a "single motion" mechanism. The breech is opened by raising a cam lever (*b*) and turning it to the left as far as it will go; the breech screw is then withdrawn from the opening through a ring carrier (*f*) for a certain distance, and afterwards carrier and screw together swing round on the hinge bolt to the right. In the closed position a projection or cam on the lever folds down into a recess in the carrier or gun, and so prevents the screw from turning when the gun is fired; this is a very important point with all B.L. or Q.F. guns, and is technically termed "locking the breech screw." The older-pattern medium guns, such as 4-inch and 5-inch, &c., have mechanisms of a similar nature for opening and closing the breech, but with the higher calibres, such as the 9·2-inch guns and upwards, some form of power-gaining appliance is necessary. In the case of the older descriptions this consists of a "ratchet lever gear" for turning the screw, and "control mechanism" for withdrawing and swinging into the open position. These are shown in Figs. 8 and 9. An improvement on this is found in a few modern guns, such as the

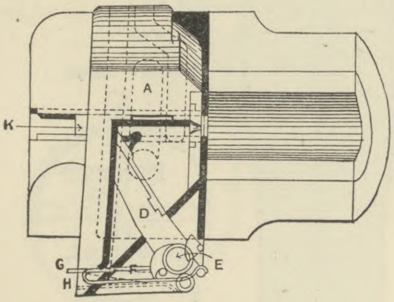

Fig. 15.

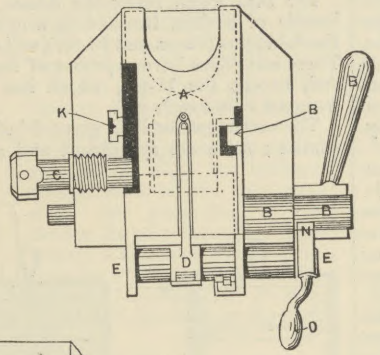

Fig. 16.

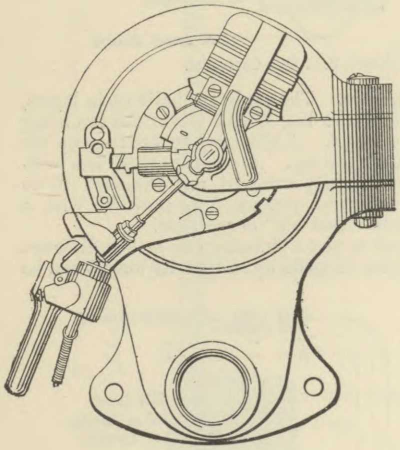

Fig. 18.

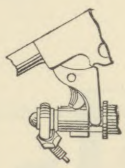

Fig. 19.

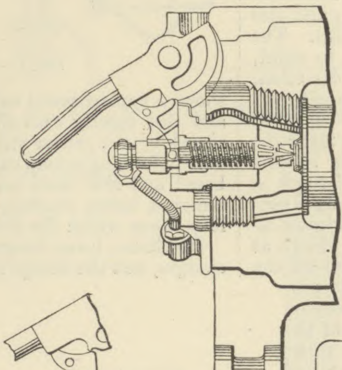

Fig. 20

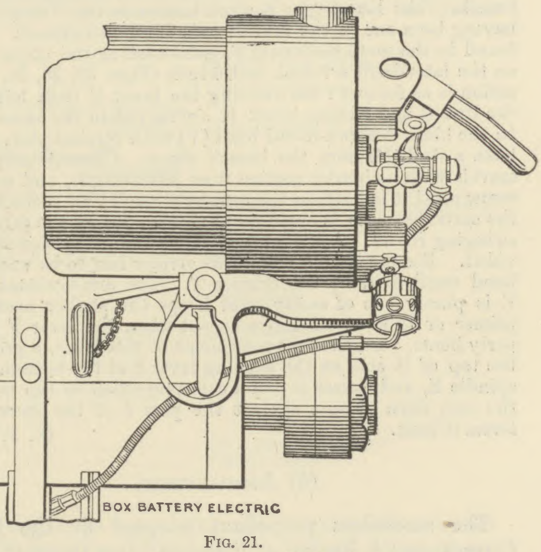

Fig. 21.

9·2 IX., where the ratchet lever gear is done away with, and a crank and pinion worked by the "control mechanism" is fitted to the top of the hinge bolt for the purpose of turning the screw, so that in this case the mechanism may be said to be "single motion"; for instance, turning the lever A (Fig. 10) opens the breech, by first turning the crank B into the roller path C on the screw and forcing it over, then by means of a pinion (D) on the hinge bolt, acting on a horizontal rack on the side of the screw, drawing the latter out and finally swinging it round into the open position.

The latest type of mechanism will now be described in connexion with the 9·2 X. (Figs. 11, 12, 13). The screw A is of the "Welin" pattern, and is carried on an arm (D) instead of in a ring; the obturator is of the pad system, only known as the "steep cone" pattern, as will be seen on comparing it with that of the 15-pr.; the advantage gained thereby is that the least withdrawal movement clears it off its seating and enables it to be swung round into the open position. The turning of the screw is effected by means of a hand-wheel[1] (Z) working a shaft with worm, connected to a worm wheel (I) on the hinge bolt L; the latter revolving causes a pinion (N) which is on it to act on another pinion (T) on which are skew bevel teeth; these cause a link (U) pivoted at M to revolve, and draw with it another link (B), to which it is pivoted. Now B fits at A′ on to a stud on the breech screw, and so the turning is effected. When sufficient turn has been given to the screw it becomes fixed to the arm by a catch (C), consequently further movement of the lever Z causes the arm and screw to swing round into the open position. The breech screw is connected to the arm by an interrupted screw thread (D′), so that in turning it moves slightly to the rear on the arm and presses against a sleeve (O) which conveys the pressure back through a spring (R) and washer (Q) to the nut P

[1] This has now been replaced by a lever across the face of the breech.

on the axial vent; in this way the pad is pulled off its seating and made to follow up the screw.

The lock which is combined for electric and percussion firing is shown in Fig. 14; it is carried on a slide box (L) and has a guide bolt (W) (Fig. 11) which fits into the sliding plate V. This plate is actuated by being connected to a cam groove (U′) carried by the link U; as soon as the link revolves the plate is drawn to the right, carrying the lock with it, and so the gun cannot be fired unless the breech is properly closed. The movement of the lock actuates an extractor which ejects the fired tube; a new tube is then put in, and in closing the breech the lock resumes the firing position. For electric firing, a lead passes along the arm D and makes contact with the insulated needle G through which the current is conveyed to the tube; the return circuit is an "earth one." For percussion firing the handle E is pulled to the rear; this draws back the striker F which includes needle G and firing pin H, against the main spring J, until the trigger K engages in front of the projection S on the striker and holds it back; the gun can then be fired by means of a lanyard hooked to the trigger at Y.

Q.F. Mechanisms.—Of the smaller descriptions, the Hotchkiss (Figs. 15, 16, 17) is the one chiefly in use. The breech is closed by a wedge (A) actuated by a crank (B) and handles, the turning of which causes a projection (M) to bear on the toe (N) of a rocking shaft (E), which in revolving effects the cocking. On closing the breech, a trigger sear (G) comes up under a trigger, which on being pulled forces down the sear, releases it from the cock notch, and allows the hammer D to fly forward and fire the gun. An extractor for throwing out the cartridge case is actuated by a groove in the wedge. Of the mechanisms for the heavier descriptions employing breech screws, one of the earlier types will be found on many 4·7-inch guns (Figs. 18, 19, 20, 21). A cam lever is employed to lock, turn, and swing the coned screw, which is carried on an arm. A striker is used, which for percussion firing is automatically cocked in opening the breech. The latest type is often known as the "single motion," having been one of the first of this kind introduced. It will be found in the more modern Q.F. guns such as the 12-prs., and also on the later-built 4·7-inch and 6-inch (Figs. 22, 23, 24, 25). The action is as follows: On drawing the lever F from left to right, the link G and sliding block H are moved in the same direction. In the block is a gun-metal bush (V) with vertical play, and in the bush a stud (D) from the breech screw. Consequently this stud travels with a circular motion from left to right, and so turns the screw until it is held on the arm by a catch; an extractor to start the cartridge case is acted on at C (Fig. 25) by the carrier arm in swinging round. A striker for electric and percussion firing is provided. For percussion firing this striker has to be withdrawn by hand until held by the trigger T. The arrangement shown at E is purely one of safety, and keeps the striker needle off the primer or tube at all times except when the lever F is properly home. On the first movement of this lever, a groove on the top of it acts on the turning lever S at the bottom of the spindle E, and causes it and a cam projection on top to turn; the cam then presses against the part I of the striker and forces it back. (C. P. M.)

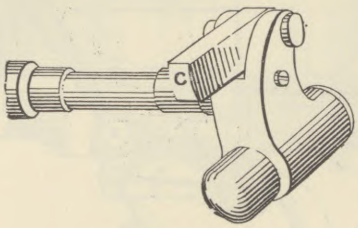

FIG. 25.—Extractor.

(*b*) AMMUNITION.

The smokeless propellant adopted by the British Government is known as "cordite" (see PROPELLANTS). It is used for all arms, the only variation being in the diameter and length of the sticks employed. On account of the importance of a clear front, in order to sustain a rapid fire, smokeless powder is a necessity with quick-firing guns, and confers advantages upon the defenders of a position which can scarcely be too highly estimated.

Cartridges.—The charge of a gun is made up in a convenient form for handling and loading, for which purpose the cordite is enclosed in a cartridge, made of silk cloth or of red shalloon. These materials fulfil the necessary conditions for a cartridge: to be strong enough to bear reasonable knocking about on service, to allow the flash from the tube to penetrate and still be of close texture, and—most important—to consume entirely and not leave smouldering fragments in the bore.

Cordite is somewhat difficult to ignite in a gun, and so every cartridge has a primer of fine-grain gunpowder, placed so as to intercept the flash from the tube; the outer side of this primer is made of shalloon, to allow the flash to penetrate with greater ease. The charge for heavy guns, above the 6-inch, is made up in separate cartridges containing $\frac{1}{2}$ and $\frac{1}{4}$ charges, both for convenience in handling and to allow a reduced charge to be used. In order to ensure uniform results, the space allowed for the charge in the chamber of the gun should not vary from round to round.

For B.L. guns, below the 6-inch, the cartridge consists of a bundle of cordite, inserted in a cylindrical bag, of shalloon for the field guns (12-pr. and 15-pr.), and of silk cloth for the remainder. These cartridges have a primer of fine-grain powder covering each end, except the 15-pr., which has a piece of gun-cotton yarn wrapped round each end.

The cartridges for B.L. guns, 6-inch and upwards, are generally similar; some are cylindrical and some slightly coned. Fig. 1 shows a typical coned cartridge. The cordite is built up in layers, and tied tightly with silk. The bag is silk cloth, the top being closed by the primer stitched on. A silk cord becket runs up the centre, forming a loop outside the top. Above the primer is a millboard and silk cloth cover, lightly attached, and intended to be removed before loading, for which purpose it is provided with a loop, upon which the words "Tear off" are printed.

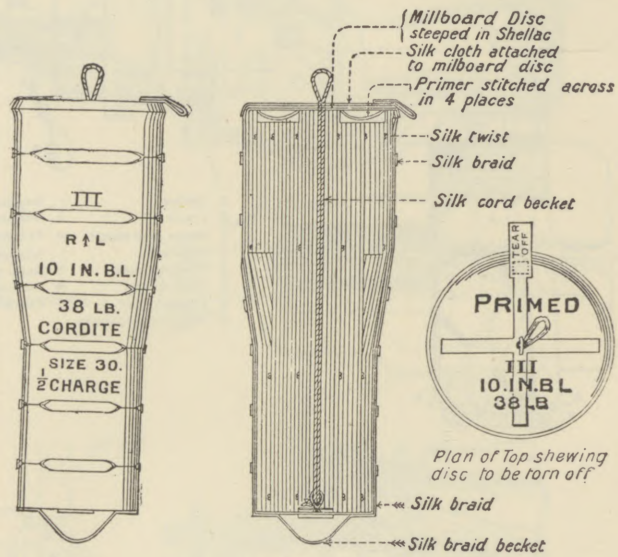

FIG. 1.—10-inch B.L. Gun Cartridge.

Howitzers, being designed to give a plunging fire, require different charges, and the charge must be made up so that its weight can be easily altered. B.L. howitzer cartridges are all made on the same model, the material being shalloon. Small-sized cordite is used, and the charge is formed of a mushroom-shaped core, on the stalk of which three rings containing cordite are placed. The bottom

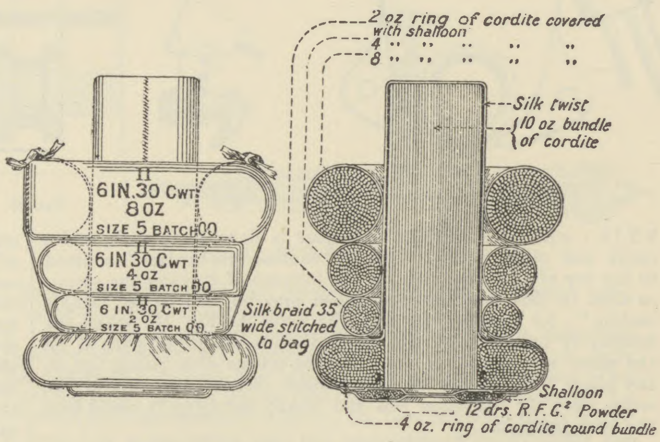

FIG. 2.—6-inch B.L. Howitzer Cartridge.

of the core contains the primer. The rings can be tied to the core by two silk braids, and thus a handy means of varying the charge is provided, since the core alone, or core and one or more rings, may be used (Fig. 2). The table at the end gives the weights of a few important cartridges.

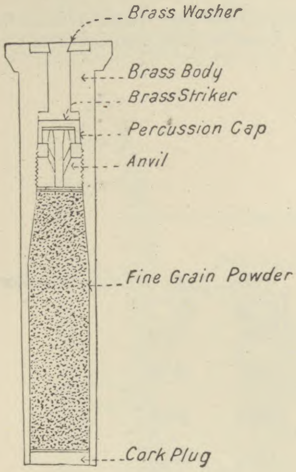

FIG. 3.

These cartridges are ignited in the gun by means of "tubes," fired by percussion, electricity, or friction. They are known as "vent-sealing tubes," by which is understood a tube which fits accurately into the top of the vent and is held in it by the lock of the gun. The force of the explosion expands the tube against the walls of the vent, and so prevents escape of gas past it, while the internal arrangements of the tube preclude the possibility of gas forcing its way through. This system is necessary because B.L. guns are axially vented, and the forcible expulsion of a tube might injure the men behind the gun; and also because the rush

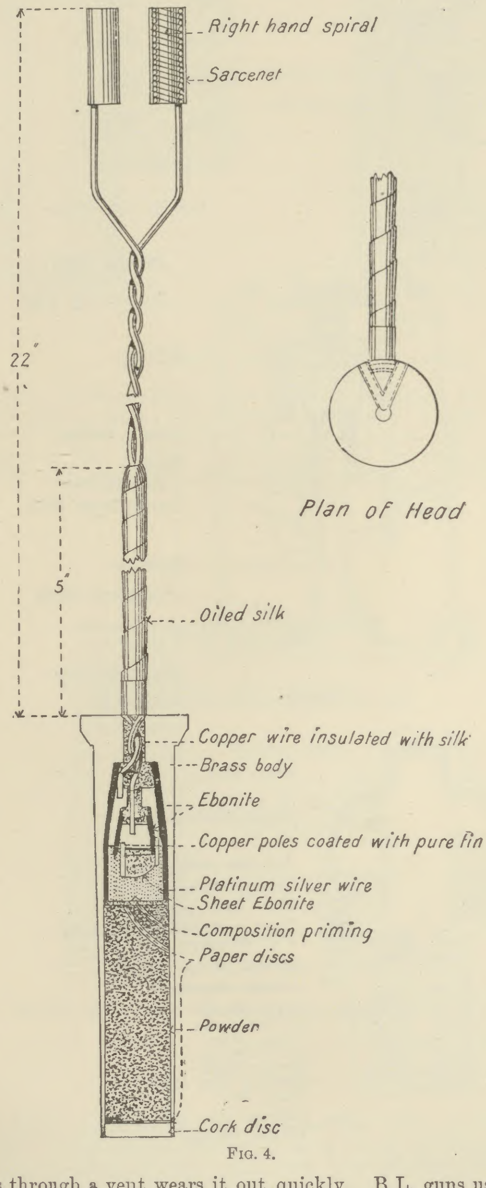

FIG. 4.

of gas through a vent wears it out quickly. B.L. guns use tubes designated by the letter "P," except in the case of field guns and howitzers, which take "T" friction tubes. There are three "P" tubes, one percussion and two electric. The "T" tube is held in the vent by a bayonet joint at the end of the vent. The outer dimensions of the three "P" tubes are the same; their construction will be understood from the figures.

Fig. 3.—The percussion tube has a striker, below which is a percussion cap on an anvil, the body of the tube being filled with pistol powder. The striker of the gun lock forces the striker against the cap and so fires the tube.

Fig. 4.—The *Electric "P" tube* has two insulated wires led into the interior and attached to two insulated brass cones. These cones are connected by a thin wire or "bridge" of platinum-silver, which is surrounded by "priming composition" (gun-cotton dust and mealed powder). The remainder of the tube is filled with powder. The tube is held in by the lock and the wires connected to the leads from a battery; on a current passing, the bridge is heated to incandescence and thus fires the priming composition.

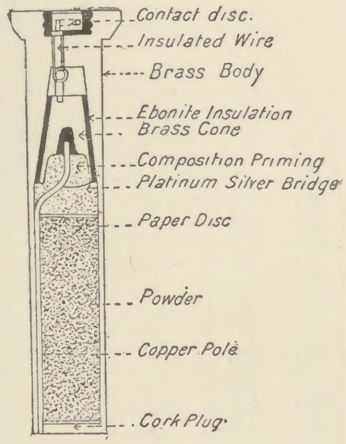

FIG. 5.

Fig. 5.—In the *Wireless Electric "P" tube* the mechanism of the lock makes electrical contact with an insulated patch in the head of the tube. This patch is connected by an insulated wire with a brass cone, also insulated, between which and the side of the tube is the "bridge," surrounded by priming composition. The current passes through the lock to the insulated patch, thence through the bridge, which it heats, to the side of the tube, and back to the battery through the metal of the gun and mounting—technically known as an "earth return." This tube is used by guns having "wireless" electric locks.

Fig. 6.—The "T" tube is simple in its construction. The head fits into the bayonet joint, and the tube is fired by the withdrawal of the friction wire by means of a lanyard, which fires the friction

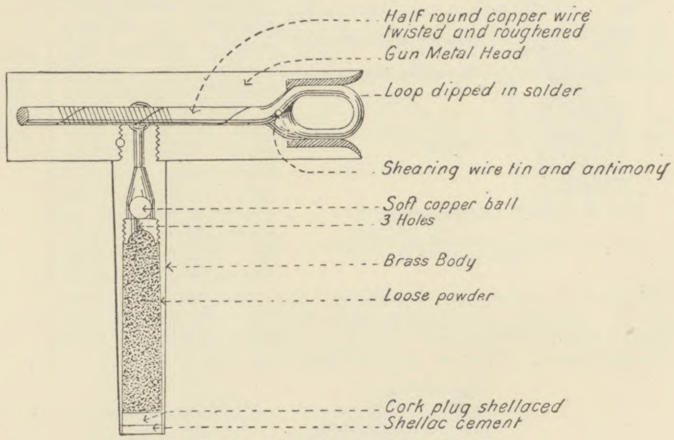

FIG. 6.

composition and so the tube. The copper ball is driven by the explosion into the cone above it, and so prevents escape of gas through the tube. The larger muzzle-loading guns use vent-sealing tubes, friction and electric; distinguished by the letter "V."

Projectiles.—The following projectiles, which will be briefly considered in their order, are fired from B.L. guns: common, lyddite, and shrapnel shell, armour-piercing (A.P.) shot and shell, and case shot. A few fire star-shell, and Palliser shot are occasionally used. The shells are made of steel.

For the same calibre, the weight of a modern B.L. projectile is greater than that of a R.M.L.; for example:—

12-inch R.M.L., weight of projectile, 714 lb.
12-inch B.L. Mark VIII., weight of projectile, 850 lb.

A convenient way of expressing the relation between the weight of a projectile and the calibre of the gun is given by the fraction $\frac{w}{d^3}$

(w=weight of projectile in pounds, d=diameter of bore in inches). For the latest guns $\frac{w}{d^3}$ is approximately equal to 0·5.

These projectiles are caused to rotate by a "driving band" of copper, pressed into a groove round the base, which takes the rifling of the gun. It is known as the "Vavasseur broad driving band." The heavier projectiles have a driving band with a lip or gas-check.

This is intended to prevent rush of gas past it and so help to lessen the erosion of the bore. A white band painted round a projectile near the point denotes that it is made of steel, though all steel shells have not got it; and a red band signifies that the shell is filled or "live."

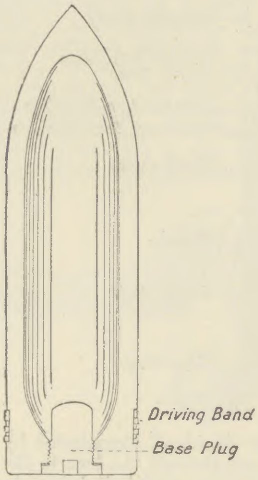

Fig. 7.—Pointed Common Shell (cast steel).

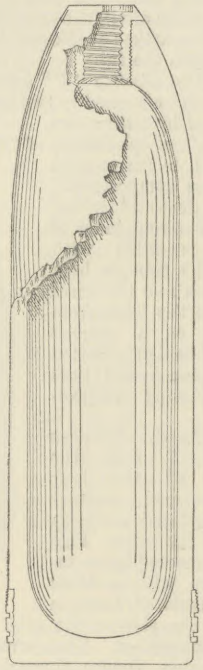

Fig 8.—Lyddite Shell (forged steel).

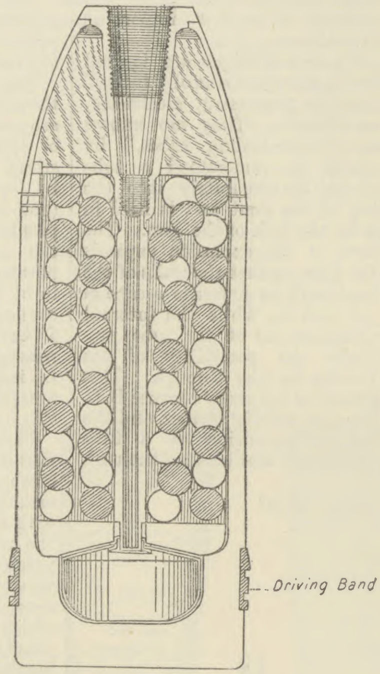

Fig. 9.—Shrapnel Shell (steel).

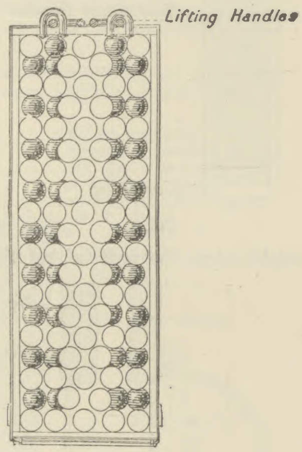

Fig. 10.—Case Shot.

Common shells are of two sorts, the ordinary common taking a fuze in the nose, and the pointed common taking a base fuze. These shell are really locomotive mines containing bursting charges of powder. The bursting charge is in a bag, to prevent premature ignition from friction with the walls of the shell, and consists of a mixture of pebble and fine-grain powders, known as "P" mixture. A common shell will penetrate a little over half its calibre of Harveyed steel with a striking velocity of 2000 feet per second. They are painted black (Fig. 7).

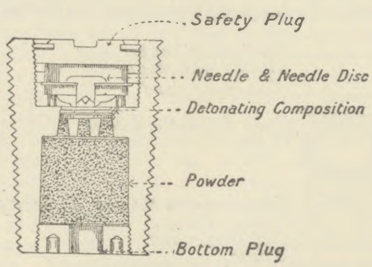

Fig. 11.—Direct-Action Percussion Fuze (scale ⅝).

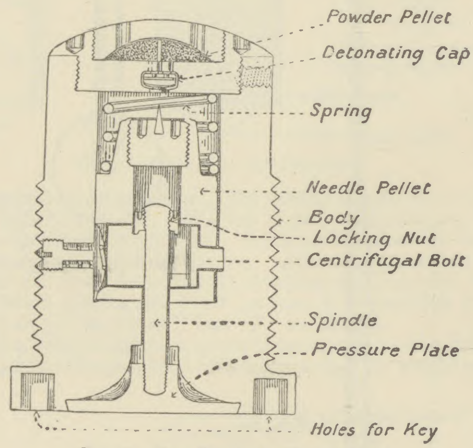

Fig. 12.—Base Percussion Fuze (scale ⅝)

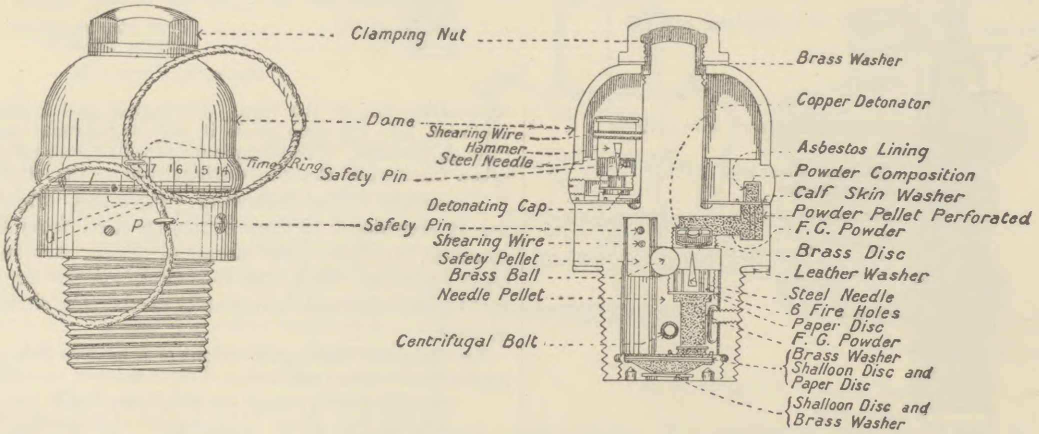

Fig. 13.—Time and Percussion Fuze (scale ⅝).

The long-felt want of a shell containing a high explosive, to be detonated on impact, is now supplied by *lyddite shells.* These are carefully made of forged steel with a solid base, to prevent an chance of premature explosion in the gun, which would be disastro

They resemble common shell. The shell is filled with lyddite, with a central hole for the exploder; a percussion fuze is used. The same shell will contain a greater weight of lyddite than of P mixture, and roughly the explosive effect of a lyddite shell may be taken as about three times as great as that of a powder shell of the same size. Lyddite shells, when properly detonated, have great local shattering effect; the tough steel is broken up into a large number of fragments, ranging in size from a pea to pieces weighing three or four pounds. These pieces are projected in every direction with great force, some even having a backward effect. The greatest effect is perhaps to the right and left of the line of fire, and any living creature near the explosion would be riddled by tiny fragments of steel. It has been stated that the blast kills at considerable distances, but the evidence of this is inconclusive, and the effect may rather be looked for in the small pieces of steel. In this respect the effect is entirely different from that of a powder charge, which would tear the same shell into a few large pieces and would have no backward effect at all. Lyddite shells are used with B.L. and Q.F. guns, the smallest being the 4-inch. The largest at present is the 10-inch. They are practically the only shell fired from the 5-inch and 6-inch B.L. howitzers. They are painted yellow (Fig. 8).

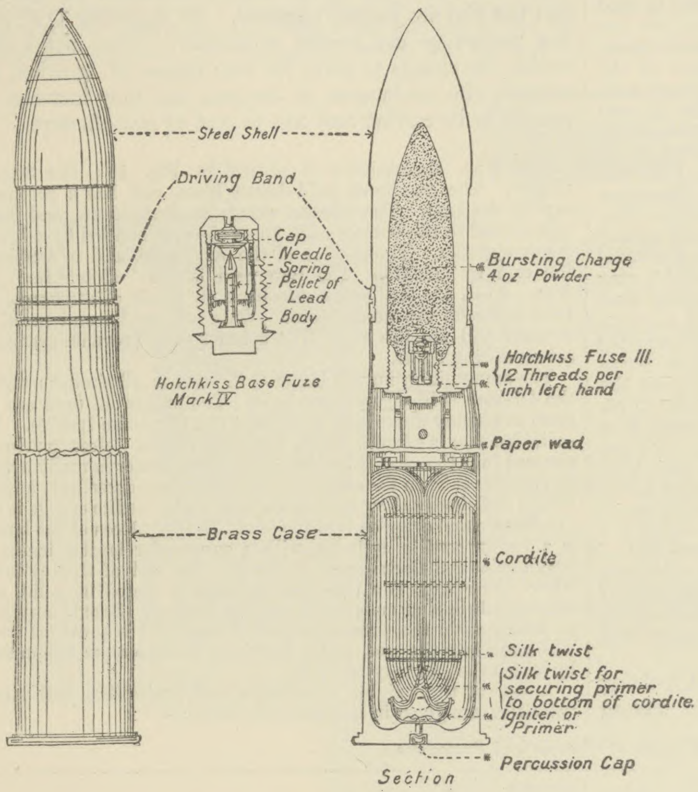

FIG 14.—6-pr. Q.F. Cartridge (scale ⅓).

The *shrapnel* shell is essentially a man-killing projectile, and depends for its effect upon the number of bullets it contains. The bursting charge is in the base, and is only sufficient to blow off the head, which is lightly attached, and thus release the bullets with which the body of the shell is filled. A central pipe conveys the flash from the fuze to the bursting charge. A time fuze is used, and is set so as to burst the shell while it is in the air, from 60 to 80 yards short of the target, and the bullets then stream forward in a cone-shaped shower, covering a large front. For effect the bullets should have a striking velocity of not less than 400 feet per second. Field guns use practically only shrapnel. They are painted black with a red tip (Fig. 9).

Armour-piercing shot are fired from the heavier guns, and, as their name indicates, are used for the destruction of armour, and have no bursting charge. They are pointed projectiles made of steel specially hardened. Roughly, with a striking velocity of 2000 feet per second an A.P. shot should perforate two calibres of wrought iron, one calibre of Harveyed steel, or ⅘ calibre of Krupped armour. They are painted black with a white tip and a white band below it. A.P. shells are fired from B.L. and Q.F. guns, and are made of hardened steel. They have a small bursting charge of powder and a base fuze. They are thicker in the point and shoulder than a common shell. Their penetrative power is slightly below that of A.P. shot. They are painted black with two white bands near the tip.

Case shot are fired from the majority of B.L. guns, and are used at short ranges. They consist merely of a weak envelope filled with bullets. The envelope must be strong enough not to break up before leaving the gun (Fig. 10).

In order to explode shell at the right moment "fuzes" are used. These are either "percussion" (of which there are two descriptions, one to act on "impact" and the other on "graze") or "time" fuzes, which can be set so as to act after some predetermined interval of time. Time fuzes usually contain an alternative percussion arrangement, and are known as "time and percussion" fuzes. An example of each kind is illustrated in the figures.

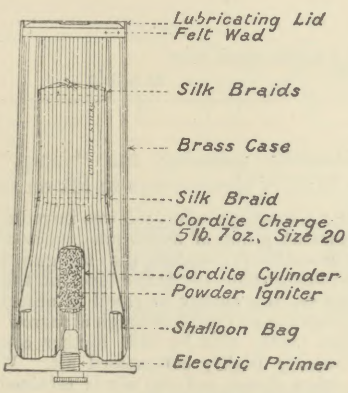

FIG. 15.—4·7-inch Q.F. Cartridge (greatly reduced scale).

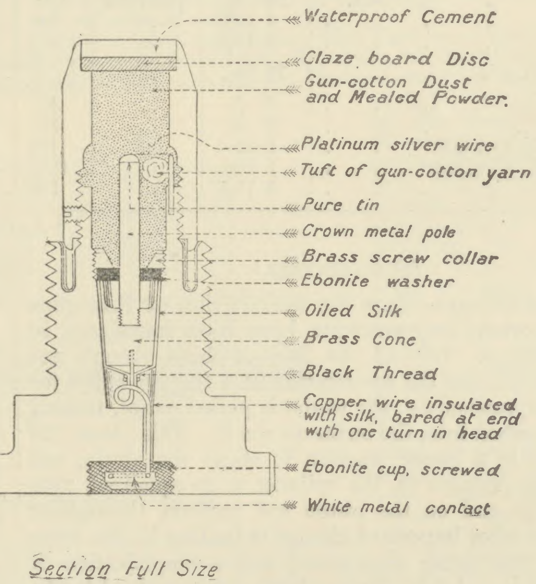

FIG. 16.—Electric Primer

The *direct-action* fuze is intended to act upon impact, and its construction will be understood from the figure. On impact the needle is crushed in against the detonator and so fires the fuze. This fuze screws into the nose of the shell (Fig. 11).

The *base fuze* is of the graze type. In it a needle pellet is prevented from movement by a "centrifugal bolt," which has a heavy head and is withdrawn by the spin of the shell, thus unlocking the pellet and permitting it to strike the detonator, when the shell is checked by grazing. For safety the centrifugal bolt is kept in position by a locking nut on a spindle connected to a pressure plate, which is forced in on discharge and so raises the nut. The spiral spring round the top of the pellet prevents premature action while the shell is in flight. This fuze is used with pointed common and A.P. shell (Fig. 12).

The time and percussion fuze consists of two distinct parts. The lower half of the fuze contains the percussion part, on the graze principle. A needle pellet is locked by a centrifugal bolt, as in the base fuze, and has also a ball preventing its forward movement. This ball is kept in place by the safety pellet, which is suspended on a shearing wire. On discharge the inertia of the pellet breaks this wire, the pellet falls into a recess, and the ball follows it. On graze the needle pellet flies forward. Connecting this part with the time part is a channel filled with powder. Opposite this channel, on the outside of the fuze, is the setting mark, a black triangle. The time part consists of a ring covered by a dome and clamped by a nut. On the under side of this ring is a groove, running nearly round, filled with slow-burning composition. At one end of the composition is a percussion cap with a hammer suspended on a thin wire above it. On discharge the hammer falls and lights the end of the composition, which burns slowly round until it reaches the connecting channel, when the fuze is fired. The outside of the ring is graduated from 0 to 18, and the fuze is set by turning the ring till the required graduation is opposite the setting mark, and clamping the nut. The gas evolved by the burning composition escapes through a side hole. Before use the safety pellet and the hammer are supported by safety pins, which are withdrawn before loading. The fuze burns about 12·5 seconds, corresponding to a range of about 3700 yards in the 12-pr. of 6 cwt., or 4100 yards in the 15-pr. A larger fuze of similar design burns 16 seconds. These fuzes are used in shrapnel shell (Fig. 13). A fuze of similar size and design to the first of the two above described, but burning for 22 seconds, has recently been issued. This time fuze corresponds to a range of about 5800 yards in both these guns.

Q.F. Ammunition.—The ammunition for quick-firing (Q.F.) guns differs from that already described in having the charge enclosed in a metal case, containing means of ignition at the base. The case acts as an obturator by being expanded against the inside of the gun. In the smallest Q.F. guns, the 6-pr. and 3-pr., "fixed ammunition" is used; that is, the shell is attached to the case and the two are loaded together. In the other Q.F. guns the projectiles are loaded separately. The metal cases enable the charge to carry its own means of ignition, and simplify the mechanism of the gun, but they increase the weight to be carried and add to cost of manufacture.

The 6-pr. ammunition is shown in Fig. 14; the 3-pr. is similar. The case is of solid-drawn brass, and has a percussion cap in the base. The cordite charge is dropped in, and has a primer tied to the bottom; the space above it is filled by a brown-paper cylinder. The shell is of the A.P. type, and is secured in the case by indents. The fuze used is the "Hotchkiss" base fuze. In it, the lead pellet sets back on shock of discharge, and thus unmasks the needle point. On graze, needle and pellet fly forward and fire the cap. The spiral spring prevents premature action during flight.

The ammunition for the larger Q.F. guns is all similar; that of the 4·7-inch is illustrated as a type. The projectiles fired are the same as already described; all except the 12-pr. fire lyddite. The cartridge case is of solid-drawn brass, having an "electric primer" screwed into the base (Figs. 15, 16). This primer is really a wireless electric tube on the same principle as already described; and the figures sufficiently show its construction. The cordite charge is tied in a bundle and dropped into the case. In the bottom of the bundle is a hollow cordite cylinder, with a gunpowder igniter inside it. The nose of the electric primer fits into the end of this cylinder. Above the charge is a wad, and the case is closed by a lid, containing lubricating material to prevent fouling. Should anything go wrong with the primer, a steel "adapter" is provided which will screw into the case, and is bored out to take a percussion tube, by which the gun may be fired.

A few of the weights of charges and projectiles, and muzzle velocities, are given in the following table:—

Table of Weights of Charges and Projectiles.

Gun.	Weight of Charge. Cordite.	Made up in ½ or ¼ Cartridges.	Weight of Projectile.	Bursting Charge of Common Shell.	Muzzle Velocity. Feet per Second.	Remarks.

T. H. C.

(c) CARRIAGES.[1]

Coast Artillery.—Since the introduction of B.L. guns many important improvements have been introduced in gun mountings. One of the first of these, though not entirely novel, was the substitution of a tension buffer for one in compression, *i.e.*, the piston is pulled out of, instead of being pushed into, the buffer on recoil. This places the piston rod in a better position to stand the strain, and enables the pressure in the cylinder to be equalized, thus making the pull on the piston rod uniform throughout recoil. Another important change is loading in the firing position, time being thus saved and a simplification of gears effected. Again, the gun-layer can now stand to the hand-wheel whilst the gun is fired. An improvement in the principle of construction was the lowering of the carriage, considerably reducing the "jump," *i.e.*, the tendency of the front of the carriage to lift on firing.

Hydro-Pneumatic Mountings.—In 1888 was introduced the first of a large and important group of hydro-pneumatic disappearing mountings. The essential principle is that the gun, mounted on a low site, shall on firing recoil below the level of the protecting parapet. In doing so, the energy of recoil is absorbed, chiefly by forcing a large volume of liquid through a narrow opening or "recoil valve," but partly also by still further compressing a large volume of already highly compressed air. When recoil ceases the recoil valve closes, and the air is retained at a very high pressure, ready to raise the gun to the firing position again after loading.

Fig. 1 shows a general view of the 6-inch B.L. disappearing mounting, Mark IV.; Fig. 2 is a vertical, and Fig. 3 a transverse section through the recoil cylinder.

The gun trunnions (Fig. 1) are supported by the two arms of the elevator A, which is pivoted to the front of the lower carriage at B. The breech is supported by the two elevating bars C, whose lower ends are attached to the elevating arcs D. These arcs are worked by the elevating gear actuated by the hand-wheel E. The arcs are struck with the bars C as radii and their centres are

[1] The following abbreviations are employed in this article. R.M.L., Rifled muzzle-loader. B.L., Breech-loader. Q.F., Quick-Firing. H.P., Hydro-pneumatic.

the positions of the upper ends of these bars with the gun in the loading position, so that elevation can be given whilst the gun is being loaded. The lower carriage rests on a ring of live rollers G which are free to traverse round on a circular racer H, motion being given by traversing gear actuated by the hand-wheel I. Supported by vertical stanchions attached to the lower carriage is a horizontal circular shield J through which the gun rises to the firing position. Shield sights by which the gun can be laid for line are shown at KK. The manganese bronze ram F which is attached to the elevator by the crosshead L, is forced on recoil into the central chamber of the recoil cylinder (Figs. 2 and 3), the cylinder being supported by trunnions resting in the brackets of the lower carriage at M. There are ten chambers NN[1] (Figs. 2, 3) all of which are connected at the bottom with the recoil valve chamber O, and therefore with one another. Nine of these contain liquid in their lower portions, and highly compressed air above, and are connected at the top by a channel P to equalize the pressures in each chamber. The tenth chamber N′, which is

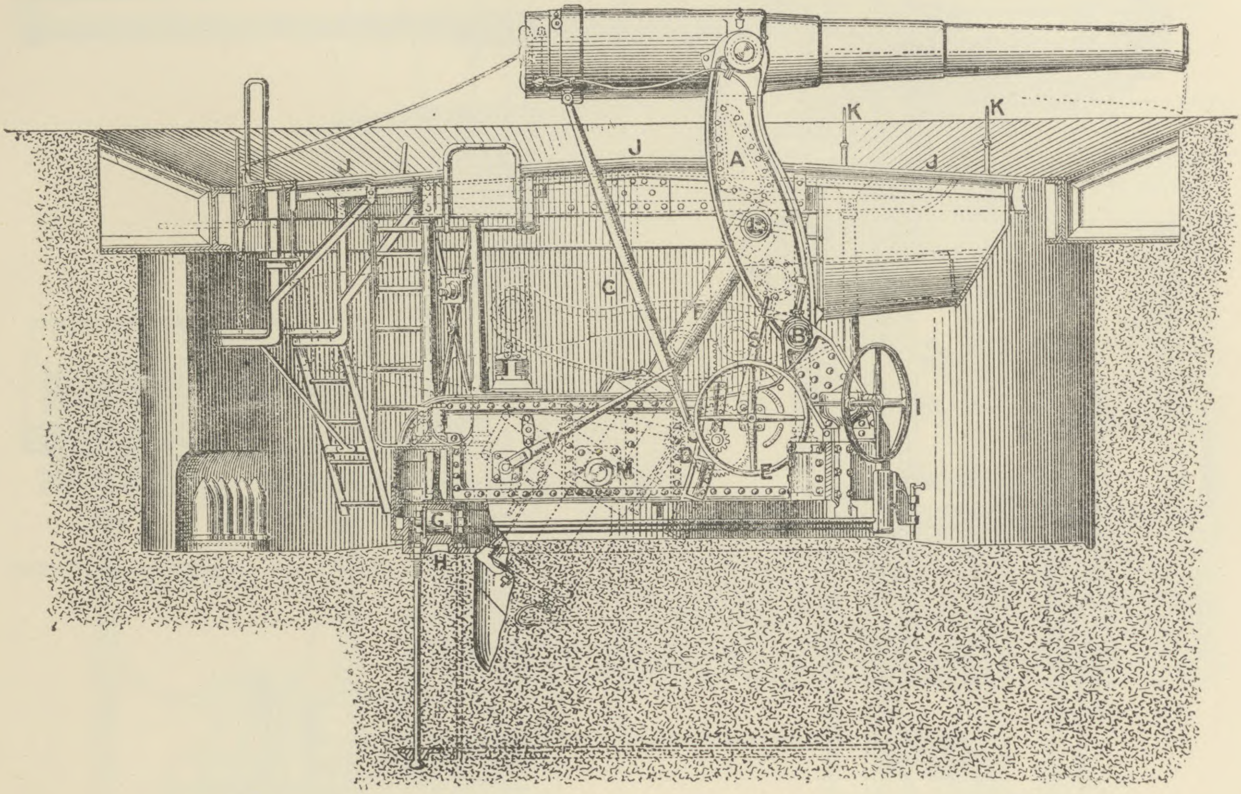

Fig. 1.—Diagram of a 6-inch B.L. Disappearing Mounting, Mark IV.

situated lowest in the cylinder, contains liquid alone, and has at its upper end the raising valve Q. On recoil, the liquid in the central chamber is forced by the ram through the recoil valve R, into the outer chambers N, thus further compressing the air. R being a non-return valve the air is maintained in this highly used consists of methylated spirits, mineral oil, distilled water, and carbonate of soda.

Heavy Barbette Mountings.—Figs. 4 and 5 represent the Mark V. mounting for the 9·2-inch B.L. gun, the latest development in heavy barbette mountings. Though resembling the H.P. group in the joint use of liquid and air, this mounting possesses the great advantage of having a separate chamber for each, thus eliminating aëration.

9·2-inch Mounting.—Fig. 5 shows a general view of the mounting, Fig. 4 a longitudinal section through the cradle to a larger scale. The gun, which is trunnionless, and to which is attached the crosshead A, recoils in the cradle C, supported by guides D, which slide in longitudinal grooves in the cradle. To the crosshead is attached the buffer cylinder B, so that on recoil, the gun, guides, crosshead, and buffer move together. The cradle of cast

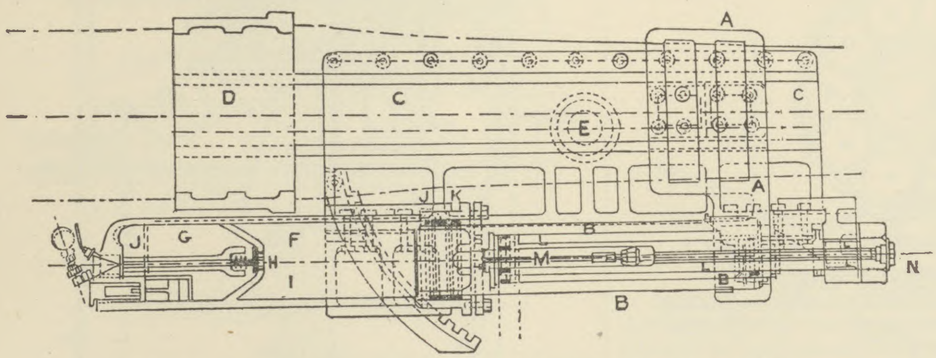

Fig. 4.—Longitudinal section through cradle of 9·2-inch B.L. Gun shown in Fig. 5.

compressed state during loading. The gun is raised by pushing the lever S (Fig. 1) to the front, which actuates the rack T, thus opening Q, which allows the air in the nine chambers to force liquid from the tenth chamber N′ into the central ram chamber, lifting the ram. U is a pump by which the gun can be pumped down at drill. Worked by the lever V, it sucks the liquid from the ram chamber and delivers it against the air-pressure into the nine chambers N.

A serious drawback to this type of mounting is the aëration of the liquid due to the churning it receives on recoil. The liquid steel with trunnions E resting in trunnion holes in the lower carriage, has attached to it in rear the air-chambers F and G in one manganese bronze casting, in which a high initial pressure is maintained. To the front of the cradle is attached the piston and piston rod L, in one forging. On recoil the buffer is drawn over the piston, whilst simultaneously the buffer cylinder is forced into the front air-chamber F, further compressing the air and forcing the bulk of it through the valve H into the inner chamber G. At the conclusion of recoil the expansion of the air forces the buffer, and with it the gun, to the front. The valve H closes and the air has to pass through a narrow hole before it can act on the end of the buffer, thus preventing any violent action. To prevent leakage of air between the air-chamber and buffer there is an ingenious arrangement consisting of a gland K, packed with a viscous liquid. This liquid packing is in communication with an "intensifier" I by means of a pipe J. This consists of a cylinder containing a piston and rod, the front face of which is in communication with the air-chamber, whilst in rear of it there is liquid communicating with the pipe. On recoil, since the front face of the piston is greater than the rear, the pressure exerted

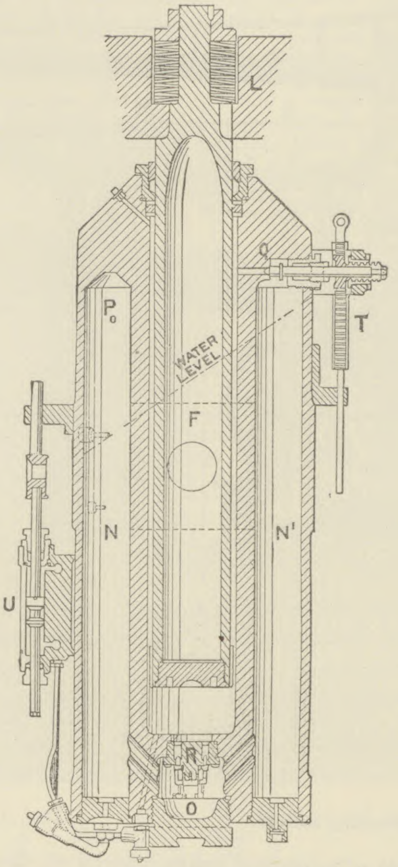

Fig. 2.—Vertical Section through Recoil Cylinder of Fig. 1 (on enlarged scale).

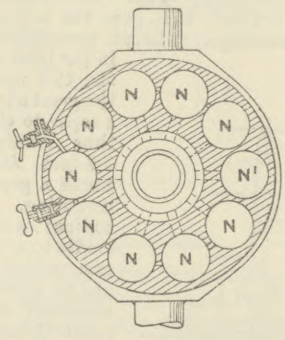

Fig. 3.—Transverse Section through Recoil Cylinder of Fig. 1 (on enlarged scale).

on the liquid is greater than that of the air, and the gland K is made air-tight. To prevent the gun from returning too violently to the firing position there is a "control ram" M bolted into the rear end of the buffer, the action of which is the same as that described for the 6-inch Q.F. It is adjusted by means of a long valve spindle and sleeve projecting from the end of the piston-rod at N. To lessen the labour of elevating, the cradle trunnions are supported on a ring of hard steel balls, but since the jar of firing would damage them, it is arranged that the trunnions shall take a bearing in the solid trunnion holes of the lower carriage at the instant of firing. The mounting is supplied with an automatic sight, and the gears used for elevating and traversing the gun present no very special features. The arrangements for loading present a good example of the way in which heavy charges are

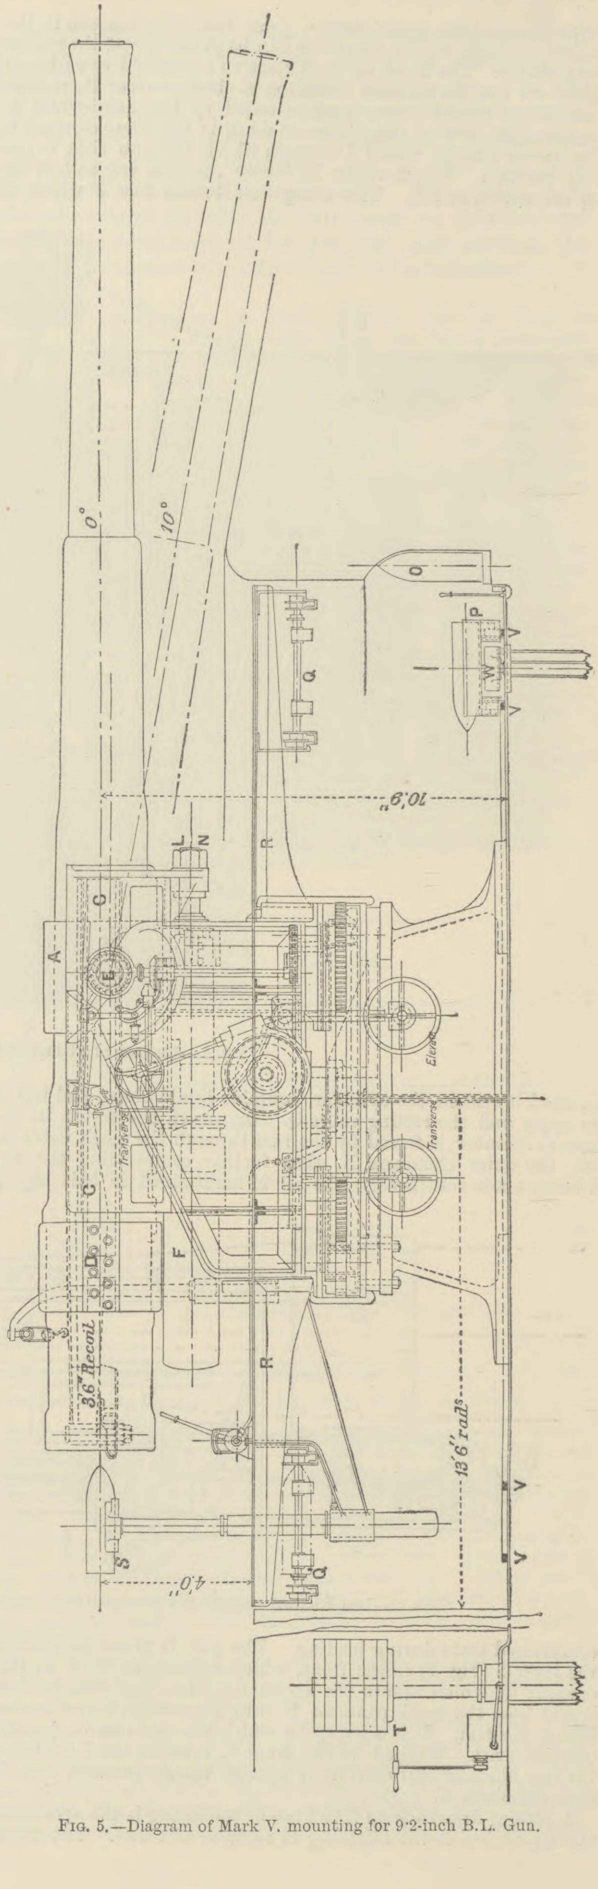

Fig. 5.—Diagram of Mark V. mounting for 9·2-inch B.L. Gun.

handled. The projectiles as seen in the recess at O are tilted into the carrier P, which runs on the circular rails V until the shot is over the ram W by which it is raised, and transferred to the carrier Q, which runs on circular rails underneath the shield RR to Q′. Here it is raised by the ram S, until opposite the breech. There is a hydraulic accumulator, T.

Quick-firing Gun Mountings.—In 1890 the first of the important group of Q.F. gun mountings was introduced, and the

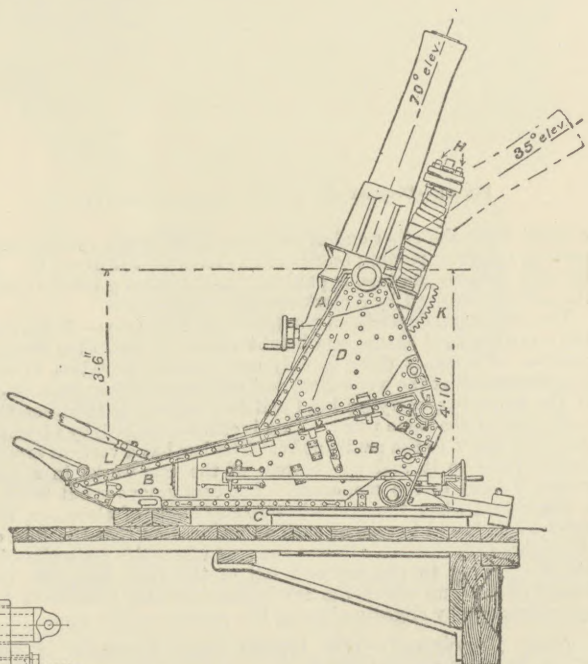

Fig. 9.—Showing Fig. 8 lowered and with Wheel removed.

latest development of this type is the Mark II. mounting for the 6-inch gun.

Six-inch Mounting (Figs. 6, 7).—The principles aimed at in its design are—

1st, Compactness; 2nd, adequate protection for the gun detachment, gears, mounting and breech of gun; 3rd, increased rate of fire, by arranging that the gun shall return to and be loaded in the firing position, at any angle of elevation, instantly after recoil; by enabling the gun-layer personally to elevate and train the gun; by the introduction of "an automatic sight," thus doing away with the necessity for setting sights, and making the gun independent of range-finders; by placing the sights on the cradle, thus enabling the layer to keep his eye to the sight whilst actually firing; and by the use of ball bearings which lighten the work of traversing.

Fig. 6 shows a side elevation of the mounting with half the shield removed; Fig. 7, a longitudinal section of part of the cradle through the axis of the buffer. The gun, which is trunnionless, recoils in the cradle A. The cradle contains a buffer B and two cylindrical boxes containing springs S. Attached to the breech of the gun is a piston-rod C with piston D. The piston is supplied with a "port" or opening E, through which the oil passes on recoil. The pressure inside the buffer, which would otherwise vary with the varying velocities at each point of recoil, is equalized throughout by varying the size of the port E. This is done by inserting in the buffer an "equalizing strip" F of varying section, over which the port has to pass. On recoil, the rods J which are attached to the gun in rear and screwed into the flanged cylinder H in front, force back the front of the springs S, whose rear ends butt up against the rear of the spring boxes. After recoil the springs return the gun to the firing position. To prevent their doing this too violently, the piston rod has a cylindrical hole in front which becomes filled with oil on recoil. Before the piston can come up against the front of the buffer, this oil must be displaced by the "control ram" G which checks the forward movement of the gun. The cradle trunnions resting in trunnion holes in the lower carriage allow of the elevation of the gun by the elevating gear K, which drives the elevating arc L attached to the cradle at M. In Fig. 6 the lower carriage is almost entirely hidden by the gears carried upon it, namely the elevating gear K; the traversing gear N, which works a spur pinion gearing into the rack O attached to the pedestal P; the elevation indicator Q and R for recording the angle of elevation of the gun; and the brackets S which support the 6-inch armour plate T. The whole weight of the lower carriage, cradle, and gun is taken by a horizontal ring of hard steel balls resting on the top of a massive forged steel "pivot" U, the lower portion of which is shown supported in the cast-iron pedestal P. The elevation indicator consists of a sector Q bolted to the cradle trunnion. To its edge is attached

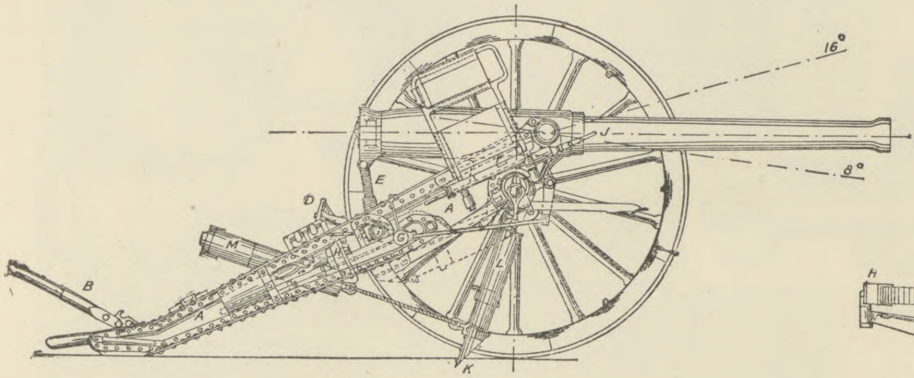

FIG. 11.—Diagram of 15-pr. B.L. Carriage, Mark III.

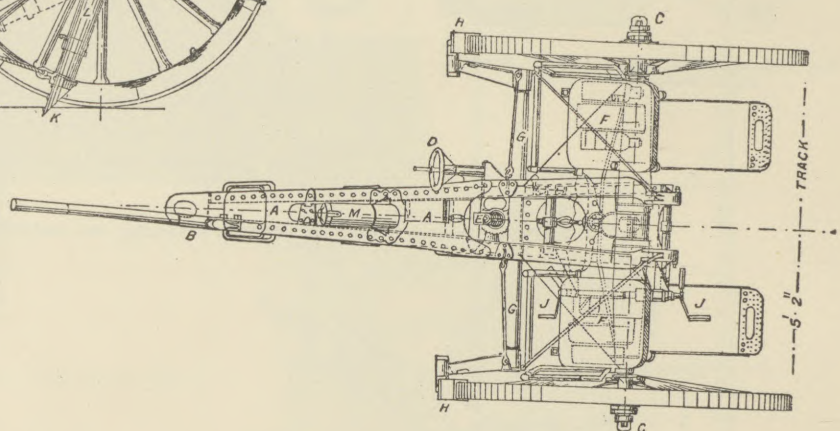

FIG. 12.—Plan of Carriage shown in Fig. 11

a metal tape, the other end of which is fixed to the spindle supporting a pointer reading angles of elevation on the drum R. As the gun elevates the tape is paid up, the slack being taken in and the pointer revolved by a clock spring.

The *Auto-sight* depends on the following principle:—If the gun has a certain fixed charge and height above the sea, then for any position of a target there is only one suitable elevation of the gun to strike it at the water-line, and only one suitable inclination of the sight bar, carrying hind and fore sights, to intersect the water-line at the same point. This is effected (Fig. 6) by pivoting the sight bar V to the cradle at W. The bar has a vertical arm X rigidly fixed to it, and the bottom of the arm works in a cam groove Y fixed to the mounting. The cam groove is cut to such a shape that when the gun takes up any angle of elevation, the sight bar is forced to assume such an inclination that the line of the sights cuts the water-line at the spot where the projectile will hit it. Owing to the rise and fall of the tide, however, the height of the gun above the sea varies, but this is allowed for approximately by slightly altering the position of the cam.

Siege Carriages.—The typical siege howitzer is the 6-inch B.L. of 30 cwt. (Figs. 8, 9, 10).

Six-inch Howitzer Carriage.—Fig. 8 shows the gun and cradle A mounted on its travelling carriage, from which it can be fired up to angles of 35°; whilst in Fig. 9 the wheels have been removed, the trail B has been lowered on to the pivot plate C, and secured to a pivot plug screwed into the plate; to the trail is fitted the top carriage D, and when the gun and cradle are mounted thus, 70° elevation can be given. The gun recoils through the cradle in which are two hydraulic buffers side by side (Fig. 10), the piston rods E of which are attached to the gun, so that the recoil of the gun draws the pistons J to the rear. Considering now the right buffer only, forged in one with the piston and piston-rod is a tail rod F of larger diameter than the piston-rod. This rod on recoil is dragged into the buffer, displacing some of the oil which entirely fills the cylinder. The displacement of the oil forces the front of the buffers G, against which rest the rear ends of the springs, forward, the front of the springs being prevented from moving by the rods H. After recoil the springs expand, setting up a liquid pressure which acts on both faces of the piston J. The rear face being the largest, the piston and with it the howitzer are returned to the firing position. The elevating gear, which can be placed on the left side of either the trail or the top carriage, actuates the arc K bolted to the left side of the cradle. The mounting, as in Fig. 8, is traversed by handspikes; whilst in Fig. 9, the ends of a chain which is passed round the capstan L are attached to hold-fasts right and left. With the gun on its travelling carriage an anchorage buffer M is used to check the recoil of the whole mounting, and springs to run it up again.

Field Artillery.—A great change has been effected in the mountings for the field artillery gun by the addition of brake gear and a non-recoil attachment designed by Sir G. Clarke. The object has been by controlling the recoil of the carriage to increase the rate of fire, and reduce the labour of running up. Most of the Continental Powers have tried to attain the same object, the usual plan being the adoption of some form of plough attached to the point of the trail, digging into the ground, and reducing recoil.

The design of field artillery guns and carriages is so absolutely limited by the weight that can fairly be put behind a team of six horses, that the field artillery equipment must necessarily be only a compromise.

Figs. 11 and 12 represent the Mark III. carriage for the 15-pr. B.L. gun—Fig. 11 in elevation, Fig. 12 in plan.

15-pr. Carriage.—The trail A is built up of plate and angle steel. There is a socket B for the handspike used in laying. The axletree C is of tubular steel and fastened to the breast of the trail. The elevating screw E is telescopic, thus giving increased rapidity in laying. It is worked by bevel gearing actuated by the hand-wheel D. Two rounds of ammunition are carried in each of the axletree boxes F, which are fitted as seats for the gunners. The travelling brake consists of the shaft G with arms and brake blocks H, the whole being forced on to the wheels when necessary by a system of levers and rods, actuated by the screw with handles J. The arrangement for checking recoil consists of a spade K attached to the bottom of a telescopic case, containing springs L, and hinged underneath the breast of the carriage. The spade is attached by a steel wire rope to a rod compressing a second set of springs in the steel cylinder M. On recoil the plough is forced into the ground. The cylinder L telescopes, compressing the springs and allowing the carriage to recoil. The rope simultaneously tautens and compresses the springs in M, which after recoil expand and return the gun to the firing position.

Mountain Carriages.—The carriage for the 2·5-inch gun is packed for transport on three mules. One carries the axletree, a second the wheels and elevating gear, and a third the trail. Each mule in addition carries a number of small stores. It requires about ten seconds to assemble the carriage. (C. R. B. O.)

III. United States.

The material of the United States artillery is divided into four general classes, namely, mountain, field, siege, and sea-coast guns.

The mountain artillery comprises the 1″·65 and 3″ Hotchkiss rifles, and their mounts and ammunition. The field artillery comprises the 3″·2 and 3″·6 rifles, and the 3″·6 mortar. These pieces are all breech-loaders of gun-steel, and have conical gas check seats, cylindrical powder chambers of larger diameter than the bores and connecting with them by a slope forming a seat for the rotating band. The tops of the lands at the beginning of rifling are also cut away, forming a slope to allow the band to be gradually forced to its full depth in the rifling. These general features are followed in the manufacture of all guns. The 3″·2 and 3″·6 rifles consist of a tube and jacket assembled by shrinkage. The former gun is intended for horse artillery, the latter for field batteries. In practice, however, the former is generally used for all purposes. The field carriage is made of steel, weighing 1300 pounds. It is of the usual type, having recoil on the ground, which is restrained by bowspring brakes fastened to the axle and engaging over the wheels. This brake also serves as a travelling brake, a simple arrangement permitting it to be thrown on or off the wheels when desired. The wheels used in the field and siege service are of the Archibald pattern. The limbers, except in minor details, are the same for carriage, caisson, and battery waggon, the bodies of which are made of metal. The limber and caisson chests are the same, and are made of wood covered with canvas and reinforced by iron. Each is divided into three compartments, the end ones containing twenty-one projectiles each in bronze supports, and the middle one forty-two cartridges and two haversacks. The limber complete with ammunition weighs 1780 pounds, and the caisson and limber complete with ammunition, 4607 pounds. The ordnance department of the army has designed a 3″ field rifle to supplant those now in service, when a suitable non-recoil carriage shall have been selected. It has also decided upon a 5″ field

A, breech-plate; B, breech-block; C, cam; CL, cam links; D, gas check disc; H, hinge-pin; LB, lock bolt; LC, tray-latch catch; N_1, spindle nut; N_2, lock nut; P, gas check pad; R_1, R_2, R_3, split rings; RC, rotating crank; RL, rotating crank lock; RP, rotating pinion; RR, rotating ring; S, obturating spindle; SB, spring bolt; SC, securing catch; SL, securing latch; SW, spindle-washers; T, tray (console); TC, translating crank; TL, tray-latch; TR, translating roller; TS, translating stud; V, vent-cover.

howitzer, the carriage for which will resemble the field carriage, and awaits the determination of the latter. The data for these two guns are included in the tables at the end. The 3″·6 mortar, consisting of a single forging of steel, is a short piece intended for vertical fire against troops protected by entrenchments or irregularities of the ground from the direct fire of field guns, and will be largely supplanted by the field howitzer. The maximum range is about 3450 yards, and the charges required to cover all ranges from 400 to 3450 yards are four in number. The carriage, weighing 275 pounds, is made of cast steel in one piece. Elevation is given by a quadrant, and a clamp is provided to fix the mortar at any elevation. The carriage rests on a wooden platform, and is restrained in recoil by heavy ropes attached to stakes in front. Changes in azimuth are given by means of a pointing scale graduated to $\frac{1}{1000}$th of the range.

The field artillery ammunition comprises cast-iron shell, shrapnel, and canister. A steel shell holding a larger bursting charge is also provided for the howitzer. The canister, containing 226 balls, consists of a hollow cylinder of malleable iron, the rear end closed by a cast head. Around the case are several slits, their ends overlapping to secure a thorough breaking up on discharge. There are several small holes through the head through which the gas enters on discharge, driving the balls forward and assisting in the destruction of the case. The shrapnel contains 162 hard lead balls, assembled in circular layers, and held in position by cast-iron separators, which increase the effect of the explosion by furnishing additional fragments. The base is made of cast-iron threaded to the interior of the cylindrical case. Recent improvements have had in view the omission of the separators permitting the addition of a number of lead balls con-

tained in steel jackets. The head of the shrapnel, containing the powder chamber, is made of cast-iron, bored and threaded to receive the fuse. The body is made of a lap-welded tube weakened for fracture by grooves in the sides.

Siege Artillery.—This comprises the 5″ rifle, the 7″ howitzer, and 7″ mortar, all breech-loading rifled pieces, following the general description of the field guns. Excepting the mortar, which is a single forging, they are constructed on the "built-up" principle. The rifle consists principally of a tube, jacket, and sleeve, the tube being unsupported for a distance of 56 inches from the muzzle. The carriage for the rifle consists essentially of two steel flasks parallel to each other, connected by a bottom and top plate and transom. The carriage is similar in general design to the field carriage, except that the trunnions of the gun are relatively much higher from the ground, the axes of the trunnion beds being 72 inches above the horizontal platform upon which the carriage rests. The elevating apparatus is a double screw similar to that in the field carriage. A limber is provided for travelling, which also serves for the howitzer carriage. This and the howitzer carriage are mounted on a wooden platform weighing about 5100 pounds, and having a metal pintle to which the carriages are attached through the medium of a hydraulic cylinder to restrain their movement in recoil, after which they are moved forward by handspikes. The carriage weighs 2820 pounds, and permits the gun to be fired at any elevation from minus 10 degrees to plus 38 degrees. The howitzer consists essentially of the same parts as the rifle. The carriage, while somewhat similar to that for the rifle, differs from it in that the howitzer is permitted to recoil upon it, thus reducing the strains. The piece is mounted on two trunnion carriages upon slides inclining to the rear and downwards at an angle of 18°, upon which it has a recoil of 6 inches. Recoil on the slides is checked by hydraulic cylinders placed in front of the trunnion carriages, and in the rear by two courses of springs, one on each side, serving also to return the piece to the firing position. The height of the trunnions of the piece is the same as that for the siege rifle, although in a more recent design this height has been reduced to 60 inches. The wheels, weighing 375 pounds each, are the same as for the siege rifle. The weight of the carriage, including the wheels and hydraulic brakes, is about 3000 pounds, and the howitzer can be elevated from minus 5° to plus 40°. The 7″ mortar fills the need of the service for a piece for vertical firing in siege operations against strongly entrenched and covered positions, and is adapted to use the same projectiles as the howitzer. It consists of a single forging with trunnions combined, whereby a construction of satisfactory strength with minimum weight is best obtained. The service required is to deliver relatively heavy projectiles at short or moderate ranges, to supplement the curved fire of the howitzer by vertical fire at medium ranges, and to cover the field at shorter ranges which are inaccessible to the howitzer. The projectile of normal weight is fixed at 125 pounds, having a velocity of 700 F.S., with a maximum range of about 4200 yards. The carriage is made of steel plate, and in its method of checking recoil and returning the piece to the firing position resembles the howitzer carriage. It is, however, not a wheeled carriage, but rests upon a wooden platform to which it is fastened by cast steel clip plates bolted down. Traversing is effected by pinch bars engaging in teeth cast in the plates. Elevation is accomplished by bars fitted into sockets bolted to the faces of the trunnions, the piece being clamped in any position by a screw through the left cap square. The limits of elevation for ordinary fire are from plus 30° to plus 65°. The wooden platform weighs 3720 pounds and the carriage 1720 pounds. This platform is not quite heavy enough to secure proper stability, at least in loose soil, but in view of the fact that it must be transported, reliance must be had on material gathered near the place of use for a solid sub-construction, to which the platform can be secured by means of holding-down bolts provided for the purpose. Cast-iron and steel shell and shrapnel are used with siege artillery depending upon the results desired. The shrapnel is similar to that described for field artillery, except that a central tube extends from the powder chamber to the head of the base. The 5″ shrapnel contains 280 hard lead balls and other parts, making the number of pieces before firing 356. The howitzer shrapnel contains 390 balls, and a total of 461 pieces. The mortar shrapnel contains 449 balls and other parts, making the total number of pieces before firing 550. As an instance of the manner in which these shrapnel behave in service, it may be noted that in some recent firings the howitzer shrapnel gave about 800 dangerous fragments.

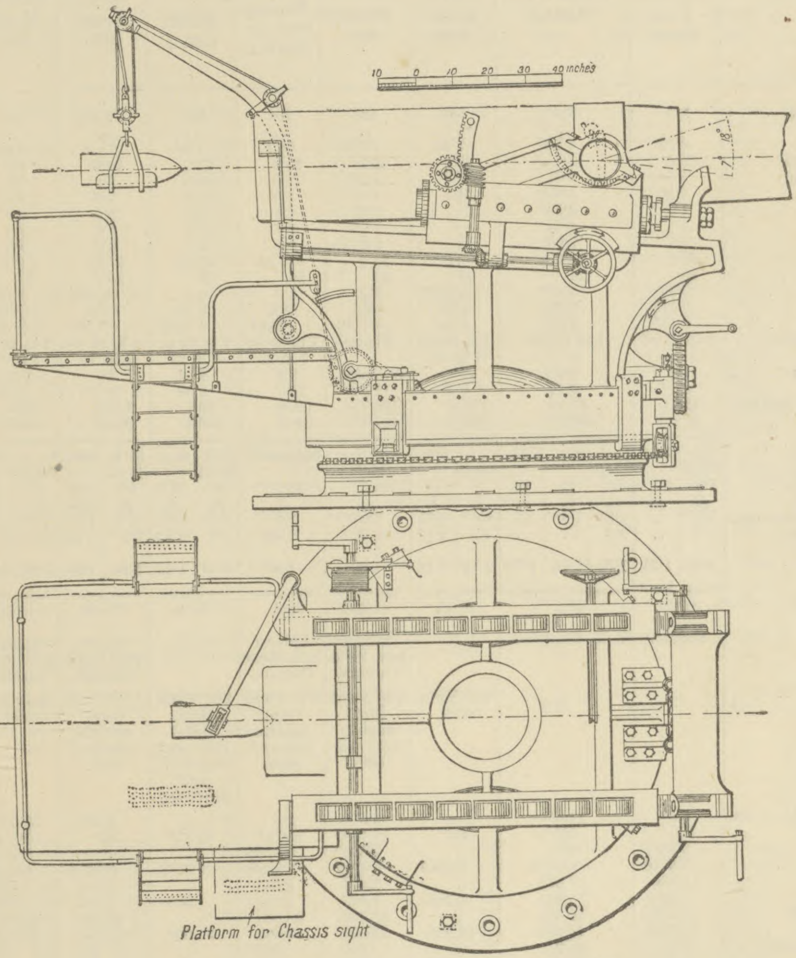

Fig. 3.—Diagram of Barbette Carriage for 8-inch B.L. Rifle.

Coast Artillery.—The sea-coast artillery consists of 5-inch and 6-inch rapid-fire guns, 8-inch (Fig. 1), 10-inch, and 12-inch rifles (Fig. 2), and 12-inch mortars; with the exception of the mortars model of 1886, which have cast-iron bodies with steel jackets, these are built up of gun steel, and all are breech-loading with rifled bores. The number of hoops has been successively reduced, as steel manufacturers have become able to make larger forgings, and the greater length of the hoops much increases the stiffness of the guns. In the 5-inch guns the tube is given an initial tension, in addition to that caused by the shrinkage of the jacket, by heating and cooling from the interior. There are also a number of 6-pounder rapid-fire guns on wheeled carriages, and 15-pounder rapid-fire guns on a form of pillar-mounting. The 5-inch rapid-fire guns are mounted in barbette on pillar-mount carriages, similar to the Armstrong pattern, and on pedestal mounts, which are very similar in all countries. The 6-inch rapid-fire guns are mounted on pedestal mounts and on disappearing carriages, arranged to be manœuvred by one man. In the latter mounting rapidity of fire is somewhat sacrificed for cover, but six or seven rounds per minute can be attained.

The 8-inch, 10-inch, and 12-inch rifles are mounted on barbette or disappearing carriages, depending upon their situation. The barbette carriages are all of the same design, and differ only in size and weight (Fig. 3). They are of the centre pintle form, and consist essentially of two side frames mounted on a turn-table, and a top carriage, consisting of trunnion beds and recoil cylinders. Where strength permits a superior quality of cast-iron is used for the construction of the larger parts. The turn-table proper for all carriages consists of an upper and lower roller path, between which are forged steel conical rollers, securely held in place by concentric distance rings. The top carriage rests, on each side, on steel rollers mounted in U-shaped recesses in the tops of the side frames, which have an inclination upwards and to the rear of 4°. The piston-rods pass through lugs which project upwards from the front ends of the rails, and are secured by the necessary nuts and check-nuts. The front surface of these lugs and rails is planed as a shoulder for a shield to protect the cannoneers, which has not yet been supplied. During recoil the pistons remain stationary, the top carriage with its cylinders being drawn over them. The energy of recoil is taken up by the uniform resistance which the liquid in the cylinders offers to being driven through varying orifices caused by throttling bars, whose inner surfaces are curved. After recoil, the gun returns to the firing position by the action of gravity.

The gun is pointed in azimuth and elevation by suitable gearing. A crane is provided for raising the projectile to the breech of the piece, and a loading platform of suitable dimensions to permit the operation of loading to be performed by the necessary number of men, is attached in rear. The carriage permits the gun to be traversed 320°, and elevated from minus 7° to plus 15°. The gun can be laid by means of a telescopic sight attached to the right trunnion, or to a standard on the right side frame, or by the indirect method.

The disappearing carriages are of the "Buffington-Crozier" type (Fig. 4). The turn-table, chassis rails, or side frames, and top carriage, are similar in general design to those for barbette carriages. The trunnions of the gun rest in trunnion beds at the upper ends of the gun levers, which are pivoted near the middle point upon an axle resting in beds in the top carriage. The lower ends of these levers are joined to a steel crosshead, from which the counter-weight is suspended. This crosshead clips over vertical guides cast on the inside of the chassis rails, by which it is constrained to move in a vertical direction. Ratchet teeth are cut on the front faces of the clips to be caught by pawls pivoted to the chassis rails, and in this way the counter-weight is held up, and the gun is prevented from returning to the firing position after recoiling. The counter-weight is just sufficient to raise the gun to the firing position when loaded. The energy of recoil is absorbed as described for barbette carriages. Equality of resistance in the cylinders, as in the barbette carriages, is obtained by connecting their pressure ends by an equalizing pipe. Pointing in azimuth is performed by suitable

* Ounces.

† Maximum. The weight of charge varies with the range; for issues in bulk the average charge is assumed to be ¾ the maximum.

‡ The kind of powder varies with the range.

§ For 800-pound shell.

‖ Without fuze.

¶ Gun-cotton.

φ The use of the 16½ lb projectile with this rifle is to be discontinued. The charge for this projectile was 12·87 ozs. smokeless powder, resulting in a velocity of 1450 F.S. with a pressure of 35,000 lb per square inch.

θ For 1000-pound shell; with the 800-pound shell the velocities are 1150 and 1325 F.S. with brown and smokeless powder respectively.

gearing. The gun is elevated and depressed by means of a rack on the chassis rails, connected to the gun by two long arms; any movement of the rack up or down is thus communicated to the gun. While theory requires, in order that the gun shall always return to the same angle for loading whatever may be the firing angle, that the rack and its guide shall be struck with a radius equal to the length of the elevating arms, using the point of attachment to the gun in the loading position as a centre, the expense of manufacture has made it desirable to make them straight. These are so placed, however, as to cause only a slight variation in the loading angle, which is about 4°. Ammunition is served to the gun on ammunition trucks, permitting the projectile to be raised to the proper height for loading and to be given the same inclination that the gun has in the loading position. The gun can be pointed by means of indirect laying, or of a telescope sight placed on the right trunnion or on a sight standard attached to the rear of the carriage at such a height as to look over the interior crest.

In these carriages the centre of gravity of the gun-counterweight system moves some distance to the rear, greatly relieving the firing strains. The character of motion also permits the muzzle to project some distance over the interior crest. From the fact that the lower ends of the gun levers are constrained to move vertically, and their centres nearly horizontally to the rear, the path of the trunnion of the gun is an ellipse. The breech of the gun, being connected by a fixed arm to the elevating rack, travels in the arc of a circle. The combination of these two movements causes the muzzle of the gun to move almost directly to the rear, parallel to the superior slope, until it has passed the interior crest, when it turns suddenly downwards. These carriages are hardly more complicated than barbette carriages, having the same hydraulic cylinders and the same slide rails. There are no valves and no fluid under compression, except during the instants of recoil, and after long standing they can be prepared for immediate use by simply filling the cylinders with oil. The character of motion has other advantages besides that of causing the piece to describe a suitable path in recoil. The top carriage starts with only about one-half the acceleration of the piece, thus diminishing the shocks and strains brought upon it and the gun levers. At the beginning of the motion, when the gun has its greatest velocity, the counter-weight has relatively the least, so that the latter starts from rest very slowly, and the operation brings no sudden or undue strains upon any part of the mechanism.

The barbette and disappearing carriages are manœuvred and loaded by hand power. Electric power may be applied if desired. Guns mounted on the former carriages have not quite the rapidity of fire of corresponding calibres on disappearing carriages. This is due to the fact that guns on the latter carriages always return to the loading position with the proper loading angle, while on

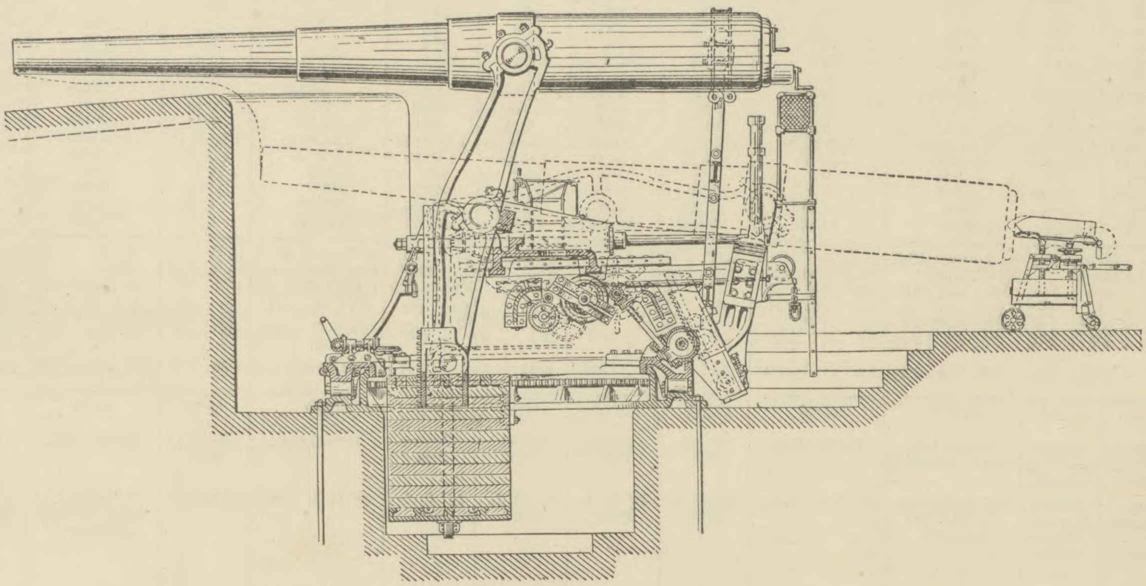

Fig. 4.—Diagram of Disappearing Carriage L.F. for 10-inch B.L. Rifle.

the former they must be brought nearly to a horizontal position for loading, the operations of which are performed on a platform at some distance from the ground, to which the charge and projectile must be raised at each discharge. Recent trials with disappearing carriages indicate that ten rounds can be fired from 8-inch guns in twelve minutes, from 10-inch guns in fourteen minutes, and from 12-inch guns in seventeen minutes, meaning in the latter case that 14,500 pounds of ammunition are handled for the ten rounds.

There are two kinds of mortar carriages, designated respectively as "model of 1891" and "model of 1896." The former is of the "Raskasoff, Easton, and Anderson" type, in which two triangular side frames are mounted on a turn-table, and the mortar recoils downwards and to the rear at an angle of 50° to the horizon, the mortar being held in the firing position by two columns of springs placed in spring cylinders cast in the side frames. The turn-table of the model of 1896 carriage (Fig. 5) is similar to that of the model of 1891. The top carriage or saddle in which the mortar is mounted consists of two arms connected by a heavy web, inclined to the rear and upwards at an angle of 45°. The upper ends of the arms form the trunnion beds, while the lower ends are held by a fulcrum shaft attached to the turn-table. The saddle is supported at a point about one-third of its length from the fulcrum by five columns of double springs arranged in a row side by side. The recoil is checked by two hydraulic cylinders, one on each side, the pistons of which are attached to the cradle near the gun trunnions. The action of the carriage when the piece is fired is as follows: The saddle revolves about its fulcrum to the rear and downwards, carrying the mortar and compressing the spring columns. As the piece moves down the two crank pins force down the crossheads and piston-rods until the resistance of the hydraulic cylinders stops the motion. The springs, acting against the saddle, reverse the motion and raise the piece to the firing position. The mortar must be brought to a horizontal position for loading, and the shot is served to it by means of a truck, passing the shell direct from the truck into the mortar.

Ammunition.—Armour-piercing shot and shell are used with the rifles, the difference between them being as regards penetrative power and interior capacity for high explosive charge. Deck-piercing and torpedo shells, weighing 800 and 1000 pounds, are used with the mortars, depending upon the range. The heavy torpedo shells are $4\frac{1}{2}$ calibres long, and are designed to carry a large bursting charge, so as to have great effect on striking in the vicinity of a battleship. The extreme range of these mortars is about six miles, but they are intended to cover all ranges by variation of charge and projectile and angle of elevation.

Breech Mechanisms.—In all of the guns, except the mountain guns, the breech mechanism belongs to the interrupted screw system, using the plastic pad for obturation, excepting only the 3·6″ mortar, which has the "Freyre" check. In the guns of larger calibre the gas-check cups are replaced by split rings, which are slightly larger than the conical seats, and are sprung together by being forced into their places. In action they are held against the walls of the gun by the plastic pad, thus preventing an escape of gas. In the field and siege guns the block is carried in a ring, which supports it when open. Rotation is given by means of a handle fixed or pivoted near the top, and the block is withdrawn through the carrier ring and swung open by hand. The breech-blocks of the rifles of old model and of the mortars are rotated by means of crank handles, and withdrawn from the piece on to a bronze tray by means of a screw, and are then swung open by hand. In the latest improved mechanism the continuous movement of rotation, translation, and swinging of the block and tray are effected by the operation of a single crank. The newer mechanisms for field and siege material will conform to those for the rapid-fire guns, where the block is opened by the single movement of a lever, of which there are numerous similar types.

Wire Guns.—Several systems of wire guns have been tested in the United States with a view to their adoption. All have failed under test, or have had objections which were not overcome, excepting the Crozier, in accordance with which a 10-inch gun was constructed and exhaustively tested at the Army Proving Ground. The test of this gun was highly successful, but up to 1901 none had been installed in fortifications.

Means of Sighting.—All field, siege, and sea-coast guns, excepting the mortars, are provided with both open and telescopic sights. The mortars are pointed by indirect laying, elevation being given by a quadrant. The telescopic sight is somewhat similar to the Scott, erecting the image and having a larger field. For the rapid-fire guns a bar sight is used, having a peep sight and a telescopic sight side by side. Electric night sights are also provided.

Fuzes.—Three kinds of fuzes are used: the base percussion, the point combination time and percussion, and a detonating fuze for high explosive shells. The first is used with all shells not containing high explosive, and the combination fuze is used with shrapnel alone. There are two sizes of the latter fuze, one burning to 15 seconds and the other to 28 seconds. The former is adapted to high-velocity fire with field and siege guns, and the latter for firings with the field and siege mortars and the siege howitzer. These fuzes are graduated to sixths of seconds. This method has been preferred to one giving the range in yards, since it permits the interchange of fuzes in projectiles for guns of different calibres. The fuzes for the field projectiles and 5-inch shrapnel are issued and transported with the projectiles ready for firing. The remaining fuzes for siege and sea-coast service are packed in tin waterproof cases for separate transportation, to be inserted in the projectile at or near the firing ground.

Powder.—The sphero-hexagonal black powders and brown prismatic powder in store will be used principally for practice until the supply is exhausted, after which smokeless powders will alone be supplied. Many experiments to determine the most suitable smokeless powders have been made since 1890. At present that which appears to meet with most favour is a pure gun-cotton powder made from cotton, of which only about 1 per cent. is insoluble. This has a cylindrical multi-perforated grain, the size depending upon the calibre. All powders are stored in hermetically sealed cases to prevent deterioration.

High Explosives.—Various high explosive charges for shells have been recommended and provisionally adopted, but this matter

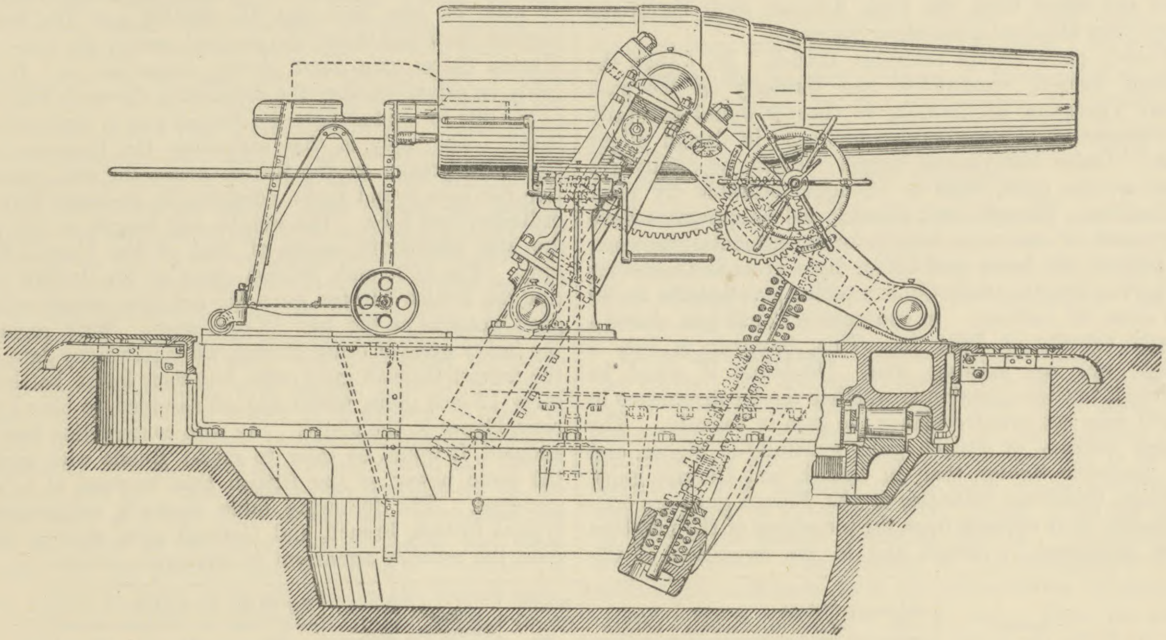

Fig 5.—Diagram of Carriage for 12-inch B.L. Mortar.

cannot as yet be considered settled. The war with Spain caused renewed activity in the field of invention, and recent experiments indicate two or three promising explosives for shells of all calibres to replace gun-cotton, which is now used.

Range-Finders.—The only range-finder thus far issued is the "Lewis Depression Range and Position Finder," of which there are two types. The type "A" is an instrument weighing about 700 pounds, designed for permanent installation on a concrete foundation at a considerable distance from the guns of a battery. A complete automatic replotter is carried on the table of each instrument, by the use of which the observer can instantly convert the range and direction of the target as read from the instrument into the corresponding range and direction from the gun itself. The corrections necessary for effects of curvature and normal refraction are made in the construction of the range scale, and corrections for changes in tide and abnormal refraction are controlled by the observer through mechanical devices. The type "B" instrument is light and portable, and somewhat resembles a transit in the ease and quickness of its adjustment. This type is designed as an emergency instrument, to be used in case of accident to the type "A," or when the lines of communication between the main position-finder and the gun are broken. The accuracy of this instrument is not so great as that of the larger one, but the error in range is said not to exceed 1 per cent. up to 8000 yards.

(C. B. W.)

IV. Other Powers.

The readiest method of presenting information in regard to the ordnance of foreign countries is to take the description of the British ordnance as a basis, and to state the principal differences exhibited in others. It is in a comparison of strength that the interest really lies. The following are the chief elements to note as indicating power in various ways:—

Muzzle Energy.—This is an expression for the actual blow delivered by a projectile leaving the muzzle of the gun. It is written $\frac{WV^2}{2g}$; W, on the British system, being the shot-weight in lb, V^2 the square of velocity in feet per second, and g the force of gravity in feet per second. The result is divided by 2240 to convert pounds into tons, the blow being most conveniently expressed in foot tons, *i.e.*, the number of tons that could be lifted through one foot by the energy of the blow if applied in a suitable shape. A comparison of energies is then a comparison of the blows delivered. The cost of manufacture and the necessary provision for the carriage of a gun mainly depend on its weight, and the simplest estimate of the success of any gun, as an investment, is the blow produced for each ton of metal. This is obtained by dividing the total energy by the weight of the gun in tons. The 12-inch wire-gun, Mark IX., gives 718, and the old 12-inch muzzle-loader only 273 foot tons per ton of gun.

Fire Energy per Minute.—The introduction of quick fire made it imperative to consider speed in any comparison of efficiency. This is done by multiplying the energy of the blow by the number of rounds delivered in a minute, the result being the total hitting or energy per minute. Thus, a 6-inch Q.F. gun, with a muzzle energy of 4840 foot tons, if it fires three times in a minute, has an energy per minute of 14,520 foot tons.

With these remarks the comparison of energies and other data given in tables will be intelligible. As, however, continual progress is made, it may be well to direct attention to certain annual publications giving trustworthy information. The Austrian *Marine Almanack*, published at Pola, is the first authority on Continental armaments. Much of its data is official, but not by any means all, and, in common with all works, it is apt to be specially behindhand in Russian guns. Brassey's *Naval Annual* gives official figures obtained directly concerning British and American guns, as well as Elswick, Krupp, Schneider-Canet, and Vickers Q.F. guns. Its figures on Continental guns are taken from the Pola *Annual*, with occasional corrections obtained from other sources.

French guns closely resemble British. M. Canet, the leading French constructor, was formerly on the staff of Mr Vavasseur of Elswick, so that it would naturally be supposed that considerable similarity in design might exist. Canet has pushed length farther, especially for coast-service guns, than is thought desirable by most authorities. Though both Elswick and Krupp guns have been made of enormous length for experimental purposes, 40 calibres for heavy and 50 for light guns is their limit for service length, while Canet's tables give lengths to 60 and even 80 calibres. In one case a Canet gun shows a muzzle velocity of 3281 f.s. This, however, is only a design, not an existing gun. Doubtless it could be achieved, but the question is whether the inconvenience in length does not counterbalance the gain in velocity. The muzzle velocity of French guns generally is higher, and the projectile lighter, than in British and German guns. In many tables the velocities of the French guns are only estimated, as is obvious from the roundness of the numbers when expressed in metres, and in the repetition of the same exact figures for many guns in tables converted into British units. German heavy guns made by Krupp are of about the same length as British pieces of the same calibre, but generally discharge heavier projectiles, the velocity being lower. The following table gives a comparison of the most powerful guns afloat in British, French, and German battleships, an American piece being added :—

Nation.	Calibre in inches.	Weight of Gun in tons.	Length of Bore in calibre.	Weight of Shot in lb.	Muzzle Velocity in ft. sec.	Muzzle Energy in ft. tons.	Energy per Ton of Gun.
British wire	12	46	35·4	850	2367	33,020	718
French .	12	45·9	40	643·8	2625	30,750	670
German .	11·02	43·4	40	562	2362	20,750	501
U.S.A. .	12	45·2	35·0	850	2100	25,985	575

There is a German 12-inch gun, but of an old type, giving inferior results and not mounted in the newest ships, so that the 11-inch is a fairer representative piece. It may be seen here that the British gun hits far the hardest blow and shows the greatest energy per ton. The United States gun most closely resembles it. It may fairly be asked whether the superiority shown in this table is not due to the fact that the British gun is more severely taxed. The reply is, that supposing the pressure to be somewhat greater in the British piece, the wire construction has been found to be considerably stronger than the ordinary steel tube. The weight and length of the piece are also slightly in excess of that of the United States gun. The 100- and 105-ton guns of the Italian navy, like the British 110-ton guns, are not now considered such good weapons as the last 12-inch guns. With regard to the heavy guns of other Powers, no trustworthy data as to the newest Russian guns exist, but their latest battleships carry 12-inch guns, which may be assumed to bear a close resemblance to the above. As wire construction has been adopted, it would be safer to credit Russia with guns of the same power as the British than to guess at a lower standard. The following table shows a comparison of typical British, French, and German guns such as might form the primary armament of armoured cruisers :—

Nation.	Calibre in inches.	Weight of Gun in tons.	Length of Bore in calibres.	Weight of Shot in lb.	Muzzle Velocity in ft. secs.	Muzzle Energy in ft. tons.	Energy per Ton of Gun. ft. tons.	Perforation wrought-iron in ins.		
								At muzzle.	At 2000 yds.	At 3000 yds.
British wire .	9·2	25	40	380	2347	14,520	581	27·6	20·7	18·0
French . .	9·45	22·4	40	317·5	2625	15,170	677	29·4	20·6	17·2
German . .	9·45	25·4	40	474	2067	14,050	553	26·8	20·0	17·7

The velocity of the French gun (800 metres) is doubtless only estimated, nine guns in the table having the same identical round figures. Practically it might probably prove to be somewhat less than here shown. Taking the figures as they stand, the French piece looks best at the muzzle, where its energy is highest, and its energy per ton of gun is nearly 20 per cent. better than the others. At 2000 yards, however, the British gun has passed it in penetration, and at 3000 yards the German also, owing to the resistance of the air telling more on the light projectile. Italian and Japanese guns, being principally supplied by Elswick and Krupp, closely resemble the British and German armaments. In some cases Elswick supplied to Japan rather longer pieces and Q.F. guns of larger calibre than had at that time been adopted in the British service. In short, the newer Japanese ships are likely to be in the very front in power of armament. Austria, Holland, and Denmark have obtained their most powerful and newest guns from Krupp, although the two latter countries have some Elswick guns. The same is generally true of Sweden and Norway, China, and the South American Governments. The latter are chiefly remarkable for cruisers obtained from Elswick, mounting Q.F. batteries of extraordinary power. The energy of fire per minute of the broadside of these cruisers is enormous.

With regard to heavy guns, then, the state of matters may be summed up thus :—The ordnance of foreign Powers closely resembles that of the United Kingdom, the greater number of guns being furnished by Krupp, Elswick, or Canet. New guns differ but slightly in proportions, and therefore when similarly charged deliver similar blows; but experiments indicate that the wire construction adopted in Great Britain, and to some extent in Russia, increases the strength of the piece. Consequently, such guns are capable of delivering harder blows than others when all are worked to the same limit of safety.

Probably the most important guns at the present time for naval warfare are not the heavy primary guns, but the heavier classes of Q.F. guns mounted on broadside or secondary armaments behind medium armour. The reason for this is that the blows delivered by the heavy primary guns are comparatively few, and the light unprotected guns may be too much exposed for them to be manned in close action, while their small destructive capacity limits their scope to unarmoured structures. In the adoption of this important class, *i.e.*, the more powerful Q.F. guns, Great Britain took the lead, the first pieces made at Elswick having been proposed and designed by Sir Andrew Noble. In 1886 Elswick had 30-pounder Q.F. guns. In 1890 Krupp and Gruson, and doubtless Canet, had perfected light Q.F. guns; but the appearance in 1888 of 4·7-inch Q.F. pieces in the armaments of the *Nile* and *Trafalgar*, and of those of 6-inch, discharging 100-℔ shells, in the *Ramillies* class in 1890, marked a great stride in British naval armaments. The French at that time had only small 65-mm. (2·57-inch) Q.F. pieces, discharging a shell weighing 8½ ℔ in the *Carnot*, and Germany had 10·5-cm. pieces in the *Brandenburg* class. Nor was the advantage limited to priority in time. From an early date Elswick guns were laid by sights on the fixed part of the carriage, so that the eye would be right on the sights, undisturbed by the recoil of the gun. This feature, on which special stress was laid some years afterwards in the French parliamentary discussions, was found in very few Q.F. guns even in the Chicago Exhibition in 1893. Now things are greatly changed: Germany shows the entire armaments of her new turret-ships as Q.F. guns, including the 9·4-inch pieces of the turrets; and France shows 6·4-inch Q.F. guns in her new cruisers and battleships. In the British navy some of the features of quick firing are embodied in the heaviest pieces, including the 12-inch, which probably compares well in speed of loading with foreign guns of the same calibre; but quick-firing proper is considered to cease in England when the projectile becomes too heavy for ready manipulation by hand; and this consideration has caused the 6-inch gun Q.F. armament to be retained up to the present time, although Elswick has long advocated the 8-inch embodied in the armaments of Chilian and other cruisers. At the present time a Q.F. gun of about 7·5 inches calibre is likely to be adopted in the British navy. The important matter is the relation of the power of the Q.F. gun to the armour protecting that of the enemy, and, conversely, of the enemy's fire to British protection. So far the advantage on the side of the British armaments has been so marked that it is hardly too much to say that their Q.F. guns are able easily to attack those on nearly all foreign war-vessels with success, while well protected themselves from counter-attack. The official tables of Schneider-Canet Q.F. guns begin at 37-mm. (1·46-inch), and extend up to 24-cm. (9·45-inch). Those of Krupp begin similarly at 37-mm. (1·46-inch) and extend to 30·5-cm. (12·01-inch). In short, all now apply means for increasing the speed of fire to all guns, but their means gradually cease to be applicable as the calibre increases.

Land-Service Guns.—Siege guns in many cases correspond with the heavier Q.F. guns mentioned above, so that the pieces deserving notice are the field guns, including howitzers. The most important feature is the application of quick fire; and as it is necessary for quick laying that the gun should not recoil or depart far from the direction in which the previous round was laid, field guns which are free to move instead of being on fixed mountings require brakes to check their recoil; so that one necessary element in the power of field artillery is an efficient brake. The gun generally has a measure of recoil and recovery provided by means of a recoil cylinder fixed in the carriage, the latter being checked from running back by a spade, rope, or other brake. France up to 1902 kept its newest field equipment secret, but it is known that Q.F. guns exist in some proportion, and the calibre is said to be 2·95 inches. The gun acts on a recoil cylinder on the carriage, and the latter has a strong spade brake fixed on the trail. Germany has completely introduced Q.F. field guns; the gun breech opens to the side on the wedge system. It seems doubtful if it is nearly as quick as some systems. There is no recoil cylinder on the carriage, which is checked by rope and spade brakes. The gun ordinarily fires shrapnel shell, but high explosive shells with a wide-spreading burst are issued, to search behind cover and act as a substitute for a howitzer shell. In Austria the existing field guns have been improved and modified for temporary need, so as to achieve about five rounds per minute; a spade brake is used. Russia has introduced quick fire into her field equipment. The carriage is checked in recoil by a spade brake. There is also a sliding arrangement, and a system of indiarubber pads in the body of the carriage. The gun is kept secret, but is said to fire from four to five rounds a minute. Italy, Spain, and Belgium have experimented with Q.F. guns. (C. O.-B.)

Ordu, the ancient *Cotyora*, a town on the north coast of Asia Minor, between Samsún and Kerasund, connected with Sivas by a carriage road, and with Constantinople and Trebizond by steamer. Population, 5800 (900 Moslems, 3000 Greeks, 1900 Armenians).

Örebro, an ancient town of Sweden, near the west extremity of Lake Hjelmar, 124 miles west of Stockholm by rail. It has a considerable trade in iron by way of the lakes Hjelmar and Mälar. Population (1880), 11,785; (1890), 14,547; (1900), 22,013.

Ore-dressing.—When the miner hoists his ore to the surface, the contained metal may be either in the native uncombined state, or combined with other substances forming minerals of more or less complex composition. In both cases the valuable mineral is always associated with minerals of no value. The province of the ore-dresser is to separate the "values" from the waste by mechanical means, obtaining thereby "concentrates" and "tailings." The province of the metallurgist is to extract the pure metal from the concentrates by chemical means, with or without the aid of heat. There are also a number of non-metallic minerals which do not have any value, or at best do not reach their highest value until they have been subjected to some form of mechanical preparation; among them are diamonds, graphite, corundum, garnet, asbestos, and coal. Ore-dressing, for the purposes of this article, may be divided into three parts: (1) properties of minerals which render aid in their separation; (2) simple operations; (3) operations combined to form processes or mills.

Properties.

(1) The *specific gravity* of minerals varies greatly, some being heavy, others light. The rate of settling in water is affected by the specific gravity in this way: of two particles of the same size but different specific gravity, the heavier settles more rapidly than the lighter, while of two particles of different specific gravity which settle at the same rate in water, that of higher specific gravity is of smaller diameter than the other. The same statements are true in regard to settling in air, and in regard to momentum in air when the particles are thrown out in a horizontal direction. *Colour, lustre, and fracture* are of especial value in hand-picking, to aid the eye in selecting the mineral sought. Instances are, of colours, the white of quartz, the pale straw colour of feldspar, the dull yellow of limonite, the brass yellow of chalcopyrite, the pale metallic yellow of pyrites; of lustres, the vitreous of quartz, the adamantine of diamond and

cerussite, the resinous of blende, the earthy of limonite, and the metallic of pyrite; and of fractures, the cleavage planes of feldspar and galena, the conchoidal fracture of quartz and pyrite, the granular of some forms of magnetite and blende. *Magnetism* is a most direct and simple method of separating minerals where it is available. The discovery that by the use of electro-magnets of great power, minerals formerly regarded as non-magnetic are attracted, has made it possible to separate several classes of minerals present in an ore; for example, the strongly magnetic mineral may first be taken out, then the mildly magnetic, and last the weakly magnetic, the non-magnetic being left behind. *Adhesion* acts when brightly burnished particles of gold issuing with the sand from the stamp mill come in contact with an amalgamated copper plate, for they are instantly plated with mercury and adhere to the copper, while the sand is carried forward by the water. In this way a very perfect separation of the gold from the sand is effected. In the South African diamond fields it has been found that if the diamond-bearing sand is taken in a stream of water over a smooth surface covered with a suitable coating of grease, the diamonds will adhere to the grease while the sand does not. *Decrepitation* is the property possessed by some minerals of flying to pieces when heated suddenly. If, for example, blende and barite occur together in a product where the grains are about the same size, they cannot be separated by water, being of nearly the same specific gravity, but when dropped upon a heated iron plate, the barite flies into small particles, and can then be separated from the blende by sifting. This principle, however, can only rarely be applied.

Simple operations.

(2) The concentration of ores always proceeds by steps or stages. Thus the ore must be crushed before the minerals can be separated, and certain preliminary steps, such as sizing and classifying, must precede the final operations which produce the finished concentrates. The more important of these simple operations will now be described.

The ore as mined contains the valuable minerals attached to and enclosed in lumps of waste rock. The province of *crushing* or disintegrating is to sever or unlock the values from the waste, so that the methods of separation are then able to part the one from the other. In crushing ores it is found wise to progress by stages, coarse crushing being best done by one class of machine, medium by another, and fine by a third. Coarse crushing is accomplished by *breakers* of the Blake type (Fig. 1) or of the Gates Comet type (Fig. 2). All of these machines break by direct pressure, caused by a movable jaw, *a* (Figs. 1, 2), approaching towards and receding from a fixed jaw, *b*. The largest size ever fed to a breaker is 24 inches in diameter, and the smallest size to which the finest crushing commonly done by these machines brings the ore is about $\frac{3}{4}$-inch diameter. The machine is generally supplied with ore in lumps not larger than 9 inches in diameter, and crushes them to about $1\frac{1}{2}$ inch in diameter. Medium-size crushing is done mostly by rolls or steam stamps. *Rolls* (Fig. 3) crush by direct pressure caused by the ore being drawn between two revolving rolls held closely together. They make the least fine slimes or fines to be lost in the subsequent treatment, and are therefore preferred for all brittle minerals. The *steam stamp* works upon the same principle as a steam hammer, the pestle being forced down by steam pressure acting through piston and cylinder with great crushing force in the mortar. Steam stamps have been very successful with the native copper rock, because they break up the little leaves, flakes, and filaments of copper, and render them susceptible of concentration, which rolls do not. Fine crushing is done by gravity stamps, pneumatic stamps, by centrifugal roller mills, by amalgamating pans, by ball mills, by Chile edgestone mills, and by arrastras. The *gravity stamp* (Fig. 4) is a pestle of 800 lb weight more or less, which is lifted by a revolving cam and falls by the force of gravity to strike a heavy blow in the mortar and do the work of crushing; the frequent revolution of the cam gives a more or less rapid succession of blows. Gravity stamps are especially adapted to the fine crushing of gold ores, which they reduce to $\frac{1}{30}$-inch and sometimes even to $\frac{1}{80}$-inch grains. The blow of the stamp upon the fragments of quartz not only liberates the fine particles of gold, but brightens them so that they are quickly caught upon the amalgamated plates. The *pneumatic stamp* has a heavy pestle, which is moved up and down by direct connexion with a crank; but since the height of the ore in the mortar varies, the pestle must have the means also of varying its movement to avoid breakage. To this end an air cylinder with piston is inserted in the stem, the elasticity of the air within the cylinder not only giving the needed variation of throw, but increasing the force of the blow in the mortar. The *centrifugal roller mills* are suited to fine crushing of middle products, namely, by-products composed of grains containing both values and waste, since they avoid making much fine slimes. They crush by the action of a roller, rolling on the inside of a steel ring, both having vertical axes. The *amalgamating pan* is suitable for grinding silver ores for amalgamation where the finest grinding is sought, together with the chemical action from the contact with iron. It crushes by a true grinding action of one surface sliding upon another. The *Chile edgestone mill* is employed for the finest grinding ever used preparatory to concentration. The *arrastra* or drag-stone mill grinds still finer for amalgamating.

A considerable class of workable minerals, among which are surface ores of iron and surface phosphates, contain worthless clay mixed with the valuable material, the removal of which is accomplished by the *log washer*. This is a disintegrator consisting of a long narrow cylinder revolving in a trough which is nearly horizontal. Upon the cylinder are knives or paddles set at an angle, which serve the double purpose of bruising and disintegrating the clay and of conveying the cleaned lump ore to be discharged at the upper end

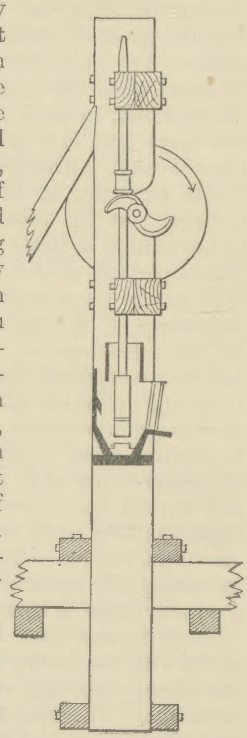

FIG. 4.—Gravity Stamp.

of the trough, the water meanwhile washing away the clay at the lower end.

Roasting for Friability.—When two minerals—for example, pyrites and cassiterite,—one of which is decomposed and rendered porous and friable by heat and oxygen, are roasted in a furnace, the pyrites becomes porous oxide of iron, while the cassiterite is not changed. A gentle crushing and washing operation will then break and float away the lighter iron oxide, leaving the cassiterite behind.

Sizing.—If crushed ore be sifted upon a screen with holes of definite size, two products will result—the oversize which is unable to pass through the screen and the undersize which does pass. If the latter size be sifted upon another screen with smaller holes, it will again make oversize and undersize. Rittinger adopted for close sizing the following diameters in millimetres for the holes in a set of screens: 64, 45·2, 32, 22·6, 16, 11·3, 8, 5·6, 4, 2·8, 2, 1·4, 1. Each of these holes has an area double that of the one next below it; this may be called the screen ratio. A process which does not need such close sizing might use every other screen of the above set, and in extreme cases even every fourth screen. In mills the screen ratio for coarse sizes often differs from that for fine. Sizing is done by cylindrical screens revolving upon their axes (Fig. 5), by flat shaking screens, and by fixed screens with a comparatively steep slope. Wire cloth with square holes and steel plate punched with round holes are both used. To remove the largest lumps in the preliminary sizing fixed-bar screens are preferred, on account of their strength and durability.

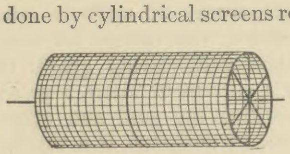

Fig 5.—Trommel or Revolving Screen.

Sizes smaller than can be satisfactorily handled by screens are treated by means of *hydraulic classifiers* and *box classifiers* (*spitzkasten*). The lower limit of screening and therefore the beginning of this work varies from grains of 5 millimetres to grains of 1 millimetre in diameter. A hydraulic classifier (Fig. 6) is a trough-like washer through which the water and sand flow from one end to the other. In the bottom, at regular intervals, are pockets or pits with hydraulic devices which hinder the outflowing discharge of sand, *b*, by an inflowing stream of water, *a*. By regulating the speed of these water currents, the size of the grains in the several discharges can be regulated, the first being the coarsest and the overflow at the end the finest. Box classifiers are similar, except that the pockets are much larger and no inflowing clear water is used; they therefore do their work much less perfectly. Classifiers do not truly size the ore, but merely class together grains which have equal settling power. In any given product, except the first, the grain of high specific gravity will always be smaller than that of low. The box classifiers are suited to treating finer sizes than the hydraulic classifiers, and therefore follow them in the mill treatment.

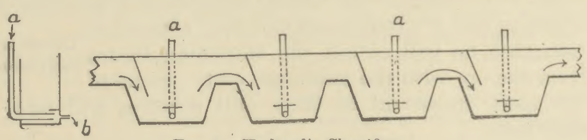

Fig. 6.—Hydraulic Classifier.

Picking floors are areas on which men, boys, or girls pick out valuable mineral which is rich enough to ship at once to the smelter. The picking is often accompanied and aided by breaking with a hammer. *Picking tables* are generally so constructed that the pickers can sit still and have the ore pass before them on a moving surface, such as a revolving circular table or travelling belt. Stationary picking tables require the ore to be wheeled to and dumped in front of the pickers. Picking out the values by hand has the double advantage that it saves the power and time of crushing, and prevents the formation of a good deal of fine slimes which are difficult to save.

Jigs treat ores ranging from $1\frac{1}{2}$ inch in diameter down to $\frac{1}{50}$ inch. If an intermittently pulsating current of water is passed up through a horizontal sieve on which is a bed of ore, the heavy mineral and the quartz quickly form layers, the former beneath the latter. The machine by which this work is done is called a jig (Fig. 7), and the operation is called jigging. The pulsating current is obtained by placing a vertical longitudinal partition, *c*, extending part of the way down to the bottom of the jig box. The sieve *a* is firmly fastened on one side of the partition, and on the other a piston, *d*, is moved rapidly up and down by an eccentric, causing an up-and-down current of water through the sieve *a*. The sieve is fed at one end, *e*, with a constant supply of water and ore, and the quartz overflows at the other. The constantly accumulating bed of concentrates is either discharged through the sieve into the space below, *g*, called the hutch, or by some special device at the side. On jigs where the concentrates pass through the sieve, a bed of heavy mineral grains too large to pass holds back the lighter quartz. The quartz overflow from one sieve, *a*, generally carries too much value to be thrown away, and it is therefore jigged again upon a second sieve, *b*. In jigging difficult ores, three, four, five, and even six sieves are used. A succession of sieves gives a set of products graded both in kind and in richness, the heavier mineral, as galena, coming first, the lighter, as pyrites and blende, coming later. The best jigging is done upon closely sized products using a large amount of hydraulic water added beneath the sieve. Very good jigging may, however, be done upon the products of hydraulic classifiers, where the heavy mineral is in small grains and the quartz is large, by using a bed on the sieve and diminished hydraulic water, which increases the suction or downward pull by the returning plunger.

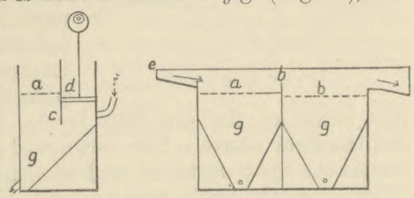

Fig. 7.—Harz Jig.

Bumping Tables.—Rittinger's table is a rectangular gently-sloping plane surface which by a bumping motion throws the heavy particles to one side while the current of water washes down the quartz to another, a wedge-shaped divider separating and guiding the concentrates and tailings into their respective hoppers. The capacity on pulp of $\frac{1}{30}$- to $\frac{1}{50}$-inch size is some 4 tons in twenty-four hours. In the Wilfley table (Fig. 8) and those derived from it a gentler vanning motion is substituted for the harsh bump; they have a greatly increased width and a set of riffle blocks, *b*, at right angles to the direction of flow, *c*, tapering in height towards the side where the concentrates are discharged, *d*. This combination has produced a table of great efficiency and capacity for treating grains from $\frac{1}{8}$ inch in diameter down to $\frac{1}{200}$ inch or even finer. The capacity on $\frac{1}{30}$-inch pulp is from 15 to 25 tons in twenty-four hours.

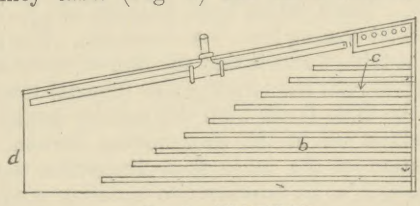

Fig. 8.—Wilfley Table.

Vanners are machines which treat ores on endless belts, generally of rubber with flanges on the two sides. The belt (Fig. 9) travels up a gentle slope, *a*, on horizontal transverse rollers, and is shaken about 200 times a minute, either sidewise or endwise, to the extent of about one inch. The lower 10 feet is called the concentrating plane, *b*, and slopes 2·78 per cent. more or less from the horizontal; the upper 2 feet of length is called the cleaning plane, *c*, and slopes 4·45 per cent. more or less. The ore is fed on with water at the intersection of the two planes, *d*. The vibration separates the ore into layers, the heavy beneath and the light above. The downward flow of the water carries the light waste off and discharges it over the tail roller *e* into the waste launder, while the upward travel of the belt carries up the heavy mineral. On the cleaning plane the latter passes under a row of jets, *f*, of clean water, which remove the last of the waste rock; it clings to the belt while it passes over the head roller, and only leaves it when the belt is forced by the dipping roller to dip in the water of the concentrates tank *g*. The cleaned belt then continues its return journey over the guide roller *h* to the tail roller *e*, which it passes round, and again does concentration duty. Experience proves that for exceedingly fine ores the end shake with steep slope and rapid travel does better work than the side-shake vanner. For ordinary gold stamp-mill pulp, where cleanness of tailings is the most important end, and where to gain it the engineer is willing to throw a little quartz into the heads, the end-shake vanner is again probably a little better than the side shake, but where cleanness of concentrates is sought the side-shake vanner is the most satisfactory.

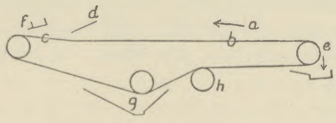

Fig. 9.—Frue Vanner.

Slime-tables are circular revolving tables (Fig. 10) with flattened conical surfaces, and a slope of $1\frac{1}{8}$ inch more or less per foot from centre to circumference; a common size is 17 feet in diameter, and a common speed one revolution per minute. These tables treat material of $\frac{1}{100}$ inch and less in diameter coming from box classifiers. The principle on which the table works is that the film of water upon the smooth surface rolls the larger grains (quartz) towards the margin of the table faster than the smaller grains (heavy mineral) which are in the slow-moving bottom current. The revolution of the table then discharges the quartz earlier at *a*, *a*, *a*, *a*, an intermediate middling product next at *b*, and the heavy mineral last at *c*. Suitable waste-launders and catch-boxes are supplied for the three products. The capacity of such a table is 12 tons or more of pulp, dry weight, in twenty-four hours. *Frames* are rectangular slime-tables which separate the waste from the concentrates on the same principle as the circular tables, though they run intermittently. They treat very fine pulp, and after being fed for a short period (about fifteen minutes) the pulp is shut off, the concentrates are flushed off with a douche of water and caught in a box, and the feed pulp is again turned on. They are much used in the Cornish tin works. *Canvas tables* are rectangular tables with plane surfaces covered with cotton duck (canvas) free from seams; they slope about $1\frac{1}{2}$ inch to the foot. They are fed with stamp-mill pulp, with the tailings of vanners, or, best of all, with very fine pulp overflowing from a fine classifier. The rough surface of the duck is such an efficient catching surface that they can run for an hour before the concentrates are removed—an operation which is effected by shutting off the feed pulp, rinsing the surface with a little clean water, and hosing or brooming off the concentrates into a catch-box. The feed-pulp is then again turned on and the work resumed. They have been more successful than any other machine in treating the finest pulp, especially when their concentrates are finally cleaned on a steep slope end-shake vanner.

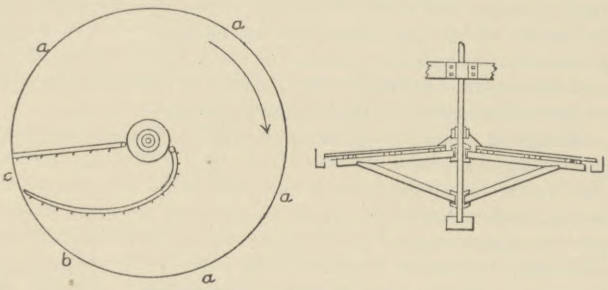

Fig. 10.—Convex Revolving Slime-table.

Buddles act in principle like slime-tables, but they are stationary, and they allow the sand to build itself up upon the conical surface, which is surrounded by a retaining wall. When charged, the tailings are shovelled from the outer part of the circle, the middlings from the intervening annular part, and the concentrates from the inner part. They treat somewhat coarser sizes than the slime-table. When wooden blocks or cobble-stones of uniform size are placed in the bottom of a sluice, the spaces between them are called *riffles*; and when gold-bearing gravel is carried through the sluice by a current of water, a great many eddies are produced, in which the gold and other heavy minerals settle. The *kieve* or *dolly-tub* is a tub as large or larger than an ordinary oil barrel, with sides flaring slightly upwards all the way from the bottom. In the centre is a little vertical shaft, with hand-crank at the top and stirring blades like those of a propeller at the bottom. Fine concentrates from buddles or slime-tables are still further enriched by treatment in the kieve. The kieve is filled perhaps half full of water, and the paddles set in motion; concentrates are now shovelled in until it is nearly full, the rotation is continued a little longer, and then the shaft is quickly withdrawn and the side of the kieve steadily thumped by a bumping-bar as long as settling continues. When this is completed, the water is syphoned off, the top sand skimmed off and sent back to the buddle, and the enriched bottom material shovelled out and sent to the smelter.

Combined operations.

(3) In designing concentration works, the millwright seeks so to combine the various methods of coarse and fine crushing and of preliminary and final concentration that he will obtain the maximum return from the ore with the minimum cost. Some of the more important of these mill schemes will now be described.

The *hand-jig process* used for the *zinc and lead* ores of Missouri is first to clean the ore from adhering clay by raking it back and forth in a sluice with a running stream of water, and then shovel it upon a sloping screen with holes of about one inch, where it yields oversize and undersize. The former is hand-picked into lead ore, zinc ore, and waste, while the latter is jigged upon a hand-jig and yields several layers of minerals removed by a hand-skimmer. The top skimmings are waste, the middle skimmings come back with the next charge to be jigged over, and the bottom skimmings go to a second jig with finer screen. The coarsest of the hutch product goes to the second jig, the finest is sold to a sludge mill. The second jig makes top skimmings which are sent back to the first jig, middle skimmings which are zinc concentrates, and bottom skimmings and hutch, which are both lead concentrates.

In the *Missouri zinc-concentrating mill* the ore carrying blende and calamine with a little galena is in very large crystallizations and contains, when crushed, very little in the way of included grains. It is crushed by Blake breaker and rolls, to pass through a sieve with holes $\frac{3}{4}$ inch in diameter, and is then treated on a jig with six consecutive sieves, yielding discharge and hutch products from each sieve, and tailings to waste. The earlier discharges are finished products, while the later are re-crushed and re-treated on the same jig. The hutch products are treated on a finishing-jig with five sieves, and yield galena from the first discharge and hutch, and zinc ore from the others. The capacity of such jigs is very large, even to 75 or 100 tons per day of ten hours.

In the *diamond washing* of Kimberley, South Africa, the material taken from the mine is weathered by exposure to the air and rain for several months, and the softening and disintegration thus well started are completed by stirring in vats with water. Breaker and rolls were tried in order to hasten the process, but the larger diamonds were broken and ruined thereby. The material from the vats is screened and jigged, and of the jig concentrates containing about 2 per cent. of diamonds the coarser are hand-picked and the finer are treated on a greased surface.

Lead and copper ores contain their values in brittle minerals, and are concentrated in mills which vary somewhat according to local conditions; the one here outlined is typical of the class. The ore is crushed by breaker and rolls, and separated into a series of products diminishing in size by a set of screens, hydraulic classifier, and box classifier. All the products of screens and hydraulic classifiers are jigged on separate jigs yielding concentrates, middlings, and tailings; those of the box classifier are treated on the slime-table, vanner, or Wilfley table, yielding concentrates and tailings and perhaps middlings. The coarser middlings contain values attached to grains of quartz and are therefore sent back to be re-crushed and re-treated. The finer middlings contain values difficult to save from their shape only, and are sent back to the same machine or to another to be finished.

The *native copper rock of Lake Superior* is broken by powerful breakers, sometimes preceded by a heavy drop-hammer weighing nearly a ton. The operation is accompanied by hand-picking, yielding rich nuggets with perhaps 75 per cent. of copper ready for the smelter; at some mines a second grade is also picked out which goes to a steam finishing-hammer and yields cleaned mass copper for the smelter and rich stamp stuff. The run of rock which passes by the hand-pickers is of a size that will pass through bars 3 inches apart, and goes to the steam stamps. The stamps crush the rock to pass through a screen with round holes $\frac{3}{16}$ inch in diameter. This sand is treated in hydraulic classifiers with four pockets, the products from the pockets being jigged by four roughing-jigs yielding finished mineral copper for the smelter, included grains for the grinder, partially concentrated products for the finishing-jigs, and tailings which go to waste. The overflow of the hydraulic classifier runs to a tank of which the overflow is sent to waste in order to diminish the quantity of water, while the discharge from beneath, treated upon slime-tables, yields concentrates, middlings, and tailings. The middlings are re-treated. The stamp mortars are cleaned out periodically, even several times a day, and yield rich nuggets of copper and unfinished material which is sent back to the mill. Putting all the finished concentrates together, they will assay from 60 to 80 per cent. of copper according to circumstances. The extraction from the rock is from 50 to 80 per cent. of the copper contained in it.

Cornwall Tin.—Tinstone in Cornwall occurs associated with sulphides, wolfram, quartz, feldspar, slate, &c., and is broken by spalling-hammers to 3-inch lumps. Hammers make less slimes than the rock-breakers, and they also break the ore more advantageously for the hand-picking. The latter rejects waste, removes as far as possible the hurtful wolfram, and classes the values into groups according to richness. Gravity or pneumatic stamps then crush the ore to $\frac{1}{50}$ inch, and stripes (a species of long rectangular buddle) yield heads, middlings, tailings, and fine slimes: the first three are sent separately to circular buddles, and the last to frames. The buddles yield heads, middlings, and tailings: the middlings are re-treated, the tailings are all waste; the heads are still further enriched by kieves, which yield tops to the buddle again and bottoms shipped to the smelter. The fine slimes are treated on frames, the concentrates of which go to buddles; of these the heads go to kieves.

The *Missouri zinc-lead sludge mill* takes the finest part of the hutch product of the hand-jigs. The treatment begins on revolving screens with two sizes of holes, 25 mm. and 1 mm.: these take out two coarser sizes, of which the coarser is waste and the other is jigged, yielding concentrates and waste. The main treatment begins with the finest size, which is much the largest product. It is fed to a convex circular buddle (first buddle), and yields a coarser product at the outer part of the circle and a finer product in the inner. The finer product is treated by a series of buddlings which vary somewhat, but in general are as follows: fed to a second buddle it yields zinc and lead ore in the centre, next zinc ore, next middlings which come back, and, outside of all, tailings. The zinc-lead ore is set on one side until enough has accumulated to make a buddle run, when it is run upon a third buddle yielding in the central part pure lead concentrates, next lead ore (which is returned to this treatment), next zinc ore, and outside of all a zinc product which is fed to the second buddle. The coarse outside product of the first buddle is treated in much the same way as the fine, but it yields practically no lead zinc product, which simplifies the series of buddlings necessary.

Gold Mill.—Gold ores usually contain their value in two conditions—the free gold, which can be taken out by mercury, and the combined gold, in which the metal is either coated with or combined with compounds of sulphur, tellurium, &c. The usual gold-milling scheme is to crush the ore by rock-breaker to about $1\frac{1}{2}$ inch diameter, and then to crush with water by gravity stamps, a little mercury being added to the mortar from time to time to begin the amalgamation at the first moment the gold is liberated. The pulp leaves the mortar through a screen with holes or slots $\frac{1}{30}$ to $\frac{1}{60}$ inch in width, and is then passed over amalgamated plates of copper or silver-plated copper. The free gold, amalgamated by the mercury, adheres to the mercurial surface on the plate; the rest of the pulp flows on through mercury traps to catch any of the mercury, which drains off the end of the plate. The plates and mortar are periodically cleaned up, the plates being scraped to recover the amalgam and leave them in good condition to do their work: if plates are used inside the mortar, they are cleaned in the same way. The residue of partly crushed ore in the mortar, with amalgam and free mercury scattered through it, is ground for a time in a ball mill, panned to recover the amalgam, and returned to the mortar. The pulp flowing away from the mercury traps flows to a Frue vanner or Wilfley table, on which it yields concentrates for the chlorination plant or smelter, and tailings: these are waste when the heavy mineral is of low grade, but if the vanner concentrates are of high grade, they still contain values in very fine sizes which can and should be saved. Recent improvements in California for saving this material have been made. The vanner tailings are sent to a fine classifier, from which the light overflow only is saved; this is treated upon canvas tables yielding concentrates and tailings, and these concentrates, treated upon a little end-shake vanner with steep slope and rapid travel, give clean, very fine, high-grade concentrates for the chlorination works.

Iron Ores.—The brown ores of iron from surface deposits are contaminated with a considerable amount of clay and some quartz. The crude ore from surface pits or shallow underground workings is treated in a log washer and yields the fine clay, which runs to waste, and the coarse material which is caught upon a screen and hand-picked, to free it from the little quartz, or jigged if it contains too much quartz. The magnetic oxide of iron occurs associated with feldspar and quartz, and can often be separated from them by the magnet. The ore, after being broken by breaker and rolls to a size varying from $\frac{1}{4}$ to $\frac{1}{16}$ of an inch in diameter, goes to a magnetic machine which yields (1) the strongly magnetic, (2) the weakly magnetic, and (3) the non-magnetic portions. The second or middlings product contains grains of magnetite attached to quartz, and is therefore re-crushed and sent back to the magnets; the strongly magnetic portion is shipped to the furnace; and the waste to the dump heap. In concentrating certain zinc sulphides, siderite (carbonate of iron) follows the zinc, and would seriously injure the furnace work. By a carefully adjusted roasting of the product in a furnace the siderite is converted into magnetic oxide of iron, and can then be separated from the zinc ore. A special magnet of very high power has been designed for treating the franklinite of New Jersey, a mineral which is non-magnetic in the usual machines. The ore, crushed by breaker and rolls and hand-picked to remove garnet, is treated upon a belt with a roughing magnet to take out the most magnetic portion, and then very closely sized by screens with 16, 24, 30, and 50 meshes per linear inch. The several products are treated each on its own magnetic machine, yielding the franklinite for the zinc oxide grates, and followed by spiegel furnace; the residue, which is jigged, yields the zinc silicate and oxide for the smelter furnaces, and waste carrying the calcite quartz and mica.

Gold dredging is the method employed for saving the values from gold-bearing sand and gravel in river bottoms. A flat boat is built, provided with guy-ropes or spuds, or both, for holding it still. The spuds are vertical posts or legs which can be forced down by powerful tackles through sockets in the boat, and so lift it as it were upon legs. At one end of the boat is a powerful endless-chain bucket-dredge, which scrapes the gravel from the bottom and elevates it to a revolving screen in the boat. This in turn sifts out the boulders, which are at once elevated to the bank of the river, while the fine material flows over tables covered with cocoa matting which acts like fine riffles, catching the gold in the interstices. The matting is periodically lifted up and thoroughly rinsed off, the rinsings are panned for gold, and the matting returned for another charge. The fine sand and gravel passing over the end of the tables is sent by the elevator to the river bank.

Asbestos, when of good quality, is in compact masses, which by suitable bruising and beating are resolved into fine flexible fibres. The Canadian asbestos is associated with serpentine, and is crushed by breakers to $\frac{3}{4}$ inch, screened on $\frac{1}{16}$-inch screens to reject fines. The values are removed by hand-picking and are crushed by rolls carefully set so as not to break the fibre; this product is then sized by screens and the various sizes are sent to the Cyclone pulverizer, which by beating liberates the individual fibres. It then goes to a screen with eleven holes to the linear inch, and yields a granular undersize and oversize, and a fibrous oversize which is drawn off by a suction fan to a settling-chamber with air outlets covered by fine screen cloth. This fibrous product is the clean mineral for the market. A special treatment separates the fibres of different lengths.

The usual method of dressing *corundum and emery*, after the preliminary breaking, is to treat the material in an edge-stone mill fitted with light wooden rollers. The action is that of grinding one particle against another, whereby the talc, chlorite, mica, &c., are worn off from the harder mineral. A constant current of water carries off the light impurities. This is called the "muller" process. At Corundum Hill, North Carolina, the first step in removing the impurities from "sand" corundum is to subject it to the scouring action of a stream of water while it is being sluiced from the mine to the mill, the action being increased by several vertical drops of 5 to 10 feet in the sluice. After reaching the mill all that will not pass through a 14-mesh screen is crushed by rolls, and the undersize of the screen is treated in a washing trough; this removes part of the light waste, and the "mullers" mentioned above complete the cleaning.

Graphite occurs in schist, but being of less specific gravity than the other minerals which enter into the composition of the schist, it settles later than they do. It also breaks into thin scales, which reduces its settling rate still further. The ore is broken by breakers, and by Chile edge-stone mills or by gravity stamps, to a size varying with the character of the minerals from perhaps $\frac{1}{20}$ to $\frac{1}{80}$ inch diameter. The pulp is then conveyed through a series of settling tanks of which the later are larger than the earlier. The quartz and other waste minerals settle in the earlier tanks, while the graphite settles later: the latest tank gives the best graphite. In the Dixon Company's works in New York some forms of concentrators are believed to have replaced the slower settling tanks.

Gold Hydraulicking.—The gold contained in surface gravel deposits is saved by one of the several schemes included in hydraulicking. A source of water power with very high head furnishes the water to a powerful jet called a "giant"; this washes down the gravel bank and conveys the coarse and fine material first to a head-sluice with riffles, which may be one hundred feet or more long, and then to a tail sluice, also with riffles, which may be several miles long. Periodically, once a month perhaps, the head-sluice is cleaned up, the riffle-blocks being removed and cleaned, and the sand which is washed down and caught in a temporary tank at the foot panned for its gold with hand-pans. The riffle-blocks are then replaced and work proceeds as before. At the end of the season the long tail-sluice also is cleaned up in the same way. Gravel containing 5 cents a cubic yard has in places paid well.

The *phosphates* of Florida are of four kinds: hard rock, soft rock, land pebble, and river pebble. The hard rock is crushed by toothed rolls, and cleaned in log washers. The washed product is screened; the sizes finer than $\frac{1}{16}$ inch are thrown away because too poor; the other sizes are dried and sold, some waste having been picked out of the coarsest. The soft rock is simply dried, ground, and sold. Land pebble is treated by log washers, any clay balls remaining being removed by a screen, and the phosphate dried and sold. In special cases land pebble is treated by hydraulicking, followed by a log washer, and this again by a powerful jet washer, to remove the last of the clay. River pebble is taken from the river by centrifugal pumps, and screened on two screens with 1-inch and $\frac{1}{16}$-inch holes respectively; the oversize of the first sieve and the undersize of the second sieve are thrown away because of too low grade. (R. H. R.)

Oregon, one of the north-western states of the American Union, situated on the Pacific coast, bounded on the N. by the state of Washington, on the E. by the state of Idaho, on the S. by the states of California and Nevada, and on the W. by the Pacific Ocean.

Population.—In 1880 the population was 174,768; in 1890 it had risen to 313,767, and in 1900 to 413,536, giving a density per square mile of 4·4 in 1900, as compared with 3·3 in 1890. The population was classified in 1900 as follows: males, 232,985; females, 180,551; native-born, 347,788; foreign-born, 65,748 (white, 394,582; negro, 1105; Chinese, 10,397; Japanese, 2501). Of the 116 incorporated cities, towns, and villages, twelve had a population of over 2000, but only three had over 5000, namely, Portland, one of the most important towns on the Pacific coast, with 90,426; Astoria, with 8381; and Baker City, with 6663 inhabitants. The urban population was 23·9 per cent. of the total. The school population (from 4 to 20 years) was, in 1890, 99,543; and in 1899, 133,181. The total land surface is approximately 94,560 square miles.

Agriculture.—Of farm products there were raised in 1899 21,949,536 bushels of wheat, of the value of $11,633,254; 1,255,264 tons of hay, of the value of $8,598,555, and 14,400,000 ℔ of hops. Other farm products included barley, corn, rye, buckwheat, and potatoes. The total farm and orchard products for the year amounted to $45,530,737, including 10,999,251 ℔ of butter, of the value of $3,024,508. The wool crop was 18,028,776 ℔. On 1st January 1900 there were in the state 189,427 horses and mules, valued at $5,727,164; 637,433 cattle, valued at $15,776,411; 2,446,695 sheep, valued at $6,532,676; and 87,532 swine, valued at $700,256.

Lumber.—The manufacture of lumber in 1900 amounted to 776,978,000 feet board measure, exclusive of custom sawing, as compared with 470,146,000 feet in 1890. The total number of wage-earners employed in this industry in 1900 was 4084, and the lumber products were valued at $10,352,167. The standing timber in the state, as appears from a survey made by the general Government in 1899, reaches a total of 234,653,000,000 feet board measure, and consists mainly of the Douglas fir, known in the lumber trade as the Oregon pine. The Bull Run national forest reserve, from which the city of Portland obtains its water-supply, consisting of 142,080 acres, and the Cascade national forest reserve, consisting of 4,492,800 acres, are contiguous, and constitute the largest forest reserve in the United States. Besides these there is the Ashland reserve.

Fish Canning and Preserving.—This is one of the most important industries in the state. The methods employed in taking fish tend to exhaust the fisheries and lessen the catch. The product of the Columbia river for 1895, as shown by the report of the United States Fish Commission, exceeded in value that of any other river in the world. The use of refrigerator cars has resulted in large annual shipments of fresh fish from Portland to the Eastern states and Europe, and this has lessened the canned product, the value of which in 1900 was $1,788,809.

Mining.—Gold mining has largely increased, the estimated output for 1900 exceeding $5,000,000 in value. The most productive gold-fields are in the counties of Baker and Grant. There is a constantly growing yield of gold from the mines of southern Oregon, and from the recently developed district in Lane county known as the Bohemia.

Manufacturing.—The following table shows the manufacturing and mechanical industries as returned at the censuses of 1890 and 1900, and the percentage of increase for the decade:—

	1890.	1900.	Percentage of Increase.
Number of establishments	1,523	3,088	102·8
Capital	$32,122,051	$33,422,393	4·0
Wage-earners, average number	16,760	17,236	2·8
Total wages	$9,559,734	$8,333,433	12·8 [1]
Cost of material used	$21,793,578	$26,099,855	19·8
Value of products	$41,432,174	$46,000,587	11·0

Those of most importance are lumber and timber products, flouring and grist mill products, canning and preserving fish, and slaughtering and meat-packing. A beet-sugar factory, in operation in the eastern part of the state, employed in 1899 between 130 and 140 employés. It cut during that season 11,295 tons of beets, and manufactured 2,200,000 ℔ of sugar. The product of the paper and pulp industry of the state for 1900 was of the value of $856,646. There were five manufactories, employing 716 wage-earners, engaged in this industry, and the capital invested was $2,161,186.

Railways and Commerce.—The Oregon Railway and Navigation Company owns and works 1130 miles of railway, including extensions of branch lines into portions of the state of Washington. It is the connecting line for two of the transcontinental railways of the state—the Union Pacific and its allied line, the Oregon Short Line, with which it connects at the eastern boundary of the state, and the Great Northern Railway, with which it connects at Spokane, in the state of Washington. It works river steamers on the Columbia and lower Willamette and Snake rivers, and a line of ocean steamships between Portland and San Francisco. The Southern Pacific Railway works 655·76 miles in the state; the Corvallis and Eastern, 142 miles; and the Astoria and Columbia River, 82½ miles.

In 1899 the foreign commerce was $10,639,068, of which $1,522,095 consisted of imports. Wheat shipments from the port

[1] Decrease.

of Portland were 12,431,807 bushels, of which 8,946,335 were shipped to Europe and Africa.

Banks.—Individual deposits in the national banks of the state during 1899 reached $11,781,130, and the bank clearings for the same year were $91,652,230. There are no statistics of the business done by private banks, of which there is a large number.

State Finances.—The state has no debt. The value of taxable property in 1898 was $133,533,577, and the rate of levy $5\frac{7}{10}$ mills. The revenue raised was $761,141. The lowest rate of levy was 3 mills, in 1894; the highest, 7 mills, in 1892. The average rate for twelve years ending with 1898 was 4·73 mills.

Education.—The cost of public education in 1880 was $339,080; in 1890, $1,062,890; and in 1899, $1,327,781. The average annual expenditure of public funds on this account for ten years ending with 1899 was $1,267,321. The state maintains a university, an agricultural college, and four normal schools. The two former have endowments from the sale of public lands granted to the state for these objects by Congress. The university has a further endowment of $50,000 derived from a private source. All are supported by liberal appropriations of public money by the Legislature. The general faculty of the university, including lecturers in the schools of law and medicine, consists of the president and fifty-three professors, instructors, and assistants. The number of students in 1899–1900 was 320. The agricultural college has, in common with such colleges in all the states, and in addition to the funds derived from the state grant and appropriations, endowments from the general Government of $25,000 annually for the benefit of agriculture and the mechanic arts, and $15,000 annually for an agricultural experiment station in connexion with the college. The object of the college, in its general scope, is "to promote the liberal and practical education of the industrial classes" by teaching such branches as are related to agriculture and the mechanic arts, and including military tactics. The endowments permit scientific and classical studies. The faculty of instructors consists of a president and twenty-eight professors, assistants, and instructors. The enrolment of students for 1888–89 was 151, and for 1899–1900, 405.

Charitable and Penal Institutions.—The state maintains at Salem, the capital, an asylum for the insane, a penitentiary, and a reform school. The insane asylum had 628 inmates in 1891 and 1160 in 1899. The penitentiary had 324 inmates in 1891 and 322 in 1899. The reform school had 99 inmates in 1899. The state also maintains separate schools for deaf mutes and for the blind, and also makes liberal appropriations for various "homes" and societies, organized as private charities.

Religion.—In 1890 the state had 969 religious organizations, with an aggregate of 70,524 members. The total value of church property was $2,829,150. In respect of numbers the principal denominations rank in the following order: Roman Catholic, Methodist, Baptist, Presbyterian, Congregational, Episcopalian.

Constitutional Changes: Politics.—There is a strong conservative tendency in the state. Constitutional amendments submitted to popular vote from time to time, since the admission of the state into the Union in 1859, have uniformly been defeated; among them an amendment repealing an obsolete provision to exclude free negroes from the state. The election of 1900, however, showed a growing sentiment in favour of woman suffrage. When the woman suffrage amendment was first submitted in 1884, it was defeated by a large majority. The vote in 1900 upon the same amendment stood, for the amendment, 26,265, against 28,402. The Republican party is dominant. In 1896, with three opposition candidates for Congress in one district and four in the other, its plurality was 441, while the combined opposition vote was 25,510 greater than the Republican vote. This result was due in large part to the equivocal position of the party in that year on the money question, and the nomination in consequence of a distinctively gold standard candidate for Congress in the largest district. In 1900 the Republican candidates for Congress had a plurality in the state of 12,407 votes, and a majority over the combined vote of three opposition parties of 3670. (C. B. B*.)

Oregon City, a city of Oregon, U.S.A., capital of Clackamas county, on the Willamette river, at the falls, and on the Southern Pacific Railway, 12 miles south of Portland, in the north-western part of the state, at an altitude of 100 feet. Fine water-power is afforded by the falls, 40 feet high, which is utilized in lumber, flour, paper, and pulp mills. The surplus power from the falls is wired to neighbouring cities for manufacturing, transportation, and lighting purposes. Population (1880), 1263; (1890), 3062; (1900), 3494, of whom 535 were foreign-born.

Orel, a government of Middle Russia, bounded by Kaluga and Tula on the N., Voronezh and Tamboff on the E., Kursk on the S., Tchernigoff and Smolensk on the W. Its area covers 18,040 square miles. Beside the Jurassic clays (Oxford and Kellowey), which were known to cover the Devonian deposits, Cretaceous deposits were found to have a wide extension. They consist of marls, white chalk, sandy chalk, phosphorite sands, very rich in fossils, and white and yellow sands and sandstones. Tertiary sands, sandstones, and glauconite clays are found in the south-west. Loess has a wide development.

In January 1897 the population reached 2,054,749, of whom 1,052,765 were women, and 228,618 lived in towns. The area under culture has slightly increased, from 59 per cent. of the total surface to 62 per cent., and the average annual crops of 1894–99 were: rye, 9,623,000 cwts.; wheat, 768,000; oats, 5,912,000; all cereals, 17,753,000 cwts. The eastern black-earth districts grow enough of their own crops for the whole year; to the others grain has to be imported. There were, in 1897, 427,410 horses, 243,370 cattle, 639,880 sheep, and 153,270 swine. Industrial activity is on the increase, and the aggregate return of all the 8537 large and small factories attained £1,569,800. The government is divided into twelve districts, of which the chief towns and their population in 1897 are: Orel, capital of the government (69,858), Bolkhoff (20,703), Bryansk (23,520), Dmitrovsk (5259), Elets (37,455), Karacheff (15,605), Kromy (5429), Livny (20,574), Maloarkhangelsk (7799), Mtsensk (9355), Sevsk (9167), and Trubchevsk (6899).

Orenburg, a province of East Russia, in the southern Urals, bounded by Ufa and Perm on the N., by Tobolsk on the E., by Turgai on the S.E., by Uralsk and Samara on the W. It has an area of 73,816 square miles. Its population has nearly doubled since 1860, and was 1,609,388 in 1897, of whom 149,373 lived in towns. It is rich in various minerals: gold, copper, and iron ore, rock and lake salt, semi-precious stones, sandstones, &c. Traces of coal have been discovered. Gold is extracted chiefly from alluvial deposits, about 116,400 oz. every year; as also some silver, 2160 oz. Nearly one-fifth of all the copper ore extracted in Russia comes from Orenburg (about 16,000 tons annually). Iron ores, including magnetic ore, exist in large quantities, and every year 16,000 to 20,000 tons of cast iron and 11,500 tons of iron are obtained. Coal has also been found on the Mias and near Iletsk. The extremely rich layers of rock salt at Iletsk yield about 24,000 tons of salt every year. Owing to the fertility of the soil, agriculture is carried on on a large scale; in an average year nearly 6,000,000 cwts. of grain—chiefly wheat and oats—are available for export. The annual average of the crops for 1894–99 was: wheat, 7,309,300 cwts.; rye, 1,362,000; oats, 3,117,000; all cereals, 12,999,000 cwts. Kitchen-gardening is carried on on a large scale, and gives occupation to nearly 11,000 persons. Cattle-breeding is conducted on an extensive scale by both Russians and Bashkirs, there being in 1895, 531,000 horses, 509,800 horned cattle, and 730,000 sheep. Various kinds of animal produce are largely exported, and by knitting "Orenburg shawls" of goat's wool the women earn £10,000 every year. The growth of the industries is slow, but trade, especially with the Kirghiz, is prosperous, and the annual returns of the Orenburg and Troitsk markets are estimated at £700,000. The chief towns of the five districts into which the government is divided are: Orenburg, Orsk (14,036), Tchelyabinsk (19,891), Troitsk (23,128), and Verkhneuralsk (11,802).

Orenburg, capital of the above government, on the Ural river, and connected by rail with Samara (262 miles). It is a large city, and had in 1897 a population of 72,740 (34,927 women), of whom about 30 per cent. were Tatars, Jews, Bashkirs, &c. The fortress has lost its former importance. A "Barter House," one mile from the town, has been built in the shape of a fort. The importance of Orenburg as a centre of trade with central Asia has decreased since the opening of the Transcaspian Railway; but, on the other hand, it has become an important centre for the export of horses, cattle, and meat to markets in the interior of Russia. From 20,000 to 100,000 horses, 40,000 to 160,000 cattle, and 450,000 to 750,000 sheep are sold every year at the Barter House. Formerly most of these were sent alive to Russia; now, from 50,000 to 60,000 head of cattle and sheep are killed every year at the municipal slaughter-houses, and 150,000 sheep in private *abattoirs*, the whole being exported in cold-storage waggons. Cattle are also bought by wandering merchants in the Steppe provinces and Turkestan. Every year from 8950 to 23,500 tons of frozen meat, tallow, hams, sausages, butter, cheese, and game are exported by rail to Samara. Besides these, nearly a million of hides and sheep-skins, goat and astrakhan skins, as well as wool, horse hair, bristle, down, horns, bones, &c., are exported. There are gymnasia for boys and for girls, two cadet corps, one theological seminary, seminaries for Russian and Kirghiz teachers, a museum, a theatre, branches of the Russian Geographical Society and the Gardening Society, a military arsenal, and a custom-house.

Orense, an inland province in the north-west of Spain. Its area is 2738 square miles, and it is divided into 11 administrative districts and 97 parishes. Population, 388,835 in 1877, and 402,873 in 1897. The birth-rate is 3·13 per cent., the death-rate 2·93, and the proportion of illegitimate births 6·07 per cent. of the total births. The climate is very varied, mild in some valleys, cold and damp in the highlands, rainy near the northern border, and subject to rapid changes of temperature. The railway from Monforte to Vigo runs through the province, but the means of communication are very crude. The provincial industries are in a backward condition. There are a few iron foundries of a primitive sort, but lack of transport and of cheap coal hinder the growth of mining and manufactures.

Though the soil is fertile and well watered, agricultural products are not so important as arboriculture. The oak, beech, pine, chestnut, walnut, and plane grow in abundance on the hills and mountains; pears, apples, cherries, almonds, figs, roses, olives, and the laurel in the valleys, and even oranges and lemons in sheltered spots like Ribadavia. In 1897 the vine was grown on 29,760 acres, wheat on 3972, and a large area was devoted to pod-fruit, rye, and oats. The live stock included 3716 horses, 2463 mules, 5443 asses, 35,958 cattle, 105,303 sheep, 31,487 goats, and 72,227 pigs.

Orense, the capital of the above province, stands on the left bank of the Miño, and on the railway from Monforte to Juy and Portugal. It has a theatre, primary schools, and an institute, seminary, training schools for teachers of both sexes, and public libraries. In the older streets some residences of the nobility are good specimens of mediæval architecture. Population (1887), 14,168; (1897), 15,250.

Orghyeeff, a district town of Russia, in the province of Bessarabia, 28 miles north of Kishineff railway station. It stands on the seat of an old Dacian fortress, Petrodava, or Orhei, of which the ruins still exist. Population (1897), 13,356, chiefly Russian, but containing also Armenians, Jews, and Germans. It was annexed to Russia in 1812.

Oriente, or LA REGION ORIENTALE, a vast undefined territory belonging to the republic of Ecuador, comprising the whole eastern part of the republic. It was formed in 1884 of the older territories of Napo, Canelos, and Zamora. The boundaries have still to be settled by treaties with the coterminous republics. Its southern boundary is the Marañon river from its source to its mouth. Its eastern boundary runs along the 70° of W. long. Its northern boundary is a conventional line nearly parallel to the course of the Rio Putumayo. The population of El Oriente, nearly entirely composed of wild Indian tribes, was estimated in 1887 to be about 80,000.

Orihuela, a town of Spain, province of Alicante, on the river Segura, which divides the city into two parts, Roig and San Augustus, connected by two bridges. There has been progress in agriculture, and in the manufactures of silk, linen, wool, leather, and starch, and tanning. The streets have been improved and many public buildings restored. Population (1887), 24,364; (1897), 26,951.

Orillia, a town and port of entry of Simcoe county, Ontario, Canada, situated 64 miles north of Toronto, on Lake Couchiching and on the Grand Trunk Railway. It is a favourite summer resort, and has steamboat communication with other ports on Lakes Simcoe and Couchiching. It contains an asylum maintained by the provincial government, also saw and grist mills and iron foundries. Population (1881), 2910; (1891), 4752; (1901), 4907.

Orinoco, The, a river in the north of South America, falling north-east into the Atlantic between 60° 20′ and 62° 30′ W. It is approximately 1500 miles long, but it is several hundred miles longer if measured by its Guaviare branch. Lying south and east of the main river is a vast, densely forested region called Venezuelan Guiana, diversified by ranges of low mountains, irregular broken ridges and granitic masses, which define the courses of many unexplored tributaries of the Orinoco. The upper part of the river was ascended in 1857 by Michelena y Rojas to the Mawaca, a point about 170 miles above the northern entrance to the Casiquiare canal, and then a few miles up the Mawaca. A little knowledge about its sources above these points was given by the savages to de la Fuente in 1759 and to Mendoza in 1764, and we are also indebted to Humboldt for some vague data.

Physical features.

The principal affluent of the Orinoco from the Guiana district is the *Ventuari*, the head-waters of which are also unknown. It is an important stream, which, running south-west, joins the Orinoco about 90 miles above its Guaviare branch. Two other large tributaries of the Orinoco flow north from the interior of this mysterious Guiana region, the Caura and the Caroni. The former has recently been explored by André, who found it greatly obstructed by falls and rapids; the latter is about 800 miles long, 400 of which are more or less navigable.

South of the Guaviare, as far as the *divortium aquarum*, between it and the Rio Negro branch of the Amazon, the country is dry and unswept by moisture-laden winds, so that no streams of moment are found in its southern drainage area; but north of it, as far as 6° 30′ N., the north-east trade winds, which have escaped condensation in the hot lower valley of the Orinoco, beat against the cold eastern slopes of the lofty Colombian Andes, and ceaselessly pour down such vast volumes of water that the almost countless streams which flow across the plains of Colombia and western Venezuela are taxed beyond their capacity to carry it to the Orinoco, and for several months of the year they flood tens of thousands of square miles of the districts they traverse. Among these the Apure, Arauca, Meta, and Guaviare hold the first rank.

The *Apure* is formed by two great rivers, the *Uribante* and *Sarare*. The former, which rises in the Sierra de Merida, which overlooks the Lake of Maracaibo, has 16 large affluents; the latter has its sources near the Colombian city of Pamplona, and they are only separated from the basin of the river Magdalena by the "Oriental" Andean range. From the Uribante–Sarare junction to the Orinoco the length of the Apure is 645 miles, of which Codazzi makes the doubtful claim that 564 are navigable, for there are some troublesome rapids 114 miles above its mouth, where the Apure is three miles wide. The numerous affluents which enter it from the north water the beautiful eastern and southern slopes of the Merida, Caraboso, and Caracas mountain ranges. A few of them are navigable for a short distance; among these the most important is the many-armed Portugueza, on the main route south from the Caribbean coast to the *llanos*. A few large streams enter the lower Apure from the south, but they are frequently entangled in lateral canals, due to the slight elevation of the plains above sea-level, the waters of the Apure, especially during flood time, having opened a great number of *caños* before reaching the Orinoco.

The "Oriental" Andes of Colombia give birth to another great affluent of the Orinoco, the *Arauca*, which soon reaches the plain and parallels the Apure on the south. Perez says that the Sarare branch of the Apure has formed a gigantic dam across its own course by prodigious quantities of trees, brush, vines, and roots, and thus, impounding its own waters, has cut a new channel to the southward across the lowlands and joined the Arauca, from which the Sarare may be reached in small craft and ascended to the vicinity of Pamplona. The Arauca is navigable for large boats and barges up to the Andes, and by sail to its middle course. In floods, unable to carry the additional water contributed by the Sarare, it overflows its banks, and by several *caños* gives its surplus to the Capanaparo, which, about 18 miles farther south, joins the Orinoco.

The *Meta* is known as such from the union of two Andean streams, the Negro and Humadea, which rise near Bogotá. At their junction, 700 feet above sea-level, it is 1000 feet wide and 7 feet deep in the dry season, but in flood the Meta rises 30 feet. It is navigable up to the old "Apostadero," about 150 miles above its mouth, but launches may ascend it, in the wet season, about 500 miles, to the junction of the Negro with the Humadea. In the dry season, however, it is obstructed by reefs, sandbanks, shallows, snags, trees, and floating timber from the "Apostadero" up, so that even canoes find its ascent difficult, while savage hordes along its banks add to the dangers to be encountered.

The *Guaviare* is the next great western tributary of the Orinoco. Eugenio Alvarado, a Spanish commissioner for the boundary delimitation of Colombia with Brazil in 1759, informed the viceroy at Bogotá that the rivers Arivari and Guayabero rise between Neiva and Popayan, and unite to take the composite name of Guaviare. In those times they called it Guaibari, or Guayuare. The Guaviare is about 500 miles long, of which 300 are called navigable, although not free from obstructions. Its upper portion has many rapids and falls. The banks are forested throughout, and the river is infested by numerous alligators, so ferocious that they attack canoes. Two-thirds of the way up, it receives its Ariari tributary from the north-west, which is navigable for large boats. Near its mouth the Guaviare is joined by its great south-western affluent, the *Ynirida*. Above its rapid of Mariapiri, 180 miles up, this stream runs swiftly through a rough country, but for a long distance is a succession of lakes and shallow, overflowed areas. Its head-waters do not reach the Andes.

Between the Guaviare and the Meta the Orinoco is obstructed by the famous *Maipures cataract*, where, in several channels, it breaks through a granite spur of the Guiana highlands for a length of about 4 miles, with a total fall of about 40 feet, and then, after passing two minor reefs, reaches the Atures rapids, where it plunges through a succession of gorges for a distance of about 6 miles, winding among confused masses of granite boulders, and falling about 30 feet. At the mouth of the Meta it is about a mile wide, but as it flows northwards it increases its width until, at the point where it receives its Apure affluent, it is over 2 miles wide in the dry season and about 7 in floods. It rises 32 feet at Cariben, but at the Angostura, or narrows, where the river is but 800 feet wide, the difference between high and low river is 50 feet, and was even 60 in 1892.

The Orinoco finds its way to the ocean through a delta of about 700 square miles area, so little above sea-level that much of it is periodically flooded. The river is navigable for large steamers up to the *raudal* or rapid of Cariben, 700 miles from the sea, and to within 6 miles of the mouth of the Meta. Maintaining its eastern course from the Apure, the main stream finds its way along the southern side of the delta, where it is called the *Corosimi river*, and enters the sea at the Boca Grande; but in front of the Tortola island, at the commencement of the Corosimi and 100 miles from the sea, it throws northwards to the Gulf of Paria another great arm which, about 100 miles long, and known as the *Rio Vagre*, bounds the western side of the delta. *En route* to the gulf the Vagre sends across the delta, east and north, two *caños* or canals of considerable volume, called the *Macareo* and *Cuscuino*. The delta is also cut into many irregular divisions by other canals which derive their flow from its great boundary rivers, the Corosimi and Vagre, and its numerous islands and vast swamps are covered with a dense vegetation. The Boca Grande outlet is the deepest, and is the main navigable entrance to the Orinoco at all seasons, the muddy bar usually maintaining a depth of 16 feet.

The Casiquiare Canal.—A missionary explorer, Padre Roman, in 1743, was the first to report that the upper Orinoco river was connected with the Negro branch of the Amazon by a canal. Little faith was attached to the statement until it was verified, in 1756, by the Spanish boundary-line commission of Yturriaga y Solano. The actual elevation of this "canal" above sea-level is not known, but a knowledge of it is of primary importance to a study of the hydrography of South America. Travellers in general give it as from 400 to 900 feet, but, after considerable study of the question of elevations in South America, the writer believes that the Casiquiare canal does not exceed 300 feet elevation. It is about 300 miles long, with an average depth of 30 feet, and has a violent current towards the Rio Negro. From its own extensive drainage basin it receives several rivers of considerable volume, so that, parting from the Orinoco with a width of only 220 feet, it swells to about five times that before reaching its Negro outlet, thus showing that the quantity of water contributed to it by the Orinoco is small in comparison to what it gathers *en route*. It is not, as is generally supposed, a sluggish canal on a flat tableland, but a great, rapid river, which, if its upper waters had not found contact with the Orinoco, would belong entirely to the Negro affluent of the Amazon. To the west of the Casiquiare there is a much shorter and more facile connexion between the Orinoco and Amazon basins, called the isthmus of Pimichin, which is reached by ascending the Terni branch of the Atabapo affluent of the Orinoco. Although the Terni is somewhat obstructed, it is believed that it could easily be made navigable for small craft. The isthmus is 10 miles across, with undulating ground, nowhere over 50 feet high, with swamps and marshes. It is much used for the transit of large canoes, which are hauled across it from the Terni river, and which reach the Negro by the little stream called the Pimichin.

Population, trade, &c.

The Spanish *conquistador* and his descendants have not been a blessing to the basin of the Orinoco. All they can boast of is the destruction of its population and products, so that the number of inhabitants of one of the richest valleys in the world is less to-day than it was four centuries ago. The entire river trade centres upon *Ciudad Bolivar*, on the right bank of the Orinoco, 373 miles above its mouth. It has a population estimated at 15,000. The only other river port of any importance is *San Fernando* (3000 inhabitants), on the Apure. It is a stopping-point for the incipient steamer traffic of the valley, which is principally confined to the Apure and lower Orinoco. It occupies, however, but a few small steam craft. There is steam connexion between Ciudad Bolivar and the island of Trinidad, which supplies 90 per cent. of the foreign imports of the Orinoco. A French steamer carries cattle from the valley to the neighbouring foreign colonies, and a few local steamers do a coasting trade between the river and the Caribbean ports of Venezuela. A transit trade with Colombia, *viâ* the Meta river, was lately carried on, with promising results, by two small steamers, but was suspended by order of the Venezuelan Government.

According to British consular reports, the tonnage of commerce for Ciudad Bolivar was as follows:—

	1897.	1898.	1900.
Registered tonnage entered	29,549	22,326	22,917
,, ,, cleared	28,818	21,762	23,470
Total movement	58,367	44,088	46,387
Total vessels entered	64	70	73
,, ,, cleared	69	59	74

This table represents the foreign and river trade of the Orinoco river and its branches at the close of the 19th century. (G. E. C.)

Orissa, a province of British India, in Bengal, consisting of four British districts and about sixteen tributary states.

The historical capital is Cuttack; and Puri, with its temple of Jagannath, is world-famous. It differs from the rest of Bengal in being under a temporary settlement of land revenue. A new settlement for a term of thirty years has just been concluded, which will raise the total land revenue from Rs.13,84,000 to Rs.21,05,000, or by more than one half; but the greater part of this increase will be levied gradually during the first eleven years of the term. To obviate destructive inundations and famines, the Orissa system of canals has been constructed, with a capital outlay of Rs.2,64,91,769, or nearly two millions sterling. In 1897–98 the total area irrigated was 200,943 acres, yielding a revenue of Rs.3,14,729. In addition, tolls on navigation yielded Rs.1,62,939. The net profits were Rs.12,005, not including any charge for interest. Embankments were maintained at a further cost in that year of Rs.2,04,797. The province is traversed by the East Coast Railway, which was opened throughout from Calcutta to Madras in 1901.

The division of ORISSA consists of the three British districts of Cuttack, Puri, and Balasore, together with the forfeited state of Angul and the tract known as the Khondmals. Total area, 9853 square miles; population (1881), 3,789,799; (1891), 4,047,352; (1901) 4,350,372, showing an increase of 7 per cent. between both 1881 and 1891 and 1891 and 1901; average density, 442 persons per square mile. According to the census of 1891, the total number of persons in all India speaking Uriya is 9,010,957, showing that the linguistic area (extending into Madras and the Central Provinces) is much larger than the political province.

The tributary states of ORISSA occupy the hills between the British districts and the Central Provinces. The most important are Moharbhanj, Keonjhar, Dhenkanal, Bod, and Nayagarh. Total area, 14,387 square miles; population (1881), 1,410,183; (1891), 1,696,710; (1901), 1,959,556; showing between 1881 and 1891 an apparent increase of 21 per cent., partly due to improved enumeration, and between 1891 and 1901 an increase of 15·5 per cent. In 1897–98 four states under British administration (including Dhenkanal) had a total revenue of Rs.4,80,000. Moharbhanj and Dhenkanal have each an efficient English high school, with a boarding-house attached. In 1897–98 the total number of schools was 1314, attended by 17,658 pupils. The raja of Moharbhanj is distinguished for his intelligent administration. He has declared 1075 square miles, or more than one-fourth of the area of his state, to be reserved forest.

Oristano, a town and archiepiscopal see of the province of Cagliari, Sardinia, Italy, near the west coast, 58 miles by rail north-north-west of Cagliari, in a marshy and unhealthy position, near the mouth of the river Tirso. The cathedral is an 18th-century structure. There are remains of the mediæval walls. Its industries embrace the manufacture of pottery, flour-milling, linen and hemp weaving, and tunny-fishing. Population (1899), 7000.

Orkney, a county of Scotland, formed of a group of islands in the North Sea, the most southerly being separated from Caithness by the Pentland Firth.

Area and Population.—According to the latest official estimate, the area of the islands (foreshore included) is 249,565 acres, or about 300 square miles. Of the 68 islands and islets, 29 are inhabited. The population was in 1881, 32,044; in 1891, 30,453; and in 1901, 28,698, of whom 14,027 were males and 14,671 were females. Taking the land area only (240,476 acres, or 375·7 square miles), the number of persons to the square mile was 81, and the number of acres to the person 7·9. The population decreased between 1881 and 1891 by 4·9 per cent., and between 1891 and 1901 by 5·8 per cent. Between 1881 and 1891 the excess of births over deaths was 2665, and the decrease of the resident population 1591. The following table gives births, deaths, and marriages, with the percentage of illegitimate births:—

Year.	Deaths.	Marriages.	Births.	Percentage of Illegitimate.
1880	466	174	755	6·0
1890	502	126	625	4·96
1899	445	164	553	6 1

The birth-rate, death-rate, and marriage-rate are all below the rates for Scotland. The following table gives the birth-rate, death-rate, and marriage-rate per thousand of the population for a series of years:—

	1886.	1881–90.	1890.	1891–98.	1899.
Birth-rate	23·60	23·08	20·44	20·25	19·00
Death-rate	14·57	14·55	16·42	14·48	15·29
Marriage-rate	5·44	4·81	4·12	4·65	5·63

There were 88 Gaelic-speaking persons in the county in 1891, and 31 foreigners. Valuation in 1889–90, £65,910; 1899–1900, £64,092.

Administration.—Orkney unites with Shetland to send a member to Parliament, and Kirkwall (3660), its county town, and the only royal burgh, is one of the Wick group of parliamentary burghs. There are 21 civil parishes, with a combination poorhouse at Kirkwall; the number of paupers and dependents in September 1899 was 871. Orkney forms a sheriffdom with Shetland and Caithness, and there is a resident sheriff-substitute at Kirkwall. Twenty school boards manage 61 schools, which had in 1898–99 an average attendance of 4327. Kirkwall and Stromness public schools give secondary education.

Agriculture.—In 1898 the percentage of cultivated area was 42·7. In 1895 the average size of the 3267 holdings was 33 acres. The percentage under 5 acres was 14·66, between 5 and 50 acres 70·89, and over 50 acres 14·45. There were 306 farms between 50 and 100 acres, 135 between 100 and 300, and 31 over 300, one being above 1000 acres in extent. Farming is, on the whole, not below the average lowland Scottish standard. The crofters' houses are now superior to those in almost any part of the Highlands, being rebuilt of stone and lime, instead of stones and clay. The following table gives the principal acreages at intervals of five years from 1880:—

Year.	Area under Crops.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	104,958	37,278	17,147	30,575	18,656	1,302
1885	113,246	38,516	17,675	32,297	23,689	1,069
1890	110,435	38,498	17,624	33,004	20,406	898
1895	106,188	38,525	17,595	32,283	17,544	241
1899	107,376	38,268	17,606	33,805	17,440	257

The following table gives the live stock during the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or Calf.	Sheep.	Pigs.
1880	6,100	25,416	9,101	29,592	3,312
1885	6,094	25,239	9,476	32,178	4,398
1890	5,861	24,040	8,989	32,408	4,587
1895	6,350	26,832	9,390	32,050	3,580
1899	6,839	28,428	9,858	36,836	2,586

There were only 11 acres under wood in 1895. At the census of 1891, 5349 men and 637 women were returned as being connected with agriculture.

Industries and Trade.—The principal industry, apart from agriculture, is fishing. There are 22 stations in the Orkney fishery district, some statistics about which are given in the following table:—

Year.	Boats.			Value of Gear.	Resident Fishermen and Boys.	Total Value of all Fish.
	No.	Tons.	Value.			
1890	656	3816	£17,013	£12,532	2,142	£39,733
1894	692	3265	£11,464	£10,229	1,706	£60,555
1898	501	2789	£10,800	£4,317	1,292	£53,359
1899	502	2876	£10,777	£12,397	1,309	£44,394

Of the total value of fish in 1899, £28,359 was the value of the herring catch, and £7474 the value of shellfish. In 1899, 2050 persons were employed in the district in the various branches of the sea fisheries.

Orleans, chief town of department Loiret, France, 75 miles south-west of Paris by rail. It is the headquarters of the 5th army corps, the seat of the Court of Appeal for departments Loiret, Indre-et-Loire, and Loir-et-Cher; of the central prison for the same departments, of a Protestant consistory for the departments of Loiret, Loir-et-Cher, and Yonne, and of a school of artillery. The Corn Exchange now serves as a hall for *fêtes.* Amongst modern buildings may be noted the churches of St Marc (1886), St Marceau (1892), in the suburbs of the same names, and in the latter suburb also a church commemorative of Joan of Arc (1895), and St Lawrence in the Madeleine suburb. A large hair-pin factory employs about 100 persons, and turns out 100,000 pins per day. Orleans was the ancient *Cenabum*, not *Genabum*, as has been proved by several ancient inscriptions. It was reduced to ruins by Cæsar in 52 B.C. Population (1891), 54,270; (1901), 59,568.

Orleans.—Since the article in *Ency. Brit.* vol. xvii. on the Orleanist princes was published, some additional names of importance require to be added to the account there given. For a complete list of the Orleans family reference must be made to the *Almanach de Gotha*, but the accompanying genealogical table of the descendants of Louis Philippe will be of assistance.

Reference may be made to the articles PARIS, COMTE DE (with his son, the DUC D'ORLEANS) and JOINVILLE, PRINCE DE, for information concerning those members of the family. It is only necessary here to give further details about two others whose names won distinction in recent years, the duc d'Aumale and Prince Henri d'Orleans.

HENRI-EUGÈNE-PHILIPPE-LOUIS D'ORLÉANS, duc d'Aumale (1822–1897), was the fourth son of King Louis Philippe I. and of his wife Marie Amélie. He was born at Paris, 16th January 1822, and was educated at the College of Henry IV. At seventeen he entered the army, and saw service in Algeria, where he distinguished himself. In May 1843, after the capture of Abd-el-Kader, he was made lieutenant-general. In 1847 he was made governor of the French possessions in Africa, but in 1848, when the February revolution broke out, he handed over his office to General Cavaignac and went to England, where he lived for some years, occupying himself with historical work and contributing to the *Revue des Deux Mondes.* He married in 1844 the Princess Caroline, daughter of the prince of Salerno; she died in 1869. They had two sons, the prince de Condé (d. 1866) and the duc de Guise (d. 1872). In 1869 two volumes of the duke's *Histoire des Princes de Condé* were published. In 1870, when the Franco-German war broke out, his request for employment in the field was refused. In 1871 he was elected a deputy for the department of Oise, and in 1872 was elected a member of the French Academy. He took an important part in the events leading to the downfall of Thiers. In 1873 he presided at the Bazaine court-martial, and was then given the command of the 7th army corps. In 1879 he was made inspector-general of the army corps, and in 1880 a member of the Académie des Beaux Arts. In 1883, however, he was included in the decree against the Orleanist princes, by which they now retired from the army; and in 1886 the duc d'Aumale formally protested to the President of the Republic against

(b. 1773; d. 1850) LOUIS PHILIPPE = Marie Amélie, dau. of Ferdinand IV. of Naples

- Ferdinand of France (duc d'Orléans), Dauphin (b. 1810; d. 1842) = Hélène, duchess of Mecklenburg-Schwerin
  - Philippe (comte de Paris) (b. 1838; d. 1894) = Isabelle d'Orléans, dau. of Antoine, duc de Montpensier
    - Amélie
    - Philip (duc d'Orléans) (b. 1869)
    - Hélène
    - Isabelle
    - Louise
    - Ferdinand (b. 1884)
  - Robert (duc de Chartres) (b. 1840) = Françoise d'Orléans, dau. of prince de Joinville
    - Marie
    - Henri (b. 1867; d. 1901)
    - Marguerite
    - Jean = Isabelle, d. of Philippe, comte de Paris
- Louise = King Leopold I. of Belgium
- Marie = Duke Frederick of Würtemberg
- Louis (duc de Nemours) (b. 1814; d. 1896) = Victoria Louise of Saxe-Coburg-Gotha
  - Gaston (comte d'Eu) = Isabelle of Braganza
    - Pierre
    - Louis
    - Antoine
  - Ferdinand (duc d'Alençon) = Sophie of Bavaria
    - Louise
    - Emmanuel = Henriette of Belgium
  - Blanche
- Clémentine (b. 1817; d. 1881) = August Victor of Saxe-Coburg-Gotha
- François (prince de Joinville) (b. 1818; d. 1900) = Françoise de Braganza
  - Françoise = Robert, duc de Chartres
  - Pierre (duc de Penthièvre)
- Henri (duc d'Aumale) (b. 1822; d. 1897) = Caroline of Bourbon
  - Prince de Condé (b. 1845; d. 1866)
  - Duc de Guise (b. 1854; d. 1872)
- Antoine (duc de Montpensier) (b. 1824; d. 1890) = Louise, Infanta of Spain
  - Isabelle = comte de Paris
  - Antoine = Eulalie, Infanta of Spain
    - Alphonse
    - Louis-Fernando

his treatment by General Boulanger, but the only result was that he was formally exiled from French territory, and retired to Brussels. The duc d'Aumale had an immense fortune, and in 1886 he announced that, after his death, his château of Chantilly with its contents would go to the French Institute. On its request the Government repealed in 1889 his decree of exile, and he returned to France. He died in Sicily on the 7th of May 1897, his death being undoubtedly accelerated by the disaster of the fire at the charity bazaar in Paris, where his niece, the duchesse d'Alençon, lost her life.

Henri, Prince of Orleans (1867–1901), eldest son of Robert, duc de Chartres, was born at Ham, near Richmond, Surrey, on the 16th of October 1867. In 1889, at the instance of his father, who paid the expenses of the tour, he undertook, in company with MM. Bonvalot and Dedecken, a journey through Siberia to Siam. In the course of their travels they crossed the mountain range of Tibet, and the fruits of their observations, submitted to the Geographical Society of Paris (and later incorporated in *De Paris au Tonkin à travers le Tibet inconnu*, published in 1892), brought them conjointly the gold medal of that society. In 1892 the prince made a short journey of exploration in East Africa, and shortly afterwards visited Madagascar, proceeding thence to Tongking. From this point he set out for Assam, and was successful in discovering the sources of the river Irrawaddy, a brilliant geographical achievement which secured the medal of the Geographical Society of Paris and the cross of the Legion of Honour. In 1897 he revisited Abyssinia, and political differences arising from this trip led to a duel with the comte de Turin, in which both combatants were wounded. While on a trip to Assam in 1901 he died at Saigon of dysentery on 9th August. Prince Henri was a somewhat violent Anglophobe, and his diatribes against Great Britain contrasted rather curiously with the cordial reception which his position as a traveller obtained for him in London, where he was given the gold medal of the Royal Geographical Society.

Orléans, Louis Philippe Robert, Duc d' (1869-——), eldest son of the comte de Paris, was born at York House, Twickenham, 6th February 1869. The law of exile against the French princes having been abrogated in 1871, he returned with his parents to France. He was first educated by a private tutor, and then followed the courses of the municipal collège at Eu. In 1882 he entered the College Stanislas, Paris, and took a first prize in a competitive Latin translation. On the death of the comte de Chambord, the comte de Paris became head of the Bourbons; and in 1886 he and his son were exiled from France. Queen Victoria appointed the duke of Orleans a supernumerary cadet at the Royal Military College, Sandhurst. After passing his examinations he received a commission in the 4th battalion of the 60th Rifles, then quartered in India. In January 1888 the duke went out to India, accompanied by Colonel de Parseval as military governor and adviser. At Bombay he was received by the duke of Connaught and Lord Reay, and at Calcutta he became the guest of the Viceroy, the marquis of Dufferin, who organized for the duke and his cousin, Prince Henry of Orleans, a grand tiger-shooting expedition in Nepaul. The duke now reported himself to the commander-in-chief (now Earl Roberts), and joined his regiment at Chakrata. After seeing considerable service, the duke ceased his connexion with the Indian army in February 1889, and returned to England. On attaining his majority, he entered Paris, and proceeding to the *mairie*, expressed his desire, as a Frenchman, to perform his military service. This act caused great excitement, and he was arrested in conformity with the law of 1886, which forbade the soil of France to the direct heirs of the families which had reigned there. He was tried, and sentenced to two years' imprisonment; but he was liberated by President Carnot after a few months' nominal incarceration, and conducted to the Swiss frontier. This escapade won for him the title of "Le Premier Conscrit." After the comte de Paris's funeral, the duke received his adherents in London, and then removed to Brussels, as being nearer France. On 5th November 1890 the duke married the Archduchess Maria Dorothea of Austria, the ceremony taking place at Vienna. It was alleged that some of his followers were implicated in the conspiracies against the French Republic in 1899. A letter which the duke wrote in 1900, approving the artist whose caricatures were grossly insulting to Queen Victoria, excited great indignation both in England and in many French circles, and estranged him from many with whom he had formerly been upon friendly terms; but after Queen Victoria's death it was allowed to become known that this affair had been forgotten and forgiven by the British royal family.

Ormerod, Eleanor A. (1828–1901), English entomologist, was the daughter of George Ormerod, F.R.S., author of *The History of Cheshire*, and was born at Sedbury Park, Gloucestershire, on the 11th of May 1828. From her earliest childhood insects were her delight, and the opportunity afforded for entomological study by the large estate upon which she grew up and the interest she took in agriculture generally soon made her a local authority upon this subject. When, in 1868, the Royal Horticultural Society began forming a collection of insect pests of the farm for practical purposes, Miss Ormerod largely contributed to it, and was awarded the Flora medal of the society. In 1877 she issued a pamphlet, *Notes for Observations on Injurious Insects*, which was distributed among persons interested in this line of inquiry, who readily sent in the results of their researches, and was thus the beginning of the well-known *Annual Series of Reports on Injurious Insects and Farm Pests.* In 1881 Miss Ormerod published a special report upon the "turnip-fly," and in 1882 was appointed consulting entomologist to the Royal Agricultural Society, a post she held until 1892. For several years she was lecturer on scientific entomology at the Royal Agricultural College, Cirencester. Her fame was not confined to England: she received silver and gold medals from the University of Moscow for her models of insects injurious to plants, and her treatise on *The Injurious Insects of South Africa* showed how wide was her range. In 1899 she received the large silver medal from the Société Nationale d'Acclimatation de France. Among others of her works are the *Cobden Journals*, *Manual of Injurious Insects*, and *Handbook of Insects injurious to Orchard and Bush Fruits.* Almost the last honour which fell to her was the honorary degree of LL.D. of Edinburgh University—a unique distinction, for she was the first woman upon whom the university had conferred this degree. The dean of the legal faculty in making the presentation aptly summed up Miss Ormerod's services as follows: "The pre-eminent position which Miss Ormerod holds in the world of science is the reward of patient study and unwearying observation. Her investigations have been chiefly directed towards the discovery of methods for the prevention of the ravages of those insects which are injurious to orchard, field, and forest. Her labours have been crowned with such success that she is entitled to be hailed the protectress of agriculture and the fruits of the earth—a beneficent Demeter of the 19th century." She died at St Albans on the 19th of July 1901.

Ormskirk, a market town and, since 1894, urban district in the Ormskirk parliamentary division of Lancashire, England, 11 miles north-east of Liverpool by rail. In 1896 a corn exchange and news-room were erected. Public pleasure grounds were opened in 1894, and in the same year an isolation hospital. Population (1881), 6651; (1891), 6298; (1901), 6857.

Ornament.—Ornament is in its nature accessory, and implies a thing to be ornamented, which is its active cause and by rights suggests its design. It does not exist apart from its application. Nor is it properly *added* to a thing already in existence (that is but a makeshift for design), but is rather such modification of the thing *in the making* as may be determined by the consideration of beauty. For example, the construction and proportions of a chair are determined by use (by the necessity of combining the maximum of strength with the minimum of weight, and of fitting it to the proportions of the human body, &c.); and any modification of the plan, such as the turning of legs, the shaping of arms and back, carving, inlay, mouldings, &c.—any reconsideration even of the merely utilitarian plan from the point of view of art—has strictly to do with Ornament, which thus, far from being an afterthought, belongs to the very inception of the thing. Ornament is good only in so far as it is an indispensable part of something, helping its effect without hurt to its use. It is begotten of use by the consideration of beauty. The test of ornament is its *fitness.* It must occupy a space, fulfil a purpose, be adapted to the material in which and the process by which it is executed. This implies *treatment.* The treatment befitting a wall space does not equally befit a floor space of the same dimensions. What is suitable to hand-painting is not equally suitable to stencilling; nor what is proper to mosaic proper to carpet-weaving. Neither the purposes of decoration nor the conditions of production allow great scope for naturalism in ornament. Its forms are derived from nature, more or less; but repose is best secured by some removedness from nature—necessitated also by the due treatment of material after its kind and according to its fashioning. In the case of recurring ornament it is inept to multiply natural flowers, &c., which at every repetition lose something of their natural attraction. The artist in ornament does not imitate natural forms. Such as he may employ he transfigures. He does not necessarily set out with any idea of natural form (this comes to him by the way); his first thought is to solve a given problem in design, and he solves it perhaps most surely by means of abstract ornament—witness the work of the Greeks and of the Arabs. The extremity of tasteless naturalism, reached towards the beginning of the Victorian era, was the opportunity of English reformers, prominent amongst whom was Owen Jones, whose fault was in insisting upon a form of ornament too abstract to suit English ideas. William Morris and others led the way back to nature, but to nature trained in the way of ornament. The Styles of ornament, so-called, mark the evolution of design, being the direct outcome of Greek, Roman, Byzantine, Gothic, or other conditions, in days when fashion moved slowly. Post-Renaissance ornament goes by the name of the reigning king; but the character of the historic periods was not sought by artists; it came of their working in the way natural to them and doing their best. "Style," as distinguished from "the Styles," comes of an artist's intelligent and sympathetic treatment of his material, and of his personal sincerity and strength. International traffic has gone far to do away with national characteristics in ornament, which becomes yearly more and more alike all the world over. The subsidiary nature of ornament and its subjection to conditions lead to its frequent repetition, which results in *pattern,* repeated forms falling inevitably into lines, always self-asserting, and liable to annoy in proportion as they were not foreseen by the designer. He cannot, therefore, safely disregard them. Indeed, his first business is to build pattern upon lines, if not intrinsically beautiful, at least helpful to the scheme of decoration. He may disguise them; but capable designers are generally quite frank about the construction of their pattern, and not afraid of pronounced lines. Of course, adaptation being all-essential to pattern, an artist must be versed in the technique of any manufacture for which he designs. His art is in being equal to the occasion. (L. F. D.)

Orne, a department of the north-west of France, watered by the Orne.

Area, 2372 square miles. The population decreased from 376,126 in 1881 to 325,445 in 1901. Births in 1899, 5961, of which 315 were illegitimate; deaths, 7554; marriages, 2311. Out of 1,414,780 acres of land cultivated in 1896, 773,110 acres were arable, and nearly 494,000 acres were green crop and grass lands. In 1899 the wheat crop was valued at £682,000; barley, £206,000; oats, £402,000; potatoes, £336,000; green crop (trefoil, lucern, and sainfoin), £278,000; natural pastures, £448,000; grass lands, £496,000; cider-apples, £480,000. The live stock in 1899 included 62,000 horses, 216,100 cattle, 70,460 sheep, and 37,000 pigs. Though without metallic ores, Orne possesses industries in metals—pin factories at Laigle, &c. The textile industry is especially developed around Flers and Alençon, where cotton stuffs are manufactured. Alençon, the capital, had 14,886 inhabitants in 1901.

Orosháza, a market town of Hungary, in the county of Békés, 33 miles north-east of Szegedin. The inhabitants are mainly agriculturists and artisans, and carry on a brisk trade in swine. There are five steam mills and many financial institutions. Population (1891), 19,956; (1901), 21,385.

Orsha, a district town of Russia, government of Moghileff, and 112 miles by rail west-south-west of Smolensk on the Moscow–Brest railway, on the Dnieper. Its industries are insignificant, but it is an important entrepôt for grain, seeds, and timber, which are shipped both by rail and on the Dnieper. Population (1897), 13,161.

It is a very old town, mentioned in the annals under the name of Rsha in 1067. In the 13th century it was taken by the Lithuanians, who fortified it. In 1604 the Poles founded there a Jesuit college. The Russians besieged Orsha more than once in the 16th and 17th centuries, and finally annexed it in 1772.

Orsk, a district town of Russia, government and 150 miles south-east of Orenburg, on the right bank of the Ural river. Being situated on the prairies, cattle-breeding prospers. It has tanneries and tallow-melting establishments, and is a centre for trade in cattle and various animal produce imported from central Asia. Population (1897), 14,036.

Orsova, a market town of Hungary, in the county of Krassó-Szörény, near the pass of Vaskapú (Iron-Gates), on the Danube. As an important railway station on the frontiers of Hungary, Servia, and Rumania, it has a thriving trade. It has numerous financial institutions, a saw-mill, and several Government edifices. The private walls of the old Roman city of Tierna have been demolished. Near the railway station stands a handsome chapel, called the Crown Chapel, which was erected in 1855 on the spot where Louis Kossuth concealed the crown at the close of the Hungarian war of liberty. The islet of Ada-Kaleh, opposite to the town, was ceded in 1878 by the Turkish Government to Hungary. Population (1891), 3564; (1901), 4610.

Orta, a lake of Italy, lying west from Lago Maggiore, and due north of Vercelli. It has an area of 7 square miles, and is 8 miles long and from $\frac{1}{4}$ to $4\frac{3}{4}$ miles wide. A subaqueous ridge divides it into two basins, of which the north is the deeper, descending to a maximum depth of 469 feet. The altitude of the lake is 951 feet above sea-level. The area of the drainage basin is 39 square miles. The temperature of the bottom never falls below 39·2° F. This lake seems to owe its origin to glacial action. By means of the Strona, which flows out of its northern extremity, it communicates with the Toce, which flows into Lago Maggiore.

Orthodox Eastern Church.—The object of this article is to enumerate all the Christian Churches of the East, and to sketch shortly their present condition; *i.e.*, both those which together constitute the Orthodox Eastern Church and also those which have a common origin with it, but which, for one reason or another, have separated from communion with it. (See *Ency. Brit.*, ninth edition, art. GREEK CHURCH.)

I. The ORTHODOX EASTERN CHURCH, which is frequently spoken of as "the Greek Church," and which has for its full official title "The Holy Orthodox Catholic Apostolic Eastern Church" (ἡ ἁγία ὀρθόδοξος καθολικὴ ἀνατολικὴ ἐκκλησία), is the historical representative of the churches of the ancient East. It consists of (*a*) those churches which have accepted all the decrees of the successive general councils and have remained in full communion with one another, (*b*) such churches as have derived their origin from these by missionary activity, or by abscission without loss of communion. In the Eastern churches, unlike the Western, there has never been any pronounced tendency towards an organized unity under a single head, of the kind which in the Roman world gave rise to the Papacy. Their bishops preserve, indeed, their ancient dignities and precedence, but are equals in their inherent power; and the authority of patriarchs and metropolitans is recognized as being committed to them by the synodical voice of their brethren. Again, not only is it the fact that the ancient patriarchs and other heads of local churches have independent authority within their own spheres, but it has been fully recognized, from the end of the 16th century at any rate, that a separate and independent organization is the natural corollary of complete political separation. On the other hand, the Orthodox Eastern Church has always laid especial stress upon the unchanging tradition of the faith, and has claimed orthodoxy as its especial characteristic. The "Feast of Orthodoxy" (ἡ κυριακὴ τῆς ὀρθοδοξίας), celebrated annually on the first Sunday of the Greek Lent, was founded in honour of the restoration of the Holy Images to the churches after the downfall of Iconoclasm (19th February 842); but it has gradually assumed a wider significance as the celebration of victory over all heresies, and is now one of the most characteristic festivals of the Eastern Church. In addition to the ancient churches which have separated themselves from the orthodox faith, many have ceased to have an independent existence, owing either to the conquests of Islam or to their absorption by other churches. For example, the church of Mount Sinai may be regarded as all that survives of the ancient church of northern Arabia; the autocephalous Slavonic churches of Ipek and Okhrida, which derived their ultimate origin from the missions of Cyril and Methodius, were absorbed in the patriarchate of Constantinople in 1766 and 1767 respectively; and the Church of Georgia has been part of the Russian Church since 1801. At the present day, then, the Orthodox Eastern Church consists of twelve mutually independent churches (or thirteen if we reckon the Bulgarian Church) using their own language in divine service (or some ancient form of it, as in Russia) and varying not a little in points of detail, but standing in full communion with one another, and united as equals in what has been described as one great ecclesiastical federation. However, in using such language it must be remembered that we are not dealing with bodies which were originally separated from one another and have now entered into fellowship, but with bodies which have grown naturally from a single origin and have not become estranged. These bodies are the following:—

1. *The Patriarchate of Constantinople* or *New Rome.*—The Ecumenical Patriarch, as he has been called since early in the 6th century, is the most exalted ecclesiastic of the Eastern churches, and his influence reaches far outside the lands of the patriarchate. His jurisdiction extends over the dominions of the Sultan in Turkey, together with Asia Minor and the Turkish islands of the Aegean; there are eighty-two metropolitans under him, and the "monastic republic" of Mount Athos. He has great privileges and responsibilities as the recognized head of the Greek community in Turkey, and enjoys also many personal honours which have survived from the days of the Byzantine emperors.

The Patriarch has his own court at Phanar, and his own prison, with a large civil jurisdiction over, and responsibility for, the Greek community. In ecclesiastical affairs he acts with two governing bodies—(*a*) a permanent Holy Synod (Ἱερὰ Σύνοδος τῆς Ἐκκλησίας Κωνσταντινουπόλεως), consisting of twelve metropolitans, six of whom are re-elected every year from the whole number of metropolitans, arranged in three classes according to a fixed cycle; (*b*) the Permanent National Mixed Council (Διαρκὲς Ἐθνικὸν Μικτὸν Συμβούλιον), a remarkable assembly, which is at once the source of great power by introducing a strong lay element into the administration, and of a certain amount of weakness by its liability to sudden changes of popular feeling. It consists of four metropolitans, members of the Holy Synod, and eight laymen. All of these are chosen by an electoral body, consisting of all the members of the Holy Synod and the National Mixed Council, and twenty-five representatives of the parishes of Constantinople. The election of the Patriarch is also, to a considerable extent, popular. An electoral assembly is formed for the purpose, consisting[1] of the twelve members of the Holy Synod, the eight lay members of the National Mixed Council, twenty-eight representatives of as many dioceses (the remaining dioceses having only the right to nominate a candidate by letter), ten representatives of the parishes of Constantinople, ten representatives of all persons who possess political rank, ten representatives of the Christian trades of Constantinople, the two representatives of the secretariat of the patriarchate, and such metropolitans, to the number of ten but no more, as happen to be in Constantinople at the time for some canonical reason (παρεπιδημοῦντες). On the death or deposition of the Patriarch, the Holy Synod and the National Mixed Council at once meet and elect a temporary substitute for the Patriarch (Τοποτηρητής). Forty days afterwards the electoral assembly meets, under his presidency, and proceeds to make a list of twenty candidates (at the present day they must be metropolitans), who may be proposed either by the members of the electoral assembly or by any of the metropolitans of the patriarchate by letter. This list is sent to the Sultan, who has by prescription the right to strike out five names. From the fifteen which remain the electoral assembly chooses three. These names are then submitted to the clerical members of the assembly, *i.e.*, to the members of the Holy Synod and the παρεπιδημοῦντες, who meet in church, and, after the usual service, make the final selection. The Patriarch-elect is presented to the Porte, which thereupon grants the berat or diploma of investiture and several customary presents; after which the new ruler is enthroned. The Patriarch has the assistance and support of a large household, a survival from Byzantine times. Amongst them, actually or potentially, are the Grand Steward (μέγας οἰκόνομος), who serves him as deacon in the liturgy and presents candidates for orders; the Grand Visitor (μέγας σακελλάριος), who superintends the monasteries; the Sacristan (σκευοφύλαξ); the Chancellor (χαρτοφύλαξ), who superintends ecclesiastical causes; the deputy-Visitor (ὁ τοῦ σακελλίου), who visits the nunneries; the Protonotary (πρωτονοτάριος); the Logothete (λογοθέτης), a most important lay officer, who represents the Patriarch at the Porte and elsewhere outside; the Censer-bearer, who seems to be also a kind of captain of the guard (καντρίσιος or κανστρήνσιος); the Referendary (ῥεφερενδάριος); the Secretary (ὑπομνημογράφων); the Chief Syndic (πρωτέκδικος), who is a judge of lesser causes; the Recorder (ἱερομνήμων); and so on, down to the cleaners of the lamps

[1] The numbers have varied from time to time.

(λαμπαδάριοι), the attendant of the lights (περιεισερχόμενος), and the bearer of the images (βασταγάριος) and of the holy ointment (μυροδότης).

2. The *Patriarchate of Alexandria*, consisting of Egypt and its dependencies, was at one time the most powerful of all, and the Patriarch still preserves his ancient titles of "pope" and "father of fathers, pastor of pastors, archpriest of archpriests, thirteenth apostle, and œcumenical judge." But the secession of the greater part of his church to Monophysitism [COPTIC CHURCH], and the Mahommedan conquest of Egypt, have left him but the shadow of his former greatness; and at the present time he has only the bishop of Libya under him, and rules over some 20,000 people at the outside, most of whom are settlers from elsewhere. 3. The *Patriarchate of Antioch*, including Cilicia, Syria (all but Palestine), and Mesopotamia, with fourteen metropolitans. The Patriarch is "father of fathers and pastor of pastors," but retains little of his ancient importance. 4. The *Patriarchate of Jerusalem*, which comprises Palestine only, and derives its chief influence from the position of Jerusalem as a place of pilgrimage. The Patriarch has under him five archbishops and five bishops. 5. The ancient *Church of Cyprus*. 6. The *Church of Mount Sinai*, consisting of little more than the famous monastery of St Catherine, under an archbishop who frequently resides in Egypt. It has, however, a few branch houses (μετόχια) in Turkey and Greece. The archbishop is chosen, from a list of candidates submitted by the monks of St Catherine, by the Patriarch of Jerusalem and his Synod; and the Patriarch consecrates him. 7. The *Hellenic Church*, *i.e.*, the church of the kingdom of Greece, which declared itself independent in 1833, though the claim was not admitted by the Patriarch of Constantinople till 1850. By the Greek constitution of 16th/28th November 1864 "the Orthodox Church of Greece remains indissolubly united, as regards dogmas, to the great Church of Constantinople, and to every other church professing the same doctrines, and, like these churches, it preserves in their integrity the apostolical constitutions and those of the councils of the Church, together with the holy traditions; it is αὐτοκέφαλος, it exercises its sovereign rights independently of every other church, and it is governed by a synod of bishops." 8. *The Servian Church.*—After the suppression of the Church of Ipek in 1766, Servia became ecclesiastically subject to Constantinople; but in 1830 the Sultan permitted the Serbs to elect a Patriarch (as a matter of fact he is merely styled Metropolitan), subject to the confirmation of the Patriarch of Constantinople. Eight years later the seat of ecclesiastical government was fixed at Belgrade; and when Servia gained its independence its church became autocephalous. 9. *The Rumanian Church.*—The fall of the church of Okhrida in 1767 had made Moldavia and Wallachia ecclesiastically subject to Constantinople. On the union of the two principalities under Alexander Couza (December 1861) the Church was declared autocephalous under a Metropolitan at Bucharest; and the fact was recognized by the patriarchs, as it was in the case of Servia, after the Treaty of Berlin had guaranteed their independence. 10. The *Church of Montenegro* has from early times been independent under its bishops, who from 1516 to 1851 were also the temporal rulers, under the title of Vladikas, or prince-bishops. 11. The *Orthodox Church in Austria-Hungary*, which, however, really consists of three independent sections: the Servians of Hungary and Croatia, under the Patriarch of Carlowitz; the Rumanians of Transylvania, under the Archbishop of Hermannstadt; and the Ruthenians of Bukovina, under the Metropolitan of Czernowitz. 12. The *Russian Church*, with which is incorporated the ancient Church of Georgia, now under a Russian Exarch who is a member *ex officio* of the Holy Synod of Moscow.

13. The *Bulgarian Church*, unless indeed it be classed with the separated churches. It differs from the national churches already mentioned in that it had its origin in a revolt of Turkish subjects against the patriarchal authority. From the earliest times the Bulgarians had occupied an anomalous position on the borders of Eastern and Western Christendom, but they had ultimately become subject to Constantinople. The revival of Bulgarian national feeling near the middle of the 19th century led to a movement for religious independence, the leaders of which were the archimandrite Neophit Bozveli and the bishop Ilarion Mikhailovsky. The Porte espoused the cause of the Bulgarians, partly to pacify them, but still more to strengthen its hold on all the Christians of Turkey by fostering their differences. Ultimately, on 28th February 1870, the Sultan issued a firman constituting a new church, including all Bulgarians who desired to join it within the vilayet of the Danube (*i.e.*, the subsequently-formed principality of Bulgaria), and those of Adrianople, Salonica, Kossovo, and Monastir (*i.e.*, part of Macedonia, Eastern Rumelia, and a tract farther south). The members of this Church were to constitute a *millet* or community, enjoying equal rights with the Greeks and Armenians; and its head, the Bulgarian Exarch, was to reside at Constantinople. Naturally, this was resented by the Patriarch Anthimus, who stigmatized the racial basis of the Bulgarian Church under the name of Phyletism. A local synod at Constantinople, in August 1872, pronounced it schismatical; Antioch, Alexandria, and Greece followed suit; Jerusalem pronounced a modified condemnation; and the Servian and Rumanian churches avoided any definite expression of opinion. Russia was more favourable. It never actually acknowledged the Bulgarian Church, and Bulgarian prelates may not officiate publicly in Russian churches; on the other hand, the Holy Synod of Moscow refused to recognize the Patriarch's condemnation, and Russian ecclesiastics have secretly supplied the Bulgarians with the holy oil. Above all, when Prince Boris, the heir-apparent of the principality, was received into the Bulgarian Church on 14th February 1896, the Tsar was his godfather. The future of the Church remains doubtful. On the one hand, on accepted orthodox principles every believer ought to wish to see it once more under the Patriarch, since even the principality is still under Turkish suzerainty; on the other hand, its independence has a high value to the Bulgarians as the expression of their national hopes. If Bulgaria were to be constituted a kingdom, this would naturally affect the status of the Bulgarian Church in that kingdom, so far as the Patriarch is concerned; and the regulation of the Church in the principality (as apart from the Turkish provinces) by statute of 1883, into eleven eparchies or metropolitan dioceses, may be regarded as a step in this direction. But this could of course do nothing to validate the sections of the Bulgarian Church in Macedonia and other Turkish provinces. The position is further complicated by the fact that many Bulgarians, both within and without the principality, still remain subject to the Patriarch. Nevertheless, owing to its schools and other activities, the Bulgarian Church undoubtedly makes headway both in the principality and in Macedonia.

At the present day, although the signs of weakness which have characterized the past are still present, the condition of the Greek orthodox churches is on the whole satisfactory, and signs of improvement are not wanting. The encyclical on unity of Pope Leo XIII. (1895) called forth a reply from the Patriarch Anthimus V. of

Constantinople and his Synod, which is eminently learned, dignified, and charitable. The theological school of the patriarchate, at Halkē, is not undistinguished, and the University of Athens has an excellent record. Whilst the parochial clergy are still as unlearned as ever, there are not a few amongst the higher clergy who are distinguished for their learning beyond the limits of their own communion: for example, the metropolitan Ph. Bryennios, who discovered and edited the Didachē; the archbishop N. Kalogeras, who discovered and edited the second part of the commentary of Euthymius Zigabenus on the New Testament; the archimandrite D. Latas, author of a valuable work on Christian archæology (Athens, 1883); and the Logothete S. d'Aristarchi, who has published a valuable collection of the recently discovered homilies of the Patriarch Photius. This latter work is published at the Phanar press, erected as a memorial to Theodore of Tarsus, archbishop of Canterbury, by Greek and English churchmen, which was set up by the Patriarch Constantine V. in 1899, and at which is being prepared also an authorized version of the Scriptures in ancient Greek. (On the other hand, an attempt made in 1901 by the Holy Synod at Athens, with the co-operation of the Queen of Greece, to circulate a modern Greek version of the New Testament led to an ebullition of popular feeling which could only be pacified by the withdrawal of the obnoxious version and the abdication of the Metropolitan of Athens.) The Patriarch Constantine V. was deposed 12th April 1901, and was succeeded on 28th May by Joachim III. (and V.), who had previously occupied the patriarchal throne from October 1873 to April 1884, when he was deposed through the ill-will of the Porte and banished to Mount Athos. His re-election has therefore no little importance. He is a strong man and a resolute reformer, inclined to look favourably upon the plans for reorganization and reconstruction which find no little support amongst the laity and the younger monastic clergy. Like his predecessor, and in this resembling also many of the leading Russian clergy, he is very well disposed towards the English Church; and not a little has been done in the way of establishing friendly communication between the Orthodox and the Anglican Churches, as, for example, in providing for spiritual ministrations to the sick, the dying, and the dead of either communion when their own clergy are out of reach. But undoubtedly the question of the most pressing importance with regard to the future of Eastern Christendom is the relation between Russia and Constantinople. The Œcumenical Patriarch is, of course, officially the superior; but the Russian Church is numerically by far the greatest, and the tendency to regard Russia as the head, not only of the Slav races, but of all orthodox nations, inevitably reacts upon the Church, in the form of what has been called pan-orthodoxy. The Russian Church is the only one which is in a position to display any missionary activity. It has been a powerful factor in the development of several of the churches already spoken of, especially those of Servia and Montenegro, which are usually very much subject to Russian influences (Ῥωσσόφρονες or Ῥωσσώφιλοι). It has taken great interest in non-orthodox churches, such as those of Assyria, Abyssinia, and Egypt. Above all, it has shown an increasing tendency to intervene in the affairs of the three lesser patriarchates, the ultimate result of which it is not easy to foresee.

II. The Separated Churches of the East.—These are the various churches which have severed themselves or drifted into separation from the Orthodox Eastern Church for reasons either doctrinal or practical, mostly through their dissent from the decrees of councils of the 5th century. (1) The *Church of Armenia* (see *Ency. Brit.*, ninth edition, vol. ii. p. 548), a national church dating from the earliest days, was hindered by persecution from taking any part in the council of Chalcedon, A.D. 451, and subsequently repudiated it. But although it undoubtedly accepted the Henoticon of the Emperor Zeno (an abortive attempt to bring together the two parties), at the synod of Varalschapad, in 491, the Patriarch Narses definitely repudiated the Eutychian heresy in 1166. The writings of Armenian theologians have certain "aphthartodocetic" tendencies (*e.g.*, the human body of the Lord is spoken of as being by nature incorruptible), but they appear to show no signs of Eutychianism properly so called. At the present day the relations between the Armenian Church and the Œcumenical Patriarch are decidedly friendly, and in certain circumstances single Armenians may be admitted to communion in Greek churches. The head of the Church is the Patriarch of Etchmiadzin, in the Russian province of Erivan, who bears the title of Catholicos (*Katoghikos*) of Armenia. There are also Patriarchs of Sis, Aghtamar, Constantinople, and Jerusalem. The two last-named are only bishops with the honorary rank of patriarch, their importance springing from their relations with the Turkish Government. Owing, however, to the Turkish practice of organizing and governing its peoples by their religion, the Armenian Patriarch of Constantinople has become the official representative of the Armenian community in Turkey, and is thus of little less practical importance than the Catholicos himself. (2) The *West Syrian* or *Jacobite Church*, which is definitely Monophysite, under a head who bears the title of patriarch of Antioch and is always called (since the 14th century) *Mar* (= Lord) *Ignatius* (see *Ency. Brit.*, ninth edition, vol. xiii. p. 538). (3) The *Coptic Church* of Egypt, which is also Monophysite. (4) The *Abyssinian Church*, also Monophysite, and dependent upon that of Egypt. (5) The *East Syrian*, *Assyrian*, or *Chaldee Church*, which is scattered over Kurdistan, and is Nestorian in doctrine [Nestorians]. (6) A few more or less independent communities, such as the so-called *Christians of St Thomas* in South India, who were Nestorian in origin, but have become Jacobite in modern days (see *Ency. Brit.*, ninth edition, vol. xxiii. p. 308). In addition to these separated churches, there are a number of "Uniat" bodies, *i.e.*, bodies which have been incorporated in the Roman communion without giving up their ancient rites and customs (see *Ency. Brit.*, ninth edition, vol. xx. p. 630); and there are also certain isolated dissenting bodies.

(W. E. Co.)

Oruro, a department of Bolivia, bounded on the N. by the department of La Paz, on the E. and S. by Cochabamba and Potosi, on the W. by Peru. Area, 21,350 square miles. Population (in 1893), 189,840; in 1898, estimated at 112,300, of whom 85,000 were Indians. Capital, Oruro (16,000). The department is divided into three provinces. In 1898 it had 29 schools and 1280 pupils.

Orvieto, a town and bishop's see of the province of Perugia, Umbria, Italy, on the Paglia, 78 miles by rail north by west of Rome. It crowns an isolated eminence (1165 feet), and is approached on the east by a funicular railway. In addition to the cathedral may be mentioned the church of San Andrea, with 11th-century tower; the church of San Giovenale, of the 11th century; the palace of the Popes, which since 1898 has sheltered the municipal museum, the latter rich in ancient Etruscan remains and mediæval sculptures, cathedral plans, &c.; and the communal offices, dating from the 12th century, but rebuilt in the 14th, the façade in 1585. The citadel, planned in 1364 by Cardinal Albornoz, is now laid out as a public garden. A noteworthy Etruscan necropolis, discovered in 1874, has yielded numerous Greek and Etruscan funereal urns, &c. Good wine is made. Population (1899), 7500.

Oscar II., King of Sweden and Norway (1829–——), was born at Stockholm on the 21st of January 1829, and succeeded his brother, Carl XV., upon the throne of Sweden and Norway on the 18th of September 1872. He was the third son of Oscar I. and Josephine, the daughter of Eugène de Beauharnais, Prince of Leuchtenberg, the son of the Empress Josephine. His elder brother Gustav had died young. His younger brother Auguste died in 1873. In 1857 he married Princess Sophia, youngest daughter of Duke Wilhelm of Nassau and Princess Pauline of Würtemberg, by whom he had issue Gustaf, the crown prince, born at Drottningholm on the 16th of June 1858; Oscar, who took the title of Prince Bernadotte, and renounced his royal rights on his marriage with Miss Ebba Munck (afterwards Countess Wisborg) at Bournemouth; Carl, duke of Westergötland, who married Princess Ingeborg of Denmark; and Eugène, duke of Nerike, who has devoted the greater portion of his time to painting in his studio at Stockholm. It was not only as monarch of the double Scandinavian throne, or as grandson of the famous Marshal Bernadotte, that King Oscar II. won a reputation in far wider circles than those which are influenced by considerations of dynasty or descent, for his chief title to the recognition of posterity is to be found in the tact with which he has handled delicate and difficult international problems, and the artistic and literary work by which he has been distinguished. Tall and dark, with flashing eyes, and well-moulded head upon a pair of massive shoulders, Oscar II. could never have been mistaken for anything but a true Bernadotte. Faced by the constant preoccupations of a domestic struggle whenever he turned to the politics of the two nations, it was only natural that the king should seek what solace was possible, in the scanty leisure of a throne, in those artistic and literary pursuits which had almost wholly claimed his interest as duke of Östergötland. The list of his published works, which contains poetry, history, research, translations, speeches, criticisms, would not disgrace the reputation of an author whose life had been entirely subordinated to the labours of his pen. In 1881 an exhaustive bibliography of the writings of Oscar II. was issued by "C. M. C.," who asserts that the king's first appearance in print was made in 1849, when he contributed an article on the battle of Eckernförde to the *Journal of Army Veterinary Science.* In 1858, as an anonymous competitor, Oscar II. won the second prize of the Swedish Academy with a collection of lyrical and narrative poems called *Memorials of the Swedish Fleet*, which contained some touching lines on the death of the captain of the frigate *Eugénie*, the ship on which he paid his first of many visits to British shores. Between 1859 and 1872 he published five pamphlets of occasional verse, which he collected in the latter year under the general title of *New and Old by O* * * *. In 1859 he published, in the *Annals of the Swedish Academy*, "Contributions to the Military History of Sweden in the years 1711, 1712, 1713," and these he brought out as a separate volume in 1865. In the same year appeared his translation of Herder's *Cid*, which he always considered one of his best literary efforts; and in 1861 he published a poetical version of Goethe's *Torquato Tasso*, with a charming dedication to his wife. In recognition of these scholarly labours he was elected a corresponding member of the Frankfort Academy of Sciences. The king published his *Collected Works* in two volumes in 1875–76, three years after he came to the throne. His poems have since been translated into French, German, Danish, Italian, and Magyar. The lines entitled *In My Home* have especially appealed to his own subjects, for they were written in that castle by the Sound of Helsingborg called after his Queen Sophia; and, besides the tender picture of family happiness and love which they reveal, they recall a number of those old sagas which are so dear to the heart of every Scandinavian. His first drama, *Castle Cronberg*, was also written under the same gentle influences, within a year of his marriage. It was originally composed in French, and is still a favourite piece in Swedish theatres. An English version of his *Memoirs of Charles XII.* was brought out in 1879, and while it astonished foreign readers by the skill with which it treated a subject already handled by the masterly eloquence of Voltaire, it also impressed them with far deeper evidences of accuracy and research. In 1885 King Oscar's *Address to the Academy of Music* was published with annotations. His majesty's fine collection of old printed and manuscript music, ever at the service of the intelligent amateur, is but one sign of his enthusiasm for the subject. The first English version of the most celebrated of these musical essays appeared, with the king's approval, in *Literature* for 19th May 1900. Whether in the case of his poetry, his prose, his military and naval knowledge, or the scholarship which made him worthy to be the only Swedish king who ever fairly earned his degree of Doctor of Philosophy at Lund—King Oscar II. conscientiously tried to lay all his varied talents, in their highest sense, at the service of his subjects. Nor was his wide culture limited by its merely personal expression. He welcomed many International Congresses to Sweden. He encouraged the universities and the cause of general education throughout Scandinavia, a movement in which he had already become deeply interested before his accession.

The progress of parliamentary and of party government in Sweden and Norway has led to many contentions. But whether the pressing problems for the moment were the question of separate foreign ministries, of separate flags, or of separate consulates, unity under his royal standard was the invariable policy of the monarch. In questions of international arbitration he was always deeply interested, and on several occasions took a prominent part. In 1889 he appointed the chief justice of Samoa, at the request of Great Britain, Germany, and the United States. In 1897 he was given the power to appoint a fifth arbitrator in certain circumstances in the dispute between Great Britain and Venezuela. In the same year he accepted the position of decisive umpire in the Anglo-American Arbitration Treaty which was signed at Washington, but did not secure a sufficient majority of votes in the Senate. In 1899 he again accepted the office of arbitrator in the matter of certain claims in Samoa affecting Great Britain, Germany, and the United States. His peculiar position among the sovereigns of Europe, outside their dynastic complications, yet essential to the balance of their powers, especially fitted him for these international services, to which he brought an acute and scholarly intelligence. But his well-known impartiality did not prevent him from occasionally asserting his opinions with no uncertain sound. In an outspoken declaration published in the columns of *The Times* of 2nd May 1900, he asserted his full sympathy with the United Kingdom in the course which had been thrust upon her in South Africa. The courage with which such sentiments were uttered, at a time when European opinion was almost universally hostile, was only less admired than the evident sincerity of which they were as graceful an expression.

The king's eldest son married in 1881 at Carlsruhe (being then in his twenty-third year) the Princess Victoria, daughter of Frederick William Louis, grand duke of Baden, by his wife Louise, princess of Prussia. This lady was therefore first cousin to the German Emperor William II. through her grandfather, the Kaiser Wilhelm I.; and through her grandmother Sophia, princess of Sweden, she was descended from the old royal Scandinavian stock of Gustavus Vasa. This interesting alliance connects the Bernadottes with one of the great ruling houses of Europe, and in years to come promises to set upon the throne of Sweden and Norway a sovereign who will unite in his veins the blood of Napoleon's famous marshal and of Sweden's warrior-king. The sons living (1902) by this marriage are Gustavus Adolphus, duke of Scania, born at Stockholm in November 1882; William, born in 1884; and Eric, born in 1889.

Oschatz, a town of Germany, on the Döllnitz, 18 miles by rail north-west of Meissen, in the circle of Leipzig, kingdom of Saxony. There are burgher, *real*, and commercial schools, and a seminary for teachers, as also the making of sugar, felt, weighing machines, woollens, and leather. Population (1890), 9392; (1900), 10,652.

Oschersleben, a town of Prussia, province of Saxony, 24 miles by rail west-south-west of Magdeburg. It has lignite mines, sugar refining, iron foundries, machine shops, breweries, brick-kilns, &c. The place is first mentioned in 803. Population (1885), 9671; (1900), 13,413.

Osh, a district town of Russian Turkestan, government of Fergana, 31 miles east-south-east of Andijan railway terminus, on the Akbura, altitude 3300 feet. It consists of two parts, native and Russian, of which the latter is quite new and has its streets planted with trees. Its population in 1897 was 36,474, of whom only about 400 were Russians. It has a Russian and a Russian and Sart school, four Mussulman schools, and a small hospital. Its trade with China is considerable.

O'Shanassy, Sir John (1818–1883), British colonial statesman, was born in 1818 at Holycross Abbey, near Thurles, Tipperary, his father being a land surveyor. He married in 1839, and the same year emigrated to the Port Phillip district of New South Wales, where he was for some time engaged in farming, and subsequently commenced business in Melbourne. His remarkable abilities attracted the attention of Dr Geoghegan, who afterwards became Roman Catholic bishop of Adelaide, by whom he was induced to take part in public affairs. He was one of the founders, and later the president, of the St Patrick's Society of Melbourne, represented the Roman Catholic body on the denominational board of education, and was a member of the Melbourne corporation. When Port Phillip was separated from New South Wales in 1851 and became the colony of Victoria, Mr O'Shanassy was returned to the Legislative Council as one of the members for Melbourne. A few weeks after the new colony began its independent existence gold was discovered, and the local government had to solve a number of difficult problems. The only member of the first executive who possessed any great talent for administration was the Attorney-General, Mr (afterwards Sir) W. F. Stawell. The Legislature was composed partly of elected representatives, and partly of nominees, official and non-official, appointed by the governor in council. The great natural ability of Mr O'Shanassy forced him to the front, and for some time the policy of the country was virtually shaped by him and Mr Stawell. It was very much owing to the strong position taken by Mr O'Shanassy that the powers of the Legislative Council were enlarged by the duke of Newcastle, who was at that date Secretary of State for the Colonies, and that it was allowed to control not only the ordinary revenue raised by taxation, but also the territorial, which was derived from the proceeds of the sale and occupation of Crown lands. From that date the Legislative Council, led by Mr O'Shanassy, became virtually supreme, and was enabled to expend the large sums which came into the exchequer of the colony, directly or indirectly through the discovery of gold, upon public works and the various services of the Government. After the Ballarat riots in 1854, Mr O'Shanassy was one of the members of a commission appointed to inquire into the condition of the gold-fields, and his report and that of his colleagues was the foundation of the mining legislation which, initiated in Victoria, was gradually followed by all the Australasian colonies. Mr O'Shanassy, together with Sir Andrew Clarke, was one of the framers of the constitution under which not only was the whole of the Legislature elected by the people, but the ministry became responsible to the local parliament. Under this constitution Mr O'Shanassy was returned in 1856 to the Legislative Assembly for Melbourne and Kilmore, but took his seat for the latter constituency. Early in 1857 the Haines Government, the first formed after the concession of responsible government, from among the members of the old Executive Council, was defeated, and Mr O'Shanassy having been sent for by the governor, Sir Henry Barkly, formed a ministry of which he became the premier. But he encountered strong opposition as soon as he met Parliament, and was defeated after holding office for little more than six weeks. He returned to power in 1858 as chief secretary and premier, on the defeat of the Haines Government through the rejection of the schedule to their increase of members Bill, and was again elected for Kilmore. One of the first duties of the new ministry was to inaugurate the system of railways, and to raise the necessary funds for their construction. Several propositions were made to the Government of Victoria by the great finance houses of the United Kingdom, and the propositions of Baring Brothers were brought to the colony by Mr Childers. Mr O'Shanassy decided to float a loan of eight millions sterling through the instrumentality of six of the Melbourne banks, and he commenced the series of borrowings by the Australian governments which subsequently attained such large proportions. In 1859 the second O'Shanassy ministry had to resign after a vote of want of confidence, and its leader remained in opposition till August 1861, when he defeated the Heales ministry on their budget, and formed his third administration. During the two years that it held office the Government passed an Education, a Local Government, a Civil Service, and a Land Act. The object of this last was to abolish the old system of selling the Crown lands by auction, and to substitute another which insisted rather upon residence and cultivation than upon obtaining the highest possible price. The Act did not carry out all the intentions of its framers, but it was a step in the right direction. The O'Shanassy Government was defeated in June 1863, and its chief never again succeeded in regaining office. He remained in opposition, and as leader of the Conservative or, as it was termed, the Constitutional party, was a steady opponent of the measures introduced by Mr M'Culloch and advocated by Mr Higinbotham. In 1864 he was re-elected for Kilmore, but he did not stand at the general election of 1866, and paid a visit to Europe. In that year he was created by Pope Pius IX., in recognition of his services in the cause of Roman Catholic education, a Knight of the Order of St Gregory the Great. In 1867 he returned to Victoria, and was elected a member for the central province in the Legislative Council. In 1870 he was created C.M.G., and in 1874 K.C.M.G. In the latter year he resigned his seat in the Council, and did not re-enter public life until 1877, when he was returned to the Assembly for Belfast. His strongly expressed Conservative opinions and his devotion to the interests of the Roman Catholic Church impaired his influence in the Legislature, which had become extremely democratic during the eleven years that he had been absent from it; and although Sir John was a fearless critic of the policy of the Government, he never succeeded in defeating it. He had a singularly comprehensive grasp of all constitutional questions, was an eloquent speaker, and an ardent free-trader. He retired from Parliament in 1880, and died in 1883. (G. C. L.)

O'Shaughnessy, Arthur William Edgar (1844–1881), English poet, was born in London on 14th March 1844, and at the age of seventeen obtained through the first Lord Lytton, who took a peculiar interest in him, the post of transcriber in the library of the British Museum. Two years later he was promoted to be an assistant in the natural history department, and took up the ichthyological branch of the work; for this he had probably little natural aptitude, but he so carefully qualified himself as to become in time an authority. He published his *Epic of Women* in 1870, *Lays of France* in 1872, and *Music and Moonlight* in 1874. In his thirtieth year he married a daughter of John Westland Marston, and during the last seven years of his life printed no volume of poetry. *Songs of a Worker* was published posthumously in 1881, O'Shaughnessy dying on the 30th of January in that year from the effects of a chill upon a delicate constitution. The qualities of O'Shaughnessy's poetry are those of the true singer; its defect the lack of importance in theme and dignity in thought. His melodies are often magnificent; and, as in *The Fountain of Tears*, the richness of his imagery conceals a certain vagueness and indecision of the creative faculty. He was also very felicitous in bold uses of repetition and echo, by which he secured effects which for haunting melody are almost inimitable. His spirit is that of a mild melancholy, drifting helplessly through the realities of life and spending itself in song. Where the inspiration of the moment fails him, and nothing but the music is left, the insubstantiality of his talent becomes clear. By some critics he has been occasionally disparaged, but reparation was done to his memory by Francis Turner Palgrave, who, in the second series of the *Golden Treasury*, said with some exaggeration that his metrical gift was the finest, after Tennyson, of any of the later poets, and that he had "a haunting music all his own." (A. WA.)

Oshima, a group of three small islands belonging to Japan, lying southwards of Kiushiu, in 30° 50′ N. and 130° E. Their names, from west to east, are Kuro-shima, Iwo-jima and Taka-shima. Kuro-shima rises to a height of 2475 feet, and Iwo-jima has an active volcano 2480 feet high. These islands are not to be confounded with Oshima, the most northerly island of the Izu-no-shichito, or with the northern group of the Luchu Islands. There are several other islands of the same name in Japan, the term Oshima signifying merely "big island." One of the best known lies off the Kii promontory, and has been the scene of many maritime disasters.

Oshkosh, a city of Wisconsin, U.S.A., capital of Winnebago county, on the Fox river, at its mouth in Winnebago Lake, in the eastern part of the state, at an altitude of 756 feet. The city is divided into thirteen wards; its streets are paved with wood or are gravelled, and it has a water-supply by the Holly system. The schools are excellent, and there is a public library. It is on three railways, the Chicago and North-Western, the Chicago, Milwaukee, and St Paul, and the Wisconsin Central. It has extensive manufactures. In 1900 the number of establishments reported was 285, with a total capital of $8,018,038, employés numbering 4587, and a product valued at $8,781,248. The largest item was lumber, valued at $2,449,430. Besides this, carriages and waggons, furniture, flour, and iron and steel goods were produced, and other minor articles. The city contains the state normal school and an insane asylum. The assessed valuation of real and personal property was, in 1898, $9,279,993; the net debt of the city was $375,316; and the rate of taxation was $26.50 per $1000. Population (1890), 22,836; (1900), 28,284, of whom 7356 were foreign-born. There were 9490 persons of school age (five to twenty years). Of 7513 males, twenty-one years of age and over, 252 were illiterate (unable to write).

Osimo, a town and episcopal see of the province of Ancona, the Marches, Italy, 10 miles south of Ancona. It still retains a portion of its ancient town wall (2nd cent. B.C.), and possesses a cathedral, and a town hall with antiquities. Silk-spinning and the raising of cocoons are carried on. It is the ancient Picenian town of *Auximum*. Population (1899), about 5000.

Oskaloosa, a city of Iowa, U.S.A., capital of Mahaska county, between the Des Moines and Skunk rivers, on the Chicago, Burlington, and Quincy, the Iowa Central, and the Chicago, Rock Island, and Pacific railways, south-east of the centre of the state, at an altitude of 833 feet. It is in an agricultural and coal-mining region. Penn College, situated here, had, in 1899, 14 instructors and 300 students. Population (1890), 6558; (1900), 9212, of whom 649 were foreign-born and 344 negroes.

Oskarshamn, a seaport town of Sweden, county of Calmar, on a bay of the east coast, opposite the north end of the island of Öland, 40 miles north of Calmar. It was called Döderhultsvik down to 1856. It exports timber ($3\frac{1}{2}$ to $4\frac{1}{4}$ million cubic feet annually) and granite; and imports coal, petroleum, salt, and groceries. The port is often closed for a couple of months in the depth of winter. The industries embrace iron-works, match factories, &c. There are two dry docks. Population (1880), 5382; (1890), 5853; (1900), 7077.

Osman (1832–1900), Turkish mushir (field-marshal), was born at Tokat, in Asia Minor, in 1832. Educated at the military academy at Constantinople, he entered the cavalry in 1855, and served under Omar Pasha in the Russian war of 1853–56, in Wallachia and the Crimea. Appointed a captain in the Imperial Guard, he went through the campaigns of the Lebanon in 1860 and of Crete in 1867 to 1869, under Mustapha Pasha, when he distinguished himself at the capture of the convent of Hagia Georgia, and was promoted lieutenant-colonel. He served under Redif Pasha in suppressing an insurrection in Yemen in 1871, was promoted major-general in 1874, and general of division in 1875. Appointed to command the army corps at Widin in 1876 on the declaration of war by Servia, he defeated Tchnernaieff at Saitschar and again at Yavor in July, invaded Servia and captured Alexinatz and Deligrad in October, when the war ended. Osman was promoted to be mushir, and continued in the command of the army corps at Widin. When the Russians crossed the Danube in July 1877, Osman moved his force to Plevna, and, with the assistance of his engineer, Tewfik Pasha, entrenched himself there on the right flank of the Russian line of communication, and gradually made the position a most formidable one. He repulsed the three general assaults of the Russians on the 20th and 30th July and the 11th September, inflicting on them great loss —some 30,000 men in the three battles. He held the position, after being closely invested, until the 9th December, when, compelled by want to cut his way out, he was severely wounded and forced to capitulate. This famous improvised defence of a position delayed the Russians for five months, and entailed their crossing the Balkan range in the depth of winter after the third battle of Plevna. The Sultan conferred on Osman the Grand Cross of the Osmanie in brilliants and the title of "Ghazi" (victorious), and, when he returned from imprisonment in Russia, made him commandant of the Imperial Guard, grand-master of the artillery, and marshal of the palace. In December 1878 he became War Minister, and held the post, with a small break, until 1885. He died at Constantinople, in the palace built for him by the Sultan near Yildiz Kiosk, on 4th April 1900, and his body was buried with great pomp in the Sultan Muhammad Mosque. (R. H. V.)

Osman Digna. See EGYPT: *Military Operations.*

Osnabrück, a town and episcopal see of Prussia, province of Hanover, 31 miles by rail north-east of Münster, in a valley on the north side of the Teutoburger Forest. The town is adorned with a bronze equestrian statue of the Emperor William I. (1899), a monument of the war of 1870–71 (1880), and statues of Justus Möser (1836) and the Hanoverian minister Stüve (1882). The cathedral is undergoing extensive alteration. Osnabrück is a place of considerable industry, possessing iron and coal mines, iron foundries, machine shops, stone quarries, and various iron manufactures. Population (1885), 35,899; (1900), 51,574.

Ossett, with GAWTHORPE, a municipal borough (incorporated 1890), railway station, and parish in the Morley parliamentary division of Yorkshire, England, 3 miles west-north-west of Wakefield. It has baths similar in their properties to those of Cheltenham. New technical school buildings were erected in 1890, and a public library has been opened. Population (1891), 11,123; (1901), 12,886.

Ossining, a village of Westchester county, New York, U.S.A., known as Sing-Sing previous to 1901. It is situated on the east bank of the Hudson river, where it widens into Tappan Bay, 31 miles north of New York City, and on the New York Central Railroad. Its situation is on a steep slope descending from a height of from 200 to 300 feet to the river, on which it is laid out irregularly. Sing-Sing prison is located here, and several excellent schools for boys and girls. Population (1900), 7939, of whom 1642 were foreign-born and 308 negroes.

Ostashkoff, a district town of Russia, government and 162 miles west-north-west of Tver, on Lake Seliger, situated in a damp and insalubrious climate. Its population grows, nevertheless, by immigration, and was 10,457 in 1897. It has several tanneries, and is a great centre for the making of boots and shoes as a domestic trade (400,000 pairs per annum), agricultural implements, fishing-nets, and building of boats. It has good fishing, and steamers ply on the lake.

Ostend, or OSTENDE, a seaport of Belgium, in the province of West Flanders, 14 miles by rail west of Bruges. It is the seaward terminus of important Continental main lines of railway, *e.g.*, from the north of France, from Switzerland, *viâ* Strasburg, and from Cologne and central Germany, and a landing-place in one of the principal express routes (Dover–Ostend) between England and the Continent. The mail service between Dover and Ostend was started on 3rd March 1846, and between then and the end of that year 4525 passengers were carried between the two ports; but by 1899 the number of passengers so carried had increased to 124,724 annually. The growth of the general traffic of the port is shown by the following statistics: in 1860, 704 vessels of 66,950 tons entered; in 1880, 1308 vessels of 244,831 tons; and in 1899, 2000 vessels of 1,156,907 tons (of which 1927, of 1,124,026 tons, were steam vessels). In 1898 what was virtually an additional new harbour was planned and begun, the cost of the necessary works being borne partly by the State, partly by the municipality of Ostend. The excavations extend inland as far as the hamlet of Slykens, a distance of three-quarters of a mile; and the works embrace a basin for the royal mail steamers (Dover–Ostend boats) and other Government vessels, with a depth of 26¼ to 32¾ feet beside the quays; another basin for shipping generally, 3300 feet long, 295 feet to 820 feet wide, and 23 feet deep during the height of the tide; two dry docks; and a new harbour railway station. The approach to the old harbour, as well as the anchorage outside, has been improved by cutting three gaps, each 16½ feet minimum depth, and 1640 feet, 1150 feet, and 2620 feet wide respectively, through the Strombank sand-bar, which stretches 12 miles parallel to the shore at a distance of 1¼ miles from it. Ostend is also one of the principal fishing ports of the kingdom, the deep-sea fishing being carried on by about 300 men in sailing smacks and 1300 men in steam trawlers. Oysters and lobsters are preserved and fattened on a large scale, being brought in the first instance from the east of England, France, and Norway. Ostend is even more celebrated as a seaside resort than as a seaport. In the height of the season, which lasts from 1st May to 15th October, it is visited by some 40,000 persons, attracted partly by the excellent sea-bathing, partly by the fashionable social life and the amusements which minister to it, and partly by the licensed gambling which takes place in the *kursaal.* Along the sea-front of the town extends for a distance of 2½ miles, that is, as far west as Mariakerke (which was incorporated with Ostend in 1899), a magnificent promenade, 100 feet broad, constructed entirely of hardened bricks, and backed by handsome villas with open fronts; by a crowd of hotels, some of them built on a palatial scale; by the *kursaal,* which has a concert hall capable of seating 5000 persons; and by the villa of the king of the Belgians. Out of the season almost all the hotels on the sea-front are closed. The licence for public gaming in Ostend was extended, to the lessees who then held it, for the space of two years from the autumn of 1901. The two principal churches are both quite new—St Peter and St Paul's, originally founded in 1072, has been rebuilt, after being burnt down in 1896; and St Catherine's was built in 1883, on the model of a Ghent church of the 13th century. There is also a third church, St Joseph's (1901). The pleasure-resorts embrace the large Leopold Park, the Marie Henriette Park, the casino or ball-rooms in the Hôtel de Ville, and the restaurant at the pier-head (*estacade*). Ostend vies with Scheveningen in Holland for priority as the most expensive seaside resort on the Continental shores of the North Sea. It is connected by steam tramway with the quieter sea-bathing resorts of Blankenberghe (13 miles), to the north-east, and Middelkerke, Westende, and Nieuport (11 miles), to the south-west. By the Canal de Bruges, Ostend has water communication with the city of Bruges, and thence by other canals with Ghent, Eecloo, Sluis, and other towns of Belgium. Population (1880), 19,307; (1890), 24,688; (1900), 39,484.

Osterode, a town of Prussia, province of Hanover, at the south foot of the Harz Mountains, 34 miles north-west of Nordhausen by rail. It is the seat of various industries—woollens, cottons, white lead, copper and puddling works, tanning, gypsum quarries, dyeworks, &c. The church of St Ægidius contains tombs of the dukes of Grubenhagen. Population (1885), 6435; (1900), 7099.

Osterode, a town of Prussia, province of East Prussia, 75 miles by rail north-east of Thorn, on Lake Drewenz. It has three churches, a synagogue, a castle built by the Teutonic knights in 1270, and a normal school (males). The place has a trade in agricultural products and timber, and such industries as saw-milling, tar production, dyeing, brewing, and manufacture of paper and machinery. Population (1885), 7123; (1900), 13,163.

Östersund, a town of Sweden, capital of the county of Jämtland, situated on the east shore of Stor (Great) Lake, 364 miles north by west of Stockholm by rail. Immediately facing the town is the lofty island of Frös, with which it is connected by a bridge 1418 feet long. It was founded in 1786. Population (1880), 2854; (1890), 5333; (1900), 6866.

Ostia, the ancient port of Rome, Italy, situated at the mouth of the Tiber. The principal survivals of the place are graves, from which numerous remains have been taken; baths, excavated in 1891; the headquarters of the fire-cohort; the forum, excavated in 1880–81, with the basement of a temple, 82 feet long by 39 feet broad; theatre; sanctuary of Mithras; three tiny temples, one dedicated to Venus; the sanctuary of Cybele; and another large temple. The modern village of Ostia, which gives name to one of the most important episcopal sees of the Church of Rome, was founded by Pope Gregory IV. in 830. At Porto the chief edifices are the cathedral of Santa Rufina, dating from the 10th century, but modernized; the bishop's palace; and the villa of Prince Torlonia. At Fiumicino, a port since 1825, there is sea-bathing. Population of all three places, about 1200. In 1884 a beginning was made with the draining of the Agro Romano, that is, the marshes of Ostia, the Isola Sacra, and Maccarese, by constructing banks and canals, and lifting out the water from the enclosed marshes by turbines.

Ostrau, the name of two Austrian towns in the Ostrau-Karwin coal-mining district. 1. Mährisch-Ostrau (Moravian Ostrau), situated on the right bank of the Ostrawitza, near its confluence with the Oder. It has a station on the Austrian Northern Railway, between Vienna and Cracow. It derives its importance from the extensive neighbouring coal-mines, and the blast furnaces and iron-works which they have called into existence. The manufactures comprise sheet-iron, boilers, zinc, brick and tiles, paraffin, petroleum, soap, rum, liqueurs, &c. The Rothschild iron-works at Witkowitz are in the vicinity. Population (1890), 19,243; (1900), 30,125. 2. Polnisch-Ostrau (Polish Ostrau), a mining town in the government district of Freistadt in Austrian Silesia, opposite Mährisch-Ostrau. It has large coal-mines, which form the south-western portion of the extensive Upper Silesian coal-fields, the largest Austrian deposit. Population (1890), 13,176; (1900), 18,761.

Ostrofsky, Alexander Nikolaivich (1823–1886), Russian dramatic author, was born on the 12th of April 1823 in Moscow, where his father was an official of the Senate. After passing through the gymnasium, he studied law in the university, which he quitted without having submitted to the final examination. He was then employed as a clerk in the office of the "Court of Conscience," and subsequently in that of the Commercial Court at Moscow. Both tribunals were called upon to settle disputes chiefly among the Russian merchant class, from which Ostrofsky was thus enabled to draw the chief characters for his earliest comedies. Among these are *Byednaya Nivesta* ("The Poor Bride"), *Byednost ne Porok* ("Poverty not a Vice"), and *Ne v'svoi sani ne sadis* (literally "Don't put yourself in another's sledge," but really meaning "Don't put yourself in a position for which you are not suited"). Of this last Nicholas I. said, "it was not a play, but a lesson." The uncultured, self-satisfied Moscow merchants are strikingly portrayed in *Grozá* ("The Tempest") and *Svoyi lyudi sochtyomsya* ("Between near relatives no accounts are needed"), which was originally called "The Bankrupt." The last-mentioned comedy was prohibited for ten years, until the accession of Alexander II., and Ostrofsky was dismissed the Government service and placed under the supervision of the police. The Liberal tendencies of the new reign, however, soon brought relief, and with a view to the great reforms of the 'sixties, then under consideration, Ostrofsky was one of several well-known literary men who were sent into the provinces to report on the condition of the people. Ostrofsky's field of inquiry lay along the upper Volga, a part of the country memorable for some of the most important events in Russian history. This mission induced him to write several historical dramas of great merit, such as *Kuzma Zakharich Minin Soukhorouk* (the full name of the famous butcher who saved Moscow from the Poles); "The False Demetrius" and "Vassily Shuisky"; *Vassilisa Melentieva* (the name of a favourite Court lady of Ivan the Terrible), and the comedy, *Voivoda eeli Son na Volge* ("The Military Commander," or "A Dream on the Volga"). Many of his later works treat of the Russian nobility, and include *Byeshani Dengi* (literally "Mad Money"), *Vospeetinitsa* ("A Girl brought up in a Stranger's Family"), and *Volki e Ovtsi* ("Wolves and Sheep"); others relate to the world of actors, such as *Liess* ("Forest"), *Bez vini vinovatiya* ("Guiltlessly guilty"), and *Talenti e Pokloniki* ("Talents and their Admirers"). Ostrofsky enjoyed the patronage of Alexander III., and received a pension of 3000 roubles a year. With the help of Moscow capitalists he established in that city a model theatre and school of dramatic art, of which he became the first director. He also founded the Society of Russian Dramatic Art and Opera Composers. His death took place on 24th June 1886, while travelling to his estate in Kostroma. (G. D.)

Ostrog, a district town of Russia, government of Volhynia, 90 miles west of Zhitomir and near the Zdolbunovo railway junction, at the confluence of the Wilia with the Goryn. It has, besides the usual primary schools, gymnasia for boys and for girls, and a brotherhood of Cyril and Methodius, which also maintains schools of its own. The tanning of lighter leather is a widely-spread domestic trade. Population (1897), 14,530.

Ostrogozhsk, a district town of Russia, government and 86 miles by rail south of Voronezh (*viâ* Liski), on the Tikhaya Sosna. It was founded by Little Russians in 1652. It is a centre for wholesale trade in horses, cattle, and tallow, and has several tanneries. Population (1897), 21,891.

Ostrów (Russian, *Ostrov*), a town of Russian Poland, government of Łomża, 53 miles north-east of Warsaw, 10 miles north of the railway to St Petersburg. It has agricultural machinery works. Population (1897), 11,264. Another town of the same name is in the government of Siedlce, district of Włodawa. Population, 4410. A third town of the same name is the Russian district town Ostrov, in the government of and 33 miles by rail south-south-west of Pskoff, on Velikaya river. It is a centre for trade in flax and linseed. Population, 6252.

Oswego, a city of New York, U.S.A., capital of Oswego county, on the southern shore of Lake Ontario, at an altitude of 300 feet. It is regularly laid out on a level site, with broad, mainly unpaved streets, is divided into eight wards, and its water-supply is pumped from the Oswego river, the works being owned by private parties. Oswego is on the Delaware, Lackawanna, and Western, the New York Central and Hudson River, and the New York, Ontario, and Western railways, and these, with boats on the lake, give it a large commerce, principally in coal, grain, and lumber. The ample water-power furnished by the Oswego river has caused a great development in manufactures. In 1900 the city contained 207 manufacturing establishments, with a total capital of $7,322,907. They employed 3845 hands, and the product was valued at $8,137,950. Chief among these products are those of foundry and machine shops, hosiery and knitted goods, and malt. Population (1890), 21,842; (1900), 22,199, of whom 3989 were foreign-born and 57 negroes.

Oswestry, a municipal borough and market town in the Oswestry parliamentary division of Shropshire, England, 18 miles north-west of Shrewsbury, on the Great Western and Cambrian railways. The old town hall has been demolished and new municipal buildings have been opened. The Cambrian Railway Company employ some 300 men at their carriage and engine works here. The castle grounds, laid out by public subscription, were opened in 1890. Population (1891), 8496; (1901), 9579.

Otago. See New Zealand.

Otaheite. See Tahiti.

Otley, a market town and railway station in the Otley parliamentary division of Yorkshire, England, 10 miles north of Bradford. A recreation hall was opened in 1895. In 1897 premises for art and science schools were erected. One of the chief industries is the making of printing machines. The neighbouring range of hills, known as the Chevin, abounds in good stone for building purposes, which was used for the foundations of the Houses of Parliament, and is despatched to all parts of England. Population (1891), 7838; (1901), 9230.

Ottawa, a river of Canada and the largest tributary of the St Lawrence. It rises in northern Quebec, in 75° 35′ W. and 47° 53′ N., and flows westwards 330 miles to Lake Temiscaming; from the outlet of the latter it flows in a south-easterly direction for 250 miles, and then easterly to its confluence with the St Lawrence at the island of Montreal. It drains an area of 56,470 square miles, and is 730 miles long. The principal tributaries from the left bank are the Rouge (120 miles long), North Nation, Petite Nation, Lievre (215 miles), Gatineau (245 miles), Coulonge, Black, Dumoine, and Keepawa; from the right bank, the South Nation, Mississippi, Madawaska, Petewawa, Mattawa, Montreal, and Blanche. Canals at St Anne, Carillon, and Grenville permit the passage of vessels, drawing 9 feet, up to Ottawa city; thence the Ottawa and Georgian Bay canal is projected, by way of the Ottawa, Mattawa, and French rivers, to Lake Huron. This canal, if constructed, will form the shortest route from Chicago, Duluth, &c., to the sea-board.

Ottawa (formerly Bytown), a city of Carleton county, Ontario, and the capital of the Dominion of Canada, situated on the right bank of the river of the same name, 101 miles west of Montreal. The main tower of the parliament buildings is in 75° 42′ 03″ W. and 45° 25′ 28″ N. The city stands on ground elevated from 60 to 155 feet above the river—185 to 280 feet above the sea—and is underlain by rocks of the Trenton and Utica groups, the former outcropping in precipitous bluffs on the river front. It is on the main line of the Canadian Pacific Railway and is the terminus of the Canada Atlantic, Ottawa and Parry Sound, Ottawa and New York, and Ottawa and Gatineau railways, and of the Montreal and Ottawa, Prescott and Brockville branches of the first-named railway. Electric railways afford rapid and easy communication with all parts of the city and with the neighbouring towns of Aylmer and Britannia, and during the summer months steamers ply to Montreal and ports on the Ottawa river and Rideau canal. A railway bridge and a road bridge—the latter a new structure replacing the famous Chaudière suspension bridge—connect Ottawa with the city of Hull on the opposite or Quebec bank of the river, and a third for railway and vehicular traffic gives the Pontiac Pacific Junction and Ottawa and Gatineau railways access to the centre of the city. Ottawa is the seat of the Dominion Government, the supreme and exchequer courts, and residence of the Governor-General. The parliament and departmental buildings are beautifully situated on Parliament Hill, a park of about 25 acres in extent, elevated 150 feet above the river and with precipitous limestone bluffs facing the river and canal. The parliament and eastern and western departmental buildings are in Italian Gothic of the 13th century, and form three sides of a great quadrangle, the fourth side being occupied by the Langevin departmental building. The latter, a fine massive structure, built of brown sandstone from New Brunswick, stands just outside the parliament grounds proper and on the opposite side of Wellington Street. The University of Ottawa—the Roman Catholic university of Ontario—occupies an advantageous situation on Wilbrod Street. It grants degrees in arts and sciences, and has about 475 students, drawn from all parts of Canada and the United States. Other prominent buildings are the post office, city hall, normal school, collegiate institute, printing bureau, court-house, Christ Church Cathedral, and the Basilica. The city charities are numerous, and include eight hospitals (three general hospitals and five others), nine homes for children and the aged and infirm, and two training schools for nurses. There are eighteen public schools, with 109 teachers and 6145 pupils, including kindergartens; twenty-four Roman Catholic separate schools, with 96 teachers and 4140 pupils; also a collegiate institute, the normal school for eastern Ontario, model school, ladies' college, six convents, and two monasteries. Ottawa contains many flourishing industries, including large saw, flour, and planing mills, foundries and manufactories of calcium carbide, street cars, waggons, and porcelain and carbon for electrical purposes. It is the seat of the head office of the Bank of Ottawa, and contains eleven branches of other banks. Incorporated as a city in 1854, the population in 1881 numbered 27,412; in 1887 New Edinburgh was annexed, and in 1889 three other suburbs, Stewarton, Rochesterville and Mount Sherwood, were brought in. In 1891 the population had increased to 44,154, and in 1901 to 59,928. The total assessment in 1885, exclusive of corporation and Government property, was $11,545,735; in 1895, $21,247,220; and in 1902, $27,420,740; exemptions in 1902, $16,337,150; assessed value of real estate, $24,738,690. The value of the exports for the year ending 30th June 1901 was $464,587; imports, $3,356,791; customs duty, $592,445. The city returns two members to the Dominion House of Commons, and two to the provincial legislature. A mayor and twenty-four aldermen — the latter representing the eight wards into which the city is divided—constitute the municipal government. It is the seat of a Roman Catholic archbishop and an Anglican bishop. (J. WH*.)

Ottawa, a city of Illinois, U.S.A., capital of Lasalle county, on the Illinois river, at the mouth of the Fox, on the Illinois and Michigan canal, and on the Chicago, Burlington, and Quincy, and the Chicago, Rock Island, and Pacific railways, north of the centre of the state, at an altitude of 484 feet. The city is on a level site on the first terrace above the river, and its plan is regular. Its water-supply is derived from artesian wells, and it has a good sewer system. In 1900 it contained 120 manufacturing establishments having a capital of $2,783,357, 1233 wage-earners, and a product valued at $2,042,148. Population (1890), 9985; (1900), 10,588, of whom 1804 were foreign-born.

Ottawa, a city of Kansas, U.S.A., capital of Franklin county, on the Osage river, which here is not navigable, and on the Atchison, Topeka, and Santa Fé and the Missouri Pacific railways, in the eastern part of the state, at an altitude of 891 feet. The site of the city is level and its plan regular. Its manufacturing establishments consist in part of railway works, flour mills, and beet-sugar factories. Population (1880), 4032; (1890), 6248; (1900), 6934, of whom 333 were foreign-born and 550 negroes.

Ottensen, formerly a town of Prussia, province of Schleswig-Holstein. It has since 1889 been united with Altona.

Ottumwa, a city of Iowa, U.S.A., capital of Wapello county, on the Des Moines river, in the south-eastern part of the state, at an altitude of 649 feet. The city spreads back from the river over a succession of terraces, rising one above another, and is well laid out, with good water-supply and sewerage systems and a steam heating plant. It is on the Chicago, Burlington, and Quincy, the Chicago, Fort Madison, and Des Moines, the Chicago, Milwaukee, and St Paul, the Chicago, Rock Island, and Pacific, and the Wabash railways, which give it a large trade. This is mainly in coal, since the city is in the midst of the great Iowa coal-field. In 1900 it had 160 manufacturing establishments with $3,403,321 capital, 2095 wage-earners, and products valued at $9,129,862. Population (1890), 14,001; (1900), 18,197, of whom 1759 were foreign-born and 598 negroes.

Oudh, or AWADH (*Ajodhya*), a historic tract in northern India, and still a separate administration not completely amalgamated with the North-Western Provinces. Area, 23,965 square miles; population (1891), 12,650,831; (1901), 12,884,150, showing an increase of 2 per cent. The capital is Lucknow. Oudh is a "non-regulation" province, with an independent judicial system; and the existence of the *talukdars* will always preserve an interesting distinction.

The statistics of Oudh are for the most part included under the North-Western Provinces (*q.v.*). Between 1881 and 1891 the population increased by 11 per cent., or more than twice as fast as in the North-West, owing to the extension of cultivation in the submontane tract. Excluding the two cities of Lucknow and Fyzabad, the average density ranged from 305 persons per square mile in the northern district of Kheri to 649 persons in the central district of Bara Banki. Classified according to religion, Hindus numbered 11,016,209, or 87 per cent. of the total population; Mahommedans, 1,620,930, or nearly 13 per cent.; Christians, 9312, of whom 5493 were Europeans and 1545 Eurasians, leaving 2274 for native converts; "others" (chiefly Sikhs and Jains), 4380. Out of a total area of 15,337,846 acres, the amount permanently settled with *talukdars* on privileged terms is 1,112,921, chiefly in the two districts of Gonda and Bahraich. The incidence of assessment is R.1 : 1 : 9 on the temporarily settled and Rs.0 : 14 : 7 on the permanently settled land. In 1896–97 the total cultivated area was 8,072,586 acres, of which 2,398,200 acres were cropped more than once. The irrigated area was 2,266,346 acres, entirely from wells and tanks, for there are no Government canals in Oudh. The principal crops are rice, wheat, barley, pulse, millet, sugar-cane, and opium. The area under indigo was 22,877 acres. Oudh has no manufactures or mines. The only large factory is one for making paper at Lucknow. The chief railway system is that of the Oudh and Rohilkhand, which crosses the Ganges opposite Cawnpore and Benares, and is now connected with northern Bengal.

Ougrée, a town of Belgium, in the province and four miles south-west of the town of Liége by rail. It has five blast-furnaces and large industrial establishments, and is situated in the Liége coalfield district. Population (1880), 7978; (1890), 10,241; (1900), 13,020.

Ouseley, Sir Frederick Arthur Gore (1825–1889), English composer, was the son of Sir Gore Ouseley, ambassador to Persia, and nephew to Sir William Ouseley, the eminent Oriental scholar. He was born 12th August 1825 in London, and very soon manifested an extraordinary precocity in music, composing an opera at the age of eight years. In 1844, having succeeded to the baronetcy, he entered at Christ Church, and graduated B.A. in 1846 and M.A. in 1849. He was ordained in the latter year, and, as curate of St Paul's, Knightsbridge, served the parish of St Barnabas, Pimlico, until 1851. In 1850 he took the degree of Mus.B. at Oxford, and four years afterwards that of Mus.D., his exercise being the oratorio *St Polycarp*. In 1855 he succeeded Sir Henry Bishop as professor of music in the University of Oxford, was ordained priest, and appointed precentor of Hereford. In 1856 he became vicar of St Michael's, Tenbury, and warden of St Michael's College, which under him became an important educational institution both in music and general subjects. His works include a second oratorio, *Hagar* (Hereford, 1873), a great number of services and anthems, chamber music, songs, &c., and theoretical works of great importance, such as *Harmony* (1868) and *Counterpoint* (1869), and *Musical Form* (1875). One of his most useful works is a series of chapters on English music added to the translation of Emil Naumann's *History of Music*, the subject having been practically ignored in the German treatise. A profoundly learned musician, and a man of great general culture, Ouseley's influence on younger men was wholly for good, and he helped forward the cause of musical progress in England perhaps more effectually than if he himself had been among the more enthusiastic supporters of "advanced" music. The work by which he is best known, *St Polycarp*, shows, like most compositions of its date, the strong influence of Mendelssohn, at least in its plan and scope; but if Ouseley had little individuality of expression, his models in other works were the English church writers of the noblest school. He died at Hereford, 6th April 1889. (J. A. F. M.)

Ovar, a town of Portugal, district Aveiro, situated at the north extremity of the lagoon (*ria*) of Aveiro, and 21 miles south of Oporto. Millet, wheat, and vegetables (especially onions) are the chief products. The people are principally engaged in the fisheries. Population, about 12,000.

Overbury, Sir Thomas (1581–1613), English poet and essayist, and the victim of one of the most sensational crimes in English history, was the son of Nicholas Overbury, of Bourton-on-the-Hill, and was born in 1581 at Compton Scorfen, near Wilmington, in Warwickshire. In the autumn of 1595 he became a gentleman commoner of Queen's College, Oxford, took his degree of B.A. in 1598, and came to London to study law in the Middle Temple. He found favour with Sir Robert Cecil, travelled on the Continent, and began to enjoy a reputation for an accomplished mind and free manners. About the year 1601, being in Edinburgh on a holiday, he met Robert Carr, then an obscure page to the earl of Dunbar; and so great a friendship was struck up between the two youths that they came up to London together. The early history of Carr remains obscure, and it is probable that Overbury secured an introduction to Court before his young associate contrived to do so. At all events, when Carr attracted the attention of James I., in 1606, by breaking his leg in the tilt-yard, Overbury had for some time been servitor-in-ordinary to the king. He was knighted in June 1608, and in 1609 he travelled in France and the Low Countries. He seems to have followed the fortunes of Carr very closely, and "such was the warmth of the friendship, that they were inseparable, . . . nor could Overbury enjoy any felicity but in the company of him he loved [Carr]." When the latter was made Lord Rochester in 1610, the intimacy seems to have been sustained. But it was now destroyed by a new element. Early in 1611 the Court became aware of the mutual attraction between Rochester and the infamous and youthful countess of Essex, who seemed to have bewitched the handsome Scots adventurer. To this intrigue Overbury was from the first violently opposed, pointing out to Rochester that an indulgence in it would be hurtful to his preferment, and that the woman, even at this early stage in her career, was already "noted for her injury and immodesty." He went so far as to use, in describing her, a word which was not more just than scandalous. But Rochester was now infatuated, and he repeated to the countess what Overbury had said. It was at this time, too, that Overbury wrote, and circulated widely in MS., the poem called "His Wife," which was a picture of the virtues which a young man should demand in a woman before he has the rashness to marry her. It was represented to Lady Essex that Overbury's object in writing this poem was to open the eyes of Rochester to her defects. The situation now resolved itself into a deadly duel for the person of Rochester between the mistress and the friend. The countess contrived to lead Overbury into such a trap as to make him seem disrespectful to the king, and she succeeded so completely that he was thrown into the Tower on the 22nd of April 1613. It was not known at the time, and it is not certain now, how far Rochester participated in this first crime, or whether he was ignorant of it. But the queen, by a foolish phrase, had sown discord between the friends; she had called Overbury Rochester's "governor." It is, indeed, apparent that Overbury had become arrogant with success, and was no longer a favourite at Court. Lady Essex, however, was not satisfied with having had him shut up; she was determined that "he should return no more to this stage." She had Sir William Wade, the honest Governor of the Tower, removed to make way for a creature of her own, Sir Gervaise Elvis (or Helwys); and a gaoler, of whom it was ominously said that he was "a man well acquainted with the power of drugs," was set to attend on Overbury. This fellow, afterwards aided by Mrs Turner, the widow of a physician, and by an apothecary called Franklin, plied the miserable poet with sulphuric acid in the form of copper vitriol. But his constitution long withstood the timid doses they gave him, and he lingered in exquisite sufferings until the 15th of September 1613, when more violent measures put an end to his existence. Two months later Rochester, now earl of Somerset, married the chief murderess, Lady Essex. More than a year passed before suspicion was roused, and when it was, the king showed a hateful disinclination to bring the offenders to justice. In the celebrated trial which followed, however, the wicked plot was all discovered. The four accomplices were hanged; the countess of Somerset pleaded guilty but was spared, and Somerset himself was disgraced. Meanwhile, Overbury's poem, *The Wife*, was published in 1614, and ran through six editions within a year, the scandal connected with the murder of the author greatly aiding its success. It was abundantly reprinted within the next sixty years, and it continued to be one of the most widely popular books of the 17th century. Combined with later editions of *The Wife*, and gradually adding to its bulk, were "Characters" (first printed in the second of the 1614 editions), "The Remedy of Love" (1620), and "Observations in Foreign Travels" (1626). Later, much that must be spurious was added to the gathering snow-ball of Overbury's *Works*. Posterity has found the praise of his contemporaries for the sententious and graceful moral verse of Overbury extravagantly expressed. *The Wife* is smooth and elegant, but uninspired. There is no question that the horrible death of the writer, and the extraordinary way in which his murderers were brought to justice, gave an extraneous charm to his writings. Nor can we be quite sure that Overbury was in fact such a "glorious constellation" of all the religious virtues as the 17th century believed. He certainly kept very bad company, and positive evidence of his goodness is wanting. But no one was ever more transcendently canonized by becoming the victim of conspirators whose crimes were equally detestable and unpopular. (E. G.)

Overyssel, a Dutch province east of the Yssel, bordering on the Zuider Zee. Five basins are to be distinguished: (1) the Almelo, which communicates with (2) the Regge. These two are divided by a range of hills to the west of them from the basins of (3) the Salland, which discharges its waters into (4) the Vecht, which again has its outfall in (5) the Zwarte Water, which communicates by the Zwollsche Diep with the Zuider Zee and by the Willemsvaart with the Yssel. Meppeler Diep from Drenthe and Dedemsvaart from the north-east of Overyssel both discharge into the Zwarte Water. Most of the uncultivated land lies in the east of the province, the cultivated land in the west and on the banks of the small rivers. About 18 per cent. of the surface consists of ploughland, 32 per cent. of natural pastures and grasslands, and fully 30 per cent. of uncultivated land. Population (1879), 247,136; (1900), 338,408.

Oviedo, a maritime province of northern Spain. It has an area of 4091 miles, and is divided into 16 administrative districts and 79 parishes. Population, 595,420 in 1887, and 612,663 in 1897. The birth-rate is 2·85 per cent., the death-rate 2·49 per cent., and the proportion of illegitimate births 4·01 per cent. of the total births. That section of the Cantabrian mountains which forms its southern border includes about a dozen peaks ranging from 3800 to 8000 feet. There are picturesque lakes among the mountains, and the principal rivers that descend to the coast are the Nalon, Narcea, Navia, Pilona, Sella, and Eo, which wind through well-wooded and frequently fertile, well-cultivated vales. The climate is generally mild and temperate, with abundant rains, though bitterly cold during some months in the higher mountains. The means of communication have been much improved. A railway has been constructed through some of the most difficult parts of the Cantabrian chain, the construction of the line affording remarkable evidence of engineering skill. A branch runs from Oviedo to Trubia, where the Government arms factory and foundries occupy more than a thousand hands. There are also several other railways, including numerous narrow-gauge lines built by mining companies and metallurgic establishments. Oviedo is rich in forests, coal mines, streams and waterfalls that have materially contributed to the development of its manufacturing and metallurgical industries, especially the latter, there being an abundant supply of ores in the province. There are flourishing copper works in Aviles; manufactures of fine textiles, coarse cloth, and ribbons in Salas, Pilona, Casas, and Aviles; of paper in Pianton; of porcelain and glass in Gijon, Aviles, and Pola de Surro; of arms in Oviedo and Trubia; while foundries and works for the manufacture of agricultural implements, rails, and pig-iron are numerous. One company uses annually 35,000 tons of coal, 25,000 tons of coke, 33,000 tons of iron ore, and employs 2300 hands to turn out over 30,000 tons of iron; another consumes 100,000 tons of coal, 46,000 tons of ore, and turns out nearly 50,000 tons of iron, mostly for consumption in Spain. The fisheries and the salting of tunny and sardines are important, and much butter and cheese is made in the province for the interior of Spain. The principal exports are fruit, preserved meats and fruit, cheese, butter, fish, wheat, flour, cider, oil, soap, coal, glass, and iron.

Agriculture is not very important in Oviedo. In 1897 wheat was grown on 18,855 acres; rye, oats, barley, maize, on 6662 acres; pod-fruit on 14,712 acres; and vines on 57,370 acres. The live stock included 8494 horses, 2018 mules, 3619 asses, 363,977 cattle, 116,402 sheep, 31,122 goats, and 134,955 pigs. It is the mines that furnish the real wealth. There are 19 quicksilver, 3 zinc, 3 copper, 55 iron, 453 coal, and 2 manganese mines actually worked, giving employment in 1899 to 12,050 hands, of whom 11,279 worked in the coal-mines alone. The output was 10,907 tons of quicksilver ore, 360 of zinc, 886 of copper, 63,965 of iron, 1,397,152 of coal, and 340 of manganese. The mining industries further employed 4874 hands, of whom 3853 were engaged in the ironworks. The output for 1898 was 92 tons of quicksilver, 6031 tons of zinc in bars or sheet, 14,925 tons of steel, 2900 of wire, 38,216 of iron in different shapes, 138,643 tons of coke, 120,176 tons of coal agglomerate. (A. E. H.)

Oviedo, the capital of the above province, on the river Nalon, 16 miles from the coast, in a broad and picturesque valley. Its population was 42,716 in 1887 and 46,376 in 1897. The town has grown chiefly in the suburb near the station and in the modern suburb of Uria, near the great hospital and fine promenade close to the convent of San Francisco. Few towns in Spain have better schools for primary and higher education, and there are an institute, a meteorological observatory, schools for teachers and fine arts, adult classes for the working classes, an archæological museum, several public libraries, and a university (with a fine library). The markets are the centre of a thriving trade in agricultural products, and the principal industries are manufactures of arms, textiles of cotton and wool, iron goods, marble, leather, and matches.

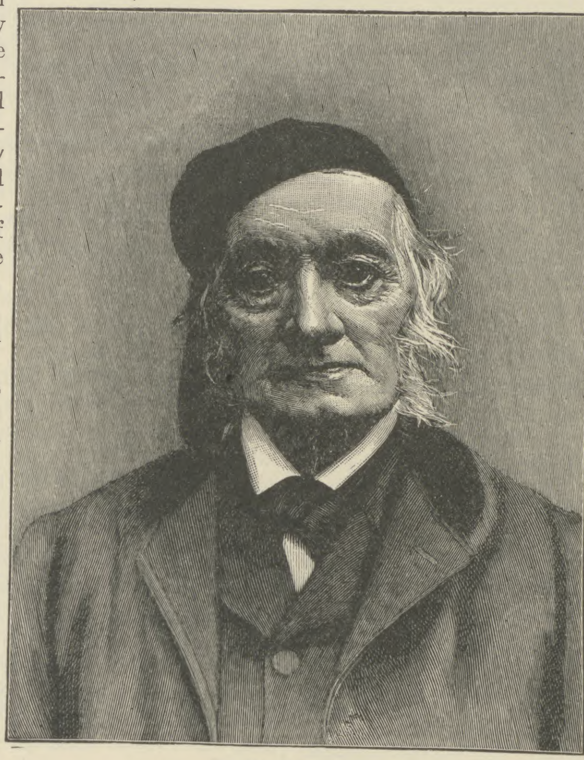
Owatonna, a city of Minnesota, U.S.A., capital of Steele county, in the south-eastern part of the state, at the intersection of lines of the Chicago and North-Western, the Chicago, Milwaukee, and St Paul, and the Burlington, Cedar Rapids, and Northern railways, in a rich farming country. Population (1890), 3849; (1900), 5561, of whom 1160 were foreign-born.

Owego, a village of New York, U.S.A., capital of Tioga county, on the north branch of the Susquehanna river, at the mouth of Owego creek, in the southern part of the state, at an altitude of 822 feet. It is on three railways, the Erie, the Delaware, Lackawanna, and Western, and the Lehigh Valley. It is in a rich agricultural region, and has manufactures of flour, lumber, and woollen goods. Population (1890), 5141; (1900), 5039, of whom 301 were foreign-born and 214 negroes.

Owen, Sir Richard (1804–1892), English biologist, was born at Lancaster on 20th July 1804, and received his early education at the grammar school of that town. In 1820 he was apprenticed to a local surgeon and apothecary, and in 1824 he proceeded as a medical student to the University of Edinburgh. He left the university in the following year, and completed his medical course in St Bartholomew's Hospital, London, where he came under the influence of the eminent surgeon, John Abernethy. He then contemplated the usual professional career; but his bent was evidently in the direction of anatomical research, and he was induced by Abernethy to accept the position of assistant to William Clift, conservator of the museum of the Royal College of Surgeons. This congenial occupation soon led him to abandon his intention of medical practice, and his life henceforth was devoted to purely scientific labours. He prepared an important series of catalogues of the Hunterian collection in the Royal College of Surgeons; and in the course of this work he acquired the unrivalled knowledge of comparative anatomy which enabled him to enrich all departments of the science, and specially facilitated his researches on the remains of extinct animals. In 1837 he was appointed Hunterian professor in the Royal College of Surgeons, and in 1849 he succeeded Clift as conservator. He held the latter office until 1856, when he became superintendent of the natural history department of the British Museum. He then devoted much of his energies to a great scheme for a National Museum of Natural History, which eventually resulted in the removal of the natural history collections of the British Museum to a new building at South Kensington, the British Museum (Natural History). He retained office until the completion of this work in 1884, when he received the distinction of K.C.B. Sir Richard Owen lived quietly in retirement at Sheen Lodge, Richmond Park, until his death on 18th December 1892.

While occupied with the cataloguing of the Hunterian collection, Owen did not confine his attention to the preparations before him, but also seized every opportunity of dissecting fresh subjects. He was especially favoured with the privilege of investigating the animals which died in the Zoological Society's gardens; and when that society began to publish scientific proceedings in 1831, he was the most voluminous contributor of anatomical papers. His first notable publication, however, was his *Memoir on the Pearly Nautilus* (London, 1832), which was soon recognized as a classic. Henceforth he continued to make important contributions to every department of comparative anatomy and zoology for a period of over fifty years. In the sponges Owen was the first to describe the now well-known "Venus's flower basket" or *Euplectella* (1841, 1857). Among Entozoa his most noteworthy discovery was that of *Trichina spiralis* (1835), the parasite infesting the muscles of man in the disease now termed trichinosis (see also Paget, Sir James). Of Brachiopoda he made very special studies, which much advanced knowledge and settled the classification which has long been adopted. Among Mollusca, he not only described the pearly nautilus, but also *Spirula* (1850) and other Cephalopoda, both living and extinct; and it was he who proposed the universally-accepted subdivision of this class into the two orders of Dibranchiata and Tetrabranchiata (1832). The problematical crustacean *Limulus* was also the subject of a special memoir by him in 1873.

Owen's technical descriptions of the Vertebrata were still more numerous and extensive than those of the invertebrate animals. His *Comparative Anatomy and Physiology of Vertebrates* (3 vols., London, 1866–68) was indeed the result of more personal research than any similar work since Cuvier's *Leçons d'Anatomie Comparée.* He not only studied existing forms, but also devoted great attention to the remains of extinct groups, and immediately followed Cuvier as a pioneer in vertebrate palæontology. Early in his career he made exhaustive studies of teeth, both of existing and extinct animals, and published his profusely illustrated work on *Odontography* (1840–45). He discovered and described the remarkably complex structure of the teeth of the extinct animals which he named Labyrinthodonts. Among his writings on fishes, his memoir on the African mud-fish, which he named *Protopterus*, laid the foundations for the recognition of the Dipnoi by Müller. He also pointed out later the serial connexion between the teleostean and ganoid fishes, grouping them in one sub-class, the Teleostomi. Most of his work on reptiles related to the skeletons of extinct forms, and his chief memoirs on British specimens were reprinted in a connected series in his *History of British Fossil Reptiles* (4 vols., London, 1849–84). He published the first important general account of the great group of Mesozoic land-reptiles, to which he gave the now familiar name of Dinosauria. He also first recognized the curious early Mesozoic land-reptiles, with affinities both to amphibians and mammals, which he termed Anomodontia. Most of these were obtained from South Africa, beginning in 1845 (*Dicynodon*), and eventually furnished materials for his *Catalogue of the Fossil Reptilia of South Africa*, issued by the British Museum in 1876. Among his writings on birds, his classical memoir on the *Apteryx* (1840–46), a long series of papers on the extinct Dinornithidæ of New Zealand, other memoirs on *Aptornis*, *Notornis*, the dodo, and the great auk, may be specially mentioned. His monograph on *Archæopteryx* (1863), the long-tailed, toothed bird from the Bavarian Lithographic Stone, is also an epoch-making work. With regard to living mammals, the more striking of Owen's contributions relate to the monotremes, marsupials, and the anthropoid apes. He was also the first to recognize and name the two natural groups of typical Ungulata, the odd-toed (Perissodactyla) and the even-toed (Artiodactyla), while describing some fossil remains in 1848. Most of his writings on mammals, however, deal with extinct forms, to which his attention seems to have been first directed by the remarkable fossils collected by Darwin in South America. *Toxodon*, from the pampas, was then described, and gave the earliest clear evidence of an extinct generalized hoofed animal, a "pachyderm with affinities to the Rodentia, Edentata, and Herbivorous Cetacea." Owen's interest in South American extinct mammals then led to the recognition of the giant armadillo, which he named *Glyptodon* (1839), and to classic memoirs on the giant ground-sloths, *Mylodon* (1842) and *Megatherium* (1860), besides other important contributions. At the same time Sir Thomas Mitchell's discovery of fossil bones in New South Wales provided material for the first of Owen's long series of papers on the extinct mammals of Australia, which were eventually reprinted in book-form in 1877. He discovered *Diprotodon* and *Thylacoleo*, besides extinct kangaroos and wombats of gigantic size. While occupied with so much material from abroad, Owen was also busily collecting facts for an exhaustive work on similar fossils from the British Isles, and in 1844–46 he published his *History of British Fossil Mammals and Birds*, which was followed by many later memoirs, notably his *Monograph of the Fossil Mammalia of the Mesozoic Formations* (Palæont. Soc., 1871). One of his latest publications was a little work entitled *Antiquity of Man as deduced from the Discovery of a Human Skeleton during Excavations of the Docks at Tilbury* (London, 1884).



Sir Richard Owen.
(From a photograph by Elliott and Fry, London.)

Owen's detailed memoirs and descriptions require laborious attention in reading, on account of their nomenclature and ambiguous modes of expression; and the circumstance that very little of his terminology has found universal favour causes them to be more generally neglected than they otherwise would be. At the same time it must be remembered that he was a pioneer in concise anatomical nomenclature; and, so far at least as the vertebrate skeleton is concerned, his terms were based on a carefully reasoned philosophical scheme, which first clearly distinguished between the now familiar phenomena of "analogy" and "homology." Owen's theory of the *Archetype and Homologies of the Vertebrate Skeleton* (1848), subsequently illustrated also by his little work *On the Nature of Limbs* (1849), regarded the vertebrate frame as consisting of a series of fundamentally identical segments, each modified according to its position and functions. Much of it was fanciful, and failed when tested by the facts of embryology, which Owen systematically ignored throughout his work. However, though an imperfect and distorted view of certain great truths, it possessed a distinct value at the time of its conception. To the discussion of the deeper problems of biological philosophy he made scarcely any direct and definite contributions. His generalities rarely extended beyond strict comparative anatomy, the phenomena of adaptation to function, and the facts of geographical or geological distribution. His lecture on "virgin reproduction" or Parthenogenesis, however, published in 1849, contained the essence of the theory of the germ-plasm elaborated several years afterwards by Weismann; and he made several vague statements concerning the geological succession of genera and species of animals and their possible derivation one from another. He referred especially to the changes exhibited by the successive forerunners of the crocodiles (1884) and horses (1868); but it has never become clear how much of the modern doctrines of organic evolution he admitted. He contented himself with the bare remark that "the inductive demonstration of the nature and mode of operation" of the laws governing life would "henceforth be the great aim of the philosophical naturalist."

See *The Life of Richard Owen*. By his grandson, Rev. RICHARD OWEN. 2 vols. London, 1894. (A. S. WO.)

Owensboro, a city of Kentucky, U.S.A., capital of Daviess county, on the south bank of the Ohio river in the north-western part of the state, at an altitude of 386 feet. It has three railways, the Illinois Central, the Louisville, Henderson, and St Louis, and the Louisville and Nashville, and through these and boats on the river it has a large trade. It is in the Indiana–Kentucky coal field, and some coal is mined in its vicinity. Its industries consist largely in the manufacture of tobacco and distilling of whisky. Population (1890), 9837; (1900), 13,189, of whom 308 were foreign-born and 3061 negroes.

Owen Sound, a town and port of entry in Ontario, Canada, and capital of Grey county, situated 99 miles north-west of Toronto, on Georgian Bay. It is the terminus of branches of the Canadian Pacific and Grand Trunk railways, and of the Canadian Pacific and other steamship lines plying to ports on Lakes Huron and Superior. Its harbour is one of the best on Lake Huron, and navigable by lake vessels of the largest size. It contains manufactories of mill machinery, agricultural implements, furniture, and sewing-machines, flour-mills, saw-mills, and large grain elevators. Population (1881), 4426; (1891), 7497; (1901), 8776.

Owosso, a city of Shiawassee county, Michigan, U.S.A., on the Shiawassee river, and on the Ann Arbor, the Grand Trunk, and the Michigan Central railways, east of the centre of the Lower Peninsula, at an altitude of 744 feet. It has a regular plan, is divided into five wards, and has a good water-supply. The river furnishes power for its manufactures, which consist in large part of lumber and furniture. Population (1880), 2501; (1890), 6564; (1900), 8696, of whom 1396 were foreign-born.

Oxford, a midland county of England, bounded on the S. by the Thames, on the W. by Gloucester, on the N. by Warwick, on the N.E. by Northampton, and on the E. by Buckingham.

Area and Population.—The area of the ancient county is 483,614 acres, or 756 square miles, with a population in 1881 of 179,551, and in 1891 of 185,669, of whom 89,649 were males and 96,020 females; and in 1901, 182,768, the number of persons per square mile being 242, and of acres to a person 2·6. The area of the administrative county as given in the census returns was 480,608 acres, with a population in 1891 of 145,449, or including the county borough of Oxford, 485,322 acres, with a population in 1891 of 191,193; but certain changes in the administrative area have since taken place. In 1895 there were transferred to Buckingham the part of the parish of Ibstone in Oxford and the parish of Stokenchurch; and in the same year there were transferred to Oxford the parish of Kingsey in Buckingham, and the parish of Mollington in Warwick. The area of the registration county is 490,146 acres, with a population in 1891 of 188,220, of whom 83,862 were urban and 104,358 rural; and in 1901, 186,767, of whom 88,558 were males and 98,209 females. Within the registration area the percentage of increase between 1881 and 1891 was 3·49, but between 1891 and 1901 there was a decrease of ·7 per cent. Between 1881 and 1891 the excess of births over deaths was 23,710, and the actual increase of population was 6353. The following table gives the numbers of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	1063	5725	3266	145	146
1890	1184	5182	3203	111	113
1898	1287	4635	2710	126	131

The number of marriages in 1899 was 1315, of births 4543, and of deaths 2899. The following table shows the marriage-, birth-, and death-rate, with the percentage of illegitimate births, for a series of years:—

	1870–79.	1880.	1880–89.	1890.	1888–97.	1898.
Marriage-rate . .	13·4	11·1	12·6	12·6	12·8	13·4
Birth-rate . .	31·7	31·5	30·0	27·6	27·0	24·1
Death-rate . .	19·3	18·0	16·9	17·1	16·1	14·1
Percentage of illegitimacy . .	6·0	5·1	5·4	4·3	5·1	5·4

In 1891 there were in the county 649 natives of Scotland, 584 natives of Ireland, and 359 foreigners.

Constitution and Government.—The ancient county is divided into three parliamentary divisions, and it also includes part of the parliamentary borough of Oxford, returning one member, in addition to which the University of Oxford returns two members. The administrative county contains five municipal boroughs—Banbury (12,967), Chipping Norton (3780), Henley-on-Thames (5984), Oxford (49,413), and Woodstock (1684). Oxford is a county borough. The following are urban districts: Bicester (3023), Caversham (6580), Thame (2911), Wheatley (872), and Witney (3574). Oxfordshire is in the Oxford circuit, and assizes are held at Oxford. The boroughs of Banbury, Henley-on-Thames, and Oxford have separate commissions of the peace, and Banbury and Oxford have in addition separate courts of quarter sessions. The ancient county, which is mostly in the diocese of Oxford, contains 234 ecclesiastical parishes or districts, and parts of 10 others.

Education.—On account of the famous university in the borough of Oxford and other educational institutions there, the county as regards education holds perhaps the premier position in England. In connexion with the university there is a day training college for schoolmasters, and there is also in Oxford a residential training college for schoolmistresses (diocesan), which takes day students. The total number of elementary schools in the county on 31st August 1899 was 266, of which 28 were board and 238 voluntary schools, the latter including 219 National Church of England schools, 3 Wesleyan, 6 Roman Catholic, and 10 "British and other." The total school board receipts for the year ended 29th September 1899 were over £20,138. The income under the Agricultural Rates Act was over £663.

Communications.—An important addition to the railway facilities of the county has been made by a branch line of the Great Central running from Princes Risborough in Bucks to the Great Western at Banbury.

Agriculture.—Nearly seven-eighths of the area of the county is under cultivation, and of this area about three-tenths is under corn crops and nine-twentieths in permanent pasture. Over 2000 acres are under orchards and about 26,000 under woods. Although with the diminution of the acreage under corn crops the acreage under wheat has somewhat diminished, it and barley still occupy each about a third of the corn crop area, while oats occupy about a fourth, and there is also a considerable acreage under beans. More than half the total acreage under green crops is occupied by turnips, and vetches and tares are also largely grown. The following table gives the larger main divisions of the cultivated area at intervals from 1880:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	418,311	158,404	54,201	46,297	146,929	12,478
1885	417,822	147,349	53,524	49,735	158,593	8,610
1890	414,966	136,700	46,684	48,161	176,113	7,192
1895	415,616	123,419	45,663	50,201	187,668	8,345
1900	411,682	120,898	43 215	50,111	193,716	3,522

The following table gives particulars regarding the principal live stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	17,276	51,204	17,286	279,159	31,559
1885	18,193	60,124	20,185	299,172	38,536
1890	17,739	56,443	20,353	266,594	44,110
1895	17,798	53,434	19,165	241,742	44,737
1900	17,276	61,851	20,653	230,325	31,032

Manufactures and Minerals.—According to the report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 6774, as compared with 6721 in 1896. Of the 4432 persons employed in non-textile factories, 1354 were employed in the manufacture of paper. Workshops employed 1608 persons, of whom 1048 were employed in clothing industries. Banbury is famed for its cakes; there is some decline in the glove trade at Woodstock. In 1899 from quarries under 20 feet deep 166,163 tons of iron ore, valued at about £18,000, were raised. The other minerals include clay (30,002 tons).

Oxford.—The county town of Oxfordshire lies at the junction of the Thames (locally known as the Isis) and the Cherwell, 55 miles from London by road and 63½ by rail. Population (1881), 35,264; (1891), 45,742; (1901), 49,413. The rateable value is £387,609. It is represented in Parliament by one member, having lost its second by the redistribution of 1885, before which date it had been disfranchised entirely for a year owing to the bribery practised at the election of 1881. The number of voters on the register at the election of 1885 was 6983; at that of 1892, 7476; at that of 1895, 7637; in 1901, 8310. Since 1889 the government has been in the hands of a city council, appointed under the Local Government Act of 1888, and consisting of 45 councillors (36 from the city and 9 from the University) and 15 aldermen (12 from the city and 3 from the University). In this joint body are vested the powers of the former municipality and of the local board; to it also has been transferred the share in the control of the police once exercised by the proctors of the University. At the time of the formation of the city council the outlying districts of Summertown on the north, Cowley St John on the east, and Grandpont and New Hincksey on the south were incorporated. The growth of the city has been rapid since 1880. Although no new manufactures of importance have been introduced, Oxford has become to a very large extent a "residential" town, owing partly to its proximity to London, but chiefly to the opening up of University society through the abolition of compulsory celibacy by the statutes of the University Commission (1882). The most important new buildings are the theatre (1886), the Corn Exchange (1896), both in George Street, and the municipal buildings, designed by Mr Hare, and opened by the prince of Wales in May 1897. As a result of this development the city has in some respects lost its picturesqueness; old houses have disappeared everywhere. The most important piece of destruction has been the removal of Carfax church (1896). The tower, however, remains, and is now used for an illuminated clock (1898). Magdalen bridge was widened in 1885 to accommodate the increased traffic. Electric light was introduced in 1892. The water-supply has been greatly improved by a new pumping station above the King's Weir (1887), and by new filter beds (1884). A hospital for infectious diseases has been opened at Cold Harbour (1886), the Oxford Eye Hospital has obtained a permanent home in Walton Street (1894), and the Radcliffe Infirmary has been considerably enlarged (1894); so too has the Acland Nursing Home (1897), which is now in the Banbury Road. Outside cemeteries at Rose Hill, at Summertown, and near Botley were opened in 1893. As a result of improved water and drainage the death-rate of Oxford has fallen. In 1885 it was 16·8; in 1890, 17; in 1895, 15·66; in 1901, 13·85.

Magdalen College opened the new buildings (designed by Sir A. Blomfield) for its school in 1894, and technical schools have been started in St Ebbe's (1894) and St Clement's. The progress in the numbers of the University has been comparatively slow, as the following table will show:—

	Matriculations.	B.A.'s.	Honours in the Final Schools.
1880	758	483	315
1885	749	522	366
1890	771	584	376
1895	863	608	413
1900	839	558	429
1901	837	594	444

The average of matriculations in the last decade of the 19th century was about 60 above that in the previous decade (829 as against 770), while the increase in graduations, especially in honours, has been much larger. In one other department of the University — its revenue — there has been no appreciable progress; but in every other respect there has been rapid development. The Bodleian Library steadily increases, and the basement of the Ashmolean has been fitted up to receive books. The collections once housed there have been transferred to a New Ashmolean Museum, in close proximity to the University Galleries in Beaumont Street; these have been twice extended (1888 and 1894). The Science Museum is ever growing. Apart from minor developments, the Physiological Laboratory was opened in 1885, and the department of Human Anatomy in 1893; the new Library (the gift of the Drapers' Company) was begun in 1898, and a Morphological and a Pathological Laboratory was opened in 1901. The block of the New Schools has also been completed by the addition of the Non-Collegiate Delegacy at its north-east corner (1888). In 1887 the Pitt Rivers anthropological collection found a home in a new annexe on the north-east side of the Science Museum. The Picture Gallery has received the Combe bequest of the works of Pre-Raphaelite painters, especially of Holman Hunt; and the Art Museum has been enormously increased by the gifts of Mr Drury Fortnum (d. 1899). The Indian Institute, too, has been completed (1896). Of a different kind has been the work at St Mary's church, where the spire was rebuilt in 1895, after being sheathed in scaffolding for three years. During the last twenty years of the 19th century there was a greater amount of college building than in any similar period in the history of the University. St Swithun's quad at Magdalen (finished 1884) and the President's house (1888) (the work of Messrs Bodley and Garnier), the new quad (1887) and the President's house (1888) at Trinity (the work of Mr. T. G. Jackson, R.A.), and the new quad at Brasenose College, with its front to the High Street (also Mr Jackson's work), are only the most conspicuous amongst many instances. The religious life of the University has been enriched by a number of new foundations. The Pusey House (1884) led the way, and its example has been followed by such Nonconformist institutions as Mansfield College (1889) and Manchester New College (1893). All three of these are centres of theological study, but not residences for undergraduates. Private halls for Jesuit (1896), Benedictine (1900), and Unitarian (1900) students have also now been opened; the first of these is called Campion Hall. Hannington Hall (1897) has been founded as a centre of missionary interest, on the site of the old New Inn Hall. New Final Schools have been founded in Oriental languages (first held 1887), and in English language and literature (1897). New degrees for the encouragement of research, the B.Lit. and B.Sc. (founded in 1895, and completed in 1900 by the institution of research doctorates), have attracted graduates from the universities of other countries. In 1899 a geographical department was opened, which is jointly supported by the University and by the Royal Geographical Society. Of more bearing on practical life are the Day Training College Delegacy (1892) and the diploma in education (1896). Under the former elementary school teachers are enabled to take their training course at Oxford, and do so in growing numbers; the latter is under the supervision of the Locals Delegacy, and is increasingly taken by secondary teachers every year. To the two original foundations for the education of women, Somerville College and Lady Margaret Hall (which have both largely increased their buildings), are now added two more women's halls—St Hugh's (1886) and St Hilda's (1893). The number of women students is over 200. An attempt to obtain their admission to the degrees of the University (as well as to its examinations) was very decisively defeated in 1896.

There has, too, been a great increase in the work done by Oxford in the world outside. The number of candidates examined by the Delegacy for Local Examinations has increased from 2301 in 1885 to 10,337 in 1901. The University Extension movement has become as important as at Cambridge, where it originated. Started in Oxford in 1877, it had at first little success; since 1885, however, it has rapidly advanced, and has been under a special Delegacy since 1892. In 1900–01, 177 courses of lectures were given to nearly 18,000 students (aggregate average attendance). Special features of the Oxford work have been the "summer meetings" and the foundation of the Extension College at Reading (1892). The former were begun in August 1888. There were nearly 1200 students from all parts of the world at that (the tenth) of August 1901. Similarly, Oxford has become a great centre for educational conferences of all kinds. The Headmasters' Conference met there in 1890, the National Union of Teachers in 1894, and the British Association in the same year. There have been countless others, great and small, for which the New Examination Schools furnish an admirable meeting-place. But with all its developments the life of the University itself has changed but little. "Town and Gown rows" have practically disappeared, though there may probably be some of the old feeling under the surface. At all events, the privileges of the University in jurisdiction and other departments are still attacked, and a suggested compromise as to them was rejected by the city in 1893.

AUTHORITIES.—The Oxford Historical Society has continued its series of publications. The early history of the University has been admirably treated by H. RASHDALL, *Universities of Europe in Middle Ages*, 3 vols. Oxford, 1895 (Oxford is dealt with in the third volume). The various colleges are described by members of their foundations in the *College History Series*, published by Robinson. (J. WE*.)

Oxus.—Prior to the meeting of the commissions appointed for the determination of the Russo-Afghan boundary in 1885, no very accurate geographical knowledge of the upper Oxus regions existed, and the course of the river itself was but roughly mapped. Russian explorers and natives of India trained for geographical reconnaissance, and employed in connexion with the great trigonometrical survey of India, had done so much towards clearing away the mists which enveloped the actual bounds of the river, that all the primary affluents were known, although their relative value was misunderstood, but the nature of the districts which bordered the river in Afghan Turkestan was so imperfectly mapped as to give rise to considerable political complication in framing the boundary agreement between Great Britain and Russia. From Lake Victoria, in the Pamirs, which was originally reckoned as the true source of the river, to Khamiab, on the edge of the Andkhui district of Afghan Turkestan, for a distance of about 680 miles, the Oxus forms the boundary between Afghanistan and Russia. For another 550 miles below Khamiab it follows an open and sluggish course till it is lost in the Sea of Aral, being spanned at Charjui, 150 miles below Khamiab, by the wooden bridge which carries the Russian railway from Merv to Samarkand. The level of Lake Victoria is 13,400 feet above sea. At Khamiab the river is probably rather less than 500 feet.

Sources.—For many years a lively geographical controversy circled about the sources, and the discussion derived some political significance from the fact that the true source, wherever it might be found, was claimed as a point in the Russo-Afghan boundary. The final survey of the Pamir region (the Bam-i-dunya, or "the Roof of the World"), wherein the heads of all the chief tributaries of the river lay hidden, by the Pamir Boundary Commission of 1895 established the following topographical facts in connexion with this question. The elevated mountain chain which is now called the Nicolas range, which divides the Great from the Little Pamir, is a region of vast glaciers and snow-fields, from which the lakes lying immediately north and south derive the greater part of their water-supply. On the north the principal glacial tributary of Lake Victoria forms, within the folds of the gigantic spurs of the Nicolas mountains, a series of smaller lakes, or lakelets, before joining the great lake itself. On the south a similar stream starting farther east, called Burgutai, denoting the position of a difficult and dangerous pass across the range, sweeps downwards towards Lake Chakmaktin, the lake of the Little Pamir, which is some 400 feet lower than Victoria. But at the foot of the mountain this stream bifurcates in the swamps which lie to the west of Chakmaktin, and part of its waters find their way eastwards into the lake, and part flow away westwards into the Ab-i-Panja, which joins the Pamir river from Lake Victoria at Kala Panja. This at least is the action of the Burgutai stream during certain seasons of the year, so that the glaciers and snow-fields of the Nicolas range may be regarded as the chief fountain-head of at least two of the upper tributaries of the Oxus, namely, the Aksu (or Murghab) and the Pamir river, and as contributing largely to a third, the Ab-i-Panja. Neither Lake Victoria nor Lake Chakmaktin derives any very large contributions from glacial sources other than those of the Nicolas range. It is possible that there may be warm springs on the bed of Lake Victoria, as such springs are of frequent occurrence in the Pamirs; but there is no indication of them in the Chakmaktin basin, and the latter lake must be regarded rather as an incident in the course of the Aksu—a widening of the river channel in the midst of this high-level, glacier-formed valley—than as the fountain-head of the infant stream. There are indications that the bed of Lake Victoria, as well as that of Chakmaktin, is rapidly silting, and that the shores of the latter are gradually receding farther from the foot of the hills. The glacial origin of the Pamir valleys is everywhere apparent in their terrace formations and the erratic blocks and boulders that lie scattered about their surface. It is probable that the lakes themselves are evidence of (geologically) a comparatively recent deliverance from the thraldom of the ice covering, which has worn and rounded the lower ridges into the smooth outlines of undulating downs.

The Ab-i-Wakhan Source.—Another important source of the river (considered by Curzon to be the chief source) is to be found in the enormous glaciers which lie about the upper or main branch of the Ab-i-Panja (called the Ab-i-Wakhan), which rises under the mountains enclosing the head of the Taghdumbash Pamirs. Although the superficial area of glacial ice from which the Ab-i-Wakhan derives the greater part of its volume is not equal to that found on the Nicolas range, it is quite impossible to frame any estimate of comparative depth or bulk, or to separate the volume of its contributions at any time from those which, combined, derive their origin from the Nicolas range. If the Aksu, or Murghab, and the Pamir river from Lake Victoria are to be considered in the light of independent tributaries, it is probable that the Ab-i-Panja contributes as large a volume of glacial flood to the Oxus as either of them.

Surveys.—From the point where the rivers of the Great and Little Pamirs join their forces at Kala Panja to Ishkashim, at the elbow of the great bend of the Oxus northwards, the river valley has been surveyed by Woodthorpe; and the northern slopes of the Hindu Kush, which near Ishkashim extend in slopes of barely 10 miles in length from the main watershed to the river banks, have been carefully mapped. These slopes represent the extent of Afghan territory which exists north of the Hindu Kush between Kala Panja and Ishkashim. From Ishkashim northwards the river passes through the narrow rock-bound valleys of Shignan and Roshan ere it sweeps north and west through the mountains and defiles of Darwaz. By the terms of the boundary agreement with Russia this part of the river now parts Badakshan and Darwaz from the districts of Roshan, Shignan, and Bokhara, which formerly maintained an uncertain claim over a part of the territory on the left bank of the river. All this part of the Oxus, until the river once again emerges from the Bokhara hills into the open plains bordering Badakshan on the north, falls within the area of Russian surveys, with which a junction from India has been effected both on the Pamirs and in Turkestan.

Russian Posts on the Oxus.—At Langar Kisht, a little to the east of the Oxus bend, there is a small Russian post of observation. About 50 miles north of the bend, where the Suchan or Ghund joins the Oxus from the Alichur Pamir, there is another and larger post called Charog. Here there are four officers with a guard of fifty Cossacks and two Maxims, according to Cobbold, who visited this part of the Oxus valley in 1900. On the left bank of the river the Afghans maintain a frontier post at the fort of Kala dar Panja. A road will connect Charog with the Alichur Pamir, following the general course of the Ghund stream, a road which will form a valuable link in the chain of communications between Bokhara and Sarikol. Eighty-five miles north of Ishkashim, at Kala Wamar, the river which rises in the Little Pamir, and which is called Aksu, Murghab, or Bartang, joins the Oxus from the east. It is on this river that the Russian outpost, Murghabi (or Pamirski), is situated, at an elevation of 12,150 feet above the sea. Fort Murghabi is connected by a good military road with Osh. At this point the measurement of the comparative lengths of the chief Pamir tributaries of the Oxus is as follows:—

To the head of the Aksu at Lake Chakmaktin .	260 miles.
To the head of the most easterly tributary of Lake Victoria, in the Great Pamir, about . . .	230 ,,
To the glacial sources of the Ab-i-Wakhan, about .	230 ,,

For 120 miles the two latter are united in the main stream of the Oxus, the volume of which has been further increased by the united forces of the Ghund and Shakhdara draining the Alichur Pamir and the heights of Shignan.

Nature of the Oxus Valley.—The narrow cramped valley of the river between Ishkashim and Kala Wamar is hedged in on the west by a long ridge flanking the highlands of Badakshan; on the east the buttresses and spurs of the Shignan mountains (of which the strike is transverse to the direction of the river and more or less parallel to that of the main Hindu Kush watershed) overhang its channel like a wall, and afford but little room either for cultivation or for the maintenance of a practicable road. Yet the lower elevation (for this part of the Oxus stream is not more than about 7000 feet above sea-level) and comparatively mild climate give opportunities to the industrious Tajik population for successful agriculture, of which they are not slow to avail themselves, and a track exists on the left bank of the river to Kala dar Panja opposite the Ghund (or Suchan) debouchment, which is practicable for mules. There are no bridges, and the transit of the river from bank to bank can only be effected by the use of inflated skins. Beyond the Bartang (or Murghab) confluence the valley narrows, and the difficulties of the river route increase. Between Kala Wamar (6580 feet) and Kila Khum (4400 feet), where the Oxus again bends southwards, its course to the north-west is almost at right angles to the general strike of the Darwaz mountains, which is from north-east to south-west, following the usual conformation of all this part of high Asia. Thus its chief affluents from the north-east, the Wanj and the Yaz Ghulam, drain valleys which are comparatively open, and which are said to be splendidly fertile. At Kila Khum the river is 480 feet wide, narrowing to 350 feet in the narrowest gorge. Its level varies with the obstructions formed by ice, falling as much as 28 feet when its upper channels are blocked.

Climate and Productions.—The climate of eastern Bokhara and Darwaz is delightful in summer, and Dr Regel writes of its Alpine scenery and flora in terms of enthusiastic admiration. In the valleys of the Waksh and the Surkhab to the north of Darwaz, which form an important part of the province of Karategin, maple, ash, hawthorn, pistachio, and juniper grow freely in the mountain forests, and beetroot, kohl rabi, and other vegetables are widely cultivated. About the cliffs and precipices of the Panja valley near Kila Khum the wild vine, cerasus, and pomegranate are to be found, and the plane tree and mulberry flourish in groups near the villages. Here also, amongst other plants, the sunflower decorates village gardens. The houses are built of stone and mortar, and above the thatched straw roof which surmounts the double-storeyed buildings the square watch-tower rises gracefully. Every house possesses its staircase, its well, and cisterns for irrigation; and on the whole the Aryan Tajiks of this northern section of the Oxus valley seem to be well provided with most of the comforts, if not the luxuries, of life. Their language is the language of Bokhara and Samarkand. Bokharan supremacy was re-established in 1878, when Kila Khum was occupied by Bokharan troops. Since then the right bank of the river has been politically divided from the left, and the latter now belongs to Afghanistan.

Between the Mountains and the Plains.—From Kila Khum, which fort about marks the most northerly point of the great bend of the Oxus round Badakshan, the river follows a south-westerly course for another 50 miles through a close mountainous region ere it widens into the more open valley to the south of Kolab. It now becomes a river of the plains from which the mountains on either side stand back.

Darwaz Affluents.—The topography of Darwaz south of the river is not accurately known, but at least one considerable stream of some 60 miles in length drains to the north-east, parallel to the general strike of the mountain system into the transverse course of the Oxus, which it joins nearly opposite to the lateral valleys of Yaz Ghulam and Wanj. This stream is called Pangi-Shiwa, or Shiwa, but not much is known about it. Another of about equal length, starting from the same central water-parting of this mountain block, and included within the Oxus bend, follows a transverse direction at almost right angles to the Shiwa, and joins the Oxus valley near its debouchment into the more open Kolab plains, where the course of the Oxus has again assumed a direction parallel to the mountain strike. All that we know about this river (which is called the Ragh or Sadda) is that towards its junction with the Oxus it cuts through successive mountain ridges, which renders its course impracticable as a roadway. It is necessary to avoid the river, and to pass by mountain tracks which surmount a series of local spurs or offshoots from the central plateau, in order to reach the Oxus. The existence of this route, which traverses the Darwaz mountains from east to west, cutting off the northern bend of the Oxus, and connecting those easterly routes which intersect the Pamirs by means of the Ghund and Shakhdara (and which concentrate about Lake Shiwa) with Kolab in eastern Bokhara, is important. (See BADAKSHAN.)

Karategin Affluents.—From about the point where the Oxus commences to separate the Bokharan province of Kolab from the comparatively open Afghan districts of Rustak and Kataghan, the channel of the river is no longer confined within walls of mountains of volcanic and schistose formation. The Kolab and the Surkhab (or Waksh) flow into it in broad muddy streams from the highlands of Karategin, and the river at once commences to adopt an uncertain channel wherever the outstretched arms of the hills fail to confine it within definite limits. It divides its waters, splitting into many channels, leaving broad central islands; and as the width increases, and the depth during dry seasons diminishes, opportunities for fords become comparatively frequent. Between Kolab and Pata Kesar, immediately north of the Turkestan capital of Mazar-i-Sharif, there are at least three well-known "guzars" or fords, and there are probably more. Besides the great muddy affluents from Karategin on the north, the Kabadian, the Surkhan, and the Darbant are all of them very considerable tributaries from Bokhara. The last of the three is the river on which the well-known trade centre of Shirabad is built, some 20 miles north of the river. Near the junction of the Surkhan with the Oxus are the ruins of the ancient city of Tarmez, on the northern or Bokharan bank, and the ferry at Pata Kesar (not far from the ruins of an old bridge) is the connecting link between Bokhara and Mazar hereabouts.

Badakshan Affluents.—From the south two very remarkable affluents of the Oxus join their streams to the main river between Kolab and the Mazar crossings. The Kokcha and the Khanabad (or Kunduz) are the two great rivers of Badakshan. The valley of the Kokchà leads directly from the Oxus to Faizabad, the capital of Badakshan, and its head is close above Ishkashim at the southern elbow of the great Oxus bend, a low pass of only 9500 feet dividing its waters from those of the main river. This undoubtedly was a section of the great central trade route of Asia, which once connected Fergana and Herat with Kashgar and China. (See BADAKSHAN.) Both these rivers tap the northern slopes of the Hindu Kush, and claim their sources in the unmapped mountain wilderness of Kafiristan. The Khanabad, or Kunduz, is also called locally the Aksarai. All the rivers of Central Asia are known by several names. To the west of the Kunduz no rivers find their way through the southern banks of the Oxus. Throughout the plains of Afghan Turkestan the drainage from the southern hills is arrested and lost in the desert sands.

Island.—The only island of any size in the bed of the river is the island of Paighambar, a little below the ruins of Tarmez. The inhabitants of this island, and of a smaller one in the neighbourhood called Zarshoi, wash for gold in the bed of the river.

Ruins.—At Airatan, a little above the Pata Kesar ferry, there are ruins, as also at Khisht Tapa (where the road from Kabadian to Tashkurghan leaves the river) and at Kalukh Tapa. At Khisht Tapa there is a tradition of a bridge having once existed.

Channel of the Oxus.—The Oxus river, as seen in flood at this part of its course, is an imposing stream. It is rarely less than 1000 yards wide, and in some places it is fully a mile across. Its winter channel may be estimated at from two-thirds to three-fourths of its flood channel, except where it is confined within narrow limits by a rocky bed, as at Kilif, where its unvarying width is only 540 yards. The average strength of the current in flood is about 4 miles per hour, varying from 2½ to 5 miles. The left bank of the Oxus above Kilif is, as a rule, low and flat, with reed swamps bordering the stream and a strip of jungle between the reeds and the edge of the elevated sandy desert. The jungle is chiefly tamarisk and padah (willow). Swamp deer, pheasants, and occasionally tigers are found in it. The right bank is generally higher, drier, more fertile, and more populated than the left.

Cultivation.—A wide belt of blown sand (or Chul), sprinkled with saxaul jungle, separates the swamps on the south side of the river from the cultivated plains of Afghan Turkestan; but in places, notably for about 12 miles above Khamiab, where the Russo-Afghan boundary touches the river, through the districts which are best known by the name of Khwaya Salar, and again in a less degree for 50 miles above the ferry at Kilif, a very successful war has been waged by the agricultural Turkman (of the Ersari tribes) against the encroaching sand-waves of the desert; and a strip of riverain soil averaging about a mile in width has been reclaimed and cultivated by irrigation. The cultivation, supported by canals drawn from the Oxus, the heads of which are constantly being destroyed by flood and again renewed, is of a very high order. Wheat and barley spread in broad crops over many square miles of rich soil; the fields are intersected by narrow little stone-walled lanes, bright with wayside flowers, amongst which the poppy and the purple thistle of Badghis are predominant; the houses are neatly built of stone, and stand scattered about the landscape in single homesteads, substantial and comfortable; and the spreading willow and the mulberry offer a most grateful shade to the wayfarer in summertime, when the heat is often insupportable. The fiery blasts of summer, furnace-heated over the red-hot Kizil Kum, are hardly less to be feared than the ice-cold shamshir (or north-western blizzard) of winter, which freezes men when it finds them in the open desert, and frequently destroys whole caravans.

Oxus Ferries.—The principle on which the Oxus ferries are worked is peculiar to those regions. Large flat-bottomed boats are towed across the river by small horses attached to an outrigger projecting beyond the gunwale by means of a surcingle or bellyband. They are thus partially supported in the water whilst they swim. The horses are guided from the boat, and a twenty- or thirty-foot barge with a heavy load of men and goods will be towed across the river at Kilif (where, as already stated, the width of the river is between 500 and 600 yards only) with ease by two of these animals. The Kilif ferry is on the direct high-road between Samarkand and Akcha. It is perhaps the best-used ferry on the Oxus.

Khwaya Salar.—Khwaya Salar derives some historical significance from the fact that it presented a substantial difficulty to the settlement of the Russo-Afghan boundary, in which it was assigned by agreement as the point of junction between that boundary and the Oxus. It had been defined in the agreement as a "post" on the river banks, and had been so described by Burnes in his writings some fifty years previously. But no post such as that indicated could be discovered. There was a district of that name extending from Khamiab to the neighbourhood of Kilif, and at the Kilif end of the district was a ziarat sacred to the Khwaya who bore the name. It was only after long inquiry amongst local cultivators and landowners that, about 2 miles below the ziarat, and nearly opposite to the site of the present Karkin bazaar, the position of a lost ferry was identified, which had once been marked by a riverside hamlet called by the name of the saint. The ferry had long disappeared, and with it a considerable slice of the riverside alluvial soil, which had been washed into the stream by the action of floods. The post had, in fact, subsided to the bottom of the river, but the consequences of its disappearance had been both far-reaching and expensive.

Lower Oxus.—Below Khamiab, to its final disappearance in the Aral Sea, the great river rolls in silent majesty through a vast expanse of sand and desert. Under Russian auspices a considerable strip of alluvial soil on the left bank has been brought under cultivation, measuring 4 or 5 miles in width, and there is more cultivation on the banks of the Oxus now than there is in the Merv oasis itself, but it is confined to the immediate neighbourhood of the river, for no affluents of any considerable size exist. The river is navigable below Charjui, and takes its place as an important unit in the general scheme of Russian frontier communications.

Junction with the Aral Sea.—An important feature in connexion with the course of the Oxus is the discussion that has arisen with regard to its former debouchment into the Caspian Sea. On this point much recent evidence has been collected, and it appears certain that there was a time in the post-Pliocene Age when a long gulf of the Caspian Sea protruded eastwards nearly as far as the longitude of Merv, covering the Kara Kum sands, but not the Kara Kum plateau to the north of the sands, which is separated from the sands by a distinct sea beach. At the same time another branch of the same gulf protruded northwards in the direction of the Aral, probably as far as the Sary Kamish depression, which lies to the west of the Khivan delta of the Oxus, separated from it by wide beds of loess, clays, and gravel, covering rocks of an unknown age. The Murghab river and the Hari Rud, which terminate in the oases of Merv and Sarakhs, almost certainly penetrated to the gulf of the Kara Kum, but the question whether the Oxus was ever deflected so as to enter the gulf with the Murghab cannot be said to be answered decisively at present. The former connexion between the Caspian and Aral by means of the gulf now represented by the Sary Kamish depression seems to be admitted by Russian scientists, nor would there appear to be much doubt about the connexion between the Khivan oasis and the northern extremity of the Sary Kamish. In this discussion the names of Kaulbars, Lessar, Annenkoff, Konshin, and other Russian geographers are conspicuous. The general conclusions are ably summed up by P. Kropotkin in the September number of the *Journal* of the Royal Geographical Society for 1898.

AUTHORITIES.—Although much has been written of late years about the sources of the Oxus within the region of the Pamirs, there is very little to be found in the writings of geographers of modern date descriptive of that part of its course which separates Darwaz and Afghan Turkestan from Bokhara, and that little is chiefly in the pages of reports and gazettes, &c., which are not available to the public. The following authorities may be consulted: The Report of the Pamir Boundary Commission of 1895, published at Calcutta, 1897.—REGEL, Dr A. "Journey in Karategin and Darwaz," *Investia*, Russian Geog. Soc., vol. xiii. 1882; translation, vol. iv. *Proc. R.G.S.*—MICHELL. "Regions of the Upper Oxus," vol. vi. *Proc. R.G.S.* 1884.—GRIESBACH. "Geological Field Notes," No. 3, Afghan Boundary Commission, 1885.—YATE, C. *Northern Afghanistan.* London, 1888.—CURZON. "The Pamirs," vol. viii. *Jour. R.G.S.* 1896.—KROPOTKIN. "Old Beds of the Oxus," *Jour. R.G.S.*, September 1898.—COBBOLD. *Innermost Asia.* London, 1900. To the above may be added the Reports of the Russo-Afghan Boundary Commission of 1884–85, and that of Lockhart's Mission in 1885, and the Indian Survey Reports.

(T. H. H*.)

Oyster Industry.—Oysters are more valuable than any other single product of the fisheries, and in at least twenty-five countries are an important factor in the food-supply. The approximate value of the world's oyster crop approaches £4,000,000 annually, representing over 30,000,000 bushels, or nearly 10 billion oysters. Not less than 150,000 persons are engaged in the industry, and the total number dependent thereon is fully half a million. The following table shows in general terms the yearly oyster product of the world:—

Country.	Bushels.	Value.
United States	26,853,760	£2,533,481
Canada	134,140	43,405
Great Britain and Ireland	113,700	154,722
France	3,260,190	716,778
Holland	100,000	84,400
Italy	68,750	44,000
Other European countries	29,930	40,250
Asia, Africa, and Oceania	275,000	111,400
Total	30,835,470	£3,728,436

The distinctive feature of oyster culture in continental Europe is the setting of tiles, wooden frames, and brush, on which the spat from adjacent beds is deposited; the young are subsequently reared in suitable enclosures. In Great Britain brood seed oysters, purchased in France and elsewhere, are placed on prepared grounds and left to spawn or to grow before marketing. Oyster culture in America consists in preparing the ground by the removal of rubbish and sowing shells of oysters and other molluscs, gravel, and broken stone, to which the spat will become attached.

United States.—The oyster is the chief fishery product in the United States. The states which lead in the quantity of oysters taken are Maryland, Virginia, New York, New Jersey, and Connecticut; the annual value of the output in each of these is over $1,000,000. Other states with important oyster interests are Rhode Island, North Carolina, Louisiana, and California. The oyster fisheries give employment to over 56,000 fishermen, who man 4000 vessels, valued at $4,000,000, and 23,000 boats, valued at $1,470,000; the value of the 11,000 dredges and 37,000 tongs, rakes, and other appliances used is $365,000. The quantity of oysters taken in 1898 was 26,853,760 bushels, with a value of $12,667,405. The output of cultivated oysters in 1899 was about 9,800,000 bushels, worth $8,700,000.

Canada.—Oyster banks of some importance exist in the Gulf of St Lawrence and on the coast of British Columbia. All of the grounds have suffered depletion, and cultural methods to maintain the supply have been instituted. The oyster output of the Dominion has never exceeded 200,000 bushels in a single year, and in 1898 was 134,140 bushels, valued at $217,024.

United Kingdom.—The natural oyster beds of Great Britain and Ireland have been among the most valuable of the fishery resources, and British oysters have been famous from time immemorial. The most important oyster region is the Thames estuary, the site of extensive planting operations. The present supply is largely from cultivated grounds. Important oyster-producing centres are Whitstable, Colchester, and Brightlingsea. The oysters landed on the coasts of England and Wales in 1898 numbered 35,809,000, valued at £122,320, and in 1899, 38,978,000, valued at £143,841. The Scottish fishery has its centre at Inveraray and Ballantrae, and in 1899 yielded 470,100 oysters, valued at £2356. Public oyster grounds of Ireland in 1898 produced 1,981,900 oysters, valued at £3559. The fishery is most extensive at Wicklow, Queenstown, Ballyheige, Galway, and Moville. Planting is carried on in seven counties; the oysters taken from cultivated beds in 1898 numbered 3,204,200, valued at £4966.

France.—The industry owes its importance to the attention given to oyster cultivation. In the fishery on public grounds in 1896 only 6370 fishermen were engaged, employing 1627 vessels and boats, valued at 1,473,449 francs, and apparatus worth 211,495 francs, while only 13,127,217 kilograms of oysters were taken, or about 320,000 bushels, valued at 414,830 francs. In the parks, claires, and reservoirs the private culture of oysters has attained great perfection. Fully 40,000 men, women, and children are employed, and the output in 1896 was 1,536,417,968 oysters, worth 17,537,778 francs. The principal centre is Arcachon, where in 1896 there were raised 802,880,000 oysters, valued at 4,663,040 francs.

Other Countries.—The natural oyster beds of Holland having become exhausted through neglect and overfishing, the Government about 1870 suspended all operations on public grounds and leased the available oyster-producing areas. The Scheldt estuary has become the region of greatest production. In 1897 the Dutch waters yielded 40,000,000 marketable oysters, valued at £84,000. Oyster culture in Italy is of great historic interest; the annual crop, which is almost wholly from cultivated grounds, does not exceed 25,000,000 to 30,000,000 oysters. The oyster industry of Germany, Belgium, Spain, Portugal, Russia, Denmark, and other countries of Europe does not yield over 30,000 bushels yearly, valued at about £40,000. Outside of Europe and America the industry is of little consequence. Algeria has a small fishery, the output in 1896 being valued at 33,739 francs. Oysters of large size and excellent flavour exist in Japan, and are cultivated to some extent. The annual output is estimated at 100,000 bushels, with a value of £14,000. In China the oyster product is doubtless large, but the extent of the industry is unknown. For centuries the Chinese have practised a rude form of oyster culture. The oyster grounds of New South Wales, Queensland, Tasmania, and other British colonies in the Pacific are rather extensive, but have been depleted. (H. M. S*.)

Paardeberg. See ORANGE RIVER COLONY and TRANSVAAL (*War*).

Paarl, a town of Cape Colony, a few miles north of Stellenbosch, 30 miles (36 by rail) east-north-east of Cape Town, with both of which places it is connected by rail. It stands at the point where the main line is deflected northwards by the steep Drakenstein escarpments of the outer coast range. Paarl ("Pearl") is one of the oldest places in the colony, and was so named by its Dutch settlers from a granite block crowning a rocky pedestal like a gem on a coronet. The gardens, orange groves, vineyards, and woodlands of the surrounding district make it a favourite summer resort for the citizens of Cape Town. Population (1891), 21,363 (white, 8226; natives, 13,137). (A. H. K.)

Pabianice, a town of Russian Poland, in the government and 22 miles north-west of the town of Piotrków, 10 miles from Łódz railway station. It lies amidst the extensive forests round the head-waters of the Ner, which were the hunting-grounds of the Polish kings. It has woollen, cloth, and paper mills, and manufactures agricultural implements. Population (1897), 26,900.

Pabna, or PUBNA, a town and district of British India, in the Rajshahi division of Bengal, on the river Ichhamati, near the old bed of the Ganges. Population (1881), 15,267; (1891), 16,486. The high school had 388 pupils in 1896–97.

The district of PABNA has an area of 1839 square miles; population (1881) 1,311,728, (1891) 1,362,392, (1901) 1,420,352, showing an increase of 4 per cent. between 1881 and 1891, and also between 1891 and 1901; average density, 772 persons per square mile. Classified according to religion, Mahommedans in 1891 numbered 998,776; Hindus, 361,957; Christians, 162, of whom 96 were Europeans; "others," 1497. The land revenue and rates in 1897–98 were Rs.4,69,337; the number of police was 403; boys at school in 1896–97 were 19,812, being 19·5 per cent. of the male population of school-going age; the registered death-rate in 1897 was 40 per thousand. The two staple crops are rice and jute. There are 18 jute presses, with an out-turn of 259,000 bales, valued at Rs.30,00,000. Sirajganj, on the Brahmaputra, is the largest mart for jute in Bengal, with a jute mill established in 1864. Indigo has ceased to be grown. The Eastern Bengal Railway cuts across the south-west corner of the district for five miles, near the Ganges. The district was affected by the earthquake of 12th June 1897, which was most severely felt at Sirajganj.

Pachino, a town of the province of Syracuse, Sicily, Italy, 4 miles from Cape Passaro, 26 miles south-south-west of Syracuse. It carries on the manufacture of vegetable fibre and baskets, fish-curing, cultivation of the vine, and herring-fishing (port $2\frac{1}{2}$ miles to the north-east). Population (1881), 8229; (1899), 10,000.

Pachuca, a city of Mexico, and capital of Hidalgo. It is connected with the city of Mexico by the Hidalgo, Mexican, and Central railways. It is the principal town of the state on account of its commerce, population (40,487), and mining industries. Amongst several fine buildings are the palace of justice, the scientific and literary institute, the meteorological observatory, and the school of mines and public library. The town has tramways, and several private railways in connexion with adjacent mines.

Pacific Blockade.—Pacific blockade is a term invented by Hautefeuille, the French writer on International Maritime Law, to describe a blockade exercised by a great Power for the purpose of bringing pressure to bear on a weaker state, without actual war. That it is an act of violence, and therefore in the nature of war, is undeniable, seeing that it can only be employed as a measure of coercion by maritime Powers able to bring into action such vastly superior forces to those the resisting state can dispose of, that resistance is out of the question. In this respect it is an act of war, and any attempt to exercise it against a Power strong enough to resist would be a commencement of hostilities and at once bring into play the rights and duties affecting neutrals. On the other hand, the object and justification of a pacific blockade being to avoid war, that is, general hostilities, and disturbance of international traffic with the state against which the operation is carried on, rights of war cannot consistently be exercised against ships belonging to other states than those concerned. And yet, if neutrals were not to be affected by it, the coercive effect of such a blockade might be completely lost. Recent practice has been to limit interference with them to the extent barely necessary to carry out the purpose of the blockading Powers.

It is usual to refer to the intervention of France, England, and Russia in Turkish affairs in 1827 as the first occasion on which the coercive value of pacific blockades was put to the test. Neutral vessels were not affected by it. This was followed by a number of other coercive measures described in the text-books as pacific blockades. The first case, however, in which the operation was really a blockade, unaccompanied by hostilities, and which therefore can be properly called a "pacific blockade," was that which in 1837 Great Britain exercised against New Granada. A British subject and consul of the name of Russell was accused of stabbing a native of the country in a street brawl. He was arrested, and after being kept in detention for some months he was tried for the unlawful carrying of arms and sentenced to six years' imprisonment. The British Government resented this treatment as "not only cruel and unjust towards Mr Russell, but disrespectful towards the British nation," and demanded the dismissal of the officials implicated and £1000 damages "as some compensation for the cruel injuries which had been inflicted upon Mr Russell" (State Papers, 1837–38, p. 183). The New Granada Government refused to comply with these demands, and the British representative, acting upon his instructions, called in the assistance of the West Indian fleet, but observed in his communication to the British naval officer in command that it was desirable to avoid hostilities, and to endeavour to bring about the desired result by a strict blockade only. This seems to be the first occasion on which it had occurred to anybody that a blockade without war might serve the purpose of war. This precedent was shortly afterwards followed by another somewhat similar case in which, from 16th April to 28th November 1838, the French Government blockaded the Mexican ports, to coerce the Mexican Government into acceptance of certain demands on behalf of French subjects who had suffered injury to their persons and damage to their property, through insufficient protection by the Mexican authorities.

The blockade of Buenos Aires and the Argentine coast from 28th March 1838 to 7th November 1840 by the French fleet, a coercive measure consequent upon vexatious laws affecting foreign residents in the Argentine Republic, seems to have been the first case in which the operation was notified to the different representatives of foreign states. This notification was given in Paris, and at Buenos Aires, and to every ship approaching the blockaded places. This precedent of notification was, a few years later (1845), followed in another blockade against the same country by Great Britain and France, and in one in 1842 and 1844 by Great Britain against the port of San Juan in Nicaragua. In 1850 Great Britain blockaded the ports of Greece in order to compel the Hellenic Government to give satisfaction in the Don Pacifico case. Don Pacifico, a British subject, claimed £32,000 as damages for unprovoked pillage of his house by an Athenian mob. Greek vessels only were seized, and these were only sequestered. Greek vessels *bona fide* carrying cargoes belonging to foreigners were allowed to enter the blockaded ports.

Before the next case of blockade which can be described as "pacific" occurred, came the Declaration of Paris (15th April 1856), requiring that "blockades in order to be binding must be effective, that is to say, maintained by a force sufficient really to prevent access to the coast of the enemy."

Some ill-defined measures of blockade followed, such as that of 1860, when Victor Emmanuel, then king of Sardinia, joined the revolutionary government of Naples in blockading ports in Sicily, then held by the king of Naples, without any rupture of pacific relations between the two governments; that of 1862, in which Great Britain blockaded the port of Rio de Janeiro, to exact redress for pillage of an English vessel by the local population, at the same time declaring that she continued to be on friendly terms with the emperor of Brazil; and that in 1880, when a demonstration was made before the port of Dulcigno by a fleet of British, German, French, Austrian, Russian, and Italian men-of-war, to compel the Turkish Government to carry out the treaty conceding this town to Montenegro, and it was announced that, if the town was not given up by the Turkish forces, it would be blockaded.

The blockade which first gave rise to serious theoretical discussion on the subject was that instituted by France in 1884 in Chinese waters. On 20th October 1884 Admiral Courbet declared a blockade of all the ports and roadsteads between certain specified points of the island of Formosa. The British Government protested that Admiral Courbet had not enough ships to render the blockade effective, and that it was therefore a violation of one of the articles of the Declaration of Paris of 1856; moreover, that the French Government could only interfere with neutral vessels violating the blockade if there was a state of war. If a state of war existed, England as a neutral was bound to close her coaling stations to belligerents. The British Government held that, in the circumstances, France was waging war, and not entitled to combine the rights of peace and warfare for her own benefit. Since then pacific blockades have only been exercised by the Great Powers as a joint measure in their common interest, which has also been that of peace, and in this respect the term is taking a new signification in accordance with the ordinary sense of the word "pacific." [1]

In 1886 Greece was blockaded by Great Britain, Austria, Germany, Italy, and Russia, to prevent her from engaging in war with Turkey, and thus forcing the Powers to define their attitude towards the latter Power. The instructions given to the British commander were to detain every ship under the Greek flag, coming out of or entering any of the blockaded ports or harbours or communicating with any ports within the limit blockaded; but if any parts of the cargo on board of such ships belonged to any subject or citizen of any foreign Power other than Greece, and other than Austria, Germany, Italy, and Russia, and had been shipped before notification of the blockade or after such notification but under a charter made before the notification, such ship was not to be detained.

On the blockade of Crete in 1897 it was notified that "the admirals in command of the British, Austro-Hungarian, French, German, Italian, and Russian naval forces" had decided to put the island of Crete in a state of blockade, that "the blockade would be general for all ships under the Greek flag," and that "ships of the six Powers or *neutral* Powers may enter into the ports occupied by the Powers and land their merchandise, but only if it is not for the Greek troops or the interior of the island," and that "these ships may be visited by the ships of the international fleets." (T. BA.)

Pacific Islands. See MELANESIA, MICRONESIA, POLYNESIA.

Pacific Ocean, the largest division of the hydrosphere, lying been Asia and Australia and North and South America. It is nearly landlocked to the north, communicating with the Arctic Ocean only by Bering Strait, which is 36 miles wide and of small depth. The southern boundary is now generally regarded as the parallel of 40° S., but sometimes the part of the great Southern

[1] The blockade in 1888 by Great Britain, Germany, Italy, and Portugal of Zanzibar was peculiar, being directed not against the reigning authority, but against a slave trade which that authority was powerless to stop.

Ocean (40° to 66½° S.) between the meridians passing through South Cape in Tasmania and Cape Horn is included. The north to south distance from Bering Strait to the Antarctic circle is 9000 miles, and the Pacific attains its greatest breadth, 10,000 miles, at the equator. The coasts of the Pacific are of varied contour. The American coasts are for the most part mountainous and unbroken, the chief indentation being the Gulf of California; but the general type is departed from in the extreme north and south, the southern coast of South America consisting of bays and fjords with scattered islands, while the coast of Alaska is similarly broken in the south, and becomes low and swampy towards the north. The coast of Australia is high and unbroken; there are no inlets of considerable size, although the small openings include some of the finest harbours in the world, as Moreton Bay and Port Jackson. The Asiatic coasts are for the most part low and irregular, and a number of seas are more or less completely enclosed and cut off from communication with the open ocean. Bering Sea is bounded by the Alaskan peninsula and the chain of the Aleutian Islands; the Sea of Okhotsk is enclosed by the peninsula of Kamchatka and the Kurile Islands; the Sea of Japan is shut off by Sakhalin Island, the Japanese Islands, and the peninsula of Korea; the Yellow Sea is an opening between the coast of China and Korea; the China Sea lies between the Asiatic continent and the island of Formosa, the Philippine group, Palawan, and Borneo. Amongst the islands of the Malay Archipelago are a number of enclosed areas, the Sulu, Celebes, Java, Banda, and Arafura seas. The Arafura Sea extends eastwards to Torres Strait, and beyond the strait is the Coral Sea, bounded by New Guinea, the islands of Melanesia, and north-eastern Australia.

Coasts and seas.

Extent, volume, and mean depth.

The following table gives the area and volume of the Pacific Ocean and its seas, with the mean depths calculated therefrom, as estimated by Murray (1888):—

	Area (sq. miles).	Volume (cub. miles).	Mean Depth (fathoms).
Pacific Ocean (to 40° S.)	50,308,450	141,516,050	2475
Southern Ocean (S. of the Pacific)	10,278,500	24,980,200	2139
Pacific Ocean to 66½° S.	60,586,950	166,496,250	2418
Bering Sea	859,450	621,500	636
Sea of Okhotsk	542,000	197,600	292
Sea of Japan	375,550	220,800	517
Yellow Sea	468,450	55,050	103
China Sea	1,366,600	835,200	538
Celebes Sea	181,950	288,150	1394
Sulu Sea	174,200	136,800	691
Banda Sea	422,000	417,750	871
Java Sea	360,050	34,900	85
Arafura Sea	565,200	79,150	123
Total	65,902,400	169,383,150	2253

Adopting a somewhat different arrangement, Karstens (1894) obtains the following:—

	Area (sq. kilom.).	Volume (cub. kilom.).	Mean Depth (fathoms).
Pacific Ocean to 66½° S.	161,137,973	657,926,344	2233
Bering Sea	2,264,664	2,513,558	607
Sea of Okhotsk	1,507,609	1,895,065	695
Sea of Japan	1,043,824	1,148,206	602
China Seas and Gulf of Siam	4,583,473	3,436,093	410
Sunda Archipelago	3,241,128	2,640,721	446
Sulu and Celebes Seas with Gulf of Carpentaria	1,499,659	1,983,291	723
Gulf of California	166,788	164,586	540
Total	175,445,118	671,707,864	2094

The Pacific Ocean has therefore one and three-quarter times the area of the Atlantic, the next largest division of the hydrosphere, and has more than double its volume of water. Its area is greater than the whole land surface of the globe, and the volume of its waters is six times that of all the land above sea-level. The total land area draining to the Pacific is estimated by Murray at 7,500,000 square miles, or little more than one-fourth of the area draining to the Atlantic. The American rivers draining to the Pacific are, with the exception of the Yukon, unimportant. The chief Asian rivers are the Amur, the Hwang-ho, and the Yangtse-kiang, none of which enters the open Pacific directly. Hence the proportion of purely oceanic area to the total area is greater in the Pacific than in the Atlantic, the supply of detritus being smaller, and terrigenous deposits are not borne so far from land.

Relief.

The bed of the Pacific is not naturally divided into physical regions, but for descriptive purposes the parts of the area lying east and west of 150° W. are conveniently dealt with separately (Fig. 1). The eastern region is characterized by great uniformity of depth; the 2000-fathom line keeps close to the American coast except off the Isthmus of Panama, whence an ill-defined ridge of less than 2000 fathoms runs south-westwards, and again off the coast of South America in about 40° S., where a similar bank runs west and unites with the former. The bank then continues south to the Antarctic Ocean, in about 120° W. Practically the whole of the north-east Pacific is therefore more than 2000 fathoms deep, and the south-east has two roughly triangular spaces, including the greater part of the area, between 2000 and 3000 fathoms. Notwithstanding this great average depth, the "deeps" or areas over 3000 fathoms are small in number and extent. Five small deeps are recognized along a line close to the coast of South America and parallel to it, in the depression enclosed by the two banks mentioned—they extend from about 12° to 30° S.—and are named, from north to south, Milne-Edwards deep, Krümmel deep, Bartholomew deep, Richards deep, and Haeckel deep. In the north-east the deeps are again few and small, but they are quite irregularly distributed, and not near the land. East of 150° W. the Pacific has few islands; the oceanic islands are volcanic, and coral formations are of course scanty. The most important group is the Galapagos Islands.

The western Pacific is in complete contrast to the part just described. Depths of less than 2000 fathoms occur continuously on a bank extending from south-eastern Asia, on which stands the Malay Archipelago. This bank continues southwards to the Antarctic Ocean, expanding into a plateau on which Australia stands, and a branch runs eastwards and then southwards from the north-east of Australia through New Zealand. The most considerable areas over 3000 fathoms are the Aldrich deep, an irregular triangle nearly as large as Australia, situated to the east of New Zealand, in which a sounding of 5155 fathoms was obtained by H.M.S. *Penguin*, near the Friendly Islands: and the Tuscarora deep, a long, narrow trough running immediately to the east of Kamchatka, the Kurile Islands, and Japan. A long strip within the Tuscarora deep forms the largest continuous area with a depth greater than 4000 fathoms. All the rest of the western Pacific is a region of quite irregular contour. The average depth varies from 1500 to 2500 fathoms, and from this level innumerable volcanic ridges and peaks rise almost or quite to the surface, their summits for the most part occupied by atolls and reefs of coral formation, while interspersed with these are depressions, mostly of small area, amongst which the deepest soundings recorded have been obtained. Recently the United States telegraph ship *Nero*, while surveying for a cable between Hawaii and the Philippines, sounded the greatest depth yet known between Midway Island and Guam, in 5269 fathoms, or almost exactly six miles.

The following table, showing the area of the floor of the Pacific (to 40° S.) and the volume of water at different levels, is due to Murray:—

Fathoms.	Areas (sq. miles).	Volume (cub. miles).
0–100	3,379,700	6,128,500
100–500	1,753,450	23,348,350
500–1000	1,707,650	28,323,700
1000–2000	6,902,550	52,628,500
2000–3000	39,621,550	32,545,400
3000–4000	2,164,150	1,357,900
over 4000	94,850	70,600
	55,623,900	144,402,950

So far as our knowledge goes, the present contours of the open Pacific Ocean are almost as they were in Palæozoic times, and in the intervening ages changes of level and form have been slight. There is no reason to suppose that any considerable part of the vast area now covered by the waters of the Pacific has ever been exposed as dry land. Hence the Pacific basin may be regarded as a stable and homogeneous geographical unit, clearly marked off round nearly all its margin by steep sharp slopes, extending in places through the whole known range of elevation above sea-level and of depression below it—from the Cordilleras of South America to the island chains of Siberia and Australia.

The deeper parts of the bed of the Pacific are covered by deposits

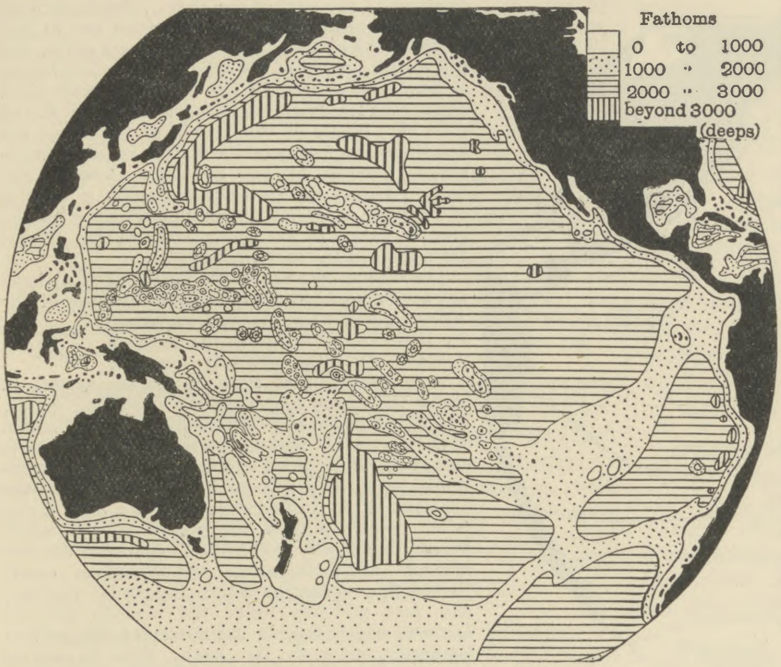

Fig. 1.—Chart of the Depths of the Pacific.

of red clay, which occupies an area estimated at no less than 105,672,000 square kilometres, or three-fifths of the whole (Fig. 2). Over a large part of the central Pacific, far removed from any possible land-influences or deposits of ooze, the red-clay region is characterized by the occurrence of manganese, which gives the clay a chocolate colour, and manganese nodules are found in vast numbers, along with sharks' teeth and the ear-bones and other bones of whales. Radiolarian ooze is found in the central Pacific in a region between 15° N. to 10° S. and 140° E. to 150° W., occurring in seven distinct localities, and covering an area of about 3,007,000 square kilometres. The *Challenger* discovered an area of radiolarian ooze between 7°–12° N. and 147°–152° W., and another in 2°–10° S., 152°–153° W. Between these two areas, almost on the equator, a strip of globigerina ooze was found, corresponding to the zone of globigerina in the equatorial region of the Atlantic. Globigerina ooze covers considerable areas in the intermediate depths of the west and south Pacific—west of New Zealand, and along the parallel of 40° S., between 80°–98° W. and 150°–118° W.—but this deposit is not known in the north-eastern part of the basin. The total area covered by it is estimated at 38,332,000 square kilometres—about two-thirds of that in the Atlantic. Pteropod ooze occurs only in the neighbourhood of Fiji and other islands of the western Pacific, passing up into fine coral sands and mud. All the enclosed seas are occupied by characteristic terrigenous deposits.

Deposits.

Partly on account of its great extent, and partly because there is no wide opening to the Arctic regions, the normal wind circulation is on the whole less modified in the north Pacific than in the Atlantic, except in the west, where the south-west monsoon of southern Asia controls the prevailing winds, its influence extending eastwards to 145° E., near the Ladrones, and southwards to the equator. In the south Pacific the north-west monsoon of Australia affects a belt running east of New Guinea to the Solomon Islands. In the east the north-east trade belt extends between 5° and 25° N.; the south-east trade crosses the equator, and its mean southern limit is 25° S. The trade winds are generally weaker and less persistent in the Pacific than in the Atlantic, and the intervening belt of equatorial calms is broader. Except in the east of the Pacific, the south-east trade is only fully developed during the southern winter; at other seasons the regular trade belt is cut across from north-west to south-east by a band twenty to thirty degrees wide, in which the trades alternate with winds from north-east and north, and with calms, the calms prevailing chiefly at the boundary of the monsoon region (5° N.–15° S., 160°–185° E.). This area, in which the south-east trade is interrupted, includes the Fiji, Navigator, and Society groups, and the Paumotus. In the Marquesas group the trade wind is constant. Within the southern monsoon region there is a gradual transition to the north-west monsoon of New Guinea in low latitudes, and in higher latitudes to the north-east wind of the Queensland coast. The great warming and abundant rainfall of the island regions of the western Pacific, and the low temperature of the surface water in the east, cause a displacement of the southern tropical maximum of pressure to the east; hence we have a permanent "south Pacific anticyclone" close to the coast of South America. The characteristic feature of the south-western Pacific is therefore the relatively low pressure and the existence of a true monsoon region in the middle of the trade-wind belt. It is to be noted that the climate of the islands of the Pacific becomes more and more healthy the farther they are from the monsoon region. The island regions of the Pacific are everywhere characterized by uniform high air temperatures; the mean annual range varies from 1° to 9° F., with extremes of 24° to 27°, and the diurnal range from 9° to 16°. In the monsoon region relative humidity is high—80 to 90 per cent. The rainfall is abundant; in the western island groups there is no well-marked rainy season, but over the whole region the greater part of the rainfall takes place during the southern summer, even as far north as Hawaii. In the trade-wind region we find the characteristic heavy rainfall on the weather sides of the islands, and a shorter rainy season at the season of highest sun on the lee side. Buchan describes the island-studded portion of the western Pacific as the most extensive region of the globe characterized by an unusually heavy rainfall. Beyond the tropical high-pressure belt, the winds of the north Pacific are under the control of an area of low pressure, which, however, attains neither the size nor the intensity of the "Iceland" depression in the north Atlantic. The result is that north-westerly winds, which in winter are exceedingly dry and cold, blow over the western or Asiatic area; westerly winds prevail in the centre, and south-westerly and southerly winds off the American coast. In the southern hemisphere there is a transition to the low-pressure belt encircling the Southern Ocean, in which westerly and north-westerly winds continue all the year round.

Meteorology.

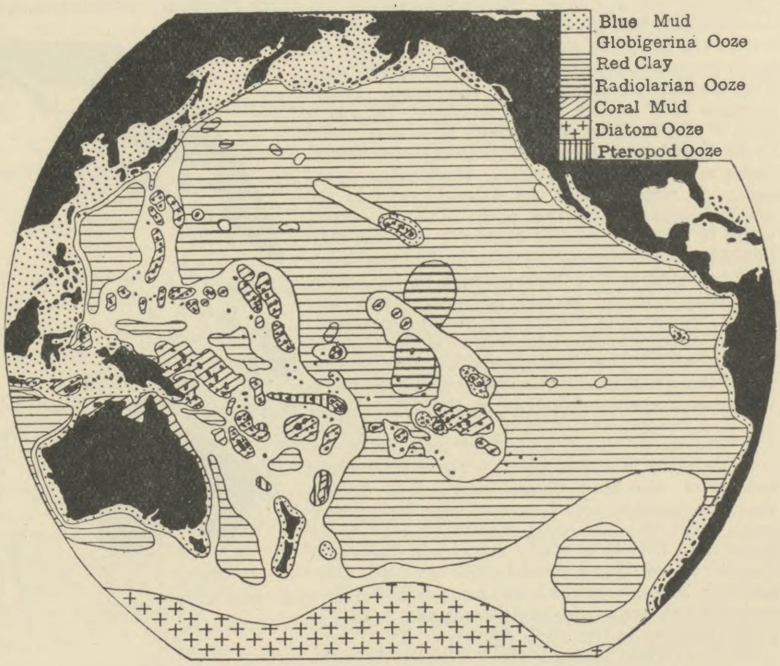

Fig. 2.—Chart of Deposits in the Pacific.

In the equatorial regions of the Pacific the mean annual temperature of the surface water is over 80°, except between 117° and 145° W., where a temperature of 75° to 80°, below the normal for the latitude, is found (Fig. 3). In the eastern Pacific the belt of high temperature lies wholly north of the equator, but in the west the temperature is over 80° from

Temperature.

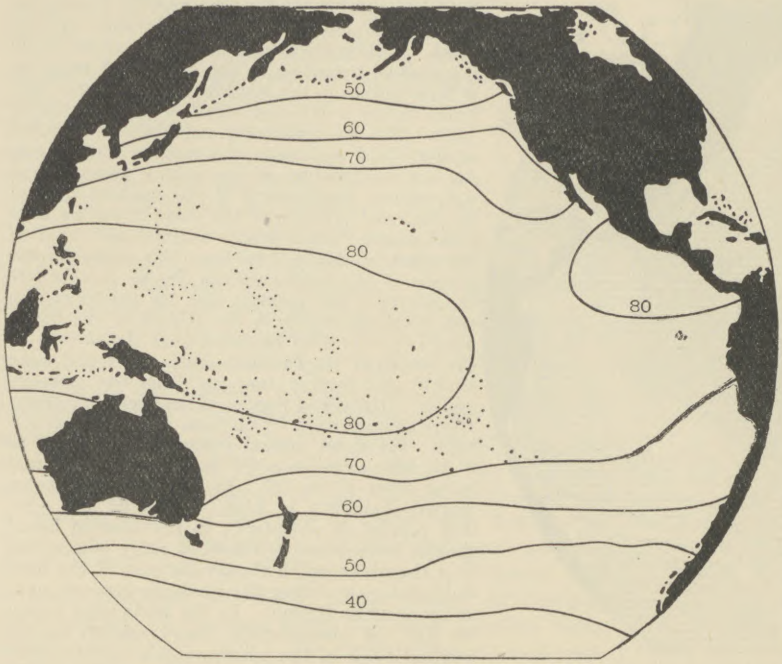

FIG. 3.—Chart of the Mean Surface Temperature of the Pacific.
(*The numbers indicate degrees Fahr.*)

20° N. to 20° S., to the east of Australia. In higher latitudes the eastern Pacific is colder than the western, at least to the parallels of 40° N. and S., but beyond this the isothermals run almost due east and west. Beyond the tropics the north Pacific is everywhere colder than the north Atlantic, especially in the east. In the open ocean the temperature everywhere falls from the surface downwards. The bottom temperature in the north Pacific averages 35·1°; south of the Sandwich Islands it is 35·0°; in the Low Archipelago it is 35·1°; and in 40° S. it is 34·7° in deep water. The isothermobaths of 50° to 70° rise nearer the surface in the equatorial regions, as in the Atlantic; and in the north Pacific, as in the north Atlantic, warm water is found at greater depths in the west than in the east. The greatest excess in the lower levels is found south-east of Japan, where in 30° N. the temperature is 60° in 200 fathoms. From this region temperature diminishes in all directions; even at the equator the temperature at 200 fathoms is only 48°. The isothermobaths sink farther below the surface near the equator, and temperatures are generally lower than in the Atlantic; in 21° S. a temperature of 36·5° occurs at a depth of 850 fathoms, compared with 1400 fathoms in the same latitude in the Atlantic. The characteristic feature of the temperature distribution in the Pacific is the thinness of warm surface layers compared with the enormous masses of cold water below, and this is specially marked in the north Pacific, where the surface layers having a temperature between 39° and 40° are not more than 20 to 30 fathoms in thickness, compared with 400 to 600 fathoms in the north Atlantic. The Pacific presents a further strong contrast with the Atlantic, inasmuch as the northern part is much colder than the southern. In the enclosed seas of the western Pacific temperature usually falls till a depth corresponding to that of the summit of the barriers which cut them off from the open ocean is reached, and below that point temperature is uniform to the bottom. In the Sulu Sea, for example, a temperature of 50·5° is reached at 400 fathoms, and this remains constant till the bottom is reached in 2500 fathoms.

The surface waters of the north Pacific are relatively fresh, the salinity being on the whole much lower than in the other great oceans. The saltest waters are found along a belt extending westwards from the American coast on the Tropic of Cancer to 160° E., then turning southwards to the equator. North of this salinity diminishes steadily, especially to the north-west, the Sea of Okhotsk showing the lowest salinity observed in any part of the globe. South and east of the axis mentioned salinity becomes less to just north of the equator, where it increases again, and the saltest waters of the whole Pacific are found, as we should expect, in the south-east trade-wind region, the maximum occurring in about 18° S. and 120° W. South of the Tropic of Capricorn the isohalines run nearly east and west, salinity diminishing quickly to the Southern Ocean. The bottom waters have almost uniformly a salinity of 34·8 per mille, corresponding closely with the bottom waters of the south Atlantic, but fresher than those of the north Atlantic.

Salinity.

The surface currents of the Pacific (Fig. 4) have not been studied in the same detail as those of the Atlantic, and their seasonal variations are little known except in the monsoon regions. Speaking generally, however, it may be said that they are for the most part under the direct control of the prevailing winds. The *North Equatorial Current* is due to the action of the north-east trades. It splits into two parts east of the Philippines, one division flowing northwards as the *Kuro Siwo* or Black Stream, the analogue of the Gulf Stream, to feed a drift circulation which follows the winds of the north Pacific, and finally forms the *Californian Current* flowing southwards along the American coast. Part of this rejoins the North Equatorial Current, and part probably forms the variable *Mexican Current*, which follows the coasts of Mexico and California close to the land. The *Equatorial Counter-Current* flowing eastwards is largely assisted during the latter half of the year by the south-west monsoon, and from July to October the south-west winds prevailing east of 150° E. further strengthen the current, but later in the year the easterly winds weaken or even destroy it. The *South Equatorial Current* is produced by the south-east trades, and is more vigorous than its northern counterpart. On reaching the western Pacific part of

Circulation.

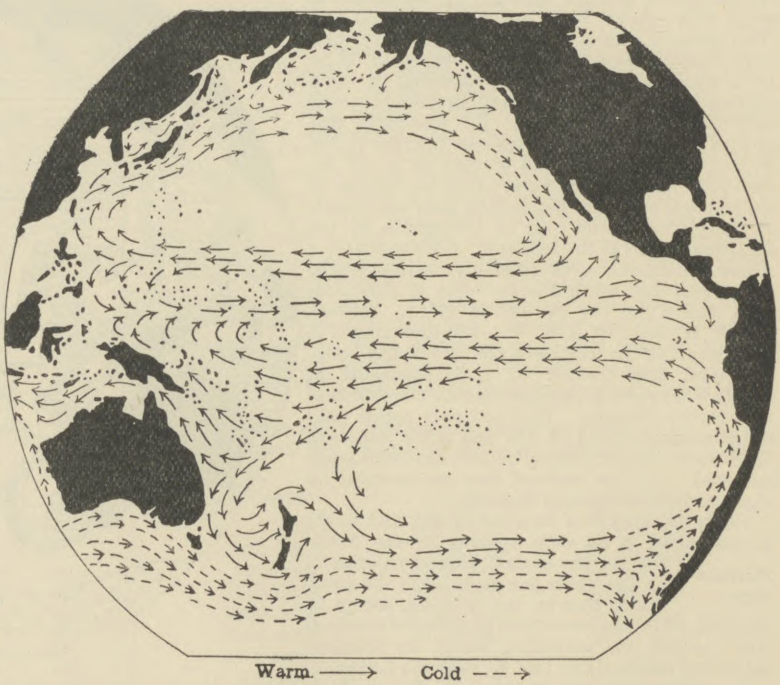

FIG. 4. Chart of the Currents of the Pacific.

this current passes southwards, east of New Zealand, and again east of Australia, as the *East Australian Current*, part northwards to join the Equatorial Counter-Current, and during the north-east monsoon part makes its way through the China Sea towards the Indian Ocean. During the south-west monsoon this last branch is reversed, and the surface waters of the China Sea probably unite with the Kuro Siwo. Between the Kuro Siwo and the Asiatic coast a band of cold water, with a slight movement to the southward, known as the *Oya Siwo*, forms the analogue of the "Cold Wall" of the Atlantic. In the higher latitudes of the south Pacific the surface movement forms part of the west wind-drift of the Roaring Forties. On the west coast of South America the cold waters of the *Humboldt* or *Peruvian Current*, corresponding to the Benguela Current of the south Atlantic, make their way northwards, ultimately joining the South Equatorial Current. The surface circulation of the Pacific is, on the whole, less active than that of the Atlantic. The centres of the rotational movement are marked by "Sargasso Seas" in the north and south basins, but they are of small extent compared with the Sargasso Sea of the north Atlantic. From the known peculiarities of the distribution of temperature, it is probable that definite circulation of water is in the Pacific confined to levels very near the surface, except in the region of the Kuro Siwo, and possibly also in parts of the Peruvian Current. The only movement in the depths is the slow creep of ice-cold water northwards along the bottom from the Southern Ocean; but this is more marked, and apparently penetrates farther north, than in the Atlantic. (H. N. D.)

Paderborn, a town and episcopal see of Prussia, province of Westphalia, 63 miles east-north-east of Dortmund by the railway to Hanover. The town hall (13th century) was restored in 1877–80, and the cathedral in 1891–93. There is a Roman Catholic seminary, with faculties in theology and philosophy. Printing and brewing are carried on, besides a trade in wool, corn, and cattle. There are mineral springs (65·5° Fahr.). Population (1885), 16,624; (1895), 19,980; (1900), 23,502.

Padron, a town of Spain, province of Corunna and diocese of Santiago, on the river Ulla, and on the Santiago–Carril railway. The population was 7662 in 1887 and 7287 in 1897. Floods are frequent. The country around is mountainous, and produces wine, wheat, and fruit. There are manufactures of cotton and woollen goods. The estuary from the bridge of Cesures at Padron to the mouth of the Ulla, a distance of 10 miles, is now only accessible for vessels of light draught, coasters, and fishing boats. Padron was one of the earliest Christian bishoprics. Normans and Saracens destroyed the ancient cathedral, of which only two towers and the 13th-century portico are still standing.

Padua, a city and capital of the province of Padua, Venetia, Italy. Its industry has greatly developed, many new factories and mills having been founded and those already existing enlarged. Corn and saw mills, distilleries, chemical factories, breweries, candle-works, ink-works, foundries, agricultural machine and automobile works, have been established and are flourishing. The trade of the district has grown to such an extent that Padua has become the central market for the whole of Venetia. The increase of railway traffic has also been noteworthy. Whereas in 1886 Padua stood twelfth on the list of important stations of the Adriatic line, it now holds the seventh place with a net revenue of nearly £80,000 per annum. The traffic of secondary and inter-provincial railways has correspondingly developed. The growth of population consequent upon this agricultural, industrial, and commercial advance has led to the extension of the inhabited area of the city. Population (1880), 70,753; (1900), 93,560.

Paducah, a city of Kentucky, U.S.A., capital of McCracken county. It is on the south bank of the Ohio river, at the mouth of the Tennessee, and on the Illinois Central and the Nashville, Chattanooga, and St Louis railways, in the western part of the state, at an altitude of 433 feet. Its trade is next in volume to that of Louisville in the state. Its traffic is in part by rail, in part by river, as it is connected by steamboat lines with all Ohio and Mississippi river ports. It is one of the largest tobacco markets, and contains many warehouses, and factories for its manufacture. There are also shipyards and a marine railway. Population (1890), 12,797; (1900), 19,446, of whom 516 were foreign-born and 5814 negroes.

Pagan, a subdivision and township of the Myingyan district of Upper Burma, 92 miles south-west by west of Mandalay. It was formerly for a period of four and a half centuries the capital of the Burmese empire. It was founded by King Pyinbya in A.D. 847, and remained the capital until the extinction of the dynasty in A.D. 1298. Pagan itself is a mere village now, but hundreds of pagodas in various stages of decay meet the eye in every direction. These are described in Yule's *Mission to Ava*. The bulk of the pagodas were built by King Anawra-hta, who overcame the Peguan king, Manuha of Thatôn. It was Anawra-hta who introduced the Buddhist religion in Upper Burma, and he carried off nearly the whole Thatôn population to build the pagodas at Pagan on the model of the Thatôn originals.

Pagani, a town of the province of Salerno, Campania, Italy, 12 miles north-west of Salerno by the railway to Naples. In the church is buried Alfonso de Liguori (1696–1787), founder of the order of the Redemptorists. It has cotton mills and macaroni factories; vegetables are grown for export. Population (1881), 12,780; (1899), about 13,000.

Paget, Sir James, Bart. (1814–1899), British surgeon, born at Yarmouth 11th January 1814, was the son of a brewer and shipowner. He was one of a large family, and his brother Sir George Paget (1809–1892), who became regius professor of physic at Cambridge in 1872, also had a distinguished career in medicine, and besides these honours was made a K.C.B. He attended a day-school in Yarmouth, and afterwards was destined for the navy; but this plan was given up, and at the age of sixteen he was apprenticed to a general practitioner, whom he served for four and a half years, during which time he gave his leisure hours to botanizing and made a great collection of the flora of East Norfolk. At the end of his apprenticeship he published with one of his brothers a very careful *Sketch of the Natural History of Yarmouth and its Neighbourhood*. In October 1834 he entered as a student at St Bartholomew's Hospital. Medical students in those days were left very much to themselves; there was no close supervision of their work, and it is probable that Paget gained rather than lost by having to fight his own way. He swept the board of prizes in 1835, and again in 1836; and in his first winter session he detected the presence of the *Trichina spiralis*, a minute parasite that infests the muscles of the human body.[1] In May 1836 he passed his examination at the Royal College of Surgeons, and became qualified to practise. The next seven years (1836–43) were spent in London lodgings, and were a time of poverty; for he made only £15 a year by practice, and his father failed in business, and could not give him any help. He managed to keep himself by writing for the medical journals, and preparing the catalogues of the hospital museum and of the pathological museum

[1] This discovery is usually credited to Owen (*q.v.*). The facts appear to be as follows. Paget was a first-year's student, and, by means of a pocket lens, found in the dissecting room that the specks in the infected muscles were parasitic worms and not, as previously thought, spicules of bone. Thomas Wormald, the senior demonstrator, who was no pathologist, sent a piece of the same muscle to Owen, who authoritatively pronounced the specks to be parasites and gave them their scientific name. It is probable that Owen did not realize that Paget had already made the discovery, and it was naturally associated with the name of the professor.

of the Royal College of Surgeons. In 1836 he had been made curator of the hospital museum, and in 1838 demonstrator of morbid anatomy at the hospital; but his advancement there was hindered by the privileges of the hospital apprentices, and by the fact that he had been too poor to afford a house-surgeoncy, or even a dressership. In 1841 he was made surgeon to the Finsbury Dispensary; but this appointment did not give him any experience in the graver operations of surgery. In 1843 he was appointed lecturer on general anatomy (microscopic anatomy) and physiology at the hospital, and warden of the hospital college then founded. For the next eight years he lived within the walls of the hospital, in charge of about thirty students resident in the little college. Besides his lectures and his superintendence of the resident students, he had to enter all new students, to advise them how to work, and to manage the finances and the general affairs of the school. Thus he was constantly occupied with the business of the school, and often passed a week, or more, without going outside the hospital gates. In 1844 he married Lydia, youngest daughter of the Rev. Henry North. In 1847 he was appointed an assistant-surgeon to the hospital, and Arris and Gale professor at the College of Surgeons. He held this professorship for six years, and each year gave six lectures in surgical pathology. (The first edition of these lectures, which were the chief scientific work of his life, was published in 1853.) In 1851 he was elected a Fellow of the Royal Society. In October 1851 he resigned the wardenship of the hospital. He had now become known as a great physiologist and pathologist; he had done for pathology in England what Virchow had done in Germany; but he had hardly begun to get into practice, and he had kept himself poor that he might pay his share of his father's debts—a task that it took him fourteen years to fulfil.

It is probable that no famous surgeon, not even John Hunter, ever founded his practice deeper in science than Paget did, or waited longer for his work to come back to him. In physiology he had mastered the chief English, French, German, Dutch, and Italian literature of the subject, and by incessant study and microscope work had put himself level with the most advanced knowledge of his time; so that it was said of him by Professor Owen, in 1851, that he had his choice, either to be the first physiologist in Europe, or to have the first surgical practice in London, with a baronetcy. His physiological lectures at the hospital were a chief cause of the raising again of its school, which in 1843 had gone down to a low point of its fortunes. In pathology his work was even more important. He fills the place in pathology that had been left empty by Hunter's death in 1793—the time of transition from Hunter's teaching, which for all its greatness was hindered by want of the modern microscope, to the pathology and bacteriology of the present day. It is Paget's greatest achievement that he made pathology dependent, in everything, on the use of the microscope—especially the pathology of tumours. He and Virchow may truly be called the founders of modern pathology; they stand together, Paget's *Lectures on Surgical Pathology* and Virchow's *Cellular-Pathologie*. When Paget, in 1851, began practice near Cavendish Square, he had still to wait a few years more for success in professional life. The "turn of the tide" came about 1854 or 1855; and in 1858 he was appointed surgeon extraordinary to Queen Victoria, and in 1863 surgeon in ordinary to the prince of Wales. He had for many years the largest and most arduous surgical practice in London. His day's work was seldom less than sixteen or seventeen hours. Cases sent to him for final judgment, with especial frequency, were those of tumours, and of all kinds of disease of the bones and joints, and all "neurotic" cases having symptoms of surgical disease. His supremacy lay rather in the science than in the art of surgery, but his name is associated also with certain great practical advances. He discovered the disease of the breast and the disease of the bones (osteitis deformans) which are called after his name; and he was the first at the hospital to urge enucleation of the tumour, instead of amputation of the limb, in cases of myeloid sarcoma.

In 1871 he nearly died from infection at a post-mortem examination, and, to lighten the weight of his work, was obliged to resign his surgeoncy to the hospital. In this same year he received the honour of a baronetcy. In 1875 he was president of the Royal College of Surgeons, and in 1877 Hunterian orator. In 1878 he gave up operating, but for eight or ten years longer he still had a very heavy consulting practice. In 1881 he was President of the International Medical Congress held in London; in 1880 he gave, at Cambridge, a memorable address on "Elemental Pathology," setting forth the likeness of certain diseases of plants and trees to those of the human body. Besides his shorter writings, he published *Lectures on Surgical Pathology* (1853), *Clinical Lectures and Essays* (1st ed. 1875), and *Studies of Old Case-books* (1891). In 1883, on the death of Sir George Jessel, he was appointed Vice-Chancellor of the University of London. In 1889 he was appointed a member of the Royal Commission on Vaccination. He died on 30th December 1899, in his eighty-fifth year. Sir James Paget had the gift of eloquence, and was one of the most careful and most delightful speakers of his time. He had a natural and unaffected pleasure in society, and he loved music. He possessed the rare gift of ability to turn swiftly from work to play; enjoying his holidays like a school-boy, easily moved to laughter, keen to get the maximum of happiness out of very ordinary amusements, emotional in spite of incessant self-restraint, vigorous in spite of constant over-work. In him a certain light-hearted enjoyment was combined with the utmost reserve, unfailing religious faith, and the most scrupulous honour. He was, all his life, profoundly indifferent toward politics, both imperial and medical; his ideal was the unity of science and practice in the professional life. (S. P.)

Pahang. See MALAY STATES (FEDERATED).

Paignton, a seaside invalid resort, in the Torquay parliamentary division of Devonshire, England, on Tor Bay, 2¾ miles south-west of Torquay by rail. The remains still exist of a palace of the bishops of Exeter. The Bible Tower, said to have been last occupied as a residence by Miles Coverdale, the translator of the Bible into English, consecrated bishop in 1551, has been again made habitable. The church of St John the Evangelist is ancient, and contains interesting monuments. There is a novitiate of the Marist Fathers, a town hall, a science and art school, a cottage hospital, various public halls, and a promenade pier. In the neighbourhood cider is made in great quantities. Population (1891), 6783; (1901), 8385.

Painesville, a village of Ohio, U.S.A., capital of Lake county, on the Grand river, near the shore of Lake Erie and on three railways, in the north-eastern part of the state. Population (1890), 4755; (1900), 5024, of whom 499 were foreign-born and 179 negroes.

Painting. See SCHOOLS OF PAINTING.

Paisley, a municipal and parliamentary burgh of Renfrewshire, Scotland, on the river Cart, 7 miles west by south of Glasgow by rail (5 stations). Borrowing powers for £130,000 were obtained in 1885–90 for the deepening of the Cart, which falls into the Clyde 3 miles below Paisley;

but the scheme was abandoned in 1891 for the time, and the debt on the river is now £123,664. Meanwhile the trustees have equipped the harbour with steam cranes, and a railway siding has been formed in connexion with it. The ancient abbey is being restored. The town hall, presented in 1882, cost £100,000. An observatory (1884–1898), three United Free churches, a court house, two Roman Catholic churches, county buildings (1891), a new post office, an Established church, an Episcopal church, a grammar school and academy (1898), a technical school, a drill hall, a magnificent memorial (Baptist) church, a new (1899) infirmary (£75,000), and a fire station are included in the erections since 1884. Electric light has been introduced (1899). The Dunn Square (1892) and the old quarry grounds converted into a recreation ground are additions to the parks and open spaces. A statue of Burns was erected in 1896, and statues of Sir Peter and Mr Thomas Coats in 1898. Thread and cotton spinning continues to be the staple industry. Of 3008 males and 7453 females who in 1891 were engaged in textile factories, 539 men and 5144 women were connected with the manufacture of cotton and linen, including thread. The thread mills form the governing factor in the combination which regulates the larger part of the thread trade of the world. From the shipbuilding yards in 1889, 15 vessels of 5423 tons were launched, and in 1899, 18 vessels of 8020 tons. The Neilson Endowed Institution had an average attendance in 1898–99 of 735. Population (1881), 55,638; (1891), 66,425; (1901), 79,355.

Pakhoi, a treaty port in the province of Kwangtung, China. The trade has declined rather than increased. In 1896 it reached a total of £773,535, whereas in 1900 the total was only £601,654; and it is probable that with the opening of the port of Kwang-chow-Wan and of the West river to steam traffic it will decline still more. The preparation of dried fish is a speciality of Pakhoi, the fish being exported to Hong Kong. The population is estimated at 25,000. The French obtained a concession to build a railway from this port to Nanning on the West river.

Pakôkku, a district in the Minbu division of Upper Burma, lying west of the Irrawaddy river and south of Mandalay, with the line of the Chin hills as a general boundary on the west. It has an area of 6210 square miles and a population of 311,959 (1891); 355,099 (1901). In 1898–99 there were 1354 villages in the district, paying Rs.8,22,535 revenue. The part of the district along the Irrawaddy and Chindwin rivers is peat and alluvial. Beyond this, however, the country rises gradually to the low Shinmadaung and Tangyi ridges, where it is very arid. To the westward there is a rapid drop to the well-watered valley of the Yaw river, and then a rise over broken, dry country before the valleys of the Myit-tha and Môln rivers are reached. The principal products are millet, sesamum, and sugar produced from toddy-palms in the riverain districts, which also grow rice, grain, peas, and beans. Tobacco and vegetables are also produced in some quantity, and maize is grown largely for the sake of the husk, which is used for native cheroot-wrappers, under the name of *yawpet*. The Yenangyat oil-fields, which produce quantities of petroleum, are in the south of the district, and iron used to be worked in a small way. There were 1053 square miles of reserved forests in the district. A good deal of teak and cutch is worked out. The yaw cutch is particularly esteemed. The average rainfall does not exceed 35 inches annually, and in many places water has to be carted for miles. West of the Pôndaung ridge, however, under the Chin hills, the rainfall exceeds 50 inches. The heat in May and June is very great, and the thermometer rises considerably above 100° F. in the shade; 110° is a common record during these months.

The great majority of the population is Burmese, but in Yaw there is a peculiar race called Taungthas, who claim to be quite distinct from both Burmese and Chins. The population in 1891 was classified thus:—Buddhists and Jains, 306,121; Hindus, 1665; Mahommedans, 1318; aborigines, Taungthas, and Chins, 2655; and Christians, 200. Of a total acreage of 3,974,147 there were 407,299 acres cropped in 1898–99. There were 492,223 acres available for cultivation, besides 19,898 acres of current fallow; 101,120 acres were under forest; and 1,196,782 were not cultivated. The headquarters town, Pakôkku, stands on the right bank of the Irrawaddy, and has grown into importance since the British occupation. It is the great boat-building centre of Upper Burma. The population in 1898 was 19,972. It may be described as the emporium of the trade of the Chindwin and Yaw river valleys. The steamers of the Irrawaddy Flotilla Company call here regularly, and it is the starting-point for the vessels plying on the Chindwin.

Palacio Valdés, Armando (1853– ——), Spanish novelist and critic, was born at Entralgo, in the province of Asturias, on 4th October 1853. His first writings were printed in the *Revista Europea*. These were pungent essays, remarkable for independent judgment and refined humour, and found so much favour with the public that the young beginner was soon appointed editor of the *Revista*. The best of his critical work is collected in *Los Oradores del Ateneo* (1878), *Los Novelistas españoles* (1878), *Nuevo Viaje al Parnaso* and *La Literatura en 1881* (1882), this last being written in collaboration with Leopoldo Alas. In 1881 he published a novel, *E. Señorito Octavio*, which shows an uncommon power of observation, and the promise of better things to come. In *Marta y María* (1883), a portrayal of the struggle between religious vocation and earthly passion, somewhat in the manner of Valera, Palacio Valdés achieved a very popular triumph which placed him in the first rank of contemporary Spanish novelists. *El Idilio de un Enfermo* (1884), a most interesting fragment of autobiography, has scarcely met with the recognition which it deserves: perhaps because the pathos of the story is too sincere and unadorned. The publication of Pereda's *Sotileza* is doubtless responsible for the conception of *José* (1885), in which Palacio Valdés gives a realistic picture of the manners and customs of seafaring folk, creates the two convincing characters whom he names José and Leonarda, and embellishes the whole with passages of animated description barely inferior to the finest penned by Pereda himself. The emotional imagination of the writer expressed itself anew in the charming story *Riverita* (1886), one of whose most attractive characters develops into the heroine of *Maximina* (1887); and from *Maximina*, in its turn, is taken the novice who figures as a professed nun among the personages of *La Hermana San Sulpicio* (1889), in which the love-passages between Zeferino Sanjurjo and Gloria Bermúdez are set off with elaborate, romantic descriptions of Seville. *El Cuarto Poder* (1888) is, as its name implies, concerned with the details, not always edifying, of journalistic life. Two novels issued in 1892, *La Espuma* and *La Fe*, were enthusiastically praised in foreign countries, but in Spain their reception was cold. The explanation is to be found in the fact that the first of these books is an avowed satire on the Spanish aristocracy, and that the second was construed into an attack upon the Roman Catholic Church. During the acrimonious discussion which followed the publication of *La Espuma*, it was frequently asserted that the artist had improvised a fantastic caricature of originals whom he had never seen; yet as the characters in Coloma's *Pequeñeces* are painted in darker tones, and as the very critics who were foremost in charging Palacio Valdés with incompetence and ignorance are almost unanimous in praising Coloma's fidelity, it is manifest that the indictment against *La Espuma* cannot be maintained. Of late, Palacio Valdés has returned to his earlier and better manner in *Los Majos de Cádiz* (1896) and in *La Algería del Capitán Ribot* (1899), in both of which he contrives to free himself from the reproach of undue submission to French influences. It can scarcely be said that he has fulfilled all the hopes that were once set upon him; but nevertheless he takes a prominent place in modern Spanish literature as a keen analyst of emotion and a sympathetic, delicate, humorous observer.

PALÆOBOTANY.

In the present article the subject of vegetable palæontology is treated from a botanical point of view. The science of botany is concerned with the vegetable kingdom as a whole, and not merely with the flora now living. The remains of the plants of former periods, which have come down to us in the fossilized state, are almost always fragmentary, and often imperfectly preserved; but their investigation is of the utmost importance to the botanist, as affording the only direct evidence of the past history of vegetable organisms. Since the publication of the *Origin of Species* the general acceptance of the doctrine of evolution has given a vastly increased significance to palæontological data. The determination of the course of descent has now become the ultimate problem for the systematist: this is a historical question, and the historical documents available are the remains of the ancient organisms preserved in the rocks. The palæobotanist thus endeavours to trace the history of plants in the past, with the hope of throwing light on their natural affinities and on the origin of the various groups. His investigations must embrace not only the comparative morphology and anatomy of fossil plants, but also their distribution over the earth's surface at different periods—a part of the subject which, besides its direct biological interest, has obvious bearings on ancient climatology and geography.

Preservation.—Before considering the results of palæobotanical research, some account must be given of the way in which the evidence is presented, or, in other words, of the modes of preservation of vegetable remains. These fall under two main heads. On the one hand, there is the mode of preservation which gives rise to casts, moulds, and generally impressions, exhibiting the *superficial* features of the specimen. The great majority of vegetable fossils are of this kind, and the term *incrustation* is used as a general term to cover all such methods of fossilization. On the other hand, there are specimens in which the tissues of the plant have been permeated by some mineral in solution, which, subsequently setting hard, has fixed and preserved the internal structure, often with astonishing perfection of detail. This second method of fossilization is termed *petrifaction.* In the case of incrustation the whole substance of the fossilized specimen—*e.g.*, a stem of *Sigillaria*—may be replaced by mineral matter, such as sandstone or shale, giving a cast of the whole, on the outer surface of which the external markings, such as the bases of leaves and the scars left by their fall, are visible in their natural form. Usually the original organic substance remains as a thin carbonaceous layer forming the surface of the cast, but sometimes it has entirely disappeared. The surrounding matrix will of course show the *mould* of the cast, with its elevations and depressions reversed. In the case of thin, flat organs such as leaves, the whole organ may be spread out in the plane of stratification, leaving its impress on the overlying and underlying layers. Here there has not necessarily been any replacement of organic by inorganic material; the whole leaf, for example, may remain, though reduced to a carbonaceous film. In such carbonaceous impression, not only are the form and markings, such as venation, perfectly preserved, but something of the actual structure may remain. The cuticularized epidermis, especially, is often thus preserved, and may be removed by the use of appropriate reagents and examined microscopically. If sporangia and spores are present, they also may persist in a perfectly recognizable form, and in fact much of our knowledge of the fructification of fossil Ferns has been derived from specimens of this kind.

In many cases *internal* casts have been formed, some large cavity, such as a fistular pith, having become filled with mineral substance, which has taken the impress of the surrounding structures, such as the wood. The common casts of Calamites are of this nature, representing the form of the hollow medulla, and bearing on their surface the print of the nodal constrictions and of the ridges and furrows on the inner surface of the wood. The whole organic substance may have been removed, or may persist merely as a thin carbonaceous layer. Mistakes have often arisen from confusing these *medullary* casts with those of the stem as a whole.

Although some information as to minute structure may occasionally be gleaned from the carbonaceous coating of impressions, the fossils preserved by *petrifaction* are the main source of our knowledge of the structural characters of ancient plants. The chemical bodies which have played the most important part as agents of petrifaction are silicic acid and calcium carbonate, though other substances, such as magnesium carbonate, calcium sulphate, and ferric oxide have also been concerned, either as the chief constituents of petrifactions, or mixed with other bodies. A large number of the most important remains of plants with structure preserved are silicious; this is the case, for example, with the famous French Permo-Carboniferous fossils of St Etienne, Autun, &c., which in the hands of Brongniart, Renault, and others have yielded such brilliant scientific results. At a more recent horizon, the silicified specimens of the Mesozoic Gymnosperms from Great Britain, France, and especially North America, are no less important. Calcified specimens are especially characteristic of the British Carboniferous formation; their preservation is equally perfect with that of the silicified fossils, and their investigation by Witham, Binney, Williamson, and others has proved no less fertile. In the Coal Measures of England and of certain German districts (*e.g.*, Langendreer in Westphalia) calcareous nodules, crowded with vegetable fragments of every kind, occur in certain mines embedded in the substance of the coal and representing its raw material in a petrified condition. Even the most delicate tissues, such as cambium and phloem, or even the endosperm of seeds, are frequently preserved cell for cell, both in calcareous and silicious material. As a rule, the petrified remains, all-important for the revelation of structure, are fragmentary, and give little idea of the habit or external characters of the plants from which they were derived. Hence they must be brought into relation with the specimens preserved as casts or impressions, in order to gain a better conception of the plant as a whole. This is often a difficult task, and generally the fragmentary nature of practically all vegetable fossils is the chief hindrance to their investigation. Owing to this, it has become the common practice of palæobotanists to give distinct generic names to detached parts of plants which may even have belonged to one and the same species. Thus the roots of *Sigillaria* are called *Stigmaria*, detached leaves *Sigillariophyllum*, and the fructifications *Sigillariostrobus*; the name *Sigillaria* applies to the stem, which, however, when old and partly decorticated has been called *Syringodendron*, while its woody cylinder has often been described under the name *Diploxylon*. This naming of portions of plants, however objectionable, is often not to be avoided; for detached organs constantly have to be described long before their relation to other parts is established—which, indeed, may never be accomplished. For example, the form and structure of *Stigmaria* have long been well known, but it has so far proved impossible to determine which Stigmariæ belonged to the genus *Sigillaria* and which to *Lepidodendron*. The correct piecing together of the fragmentary remains is one of the first problems of the palæobotanist, and the gradual disappearance of superfluous names affords a fair measure of the progress of his science. The recent advance of fossil botany has depended in a very great degree on the study of petrified specimens with their structure preserved; so far, at least, as the older strata are concerned, it is, as a rule, only with the help of specimens showing structure that any safe conclusions as to the affinities of fossil plants can be arrived at.

The subject of coal is treated elsewhere (see COAL, *Ency. Brit.* vol. vi.). Here it need only be said that the masses of vegetable substance, more or less carbonized and chemically altered, of which coal is composed, frequently contain cells and fragments of tissue in a condition recognizable under the microscope, as for example spores (sometimes present in great quantities), elements of the wood, fibres of the bark, &c. These remnants, however, though interesting as revealing something of the sources of coal, are too fragmentary and imperfect to be of any botanical importance. In lignite, on the other hand, the organized structure is sometimes excellently preserved. In the Wealden of Belgium, for example, specimens of Ferns and Coniferæ occur, in the form of lignite, which can be sectioned, like recent plants, with a razor, and exhibit an almost unaltered structure.

I. Palæozoic.

The present section is concerned with the botany of the Palæozoic age, from the oldest rocks in which vegetable remains have been found up to the close of the Permian period. The Glossopteris flora of India and the southern hemisphere, the age of which has been disputed, but is often regarded as Permo-Carboniferous, is, however, dealt with in the succeeding section, in connexion with the Mesozoic floras. The various groups of plants represented in the Palæozoic rocks will first be considered in systematic order, after which some account will be given of the succession and distribution of the various floras during the period.

In dealing with the plants of such remote epochs, the relative importance of the various groups, so far as they are known to us, is naturally very different from that which they assume at the present day. There is no evidence that the Angiospermous flowering plants, now the dominant class, existed during the Palæozoic period; they do not appear till far on in the Mesozoic epoch, and their earlier history is as yet entirely unknown. On the other hand, Gymnosperms were abundant, though belonging almost entirely to families now extinct, while the Pteridophyta attained a development far exceeding in every respect anything that they can now show. Among the lower classes of plants we have scarcely any knowledge of Palæozoic Bryophyta; Fungi were probably abundant, but their remains give us little information; while well characterized specimens are scanty among the Algæ, which, however, are better represented.

Algæ. With few exceptions, the remains of Palæozoic Algæ are of comparatively little botanical interest. A vast number of "species" have been described, but, as has been said, "by far the greater number of the supposed fossil Algæ have no claim to be regarded as authentic records of this class of Thallophytes" (Seward, 1898). The investigations of Nathorst, Williamson, and others have shown that a very large proportion of the casts and impressions attributed to Algæ had in all probability a totally different origin. Some represent the tracks or burrows of worms, crustaceans, or other animals; others, the course of rills of water on a sandy or muddy shore; others, again, the marks left on the bottom by bodies drifted along by the waves. In cases of doubt, evidence may be obtained from traces of organic structure, from the presence of carbonaceous matter, or, as Zeiller has pointed out, by the remains of animals such as Bryozoa being attached to the cast, showing that it represents a solid body and not a mere cavity or furrow. Evidence from traces of organization is alone conclusive; the presence of carbonaceous matter, though a useful indication, may be deceptive, for the organic substance may have been derived from other sources than the body which left the impression. The mere external form of the supposed Algæ is rarely so characteristic as to afford satisfactory evidence of their nature. Some of the better-attested examples, among which are a few of considerable interest, may now be considered. Of Cyanophyceæ, as we should expect, the Palæozoic remains are very doubtful. *Gloioconis*, found by Renault in a coprolite of Permian age, is regarded by him as a Cyanophycean allied to *Glœocapsa*; this may be so, but the argument which he draws from the absence of nuclei, considering the extreme rarity of recognizable nuclei even in the best-preserved fossil tissues, can hardly be taken seriously. *Girvanella*, found in Cambrian, Ordovician, and Silurian rocks, as well as in later deposits, appears to have played a part in the origination of oölitic rock-structure. It consists of minute interwoven tubular filaments, and has been variously interpreted as possibly representing the sheaths of a Cyanophycean Alga, and as constituting a Siphoneous thallus of the type of the Codieæ. The non-cellular order Siphoneæ is fairly well represented in Palæozoic strata, especially by calcareous verticillate forms referable to the family Dasycladeæ; the separate tubular joints of the articulated thallus, bearing the prints of the whorled branches, are sometimes cylindrical (*Arthroporella*, *Vermiporella*, &c.), sometimes oval (*Sycidium*) or spherical (*Cyclocrinus*). These forms, and others like them, go back to the Silurian and Ordovician; while *Gyroporella*, from the Permian, is another fairly characteristic Siphoneous type. There can be no doubt that the verticillate Siphoneæ, a group much isolated among recent organisms, are among the most ancient families of plants. The gigantic *Nematophycus*, to be described below, has been regarded as having Siphoneous affinities. Little trace of Confervaceæ has been found; *Confervites chantransioides*, apparently consisting of branched cellular filaments, may perhaps represent a Cambrian Confervoid. *Cladiscothallus*, from the Culm of Russia, in which the filaments are united to form hemispherical or globular tufts, has been compared by Renault to a *Chætophora*. This is one of the somewhat doubtful Algæ occurring in boghead coal or torbanite, a carbonaceous rock the nature of which has been much disputed, in the law courts as well as in scientific literature. The boghead of Scotland, Autun, and New South Wales is regarded by Renault and Bertrand as mainly composed of gelatinous Algæ (*Pila* and *Reinschia*), having a hollow, saccate thallus formed of a single layer of cells. It is difficult to believe that a body containing 65 per cent. of carbon can be so largely made up of gelatinous Algæ in a comparatively little altered condition; even the organic nature of the supposed thalli is not absolutely beyond doubt. Scarcely anything is known of Palæozoic Florideæ; *Solenopora*, ranging from the Ordovician to the Jurassic, resembles, in the structure of its thallus, with definite zones of growth, Corallinaceæ such as *Lithothamnion*, and may probably be of the same nature. A branched filamentous organism from the Lower Carboniferous of Scotland, described by Kidston under the name of *Bythotrephis worstoniensis*, shows some remains of cellular structure, and may probably be a true Alga, resembling some of the filamentous Florideæ in habit.

Apart from the multitude of supposed fossil Algæ described as "Fucoids," but usually not of Algal nature, and never presenting determinable characters, very little remains that can be referred to Palæozoic Brown Algæ. The most striking of all fossil Algæ, however, *Nematophycus*, may possibly be a Phæophycean. The first species of the genus, *Nematophycus Logani*, was discovered by Dawson in 1856 in the Lower and Middle Devonian of Canada, and was described by him as a Conifer under the name of *Prototaxites*. Carruthers, however, in 1872 established its Algal nature, and gave it the more appropriate name of *Nematophycus*. In *N. Logani* the stem, which is found in a silicified state, may be as much as 3 feet in diameter. The tissue is made up of large, unseptate, occasionally branching tubes, with an undulating vertical course, among which much smaller tubes are irregularly interwoven. Radially placed gaps in the tissue (erroneously interpreted at first as medullary rays, but subsequently more aptly compared to the air-spaces of large Algæ) contain very sparse hyphæ, which here branch more freely than elsewhere. The concentric rings of growth, which form a characteristic feature, are due to periodic variations in the size of the larger tubes. Transverse septa have occasionally, but rarely, been detected in the smaller hyphæ. Penhallow maintains that these smaller tubes arise as branches from the larger, but other observers have failed to confirm this. In *N. Storriei*, from the Silurian (Wenlock) of South Wales, described by Barber, there is no sharp differentiation of the two kinds of tubes; they are rarely observed to branch, except in the gaps, which in this species are not radially directed. In *N. Ortoni* (Penhallow), from the Devonian of Canada, the tubes are quite uniform, and there are no spaces or concentric rings. The tubes have their cavity dilated at intervals, and Penhallow has therefore compared them with the trumpet-hyphæ of Laminariaceæ, but no transverse septa are anywhere visible. Several other species have been described. Carruthers compared the usually non-cellular structure of *Nematophycus* with that of Siphoneæ such as *Halimeda*, while recognizing the points of resemblance to Laminariaceæ (*e.g.*, *Lessonia*) in the dimensions of the stem and its concentric rings of growth. Later writers, influenced by the occasional occurrence of transverse walls in the smaller hyphæ, have laid more stress on Laminariaceous affinities. The existence of these gigantic Algæ in Palæozoic times, attested by such well-preserved specimens, is a fact of great interest, though their systematic position is still an open question. *Pachytheca*, a spherical organism, usually about the size of a small pea, found in rocks of Silurian and Devonian age, has been much investigated and discussed, without any decisive light having been thrown on its nature. It was once regarded as connected with *Nematophycus* (with which it sometimes occurs in association), possibly as its fructification. For this view, however, there is no evidence, though the tissues of the two fossils are somewhat similar. *Pachytheca* is formed of cellular filaments resembling those of a *Cladophora*, irregularly interwoven in the central region, radiating towards the periphery, and often forked. In one case the spherical thallus was found seated in a cup-like receptacle. There can be little doubt of the Algal nature of the fossil, but beyond this it is impossible at present to carry its determination.

On the whole, it cannot be said that the Palæozoic remains have as yet thrown much light on the evolution of the Algæ, though we may not be prepared to maintain, with Zeiller, that plants of this class appear never to have assumed a form very different from that which they present at the present day.

Bacteria. The first evidence for the existence of Palæozoic Bacteria was obtained in 1879 by Van Tieghem, who found that in silicified vegetable remains from the Coal Measures of St Étienne the cellulose membranes showed traces of subjection to butyric fermentation, such as is produced at the present day by *Bacillus Amylobacter;* he also claimed to have detected the organism itself. Since that time a number of fossil Bacteria, mainly from Palæozoic strata, have been described by Renault, occurring in all kinds of fossilized vegetable and animal débris. The supposed *Micrococci* present little that is characteristic; the more definite, rod-like form of the *Bacilli* offers a better means of recognition, though far from an infallible one; in a few cases dark granules, suggestive of endospores, have been found within the rods. On the whole, the occurrence of Bacteria in Palæozoic times—so probable *à priori*—may be taken as established, though the attempt to discriminate species among them is probably futile.

Fungi. Fungi were no doubt abundant among Palæozoic vegetation. In examining the tissues of fossil plants of that epoch, nothing is more common than to meet with mycelial hyphæ in and among the cells; in many cases the hyphæ are septate, showing that the higher Fungi (Mycomycetes), as distinguished from the more algoid Phycomycetes, already existed. An endophytic Fungus of the latter group (*Peronosporites antiquarius,* W. Smith) bears very definite terminal, or intercalary, spherical vesicles, which may probably be regarded as reproductive organs—either oögonia or sporangia. A minute Fungus bearing sporangia, found by Renault in the wood of a *Lepidodendron,* and named by him *Oöchytrium lepidodendri,* is referred with much probability to the Chytridineæ. Small spores, almost certainly those of Fungi, are very common in the petrified tissues of Palæozoic plants. Spherical sacs, bearing forked spines, described by Williamson under the name of *Zygosporites,* are frequent, usually in an isolated state. Mr Seward, however, has found a Zygosporites *in situ,* terminating an apparently fungal hypha: he suggests a possible comparison with the mould *Mucor.* Bodies closely resembling the perithecia of Sphæriaceous Fungi have often been observed on impressions of Palæozoic plants, and may probably belong to the group indicated. Conceptacles containing spores, and strongly suggesting the perithecia of some Pyrenomycetous Fungus, have recently been found, in petrified material, on the leaves of an *Alethopteris,* which appears to have undergone decay before fossilization set in. The few and incomplete data which we at present possess as to Palæozoic Fungi do not as yet justify any inferences as to the evolution of these plants. The writer is not aware of any evidence for the occurrence of Palæozoic Lichens.

Bryophyta. The important class of the Bryophyta, which, on theoretical grounds, is commonly regarded as more primitive than the Pteridophyta, is as yet scarcely represented among known fossils of Palæozoic age. In the Lower Carboniferous of Scotland Mr Kidston has found several specimens of a large dichotomous thallus, with a very distinct midrib; the specimens, referred to the provisional genus *Marchantites,* much resemble the larger thalloid Liverworts. Similar fossils have been described from still older rocks. In one or two cases Palæozoic plants, resembling the true Mosses in habit, have been discovered; the best example is the *Muscites polytrichaceus* of Renault and Zeiller, from the Coal Measures of Commentry. In the absence, however, both of reproductive organs and of anatomical structure, it cannot be said that there is at present conclusive evidence for the existence of either Hepaticæ or Musci in Palæozoic times.

Pteridophyta. Our knowledge of the Vascular Cryptogams of the Palæozoic period is more extensive than of any other class of plants, and in fact it is here that the evidence of Palæontology first becomes of essential importance to the botanist. They extend back through the Devonian, possibly to the Silurian system, but the systematic summary now to be given is based primarily on the rich materials afforded by the Carboniferous and Permian formations, from which our detailed knowledge of Palæozoic plants has been chiefly derived.

In addition to the three classes, Equisetales, Lycopodiales, and Filicales, under which recent Pteridophytes naturally group themselves, a fourth class, Sphenophyllales, existed in Palæozoic times, related to the Horsetails on the one side and to the Club-mosses on the other, but with peculiarities of its own demanding an independent position. We further find that, whereas the Ferns of the present day form a well-defined and even isolated class, this was not the case at the time when the Primary rocks were deposited. A considerable number of Palæozoic plants, showing evident affinity to Ferns, have proved to exhibit at the same time characters common to Gymnosperms, especially Cycads. This interesting group of plants will be treated as an appendix to the Filicales, under Potonié's name of Cycadofilices. The arrangement which we shall adopt for the Palæozoic Pteridophyta is therefore as follows:—

I. *Equisetales.*
II. *Sphenophyllales.*
III. *Lycopodiales.*
IV. *Filicales,* with the *Cycadofilices.*

The last-named group appears to form the natural transition to the Gymnosperms which follow. We must bear in mind that throughout the Palæozoic period, and indeed far beyond it, Vascular plants, so far as the existing evidence shows, were represented only by the Pteridophyta and Gymnosperms. Although the history of the Angiosperms may probably go much farther back than present records show, it is certain that they played no considerable part in Palæozoic vegetation. Consequently, the Pteridophytes and Gymnosperms had the field to themselves, so far as regards the higher plants, and filled places in nature which have now for the most part been seized on by families of more modern origin. Hence it is not surprising to find that the early Vascular Cryptogams were, beyond comparison, more varied and more highly organized than their displaced and often degraded successors. It is among the fossils of the Palæozoic rocks that we first learn the possibilities of Pteridophytic organization.

I. *Equisetales.*—This class, represented in the recent Flora by the single genus *Equisetum,* with about twenty species, was one of the dominant groups of plants in Carboniferous times. The Calamarieæ, now known to have been the chief Palæozoic representatives of the Horsetail stock, attained the dimensions of trees, reaching, according to Grand' Eury, a height of from 30 to 60 metres, and show in all respects a higher and more varied organization than their recent successors.

Their remains occur in three principal forms of preservation: (1) carbonaceous impressions of the leafy branches, the fructifications, and other parts; (2) casts of the stem; these are usually internal, or *medullary* casts, as described above. Around the cast the organic tissues may be represented by a carbonaceous layer, on the outer surface of which the external features, such as the remains of leaves, can sometimes be traced. More usually, however, the carbonaceous film is thin, and merely shows the impress of the medullary cast within; (3) petrified specimens of all parts—stem, roots, leaves, and fructifications—showing the internal structure, more or less perfectly preserved. The correlation of these various remains presents considerable difficulties. Casts surrounded by wood, with its structure preserved, have sometimes been found, and have established their true relations. The position of the branches is shown both on casts and in petrified specimens, and has helped in their identification, while the petrified remains sometimes show enough of the external characters to allow of their correlation with impressions. Fructifications have often been found in connexion with leafy shoots, and the anatomical structure of the axis in sterile and fertile specimens has proved a valuable means of identification.

In **habit** the Calamarieæ appear to have borne, on the whole, a general resemblance to the recent Equisetaceæ, in spite of their enormously greater bulk. The leaves were constantly in whorls, and were usually of comparatively small size and of simple form. In the oldest known Calamarian, however, *Archæocalamites* (Devonian and Lower Carboniferous), the leaves were repeatedly forked. There is evidence that in some, at least, of the Calamarieæ the leaves of each verticil were united at the base to form a sheath. The free lamina, however, was always considerably more developed than in the recent family; in form it was usually linear, or narrowly lanceolate. Different genera have been founded on leaf-bearing branches of Calamarieæ; apart from *Archæocalamites*, already mentioned, and *Autophyllites* (Grand' Eury), in both of which the leaves were dichotomous, we have *Annularia*, *Asterophyllites*, and *Calamocladus* (in Grand' Eury's limited sense), with simple leaves. In some species of *Annularia* the extremely delicate ultimate twigs, bearing whorls of small lanceolate leaves, give a characteristic habit, suggesting that they may have belonged to herbaceous plants; other Annulariæ, however, have been traced with certainty into connexion with the stems of large Calamites. In *Asterophyllites*, the generic distinction of which from *Annularia* is not always clear, the narrow linear leaves are in crowded whorls, and the ultimate branches distichously arranged; in the *Calamocladus* of Grand' Eury—characteristic of the Upper Coal Measures—the whorls are more remote, and the twigs polystichous in arrangement. In all these groups a leaf-sheath has been recognized.

The distribution of the branches on the main stem shows considerable variations, on which genera or sub-genera have been founded by C. E. Weiss. In *Archæocalamites*, which certainly deserves generic rank, the branches may occur on every node, but only in certain parts of the stem; the ribs of successive internodes do not alternate, but are continuous, indicating that the leaves were superposed. Using *Calamites* as a generic name for all those Calamarian stems in which the ribs alternate at the nodes, we have, on Weiss's system, the following sub-genera:—*Stylocalamites*, branches rare and irregularly arranged; *Calamitina*, branches in regular verticils, limited to certain nodes, which surmount specially short internodes; *Eucalamites*, branches present on every node. These distinctions can be recognized on petrified specimens, as well as on the casts, but their taxonomic value is somewhat doubtful. In many Calamites there is evidence that the aërial stem sprang from a horizontal rhizome, as in the common species *C.* (*Stylocalamites*) *Suckowi*; in other specimens the aërial stem had an independent, rooting base.

The **anatomical structure** of all parts of the plant is now known, in various Calamarieæ, thanks more especially to the work of Williamson in England and of Renault in France. The stem has a structure which may be briefly characterized as that of an *Equisetum* with secondary growth in thickness (Fig. 1, Plate). The usually fistular pith is surrounded by a ring of collateral vascular bundles (see ANATOMY OF PLANTS, and PTERIDOPHYTA), each of which, with rare exceptions, has an intercellular canal at its inner edge containing the disorganized spiral tracheæ, just as in the recent genus. The cortex is often preserved; in certain cases it was strengthened by hypodermal strands of fibres, as in *Equisetum*. It is only in the rare cases where a very young twig is preserved that the primary structure of the stem is found unaltered. In all the larger specimens a broad zone of wood, with its elements in radial series, had been added. This secondary wood, in the true Calamites (*Arthropitys*, Goeppert), has a simple structure comparable to that of the simplest Coniferous woods; it is made up entirely of radial bands of tracheides interspersed with medullary rays. The pitting of the tracheides is more or less scalariform in character, and is limited to the radial walls. In favourable cases remains of the cambium are found on the outer border of the wood, and phloem is also present in the normal position, though it does not seem to have attained any considerable thickness. In the old stems the primary cortex was replaced by periderm, giving rise to a thick mass of bark. The above description applies to the stems of *Calamites* in the narrower sense (*Arthropitys* of the French authors) to which the specimens from the British Coal Measures mostly belong. *Archæocalamites* appears to have had a similar structure, but in some specimens from the Lower Carboniferous of Burntisland, perhaps referable to this genus, centripetal wood was present in the stem. In *Calamodendron* (Upper Coal Measures) the wood has a more complex structure than in *Calamites*, the principal rays including radial tracts of fibrous tissue, in addition to the usual parenchyma. *Arthrodendron* (Lower Coal Measures) approaches *Calamodendron* in this respect. The longitudinal course of the vascular bundles and their relation to the leaves in Calamarieæ generally followed the *Equisetum* type, though more variable and sometimes more complex. The attachment of the branches was immediately above the node, and usually between two foliar traces, as in the recent genus. Where the structure of the leaves is preserved it proves to be of an extremely simple type; the narrow lamina is traversed by a single vascular bundle, separated by a sheath from the surrounding palisade-parenchyma. Stomata of the usual structure have been detected in the epidermis.

The roots (formerly described as a separate genus, *Astromyelon*) were borne directly on the nodes, not on short lateral branches as in *Equisetum*. They are of similar structure in all known Calamarieæ, the main roots having a large pith, while the rootlets had little or none. The structure is in all respects that typical of roots, as shown by the centripetal primary wood, and the alternation of xylem and phloem groups observable in exceptionally favourable young specimens. A striking feature is the presence of large, radiating intercellular cavities in the cortex, suggesting an aquatic habit.

A considerable number of Calamarian **fructifications** are known, preserved, some as carbonaceous impressions, others as petrified specimens, exhibiting the internal structure. In many cases the cones have been found in connexion with branches bearing characteristic Calamarian foliage. Almost all strobili of the Calamarieæ are constructed on the same general lines as those of *Equisetum*, with which some agree exactly; in most, however, the organization was more complex, the complexity consisting in the intercalation of whorls of sterile bracts, between those of the sporangiophores. In several cases heterospory, unknown among recent Equisetaceæ, has been demonstrated in their Palæozoic representatives.

Four main types of structure may be distinguished among Calamarian strobili.

1. *Calamostachys*, Schimper. Here the whorls of peltate sporangiophores alternate regularly with those of sterile bracts, the former being inserted on the axis midway between the latter (Fig. 2). The sporangiophores, which are usually half as numerous in each verticil as the bracts, have the same form as in *Equisetum*, but each bears four sporangia only. The spores are frequently found to be still united in tetrads. In some species, *e.g.*, the British *C. binneyana*, numerous specimens have been examined and only one kind of spore observed; here, then, there is a strong presumption that the species was homosporous. In other cases, however, *e.g.*, *C. casheana*, Will., two kinds of spore occur, in different sporangia, but on the same strobilus and even on the same sporangiophore. The megaspores, of which there are many in the megasporangium, have a diameter about three times that of the microspores. The abortion of certain spores, which is known to have taken place both in the homosporous *C. binneyana* and in the megasporangia of *C. casheana*, may throw some light on the origin of the heterosporous condition. The bracts were sometimes coherent in their lower part (*e.g.*, *C. binneyana*), sometimes free (*e.g.*, *C. Lugwigi*); in all cases their free extremities formed a protection to the fertile whorl above. In some Continental species (*e.g.*, *C. Grand' Euryi*, Ren.) radial membranous plates hung down from each verticil of bracts, forming compartments in which the subjacent sporangiophores were enclosed. The anatomy of the axis is essentially similar to that of a young Calamarian twig, with some variations in detail. Strobili of the *Calamostachys* type occur in connexion both with *Annularia* and *Asterophyllites* foliage.

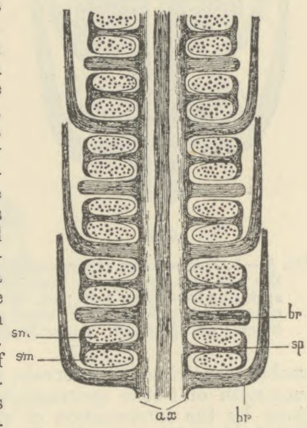

FIG. 2.—*Calamostachys.* Diagrammatic longitudinal section of the cone, showing the axis (*ax*) bearing alternate whorls of bracts (*br*) and peltate sporangiophores (*sp*) with their sporangia (*sm*). The upturned tips of the bracts are only shown in every alternate verticil.

2. *Palæostachya*, Weiss. Here, as in the previous genus, sterile and fertile verticils are ranged alternately on the axis of the cone. The only difference is that in *Palæostachya* the sporangiophores, instead of standing midway between the whorls of bracts, are inserted immediately above them, springing, as it were, from the axil of the sterile verticil (Fig. 3, A). This singular arrangement suggests doubts as to the correctness of the current interpretation of the Equisetaceous sporangiophore as a modified leaf (cf. *Cheirostrobus* below). In all other respects the two genera agree; there is evidence for the occurrence of heterospory in some strobili referred to *Palæostachya*. The anatomy of the axis is that of a young branch of a Calamite. According to Grand' Eury, the *Palæostachya* fructification was most commonly associated with *Asterophyllites* foliage. The external aspect of a *Palæostachya* is shown in Fig. 4 (Plate).

3. *Equisetum* type of strobilus. In certain cases the strobili of Palæozoic Calamarieæ appear to have had essentially the same organization as in the recent genus, the axis bearing sporangio-

phores only, without intercalated bracts. It is remarkable that fructifications of this kind have been found by Renault in close association with the most ancient of the Calamarieæ—*Archæocalamites.* In these strobili the peltate scales, like the vegetative leaves of the plant, are in superposed verticils; each appears to have borne four sporangia (Fig. 3, B). Other cones, however, namely, those known as *Pothocites*, have also been attributed on good grounds to the genus *Archæocalamites;* they are long

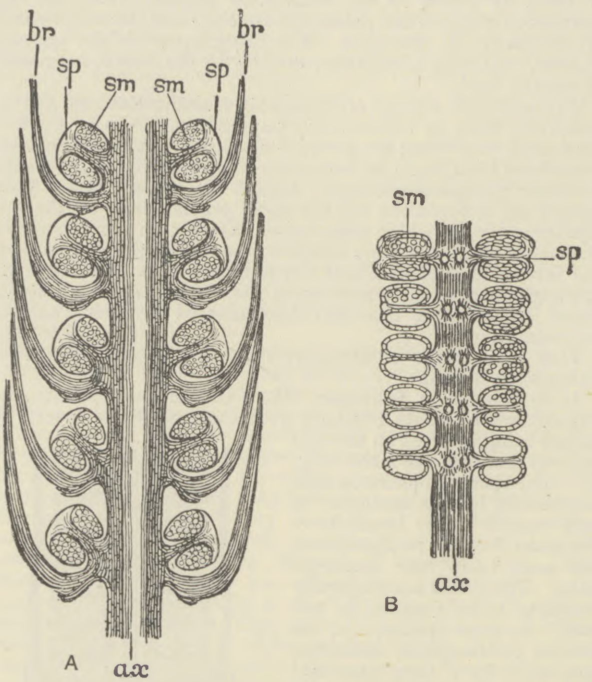

FIG. 3.—A, *Palæostachya.* Diagrammatic longitudinal section of cone, showing the axis (*ax*) bearing the bracts (*br*) with peltate sporangiophores (*sp*) springing from their axils; *sm*, sporangia. B, *Archæocalamites.* Part of cone, showing the axis (*ax*) bearing peltate sporangiophores (*sp*) without bracts; *sm*, sporangia. (*After Renault.*) (*Scott*, "*Studies.*")

strobili, constricted at intervals, and it is probable that here the succession of fertile sporangiophores was interrupted here and there by the intercalation of sterile bracts. Cones from the Middle Coal Measures, described by Kidston under the name of *Equisetum Hemingwayi*, but probably belonging to one of the Calamarieæ, bear a striking external resemblance to those of a recent *Equisetum.*

4. *Cingularia*, Weiss. This form of strobilus, from the Coal Measures of Germany, is imperfectly known, and its relation to Calamarieæ not beyond doubt. In the lax strobili the sporangiophores, which are not peltate, but strap-shaped, were borne, according to Weiss, immediately *below* the verticils of bracts, the position thus being the reverse of that in *Palæostachya.*

The Palæozoic Calamarieæ, though so far surpassing recent Equisetaceæ, both in stature and complexity of organization, clearly belonged to the same class of Vascular Cryptogams. There is no satisfactory evidence for attributing Phanerogamic affinities to any members of the group, and the view, of which Williamson was the chief advocate, that they form a homogeneous Cryptogamic family, is now fully established.

II. *Sphenophyllales.*—The class of *Sphenophyllales*, as known to us at present, is of limited extent, embracing the two genera *Sphenophyllum* and *Cheirostrobus*, which may serve as types of two families within the class. The characters of *Sphenophyllum* are known with some completeness, while our knowledge of *Cheirostrobus* is confined to the fructification; the former will therefore be described first.

1. *Sphenophyllum.*—The genus *Sphenophyllum*, of which a number of species have been described, ranging probably from the Middle Devonian, through the Carboniferous, to the Permian, consisted of herbaceous plants of moderate dimensions. The long, slender stems, somewhat tumid at the nodes, were ribbed, the ribs running continuously through the nodes, a fact correlated with the superposition of the whorled leaves, the number of which in each verticil was some multiple of 3, and usually 6. In the species on which the genus was founded the leaves, as the generic name implies, are cuneate, entire, or toothed on their anterior margin;[1] in other cases they are deeply divided by dichotomy into narrow segments, or the whorl consists of a larger number (up to 24) of apparently simple, linear leaves, which may represent the segments of a smaller number. The different forms of leaf may occur on the same plant, the deeply divided foliage often characterizing the main stem, while the cuneate leaves were borne on lateral shoots. A comparison, formerly suggested, with the two forms of leaf in Batrachian Ranunculi has not proved to hold good; the idea of an aquatic habit is contradicted by the anatomical structure, and the hypothesis that the plants were of scandent growth is more probable. The species of *Sphenophyllum* have a graceful appearance, which has been compared with that of the trailing Galiums of hedgerows. Branches sprang from the nodes, though perhaps not truly axillary in position. The cones, more or less sharply differentiated, terminated certain of the branches.

The anatomy of the stem of *Sphenophyllum*, investigated by Renault, Williamson, and others, is highly characteristic (Fig. 5, Plate). The stem is traversed by a single stele, with solid wood, without pith; the primary xylem is triangular in section, the spiral elements forming one or two groups at each angle, while the phloem occupied the bays, so that the structure resembles that of a triarch root. The leaf-trace bundles started from the angles of the stele, and forked, in passing through the cortex, to supply the veins of the leaf, or its subdivisions. The cortex was deeply furrowed on its outer surface. The primary structure is only found unaltered in the youngest stems; secondary growth by means of a cambium set in very early, xylem being formed internally and phloem externally in a perfectly normal manner. At the same time a deep-seated periderm arose, by which the primary cortex was soon entirely cut off. The secondary wood in the Lower Carboniferous species, *S. insigne*, has scalariform tracheides, and is traversed by regular medullary rays, but in the forms from later horizons the tracheides are reticulately pitted, and the rays are for the most part replaced by a network of xylem-parenchyma. There are no recent stems with a structure like that of *Sphenophyllum;* so far as the primary structure is concerned, the nearest approach is among the *Psiloteæ*, with which other characters indicate some affinity. The diarch roots of a *Sphenophyllum* have been described by Renault, who has also investigated the leaves; they were strongly constructed mechanically, and traversed by slender vascular bundles branching dichotomously.

Fructification.—Williamson thoroughly worked out, in petrified specimens, the organization of a cone which he named *Bowmanites Dawsoni;* it was subsequently demonstrated by Zeiller that this fructification belonged to a *Sphenophyllum*, the cones of the well-known species *S. cuneifolium* having a practically identical structure. The type of fructification described by Williamson and now named *Sphenophyllum Dawsoni* consists of long cylindrical cones, in external habit not unlike those of some Calamarieæ. The axis, which in structure resembles the vegetative stem in its primary condition, bears numerous verticils of bracts, those of each verticil being coherent in their lower part, so as to form a disc or cup from the margin of which the free limbs of the bracts arise. The sporangia, which are about twice as numerous as the bracts, are seated singly on pedicels or sporangiophores springing from the upper surface of the bract-verticil, near its insertion on the axis (Fig. 6). As a rule two sporangiophores belong to each bract. The sporangium is attached to the enlarged distal end of its pedicel, from which it hangs down, so as to suggest an anatropous ovule on its funiculus. Dehiscence appears to have taken place at the free end of the sporangium; the spores are numerous, and, so far as observed, of one kind only. Each sporangiophore is traversed throughout its length by a vascular bundle connected with that which supplies

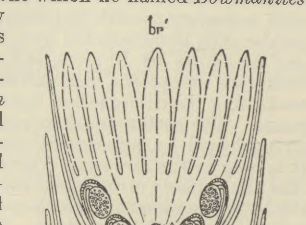

FIG. 6.—*Sphenophyllum Dawsoni.* Diagram of cone in longitudinal section. *ax*, axis; *br*, bracts; *sp*, sporangiophores, each bearing a sporangium, *sm*; *br'*, whorl of bracts in surface view.

[1] Sometimes the leaves in a whorl were of unequal size; see Fig. 3 (Mesozoic).

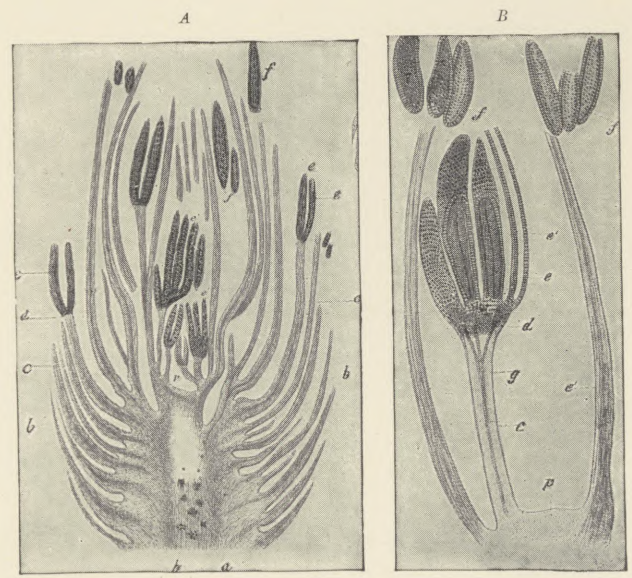

FIG. 20.—*Cordaianthus Penjoni.* *A*, Male catkin in longitudinal section: *a*, axis; *b*, bracts; *c*, *d*, filaments of stamens, bearing the pollen-sacs (*e* and *f*) at the top; *v*, apex of axis. × 6½. *B*, Stamens more highly magnified: *g*, vascular bundle of filament; *e*, pollen-sac after dehiscence. × 23. *After Renault (Scott, "Studies").*

the subtending bract. This form of fructification appears, from Zeiller's researches, to have been common to several species of *Sphenophyllum*, but others show important differences. Thus *Bowmanites Römeri*, a fructification fully investigated by Solms-Laubach, differs from *S. Dawsoni* in the fact that each sporangiophore bears two sporangia, attached to a distal expansion approaching the peltate scale of the Equisetales. It is thus proved that the sporangiophore is not a mere sporangial stalk, but a distinct organ, in all probability representing a ventral lobe of the subtending bract. In *Sphenophyllum majus*, where the cones are less sharply defined, the forked bract bears a group of four sporangia, but their mode of insertion has not yet been made out.

2. *Cheirostrobeæ.*—The family *Cheirostrobeæ* is only known from a petrified fructification (*Cheirostrobus pettycurensis*) derived from the Lower Carboniferous of Burntisland in Scotland. The excellence of the preservation has, however, rendered it possible to investigate the complex structure in detail. The cone is of large size—3·5 cm. in diameter; the stout axis bears numerous whorls of compound sporophylls, the members of successive verticils being superposed. The sporophylls, of which there are twelve in a whorl, are each composed of six segments, three being inferior or dorsal, and three superior or ventral. The dorsal segments are sterile, corresponding to the bracts of *Sphenophyllum Dawsoni*, while the ventral segments constitute peltate sporangiophores, each bearing four sporangia, just as in a Calamarian fructification (Fig. 7). The great length and

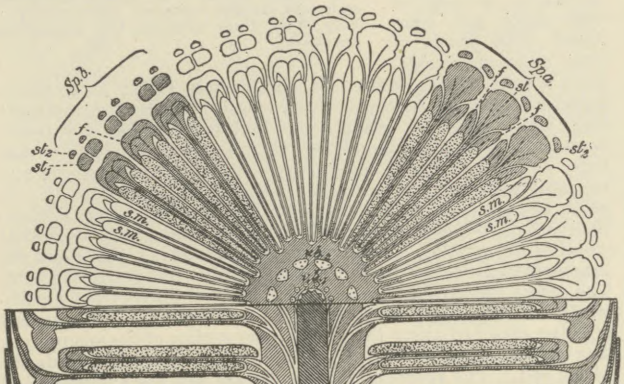

FIG. 7.—*Cheirostrobus.* Diagram of cone, the upper part in transverse, the lower in longitudinal section. In the transverse section six sporophylls, each showing three segments, are represented. *Sp.a*, section through sterile segments; *Sp.b*, section through sporangiophores; *st*, laminæ of sterile segments; *f*, peltate expansions of sporangiophores; *sm*, sporangia; *v.b*, vascular bundles; *cy*, stele of axis (*Ax*). In the longitudinal section the corresponding parts are shown. (Scott, "*Studies.*")

slender proportions of the segments give the cone a peculiar character, but the relations of position appear to leave no doubt as to the homologies with the fructification of Sphenophylleæ; as regards the sporangiophores, *Bowmanites Römeri* occupies exactly the middle place between *S. Dawsoni* and *Cheirostrobus*. The axis of the cone in *Cheirostrobus* contains a dodecarch stele, with solid wood, from the angles of which vascular bundles pass out, dividing in the cortex, to supply the various segments of the sporophylls. In the peduncle of the strobilus secondary tissues are formed. While the anatomy has a somewhat Lycopodiaceous character, the arrangement of the appendages is altogether that of the Sphenophylleæ; at the same time Calamarian affinities are indicated by the characters of the sporangiophores and sporangia.

The Sphenophyllales as a whole are best regarded as a synthetic group, combining the characters of the Lycopods and Equisetales, while showing marked peculiarities of their own. Among existing plants their nearest affinities would appear to be with the Psiloteæ, as indicated not merely by the anatomy, but much more strongly by the way in which the sporangia are borne. There is good reason to believe that the ventral synangium of the Psiloteæ corresponds to the ventral sporangiophore with its sporangia in the Sphenophyllales. Professor Thomas of New Zealand has brought forward some interesting variations in *Tmesipteris* which appear to afford additional support to this view.

III. *Lycopodiales.*—In Palæozoic ages the Lycopods formed one of the dominant groups of plants, remarkable alike for the number of species and for the great stature which many of them attained. The best known of the Palæozoic Lycopods were trees, reaching 100 feet or more in height, but side by side with these gigantic representatives of the class, small herbaceous Club-mosses, resembling those of the present day, also occurred. Broadly speaking, the Palæozoic Lycopods, whatever their dimensions, show a general agreement in habit and structure with our living forms, though often attaining a much higher grade of organization. We will first take the arborescent Lycopods, as in every respect the more important group. They may all be classed under the one family Lepidodendreæ, which is here taken to include *Sigillaria*.

Lepidodendreæ.—The genus *Lepidodendron*, with very numerous species, ranging from the Devonian to the Permian, consisted of trees, with a tall upright shaft, bearing a dense crown of dichotomous branches, clothed with simple narrow leaves, ranged in some complex spiral phyllotaxis. In some cases the foliage is preserved *in situ;* more often, however, especially in the main stem and larger branches, the leaves had been shed, leaving behind them their scars and persistent bases, on which the characteristic sculpturing of the Lepidodendroid surface depends. The cones, often of large size, were either terminal on certain of the smaller twigs, or borne laterally on special branches of considerable dimensions. In the latter case the cones have left peculiar marks on the fertile branches, for which special genera have been founded. At its base the main stem terminated in dichotomous roots or rhizophores, bearing numerous rootlets. To these underground organs the name *Stigmaria* is applied; they are not clearly distinguishable from the corresponding parts of *Sigillaria*. The numerous described species of *Lepidodendron* are founded on the peculiarities of the leaf-cushions and scars, as shown on casts or impressions of the stem. The usually crowded leaf-cushions are spirally arranged, and present no obvious orthostichies, thus differing from those of *Sigillaria*. Each leaf-cushion is slightly prominent; towards its upper end is the diamond-shaped or triangular scar left by the fall of the actual leaf (Fig. 8). On the scar are three prints, the central one alone representing the vascular bundle, while the lateral prints (*parichnos*) mark the position of merely parenchymatous strands. In the median line, immediately above the leaf-scar, is a print representing the ligule, or rather the pit in which it was seated. On the flanks of the cushion, below the scar, are two superficial prints, perhaps comparable to lenticels. In the genus *Lepidophloios* the leaf-cushions are more prominent than in *Lepidodendron*, and their greatest diameter is in the transverse direction; on the older stems the leaf-scar lies towards the lower side of the cushion. The genus *Bothrodendron*, going back to the Upper Devonian, differs from *Lepidodendron* in its minute leaf-scars and the absence of leaf-cushions, the scars being flush with the smooth surface of the stem. In the Lower Carboniferous of central Russia beds of coal occur consisting of the cuticles of a *Bothrodendron*, which are not fossilized, but retain the consistency and chemical composition of similar tissues in recent plants.

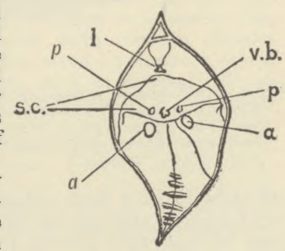

FIG. 8.—Leaf-base of a *Lepidodendron*. *s.c.*, scar left by the leaf; *v.b.*, print of vascular bundle; *p, p*, parichnos; *l*, ligule; *a, a*, superficial prints below scar. (*After Stur.*) (Scott, "*Studies.*")

The **anatomy** of *Lepidodendron* is now well known in a number of species; the Carboniferous rocks of Great Britain are especially rich in petrified specimens, which formed the subject of Williamson's extensive investigations. The stem is in all cases monostelic; in most of the forms the central cylinder underwent secondary growth, and the distinction between primary and secondary wood is very sharply marked. In *L. Harcourtii*, however, the species earliest investigated (by Witham, 1833, and

Brongniart, 1837), no secondary wood has yet been found. The primary wood of *Lepidodendron* forms a continuous cylinder, not broken up into distinct bundles; its development was clearly centripetal, the spiral elements forming more or less prominent peripheral groups. In the larger stems of most species there was a central pith, but in certain of the smaller branches, and throughout the stem in some species (*L. rhodumnense, L. selaginoides*), the wood was solid. A single leaf-trace, usually collateral in structure, passed out into each leaf. The primary structure of the stem was thus of a simple Lycopodiaceous type, resembling on a larger scale what we find in the upright stem of *Selaginella spinosa*. In most species (*e.g., L. selaginoides, L. wunschianum, L. veltheimianum*) secondary growth in thickness took place, and secondary wood was added, in the centrifugal direction, showing a regular radial arrangement, with medullary rays between the series of tracheides (Fig. 9). The tissue thus formed often attained a considerable thickness. While primary phloem can be recognized with certainty in favourable cases, the question of the formation of secondary phloem by the cambium is not yet fully cleared up. In the *Lepidodendron fuliginosum* of Williamson, shown by its

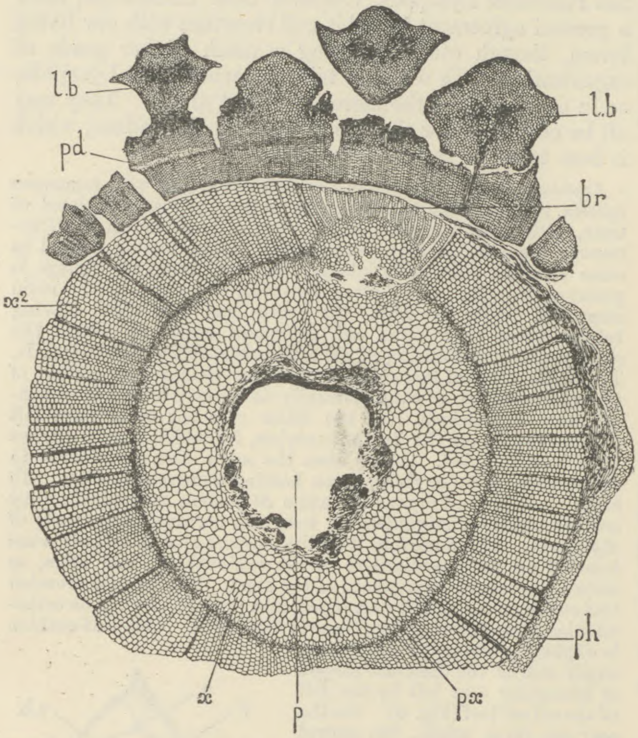

FIG. 9.—*Lepidodendron veltheimianum.* Transverse section of stem. *p*, pith, almost destroyed; *x*, zone of primary wood; *px*, protoxylem; x^2, secondary wood; *ph*, phloem and pericycle; *br*, stele of a branch; *pd*, periderm; *l.b*, leaf-bases. The primary cortex between stele and periderm has perished. ×4½. (*Scott*, "*Studies.*")

leaf-bases to have been a *Lepidophloios*, the secondary wood is very irregular, and consists largely of parenchyma. The occurrence of secondary growth in these plants, demonstrated by Williamson's researches, is a point of great interest. Some analogy among recent Lycopods is afforded by the stem of *Isoëtes*, and by the base of the stem in *Selaginella spinosa;* in the fossils the process was of a more normal type, but some of its details need further investigation. The cortex, often sharply differentiated into sclerotic and parenchymatous zones, is bordered externally by the persistent leaf-bases. The development of periderm was a constant feature, and this tissue attained a great thickness, consisting chiefly of a phelloderm, produced on the inner side of the formative layer.

The most interesting point in the structure of the leaf-base is the presence of a ligule, like that of *Isoëtes* or *Selaginella*, which was seated in a deep pit, opening on the upper surface of the cushion, just above the insertion of the lamina. The latter shows marked xerophytic adaptations; the single vascular bundle was surrounded by a sheath of short tracheides, and the stomata were sheltered in two deep furrows of the lower surface.

The cones of *Lepidodendron* and its immediate allies are for the most part grouped under the name *Lepidostrobus.* These cones, varying from an inch to a foot in length, according to the species, were borne either on the ordinary twigs, or on the special branches (*Ulodendron* and *Halonia*) above referred to. In Ulodendron the large circular, distichously arranged prints appear to have been formed by the pressure of the bases of sessile cones, while in the Halonial branches characteristic of the genus *Lepidophloios* the tubercles mark the points of insertion of pedunculate strobili. The organization of *Lepidostrobus* is essentially that of a Lycopodiaceous cone. The axis, which in anatomical structure resembles a vegetative twig, bears numerous spirally arranged sporophylls, each of which carries a single large sporangium on its upper surface (Fig. 10). The sporophyll, usually almost horizontal in position, has an upturned lamina beyond the sporangium, and a shorter dorsal lobe, so that the form of the whole is somewhat peltate. A ligule is present immediately below the lamina, its position showing that the whole of the elongated horizontal pedicel on which the sporangium is seated, corresponds to the short base of a vegetative leaf. The sporangia, usually of very large size compared with those of most recent Lycopods, have a palisade-like outer wall, and contain either an immense number of minute spores or a very small number of exceedingly large spores (Fig. 10). It is very doubtful whether any homosporous *Lepidostrobi* existed, but there is reason to believe that here, as in the closely allied *Lepidocarpon*, microsporangia and megasporangia were in some cases borne on different strobili. In other species (*e.g.,* in the cone attributed to the Lower Carboniferous *Lepidodendron veltheimianum*) the arrangement was that usual in *Selaginella*, the microsporangia occurring above and the megasporangia below in the same strobilus (diagram, Fig. 10).

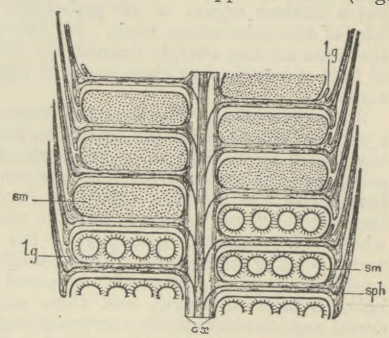

FIG. 10.—*Lepidostrobus.* Diagram of cone, in longitudinal section. *ax*, axis, bearing the sporophylls (*sph*), on each of which a sporangium (*sm*) is seated; *lg*, ligule. The upper sporangia contain numerous microspores; in each of the lower sporangia four megaspores are shown.

The genus *Spencerites* (Lower Coal Measures) differs from *Lepidostrobus* mainly in the insertion of the sporangium, which, instead of being attached along the whole upper surface of the sporophyll, was only connected with it by a small neck of tissue towards the distal end. The spores of this genus are curiously winged, and intermediate in size between the microspores and megaspores of *Lepidostrobus;* the question of homospory or heterospory is not yet decided. A more important deviation from ordinary Lepidostroboid structure is shown by the new genus *Lepidocarpon*, from the English Coal Measures and the Lower Carboniferous of Scotland. In this fructification the organization is at first altogether that of a *Lepidostrobus;* in each megasporangium, however, only a single megaspore came to maturity, occupying almost the whole of the sporangial cavity, but accompanied by the remains of its three abortive sister cells. An integument grew up from the superior surface of the sporophyll, completely enveloping the sporangium, except for a narrow crevice left open along the top. In favourable cases the prothallus is found preserved, within the functional megaspore or embryo-sac, and the whole appearance, especially as seen in a section tangential to the strobilus, is then remarkably seed-like (see diagram, Fig. 11). The seed-like body was detached as a whole from the cone, and in this condition has been known for many years under the name of *Cardiocarpon anomalum*, having been wrongly identified with a true Gymnospermous seed so named by Carruthers. The analogies with a seed are obvious; the chief difference is in the micropyle, which is not tubular, but forms a

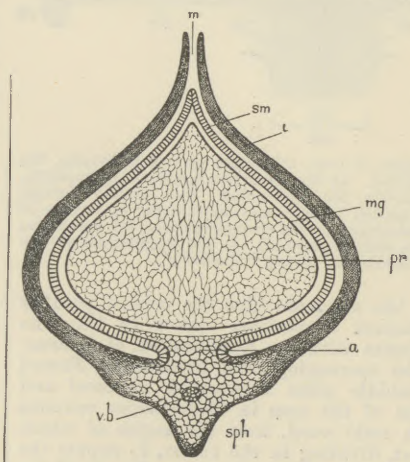

FIG. 11.—*Lepidocarpon Lomaxi.* Diagrammatic section of "seed" in plane tangential to the parent strobilus. *sph*, sporophyll; *vb*, its vascular bundle; *i*, integument; *m*, micropylar crevice; *a*, base, *sm*, wall of sporangium; *mg*, membrane of functional megaspore, which is filled by the prothallus, *pr*.

long crevice, running in a direction radial to the strobilus. *Lepidocarpon* affords a striking instance of homoplastic modification, for there is no reason to suppose that the Lycopods were on the line of descent of any existing Spermophyte. In a male cone, probably belonging to *Lepidocarpon Lomaxi*, the microsporangia are provided with incomplete integuments.

Sigillaria. — The great genus *Sigillaria*, even richer in "species" than *Lepidodendron*, ranges throughout the Carboniferous, but has not yet been detected in earlier rocks. The Sigillariæ, like the Lepidodendra, were large trees, but must have differed from those of the previous group in habit, for they appear to have branched sparingly or not at all, the lofty upright shaft terminating, like some modern *Xanthorrhœa*, in a great sheaf of long, grass-like leaves. The strobili were stalked, and borne on the main stem, among the leaves. The roots, or at least their functional representatives, resembled those of *Lepidodendron.* The chief distinctive character of *Sigillaria* lies in the arrangement of the leaf-scars, which form conspicuous vertical series on the surface of the stem. In one great division of the genus—the Eusigillariæ—the stems are ribbed, each rib bearing a vertical row of leaf-scars; the ribbed Sigillariæ were formerly divided into two sub-genera—*Rhytidolepis*, with the scars on each rib rather widely spaced, and *Favularia*, where they are approximated and separated by transverse furrows, each rib thus consisting of a series of contiguous leaf-bases. This distinction, however, has proved to have no constant taxonomic value, for both arrangements may occur on different parts of the same specimen. The species without ribs — Subsigillariæ — were in like manner grouped under the two sub-genera *Clathraria* and *Leiodermaria*; in the former each scar is seated on a prominent cushion, while in the latter the surface of the stem (as in *Bothrodendron*) is perfectly smooth. Here also the distinction has proved not to hold good, *S. Brardi*, for example, showing both conditions on the same stem. All these names, however, are still in use as descriptive terms. Generally, the Eusigillariæ are characteristic of the older Carboniferous strata, the Subsigillariæ of the Upper Coal Measures and Permian. The leaf-scars throughout the genus show essentially the same prints as in *Lepidodendron*, differing only in details, and here also a ligule was present (Fig. 12).

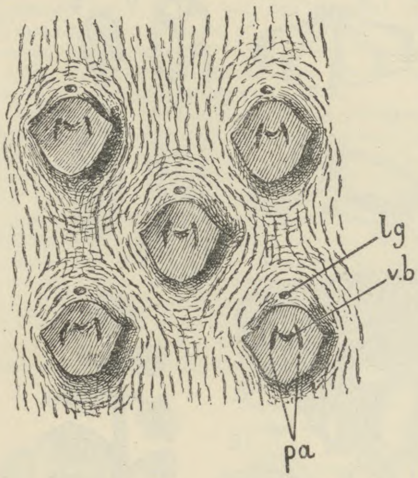

Fig. 12.—*Sigillaria Brardi.* Part of surface of stem, showing five leaf-scars. *vb*, print of vascular bundle; *pa*, parichnos; *lg*, ligule. $\times 1\frac{1}{2}$. (*After Weiss.*) (*Scott*, "*Studies.*")

The **anatomy** of *Sigillaria* is not so well known as that of *Lepidodendron*, for specimens showing structure are rare, a fact which may be correlated with the infrequency of branching in the genus. The structure of a Clathrarian *Sigillaria* (*S. Menardi*), from the Permian of Autun, was accurately described by Brongniart as long ago as 1839, and a similar species, *S. spinulosa* (= *S. Brardi*) was investigated by Renault in 1875, but it was long before we had any trustworthy data for the anatomy of the ribbed forms. This gap in our knowledge has now been partially filled up, owing especially to Bertrand's investigation of a specimen referred by him to *S. elongata*. The structure of the ribbed Sigillariæ, as at present known, essentially resembles that of a medullate *Lepidodendron*, though the ring of primary wood was narrower. Its outer margin was crenulated, the leaf-traces being given off from the middle of each bay. Secondary wood was formed in abundance, precisely as in most species of *Lepidodendron.* In the Subsigillarian species *S. Menardi* the primary wood is broken up into distinct bundles, while in *S. spinulosa* their separation is sometimes incomplete. The secondary cortex or periderm attained a great development, and in some cases shows considerable differentiation. On the whole, the anatomy of *Sigillaria* is closely related to that of the preceding group, and in fact a continuous series can be traced from the anatomically simplest species of *Lepidodendron* to the most modified *Sigillariæ.* The leaves of *Sigillaria* are practically identical in structure with those of *Lepidodendron.*

The nature of the **fructification** of *Sigillaria* was first satisfactorily determined in 1884 by Zeiller, who found the characteristic Sigillarian leaf-scars on the peduncles of certain large strobili (*Sigillariostrobus*). The cones, of which several species have been described, bear a strong general resemblance to *Lepidostrobus*, differing somewhat in the form of the sporophylls and some other details. The megaspores (reaching 2 mm. or more in diameter) were found lying loose on the sporophylls by Zeiller; the sporangia containing them were first observed by Kidston, in a species from the Coal Measures of Yorkshire. That the cones were heterosporous there can be no doubt, though little is known as yet of the microsporangia. The discovery of *Sigillariostrobus*, which was the fructification of Subsigillariæ as well as of the ribbed species, has finally determined the question of the affinities of the genus, once keenly discussed; *Sigillaria* is now clearly proved to have been a genus of heterosporous Lycopods, with the closest affinities to *Lepidodendron.*

Stigmaria.—On present evidence there is no satisfactory distinction to be drawn between the subterranean organs of *Sigillaria* and those of *Lepidodendron* and its immediate allies. These organs, still known by the name *Stigmaria* given them by Brongniart, have been found in connexion with the upright stems both of *Sigillaria* and *Lepidodendron.* In the Coal Measures they commonly occur in the underclay beneath the coal-seams. Complete specimens of the stumps show that from the base of the aërial stem four Stigmarian branches were given off, which took a horizontal or obliquely descending course, forking at least twice. These main Stigmarian axes may be 2 to 3 feet in diameter at the base, and 30 or 40 feet in length. Their surface is studded with the characteristic scars of their appendages or rootlets, which radiated in all directions into the mud. Petrified specimens of the main *Stigmaria* are frequent, and those of its rootlets extraordinarily abundant. The two parts are very different in structure: in the main axis, as shown in the common Coal Measure form *Stigmaria ficoides*, the centre was occupied by the pith, which was surrounded by a zone of wood, centrifugally developed throughout. In other species, however, the centripetal primary xylem is represented. Phloem, surrounding the wood, is recognizable in good specimens; in the cortex the main feature is the great development of periderm. The rootlets, which branched by dichotomy, contain a slender monarch stele exactly like that in the roots of *Isoëtes* and some *Selaginellæ* at the present day. The morphology of *Stigmaria* has been much discussed; possibly the main axes, which do not agree perfectly either with rhizomes or roots, may best be regarded as comparable with the rhizophores of *Selaginella;* the homologies of the appendages with the roots of recent Lycopods appear manifest. It has been maintained by some palæobotanists that the aërial stems of *Sigillaria* arose as buds on a creeping rhizome, but the evidence for this conclusion is as yet unconvincing.

Lycopoditeæ.—Under the name *Lycopoditeæ* are included those Palæozoic Lycopods—for the most part referred to the provisional genus *Lycopodites*—which from their habit appear to have been herbaceous plants; such specimens occur occasionally from the Devonian onwards. While some have uniform spirally arranged leaves, like most species of the recent *Lycopodium*, others have tetrastichous, dimorphic foliage, such as is usually found in *Selaginella*, though it must be remembered that a similar arrangement exists in certain species of *Lycopodium.* In some cases the sporangia of *Lycopodites* have been recognized, borne either on special sporophylls forming definite strobili (*e.g.*, *L. Stockii*), or on ordinary leaves (*e.g.*, *L. ciliatus*), as in the recent *Lycopodium Selago.* A form described by Zeiller, from the French Upper Coal Measures, closely resembles *Selaginella*, both in the foliage and the arrangement of the sporangia. The megaspores were, however, more numerous in each sporangium than in the recent genus. *Miadesmia*, English Lower Coal Measures, discovered by Bertrand, is the only member of the Lycopoditeæ so far found with structure preserved. In the presence of a ligule and other points there is here also an approach to the organization of *Selaginella.* Some evidence has been adduced for the heterospory of *Miadesmia;* the megasporangia attributed to it appear to present some analogies with those of *Lepidocarpon.* Although our knowledge of the Lycopoditeæ is very imperfect, their existence in Palæozoic times makes it probable that the recent genera *Lycopodium* and *Selaginella* may have been derived from forms which have always been herbaceous, rather than by reduction from the arborescent Lepidodendreæ. There is, however, some evidence that *Isoëtes*, which in several points agrees most nearly with the latter group, may actually represent its last degenerate survivors. (See *Pleuromeia*, in section II., Mesozoic.)

IV. *Filicales.*—Of all Vascular Cryptogams, the Ferns have best maintained their position down to the present day. The class was well represented in the Palæozoic period, when, indeed, it was relatively, and perhaps absolutely, far richer in species even than in the recent Flora. The great majority of specimens of fossil Ferns are preserved in the form of carbonaceous impressions of fronds, often of remarkable perfection and beauty. The characters shown by such specimens, however, when, as is usually the case, they are in the barren state, are notoriously unstable, or of small taxonomic value, among recent Ferns. Hence palæobotanists have found it necessary to adopt a purely artificial system of classification, based on form and venation of the frond, in the absence of adequate data for a more natural grouping. The well-known form-genera *Pecopteris*, *Sphenopteris*, *Odontopteris*, &c., are of this provisional nature. In the meantime, however, a number of Palæozoic fern-fructifications have been brought to light, often in connexion with the fronds that bore them, and such discoveries, aided in some cases by the observation of anatomical characters in the petrified specimens, have afforded the basis for a more natural arrangement, though as yet this is very incomplete. In habit the Palæozoic Ferns show as great variety as their recent allies: most, no doubt, were herbaceous plants, with a creeping or upright rhizome; some were climbers, using larger plants as supports; while many were tree-ferns, often of large size, and resembling the tree-ferns of the present day, though, as we shall see, of very different affinities. In the great majority the fronds were compound, perfectly comparable to the typical fern-fronds of to-day; then, as now, a certain number of simple-leaved forms were present. In one respect the fronds of many Palæozoic Ferns were peculiar, namely, in the presence in their rachis, and at the base of their pinnæ, of anomalous leaflets, often totally different in form and venation from the ordinary pinnules. These curious appendages (*Aphlebiæ*), at first regarded as parasitic growths, have been compared with the feathery outgrowths which occur on the rachis in the Cyatheaceous genus *Hemitelia*, and with the anomalous pinnules found in certain species of *Gleichenia*, at the points of bifurcation of the frond.

Marattiaceæ.—A large number of the Palæozoic Filices show indications—more or less decisive—of Marattiaceous affinities; some account of this group will first be given. The reference of these Ferns to the family Marattiaceæ, so restricted in the recent Flora, rests, of course, primarily on evidence drawn from the fructifications. Typically Marattiaceous sori, consisting of exannulate sporangia united to form synangia, are frequent, and are almost always found on fronds with the character of *Pecopteris*, large, repeatedly pinnate leaves, resembling those of Cyatheaceæ or some species of *Nephrodium*. In certain cases the anatomical structure of these leaves is known, and found to agree generally with that of recent coriaceous fern-fronds. The petiole was usually traversed by a single vascular bundle, hippocrepiform in section—a marked point of difference from the more complex petioles of recent Marattiaceæ. There is evidence that in most cases these Pecopteroid fronds belonged to tree-ferns, the stems on which they were borne reaching a height of as much as 60 feet. These stems, known as *Megaphytum* when the leaves were in two rows, and as *Caulopteris* in the case of polystichous arrangement, are frequent, especially in the Permian of the Continent; when petrified, so that their internal structure is preserved, the name *Psaronius* is employed. Their structure is a complex one, the central region containing an elaborate system of numerous anastomosing steles, accompanied by sclerenchyma; the cortex is permeated or coated by a multitude of adventitious roots, forming a thick envelope to the stem. The whole structure bears a general resemblance to that of recent Marattiaceæ, though differing in detail. We will now describe some of the fructifications, which are grouped under generic names of their own; these genera, as having a more natural basis, tend to supersede the artificial groups founded on vegetative characters. The genus *Asterotheca* includes a number of Ferns, chiefly of Coal Measure age, with fronds of the *Pecopteris* type. The sori, or synangia, ranged in two series on the under-side of the fertile pinnules, are circular, each consisting of 3 to 6 sporangia, attached to a central receptacle and partly united to each other (Fig. 13, A); the sporangia separated when mature, dehiscing by a ventral slit. Stur's genus *Hawlea* (Fig. 13, H), characterized by the separation of the sporangia, may only represent an advanced stage of an *Asterotheca*. In *Ptychocarpus* the fusion of the sporangia to form the syrangium was much more complete; *Scolecopteris* resembles *Asterotheca*, but each synangium is stalked. In all these genera there is an obvious similarity to the synangia of *Kaulfussia*, while in some respects *Marattia* or *Danæa* is approached. In another Pecopteroid genus, *Sturiella*, the synangia resemble those of *Asterotheca*, but each sporangium is provided with a band of enlarged cells of the nature of an annulus (Fig. 13, D). As a similar differentiation, though less marked, appears in the recent genus *Angiopteris*, the presumption is in favour of the Marattiaceous affinities of *Sturiella*. In the genus *Danæites*, from the Coal Measures of the Saar, the synangia are much like those of the recent *Danæa*, each sporangium opening by an apical pore. In the *Grand' Eurya* of Stur the sporangia appear to have been free from each other, as in *Angiopteris*. On the whole there is thus abundant evidence for the frequency of Marattiaceæ in the Palæozoic period, and there can be no doubt that this group of Eusporangiate Ferns was far more prominent then than in any later flora. In a certain number of genera the reference to Marattiaceæ is much more doubtful. In

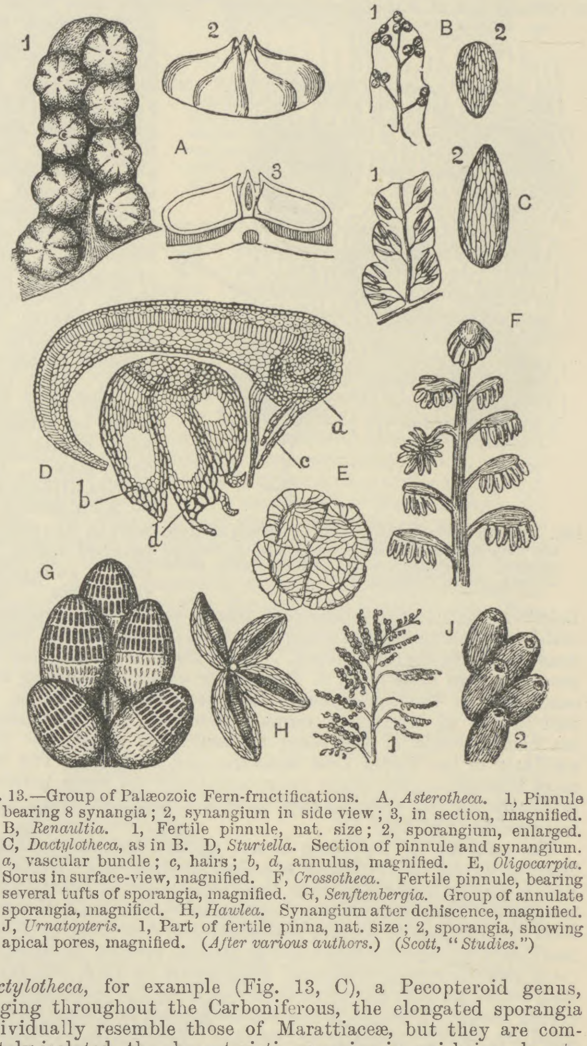

FIG. 13.—Group of Palæozoic Fern-fructifications. A, *Asterotheca*. 1, Pinnule bearing 8 synangia; 2, synangium in side view; 3, in section, magnified. J, *Urnatopteris*. 1, Part of fertile pinna, nat. size; 2, sporangia, showing apical pores, magnified. (*After various authors.*) (*Scott, "Studies."*)

Dactylotheca, for example (Fig. 13, C), a Pecopteroid genus, ranging throughout the Carboniferous, the elongated sporangia individually resemble those of Marattiaceæ, but they are completely isolated, the characteristic grouping in sori being absent; the same remark applies to the Sphenopteroid Fern *Renaultia* of Zeiller (Fig. 13, B); the foliage of *Sphenopteris*, one of the most extensive of Palæozoic frond-genera, with many different types of fructification, resembled that of various species of *Asplenium* or *Davallia*. In many Ferns of this period the fronds were dimorphic, the fertile leaves or pinnæ having a form quite different from that of the vegetative portions. This was the case in *Urnatopteris* (Kidston), with Sphenopteroid sterile foliage; the sporangia, borne on the filiform pinnules of the fertile rachis, appear to have dehisced by an apical pore (Fig. 13, J) suggesting Marattiaceous analogies. Another curious dimorphic genus is *Crossotheca*, Zeiller (Fig. 13, F), with the sterile fronds either of *Pecopteris* or *Sphenopteris*, according to the species; the sporangia, according to Zeiller's interpretation, hung down from the edges of the fertile pinnules. Here we have no clue to the affinities. The magnificent Devonian Fern *Palæopteris hibernica*, with a somewhat Adiantiform habit, bore specially fertile pinnæ; the fructification is still imperfectly understood, but the presence of stipules, observed by Kidston, has been adduced in support of Marattiaceous affinities.

Other Families.—The Marattiaceæ are the only recent family of Ferns which can be said to have existed in anything like its present form in Palæozoic times. Of other recent orders the indications are meagre and dubious, and there can be no doubt that a large proportion of Ferns from the older rocks belonged to families quite distinct from any which we recognize in the Flora of our own day. Little or nothing is known of Palæozoic Ophioglossaceæ; a species of the genus *Rhacopteris*, from the Lower Carboniferous, which had somewhat the habit, though not the morphology, of a *Botrychium*, has been referred to this family on insufficient grounds, and other indications are also doubtful. Certain fructifications have been referred to Gleicheniaceæ (*Oligocarpia*, Fig. 13, E), Schizæaceæ (*Senftenbergia*, Fig. 13, G), Hymenophyllaceæ, and Osmundaceæ, and on good grounds, so far as the external characters of the sporangia are concerned; our knowledge of the Ferns in question is, however, far too incomplete to justify us in asserting that they actually belonged to the families indicated. Numerous more or less isolated fern-sporangia occur in the petrified material of the Carboniferous formation; the presence of an annulus is a frequent character among these specimens, while synangic sori are rare; it is thus certain that families remote from the Marattiaceæ were abundantly represented during this period.

Botryopterideæ.—The family *Botryopterideæ*, first discovered by Renault, stands out with striking clearness among the Palæozoic Ferns, and differs widely from any group now in existence. The *Botryopterideæ* are chiefly known from petrified specimens; in the two genera *Botryopteris* and *Zygopteris* we have a fairly complete knowledge of all parts of the plant. The type-genus *Botryopteris*, represented both in the Permo-Carboniferous of France and in the Coal Measures of Great Britain, had a rhizome, with a very simple monostelic structure, bearing spirally-arranged compound leaves, with lobed pinnules, probably of a somewhat fleshy texture. In the French species, *B. forensis*, the plant was covered with characteristic jointed hairs, which have served to identify the various organs on which they occur. The sporangia were large pyriform sacs, shortly stalked, and borne in tufts on the branches of the fertile rachis, which developed no lamina. Each sporangium had, on one side only, a longitudinal or slightly oblique annulus, several cells in width; the numerous spores were all of the same size; certain differences among them, which have been interpreted as indicating heterospory, have now proved to depend merely on the state of preservation. The genus *Zygopteris*, of which several Carboniferous and Permian species are known, likewise had a monostelic stem, but the structure of its vascular cylinder was somewhat complex, resembling that of the most highly differentiated Hymenophyllaceæ, with which *Zygopteris* also agreed in the presence of axillary shoots. There is evidence that the stem in some species was a climbing one; the pinnate leaves, arranged on the stem in a two-fifths spiral, were dimorphic, the sterile fronds resembling some forms of *Sphenopteris*. On the fertile rachis the sporangia were borne in tufts, much as in the preceding genus; they were still larger, reaching 2·5 mm. in length, and had a multiseriate annulus, extending, however, to both sides of the sporangium (see Fig. 14, A and B). The genus *Corynepteris* of Baily is interesting from the fact that its sporangia, while individually similar to those of *Zygopteris*, were grouped in sori or synangia, resembling those of an *Asterotheca*. The family Botryopterideæ appears to have included a number of other genera, though in most cases the evidence from vegetative structure is alone available. The genus *Diplolabis* of Renault, probably identical with the *Asterochlæna* of Corda, and showing much in common with *Zygopteris* as regards anatomical structure, resembles *Corynepteris* in possessing a synangic fructification. The family as a whole is of great interest, as presenting points of contact with various recent orders, especially Hymenophyllaceæ, Osmundaceæ, and Ophioglossaceæ; the group appears to have been a synthetic one, from which several lines of descent may have sprung.

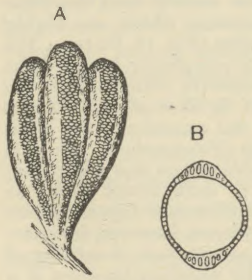

FIG. 14.—*Zygopteris pinnata.* A, Group of sporangia, in surface view. B, Single sporangium, in transverse section, showing annulus on both sides, magnified. (*After Renault.*)

A number of genera of Palæozoic fern-fronds have been described, of the fructification of which nothing is known. This is the case, for example, with *Diplotmema*, a genus only differing from *Sphenopteris* in the dichotomy of the primary pinnæ, and with *Mariopteris*, which bears a similar relation to *Pecopteris*. The same holds good of the Pecopteroid Ferns included under *Callipteris* and *Callipteridium*. In many such cases the apparent absence of fructification may be probably explained by dimorphism, the fertile fronds or pinnæ not having been as yet brought into relation with the sterile foliage. Several examples of fern-like fronds will be best considered under the heading Cycadofilices, for there is reason to believe that they belonged to plants which were in some respects intermediate between Ferns and Gymnosperms.

A natural classification of the Palæozoic Ferns will only be attainable when our knowledge of their reproduction and structural characters has become much more complete than it is at present. The great relative importance, in early periods, of eusporangiate Ferns of the Marattiaceous type is one of the most striking results hitherto arrived at. The Botryopterideæ also stand out definitely as a group now wholly extinct, but possibly having genetic relations with certain existing families. There are some indications that Ferns approaching the recent Schizaeaceæ, Osmundaceæ, and Hymenophyllaceæ may have already existed in Palæozoic times, while Cyatheaceæ and Polypodiaceæ, so predominant in the recent Flora, appear, on present evidence, to have been wholly unrepresented.

Cycadofilices.—A considerable number of Palæozoic genera are now known which in habit were more or less completely fern-like, while in their anatomical structure they combined the characters of Ferns with those of Gymnosperms. To this group the convenient name Cycadofilices has been given by Potonié. In some of the plants in question the fern-characters still predominate, in others the balance inclines to the Gymnospermous side. Unfortunately we have as yet no satisfactory knowledge of the fructification of any member of the group; the evidence at present before us is, however, sufficient to show that in the Palæozoic period a class of plants existed which, to judge by their known characters, held a position intermediate between Ferns and Gymnosperms, having a special affinity with the Cycadales and with the extinct family Cordaiteæ. A number of the most familiar fossil "fern fronds" have proved to belong to this transitional group, in which several families have been distinguished; the Lyginodendreæ are perhaps the most interesting from an evolutionary point of view.

Lyginodendreæ.—Of the genus *Heterangium*, which still stands very near the true Ferns, several species are known, the oldest being *H. Grievii*, of Williamson, from the Lower Carboniferous of Scotland. This plant had a long, somewhat slender ridged stem, the ridges corresponding to the decurrent bases of the spirally arranged leaves (Fig. 15). The specimens on which the genus was founded are petrified, showing structure rather than habit, but conclusive evidence has now been obtained that the foliage of *H. Grievii* was of the type of *Sphenopteris* (*Diplotmema*) *elegans* (Fig. 16), and was thus in appearance altogether that of a Fern, with somewhat the habit of an *Asplenium*. The stem has a single stele, resembling in general primary structure that of one of the simpler species of *Gleichenia*; there is no pith, the wood extending to the centre of the stele. The leaf-traces, where they traverse the cortex, have the structure of the foliar bundles in Cycads, for they are of the collateral type, and their xylem is mesarch, the spiral elements lying in the interior of the ligneous strand. The leaf-traces can be distinguished as distinct strands at the periphery of the stele, as shown in Fig. 17. Most of the specimens have formed a zone of secondary wood and phloem resembling the corresponding tissues in a recent Cycad; the similarity extended to minute histological details, as is shown especially in *H. tiliæoides*, a Coal Measures species, where the preservation is remarkably perfect. The cortex was strongly constructed mechanically; in addition to the strands of fibres at the periphery, horizontal plates of stone-cells were present in the inner cortex, giving both stem and petiole a transversely striated appearance, which has served to identify the different parts of the plant, even in the carbonized condition (cf. Figs. 15 and 16). The single vascular bundle which traversed the petiole and its branches was concentric, the leaves resembling those of Ferns in structure as well as in habit. *Heterangium* shows, on the whole, a decided preponderance of Filicinean characters, though in the leaf-traces and the secondary tissues the Cycads are approached. In the Coal Measures genus *Megaloxylon*, of Seward, which in structure bears a general resemblance to *Heterangium*, the primary wood consists for the most part of short wide tracheides; probably, as the secondary tissues increased, it had become superfluous for conducting purposes, and was adapted rather for water-storage. In the genus *Lyginodendron*, of which *L. oldhamium*, from the Coal Measures, is the best-known species, the central wood has disappeared altogether and is replaced by pith; the primary wood is only represented in the leaf-trace strands, which form a ring of distinct collateral bundles around the pith; thus the "medullate-monostelic" structure characteristic of the higher plants was already attained. The individual bundles, however, have the same structure as in *Heterangium*, and agree exactly with the foliar bundles of Cycads. The secondary tissues, which are highly developed, are also of a Cycadean character (Fig. 18, Plate). The vegetative organs of the plant are very completely known; the foliage has proved to be that of a *Sphenopteris*, identical with the species long known under the name of *S. Höninghausi*. Apart from the important advance shown in the anatomy of the stem, *Lyginodendron* agrees structurally with *Heterangium*. There is reason to believe that *Lyginodendron oldhamium* was a climbing plant, comparable in some respects to such recent Ferns as *Davallia aculeata*. As regards the fructification of *Lyginodendron* there is still much uncertainty; the evidence, however, indicates that it was of the type known as *Calymmatotheca*, consisting of tufts of long capsules pendent from the ultimate branches of a naked rachis; unfortunately the microscopic structure of this fructification is not certainly known, and it has even been doubted whether the capsules were of the nature of sporangia or sporocarps. In spite of this serious gap in our knowledge, there can be no question that the genus *Lyginodendron*, while having much in common with true Ferns, shows anatomically an unmistakable approach to Cycadean structure.

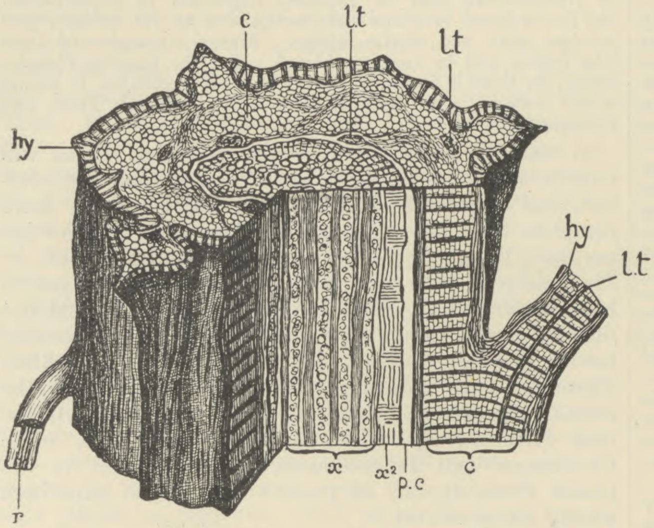

FIG. 15.—*Heterangium Grievii.* Restoration of stem, shown partly in transverse and longitudinal section, partly in surface view. *x*, primary, x^2, secondary wood; *p.c*, phloem and pericycle; *c*, cortex; *hy*, hypoderma; *l.t*, *l.t*, leaf-traces; *r*, adventitious root. The several leaf-bases are shown. (*After Williamson.*) (*Scott, "Studies."*)

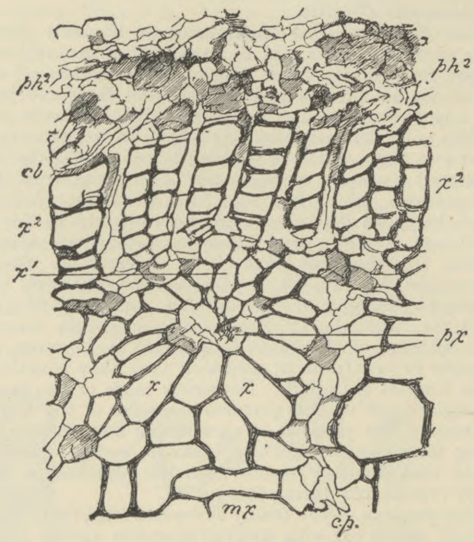

FIG. 17.—*Heterangium Grievii.* Part of the stele of the stem in transverse section, showing a primary xylem-strand and adjacent tissues. *px*, protoxylem of strand; *x*, centripetal, x^1, centrifugal primary wood; *mx*, part of the internal wood; *c.p*, conjunctive tissue; x^2, secondary wood; *cb*, cambium; ph^2, phloem. ×135. (*Scott, "Studies."*)

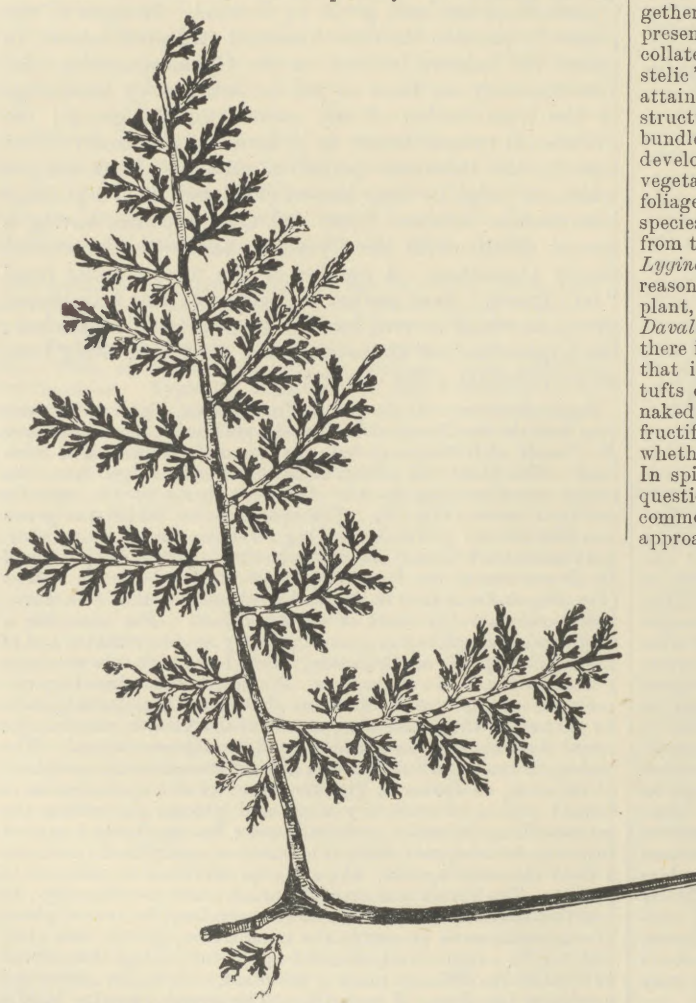

FIG. 16.—*Sphenopteris elegans* (foliage of *Heterangium Grievii*). Part of frond, ⅔ nat. size. (*After Stur.*) (*Scott, "Studies."*)

Cycadoxyleæ.—A few Coal Measures and Permian stems (*Cycadoxylon* and *Ptychoxylon*) resemble *Lyginodendron* in the general character of their tissues, but show a marked reduction of the primary wood, together with an extensive development of anomalous wood and bast around the pith, a peculiarity which appears as an individual variation in some specimens of *Lyginodendron oldhamium*. It is probable that these stems belonged to plants with the fructification and foliage of Cycads, taking that group in the widest sense. It is only quite at the close of the Palæozoic period that Cycads begin to appear. The *Lyginodendreæ* type of structure, however, appears to have formed the transition not only to the Cycadales, but also to the extinct family Cordaiteæ, the characteristic Palæozoic Gymnosperms (see p. 419).

Medulloseæ.—In some respects the most remarkable family of the Cycad-fern alliance is that of the Medulloseæ, plants often of great size, with a fern-like foliage, and a singularly complex anatomical structure without parallel among recent plants. Some of the Medulloseæ must have had a habit not unlike that of tree-ferns, with compound leaves of enormous dimensions, belonging to various frond-genera—especially, as has now been proved, to *Alethopteris* and *Neuropteris*; these are among the most abundant of the Carboniferous fronds commonly attributed to Ferns, and extend back to the Devonian. In habit some species of *Alethopteris* resembled the recent *Angiopteris*, while the *Neuropteris* foliage may be compared with that of an *Osmunda*. The *Medullosa* stems have been found chiefly in the Permo-Carboniferous of France and Germany, but a Coal Measures species (*M. anglica*) has been discovered in Lancashire. The great anatomical characteristic of the stem of the Medulloseæ is its polystelic structure with secondary development of wood and bast around each stele. In *M. anglica*, the simplest species known, the steles are uniform, and usually only three in number; the structure of the stem is essentially that of a polystelic *Heterangium*. In the Permo-Carboniferous species, such as *M. stellata* and *M. Leuckarti*, the arrangement is more complicated, the steles showing a differentiation into a central and a peripheral system; the secondary growth was extensive and unequal, usually attaining its maximum on the outer side of the peripheral steles. In certain cases the structure was further complicated by the appearance of extrafascicular zones exterior to the whole stelar system. The spirally arranged petioles (*Myeloxylon*) were of great size, and their decurrent bases clothed the surface of the stem; their structure is closely similar to that of recent Cycadean petioles; in fact, the leaves generally, like those of *Stangeria* at the present day, while fern-like in habit, were Cycadean in structure. In the case of *Medullosa anglica* we have an almost complete knowledge of the vegetative organs —stem, leaf, and root; Cycadean characters no doubt predominate, but the primary organization of the stem was that of a polystelic Fern. Some authors have been so much impressed by the similarity of this extinct family to the Cycads, that they have regarded them as being on the direct line of descent of the latter group; it is more probable, however, that they formed a short divergent phylum, distinct, though not remote, from the Cycadean stock. We have as yet no good evidence as to the fructification of the Medulloseæ; the fronds belonging to them scarcely ever show any trace of reproductive organs, and where any such indications have been detected, they are too obscure to be of any real assistance. There is, however, some indirect evidence for regarding it as not improbable that some of the isolated seeds found in the Carboniferous deposits may have belonged to members of this group.

The Cycadofilices, of which only a few examples have been mentioned, were probably very numerous during the Palæozoic period, though it is only in the comparatively rare cases where structure is preserved that the attribution is certain; in a large number of the so-called fern-fronds there is no evidence for Filicinean fructification, and it is probable that many of these belonged to this transitional or rather synthetic group, which may have been almost as extensive in early periods as that of the true Ferns.

Gymnosperms.

Gymnospermous remains are common in Palæozoic strata from the Devonian onwards. The investigations of the last quarter of the 19th century have established that these early representatives of the class did not, as a rule, belong to any of its existing families, but formed for the most part a distinct group, that of the Cordaiteæ, which has long since died out. Specimens of true Cycads or Conifers are rare or doubtful until we come to the latest Palæozoic rocks. Our present knowledge of the family Cordaiteæ is chiefly due to the two French investigators, Grand' Eury and Renault, who have successfully brought into connexion the various fragmentary remains, and made known their exact structure.

The discovery of the fossil trunks and of their rooted bases has shown that the Cordaiteæ were large trees, reaching 30 metres or more in height; the lofty shaft bore a dense crown of branches, clothed with long simple leaves, spirally arranged. Fig. 19, founded on one of Grand' Eury's restorations, gives an idea of the habit of a tree of the genus *Dorycordaites*, characterized by its lanceolate acute leaves; in the typical *Cordaites* they were of a blunter shape, while in *Poacordaites* they were narrow and grass-like. The leaves as a rule far exceeded in size those of any of the Coniferæ, attaining in some species a length of a metre. Of living genera, *Agathis* probably comes nearest to the extinct family in habit, though at a long interval. The stem resembled that of Cycads in having a large pith, sometimes as much as 4 inches in diameter; the wood, however, was dense, and had the structure of that of an Araucarian Conifer; specimens of the wood have accordingly been commonly referred to the genus *Araucarioxylon*, and at one time the idea prevailed that wood of this type indicated actual affinity with Araucarieæ. Other characters, however, prove that the Cordaiteæ were far remote from that family, and the name *Araucarioxylon* is best limited to wood from later horizons, where a near relationship to Araucarieæ is more probable.[1] In some cases the external tissues of the Cordaitean stem are well preserved; the cortex possessed a system of hypodermal strands of fibres, comparable to those found in the Lyginodendreæ. In some cases the leaf-traces passed out from the stem in pairs, as in the recent *Ginkgo*; in others the bundles of each trace were more numerous. In many Cordaiteæ the pith was *discoid*, *i.e.*, fistular, and partitioned by frequent diaphragms, as in some species of *Pinus* and other plants at the present day. The curious, transversely-ribbed fossils known as *Sternbergia* or *Artisia* have proved to be casts of the medullary cavity of Cordaiteæ; their true nature was first demonstrated by Williamson in 1850. In those stems which have been referred with certainty to the Cordaiteæ there is no centripetal wood; the spiral elements are adjacent to the pith, as in a recent Conifer or Cycad; certain stems, however, are known which connect this type of structure with that of the Lyginodendreæ; this, for example, is the case in the Permian genus *Poroxylon*, investigated by Bertrand and Renault, which in general structure has much in common with Cordaiteæ, but possesses strands of primary wood, mainly centripetal, at the boundary of the pith, as is the case in *Lyginodendron*. Corresponding strands of primary xylem have been observed in stems of the genus *Pitys* (Witham), of Lower Carboniferous age, which consisted of large trees, probably closely allied to *Cordaites*. There appears, in fact, so far as stem-structure is concerned, to have been no sharp break between the typical Palæozoic Gymnosperms and pronounced Cycadofilices such as *Lyginodendron*.

Fig. 19.—*Dorycordaites*. Restoration, showing roots, trunk, and branches bearing long lanceolate leaves and fructifications. The trunk is shown too short. (*After Grand' Eury, modified*.) (*Scott, "Studies."*)

The long, parallel-veined leaves of the Cordaiteæ, which were commonly referred to Monocotyledons before their structure or

[1] Endlicher's name *Dadoxylon* is conveniently used for Palæozoic specimens of the kind in question when nothing beyond the wood-structure is known.

connexion with other parts of the plant was known, have been shown by Renault to have essentially the same anatomy as a single leaflet of a Cycad such as *Zamia*. The vascular bundles, in particular, show precisely the characteristic collateral mesarch structure which is so constant in the recent family (see ANATOMY OF PLANTS). In fact, if the foliage alone were taken into account, the Cordaiteæ might be described as simple-leaved Cycads. The reproductive organs, however, show that the two groups were in reality very distinct. Both male and female inflorescences have frequently been found in connexion with leaf-bearing branches (see restoration, Fig. 19). The inflorescence is usually a spike bearing lateral flowers or catkins, arranged sometimes distichously, sometimes in a spiral order. The investigation of silicified specimens has, in the hands of Renault, yielded striking results. A longitudinal section of a male *Cordaianthus* (the name applied to isolated flowers) is shown in Fig. 20, A, Plate. The organ figured is one of the catkins (about a centimetre in length) which were borne laterally on the spike. Some of the stamens are inserted between the bracts, in an apparently axillary position, while others are grouped about the apex of the axis. Each stamen consists of a long filament, bearing several erect, cylindrical pollen-sacs at its summit (cf. Fig. 20, B, Plate). Some of the pollen-sacs had dehisced, while others still retained their pollen. The stamens are probably best compared with those of *Ginkgo*, but they have also been interpreted as corresponding to the male "flowers" of the Gnetaceæ. In any case the morphology of the male Cordaitean flower is clearly very remote from that of any of the Cycads or true Coniferæ. The female inflorescences vary considerably in organization; in some species the axis of the spike bears solitary ovules, each accompanied by a few bracts, while in others the lateral appendages are catkins, each containing from two to several ovules. In the catkin shown in longitudinal section in Fig. 21, A, it appears that each ovule was borne terminally, on an extremely short axillary shoot, as in *Taxus* among recent Gymnosperms. The ovule consists of an integument (regarded by some writers as double) enclosing the nucellus. In the upper part of the nucellus is a cavity or pollen-chamber, with a narrow canal leading into it, precisely as in the ovules of *Stangeria* or other Cycads at the present day (Fig. 21, B). Within the pollen-chamber, and in the canal, pollen-grains are found, agreeing with those in the anthers, but usually of larger size (Fig. 21, C). It was in this case that Renault first made the exceedingly interesting discovery that each pollen-grain contains a group of cells, presumably representing an antheridium (Fig. 21, C). Recent observations have completely confirmed Renault's interpretation of the facts, on which some doubt had been cast. In the isolated seeds of Cordaiteæ and allied Palæozoic Gymnosperms, pollen-grains are often found within the pollen-chamber, and the pluricellular structure of these pollen-grains has been repeatedly demonstrated. In the light of recent discoveries in *Ginkgo* and the Cycads there can scarcely be a doubt that spermatozoids were formed in the cells of the antheridium of the Cordaitean pollen-grain; the antheridium is much more developed than in any recent Gymnosperm, and it may be doubted whether any pollen-tube was formed. The morphology of the female inflorescence of Cordaiteæ has not yet been cleared up, but *Taxus* and *Ginkgo* among recent plants appear to offer the nearest analogies. Much further investigation will be needed before the homologies between Cordaitean flowers and the fructification of the higher Cryptogams can be established. Anatomically the connexion of the family with the Cycadofilices (and through them, presumably, with some primitive group of Ferns) seems clear, but we have as yet no indications of the stages in the evolution of their reproductive organs. The family Cordaiteæ extends back to the Devonian, and it must be borne in mind that our knowledge of their fructifications is practically limited to specimens from the latest Palæozoic horizons.

Isolated fossil seeds are common in the Carboniferous and Permian strata; in all cases they are of the orthotropous type, and resemble the seeds of Cycads or *Ginkgo* more nearly than those of any other living plants. Their internal structure is sometimes admirably preserved, so that the endosperm with its archegonia is clearly shown (Fig. 21, D). It is a curious fact that in no case has an embryo been found in any of these seeds; probably fertilization took place after they were shed, and was followed immediately by germination. There is good evidence that many of the seeds belonged to Cordaiteæ, especially those seeds which had a flattened form, such as *Cardiocarpus*, *Cycadinocarpus*, *Samaropsis*, &c. Seeds of this kind have been found in connexion with the *Cordaianthus* inflorescences; the winged seeds of *Samaropsis*, borne on long pedicels, are attributed by Grand' Eury to the genus *Dorycordaites*. Other forms of seed, and especially those which show radial symmetry, as for example *Trigonocarpon*, *Stephanospermum*, and *Lagenostoma*, are still of doubtful nature, and may have belonged, in part at least, to some of the plants grouped under Cycadofilices. The abundance and variety of Palæozoic seeds, so often of undetermined nature, indicate how much still remains to be done in the investigation of the Gymnosperms of that period.

The modern Gymnospermous orders have but few authentic representatives in Palæozoic rocks. The history of the Ginkgoales will be found in the Mesozoic section of this article, and in the article GYMNOSPERMS; their nearest Palæozoic representatives "were probably members of the Cordaitales, an extinct stock with which the Ginkgoaceæ are closely connected" (Seward). Remains referable to Cycadales, so extraordinarily abundant in the succeeding period, are scanty. The curious genus *Dolerophyllum* (Saporta) may be mentioned in this connexion. This genus, from the Permo-Carboniferous of Autun, is represented by large, fleshy, reniform leaves or leaflets, with radiating dichotomous venation; the vascular bundles have in all respects the structure of those in leaves of Cycads or Cordaiteæ. The male sporophylls are similar in form to the vegetative leaves, but

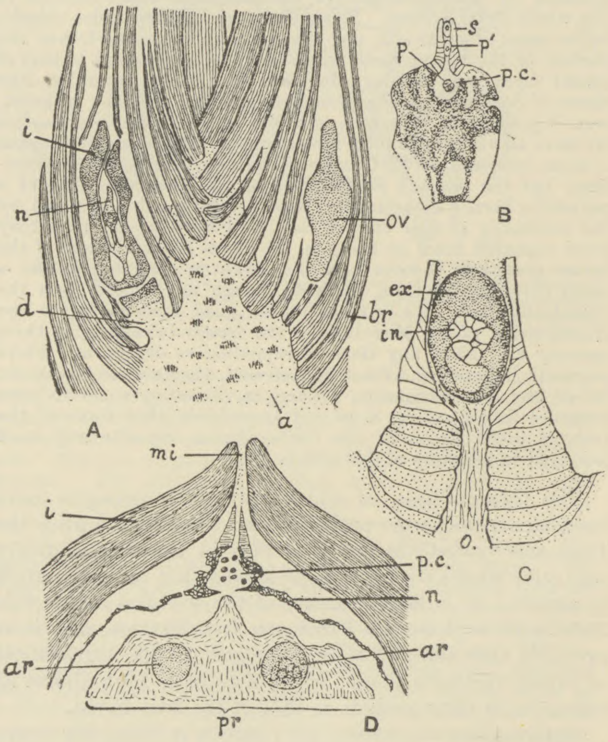

FIG. 21.—*Cordaianthus*. A, *C. Williamsoni*. Part of longitudinal section of ♀ catkin; *a*, axis, showiug v. bundles in tangential section; *br*, bracts; *d*, short axillary shoot, bearing a bracteole and a terminal ovule; *i*, integument; *n*, nucellus of ovule; *ov*, another ovule seen from the outside. × about 10. (*All after Renault.*)

smaller; sunk in their parenchyma are numerous tubular loculi, containing large pollen-grains, which are pluricellular like those of *Cordaites;* the female fructification is still unknown. The curious male sporophylls may perhaps be remotely comparable to those recently discovered in Mesozoic Cycadales of the group Bennettiteæ. Some leaves of Cycadean habit (*e.g.*, *Pterophyllum*, *Sphenozamites*) occur in the Coal Measures and Permian, and it is possible that the obscure Coal Measures genus *Noeggerathia* may have Cycadean affinities. An inflorescence from the Permian of Autun, named *Cycadospadix milleryensis* by Renault, appears to belong without doubt to this family.

Now that the numerous specimens of wood formerly referred to Coniferæ are known to have belonged to distinct orders, but few true Palæozoic Conifers remain to be considered. The most important are the upper Coal Measures or Permian genera *Walchia*, *Ullmannia*, and *Pagiophyllum*, all of which resembled certain Araucarieæ in habit. In the case of *Walchia* there is some evidence as to the fructifications, which in one species (*W. filiciformis*) appear to be comparable to female Araucarian cones. There are also some anatomical points of agreement with that family. It is probable, however, that under the same generic name very heterogeneous plants have been confounded. In the case of *Ullmannia* the anatomical structure of the leaf, investigated by Solms-Laubach, proves at any rate that the tree was Coniferous.

There is no proof of the existence of Gnetaceæ in Palæozoic times. The very remarkable plumose seeds described by Renault under the name *Gnetopsis* are of uncertain affinity.

Succession of Floras.

Our knowledge of vegetation older than the Carboniferous is still far too scanty for any satisfactory history of the Palæozoic Floras to be even attempted; a few, however, of the facts may be advantageously recapitulated in chronological order.

No recognizable plant-remains, if we except one or two doubtful Algal specimens, have so far been yielded by the Cambrian. From the Ordovician and Silurian, however, a certain number of authentic remains of Algæ (among many more that are questionable) have been investigated; they are for the most part either verticillate Siphoneæ, or the large—possibly Laminariaceous—Algæ named *Nematophycus*, with the problematical but perhaps allied *Pachytheca*. The evidence for terrestrial Silurian vegetation is still dubious; apart from some obscure North American specimens, the true nature of which is not established, Potonié has described well-characterized Pteridophytes (such as a Fern, *Sphenopteridium*, and *Bothrodendron* among Lycopods) from supposed Silurian strata in North Germany; the horizon, however, appears to be open to much doubt, and the specimens agree so nearly with some from the Lower Carboniferous as to render their Silurian age difficult of credence. The high development of the terrestrial flora in Devonian times shows, however, that land-plants must have existed far back in the Silurian ages, or still earlier. Even in the Lower Devonian, Ferns and Lepidodendreæ have been recognized; the Middle and Upper Devonian beds contain a flora in which all the chief groups of Carboniferous plants are already represented. Considering the comparative meagreness of the Devonian record, we can scarcely doubt that the vegetation of that period, if adequately known, would prove to have been practically as rich as that of the succeeding age. Among Devonian plants, Equisetales, including not only *Archæocalamites*, but forms referred to *Asterophyllites* and *Annularia*, occur; *Sphenophyllum* is known from Devonian strata in North America and Bear Island; Lycopods are represented by *Bothrodendron*, *Lepidodendron*, and the characteristic *Psilophyton*, as to the true nature of which, however, there is much doubt. Ferns such as Sphenopterideæ, *Palæopteris*, and *Adiantites*, with occasional arborescent Pecopterideæ, are frequent; other genera, *Alethopteris*, *Neuropteris*, and *Megalopteris*, more probably belonged, not to true Ferns, but to Cycadofilices; in the absence, as a rule, of any structural evidence, it is impossible to be certain of the true nature of many of the plants. The presence of Cordaitean leaves indicates that Gymnosperms of high organization already existed, a striking fact, showing the immense antiquity of this class compared with the angiospermous flowering plants. Any detailed account of the horizons of Carboniferous plants would carry us much too far. For our present purpose we may divide the formation into Lower Carboniferous, and Lower and Upper Coal Measures. In the Lower Carboniferous (Culm of Continental authors) many Devonian types survive—*e.g.*, *Archæocalamites*, *Bothrodendron*, *Palæopteris*, *Megalopteris*, &c. Among Ferns, *Diplotmema* and *Rhacopteris* are characteristic; some of the Lepidodendreæ appear to approach *Sigillariæ* in external characters. Sphenophylleæ are still rare; it is to this horizon that the isolated type *Cheirostrobus* belongs. Many specimens with structure preserved are known from the Lower Carboniferous, and among them Cycadofilices (*Heterangium*, *Calamopitys*, *Cladoxylon*, *Protopitys*) are well represented. Of Gymnosperms we have Cordaitean leaves, and the stems known as *Pitys*, which probably belonged to the same family.

The Lower Coal Measures (Westphalian) have an enormously rich flora, embracing most of the types referred to in our systematic description. *Calamarieæ* with the *Arthropitys* type of stem-structure abound, and Sphenophylleæ are now well represented. *Bothrodendron* still survives, but *Lepidodendron*, *Lepidophloios*, and the ribbed Sigillariæ are the characteristic Lycopods. The heterogeneous "Ferns" grouped under Sphenopterideæ are especially abundant. Marattiaceous Ferns are common, but arborescent stems of the *Psaronius* type are still comparatively rare. Numerous fronds such as *Alethopteris*, *Neuropteris*, and possibly *Mariopteris*, belonged, in part at least, to Cycadofilices, of which specimens showing structure are frequent in certain beds. *Cordaites*, *Dorycordaites*, and many stems of the *Dadoxylon* type represent Gymnosperms, of which the seeds begin to be common. The Upper Coal Measures (Stephanian) are characterized among the Calamarieæ, now more than ever abundant, by the prevalence of the Calamodendreæ; new species of *Sphenophyllum* make their appearance; among the Lycopods, *Lepidodendron* and its immediate allies diminish, and smooth-barked Sigillariæ are the characteristic representatives. Ferns are even more strongly represented than before, and this is the age in which Marattiaceous tree-ferns reached their maximum development. Among Cycadofilices it is the family Medulloseæ which is especially characteristic. Cordaiteæ still increase, and Gymnospermous seeds become extraordinarily abundant. In the Upper Coal Measures the first Cycadales and Coniferæ make their appearance. The Permian, so far at least as its lower beds are concerned, shows little change from the Stephanian; Conifers of the *Walchia* type are especially characteristic. The remarkable Permo-Carboniferous flora of India and the southern hemisphere is described in the next section of this article. During the earlier part of the Carboniferous epoch the vegetation of the world appears to have been remarkably uniform; while the deposition of the Coal Measures, however, was in progress, a differentiation of floral regions began. The sketch given above extends, for the later periods, to the vegetation of the northern hemisphere only.

II. MESOZOIC.

The period dealt with in this section does not strictly correspond with that which it is customary to include within the limits of the Mesozoic system. The Mesozoic era, as defined in geological text-books, includes the Triassic, Jurassic, and Cretaceous epochs; but from the point of view of the evolution of plants and the succession of floras, this division is not the most natural or most convenient. Our aim is not simply to give a summary of the most striking botanical features of the several floras that have left traces in the sedimentary rocks, but rather to attempt to follow the different phases in the development of the vegetation of the world, as expressed by the contrasts exhibited by a comparison of the vegetation of the Coal period forests with that of the succeeding Mesozoic era up to the close of the Wealden period.

Towards the close of the Palæozoic era, as represented by the Upper Carboniferous and Permian plant-bearing strata, the vegetation of the northern hemisphere, and that of several regions in the southern hemisphere, consisted of numerous types of Vascular Cryptogams, with some members of the Gymnospermæ, and several genera referred to the Cycadofilices (see section I. PALÆOZOIC). In the succeeding Permian period the vegetation retained for the most part the same general character; some of the Carboniferous genera died out, and a few new types made their appearance. The Upper Carboniferous and Permian plants may be grouped together as constituting a Permo-Carboniferous flora characterized by the predominance of Vascular Cryptogams. This flora had a wide distribution in North America, Europe, and parts of Asia; it extended to China and to the Zambezi region of tropical Africa (Map A, I. and II.).

Glossopteris flora.

On the other hand, the plant-beds of the Permo-Carboniferous age in South Africa, South America, India, and Australia demonstrate the existence of a widely-distributed vegetation which agrees in age with the Upper Carboniferous and Permian vegetation of the north, but differs from it to such an extent as to constitute a distinct flora. We must begin by briefly considering this southern Palæozoic province if we would trace the Mesozoic floras to their origin, and obtain a connected view of the vegetation of the globe as it existed in late Palæozoic times and at the beginning of the succeeding era.

In Australia, South America, and South Africa a few plants have been found which agree closely with Lower Carboniferous types of the northern hemisphere. In New South Wales, for example, we have such genera as *Rhacopteris* and *Lepidodendron* represented by species very similar to those recorded from Lower Carboniferous or Culm rocks in Germany, Austria, England, Spitzbergen, North and South America, and elsewhere. It is, in short, clear that the Culm flora, as we know it in the northern hemisphere, existed in the extreme south, and it is probable that during the earlier part of the Carboniferous period the vegetation of the world was uniform in character. We may possibly go a step farther, and assume that the climatic conditions under which the Culm plants of the Arctic regions flourished were not very different from those which prevailed in Europe, Asia, Chile, and South Australia. From strata in New South Wales overlying Devonian and Lower Carboniferous rocks certain plants were discovered in the early part of the 19th century which were compared with European Jurassic genera, and for several years it was believed that these plant-beds belonged to the Mesozoic period. These supposed Mesozoic plants include certain genera which are of special interest. Foremost among these is the genus *Glossopteris* (Fig. 1), founded by Brongniart in 1828 on specimens from India and Australia, a fern characterized by simple sub-lanceolate or tongue-shaped leaves, with a central midrib giving off lateral veins which repeatedly anastomose and form a network, like that in the leaves of *Anthrophyum*, an existing member of the Polypodiaceæ. The stems, long known from Australia and India as *Vertebraria*, have in recent years been proved to be the rhizomes of *Glossopteris*. Associated with *Glossopteris* occurs another fern, *Gangamopteris*, usually recognized by the absence of a well-marked midrib, though this character does not always afford a satisfactory distinguishing feature. An Equisetaceous plant, which Brongniart named *Phyllotheca* in 1828, is another member of the same flora; this type bears a close resemblance to *Equisetum* in the long internodes and the whorled leaves encircling the nodes, but differs in the looser leaf-sheaths and in the long spreading filiform leaf-segments, as also in the structure of the cones. *Phyllotheca* has been recognized in Europe in strata of Palæozoic age, and Professor Zeiller has discovered a new species—*P. Rallii*—in Upper Carboniferous rocks in Asia Minor (Map A, VII.), which points to a close agreement between this genus and the well-known Palæozoic *Annularia*. *Phyllotheca* occurs also in Jurassic rocks in Italy, and in Siberian strata originally described as Jurassic, but which Zeiller has shown are no doubt of Permian age. Some examples of this genus, described by Etheridge from Permo-Carboniferous beds in New South Wales, differ in some respects from the ordinary form, and bear a superficial resemblance to the Equisetaceous genus *Cingularia* from the Coal Measures of Germany. Other genera characteristic of this southern flora are mentioned later. The extraordinary abundance of *Glossopteris* in Permo-Carboniferous rocks of Australia, and in strata of the same age in India and South Africa, gave rise to the term "Glossopteris flora" for the assemblage of plants obtained from southern hemisphere rocks overlying beds containing Devonian and Lower Carboniferous fossils. The Glossopteris flora of Australia occurs in certain regions in association with deposits which are now recognized as true boulder-beds, formed during widespread glacial conditions. In India the same flora occurs in a thick series of fresh-water sediments, known as the Lower Gondwana system, including basal boulder-beds like those of Australia. Similar glacial deposits occur also in South America, and members of the Glossopteris flora have been discovered in Brazil and elsewhere. In South Africa, *Glossopteris, Gangamopteris*, and other genera, identical with those from Australia and India, are abundantly represented, and here again, as in India and South America, the plants are found in association with extensive deposits of undoubted glacial origin. To state the case in a few words, there is in South Africa, South America, Australia, and India an extensive series of sediments containing *Glossopteris, Gangamopteris*, and other genera, and including beds full of ice-scratched boulders. These strata are homotaxial with Permo-Carboniferous rocks in Europe and North America, as determined by the order of succession of the rocks, and by the occurrence of typical Palæozoic shells in associated marine deposits. The most important evidence on which this conclusion is based is afforded by the occurrence of European forms of Carboniferous shells in marine strata in New South Wales, which are intercalated between Coal Measures containing members of the Glossopteris flora, and by the discovery of similar shells, many of which are identical with the Australian species, in strata in the north-west of India and in Afghanistan, forming part of a thick series of marine beds known as the Salt Range group. This group of sediments in the extra-peninsular area of India includes a basal boulder-bed, referred on convincing evidence to the same geological horizon as the glacial deposits of the Indian peninsula (Talchir boulder-beds), South Africa (Ecca boulder-beds), Australia and Tasmania (Bacchus Marsh boulder-beds, &c.), and South America, which are associated with Glossopteris-bearing strata. We have a flora of wide distribution in South Africa, South America, Borneo, Australia, Tasmania, and India, which is clearly of Permo-Carboniferous age, but which differs in its composition from the flora of the same age in other parts of the world. This flora appears to have abruptly succeeded an older flora in Australia and elsewhere, which was precisely similar to that of Lower Carboniferous age in the northern hemisphere. The frequent occurrence of ice-formed deposits at the base of the beds in which *Glossopteris* and other genera make their appearance, almost necessitates the conclusion that the change in the character of the vegetation was connected with a lowering of temperature and the prevalence of glacial conditions over a wide area in India and the southern hemisphere. There can be little doubt that the Indian Lower Gondwana rocks, in which the boulder-beds and the Glossopteris flora occur, must be regarded as belonging to a vast continental area of which remnants are preserved in Australia, South Africa, and South America. This continental area has been described as "Gondwana Land," a tract of enormous extent occupying an area, part of which has since given place to a southern ocean, while detached masses persist as portions of more modern continents, which have enabled us to read in their fossil plants and ice-scratched boulders the records of a lost continent in which the Mesozoic vegetation of the northern hemisphere had its birth. Of the rocks of this southern continent those of the Indian Gondwana system are the richest in fossil plants; the most prominent types recorded from these Permo-Carboniferous strata are *Glossopteris, Gangamopteris*, species referred to *Sphenopteris, Pecopteris, Macrotæniopteris*, and other Ferns; *Schizoneura* (Fig. 2) and *Phyllotheca* among the Equisetales, *Nœggerathiopsis* and *Euryphyllum*, probably members of the Cordaitales (*q.v.* in section I. PALÆOZOIC); *Glossozamites* and *Pterophyllum* among the Cycadales, and various vegetative shoots recalling those of the coniferous genus *Völtzia*, a well-known Permian and Triassic plant of northern latitudes. There are no undoubted species of *Lepidodendron, Sigillaria, Stigmaria*, or *Calamites*—genera which played so great a share in the vegetation of the same age in the northern hemisphere.

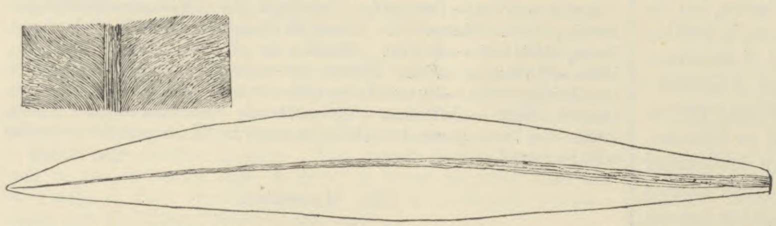

FIG 1.—*Glossopteris* frond, with portion enlarged to show the venation. (Natural size=36 cm. in length.) From Lower Gondwana rocks of India.

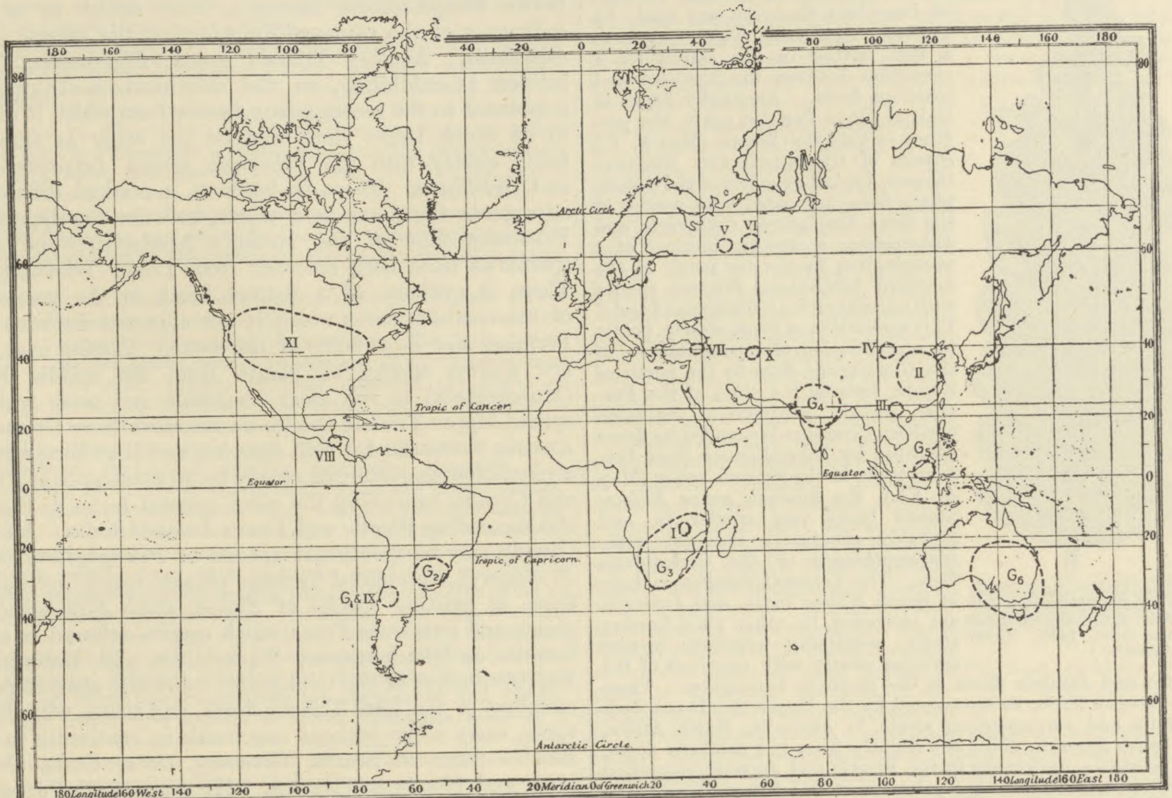
We may next inquire what types occur in the Glossopteris flora agreeing more or less closely with members of the rich Permo-Carboniferous vegetation of the north. The genus *Sphenophyllum*, abundant in the Coal Measures and Permian rocks of Europe and America, is represented by a single species recorded from India, *Sphenophyllum speciosum* (Fig. 3); *Annularia*, another common northern genus, is recorded from Australia, and the closely allied *Phyllotheca* constitutes another link between the two Permo-Carboniferous floras. The genus *Cordaites* may be compared with certain forms recorded from India, South America, South Africa, and Australia. While a few similar or even identical types may be recognized in both floras, there can be no doubt that, during



MAP A.—G_1–G_6, Glossopteris Flora. I, II. Upper Carboniferous plants of the northern hemisphere facies, in the Zambezi district and in China; III. Rhætic flora of Tongking (*Glossopteris*, &c.; associated with northern types); IV. Carboniferous plants (prov. Kansu); V. *Glossopteris*, &c., in Permian rocks in prov. Vologda; VI. Permian (Pechora valley); VII. Upper Carboniferous (Herakleion); VIII. Rhætic (Honduras); IX. Lower Jurassic, Upper Gondwana (Argentine); X. Rhætic (Persia); XI. Triassic—Cretaceous.

a considerable period subsequent to that represented by the Lower Carboniferous or Culm rocks, there existed two distinct floras, one of which had its headquarters in the northern hemisphere, while the other flourished in a vast continental area in the south. Recent discoveries have shown that representatives of the two floras coexisted in certain regions; there was, in fact, a dovetailing between the northern and southern botanical provinces. In 1895 Professor Zeiller described several plants from the province of Rio Grande do Sul in South America (Map A, G 2), including a few typical members of the Glossopteris flora associated with a European species, *Lepidophloios laricinus*, one of the characteristic types of the Coal period, and with certain ferns resembling some species from European Permian rocks. A similar association was found also in Argentine rocks by Kurtz (Map A, G_1), and from South Africa *Sigillaria Brardi*, another northern type, is recorded in company with *Glossopteris*, *Gangamopteris*, and *Nœggerathiopsis*.

FIG. 2.—*Schizoneura Gondwanensis*, from Lower Gondwana rocks of India. (*After Feistmantel.*)

The Coal-bearing strata which occupy a considerable area in China (Map A, II.), contain abundant samples of a vegetation which appears to have agreed in the main features with the Permo-Carboniferous floras of the northern hemisphere. In his account of some plants from the Coal Measures of Kansu (Map A, IV.) Dr Krasser has drawn attention to the apparent identity of certain leaf-fragments with those of *Nœggerathiopsis Hislopi*, a typical member of the Glossopteris flora; but this plant, so far as the evidence of vegetative leaves may be of value, differs in no essential respects from certain species of a European genus *Cordaites*. A comparatively rich fossil flora was described in 1882 from Tongking (Map A, III.) by Professor Zeiller—and this author has recently made important additions to his original account—which demonstrates an admixture of Glossopteris types with others which were recognized as identical with plants characteristic of Rhætic strata in Europe. In the Tongking area, therefore, a flora existed during the Rhætic period consisting in part of genera which are abundant in the older Glossopteris beds of the south,

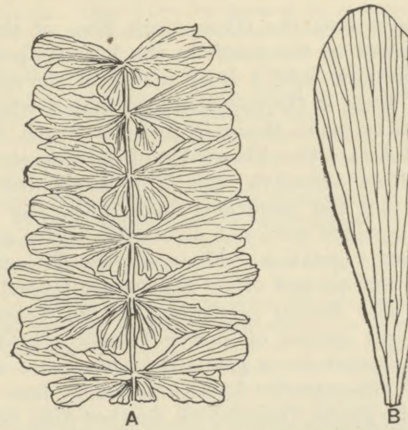


FIG. 3.—*Sphenophyllum speciosum*. From Lower Gondwana rocks, India. A, nat. size; B, leaflet enlarged. (*After Feistmantel.*)

and in part of well-known constituents of European Rhætic floras. A characteristic member of the southern botanical province, *Schizoneura Gondwanensis* (Fig. 2) of India, is represented also by a closely allied if not an identical species—*S. paradoxa*—in the Lower Trias (Bunter) sandstones of the Vosges Mountains, associated with European species which do not occur in the Glossopteris flora. Another plant found in the Vosges sandstones—*Neuropteridium grandifolium*—is also closely allied to species of the same fern recorded from the Lower Gondwana strata of India (Fig. 4) and South America, and recently discovered, but not yet described, by Mr Leslie at Vereeniging in South Africa. These two instances—the Tongking beds of Rhætic age and the Bunter sandstones of the Vosges—afford evidence of a northern extension of Glossopteris types and their association with European species. In 1898 an important discovery was made by Professor Amalitzky, which carries us a step farther in our search for a connexion between the northern and southern floras. Amalitzky found in beds of Upper Permian age in the province of Vologda (Russia) (Map A, V.) species of *Glossopteris* and *Nœggerathiopsis*, typical members of the Glossopteris flora, associated with species of the ferns *Tœniopteris*, *Callipteris*, and *Sphenopteris*, a striking instance of a commingling in the far north of the northern hemisphere Permian species with migrants from "Gondwana Land." This association of types clearly points to a penetration of representatives of the Glossopteris flora to the north of Europe towards the close of the Permian period. Evidence of the same northern extension is supplied by floras described by Schmalhausen from Permian rocks in the Pechora valley (Map A, VI.), the Siberian genus *Rhiptozamites* being very similar to, and probably generically identical with, *Nœggerathiopsis* of the Glossopteris flora. The Permo-Carboniferous beds of South Africa, India, and Australia are succeeded by other plant-bearing strata, containing numerous species agreeing closely with members of the Rhætic and Jurassic floras of the northern hemisphere. These post-Permian floras, as represented by the Upper Gondwana beds of India and corresponding strata in Australia, South Africa, and South America, differ but slightly from the northern floras, and point to a uniformity in the Rhætic and Jurassic vegetation which is in contrast to the existence of two botanical provinces during the latter part of the Palæozoic period. A few plants recently described by Potonié from German and Portuguese East Africa demonstrate the occurrence of *Glossopteris* and a few other genera, referred to a Permo-Triassic horizon, in a region slightly to the north of Tete in the Zambezi district (Map A, I.), where typical European plants agreeing with Upper Carboniferous types were discovered several years ago, and described by Zeiller in 1882 and 1901. The existence of Upper Gondwana plants, resembling Jurassic species from the Rajmahal beds of India, has recently been demonstrated in the Argentine by Dr Kurtz.

FIG. 4.—*Neuropteridium validum.* From Lower Gondwana rocks, India. (*After Feistmantel.*)

Having seen how the Glossopteris flora of the south gradually spread to the north in the Permian period, we may now take a brief survey of the succession of floras in the northern hemisphere, which have left traces in Mesozoic rocks of North America, Europe, and Asia. Our knowledge of the Triassic vegetation is far from extensive; this is no doubt due in part to the fact that the conditions under which the Triassic rocks were deposited were not favourable to the existence of a luxuriant vegetation. Moreover, the Triassic rocks of southern Europe and other regions are typical marine sediments. The Bunter sandstones of the Vosges have afforded several species of Lower Triassic plants; these include the Equisetaceous genus *Schizoneura*—a member also of the Glossopteris flora — bipinnate fern fronds referred to the genus *Anomopteris*, another fern, described originally as *Neuropteris grandifolia*, which agrees very closely with a southern hemisphere type (*Neuropteridium validum*, Fig. 4), some large Equisetaceous stems apparently identical, except in size, with modern Horsetails. With these occur several Conifers, among others *Voltzia heterophylla* and some twigs referred to the genus *Albertia*, bearing large leaves like those of *Agathis australis* and some of the Araucarias, also a few representatives of the Cycadales. Among plants from Lower Triassic strata there are a few which form connecting links with the older Permo-Carboniferous flora; of these we have a species, described by Blankenhorn as *Sigillaria oculina*, which may be correctly referred to that genus, although an inspection of a plaster-cast of the type-specimen in the Berlin Bergakademie leaves a little doubt as to the sufficiency of the evidence for adopting the generic name *Sigillaria*. Another Triassic genus, *Pleuromeia*, is of interest as exhibiting, on the one hand, a striking resemblance to the recent genus *Isoetes*, from which it differs in its much larger stem, and on the other as agreeing fairly closely with the Palæozoic genera *Lepidodendron* and *Sigillaria*. There is, however, a marked difference, as regards the floras as a whole, between the uppermost Palæozoic flora of the northern hemisphere and such species as have been recorded from Lower Triassic beds. There is evidence of a distinct break in the succession of the northern floras which is not apparent between the Permian and Trias floras of the south. Passing over the few known species of plants from the middle Trias (Muschelkalk) to the more abundant and more widely-spread Upper Triassic species as recorded from Germany, Austria, Switzerland, North America, and elsewhere, we find a vegetation characterized chiefly by an abundance of Ferns and Cycads, exhibiting the same general facies as that of the succeeding Rhætic and Lower Jurassic floras. Among Cycads may be mentioned species of *Pterophyllum* (*e.g.*, *P. Jaegeri*), represented by large pinnate fronds not unlike those of existing species of *Zamia*, some Equisetaceous plants and numerous Ferns which may be referred to such families as Gleicheniaceæ, Dipteridinæ, and Matonineæ. Representatives of the Ginkgoales constitute characteristic members of the later Triassic floras, and these, with other types, carry us on without any break in continuity to the Rhætic floras of Scania, Germany, Asia, Chile, Tongking, and Honduras (Map A, VIII.), and to the Jurassic and Wealden floras of many regions in both the north and south hemispheres. A comparative view of the plants found in various parts of the world, in beds ranging from the Upper Trias to the top of the Jurassic system, reveals a striking uniformity in the vegetation both in northern and southern latitudes during this long succession of ages. The Palæozoic types are barely represented; the arborescent Vascular Cryptogams have been replaced by Cycads, Ginkgoales, and Conifers as the dominant classes, while Ferns continue to hold their own. No undoubted Angiosperms have yet been found below the Cretaceous system. From the close of the Permian period, which marks the limit of the Upper Palæozoic floras, to the period immediately preceding the apparently sudden appearance of Angiosperms, we have a succession of floras differing from one another in certain minor details, but linked together by the possession of many characters in common. It is impossible to consider in detail this long period in the history of plant-evolution, but we may briefly pass in review the most striking features of the vegetation as exhibited in the dominant types of the various classes of plants.

Mesozoic floras.

Under the head of Algæ there is little of primary importance to record, but it is of interest to notice the occurrence of certain forms which throw light on the antiquity of existing families of Algæ. Species referred on good evidence to the Charophyta are represented by a few casts of oögonia and stem fragments, found in Jurassic and Wealden beds, which bear a striking resemblance to existing species. There is some evidence for the occurrence of similar *Chara* "fruits" in middle Triassic rocks; some doubtful fossils from the much older Devonian rocks have also been quoted as possible examples of the Charophyta. The oldest known Diatoms are represented by some specimens found entangled in the spicules of a Liassic sponge, and identified by Rothpletz as species of the recent genus *Pyxidicula*. The calcareous Siphoneæ are represented by several forms, identified

Algæ.

as species of *Diplopora, Triploporella, Neomeris*, and other genera, from strata ranging from the Lower Trias limestones of Tirol to the Cretaceous rocks of Mexico and elsewhere. It is probable that the Jurassic *Goniolina*, described from French localities, and other genera which need not be mentioned, may also be reckoned among the Mesozoic Siphoneæ. A genus *Zonatrichites*, compared with species of Cyanophyceæ, has been described as a Calcareous alga from Liassic limestones of Silesia.

The geological history of Mosses and Liverworts is at present very incomplete, and founded on few and generally unsatisfactory fragments. It is hardly too much to say, that no absolutely trustworthy examples of Mosses have so far been found in Mesozoic strata. Of Liverworts there are a few species, such as *Palæohepatica Rostafinskii* from the Lower Jurassic rocks of Cracow, *Marchantites erectus* from the Interior Oolite rocks of Yorkshire, and *M. Zeilleri* from the Wealden beds of Sussex. These fossil Hepaticæ are unfortunately founded only on sterile fragments, and placed in the Liverworts on the strength of their resemblance to the thallus of *Marchantia* and other recent genera.

Bryophyta.

The Palæozoic Calamites were succeeded in the Triassic period by large *Equisetites*, differing, so far as we know, in no essential respect from existing Equisetums. The large stems represented by casts of Triassic age, *Equisetites arenaceus* and other species, probably possessed the power of secondary growth in thickness; the cones were of the modern type, and the rhizomes occasionally formed large underground tubers like those frequently met with in *Equisetum arvense, E. sylvaticum*, and other species. *Equisetites Muensteri* is a characteristic and fairly widely spread Rhætic and Liassic species, having a comparatively slender stem, with leaf-sheaths consisting of a few broad and short leaf-segments. *Equisetites columnaris*, a common fossil in the Jurassic plant-beds of the Yorkshire coast, represents another type with relatively stout and occasionally branched vegetative shoots, bearing leaf-sheaths very like those of *Equisetum maximum* and other Horsetails. In the Wealden strata more slender forms have been found—*e.g.*, *Equisetites Burchardti* and *E. Lyelli*—in England, Germany, Portugal, Japan, and elsewhere, differing still less in dimensions from modern species. Of other Equisetales there are *Schizoneura* and *Phyllotheca*; the former first appears in Lower Gondwana rocks as a member of the Glossopteris flora, migrating at a later epoch into Europe, where it is represented by a Triassic species. The latter genus ranges from Upper Carboniferous to Jurassic rocks; it occurs in India, Australia, and elsewhere in the "Gondwana Land" vegetation, as well as in Palæozoic rocks of Asia Minor, in Permian rocks of Siberia, and in Jurassic plant-beds of Italy. This genus, like the allied *Calamites*, appears to have possessed cones of more than one type; but we know little of the structure of these Mesozoic Equisetaceous genera as compared with our much more complete knowledge of *Calamites* and *Archæocalamites*. (See section I., PALÆOZOIC.)

Equisetaceæ.

Reference has already been made to *Sigillaria oculina* and to the genus *Pleuromeia*. Of other Mesozoic representatives of the Lycopodiales, there are practically none of botanical interest. Palæobotanical literature contains several records of species of *Lycopodites* and *Selaginellites*; nearly all of them are sterile fragments, bearing a more or less close resemblance to living Club-Mosses and Selaginellas, but lacking the more important reproductive organs. A recent investigation of a plant long known from Rhætic rocks in the Severn valley as *Naiadita acuminata* has shown that this genus is in all probability a small Lycopodiaceous plant, and neither a Moss nor a Monocotyledon, as some writers have supposed. One of the most satisfactory species from European rocks is *Lycopodites falcatus*, originally described by Lindley and Hutton in 1831 from the Inferior Oolite of Yorkshire.

Lycopodiales.

Among the large number of Mesozoic Ferns there are several species founded on sterile fronds which possess but little interest from a botanical standpoint. Some plants, again, have been referred by certain authors to Ferns, while others have relegated them to the Cycads. As examples of these doubtful forms may be mentioned *Thinnfeldia*, characteristic of Rhætic and Lower Jurassic rocks; *Dichopteris*, represented by some exceptionally fine Jurassic specimens, described by Zigno, from Italy; and *Ctenis*, a genus chiefly from Jurassic beds, founded on pinnate fronds like those of *Zamia* and other Cycads, with linear pinnæ characterized by anastomosing veins. Plants referred to Schimper's genus *Lomatopteris* and to *Cycadopteris* of Zigno afford other instances of the difficulty of distinguishing between the foliage of Ferns and Cycads. The close resemblance between specimens from Jurassic rocks placed in one or other of the genera *Thinnfeldia, Dichopteris, Cycadopteris*, &c., illustrates the unsatisfactory custom of founding new names on imperfect fronds. It is of interest to note that some leaf-fragments recently found in Permian rocks of Kansas, and placed in a new genus *Glenopteris*, are hardly distinguishable from specimens of Jurassic and Rhætic age referred to *Thinnfeldia* and other Mesozoic genera. The difficulty of distinguishing between Ferns and Cycads is a necessary consequence of the common origin of these two classes; in Palæozoic times the Cycadofilices [see section I., PALÆOZOIC] played a prominent part, and even among recent Cycads and Ferns we still see a few indications of their close relationship. There is reason to believe that compound or synthetic types—partly Ferns and partly Cycads—persisted into the Mesozoic era; but without more anatomical knowledge than we at present possess, it is impossible to do more than to point to a few indications afforded by external, and to a slight extent by internal structure, of the survival of Cycadofilicinean types. The genus *Otozamites*, which it is customary and probably correct to include in the Cycadales, is represented by certain species, such as *Otozamites Beani* (Fig. 5, A), a characteristic Yorkshire fossil of Jurassic age, which in the form of the frond, bearing broad and relatively short pinnæ, exhibits a striking agreement with the sterile portions of the fronds of *Ancimia rotundifolia*. Again, another species of the same genus, *O. Bunburyanus* (Fig. 5, B), suggests a comparison with fern fronds like that of the recent species *Nephrolepis Duffi*. The scaly ramenta which occur in abundance on the leaf-stalk bases of fossil Cycads constitute another fern-character surviving in Mesozoic Cycadales. Without a fuller knowledge of internal structure and of the reproductive organs, we are compelled to speak of some of the Mesozoic plants as possibly Ferns or possibly Cycads, and not referable with certainty to one or other class. It has been found useful in some cases to examine microscopically the thin film of coal that often covers the pinnæ of fossil fronds, in order to determine the form of the epidermal cells which may be preserved in the carbonized cuticle; rectilinear epidermal cell-walls are usually considered characteristic of Cycads, while cells with undulating walls are more likely to belong to ferns. This distinction does not, however, afford a safe guide; the epidermal cells of some ferns, *e.g.*, *Angiopteris*, have straight walls, and occasionally the surface cells of a cycadean leaf-segment exhibit a fern-like character. Leaving out of account the numerous sterile fronds which cannot be certainly referred to particular families of Ferns, there are several genera which bear evidence in their sori, and to some extent in the form of the leaf, of their relationship to existing types.

Filicales.

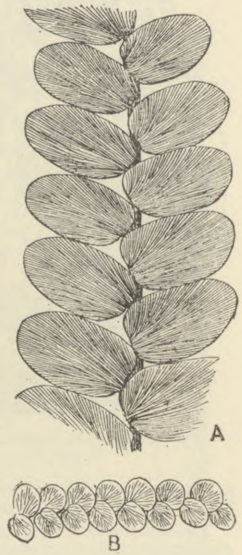

FIG. 5.—A, *Otazamites Beani.* B, *O. Bunburyanus.* Inferior Oolite, England.

The abundance of Palæozoic ferns with sporangia and sori of the Marattiaceous type is in striking contrast to the scarcity of Mesozoic species which can be reasonably included in the Marattiaceæ. One of the few forms so far recorded is that known as *Marattia Muensteri* from Rhætic localities in Europe and Asia. Some species included in the genus *Danæites* or *Danæopsis* from Jurassic rocks of Poland, Austria, and Switzerland may possibly be closely allied to the recent tropical genus *Danæa*. Of the Ophioglossaceæ there are no satisfactory examples; one of the few fossils compared with a recent species, *Ophioglossum palmatum*, was described several years ago from Triassic rocks under the name *Cheiropteris*, but the resemblance is one of external form only, and practically valueless as a taxonomic criterion. It would appear that the eusporangiate Ferns suddenly sank to a very subordinate position after the Palæozoic era.

Marattiaceæ.

The Osmundaceæ, represented by a few forms of Palæozoic age, played a more prominent part in the Mesozoic floras. A species described by Schenk from Rhætic rocks of Franconia as *Acrostichites princeps* is hardly distinguishable from *Todites Williamsoni*, a widely-distributed species in Inferior Oolite strata. This Jurassic species bore bipinnate fronds not unlike those of the South African, Australian, and New Zealand Fern *Todea barbara*, which were characterized by a stout rachis and short broad pinnules bearing numerous large sporangia covering the under surface of the lamina. Specimens of *Todites* have been obtained from England, Poland, and elsewhere, sufficiently well preserved to afford good evidence of a correspondence in the structure of their sporangia with those of recent Osmundaceæ. This Jurassic and Rhætic type occurs in England, Germany, Poland, Italy, East Greenland, North America, Japan, China, and Persia (Map A, X.). Bipinnate sterile fronds of *Todites* have in some instances been described under the designation *Pecopteris Whitbiensis*. This and other names, such as *Asplenium Whitbiense, A. nebbense, Asplenites Roesserti*, &c., have been given to bipinnate fronds of a type frequently met with in different genera and

Osmundaceæ.

families of recent Ferns, *e.g.*, *Onoclea struthiopteris*, species of *Cyathea*, *Asplenium*, *Gymnogramme*, &c. In most cases the Rhætic, Jurassic, and Wealden Ferns included under one or other of these names are sterile, and cannot be assigned to a particular family, but some are undoubtedly the leaves of *Todites*, a genus which may often be recognized by the broad and relatively short bluntly-terminated pinnules. The Jurassic species *Cladophlebis denticulata* (Fig. 6), recorded from several European localities, including Bornholm and the Arctic regions, as well as from North America, Japan, China, Australia, India, and Persia, affords an instance of a common type of bipinnate frond similar to *Todites Williamsoni*, which has been included in the Polypodiaceæ; but such meagre evidence of the soral characters as we possess also points to a comparison with the recent Osmundaceous fern *Todea barbara*. The systematic position of this Jurassic form is still undetermined.

FIG. 6.—*Cladophlebis denticulata*. Inferior Oolite, England.

Schizæaceæ.

The Schizæaceæ include a widely spread species, originally named *Pecopteris exilis*, and recently placed in a new genus, *Klukia* (Fig. 7), which is characterized by tripinnate fronds with short linear ultimate segments, bearing a single row of sporangia with an apical annulus ("monangic sori" of Prantl) on either side of the midrib. This type occurs in Rhætic and Lower Jurassic rocks of England, Poland, the Arctic regions, and Japan. *Ruffordia Gœpperti*, a Wealden type, and probably a member of the Schizæaceæ, has been recorded from England (Yorkshire and Sussex), Belgium, other European countries, and Japan.

FIG. 7.—*Klukia exilis*. 1–3, sporangia enlarged; 4, single fertile pinnule slightly enlarged; 5, fragment of pinna. Inferior Oolite, England.

Gleicheniaceæ.

The Gleicheniaceæ appear to have been represented by Triassic species in North America and Europe, and more abundantly in Jurassic, Wealden, or Lower Cretaceous rocks in Belgium, Greenland, Poland, and elsewhere. Some exceptionally perfect fragments of rhizomes have been found by Dr C. Bommer of Brussels in some Wealden deposits at Bracquegnies (not far from Baume) in Belgium; but these are not yet described. The dichotomously-branched fronds of the type represented by several recent species of *Gleichenia*, *e.g.*, *G. dichotoma*, &c., are abundant in Lower Cretaceous plant-beds of Greenland, and suggest that in the latter part of the Mesozoic period the Gleicheniaceæ held a position in the vegetation of the far north similar to that which they now occupy in the southern tropics of India and other regions.

Matonineæ.

The recent Malayan genus *Matonia* (Map B, Matonia), represented by two species, *M. pectinata* and *M. sarmentosa*, is clearly a survival in tropical latitudes of a family which occupied an important place in the vegetation of the Rhætic, Jurassic, and Wealden periods. The genera *Laccopteris* and *Matonidium* (Fig. 8) may be cited as the two most important types, both as regards geographical and geological range, of this Mesozoic family; these Ferns are recorded from England, France, Belgium, Germany, Austria, Portugal, Poland, and Italy (Map B, M_1), also from Greenland (Map B, M_2), Spitsbergen (Map B, M_3), and Persia (Map B, M_4). From the southern hemisphere, on the other hand, we know of one or two fragments only which can reasonably be referred to the Matonineæ (Map B, M_5), a fact which may point to a northern origin for this family, with its two surviving species almost confined to the Malayan region.

FIG. 8.—*Matonidium Gœpperti*. A, summit of petiole; B, fertile pinnules. Inferior Oolite, England.

Dipteridinæ.

The recent genus, *Dipteris*, with its four existing species, occurring chiefly in the Indo-Malayan region (Map B, Dipteris), is also a modern survival of several Mesozoic types represented by such genera as *Dictyophyllum* (Fig. 9), *Prothorhipis*, and *Camptopteris*, which were abundant during the Rhætic and Jurassic periods in England, Germany, Sweden, and elsewhere in Europe (Map B, D_1). The Dipteridinæ are represented also by species from Mesozoic rocks of Persia (Map B, D_2), Greenland (Map B, D_3), North America (D_4), South America (D_5), and China (D_6).

FIG. 9.—*Dictyophyllum*. Rhætic rocks of Europe. (*After Schenk.*)

Cyatheaceæ.

The Cyatheaceæ constitute another family of leptosporangiate Ferns which had several representatives in Mesozoic floras. The numerous species of fronds from Jurassic and Wealden rocks of North America and Europe referred to *Thyrsopteris*, a recent monotypic genus confined to Juan Fernandez, are in the majority of cases founded on sterile leaves, and of little or no botanical value. On the other hand, there are several fossil Ferns of Jurassic age possessing cup-like sori like those of *Thyrsopteris* and other Cyatheaceous Ferns, which indicate a wide Mesozoic distribution for this family. Among Jurassic species which should probably be classed as Cyatheaceæ, *Coniopteris hymenophylloides* is recorded from England, France, Poland, Bornholm, Italy, the Arctic regions, North America, Japan, China, Australia, and India. A few tree-ferns which may be included in this family, such as *Protopteris*, have been described from Wealden and Lower Cretaceous rocks of England, Germany, and Austria. It is by no means easy in dealing with fossil Ferns to distinguish between certain Polypodiaceæ—such as species of *Davallia*—and members of the Cyatheaceæ.

Polypodiaceæ.

It is a striking fact that among the numerous Mesozoic Ferns there are comparatively few that can with good reason be referred to the Polypodiaceæ, a family which plays so dominant a rôle at the present day. The frequent occurrence of such names as *Asplenium*, *Adiantum*, *Davallia*, and other Polypodiaceous genera in lists of fossil Ferns is thoroughly misleading. There are, indeed, a certain number of species which show traces of sori like those of modern species of *Asplenium* and other genera, but in most cases the names of recent Ferns have been used on insufficient grounds. The Wealden and Jurassic genus, *Onychiopsis* of England, Portugal, Belgium, Germany, Japan, and Australia, bears a close resemblance to the recent *Onychium* (*Cryptogamme*). Other Jurassic Ferns described by Raciborski from Poland suggest a comparison with *Davallia*. Supposed fertile fronds of *Glossopteris* have been described by several authors and referred to the Polypodiaceæ, but in no instance is the evidence enough to warrant more than the suggestion that this abundant southern Fern is a Polypodiaceous genus. The majority of the specimens included in the genus *Cladophlebis*, the Mesozoic representative of the Palæozoic *Pecopteris* type of frond, are known only in a sterile condition, and cannot be assigned to their family position. A Wealden plant, *Weichselia Mantelli*, is worthy of mention as a species of very wide geographical distribution, and one of the most characteristic members of the Wealden flora. This type is distinguished by its large bipinnate fronds bearing long and narrow pinnæ with close-set pinnules, characterized by the anastomosing secondary veins. No traces of sori have so far been found in the fronds. Similarly, the genus *Sagenopteris*, characterized by a habit like that of *Marsilia*, and represented by fronds consisting of a few spreading broadly oval or narrow segments, with anastomosing veins, borne on the apex of a common petiole, is abundant in rocks ranging from

MAP B.—M_1–M_5, Distribution of the *Matonineæ*. D_1–D_6, Distribution of the *Dipteridinæ*. G_1–G_{17}, Distribution of the *Ginkgoales* during the Mesozoic and Tertiary Periods. G_1 (Trias–Tertiary); G_2, G_3 (Rhætic–Jurassic); G_4 (Tertiary, Sakhalin I.); G_5 (Jurassic); G_6 (Jurassic and Tertiary); G_7 (Jurassic); G_8 (Rhætic–Jurassic); G_9 (Trias–Rhætic); G_{10} (Rhætic, Chile); G_{11} (Trias); G_{12} (Cretaceous–Tertiary); G_{13} (Tertiary, Alaska); G_{14} (Cretaceous–Tertiary); G_{15} (Jurassic); G_{16} (Jurassic, Spitsbergen); G_{17} (Jurassic, Franz Josef Land).

the Rhætic to the Wealden, but has not so far been satisfactorily placed. The evidence which led Nathorst and some other writers to refer this plant to the Marsiliaceæ is not convincing, and until we find well-preserved sporocarps we incline to the opinion that *Sagenopteris* is probably a genus of Ferns.

Cycadales.

The abundance of Cycadean plants is one of the most striking features of Mesozoic floras. In most cases we have only the evidence of sterile fronds, and this is necessarily unsatisfactory; but the occurrence of numerous stems and fertile shoots demonstrates the wealth of Cycadean plants in many parts of the world, more particularly during the Jurassic and Wealden periods. From Palæozoic rocks a few fronds have been described, such as *Pterophyllum Fayoli*, *P. Cambrayi*, *Plagiozamites*, and *Sphenozamites*, chiefly from French localities, which are referred to the Cycads because of their similarity to the pinnate fronds of modern Cycadaceæ. In the succeeding Triassic system Cycadean plants become much more abundant, especially in the Keuper period; from Rhætic rocks a still greater number of types have been recorded, among which may be mentioned *Nilssonia* (Fig. 10), *Anomozamites*, *Pterophyllum*, *Otozamites*, *Cycadites* (Fig. 11). The species of *Nilssonia* shown in Fig. 10 (*N. compta*) is a characteristic member of the Jurassic flora, practically identical with a form from Rhætic rocks described as *Nilssonia polymorpha*. The large frond of *Cycadites* represented in Fig. 11 (*C. Saportæ*) is from the Wealden strata of Sussex, and possibly identical with *Cycadites tenuisectus* from Portugal. In addition to these genera there are others, such as *Ctenozamites*, *Ctenis*, and *Podozamites*, the position of which is less certain. *Ctenozamites* occurs chiefly in the Rhætic coal-bearing beds of Scania, and has been found also in the Liassic clays of Dorsetshire and in the Inferior Oolite beds of Yorkshire, as well as in Rhætic strata in Persia and elsewhere; it is characterized by its bipinnate fronds, and may be compared with the recent Australian genus *Bowenia*—peculiar among living Cycads in having bipinnate fronds. *Ctenis* has been placed among the ferns by more than one author, on account of the occurrence of supposed sporangia on its pinnæ; but there is reason to believe that these so-called sporangia are probably nothing more than prominent papillose cells of the epidermis. *Podozamites* (Fig. 12) is usually considered to be a Cycad, but the broad pinnæ (or leaves) and their arrangement on the axis suggests a possible relationship with the southern Coniferous genus *Agathis*, represented by the Kauri Pine and other recent species. The considerable variation in the size of the pinnæ of *Podozamites*, as represented by species from the Jurassic rocks in the Arctic regions and various European localities, recalls the variation in length and breadth of the leaves of *Agathis*. With regard to the distinguishing features and the distribution of the numerous Cycadean leaves of Mesozoic age, the most striking fact is the abundance of fronds, which there is good reason to refer to the Cycadales in Upper Triassic, Rhætic, Jurassic, and Wealden rocks in India, Australia, Japan, China, and elsewhere in the southern hemisphere, as well in North America, Greenland, and other Arctic

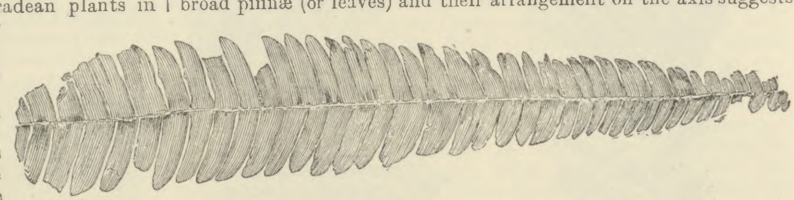

FIG. 10.—*Nilssonia compta*. Inferior Oolite, England.

lands and throughout Europe. It is noteworthy that Tertiary plant-beds have yielded hardly any specimens that can be recognized as Cycads.

A more important question is, What knowledge have we of the reproductive organs and stems of these fossil Cycads? Cycadean stems have recently been found in extraordinary abundance in Jurassic and possibly higher strata in Wyoming and other parts of the United States. Cycadean stems have been found also in the uppermost Jurassic, Wealden, and Lower Cretaceous rocks of England, India, and other parts of the world. An example of an Indian Cycadean stem from Upper Gondwana rocks is represented in Fig. 13; the surface of the trunk is covered with persistent bases (Fig. 13, A) of the fronds known as *Ptilophyllum Cutchense*, which are practically the same as the European species *Williamsonia pecten* (Fig. 17). In a section of the stem (Fig. 13, B) a large pith is seen to occupy the axial region, and this is surrounded by a zone of secondary wood, which appears to differ from the characteristic wood of modern Cycads (see GYMNOSPERMS) in having a more compact structure. The lozenge-shaped areas external to the axis of the stem represent the sections of petioles, some of which are shown in Fig. 13, A, attached to the stem. The majority of Mesozoic stems agree in external appearance with those of recent species of *Encephalartos*, *Macrozamia*, and some other genera; the trunk is encased in a mass of persistent petiole-bases separated from one another by a dense felt or packing of scaly ramenta. The structure of the leaf-stalks is like that of modern Cycads, but the

ramenta, instead of having the form of long unicellular hairs like those on the petioles and bud-scales of existing species, are exactly like the paleæ or ramental scales characteristic of the majority of ferns. This fern-like character affords an interesting survival of the close relationship between Cycads and Ferns. Some recently discovered Jurassic Cycadean stems from Wyoming are characterized by an unusually rich development of ramental scales; the ramenta from the old leaf-bases form an almost complete covering over the surface of the trunk. Professor Lester Ward has instituted a new generic name, *Cycadella*, for these woolly forms. In a few cases the fossil stems show no trace of any lateral flowering shoots, and in that respect agree with modern forms: an instance of this is afforded by a large Cycadean trunk discovered a few years ago in one of the Portland quarries, and named *Cycadeoidea gigantea* (Fig. 14). In this stem the flowers may have been terminal, as in existing Cycads. As a rule, however, the fossil stems show a marked difference from modern forms in the possession of lateral shoots given off from the axils of leaves, and terminating in a flower of complex structure containing numerous orthotropous seeds. These reproductive shoots differ in many important respects from the flowers of recent Cycads, and, chiefly on this account, it is customary to include the plants in a separate genus, *Bennettites*, and in a family—the Bennettitaceæ—distinct from that of the Cycadaceæ as represented by existing Cycads. The best preserved specimens of the true *Bennettites* type so far described are from the Lower Greensand and Wealden of England, and from Upper Mesozoic strata in North America, Italy, and France. A study of the anatomical structure of the vegetative stem, which on the whole is very similar to that of recent Cycads (Fig. 15, 1 and 2), reveals certain characters which are not met with in modern Cycads. The chief distinguishing feature is afforded by the leaf-traces; in recent species (see GYMNOSPERMS) these pursue a somewhat complicated course as they pass from the petiole towards the vascular cylinder of the stem, but in *Bennettites* the vascular bundles from the leaves followed a more direct course through the cortex of the stem (Fig. 15, 3). Among existing types the genus *Macrozamia* appears to show the nearest approach to this simpler structure of the leaf-traces. The typical *Bennettites* female flower (Fig. 15, 4 and 7), as investigated in English, French, Italian, and American specimens, may be briefly described as a short lateral shoot or peduncle, arising in a leaf-axil and terminating in a bluntly rounded apex, bearing numerous linear bracts enclosing a central group of appendages, some of which consist of slender pedicels traversed by a vascular strand and bearing a single terminal ovule enclosed in an integument, which forms a distal canal or micropyle. Associated with these seminiferous pedicels occur sterile appendages consisting of slender stalks, terminating in distal expansions, which form a fleshy covering over the surface of the flower, leaving small apertures immediately above the micropyles for the entrance of the pollen-grains. The seeds have in some cases been preserved in wonderful perfection, enabling one to make out the structure of the embryo, with its bluntly conical radicle and two fleshy cotyledons filling the exalbuminous seed (Fig. 15, 11).

FIG. 14.—*Cycadeoidea gigantea*. Portland rocks, England.

Our knowledge of the reproductive organs of the Bennettitaceæ has until recently been confined to the female flowers, as described by Carruthers, Solms-Laubach, Lignier, and others. The fortunate discovery of several hundred Cycadean stems in the United States, of Lower Cretaceous and Upper Jurassic age, has supplied abundant material, which is now being examined by Mr Wieland. This investigator has already published several short accounts of his discoveries, which give valuable information as to the morphology of the male organs, and lead us to expect results in the future of the greatest importance and interest. On some of the American stems flowers have been found, borne at the apex of lateral shoots, which possess fully developed male organs consisting of sporangia with spores (pollen-grains), surrounding a conical central receptacle bearing numerous small and probably functionless or immature ovules (Fig. 15, 10). The structure of this type of flower may be briefly described as follows. In shape and size the flower is similar to that long known as the female flower of *Bennettites* and *Williamsonia*. A number of hairy linear bracts enclose the whole; internal to these occur 12 to 20 crowded pinnate leaves (sporophylls), with their apical portions bent over towards the axis of the flower, the bases of the petioles being fused laterally into a disc surrounding the base of the conical receptacle. Numerous pairs of pinnules are attached to the rachis of each sporophyll, and the larger pinnules bear 20 to 30 synangia (sori or plurilocular sporangia) (Fig. 15, 8 and 9). The synangia consist of a stout wall composed of thick-walled cells, succeeded by a layer of more delicate and smaller elements; and internal to the wall occur two rows of sporangial loculi containing microspores. When the synangia are ripe dehiscence takes place along a median line between the two rows of loculi. In size, position, arrangement, and manner of dehiscence the sporangia bear a striking resemblance to those of *Marattia* and *Danæa* among recent Marattiaceæ. The most important point elucidated by this discovery is the very close correspondence of the male organs of the *Bennettites* flower with the sporophylls and synangia of Marattiaceous Ferns—a further relic of the common origin of Cycads and Ferns. It remains to be seen if the ovuliferous cone in the centre of the flower represents simply a functionless gynœcium, as in *Welwitschia* and abnormal cones of certain Coniferæ, or if the flowers were hermaphrodite, with both male and female organs fully developed. We have a combination in the same flower of stalked ovules, the structure of which has already been described, and interseminal scales constituting a complex gynœcium, which exhibits in certain features an approach to the Angiospermous type, and differs in structure from other Gymnosperm flowers, associated with male organs constructed on a plan almost identical with that of the sporophylls in Marattiaceæ.

It is clear that *Bennettites* differed in many essential respects from the few modern survivors of the Cycadales. The flowers were more complex in structure, and in the case of the female flowers the almost complete covering of the ovule by sterile foliar organs offers a point of contact with the ovary of the Angiosperms, suggesting a foreshadowing in the Mesozoic Cycadales of the more efficient protection of the ovule characteristic of Monocotyledons and Dicotyledons. Fossil flowers of a type more like that of modern Cycads are few in number, and it is not by any means certain that all of those described as Cycadean flowers and seeds were borne by plants which should be included in the Cycadales; a few female flowers have been described from Rhætic rocks of Scania and elsewhere under the name *Zamiostrobus*—these consist of an axis with slender pedicels or carpophylls given off at a wide angle and bearing two ovules at the distal end; the structure is in fact similar to that of a *Zamia* female flower, in which the internodes of the peduncle have been elongated so as to give a looser arrangement to the carpels. It has been suggested that one at least of the flowers, that originally described by Mr Carruthers from the Inferior Oolite of Yorkshire as *Beania gracilis*, may have been borne by a member of the Ginkgoales. From Jurassic rocks of France and Italy a few imperfect specimens have been described as carpels of Cycads, like those of the recent genus *Cycas* (see GYMNOSPERMS); while a few of these may have been correctly identified, an inspection of some of the original examples in the Paris collections leads one to express the opinion that others are too imperfect to determine. Pinnate fronds of the *Cycas* type, characterized by the presence of a midrib and no lateral veins in the linear pinnæ, are recorded from Rhætic rocks of Germany, from Wealden strata in England (Fig. 11) and Portugal, and from Liassic beds in Dorsetshire. One large specimen is figured by Heer from Lower Cretaceous rocks of Greenland, and by the side of the frond is shown a carpel with lateral ovules, as in the female flower of *Cycas*; but an examination of the type-specimen in the Copenhagen Museum led the present writer to regard this supposed carpel as valueless. Another well-known Cycadean genus is *Williamsonia*, so named by Mr Carruthers in 1870, and now applied to certain pinnate fronds—*e.g.*, those previously described as *Zamites gigas* (Fig. 16), and others known under such names as *Pterophyllum* or *Ptilophyllum pecten*, &c., both common Jurassic species—as well as to stems bearing peduncles with terminal oval flowers, similar in form to those of *Bennettites*. There is good evidence for supporting Professor Williamson's conclusions as to the organic connexion between the flowers, originally described from Inferior Oolite rocks of Yorkshire and subsequently named *Williamsonia* (Fig. 15), and the fronds of *Zamites gigas*, now known as *Williamsonia gigas* (Fig. 16). There can be little doubt that the majority of the Cycadean fronds of Jurassic and Wealden age, which are nearly always found detached from the rest of the plant, were borne on stems of the *Bennettites* type. Williamson was the first to express the opinion that the Bennettitean flowers known as *Williamsonia* were borne on the trunks which terminated in a crown of pinnate fronds of the type long known as *Zamites gigas*;

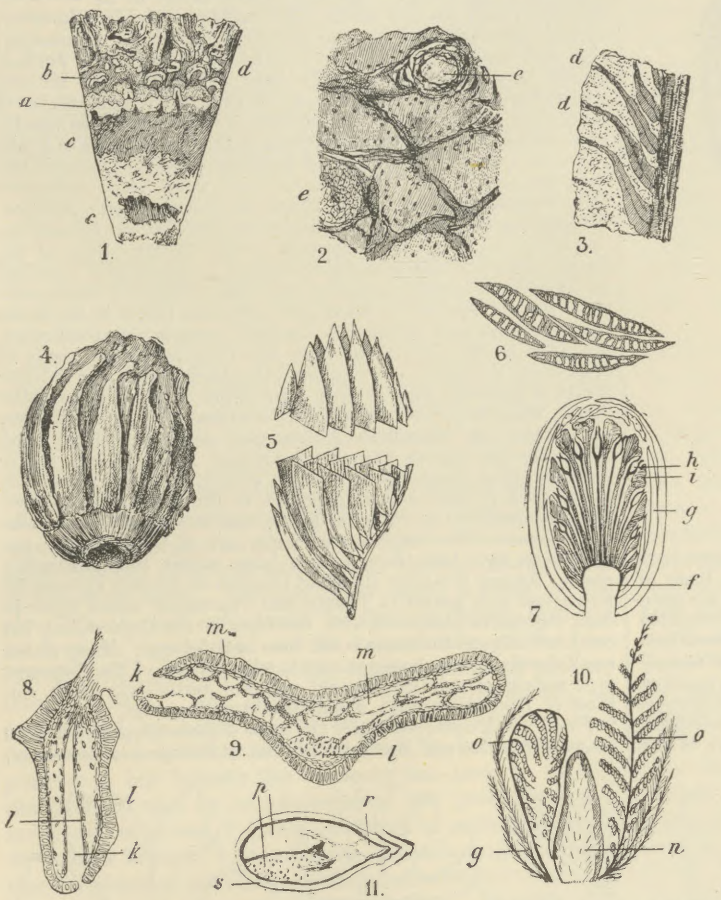

FIG. 15.—1, *Bennettites* stem: portion of transverse section of stem; *a*, vascular cylinder; *b*, leaf-traces; *c*, pith; *d*, cortex. 2, *Bennettites* stem, tangential section; *e*, flower-peduncles. 3, *Bennettites* stem, leaf-traces attached to the vascular cylinder and passing as simple strands through the cortex; *d*, cortex. 4, *Williamsonia*, Wealden, England. 5, Young leaf of *Bennettites*. 6, Ramenta of *Bennettites* in transverse section. 7, *Bennettites*, female flower in longitudinal section; *f*, apex of peduncle; *g*, bracts (shown in surface view in 4); *h*, seeds and seminiferous pedicels; *i*, interseminal scales. 8, *Bennettites*, synangium of male flower, showing line of dehiscence, *k*, and microspores, *l*. 9, Synangium, in transverse section, showing sporangial groups, *m*, and microspores, *l*. 10, *Bennettites* flower in vertical section, showing the central female portion, *n*, two sporophylls bearing synangia (male), *o*, and hairy bracts, *g*. 11, *Bennettites* seed in longitudinal section, showing the dicotyledonous embryo; *p*, cotyledons; *r*, radicle; *s*, testa. (1–3, *after Carruthers*; 5, 8, 9, and 10, *after Wieland*; 7, *after Scott*; 11, *after Solms-Laubach*.)

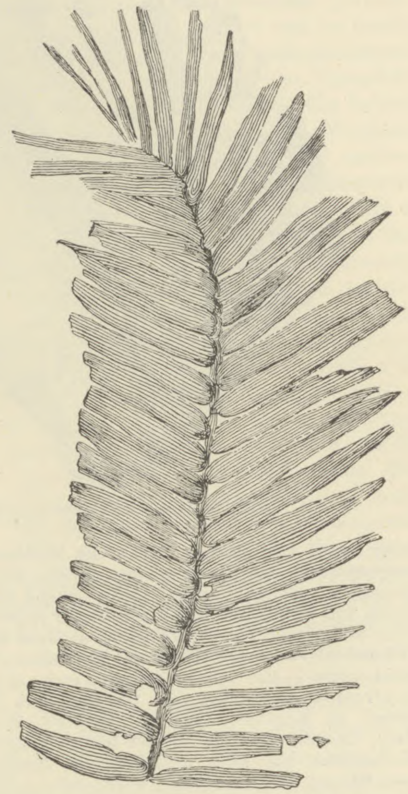

FIG. 16.—Frond of *Williamsonia gigas*. Inferior Oolite, England.

this view was regarded by Saporta and others as incorrect, and the nature of the Bennettitean foliage was left an open question. A recent re-examination of the English material in the museums of Paris and elsewhere has confirmed Williamson's conclusions. Mr Wieland of Yale has also described young bipinnate fronds, very like those of recent species of *Zamia* and *Encephalartos*, attached to a *Bennettites* stem, and exhibiting the vernation characters of

FIG. 17.—Fronds of *Williamsonia pecten.*

many recent Cycads (Fig. 15, 5). In *Williamsonia* the stem bore comparatively long fertile shoots, which, in contrast to those of *Bennettites*, projected several inches beyond the surface of the main trunk, and terminated in a flower which appears to have resembled those of the true *Bennettites*, so far at least as can be ascertained without the assistance of internal structure. The genus *Williamsonia* occurs in the Upper Gondwana rocks of India; it is recorded also from strata ranging from the Rhætic to the Lower Cretaceous period in England, Portugal, Sweden, Bornholm, Greenland, Italy, Canada, and the United States. Another member of the Bennettiteæ has been described by Nathorst from Rhætic beds in Scania, where certain Cycadean fronds, originally named by Brongniart *Anomozamites minor*, have been found in connexion with Bennettitean flowers; the specimens in the Stockholm Museum bear out Professor Nathorst's description. It would seem a safe statement to make, that the Cycadales, including both Cycadaceæ and Bennettiteæ, were represented during the Mesozoic period by a large number of species of almost world-wide distribution. These included some forms with flowers very similar to those of living genera, *e.g.*, *Androstrobus Balduini* from Bathonian rocks of France; *Zamites familiaris*, described many years ago by Corda, from Lower Cretaceous rocks of Bohemia, and *Androstrobus Nathorsti*, from Wealden beds in Sussex; but the majority of the species were characterized by flowers of a different type known as *Bennettites* and *Williamsonia*.

Ginkgoales. The living Maidenhair tree, *Ginkgo biloba* (see GYMNOSPERMS), remains, like *Matonia* and *Dipteris* among the ferns, as an isolated relic in the midst of recent vegetation. In Rhætic, Jurassic, and Wealden floras the Ginkgoales were exceedingly abundant (Map B, G_1–G_{17}); in addition to leaves agreeing almost exactly with those of the recent species (Fig. 18), there are others separated as a distinct genus, *Baiera* (Fig. 18, G), characterized by the greater number and narrower form of the segments, which may be best compared with such leaves as those of the recent fern *Actiniopteris* and of certain species of *Schizæa*. Male flowers, like those of *Ginkgo biloba*, but usually characterized by a rather larger number of oval pollen-sacs on the stamens, have been found in England, Germany, Siberia, and elsewhere in association with *Ginkgo* and *Baiera* foliage. The occasional occurrence of three or even four pollen-sacs on the stamens of the recent species affords a still closer agreement between the

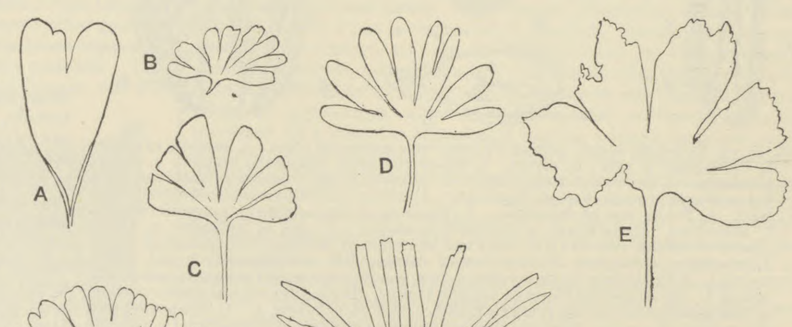

FIG. 18.—Leaves of Ginkgoales. A, *Ginkgodium*, Japan (Jurassic). B, C, D, E, F, H, *Ginkgo* leaves. extinct and living types. Seeds like those of *Ginkgo biloba* have also been recorded as fossils in Jurassic rocks, and it is not improbable that the type of flower known as *Beania*, from the Inferior Oolite rocks of Yorkshire, may have been borne by *Ginkgo* or *Baiera*. The regions from which satisfactory examples of Ginkgoales (*Baiera* or *Ginkgo*) have been recorded are shown in Map B (G_1–G_{17}). Both Tertiary and Mesozoic localities are indicated in the map.

Coniferales. An adequate account of fossil Mesozoic Conifers is impossible within the limits of this article. Coniferous twigs are very common in Mesozoic strata, but in most cases we are compelled to refer them to provisional genera, as the evidence of vegetative shoots alone is not sufficient to enable us to determine their position within the Coniferæ. There are, however, several forms which it is reasonable to include in the Araucarieæ; that this family was to the fore in the vegetation of the Jurassic period is unquestionable. We have not merely the striking resemblance of vegetative shoots to those of recent species of *Araucaria* and *Agathis*, *e.g.*, species of *Nageiopsis*, abundantly represented in the upper Jurassic beds of the Potomac area in North America, species of *Pagiophyllum* and other genera of Jurassic and Wealden age, but an abundance of fossil wood (*Araucarioxylon*) from Jurassic and Cretaceous strata in Europe, North America, Madagascar, and elsewhere agreeing with that of recent Araucarieæ, in addition to several well-preserved female flowers. Some of the fossils referred to the genus *Kaidocarpon*, and originally described as monocotyledonous inflorescences, are undoubted Araucarian cones; other cones of the same type have been placed in the genus *Cycadeostrobus* and referred to Cycads. *Araucarites Hudlestoni*, described by Mr Carruthers from the Coralline Oolite rocks of Malton in Yorkshire, *Araucarites sphærocarpa* from the Inferior Oolite of Somerset, also another cone found in the Northampton Sands, which is probably specifically identical with *A. Hudlestoni*, and named by Carruthers *Kaidocarpon ooliticum*, afford good illustrations of British Araucarian flowers. A flower of a rather different type, *Pseudaraucaria major*, exhibiting in the occurrence of two seeds in each scale an approach to the cones of Abietineæ, has been described by Professor Fliche from Lower Cretaceous rocks of Argonne. The well-known Whitby jet of Upper Liassic age appears to have been formed to a large extent from Araucarian wood. Among the more abundant Conifers of Jurassic age may be mentioned such genera as *Thuytes* and *Cupressites*, which agree in their vegetative characters with members of the Cupressineæ, but our knowledge of the cones is far from satisfactory. Many of the small female flowers borne on shoots with foliage of the *Cupressus* type consist of spirally disposed and not verticillate scales, *e.g.* those of *Thuytes expansus*, a common Jurassic species.

Fossil wood, described under the name *Cupressinoxylon*, has been recorded from several Mesozoic horizons in Europe and elsewhere, but this term has been employed in a wide sense as a designation for a type of structure met with not only in the Cupressineæ, but in members of other families of Coniferæ. The Abietineæ do not appear to have played a prominent part before the Wealden period; various older species, *e.g.*, Rhætic specimens from Scania, are recorded, but it is not until we come to the Upper Jurassic and Wealden periods that this modern family was abundantly represented. Fossil wood of the *Pinites* type (*Pityoxylon*) has been described from England, France, Germany, Sweden, Spitsbergen, North America, and elsewhere; some of the best British examples have been obtained from the so-called Pine-raft, the remains of water-logged and petrified wood of Lower Greensand age, seen at low water near Brook Point in the Isle of Wight. Well-preserved Abietineous female flowers have been obtained from the Wealden rocks of England and Belgium, *e.g.*, *Pinites Dunkeri*, *P. Solmsi*, &c.; specimens of seeds and vegetative shoots are recorded also from Spitsbergen, Franz Josef Land, and other regions. Cones of Lower Cretaceous age have been described by Fliche from Argonne, which bear a close resemblance to the female flowers of recent species of *Cedrus*. The striking resemblance between such a fossil genus as *Brachyphyllum* and the Tasmanian Conifer *Athrotaxis* is striking enough to warrant a comparison; but in this case actual proof of close relationship is lacking. The two surviving species of *Sequoia* afford an illustration of the persistence of an old type, but unfortunately most of the Mesozoic species referred to this genus do not possess sufficiently perfect cones to confirm their identification as examples of *Sequoia*. Some of the best examples of cones and twigs which have been referred to *Sequoia* are those described by Heer from Cretaceous rocks of Greenland.

There are a few points suggested by a general survey of the Mesozoic floras, which may be briefly touched on in conclusion. In following the progress of plant-life through those periods in the history of the earth of which records are left in ancient sediments, seams of coal, or old land-surfaces, we recognize at certain stages a want of continuity between the floras of successive ages. The imperfection of the geological record, considered from the point of view of evolution, has been rendered familiar by Darwin's remarkable chapter in the *Origin of Species*. Breaks in the chain of life, as represented by gaps in the blurred and incomplete documents afforded by fragmentary fossils, are a necessary consequence of the general plan of geological evolution; they mark missing chapters rather than sudden breaks in an evolutionary series. On the other hand, a study of the plant-life of past ages tends to the conviction that too much stress may be laid on the imperfection of the geological record as a factor in the interpretation of palæontological data. The doctrine of Uniformitarianism, as propounded by Lyell, served to establish geology on a firmer and more rational basis than it had previously possessed; but latterly the tendency has been to modify the Lyellian view by an admission of the probability of a more intense action of groups of forces at certain stages of the earth's history. As a definite instance, a short review may be given of the evidence of palæobotanical records as regards their bearing on plant-evolution. Starting with the Permo-Carboniferous vegetation, and omitting for the moment the Glossopteris flora, we find a comparatively homogeneous flora of wide geographical range, consisting to a large extent of arborescent Lycopods, Calamites, and other Vascular Cryptogams, plants which occupied a place comparable with that of Gymnosperms and Angiosperms in our modern forests; with these were other types of the greatest phylogenetic importance, which serve as finger-posts pointing to lines of evolution of which we have but the faintest signs among existing plants. Other types, again, which may be referred to the Gymnosperms, played a not unimportant part in the Palæozoic vegetation. No conclusive proof has so far been adduced of the existence in those days of the Cycads, nor is there more than partial evidence of the occurrence of genera which can be placed with confidence in any of the existing families of Conifers. There are, moreover, no facts furnished by fossil plants in support of the view that Angiosperms were represented either in the low-lying forests or on the slopes of the mountains of the Coal period. Passing higher up the geological series, we find but scanty records of the vegetation that existed during the closing ages of the Permian period, and of the plants which witnessed the beginning of the Triassic period we have to be content with the most fragmentary relics. It is in rocks of Upper Triassic and Rhætic age that abundant remains of rich floras are met with, and an examination of the general features of the vegetation reveals a striking contrast between the Lower Mesozoic plants and those of the Palæozoic period. Arborescent Pteridophytes are barely represented, but such dominant types as *Lepidodendron*, *Sigillaria*, *Calamites*, and *Sphenophyllum* have practically ceased to exist; Cycads and Conifers have assumed the leading rôle, and the still luxuriant fern vegetation has put on a different aspect. This description applies almost equally to the floras of the succeeding Jurassic and Wealden periods. The change to this newer type of vegetation was no doubt less sudden than it appears as read from palæobotanical records, but the transition period between the Palæozoic type of vegetation and that which flourished in the Lower Mesozoic era, and continued to the close of the Wealden age, was probably characterized by rapid or almost sudden changes. In the southern hemisphere the Glossopteris flora succeeded a Lower Carboniferous vegetation with a rapidity similar to that which marked the passage in the north from Palæozoic to Mesozoic floras. This apparently rapid alteration in the character of the southern vegetation took place at an earlier period than that which witnessed the transformation in the northern hemisphere. The appearance of a new type of vegetation in India and the southern hemisphere was probably connected with a widespread lowering of temperature, to which reference has already been made. It was from this Glossopteris flora that several types gradually migrated across the equator, where they formed part of the vegetation of more northern regions. The difference between the Glossopteris flora and those which have left traces in the Upper Gondwana rocks of India, in the Wianamatta and Hawkesbury beds of Australia, and in the Stormberg series of South Africa is much less marked than that between the Permo-Carboniferous flora of the northern hemisphere and the succeeding Mesozoic vegetation. In other words, the change took place at an earlier period in the south than in the north. To return to the northern hemisphere, it is clear that the Wealden flora, as represented by plants recorded from England, France, Belgium, Portugal, Russia, Germany, and other European regions, as also from Japan and elsewhere, carries on, with minor differences, the facies of the older Jurassic floras. It was at the close of the Wealden period that a second evolutionary wave swept over the vegetation of the world. This change is most strikingly illustrated by the inrush of Angiosperms, in the equally marked decrease in the Cycads, and in the altered character of the Ferns. It would appear that in this case the new influence, supplied by the advent of Angiosperms, had its origin in the north. Unfortunately, our knowledge of the later floras in the southern hemisphere is very incomplete, but a similar transformation appears to have characterized the vegetation south of the equator. As to the nature of the chief factors concerned in the two revolutions in the vegetable kingdom, if it is admissible to use so strong a term, only a guess can be hazarded. Physical conditions no doubt played an important part, but whatever cause may have had the greatest share in disturbing the equilibrium of evolutionary forces, it would seem that the apparently sudden appearance of Cycads and other types at the close of the Palæozoic period made a widespread and sudden impression on the whole character of the vegetation. At a later stage—in post-Wealden days—it was the appearance of Angiosperms, probably in northern latitudes, that formed the chief motive power in accelerating the transition in the facies of plant-life from that which marked what we have called the Mesozoic floras, to the vegetation of the Upper Cretaceous and Tertiary periods. With the advent of Angiosperms began, as the late Marquis of Saporta expressed it, "Une révolution, ainsi rapide dans sa marche qu'universelle dans ses effets." From the floras of Tertiary age we pass by gradual stages to those which characterize the present phase of evolutionary progress. Among modern floras we find here and there isolated types, such as *Ginkgo*, *Sequoia*, *Matonia*, *Dipteris*, and the Cycads, persisting as more successful survivals which have held their own through the course of ages; these plants remain as vestiges from a remote past, and as links connecting the vegetation of to-day with that of the Mesozoic era.

III. TERTIARY.

Lower Cretaceous.

After the Wealden period, and before the deposition of the lowest strata of the Chalk, so remarkable a change takes place in the character of the vegetation that this break must be taken as, botanically, the transition point from a Secondary to a Tertiary flora. A flora consisting entirely, with a single doubtful exception, of Gymnosperms and Cryptogams gives place to one containing many flowering plants; and these increase so rapidly that before long they seem to have crowded out many of the earlier types, and to have themselves become the dominant forms. Not only do Angiosperms suddenly become dominant in all known plant-bearing deposits of Upper Cretaceous age, but strangely enough the earliest found seem to belong to living orders, and commonly are referable to existing genera. From Cretaceous times onwards local distribution may change; yet the successive floras can be analysed in the same way as, and compared with, the living floras of different regions. World-wide floras, such as seem to characterize some of the older periods, have ceased to be, and plants are distributed more markedly according to geographical provinces and in climatic zones. This being the case, it will be most convenient to discuss the Tertiary floras in successive order of appearance, since the main interest no longer lies in the occurrence of strange extinct plants or of transitional forms connecting orders now completely isolated.

The accurate correlation in time of the various scattered plant-bearing deposits is a matter of considerable difficulty, for plant-remains are preserved principally in lacustrine strata laid down in separate basins of small extent. This it is obvious must commonly be the case, as most leaves and fruits are not calculated to drift far in the sea without injury or in abundance; nor are they likely as a rule to be associated with marine organisms. Deposits containing marine fossils can be compared even when widely separated, for the ocean is continuous and many marine species are world-wide. Plants, on the other hand, like land and fresh-water animals, occupied areas which may or may not have been continuous. Therefore, without a knowledge of the physical geography of any particular period, we cannot know whether like or unlike floras might be expected in neighbouring areas during that period. If, however, we discover plant-bearing strata interstratified with deposits containing marine fossils, we can fix the period to which the plants belong, and may be able to correlate them in distinct areas, even though the floras be unlike. This clear stratigraphical evidence is, however, so rarely found, that much uncertainty still remains as to the true age of several of the floras now to be described.

In rocks approximately equivalent to the Lower Greensand of England, or slightly earlier, Angiosperms make their first appearance; but as the only strata of this age in Britain are of marine origin, we have to turn to other countries for the evidence. The earliest Angiosperm yet found in Europe is a single monocotyledonous leaf of doubtful affinities, named by Saporta *Alismacites primævus* (Fig. 1) and found in the Valenginian strata of Portugal. These deposits seem to be equivalent to British Wealden rocks, though in the latter, even in their upper part, no trace of Angiosperms has been discovered. No other undoubted Angiosperm has yet been discovered in Europe in strata of this age, but Heer records a poplar-like leaf from Urgonian strata, a stage newer than the Valenginian, in Greenland, and Saporta has described from strata of the same date in Portugal a Euphorbiaceous plant apparently closely allied to the living *Phyllanthus* and named by him *Choffatia Francheti* (Fig. 2). We must turn to North America for a fuller knowledge of the earliest flowering plants.

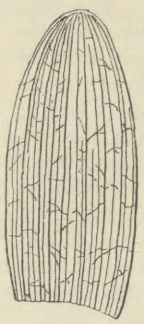

FIG. 1.—*Alismacites primævus.*

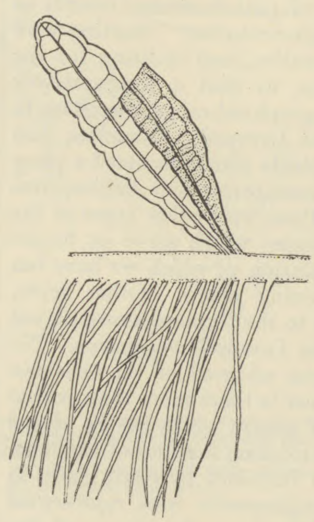

FIG. 2.—*Choffatia Francheti.*

American Cretaceous.

In Dakota a remarkable series has been discovered, lying unmistakably between marine Upper Jurassic rocks below and Upper Cretaceous above. There has been a certain amount of confusion as to the exact strata in which the plants occur, but this has now been cleared up by the researches of Lester Ward, who has shown how the Secondary flora gives place to one of Tertiary character. The lower strata—*i.e.*, those most allied to the Jurassic—contain only Gymnosperms and Cryptogams. The next division (Dakota No. 2 of Meek and Hayden) contains Gymnosperms and Ferns of Neocomian types, or even of Neocomian species; but mingled with these occur a few dicotyledonous leaves belonging to four genera. The specimens are very fragmentary, and all that can be said is that one of the forms may be allied to oak, another to fig, a third to *Sapindus*, and the fourth may perhaps be near to elm. The "Potomac Formation" of Virginia and Maryland is doubtless also mainly of Neocomian age, for though it rests unconformably on much older strata, the successive floras found in it are so allied to those of Dakota as to leave little doubt as to the general homotaxis of the series. Lester Ward records no fewer than 737 distinct forms, consisting chiefly of Ferns, Cycads, Conifers, and Dicotyledons, the Ferns and Cycads being confined mainly to the Older Potomac, while the Dicotyledons are principally represented in the Newer Potomac, though occurring more rarely even down to the base of the series. Six successive stages have been defined in the Potomac formation. The Mount Vernon beds, which occur about the middle of the series, have as yet yielded only a small number of species, though these include the most interesting early Angiosperms. Among them are recorded a *Casuarina*, a leaf of *Sagittaria* (which however, as observed by Zeiller, may belong to *Smilax*), two species of poplar-like leaves with remarkably cordate bases, *Menispermites* (possibly a water-lily), and *Celastrophyllum* (perhaps allied to *Celastrus*). *Proteophyllum*, found in the same bed, and also in the Infra-Cretaceous of Portugal, seems to have belonged to a Proteaceous plant, though only leaves without fruits have yet been discovered in deposits of this early date. Whatever doubt may be left as to the exact botanical position of these early Lower Cretaceous Angiosperms, it is clear that both Monocotyledons and Dicotyledons are represented by several types of leaves, and that the flora extended over wide areas in North America and Greenland, and is found again at a few points in Europe. There is as yet no clear evidence either of climatic zones or of the existence of geographical provinces during this period.

The next strata, the Aquila Creek series, contain a well-marked dicotyledonous flora, in which both the form and nervation of the leaves begin to approximate to those of recent times. The leading characteristic of this Middle Potomac flora is the proportion of Dicotyledons. Notwithstanding this apparent passage-bed, there is a marked difference between the Older and the Newer Potomac floras, very few species passing from the one to the other. Only 15 out of 405 plants in the older series occur in the beds above, though already more than 350 species have been determined from this newer series. The plants from the Amboy Clays, which form the most important division of the Newer Potomac series and were monographed in 1895 by Newberry, seem to belong to the commencement of the Upper Cretaceous period. It is remarkable that nearly 80 per cent. of the species are Dicotyledons, and that no Monocotyledons have been found. The mere enumeration of the genera will indicate how close the flowering plants are to living forms. Newberry records *Juglans*, *Myrica* (7 species), *Populus*, *Salix* (5 species), *Quercus*, *Planera*, *Ficus* (3 species), *Persoonia* and another extinct Proteaceous genus named *Proteoides*, Magnolia (7 species), *Liriodendron* (4 species), *Menispermites*, *Laurus*, and allied plants, *Sassafras* (3 species), *Cinnamomum*, *Prunus*, *Hymenœa*, *Dalbergia*, *Bauhinia*, *Caesalpinia*, *Fontainea*, *Colutea*, and other Leguminosæ, *Ilex*, *Celastrus*, *Celastrophyllum* (10 species), *Acer*, *Rhamnites*, *Paliurus*, *Cissites*, *Tiliœphyllum*, *Passiflora*, *Eucalyptus* (5 species), *Hedera*, *Aralia* (8 species), *Cornophyllum*, *Andromeda* (4 species), *Myrsine*, *Sapotacites*, *Diospyros*, *Acerates*, *Viburnum*, and various genera of uncertain affinities. The points that suggest themselves with regard to this flora are, that it includes a fair representation of the existing orders of warm-temperate deciduous trees; that the more primitive types, such as the *Amentaceæ*, do not appear to preponderate to a greater extent than they do in the existing temperate flora; that the assemblage somewhat suggests American affinities; and that when we take into account deficient collecting, local conditions, and the non-preservation of succulent plants, there is no reason for saying that certain other orders must have been absent. The great rarity of Monocotyledons is a common characteristic of fossil floras known only, as this one is, from leaves principally belonging to deciduous trees. With regard to suggested American affinities, it must be borne in mind that the Neocomian Angiosperms are little known except in America and in Greenland, and that we therefore cannot yet say whether families now mainly American were not formerly of world-wide distribution. We know that this was the case with some, such as *Liriodendron*; and in *Eucalyptus* we see the converse, where a genus formerly American is now confined to a far distant region. The Neocomian flora has been collected from an area extending over about 30° of latitude; but there is little evidence of any corresponding climatic change. We cannot yet say, however, that the deposits are exactly contemporaneous, and the great climatic variations that have taken place in the northern hemisphere during the existence of our living flora should make us hesitate to correlate too minutely from the evidence of plants alone.

The highest division of the Dakota series (known as Dakota No. 1) which lies immediately beneath Upper Cretaceous strata with marine fossils, contains a flora so like that of the Tertiary deposits that only the clearest geological evidence has been considered sufficient to prove that Heer was wrong when he spoke of the plants as Miocene. These highest plant-bearing strata rest, according to Lester Ward, somewhat unconformably on the Dakota No. 2; they show also a marked difference in the included plants. The genera of Dicotyledons represented are *Quercus*, *Sassafras*, *Platanus*, *Celastrophyllum*, *Cissites*, *Viburnites*.

In the central parts of North America the lacustrine plant-bearing deposits are of enormous thickness, the Dakota series being followed by marine Cretaceous strata known as the Colorado and Montana groups, and these being succeeded conformably by a thousand feet or more of lacustrine shales, sandstones, and coal-seams belonging to the Laramie series. This also contains occasional marine Upper Cretaceous fossils, as well as reptiles of Cretaceous types. An extensive literature has grown up relating to these Laramie strata, for owing to the Tertiary aspect of the contained plants, geologists were slow to recognize that they could be truly contemporaneous and interbedded with others yielding Cretaceous animals. In addition to this, the earlier writers included in the Laramie series many deposits now known to be of later date and truly Tertiary, and the process of separation is even now only partially completed. It will be safest in these circumstances to accept as our guide to the true Laramie flora the carefully compiled "Catalogue" of Mr Knowlton. According to this catalogue, the true Laramie flora includes about 250 species, more than half of which are deciduous forest trees, herbaceous Dicotyledons, Monocotyledons, and Cryptogams all being but poorly represented. Among the few Monocotyledons are leaves and fruits of palms, and traces of grasses and sedges. The Dicotyledons include several water-lilies, a somewhat doubtful *Trapa*, and many genera of forest trees still common in America. The genera best represented are *Ficus* (21 species), *Quercus* (16 species), *Populus* (11 species), *Rhamnus* (9 species), *Platanus* (8 species), *Viburnum* (7 species), *Magnolia*

(6 species), *Cornus* (5 species), *Cinnamomum* (5 species), *Juglans* (4 species), *Acer* (4 species), *Salix* (4 species), *Aralia* (3 species), *Rhus* (3 species), *Sequoia* (3 species). Of trees now extinct in America, *Eucalyptus* and *Ginkgo* are perhaps the most noticeable. So large a proportion of the trees still belongs to the flora of North America that one is apt to overlook the fact that among the more specialized plants some of the largest American orders, such as the *Compositæ*, are still missing from strata belonging to the Cretaceous period.

European Cretaceous. The imperfection and want of continuity of the records in Europe have made it necessary in dealing with the Cretaceous floras for us to give the first place to America. But it is now advisable to return to Europe, where Upper Cretaceous plants are not uncommon, and the position of the deposits in the Cretaceous series can often be fixed accurately by their close association with marine strata belonging to definite subdivisions. As these divisions of Cretaceous time will have to be referred to more than once, it will be useful to tabulate them, thus showing which plant-beds seem to be referable to each, and what are the British strata of like age. It has not yet been found possible so closely to correlate the strata of Europe with those of America, where distance has allowed geographical differences in both fauna and flora to come into play; therefore, beyond the references to Lower or Upper Cretaceous, no classification of the American Cretaceous strata has here been given. In Europe the most commonly accepted divisions of the Cretaceous period are as follows:—

England.	France, &c.
Wanting	Danian
Upper Chalk	Senonian
Middle Chalk	Turonian
Lower Chalk, Upper Greensand	Cenomanian
Gault	Albian·
	Aptian
Lower Greensand	Valenginian
	Urgonian
Wealden	Neocomian

In the Continental classification the deposits from the Gault downwards are grouped as Lower Cretaceous; but in Great Britain there is a strong break below the Gault and none above; and the Gault is therefore classed as Upper Cretaceous. The limits of the divisions in other places do not correspond, the British and Continental strata often being so unlike that it is almost impossible to compare them. The doubt as to the exact British equivalent of the Valenginian strata of Portugal, which yield the earliest Dicotyledon, has already been alluded to. The plant-bearing deposits next in age, which have yielded Angiosperms, appear to belong to the Cenomanian, though from Westphalia a few species belonging to the Cryptogams and Gymnosperms, found in deposits correlated with the Gault, have been described by Hosius and von der Marck.

In Great Britain the whole of the Upper Cretaceous strata are of marine origin, and have yielded no land-plants beyond a few fir-cones, drift-wood, and rare Dicotyledonous leaves in the Lower Chalk. Most of the deposits which have yielded Angiosperms of Cretaceous age in central Europe correspond in age with the English Upper Chalk (Senonian) but a small Cenomanian flora has been collected from the Unter Quader in Moravia. Heer described from this deposit at Moletein 13 genera, of which 7 are still living, containing 18 species, viz., 1 fern, 4 Conifers, 1 palm, 2 figs, 1 *Credneria*, 2 laurels, 1 *Aralia*, 1 *Chondrophyllum* (of uncertain affinities), 2 magnolias, 2 species of *Myrtaceæ*, and a species of walnut. Saxony yields from strata of this period at Niederschoena 42 species, described by Ettingshausen. This small flora is most remarkable, for no fewer than 6 genera, containing 8 species, are referred to the *Proteaceæ*. The Cenomanian flora of Bohemia is larger and equally peculiar. Among the Dicotyledons described by Velenovsky are the following:—*Credneria* (5 species), *Araliaceæ* (17 species), *Proteaceæ* (8 species), *Myrica* (2 species), *Ficus* (5 species), *Quercus* (2 species), *Magnoliaceæ* (5 species), *Bombaceæ* (3 species), *Laurineæ* (2 species), *Ebenaceæ* (2 species), *Verbenaceæ*, *Combretaceæ*, *Sapindaceæ* (2 species), *Camelliaceæ*, *Ampelideæ*, *Mimoseæ*, *Caesalpinieæ* (5 species), *Eucalyptus* (2 species), *Pisonia*, *Phillyrea*, *Rhus*, *Prunus*, *Bignonia*, *Laurus*, *Salix*, *Benthamia*. To this list Bayer adds *Aristolochia*. The Cenomanian flora of central Europe appears to be a subtropical one, with marked approaches to the living flora of Australia. The majority of its Dicotyledons belong to existing genera, but one of the most prolific and characteristic Cretaceous forms is *Credneria* (Fig. 3), a genus of doubtful affinities, which has been compared by different authors to the poplars, planes, limes, and other orders.

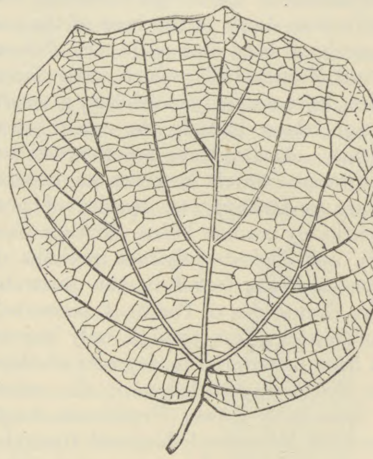

Fig. 3.—*Credneria triacuminata.*

The Cretaceous plant-beds of Westphalia include both Upper and Lower Senonian, the two floras being very distinct. Hosius and von der Marck describe, for instance, 12 species of oak from the Upper and 6 from the Lower strata, but no species is common to the two. The same occurs with the figs, with 3 species above and 8 below. The 6 species of *Credneria* are all confined to the older deposits. In fact, not a single Dicotyledon is common to these two closely allied divisions of the Cretaceous series; a circumstance not easy to explain, when we see how well the oaks and figs are represented in each. Four species of *Dewalquea*, a ranunculaceous genus allied to the hellebore, make their appearance in the Upper Senonian of Westphalia, other species occurring at Aix-la-Chapelle in deposits of about the same age. The Senonian flora of the last-named place, and that of Maestricht, are still only imperfectly known. It is unnecessary to trace the variations of the Upper Cretaceous flora from point to point; but the discoveries within the Arctic circle have been so surprising that attention must again be called to them. Besides the Lower Cretaceous plants already mentioned, Heer has described from Greenland a flora of Cenomanian age, and another belonging to the Senonian. The Cenomanian strata have yielded already 177 species, the different groups being represented in these proportions:—Cryptogams, 37, 30 of which are Ferns; Cycads, 8; Conifers, 27; Monocotyledons, 8; Apetalæ, 31; other Dicotyledons, 66. The Senonian strata have yielded 118 species, 21 of which are Cryptogams, 11 Conifers, 5 Monocotyledons, 75 Dicotyledons. Forest trees, especially oaks, are plentiful, and many of the species are identical with those found in Cretaceous deposits in more southern latitudes. Both of these floras suggest, however, that the climate of Greenland was somewhat colder than that of Westphalia, though scarcely colder than warm-temperate.

The Cretaceous deposits just described are followed by a series of Tertiary formations, but in Europe the continuity between Cretaceous and Tertiary is not quite complete. The Tertiary formations have been assigned to six periods; these are termed—Palæocene, Eocene, Oligocene, Miocene, Pliocene, Pleistocene, and each has its own botanical peculiarities. During the first period the plants were not markedly different from those of the Upper Cretaceous. Its flora is still but imperfectly known, for we are dependent on two or three localities for the plants. There is found at Sézanne, about 60 miles east of Paris, an isolated deposit of calcareous tufa full of leaves, which gives a curious insight into the vegetation which flourished in Palæocene times around a waterfall. Sézanne yields Ferns in profusion, mingled with other shade-loving plants such as would grow under the trees in a moist ravine; its vegetation is comparable to that of an island in the tropical seas. Monocotyledons are rare, the only ones of much interest being some fragments of pandanaceous leaves. The absence of Gymnosperms is noticeable. The Proteaceæ are also missing; but other Dicotyledons occur in profusion, many of them being remarkable for the large size of their deciduous leaves. Among the flowering plants are *Dewalquea*, a ranunculaceous genus already mentioned as occurring in the Upper Cretaceous, and numerous living genera of forest-trees, such as occur throughout the Tertiary period, and are readily comparable with living forms. Saporta has described about seventy Dicotyledons, most of which are peculiar to this locality. The plant-bearing marls of Gelinden, near Liége, contain the débris of a palæocene forest. The trees seemed to have flourished on neighbouring chalky heights. The most abundant species of this forest were the oaks and chestnuts, of which a dozen have been collected; laurels, *Viburnum*, ivy, several Aralias, *Dewalquea*, a *Thuja*, and several Ferns may be added. This flora is compared by Saporta and Marion with that of southern Japan. Other deposits of this age in France have furnished plants of a more varied aspect, including myrtles, araucarias, a bamboo, and several fan-leaved palms. Saporta points out the presence in these Palæocene deposits of certain types common, on the one hand, to the American Tertiary strata between the Missouri and the Rocky Mountains, and on the other, to the Tertiary flora of Greenland. The Palæocene deposits of Great Britain are of marine origin, and only yield pine-cones and fragments of *Osmunda*.

Palæocene plants.

The British Eocene and Oligocene strata yield so large a flora, and contain plant-beds belonging to so many different stages, that it is unfortunate we have still no monograph on the subject, the one commenced by Gardner and Ettingshausen in 1879 having reached no farther than the Ferns and Gymnosperms. This deficiency makes it impossible adequately to deal with the British Eocene plants, most of the material being either unpublished or needing re-examination. In the earliest Eocene plant-beds, in the Woolwich and Reading series, a small but interesting flora is found, which suggests a temperate climate less warm than that of earlier or of later periods. Leaves of planes are abundant, and among the plants recorded are two figs, a laurel, a *Robinia*, a *Grevillea*, and a palm. Ferns are scarce, Ettingshausen and Gardner recording only *Anemia subcretacea* and *Pteris* (?) *Prestwichii*. The only Gymnosperms determined are *Libocedrus adpressa*, which is close to *L. decurrens* of the Yosemite, and *Taxodium europæum*. A few plants have been found in the next stage, the Oldhaven beds, and among these are fig and cinnamon. Gardner considers the plants to point to subtropical conditions. The London Clay has yielded a large number of plants, but most of the species are represented by fruits alone, not by leaves. This circumstance makes it difficult to compare the flora with that of other formations, for not only is it uncertain which leaves and fruits belong to the same plant, but there is the additional source of doubt, that different elements of the same flora may be represented at different localities. Of some plants only the deciduous leaves are likely to be preserved, whilst other succulent-leaved forms will only be known from their woody fruits. Among the 200 plants of the London Clay are no Ferns, but 6 genera of Gymnosperms, viz., *Callitris* (2 species), *Sequoia*, *Athrotaxis* (?) *Ginkgo*, *Podocarpus*, *Pinus*; and several genera of palms, of which the tropical *Nipa* is the most abundant and most characteristic, among the others being fan-palms of the genera *Sabal* and *Chamærops*. The Dicotyledons need further study. Among the fruits Ettingshausen records *Quercus*, *Liquidambar*, *Laurus*, *Nyssa*, *Diospyros*, *Symplocos*, *Magnolia*, *Victoria*, *Hightea*, *Sapindus*, *Cupania*, *Eugenia*, *Eucalyptus*, *Amygdalus*; he suggests that the fruits of the London Clay of Sheppey may belong to the same plants as the leaves found at Alum Bay in the Isle of Wight.

Eocene and Oligocene of Great Britain.

The next stage is represented by the Lower Bagshot leaf-beds of Alum Bay. These pipeclays yield a varied flora, Ettingshausen recording 274 species, belonging to 116 genera and 63 families. Gardner, however, is unable to reconcile this estimated richness with our knowledge of the flora, and surmises that fossil plants from other localities must have been inadvertently included. He considers the flora to be the most tropical of any that has so far been studied in the northern hemisphere. Its most conspicuous plants are *Ficus Bowerbankii*, *Aralia primigenia*, *Comptonia acutiloba*, *Dryandra Bunburyi*, *Cassia Ungeri*, and the fruits of *Caesalpinia*. The floras which it chiefly resembles are first, that of Monte Bolca, and second, that of the Grès du Soissonais, which latter Gardner thinks may be of the same age, and not earlier, as is generally supposed. The total number of species found at Alum Bay, according to this author, is only about 50 or 60.

To the Bagshot Sand succeeds the thick mass of sands with intercalated plant-beds seen in Bournemouth cliffs. Each bed yields peculiar forms, the total number of species amounting to many hundred, most of them differing from those occurring in the strata below. The plants suggest a comparison of the climate and forests with those of the Malay Archipelago and tropical America. At one place we find drifted fruits of *Nipa*, *Hightea*, and *Anona*; at another perfect limbs of an American form of cactus, found also at Bovey Tracey. Other beds yield principally palms, willows, laurels, *Eucalyptus*, or Ferns; but there are no Cycads. As showing the richness of this flora, we may mention that in the only orders which have yet been monographed, Ferns are represented by 17 species and Gymnosperms by 10, though these are not the groups best represented. Gardner speaks of the Bournemouth flora as appearing to consist principally of trees or hard-wooded shrubs, comparatively few remains of the herbaceous vegetation being preserved. The lignite deposits and pipeclays of Bovey Tracey, in Devon, referred by Heer and Pengelly to the Miocene period, have now been shown by Gardner to be of the same age as the Bournemouth Beds; many of the species, including all the Dicotyledonous leaves of Bovey, occurring also at Bournemouth. One of the commonest Ferns at both localities, *Osmunda lignita*, is scarcely distinguishable from a species found in the Philippines. The higher Eocene strata of England—those above the Bournemouth Beds—are of marine origin, and yield only drifted fruits, principally fir-cones

In the volcanic districts of the south-west of Scotland

and the north-east of Ireland plant-beds are found intercalated between the lava-flows. These also, like the lignites of Bovey Tracey, have been referred to the Miocene period, on the supposed evidence of the plants; but more recent discoveries by Gardner tend to throw doubt on this allocation, and suggest that, though of various ages, the first-formed of these deposits may date back to early Eocene times. The flora found in Mull points distinctly to temperate conditions; but it is not yet clear whether this indicates a different period from the sub-tropical flora of the south of England, or whether the difference depends on latitude or local conditions. The plants include a Fern, *Onoclea hebridica*, close to a living American form; four Gymnosperms belonging to the genera *Cryptomeria*, *Ginkgo*, *Taxus* and *Podocarpus*; Dicotyledons of about 30 species, several of which have been figured. Among the Dicotyledons may be mentioned *Platanus*, *Acer* (?), *Quercus* (?), *Viburnum*, *Alnus*, *Magnolia*, *Corylus* (?), *Castanea* (?), *Zizyphus*, *Populus*, and the nettle-like *Bœhmeria antiqua*. The absence of the so-called cinnamon-leaves and the *Smilaceæ*, which always enter into the composition of Middle Eocene and Oligocene floras, is noticeable. The Irish strata yield two Ferns; 7 Gymnosperms, *Cupressus*, *Cryptomeria*, *Taxus*, *Podocarpus*, *Pinus* (2 species), *Tsuga*; and leaves of about 25 Dicotyledons. The most abundant leaf, according to Gardner, does not seem distinct from *Celastrophyllum Benedeni*, of the Palæocene strata of Gelinden; a water-lily, *Nelumbium Buchii*, occurs also in Oligocene beds on the Continent; the species of *MacClintockia* (Fig. 4) is found both in the Arctic floras and at Gelinden. Among the other plants are an alder, an oak, and a doubtful cinnamon.

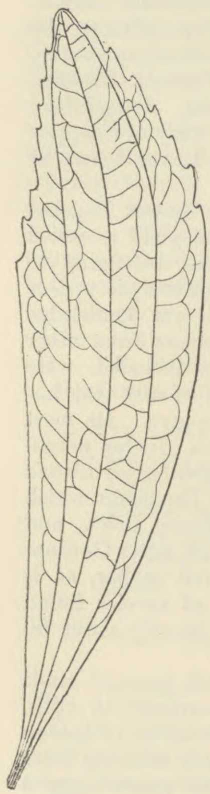

Fig. 4.—*MacClintockia trinervata.*

Leaving these Scottish and Irish deposits of doubtful age, we find in the Hampshire Basin a thick series of fluviatile, lacustrine, and marine deposits undoubtedly of Lower and Middle Oligocene date. Their flora is still a singularly poor one, though plants have been obtained at many different levels; they perhaps indicate a somewhat cooler climate than that of the Bournemouth series. Among the more abundant plants are nucules of several species of *Chara*, and drifted fruits and seeds of water-lilies, of *Folliculites* (a genus probably close to *Stratiotes*) and of *Limnocarpus* (allied to *Potamogeton*); there is little else mixed with these. Other seams are full of the twigs and cones of *Athrotaxis*, a Conifer now confined to Tasmania. Ferns are represented by *Gleichenia*, *Lygodium*, and *Chrysodium Lanzæanum*, which last has a very wide range in time; Monocotyledons, by a Sabal and a feather-palm, as well as by the two aquatic genera above mentioned; Gymnosperms, by the extinct araucarian genus *Doliostrobus*, by rare pine-cones, and by *Athrotaxis*. Dicotyledonous leaves are not plentiful, the genera recorded being *Andromeda*, *Cinnamomum*, *Zizyphus*, *Rhus*, *Viburnum*. Above the Oligocene strata in Great Britain there is a complete break, no species of plant ranging upwards into the next fossiliferous division.

Space will not allow us to deal with the numerous scattered deposits which have yielded Tertiary plants. It will be more to the purpose to take distant areas, where the order of the strata is clear, and compare the succession of the floras with that met with in other geographical regions and in other latitudes. For this study it will be most convenient to take next south and central France, for in that area can be found a series of plant-bearing strata in which is preserved a nearly continuous history of the vegetation from Upper Eocene down to Pliocene. The account is taken mainly from the writings of Saporta.

Central and southern France.

The gypsum-deposit of Upper Eocene date at Aix in Provence commences this series, and is remarkable for the variety and perfect preservation of its organic remains. Among its Gymnosperms are numerous *Cupressineæ* of African affinity belonging to the genera *Callitris* and *Widdringtonia*, and a juniper close to one indigenous in Greece. Fan-palms, several species of dragon-tree, and a banana like one living in Abyssinia represent the more peculiar Monocotyledons. Among the noticeable Dicotyledons are the *Myricaceæ*, *Proteaceæ*, *Laurineæ*, *Bombax*, the Judas-tree, *Acacia*, *Ailanthus*, while the most plentiful forms are the *Araliaceæ*. Willows and poplars, with a few other plants of more temperate regions, are found rarely at Aix, and seemingly point to casual introduction from surrounding mountains. In a general way, spiny plants, with stiff branches and dry and coriaceous leaves, dominate the flora, as they now do in Central Africa, to which region on the whole Saporta considers the flora to be most allied.

The succeeding Oligocene flora appears to be more characterized by a gradual replacement of the Eocene species by allied forms, than by any marked change in the assemblage or in the climatic conditions. It forms a perfectly gradual transition to the still newer Miocene period, the newer species slowly appearing and increasing in number. Saporta considers that in central and southern Europe the alternate dry and moist heat of the Eocene period gave place to a climate more equally and more universally humid, and that these conditions continued without material change into the succeeding Miocene stage. Among the types of vegetation which make their appearance in Europe during the Oligocene period may be mentioned the Conifers *Libocedrus salicornioides*, several species of *Chamæcyparis* and *Sequoia*, *Taxodium distichum*, and *Glyptostrobus europæus*. The palms include *Sabal hæringiana*, *S. major* and *Flabellaria*. Among the *Myricaceæ* several species of *Comptonia* are common. These new-comers are all of American type. Aquatic plants, especially water-lilies, are abundant and varied; the dry-soil *Callitris* and *Widdringtonia* become scarce.

Though we do not propose to deal with the other European localities for Eocene and Oligocene plants, there is one district to which attention should be drawn, on account of the exceptional state of preservation of the specimens. On the Baltic shores of Prussia there is found a quantity of amber, containing remains of insects and plants. This is derived from strata of Oligocene age, and is particularly valuable because it preserves perfectly various soft parts of the plants, which are usually lost in fossil specimens.

Plants in amber.

The tissues, in fact, are preserved just as they would be in Canada balsam. The amber yields such things as fallen flowers, perfect catkins of oak, pollen grains, and fungi. It enables us to determine accurately orders and genera which otherwise are unknown in the fossil state, and it thus aids us in forming a truer idea of the flora of the period than can be formed at any locality where the harder parts alone are recognizable. No doubt this amber flora is still imperfectly known, but it is valuable as giving a good idea of the vegetation, during Oligocene times, of a mixed wood of pine and oak, in which there is a mixture of herbaceous and woody plants, such as would now be found under similar conditions. The plants of which the floral organs or perfect fruits are preserved include the amber-bearing *Pinus succinifera*, *Smilax*, *Phœnix*, the spike of an aroid, 11 species of oak, 2 of chestnut, a beech, *Urticaceæ*, 2 cinnamons and *Trianthera* among the *Lauraceæ*, representatives of the *Cistaceæ*, *Ternstrœmiaceæ*, *Dilleniaceæ* (3 species of *Hibbertia*), *Geraniaceæ* (*Geranium* and *Erodium*), *Oxalidaceæ*, *Acer*, *Celastraceæ*, *Olacaceæ*, *Pittesporaceæ*, *Ilex* (2 species), *Euphorbiaceæ*, *Umbelliferæ* (*Chærophyllum*), *Saxifragaceæ* (3 genera), *Hamamelidaceæ*, *Rosaceæ*, *Connaraceæ*, *Ericaceæ* (*Andromeda* and *Clethra*), *Myrsinaceæ* (3 species) *Rubiaceæ*, *Sambucus* (2 species), *Santalaceæ*, *Loranthaceæ* (3 species). We here discover for the first time various living families and genera, but there is still a noticeable absence of many of our most prolific existing groups. Whether this deficiency is accidental or real time will show.

Miocene.

The Miocene flora, which succeeds to that just described, is well represented in Europe; but till recently there has been an unfortunate tendency to refer Tertiary floras of all dates to the Miocene period, unless the geological position of the strata was so clear as obviously to forbid this assignment. Thus the Eocene lignites of Devon and the plant-beds in the basalt of Scotland and Ireland were called Miocene; and in the Arctic regions and in North America even plant-beds of Upper Cretaceous age were referred to the same period. The reason for this was that some of the first Tertiary floras to be examined were certainly Miocene, and, when these plants had been studied, it was considered that somewhat similar assemblages found elsewhere in deposits of doubtful geological age must also be Miocene. For a long time it was not recognized that changes in the marine fauna, on which our geological classification mainly depends, correspond scarcely at all with changes in the land plants. It was not suspected, or the fact was ignored, that the break between Cretaceous and Tertiary—made so conspicuous by striking changes in the aquatic animals—had little or no importance in botanical history. It was not realized that an Upper Cretaceous flora needed critical examination to distinguish it from one of Miocene age, and that the two periods were not characterized by a sweeping change of generic type, such as took place among the marine invertebrates. It may appear absurd to a geologist that any one could mistake a Cretaceous flora for one of Miocene date, since the marine animals are completely different and the differences are striking. In the case of the plants, however, the Tertiary generic types in large part appeared in Upper Cretaceous times. Few or no extinct types are to be found in these older strata—there is nothing among the plants equivalent to the unmistakably extinct *Ammonites*, *Belemnites*, and a hundred other groups, and we only meet with constant variations in the same genus or family, these variations having seldom any obvious relation to phylogeny.

The Miocene period is unrepresented by any deposits in Great Britain; we will therefore commence with the best known region—that of central Europe and especially of Switzerland, whence a prolific flora has been collected and described by Oswald Heer. The Miocene lacustrine deposits are contained in a number of silted-up lake-basins, which were successively formed and obliterated during the uprise of the Alps and the continuous folding and bending of the earth's crust which was so striking a feature of the period. These undulations tended to transform valleys into chains of lakes, into which the plants and animals of the surrounding area fell or were washed. We thus find preserved in the Upper Miocene lacustrine deposits of Switzerland a larger flora than is known from any other period of similar length; in fact, an analysis of its composition suggests that the Miocene flora of Switzerland must have been both larger and more varied than that now living in the same country. The best known locality for the Upper Miocene plants is Oeningen, on the Lake of Constance, where have been collected nearly 500 species of plants, the total number of Miocene plants found in Switzerland being stated to be now over 900. Among the characteristics of this Miocene flora are the large number of families represented, the marked increase in the deciduous-leaved plants, the gradual decrease in the number of palms and of tropical plants, and the replacement of these latter by Mediterranean or North American forms. According to Heer, the tropical forms in the Swiss Miocene agree rather with Asiatic types, while the subtropical and temperate plants are allied to forms now living in the temperate zone in North America. Of the 920 species described by Heer, 114 are Cryptogams and 806 flowering plants. Mosses are extremely rare, Heer only describing 3 species. Vascular Cryptogams still include one or two large Horsetails with stems over an inch thick, and also 37 species of Fern, amongst the most interesting of which are 5 species belonging to the climbing *Lygodium*, a genus now living in Java. The number of Ferns is just equal to that now found in Switzerland. Cycads are only represented by fragments of two species, and this seems to be the last appearance of Cycads in Europe. The Coniferæ include no fewer than 94 species of *Cupressineæ* and 17 of *Abietineæ*, including several species of *Sequoia*. Monocotyledons form one-sixth of the known Miocene flora, 25 of them being grasses and 39 sedges; but most of these need further study, and are very insufficiently characterized. Heer records one species of rice and four of millet. Most of the other Monocotyledons call for little remark, though among them is an *Iris*, a *Bromelia*, and a ginger. *Smilax*, as in earlier times, was common. Palms, referred to 11 species, are found, though they seem to have decreased in abundance; of them 7 are fan-palms, the others including *Phœnicites*—a form allied to the date—and a trailing palm, *Calamopsis*, allied to the canes and rattans. Among the Dicotyledons, the Leguminosæ take the first place with 131 species, including *Acacia*, *Cæsalpinia*, and *Cassia*, each represented by several forms. The occurrence of 90 species of Amentaceæ shows that, as the climate became less tropical, the relative proportion of this group to the total flora increased. Evergreen oaks are a marked characteristic of the period, more than half the Swiss species being allied to living American forms. Fig-trees referred to 17 species occur, all with undivided leathery leaves; one is close to the banyan, another to the indiarubber tree. The Laurineæ were plentiful, and include various true laurels, camphor-trees, cinnamon, *Persea*, and *Sassafras*. The Proteaceæ, according to Heer, are still common, the Australian genera *Hakea*, *Dryandra*, *Grevillea*, and *Banksia* being represented. Amongst gamopetalous plants several of our largest living families, including Campanulaceæ, Labiatæ, Solanaceæ and Primulaceæ, are still missing; and of Boragineæ, Scrophularineæ, Gentianeæ, and Caprifoliaceæ there are only faint and doubtful indications. The Compositæ are represented by isolated fruits of various species. Twining lianas are met with in a species of *Bignonia*: Umbelliferæ, Ranunculaceæ, and Cruciferæ are represented by a few fruits. These families, however, do not appear to have had anything like their present importance in the temperate flora, though, as they are mainly herbaceous plants with fruits of moderate hardness, they may have decayed and left no trace. The American *Liriodendron* still flourished in Europe. Water-lilies of the genera *Nymphæa* and *Nelumbium* occur. Maples were still plentiful, 20 species having been described.

Rosaceæ are rare, *Cratægus*, *Prunus*, and *Amygdalus* being the only genera recorded. It is obvious that many of these Swiss Miocene plants will need more close study before their specific characters, or even their generic position, can be accepted as thoroughly made out; still, this will not affect the general composition of the flora, with its large proportion of deciduous trees and evergreens, and its noticeable deficiency in many of our largest living families.

From Europe it will be convenient to pass to a distant region of similar latitude, so that we may see to what extent botanical provinces existed in Eocene and Oligocene times. It so happens that the interior of temperate North America is almost the only region outside Europe in which a series of plant-bearing strata give a connected history of these periods, and in which the plants have been collected and studied. It is unfortunately still very difficult to correlate even approximately the strata on the two sides of the Atlantic, and there is great doubt as to what strata belong to each division of the Tertiary period even in different parts of North America. This difficulty will disappear as the strata become better known, but at present each of the silted-up lakes has to be studied separately, for we cannot expect so close a correspondence in their faunas and floras as is found in the more crowded and smaller basins in central Europe.

Tertiary of North America.

Perhaps the most striking characteristic of the Tertiary floras of North America, as distinguished from those of Europe, is the greater continuity in their history and greater connexion with the existing flora of the same regions. This difference is readily explained when we remember that in Europe the main barriers which stop migration, such as the Alps and the Mediterranean, run east and west, while in America the only barriers of any importance run north and south. In consequence of this peculiarity, climatic or orographic changes in Europe tend to drive animals and plants into a *cul de sac*, from which there is no escape; but in America similar climatic waves merely cause the species alternately to retreat and advance. This difficulty in migration is probably the reason why the existing European flora is so poor in large-fruited trees compared with what it was in Miocene times or with the existing flora of North America. In America the contrast between the Eocene forests and those now living is much less striking, and this fact has led to the wrong assumption that the present American flora had its origin in the American continent. Such a conclusion is by no means warranted by the facts, for in Tertiary times, as we have seen, the European flora had a distinctly "American" facies. Therefore the so-called American forms may have originated in the Old World, or more probably, as Saporta suggests, in the polar regions, whence they were driven by the increase of cold southwards into Europe and into America. The American Tertiary flora is so large, and the geology of the deposits is so intricate, that it is out of the question to discuss them more fully within the limits of this article. We may point out, however, that the early Tertiary floras seem to indicate a much closer connexion and a greater community of species than is found between the existing plants of Europe and America. Or, rather, we should perhaps say that ancient floras suggest recent dispersal from the place of origin, and less time in which to vary and become modified by the loss of different groups in the two continents. Geographical provinces are certainly indicated by the Eocene flora of Europe and America, but these are less marked than those now existing.

If we turn to a more isolated region, like Australia, we find a Lower Eocene flora distinctly related to the existing flora of Australia and not to that of other continents. Australasia had then as now a peculiar flora of its own, though the former wide dispersal of the Proteaceæ and Myrtaceæ, and also the large number of Amentaceæ then found in Australia, make the Eocene plants of Europe and Australia much less unlike than are the present floras.

Australia.

Within the Arctic circle a large number of Tertiary plants have been collected. These were described by Heer, who referred them to the Miocene period; he recognized, in fact, two periods during which Angiosperms flourished within the Arctic regions, the one Upper Cretaceous, the other Miocene. To this view of the Miocene age of the plant-bearing strata in Greenland and Spitsbergen there are serious objections, which we will again refer to when the flora has been described.

Arctic regions.

The Tertiary flora of Greenland is of great interest, from the extremely high latitude at which the plants flourished, thirty of the species having been collected so far north as lat. 81°. Taking first this most northerly locality, in Grinnell Land, we find the flora to comprise 2 horsetails, 11 Conifers (including the living *Pinus Abies*), 2 grasses, a sedge, 2 poplars, a willow, 2 birches, 2 hazels, an elm, a *Viburnum*, a water-lily, and a lime. Such an assemblage at the present day would suggest a latitude quite 25° farther south; but it shows decidedly colder conditions than any of the European Eocene, Oligocene, or Miocene strata. From lat. 78° in Spitsbergen Heer records 136 species of fossil plants. More to the south, at Disco Island in lat. 70°, the Tertiary wood seem to have been principally composed of planes and Sequoias; but a large number of other genera occur, the total number of plants already recorded being 137. From various parts of Greenland they now amount to at least 280. Among the plants from Disco, more than a quarter are also found in the Miocene of central Europe. The plants of Disco include, besides the plane and Sequoia, such warm-temperate trees as *Ginkgo*, oak, beech, poplar, maple, walnut, lime, and magnolia. If these different deposits are contemporaneous, as is not improbable, there is a distinct change in the flora as we move farther from the pole, which suggests that difference of latitude then as now was accompanied by a difference in the flora. But if this process is continuous from latitude to latitude, then we ought not to look for a flora of equivalent age in the warm-temperate Miocene deposits of central Europe, but should rather expect to find that the temperate plants of Greenland were contemporaneous with a tropical flora in central Europe. As Mr Starkie Gardner has pointed out, it does not seem reasonable to assume that the same flora could have ranged then through 40° of latitude; it is more probable that an Eocene temperate flora found in the Arctic regions travelled southwards as the climate became cooler, till it became the Miocene temperate flora of central Europe. Mr Gardner suggests, therefore, that the plant-beds of Greenland and Spitsbergen represent the period of greatest heat, and are therefore wrongly referred to the Miocene. At present the evidence is scarcely sufficient to decide the question, for if this view is right, we ought to find within the Arctic circle truly Arctic floras equivalent to the cool Lower Eocene and Miocene periods; but these have not yet been met with.

Pliocene.

A steady decrease of temperature marked the Pliocene period throughout Europe, and gradually brought the climatic conditions into correspondence with those now existing, till towards the end of the period neither climate nor physical geography differed greatly from those now existing. Concurrently with this change, the tropical and extinct forms disappeared, and the flora approached more and more nearly to that now existing in the districts where the fossil plants are found, though in the older deposits, at any rate, the geographical distribution still differed considerably from that now met with. At last, in the latest Pliocene strata (often called "pre-Glacial") we find a flora consisting almost entirely of existing species belonging to the Palæarctic regions, and nearly all still living in the country where the fossils are found. This flora, however, is associated with a fauna of large mammals, the majority of which are extinct.

The plants of the Older Pliocene period are unknown in Great Britain, and little known throughout Europe except in central France and the Mediterranean region. The forests of central France during this epoch showed, according to Saporta, a singular admixture of living European species, with trees now characteristic of the Canary Isles and of North America. For instance, of the living species found at Meximieux, near Lyons, one is American, eight at least belong to the Canaries (six being characteristic of those islands), two are Asiatic, and ten still live in Europe. Taking into account, however, the closest living allies of the fossil plants, we find about equal affinities with the floras of Europe, America, and Asia. There is also a decided resemblance to the earlier Miocene flora. Among the more interesting plants of this deposit may be mentioned *Torreya nucifera*, now Japanese; an evergreen oak close to the common *Quercus ilex*; *Laurus canariensis*, *Apollonias canariensis*, *Persea carolinensis*, and *Ilex canariensis*; *Daphne pontica* (a plant of Asia Minor); a species of box scarcely differing from the English, and a bamboo. To this epoch, or perhaps to a stage slightly later, and not to the Newer Pliocene period, as is generally supposed, should probably be referred the lignite deposits of the Val d'Arno. This lignite and the accompanying leaf-bearing clays underlie and are apparently older than the strata with Newer Pliocene mammals and mollusca. The only mammal actually associated with the plants appears to be a species of tapir, a genus which in Europe seems to be characteristically Miocene and Older Pliocene. The plants of the Val d'Arno have been described by Ristori; they consist mainly of deciduous trees, a large proportion of which are known Miocene and early Pliocene forms, nearly all of them being extinct. A markedly upland character is given to the flora of this valley through the abundance of pines (9 species) and oaks (16 species) which it contains; but this peculiarity is readily accounted for by the steep slopes of the Apennines, which everywhere surround and dominate the old lake-basin. Among the other noticeable plants may be mentioned *Betula* (3 species), *Alnus* (2 species), *Carpinus*, *Fagus* (4 species), *Salix* (4 species), *Populus* (2 species), *Platanus*, *Liquidambar*, *Planera*, *Ulmus* (2 species), *Ficus* (2 species), *Persoonia*, *Laurus* (5 species), *Persea*, *Sassafras*, *Cinnamomum* (5 species), *Oreodaphne*, *Diospyros* (2 species), *Andromeda*, *Magnolia*, *Acer* (3 species), *Sapindus*, *Celastrus* (2 species), *Ilex* (4 species), *Rhamnus* (3 species), *Juglans* (5 species), *Carya* (2 species), *Rhus*, *Myrtus*, *Cratægus*, *Prunus*, *Cassia* (3 species). These plants suggest a colder climate than that indicated by the plants of Meximieux—they might, therefore, be thought to belong to a later period. The difference, however, is probably fully accounted for when we take into consideration the biting winds still felt in spring in the valley of the Arno, and the probable large admixture of plants washed down from the mountains above. Somewhat later Pliocene deposits in the Val d'Arno, as well as the tuffs associated with the Pliocene volcanoes in central France, yield plants of a more familiar type, a considerable proportion of them still living in the Mediterranean region, though some are only now found at distant localities, and others are extinct. The flora, however, is essentially Palæarctic, American and Australian types having disappeared.

The latest Pliocene, or pre-Glacial, flora of northern Europe is best known from the Cromer Forest-bed of Norfolk and Suffolk, a fluvio-marine deposit which lies beneath the whole of the Glacial deposits of these counties, and passes downwards into the Crag, many of the animals actually associated with the plants being characteristic Pliocene species which seem immediately afterwards to have been exterminated by the increasing cold. The plants contained in the Cromer Forest-bed fall into two groups—the forest-trees, and the marsh and aquatic plants. We know little or nothing at present of the upland plants, or of those of dry or chalky soils. Forest trees are well represented; they are, in fact, better known than in any of the later English deposits. We find the living British species of maple, sloe, hawthorn, white-beam, cornel, elm, birch, alder, hornbeam, hazel, oak, beech, willow, yew, and pine, and also the spruce. This is an assemblage that could not well be found under conditions differing greatly from those now holding in Norfolk; there is an absence of both Arctic and south European plants. The variety of trees shows that the climate was mild and moist. Among the aquatic and marsh plants we find, mingled with a number that still live in Norfolk, the water-chestnut (*Trapa natans*) and *Najas minor*, neither of which is now British. On the Norfolk coast another thin plant-bed occurs locally above the Forest-bed and immediately beneath the Boulder Clay. This deposit shows no trace of forest-trees, but it is full of remains of Arctic mosses, and of the dwarf willow, and birch; in short, it yields the flora now found within the Arctic circle. The incoming of the Glacial epoch does not appear to have been accompanied by any acclimatization of the plants—the species belonging to temperate Europe were locally exterminated, and Arctic forms took their places. The same Arctic flora reappears in deposits immediately above the highest Boulder-Clay, deposits formed after the ice had passed away. These fossil Arctic plants have now been found as far south as Bovey Tracey in Devonshire, where Pengelly and Heer discovered the bear-berry and dwarf birch; London, where also *Betula nana* occurs; and at Deuben in Saxony, which lies nearly as far south as lat. 50°, but has yielded to Professor Nathorst's researches several Arctic species of willow and saxifrage. The cold period, however, was not continuous, for both in Great Britain and on the continent of Europe, as well as in Canada, it was broken by the recurrence of a milder climate and the reappearance of a flora almost identical with that now living in the same regions. This "inter-Glacial" flora, though so like that now found in the district, has interesting peculiarities. In England, for instance, it includes *Acer monspessulanum*, a southern maple which does not now extend nearer than central Europe; also *Najas graminea* and *N. minor*, both southern forms not now native of Britain. *Brassenia peltata*, a water-lily found in the warmer regions almost throughout the world, except in Europe, occurs abundantly in north Germany, but not in Great Britain. Similar inter-Glacial deposits in Tirol contain leaves of *Rhododendron ponticum*.

Pleistocene.

Space will not permit us to enter into any full discussion of the recurrence of Glacial and inter-Glacial periods, and the influence they may have had on the flora. It is evident, however, that if climatic alternations such as those just described are part of the normal routine that has gone on through all geological periods, and are not merely confined to the latest, then such changes must evidently have had great influence on the evolution and geographical distribution both of species and of floras. Whether this was so, is a question still to be decided, for in dealing with extinct floras it is difficult to decide, except in the most general way, to what climatic conditions they point. We seem to find indications of long-period climatic oscillations in Tertiary times, but none of the sudden invasion of an Arctic flora, like that which occurred during more recent times. It should not be forgotten, however, that an Arctic flora is mainly distinguishable from a temperate one by its poverty and dwarfed vegetation, its deciduous leaves and small fruits, rather than by the occurrence of any characteristic genera or families. Careful and long-continued study would therefore be needed before we could say of any extinct dwarfed flora that it included only plants which could withstand Arctic conditions.

(C. R.)

PALÆOGRAPHY.

THE principal discoveries made during recent years in the field of Palæography concern the history of Greek writing. At the time when the article on Palæography appeared in vol. xviii. (ninth edition) of this Encyclopædia, the anterior limit of our knowledge of the forms of writing to be found in documents of Greek origin was the 2nd century B.C. We are now in a position to carry back our investigations a century earlier. It is true that a few documents which have since been shown to be of the 3rd century B.C. were extant in European libraries, but they were undated, and their value as specimens of early writing was not recognized. But now the very large number of Greek papyri recovered in Egypt since 1880 have furnished material which not only extends our knowledge, but also enables us to confirm or modify views formerly held. In the history of Latin Palæography little has been added to the material already known. Comparatively few Latin documents have been found among the papyri of Egypt; still, such as they are, they are not without interest in providing us with specimens of writing of the time of the early Roman occupation of the country. It follows, then, that this supplement must mainly be a survey of the history and palæography of Greek papyri, a subject which has been most ably dealt with by Mr F. G. Kenyon in *The Palæography of Greek Papyri*, to which the student may be referred for fuller details than can be given in these pages.

The history of Greek writing on papyrus can now be followed with more or less fulness of material for more than nine hundred years. Actual dated examples range from 270 B.C. to A.D. 680. We have a fair knowledge of the leading features of the writing of the 3rd and 2nd centuries B.C.; a less perfect acquaintance with those of the 1st century B.C. For the first two centuries of the Christian era and to the middle of the 3rd century there is an almost uninterrupted series of documents; then again for two centuries there is a decline, only to be followed by abundance of material for the 6th and early 7th centuries. Thus it will be seen that, while for some periods we may be justified in drawing certain conclusions and laying down certain rules, for others we are still in a very imperfect condition of knowledge. But our knowledge will no doubt almost yearly become more exact, as fresh material is brought to light from the excavations which are now continually proceeding; and those periods in which the lack of papyri breaks the chain of evidence will sooner or later be as fully represented as the rest. The material certainly lies buried in the sands; it is our misfortune that the exact sites have not yet been struck.

The first discovery of Greek papyri was made in Europe, in 1752, when the excavations on the site of Herculaneum yielded a number of charred rolls which proved to be of a literary character. All subsequent discoveries we owe to Egypt; and it is to be observed that the papyri which are found in that country have come down to us under different conditions. Some, generally of a literary nature, were carefully deposited with the bodies of their owners in the tomb with the express intention of being preserved; hence such MSS. in several instances have come to our hands in fairly perfect condition. On the other hand, by far the larger number of those recently brought to light have been found on the sites of towns and villages, particularly in the district of the Fayûm, where they had been either accidentally lost or purposely thrown aside as of no value, or had even been used up as material for other purposes besides their original one. These are consequently for the most part in an imperfect and even fragmentary condition, although not a few of them have proved to be of the highest palæographical and literary importance.

The date of the first find of Greek papyri in Egypt was in 1778, when some forty or fifty rolls were discovered by some native diggers, who, however, kept only one of them. After this, scarcely anything appeared until the year 1820, when was found on the site of the Serapeum at Memphis, as it was reported, the group of documents of the 2nd century B.C. which have been referred to in the article PALÆOGRAPHY (*Ency. Brit.* vol. xviii. p. 149). Then followed a fruitful period when several important literary papyri were secured: in 1821, the Bankes Homer, containing the last book of the *Iliad;* in 1847, the roll containing the Lycophron and other orations of Hyperides; in 1849 and 1850, the Harris Homer, book xviii. of the *Iliad*, and a MS. of books ii.–iv.; and in 1856, the Funeral Oration of Hyperides.

But the great bulk of the Greek papyri from Egypt is the result of excavations undertaken during the last quarter of the 19th century. Within this time three very important discoveries of documents in large quantities have taken place. In 1877 a great mass of papyri was found on the site of Arsinoë in the Fayûm, being chiefly of a non-literary nature and unfortunately in a very fragmentary state; they are also late in date, being of the Byzantine period. The greater number passed into the possession of the Archduke Rainer, and are now at Vienna; the rest are divided between London, Oxford, Paris, and Berlin. After an interval, this find was followed by the recovery in 1892, in the same neighbourhood, and chiefly on the site of a village named Socnopæi Nesus, of an extensive series of documents of the Roman period, ranging from the 1st century to the middle of the 3rd century. These papyri, being of an earlier date and in better condition than the Arsinoite collection, are consequently of greater palæographical value. Most of them are now in Berlin; many are in the British Museum; and some are at Vienna, Geneva, and elsewhere. The third great find, and the most important of all, was made by Messrs Grenfell and Hunt, when excavating, in the season 1896–97, for the Egypt Exploration Fund, at Behnesa, the ancient Oxyrhynchus. Thousands of papyri were here recovered, including, among the non-literary material, a number of rolls in good condition, and comprising also a great store of fragments of literary works, among which occur the now well-known "Logia" or "Sayings of Our Lord," and fragments of the Gospel of St Matthew and of writings of various classical authors. This great collection ranges in date over the first seven hundred years of the Christian era; but in what proportion the documents fall to the several centuries cannot be determined until the series of volumes in which they are to be described for the Græco-Roman branch of the Egypt Exploration Fund shall have made some substantial progress.

These three great collections of miscellaneous documents have been supplemented by finds of other smaller groups, which fit into them and serve to make more complete the chronological series. Such are the correspondence of a Roman officer named Abinnæus of the middle of the 4th century, shared between the British Museum and the library of Geneva in the year 1892; and a miscellaneous collection, ranging from the 2nd century B.C. to the 3rd or 4th century A.D., acquired for the Egypt Exploration Fund and published by that society (*Fayûm Towns and their Papyri*, 1900). But of these smaller groups by far the most interesting is that which Mr Flinders Petrie extracted, in 1889–90, from a set of mummy-cases found in the necropolis of the village of Gurob in the Fayûm. In the manufacture of these coffins numbers of inscribed papyri had been employed, being cut into pieces and pasted together in order to form the cartonnage. The fragments thus recovered proved to be the most valuable documents for the history of Greek palæography hitherto found, supplying us with examples of writing of the 3rd century B.C. in fairly ample numbers, and thus carrying back our knowledge of the subject to a period which up to that time had remained a blank. Besides miscellaneous documents, there are included the remains of registers of wills entered up from time to time by different scribes, and thus affording a variety of handwritings for study; and, further, the value of the collection is enhanced by the presence of fragments of the *Phædo* and *Laches* of Plato and of the lost *Antiope* of Euripides and of other classical works.

The last decade of the 19th century has also been distinguished by the recovery of several literary works of the first importance, inscribed on papyri which had been deposited with the dead, and had thus remained in a fairly perfect condition. In 1889 the Trustees of the British Museum acquired a copy of the lost Ἀθηναίων Πολιτεία of Aristotle, a papyrus of the Mimes of the poet Herodas, and a portion of the oration of Hyperides against Philippides; and in 1896 they had the further good fortune to secure a papyrus containing considerable portions of the odes of Bacchylides, the contemporary of Pindar. And to the series of the orations of Hyperides the Louvre was enabled to add, in 1892, a MS. of the greater part of the oration against Athenogenes. The recovery of so many great classical works within a few years may be accepted as an earnest of further finds of the same nature, now that excavations are being carried on systematically in Egypt.

From a study of the material thus placed at our disposal, certain conclusions have been arrived at which satisfy us that the periodical changes which passed over the character of Greek writing as practised in Egypt coincide pretty nearly with the changes in the political administration of the country. The period of the rule of the Ptolemies from 323 to 30 B.C. has, in general, its own style of writing, which we recognize as the *Ptolemaic;* the period of Roman supremacy, beginning with the conquest by Augustus and ending with the reorganization of the empire by Diocletian in A.D. 284, is accompanied by a characteristic *Roman* hand; and with the change of administration which placed Egypt under the Byzantine division of the empire, and lasted down to the time of the Arab conquest in A.D. 640, there is a corresponding change to the *Byzantine* class of writing. These changes must obviously be attributed to the influence of the official handwritings of the time. A change of government naturally led to a change of the officials employed, and with the change of officials would naturally follow a change in the style of production of official documents. In illustration of this view, it is enough to call to mind the instances of such variations to be met with in the history of the palæography of mediæval Europe, due in the same way to political causes. It is interesting, too, to observe that in our own time the teaching in schools of a particular type of handwriting which finds favour in clerical examinations for the public service has not been without its influence on the general handwriting of the people.

Classifying, then, the writing of the papyri into the three groups, the Ptolemaic, the Roman, and the Byzantine, the next step is to determine, by a closer examination of the documents, the changes which characterize the several centuries traversed by those groups. In doing this, we cannot apply the exact terms which are employed in describing the MSS. of the Middle Ages. We have to do with writing which has not yet been cast into the formal literary moulds of the later times; and it has therefore been found necessary, as well as convenient, to divide the papyri simply into two series, representative of their contents and not of their style of production, namely, literary papyri and non-literary papyri. Neither series, however, it is to be remembered, has a style of writing peculiar to itself. While the literary works are, as a rule, written with more or less formality, not a few of even the more valuable of them are copies in the ordinary cursive hands of the day. Conversely, while we find non-literary documents generally written in ordinary cursive hands, whether by official scribes or by private individuals, yet occasionally we meet with one produced in the formal style more common to literary examples. Again, while applying to particular letters in papyri such technical terms as capitals, or uncials, or minuscules, we cannot convey by those terms the exact ideas which we convey when thus describing the individual letters of mediæval manuscripts. For the letters of the papyrus period were not cast in finished moulds, while the uncial writing and the minuscule writing of the Middle Ages were settled literary hands. As will presently be seen, the mediæval uncial developed directly from the literary writing of the papyri; the minuscule was a new type moulded from the cursive into a fixed literary style.

Necessarily, the non-literary papyri are much more numerous than the literary documents, and present a much greater variety of handwriting, being in fact the result of the daily transactions of ordinary life; and how very widespread was the knowledge of writing among the Greek-speaking population of Egypt is sufficiently testified by the surviving examples, coming as they do from the hands of all sorts and conditions of men. We will first examine these specimens of the current handwriting of the day before passing to the review of the more or less artificial book-writing of the literary papyri.

As already stated, the oldest material is chiefly contributed by the papyri discovered at Gurob. Among them are not only the fragments of official registers which have been mentioned, but also a variety of miscellaneous documents relating to private affairs, and in various hands of the 3rd century and early 2nd century B.C. The series of non-literary papyri bears actual dates ranging from 270 to 186 B.C. The leading characteristic of Greek writing of the 3rd century B.C. is its strength and facility. While it may not compare with some later styles in the precise formation of particular letters, yet its freedom and spontaneous air lend it a particular charm and please the eye, very much in the same way that a scholar's practised and unconscious handwriting of a good type is more attractive than the more exact formality of a clerk's hand. The letters generally are widely spread and shallow, and, particularly in the official hands, they are linked together with horizontal connecting strokes to such an extent that the text has almost the appearance of depending from a continuous horizontal line. The extreme shallowness or flatness of many of the letters is very striking, especially in the case of *delta*, *mu*, *nu*, *pi*, and *omega*. A significant indication of the antiquity of Greek cursive writing is found in connexion with one of the forms of the letter *alpha*, which is reduced to a mere angle or wedge.

A few lines from an official order of the year 250 B.C. will serve to convey an idea of the trained cursive style of this century:—

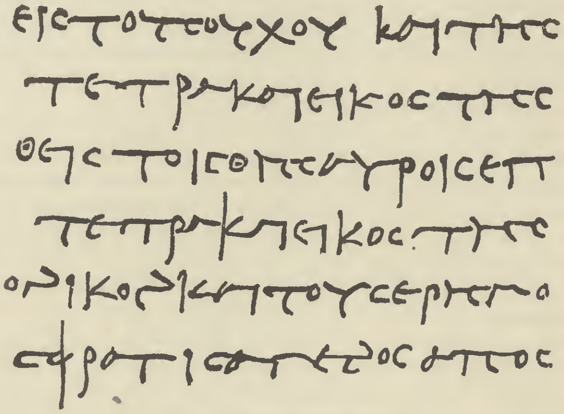

Fig. 1.—Official Order, 250 B.C.

(—εις τοπουχου και της—
—τετρα και εικοστης—
—θεις τοις θησαυροις επ—
—τετρα και εικοστης—
—ονικον και τους ερημο—
—σφραγισαμενος αποσ—)

As a contrast to this excellent hand, we give a facsimile of a section from a roughly written letter from a land steward to his employer, of about the same date:—

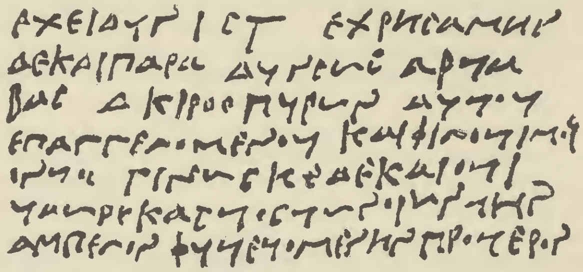

Fig 2.—Letter of a Land Steward, 3rd century B.C.

(εχει δυνις γ εχρησαμην
δε και παρα δυνεως αρτα
βας δ κριθοπυρων αυτου
επαγγελομενου και φιλοτιμου
οντος γινωσκε δε και οτι
υδωρ εκαστος των ορων την
αμπελον φυτευομενην προτερον)

Here there is none of the linking of the letters which is seen in the other example: every letter stands distinct. But while the individual letters are clumsily written, the same laws govern their formation as in the other document. The shallow, wide-spread *mu*, the cursive *nu*, the small *theta*, *omikron*, and *rho*, are repeated. Here also is seen the *tau*, with its horizontal stroke confined to the left of the vertical instead of crossing it, and the undeveloped *omega*, which has the appearance of being clipped—both forms being characteristic of the 3rd century B.C.

The trained clerical hands of the 2nd century B.C., if we may form a judgment from the evidence of such documents as those connected with the Serapeum at Memphis, already referred to, differ generally from those of the earlier century in the larger size of the lettering, and in a more perfect and less cursive formation, the older shallow type gradually disappearing, and the linking of letters by horizontal strokes being less continuous. But the Ptolemaic character marks the handwriting well through the century; and it is only towards the close of that period and as the next century is entered, that the hand begins to give way and to lose altogether its linked style and the peculiar crispness of the strokes which give it its distinctive appearance.

With the Roman period comes roundness of style, in strong contrast to the stiffness and rigid linking of the Ptolemaic hand. Curves take the place of straight strokes in the individual letters, and even ligatures are formed in pliant sweeps of the pen. This transition from the stiff to the flexible finds something of a parallel in the development of the curving and flexible English charter-hand of the 14th century from the rigid hand of the 13th century; following, it would seem, the natural law of relaxation. Roundness of style, then, is characteristic of Greek cursive writing in the papyri of the first three centuries of the Christian era, however much individual hands, or groups of hands, might vary among themselves. After that time, if we may judge from the meagre material that has been recovered, there appears to have been a reform of the Roman hand which marks the entry of Greek writing into the new phase of the Byzantine period, the characteristic features of the new style being its large scale and its formality—a deliberate calligraphic effort which culminated in the bold but artificial hand of the 6th and 7th centuries.

A specimen of cursive writing of the Roman type is selected from a papyrus (Brit. Mus. No. cxxxi.) which is of more than usual interest, as it is on the verso side of the rolls of which it is composed that the text of Aristotle's *Constitution of Athens* has been transcribed. It contains the farming accounts of the bailiff of Epimachus, son of Polydeuces, the owner of an estate in the nome of Hermopolis in the 9th and 10th years of the reign of Vespasian, that is, A.D. 78–79:—

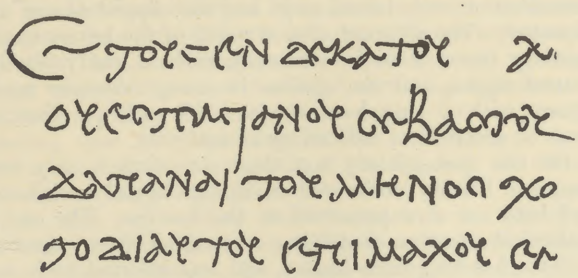

FIG. 3.—Farm Accounts, A.D. 78-79.

(ετους ενδεκατου α—
ουεσπασιανου σεβαστου—
δαπαναι του μηνος χ—
το δι αυτου επιμαχου ε—)

The fully developed Byzantine hand of the legal type is shown in a few lines from a fragmentary lease of a farm (Fig. 4) in the 6th century (Brit. Mus. pap. cxiii. 3).

In the long range covered by the Greek papyri under our hands, the formation of individual letters necessarily varied under different influences; but in not a few instances the original shapes were remarkably maintained. From those which thus remained conservative it is rash to attempt to draw conclusions as to the precise age of the several documents in which they occur. On the other hand, there are some which at certain periods adopted shapes which were in vogue for a limited time and then disappeared, never to be resumed. Such forms can very properly be regarded as sure guides to the palæographer in assigning dates. We may take a brief survey of the Greek cursive alphabet of the papyri and note some of the peculiarities of individual letters. The incipient form of the *alpha*, which gradually developed into the minuscule letter of the Middle Ages, may be traced back to the Ptolemaic documents of the 2nd century B.C.; but the more cursive letter, which was a simple acute angle, representing only two of the three strokes of which the

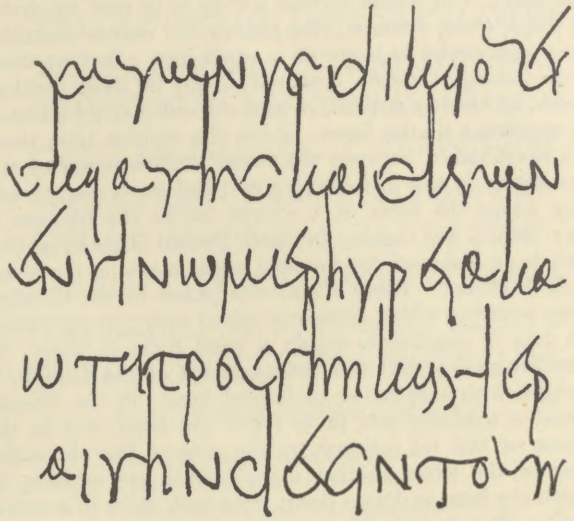

FIG. 4.—Lease of a Farm, 6th Century.

(—ς αυτων του δικαιου ε—
—ς και αυτης και εκ των—
—εντινω μερη τρεια κα—
—ω τα προς την καλλιερ—
—αι την δεσιν του π—)

primitive letter was composed, was characteristic of the 3rd century B.C., and seems to have gone out of use within the Ptolemaic period. The development of the cursive *beta* is interesting. At the very beginning we find two forms in use: the primitive capital letter and a cursive shape somewhat resembling a small *n*, being in fact an imperfectly written *B* in which the lower bow is disregarded. This form lasted through the Ptolemaic period. Then arose the natural tendency to reverse the strokes and to form the letter on the principle of *u*; but still the capital letter also continued in use, so that through the Roman and Byzantine periods the *u*-shape and the *B*-shape run on side by side. Analogously the letter *kappa*, formed on somewhat the same lines as the *beta*, runs a similar course in developing a cursive *u*-shaped form by the side of the primitive capital. *Delta* remained fairly true to its primitive form until the Byzantine period, when the elongation of the head into a flourish led on to the minuscule letter which is familiar to us in the mediæval and modern alphabet. *Epsilon*, the most frequently recurring letter in Greek texts, departs less from its original rounded uncial form than might have been expected. Frequent and varied as its cursive formations are, yet the original shape is seldom quite disguised, the variations almost in all instances arising from the devices of the scribe to dispose swiftly and conveniently of the cross-bar by incorporating it with the rest of the letter. The tendency to curtail the second vertical limb of *eta*, leading eventually to the *h*-shape, is in evidence from the first. But in the development of this letter we have one of the instances of temporary forms which lasted only within a fixed period. In the 1st century, side by side with the more usual form, there appears a modification of it, somewhat resembling the contemporary *upsilon*, consisting of a shallow horizontal curve with a vertical limb slightly turned in at the foot, Ɂ. Its development from the original H is evident: the first vertical limb is slurred, and survives only in the beginning of the horizontal curve, while the cross-bar and the second vertical are combined in the rest of the letter. This form was in general use from the middle of the 1st to the middle of the 2nd century, becoming less common after about A.D. 160, and practically disappearing about A.D. 200. The letters formed wholly or in part by circles or loops, *theta*, *omikron*, *rho*, *phi*, in the earlier centuries have such circles or loops of a small size. Just as there is an analogy between *beta* and *kappa* in their developments, as already noticed, so also do *mu* and *pi* advance on somewhat similar lines. From the earliest time there is a resemblance between the broad shallow forms of the two letters in the 3rd century B.C., and particularly when they adopt the form of a convex stroke the likeness is very close; and again, in both Roman and Byzantine periods an *n*-shaped development appears among the forms of both letters. There is also one phase in the development of *sigma* which affords a useful criterion for fixing the date of documents within a fixed limit of time. In the Ptolemaic period the letter, always of the C-form, is upright, with a flattened horizontal head; in the Roman period a tendency sets in to curve the head, and in the course of the 1st century, by the side of the old stiffer form of the letter another more cursive one appears, in which the head is drawn down more and more in a curve, C C. This form is in common use from the latter part of the 1st century to the beginning of the 3rd century. The cursive form of *tau*, in which the horizontal stroke is kept to the left of the vertical limb, without crossing it, is one of the early shapes of the letter. Lastly, the early Ptolemaic form of the *w*-shaped *omega* is noticeable from having its second curve undeveloped, the letter having the appearance of being clipped.

Before taking leave of the non-literary hands, we may briefly notice certain literary papyri which are written in cursive writing. The most important are: the astronomical treatise derived from Eudoxus, of the 2nd century B.C., among the collections of the Louvre; an anonymous work on diseases, with extracts from Menon's *Iatrica*, of the 1st or 2nd century, now in the British Museum; and, above all, Aristotle's *Constitution of Athens*, written at the end of the 1st century, also in the British Museum. To these are to be added: a papyrus containing a small portion of the eleventh book of the *Iliad*, of the 2nd century B.C., now at Geneva; an erotic fragment of the same time, in the British Museum; and the fragment of the lyric poet Alcman, of the 1st century, in the Louvre.

Literary papyri written in book-hands, distinct from the cursive writing which has been under consideration, may be divided into two classes: those which were produced by skilled scribes, and therefore presumably for the market, and those which were written less elegantly, but still in a literary hand, and were probably copied by or for scholars for their own use. By rare good fortune important literary fragments were recovered in the Gurob collection, which yielded the most ancient dated cursive documents of the 3rd century B.C., so that, from the beginning, we start with coeval specimens of both the cursive and of the book-hand, and we are in a position to compare the two styles on equal terms, and thus approximately to date the literary papyri. Palæographically, this is a matter of the first importance; for while cursive documents, from their nature, in most instances bear actual dates, the periods of literary examples have chiefly to be decided by comparison, and often by conjecture.

The literary fragments from Gurob fall into the two groups just indicated, MSS. written for sale, and scholars' copies. Of the former are some considerable portions of two works, the *Phædo* of Plato and the lost *Antiope* of Euripides. Both are written in carefully formed characters of a small type, but of the two the *Phædo* is the better executed. As the cursive fragments among which they were found date back to before the middle of the 3rd century B.C., it is reasonable to place these literary remains also about the middle of that century. Their survival is a particularly interesting fact in the history of Greek palæography, for in them we have specimens of literary rolls which may be fairly assumed to differ very little in appearance from the manuscripts of the great classical authors of Greece. Indeed, the *Phædo* was probably written within a hundred years of the death of the author.

In the facsimile of a few lines from this papyrus here placed before the reader, the characteristics of the cursive hand are also to some extent to be observed in the formal book-hand:—

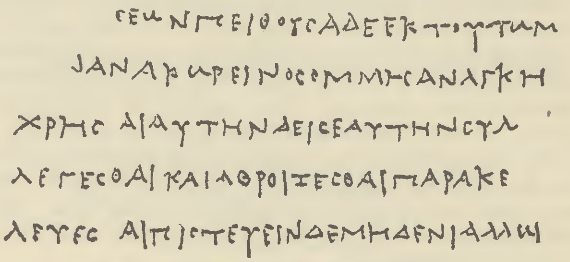

FIG. 5.—The *Phædo* of Plato, 3rd century B.C.

(—σεων πειθουσα δε εκ τουτωμ
—ανακωρειν οσομ μη αναγκη
χρησ[θ]αι αυτην δ εις εαυτην συλ
λεγεσθαι και αθροιζεσθαι παρακε
λευεσ[θ]αι πιστευειν δε μηδενι αλλωι)

The general breadth of the square letters, the smallness of the letters formed of circles and loops, and the particular formation of such letters as *pi* and the clipped *omega*, are repeated. The approach also of many of the letters to the lapidary forms is to be remarked, such as the precisely-shaped *alpha*, and the *epsilon* in many instances made square with a long head stroke. All such peculiarities must be accepted as indications of antiquity.

Of the 2nd century B.C. there are extant only two papyri of literary works written in the formal book-hand, and both are now preserved in the Louvre. The one, a dialectical treatise containing quotations from classical authors, has long been known, and was referred to in the article in the ninth edition of this work. The other is the oration of Hyperides against Athenogenes, which is an acquisition of recent date. The dialectical treatise must belong to the first half of the century, as there is on the verso side of the papyrus writing subsequently added in the year 160 B.C. The period of the Hyperides cannot be so closely defined; but the existence on the verso of later demotic writing, said to be of the Ptolemaic time, affords a limit, and the MS. has been accordingly placed in the second half of the century. While the writing of the earlier papyrus is of a light and rather sloping character, that of the Hyperides is particularly firm and square and upright.

Passing to the 1st century B.C., the papyri which have been recovered from the ashes of Herculaneum come into account. Many of them, the texts of which are of a philosophical nature, are written in literary hands, and are conjectured to have actually formed part of the library of their author, the philosopher Philodemus; they are therefore placed about the middle of the century. To the same time are assigned the remains of a roll containing the oration of Hyperides against Philippides and the third Epistle of Demosthenes (Brit. Mus. papp. cxxxiii., cxxxiv.). But the most important addition to the period is the handsomely written papyrus containing the poems of Bacchylides, which retains in the forms of the letters much of the character of the Ptolemaic style, although for other reasons it can hardly be placed earlier than about the middle of the century :—

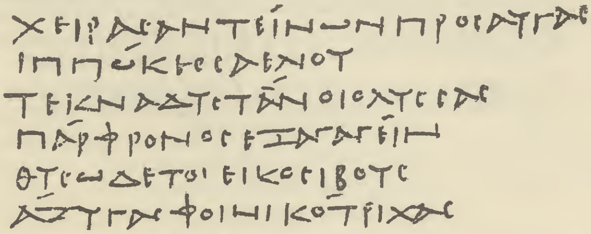

Fig. 6.—Bacchylides, 1st century B.C.

(χειρας αντεινων προς αυγας
ιππωκεος αελιου
τεκνα δυστανοιο λυσσας
παρφρονος εξαγαγειν
θυσω δε τοι εικοσι βους
αζυγας φοινικοτριχας)

With the latter half of the 1st century B.C. we quit the Ptolemaic period and pass to the consideration of the literary papyri of the Roman period; and it is especially in this latter period that our extended knowledge, acquired from recent discoveries, has led to the modification of views formerly held with regard to the dates to be attributed to certain important literary MSS. As in the case of non-literary documents, the literary writing of the Roman period differs from that of the Ptolemaic in adopting rounded forms and greater uniformity in the size of the letters.

Just on the threshold of the Roman period, near the end of the 1st century B.C., stands a fragmentary papyrus of the last two books of the *Iliad*, now in the British Museum (pap. cxxviii.), which is of sufficient extent to be noted. Then, emerging on the Christian era, we come upon one of the most beautiful surviving specimens of literary writing, which we have satisfactory reason for placing near the beginning of the 1st century. It is a fragment of the third book of the *Odyssey*, the writing of which closely resembles that of an official document (Brit. Mus. pap. cccliv.) which happens to be written in a formal literary hand, and which from internal evidence can be dated within a few years of the close of the 1st century B.C. There can be no hesitation, therefore, in grouping the *Odyssey* with that document. The contrast between the round Roman style and the stiff and firm Ptolemaic hands is here well shown in the facsimiles from this papyrus (Fig. 7) and the *Phædo* and *Bacchylides*.

In a similar style of beautiful writing are two fragments of Hesiodic poems recently published, with facsimiles, in the *Sitzungsberichte* (1900, p. 839) of the Berlin Academy. The earliest of the two, now at Strasburg, may be assigned to the first half of the 1st century; the other, at Berlin, appears to be of the 2nd century.

At this point two MSS. come into the series, in regard to which there is now held to be reason for revising views formerly entertained. The papyrus known as the Harris Homer (Brit. Mus. pap. cvii.), containing portions of the eighteenth book of the *Iliad*, which was formerly placed in the 1st century B.C., it is thought should be now brought down to a later date, and should be rather assigned to the 1st century of the Christian era. The great papyrus, too, of Hyperides, containing his orations against Demosthenes and for Lycophron and Euxenippus, which has been commonly placed also in the 1st century B.C., and by some even earlier, is now adjudged to belong to the latter part of the 1st century A.D.

At the end of the 1st or early in the 2nd century is placed a papyrus of great literary interest, containing the Mimes of the Alexandrian writer Herodas, which was discovered a few years ago and is now in the British

Museum. The writing of this MS. differs from the usual type of literary hand, being a rough and ill-formed uncial, inscribed on narrow, and therefore inexpensive, papyrus; and if the roll were written for the market, it was a cheap copy, if indeed it was not made for private use. Of the same period is a papyrus of Isocrates, *de Pace* (Brit. Mus. pap. cxxxii.), written in two hands, the one more clerical than the other; and two papyri of Homer, *Iliad* iii.–iv. (Brit. Mus. pap. cxxxvi.), and *Iliad*, xiii.–xiv. (Brit. Mus. pap. dccxxxii.), the first in a rough uneducated hand, but the latter a fine specimen of uncial writing. Then follows another famous papyrus, the Bankes Homer, containing the last book of the *Iliad*, which belongs to the 2nd century and is also written in a careful style of uncial writing.

With regard to the later literary works on papyrus that have been recovered, the period which they occupy is somewhat uncertain. The following are, however, placed in the 3rd century, during which a sloping literary hand seems to have been developed, curiously anticipating a similar change which took place in the course of development of the uncial writing of the vellum MSS., the upright hand of the 4th to 6th centuries being followed by a sloping hand in the 7th and 8th centuries:—A MS., now in the British Museum, of portions of books ii.–iv. of the *Iliad*, written on eighteen leaves of papyrus, put together in book-form, but inscribed on only one side; on the verso of some of the leaves is a short grammatical treatise attributed to Tryphon: portion of *Iliad* v., among the Oxyrhynchus papyri (No. ccxxiii.): a fragment of Plato's *Laws* (Ox. pap. xxiii.): a papyrus of Isocrates, *in Nicoclem*, now at Marseilles: a fragment of Ezekiel, in book form, in the Bodleian Library: and a fragment of the "Shepherd" of Hermas, at Berlin.

Of the 3rd century also are some fragments which are palæographically of interest, as they are written neither in the recognized literary hand nor in simple cursive, but in cursive characters moulded and adapted in a set form for literary use—thus anticipating the early stages of the development of the minuscule book-hand of the 9th century from the cursive writing of that time.

With the 3rd century the literary hand on papyrus appears to lose most of its importance. We are within measurable distance of the age of vellum, and of the formal uncial writing of the vellum MSS. which is found in some existing examples of the 4th century and in more abundant numbers of the 5th century. We have now to see how the connexion can be established between the literary handwriting of the papyri and the firmer and heavier literary uncial writing of the vellum codices. The literary hands on papyrus which have been reviewed above are distinctly of the style inscribed with a light touch most suitable to the comparatively frail material of papyrus. Only in the Bankes Homer may one detect some indication of the fulness that characterizes the vellum uncial writing. But it now appears that a larger and rounder hand was also employed on papyrus at least as early as the 1st century. In proof of this we are able to cite a non-literary document bearing an actual date, which happens to be written in characters that, exclusive of certain less formally-made letters, are of a large uncial literary type. This writing, though not actually of the finished style familiar to us in the early vellum MSS., yet resembles it so generally that it may be assumed, almost as a certainty, that there was in the 1st century a full literary uncial hand formed on this pattern, which was the direct ancestor of the vellum uncial. The tendency to employ at this period a calligraphic style, as seen in the fragments of the *Odyssey* and one of the Hesiodic poems mentioned above, supports this assumption. The document now referred to is a deed of sale written in the seventh year of Domitian, A.D. 88 (Brit. Mus. pap. cxli.). The letters still retaining a cursive element are *alpha*, *upsilon*, and in some instances *epsilon*.

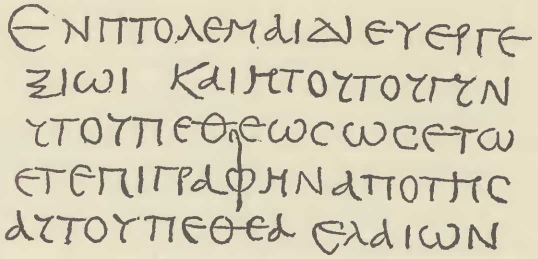

Fig. 8.—Deed of Sale, A.D. 88.

(—εν πτολεμαιδι ευεργε—
—ξιωι και η τουτου γυν—
—υ του πεθεως ως ετω—
—ετεπιγραφην απο της—
—αυτου πεθεα ελαιων—)

As evidence in support of this view that the uncial hand of the vellum MSS. is to be traced back to the period of the document just quoted, we have the important papyrus found by Mr Flinders Petrie at Hawara in Egypt, and now in the Bodleian Library, which contains a portion of the second book of the *Iliad*. The writing is of the large uncial type under consideration; and there is now full reason for assigning it to the 2nd century at latest. Before the discovery of the document of the year 88 there was nothing to give a clue to the real period of the Homer; and now the date which has been suggested is corroborated by a fragment of papyrus from Oxyrhynchus inscribed with some lines from the same book of the *Iliad* (Fig. 9) in the same large uncial type (*Ox. Pap.* vol. i. no. 20, pl. v.). In this latter instance there can be no question of the early date of the writing, as on the verso of the papyrus accounts of the end of the 2nd century or of the beginning of the 3rd century have been subsequently added.

Thus, then, in the 1st and 2nd centuries there was in use a large uncial hand which was evidently the fore-

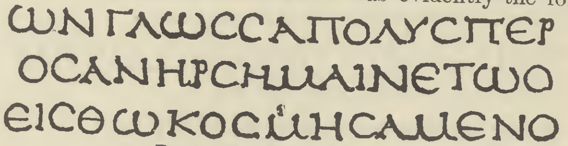

Fig. 9.—The *Iliad*, 2nd century.

(—ων γλωσσα πολυσπερ—
—ος ανηρ σημαινετω ο—
—εισθω κοσμησαμενο—)

runner of the literary uncial hand of the early vellum codices. It is also to be noted that the two literary examples just mentioned are MSS. of Homer; and hence one is tempted to suggest that, as in the production of sumptuous copies on papyrus of a work of such universal popularity and veneration as the *Iliad* this large and handsome uncial was specially employed, so also the use of a similar type for the early vellum copies of the sacred text of the Scriptures naturally followed.

While such large results in Greek papyri have rewarded recent researches in Egypt, we have to record the discovery of only a very small number of papyri inscribed in Latin, and of those very few are in perfect condition. Among the Archduke Rainer's collection at Vienna, for example, and among the large mass of documents found at Oxyrhynchus for the Egypt Exploration Fund, here and there a letter, or fragment, or military document is found. But it is hardly to be expected that any very extensive series of Latin documents should come to light in Egypt, unless by chance the archives of some Roman military station should be recovered.

We may briefly enumerate the few more important documents recently found. Among Lord Amherst's papyri is a fragment containing three of the fables of Babrius, each accompanied with a Latin version, of the 3rd or 4th century (*Amherst Papyri*, pt. ii. no. xxvi.). At Berlin are the remains of an Imperial edict, suggested to be of the time of Tiberius, which are published, with a photograph, in *Aegyptische Urkunden aus den königl. Museen*, No. 628. At Geneva is a papyrus containing Roman military money accounts, published by Nicole and Morel, *Archives Militaires du premier siècle.* A papyrus of a similar nature, of the 2nd century, is printed by Grenfell and Hunt, *Fayûm Towns* (Eg. Expl. Fund), No. cv. And a roll, now at Berlin, of the First Augustan Cohort of Spain, quartered at Apollinopolis Major in Egypt, in A.D. 156, is given in facsimile in the series of the *Palæographical Society*, ii. 165. The most perfect Latin document on papyrus, as yet recovered, is in the British

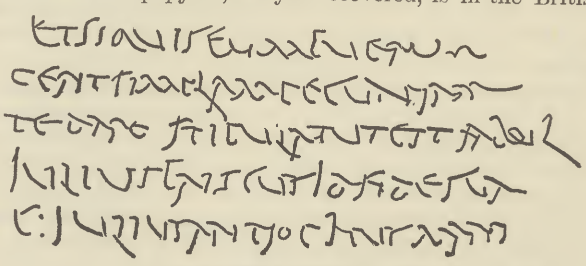

Fig. 10.—Sale of a Slave, A.D. 166.

(—et si quis eum puerum
—ccrit simplam pecuniam
—te dare stipulatus est Fabul
—Julius Priscus id fide sua

Museum, and records the purchase of a slave-boy by an officer in the Roman fleet of Misenum stationed on the

Syrian coast, A.D. 166 (*Pal. Soc.* i. 190; *Archæologia*, liv. p. 433). The writing of the body of the document is in a formal cursive, generally of the same formation as the inscriptions on the Dacian waxen tablets of the 2nd century, as will be seen from the accompanying facsimile of a few lines (Fig. 10).

With this example of legal handwriting of the 2nd century it is interesting to compare two specimens of more ordinary cursive in different styles found in private letters of about the same time. The first is taken from a fragmentary letter of the year 167, published by Grenfell and Hunt, *Greek Papyri*, series ii. No. cviii.:—

AUTHORITIES.—Of general handbooks and guides for the study of Greek and Latin palæography there have been issued:—E. M. THOMPSON, *Handbook of Greek and Latin Palæography* (1893); a third edition of WATTENBACH'S *Schriftwesen im Mittelalter* (1896); DZIATZKO, *Untersuchungen über ausgewählte Kapitel des antiken Buchwesens* (1900); and KENYON'S article on "Writing" in Hastings' *Dictionary of the Bible* (1902); also PROU'S *Manuel de Paléographie Latine et Française* (1891), and REUSENS' *Elements de Paléographie* (1897). The Palæographical Society has completed the issue of two large series of facsimiles from manuscripts (1873–1894) with classified indices (1901); and VITELLI and PAOLI have published their *Collezione Fiorentina di Facsimili Paleografici Greci e Latini* (1884–1896). For the **Palæography of Greek Papyri** a large number of works have been published:—KENYON, *The Palæography of Greek Papyri* (1899), and *Catalogue of Greek Papyri in the British Museum*, 2 vols., with atlases of facsimiles (1893, 1898).—MAHAFFY. *On the Flinders Petrie Papyri* (Royal Irish Academy, 1891, 1893).—*Mittheilungen aus der Sammlung der Papyrus Erzherzog Rainer* (1886, &c.), and *Führer durch die Ausstellung der Papyrus Erzh. Rainer* (1892).—WESSELY, *Corpus Papyrorum Raineri* (1895).—GRENFELL and HUNT. *Greek Papyri* (two series, 1896, 1897), *The Oxyrhynchus Papyri* (two parts, 1898, 1899), *Fayûm Towns and their Papyri* (1900).—GRENFELL. *Revenue Laws of Ptolemy Philadelphus* (1896). — KENYON. *Aristotle on the Constitution of Athens* (1891, 1892), with facsimile. *Classical Texts from Greek Papyri* (1891, 1892), including Herodas, with facsimile, and *The Poems of Bacchylides* (1897), with facsimile.—REVILLOUT. *Le Plaidoyer d'Hypéride contre Athénogène* (1892), with facsimile.—WILCKEN. *Tafeln zur älteren griech. Palæographie* (1891). For **Greek Palæography generally**:—WATTENBACH. *Anleitung zur griech. Palæographie* (3rd ed., 1895).—OMONT. *Facsimilés des plus anciens Manuscrits Grecs en onciale et en minuscule de la Bibliothèque Nationale du iv. au xii. siècle* (1892); *Facsimilés des Manuscrits datés de la Bibl. Nat. du ix. au xiv. siècle* (1890); *Facsimilés des Manuscrits Grecs des xv. et xvi. siècles* (1887).—MARTIN. *Facsimilés des Manuscrits Grecs d'Espagne* (1891).—ALLEN. *Notes on Abbreviations in Greek Manuscripts* (1889).—ZERETELI. *De compendiis Scripturæ codicum Græcorum, præcipue Petropolitanorum et Mosquensium* (1896).—GITLBAUER. *Die drei Systeme der griech. Tachygraphie* (1894).—WESSELY. *Ein System altgriech. Tachygraphie* (1895). For **Latin Palæography**:—The waxen tablets found at Pompeii in 1875 and 1887 have been edited by ZANGEMEISTER, *Tabulae Ceratae Pompeis repertae*, in the supplement to vol. iv. of the *Corpus Inscriptionum Latinarum* of the Royal Prussian Academy (1898).—CHATELAIN. *Paléographie des Classiques Latins* (1884–1896), and *Uncialis Scriptura codicum Latinorum novis exemplis illustrata* (1901). — DELISLE. *Album Paléographique* (1887); *Recueil de Facsimilés à l'usage de l'École des Chartes* (1880, &c.)—MONACI and PAOLI. *Archivio Paleografico Italiano* (1882, 1890). WESSELY. *Schrifttafeln zur älteren lateinischen Palaeographie* (1898).—CHROUST. *Monumenta Palæographica* (1899, &c.).—GIRY. *Manuel de Diplomatique* (1894).—MARTIN. *The Record Interpreter* (1892).—CAPPELLI. *Dizionario di Abbreviature Latine ed Italiane* (1899).—CHATELAIN. *Introduction à la Lecture des Notes Tironiennes* (1900). Several large MSS. have been reproduced, in full or in part, in photographic facsimile, namely:—The Codex Alexandrinus (Cod. A) and the Codex Vaticanus (Cod. B), of the Bible in Greek; the Codex Bezæ (Cod. D), Gospels and Acts, in Greek and Latin; the Vienna Genesis, in Greek; the Codex Sarravianus of the Pentateuch, in Greek; the Codex Rossanensis of the Gospels, in Greek; the Ashburnham Genesis, in Latin; the Utrecht Psalter, in Latin; Homer's *Iliad* (Cod. Venetus A); the Laurentian Æschylus; the Laurentian Sophocles; the Paris Demosthenes; the Oxford Plato (Cod. Clark.); the Heidelberg Plautus (Cod. Palatin.); the Vatican Virgil (Cod. Vat. 3225); the Bern Horace (Cod. 363); and the Venice Aristophanes (in progress). (E. M. T.)

Palamau, a district of British India, in the Chota Nagpur division of Bengal. It was formed out of Lohardaga, and takes its name from a former state or chiefship. The administrative headquarters are at Daltonganj. It consists of the lower spurs of the Chota Nagpur plateau, sloping north to the valley of the Sone. Area, 4905 square miles; population (1881), 551,075; (1891), 596,770; (1901), 619,421; showing an increase of 8 per cent. between 1881 and 1891, and of 3·8 per cent. between 1891 and 1901; average density, 126 persons per square mile, being the lowest in all Bengal. Classified according to religion, Hindus in 1891 numbered 496,426; Mahommedans, 50,445; Christians, 6676; aborigines, 43,223. The land revenue and rates in 1897–98 were Rs.1,23,780; number of police, 256; boys at school (1896–1897), 6860, being 15·5 per cent. of the male population of school-going age; registered death-rate (1897), 39·4 per thousand. Palamau suffered severely from drought in 1897–98. Sanction has been given for a branch of the East Indian Railway from the Sone valley, which will open up the valuable coalfield near Daltonganj; and other lines have been surveyed to afford a shorter route to Calcutta. The only articles of export are jungle produce, such as lac and *tasar* silk. The forests are unprofitable.

Palamcottah, a town of British India, in the Tinnevelly district of Madras, situated on the opposite bank of the Tambraparni river to Tinnevelly town, with which it shares a station on the South Indian Railway, 444 miles south of Madras. Population (1891), 18,612; municipal income (1897–98), Rs.25,360. It is the residence of the officials of the district. The Sarah Tucker college for women was founded in 1895; the two high schools (Church Mission and Jesuit) have nearly 600 pupils. There are three printing-presses, besides a library and reading-room.

Palanpur, a native state of India, in the Gujarat division of Bombay, on the southern border of Rajputana. Area, 3177 square miles; population (1881), 234,402; (1891), 274,864; (1901), 222,627.

The estimated gross revenue is Rs.6,59,530, of which Rs.48,680 was expended on public works in 1897–98; tribute to the Gaekwar of Baroda, Rs.50,000. The chief, whose title is diwan, is an Afghan by descent. The state is traversed by the main line of the Rajputana–Malwa railway, and contains the British cantonment of Deesa. The state suffered severely from the plague, the number of deaths to July 1898 having been 1119. The town of PALANPUR is a railway junction for Deesa, 18 miles distant. Population (1881), 17,547; (1891), 21,092; (1901), 17,799. There are a high school, with 138 pupils in 1896–97; the Jackson town hall; the Scott Hospital, opened in 1898; and a printing-press. Palanpur also gives its name to a political agency, or collection of native states; total area, 4775 square miles; population (1891), 645,526; (1901), 467,691, showing a decrease of 28 per cent., due to the effects of famine.

Palêan. See MALAY PENINSULA.

Palencia, an inland province of Spain; area, 3127 square miles. Population, 188,845 in 1887, and 193,668 in 1897. It is divided into seven districts and 250 parishes. The birth-rate is 4·43 per cent., the death-rate 3·76 per cent., and the proportion of illegitimate births 2·03 per cent. The climate is cold and damp in the northern mountainous and well-wooded part, but temperate and dry in the vast plain of the Tierra de Campos, which is rich in agricultural products.

In 1897 wheat was grown on 269,687 acres; rye, oats, barley, maize on 314,217 acres; pod fruit on 99,930 acres; vines on 57,370 acres. The province is rich in live stock. Besides all its breadstuffs, Palencia produces good, strongly alcoholic wines, much hemp, fruit, and vegetables. The most important industry is flour-milling. There are manufactures of oil, porcelain, leather, paper, cloths, and especially of rugs (in great demand in the whole peninsula). The mining interests have been chiefly developed by the opening of narrow-gauge railways, putting the province in communication with Bilbao *viâ* Robla, and very advantageous for the coal-mines near the rivers Carrion, Pisuera, and Rubagon. There are one copper and ninety coal mines, and the output is 500 tons of copper and 106,666 tons of coal a year.

Palencia, capital of the above province, on the left bank of the river Carrion and of the canal of Castilla, in a fertile country. Population, 15,050 in 1887, and 16,118 in 1897. The streets of the old town are narrow and irregular, but studded with more modern houses and public buildings. The Puente Mayer, Puente Nuevo, and Puentecillos span the river, and communicate with some new suburbs. Much has been done for education; besides an institute, there are many primary schools, a school for teachers of both sexes, a municipal academy of fine arts, a school of arts and handicrafts, and a meteorological observatory. The town is well provided with hospitals, a foundling refuge, barracks, and a bull-ring for 8000 sightseers. Local industries include the making of rugs, alcohol, leather, soap, porcelain, linen, cotton, wool, foundries, machinery, and matches.

Palermo, a city of Italy, capital of the former kingdom of Sicily, standing on a bay of the same name situated on the northern coast of the island. It is surrounded by a plain about 70 square miles in extent, bounded at a distance of from 4 to 6 miles by a semicircular mountain chain which terminates in the two promontories of Zaffarano and Monte Pellegrino. Until a century ago the form of the city was perfectly rectangular. It occupied an area of about 1 square mile. This more ancient part of the town is intersected by the two great streets, Toledo and Macqueda, which, cutting each other at right angles in the centre of the city, terminate at the four old gates called Porta Telice, Porta Nuova, Porta di S. Antonino, and Porta Macqueda. At the point where the two streets cross is the little Piazza of the Four Corners (Quattro Cantoni), which is still the centre of Palermitan life. With the increase of the population vast new quarters have grown up, especially outside Porta Nuova and Porta Macqueda. These quarters are characterized by fine squares, large straight streets planted with trees, several public gardens, and numerous villas in the English style surrounded by gardens. Among the modern edifices are the two theatres, called the Politeama and the Teatro Massimo, which are two of the most gorgeous in Italy. The city is the commercial centre of western Sicily. The climate in winter is extremely mild, the sky usually clear, and the atmosphere always free from fog. The plain is planted with orange and lemon groves and with abundance of palm-trees, which, though their fruit does not attain maturity, give to the landscape an Oriental aspect—an aspect further enhanced by the numerous acanthus, cactus, stone-pine, and gigantic plane trees. The interior of the city—now well supplied with good water—does not wear that neglected and dirty aspect often noticeable in southern cities. Shops and streets are extremely clean, and the bearing of the population is reserved and dignified. The inhabitants, indeed, present the appearance of an economic well-being possibly out of keeping with their financial condition. Industrial development is as yet slight, although a large shipbuilding yard has been established. But owing to the university, the libraries, the museum, and the scientific institutions, Palermo remains the centre of Sicilian culture and exerts great moral and intellectual influence over the rest of the island. Population, 291,000.

Like most other Italian universities, the university is subject to the general laws upon higher education, namely, the fundamental Casati Law of 1859, the Matteucci Law of 1860, and the Baccelli Law of 1881. It was given first-class status in 1860, and since then has possessed the four faculties which exist in all Italian universities of the first class—jurisprudence, medicine and surgery, letters and philosophy, natural sciences and mathematics. A school of pharmacy and a school of practical engineering have been added. The ordinary and extraordinary professors in all the faculties numbered seventy-one in 1899. The number of *liberi docenti* or free chairs (corresponding to the *agrégation* of French universities, or, more exactly, to the *Privat-docenten* of German universities) was almost equal to that of the official professors. The institution known as a Consorzio Universitario arranges for the payment by the communal and provincial authorities of a part of the cost of the scientific laboratories annexed to the chairs of experimental science, and of the training school connected with the faculty of philosophy and letters. The number of students grew from 300 in 1872 to 1495 in 1897, but the number has since somewhat decreased, having been 1225 in 1898, 1148 in 1899, and 1161 in 1900. The chief cause of this diminution is the increasing emigration of Sicilian students —especially those who intend to study electricity, for which no provision exists at Palermo—to the better-equipped universities of Naples, Rome, or Turin. A number of professors have also migrated from Sicily to the northern Italian universities.

The number of entrances and clearances at the port in 1896 was 7192 vessels of 3,164,465 tons, unloading and loading 681,014 tons of goods; in 1898 the figures were 6921 vessels of 3,266,833 tons, unloading and loading 677,932 tons of goods.

Palestine, or the HOLY LAND, the southern third of Syria, bounded on the W. by the Mediterranean, on the S. by a line somewhat indeterminately drawn from the southern end of the Dead Sea westwards, on the E. by the desert of Syria and Arabia, and on the N., rather indefinitely, by the Lebanon and Anti-Lebanon, between 31° and 34° N. and 34° and 37° W.

Geology.—The physical features closely conform to its geological structure. Proceeding from west to east, they are: (1) A maritime district, of varying width, that extends along the coast of the Mediterranean, and is formed of raised beaches and sea-beds which range from the Pliocene period downwards, and rest upon calcareous sandstones of Upper Eocene age. (2) The hill-country which stretches southwards from Lebanon through Galilee, Samaria, and Judæa, to the desert tableland called Badiet et-Tíh. It is composed of cretaceous limestone, with beds and bands of marl and flint, which is covered here and there by outlying patches of nummulitic limestone. Westwards the limestone passes under the calcareous sandstone; eastwards, though concealed by more recent deposits, it underlies nearly the whole of the Jordan valley, and is broken off, along the line of the great fault, against older formations. (3) The Jordan-ʿAraba depression, which follows the line of a fault, or fracture of the earth's crust that has produced a vertical displacement of the strata, those on the west side of the depression being lowered, and those on the east side elevated. In the valley itself there are remains of lake-deposits which reach to a height of 1200 feet, and indicate the varying levels of the great inland sea of the Pliocene period (see DEAD SEA). (4) The hill-country of Gilead and the table-land of Moab, formed of cretaceous limestone resting, in descending order, upon variegated "Nubian" sandstone of Lower Cretaceous age, limestone of the Carboniferous period, red sandstone, conglomerates, and crystalline rocks of great geological antiquity. East of the Dead Sea and the Jordan the limestone is overlaid in places by sheets of basalt of post-Tertiary date, most conspicuous in the north, where they form the surface of the Haurán, Jaulán, and Lejá districts. West of Jordan volcanic lavas are found round the Sea of Galilee, in the plain of Jezreel, and in a few other localities.

Political Geography. — Considerable light has been thrown upon the condition of Palestine in the 14th century B.C. by the discovery of the Tell el-ʿAmarna letters, which describe the breaking up of the Egyptian empire in that country during the last years of Amenhotep III. and the reign of Akhenaten, and the extension southwards of the Amorite and Hittite power prior to the Hebrew invasion. Palestine, except for the independent sanjak of el-Khuds (Jerusalem), now forms part of the vilayets of Beirút and Suríya (Damascus), including the sanjaks of ʿAkka, Náblus, Haurán, Belka, and Kerak.

Recent History.—Since 1880 great changes have taken place. The effective occupation, by Turkish troops, of the country east of Jordan, from Damascus to Máán and the Gulf of ʿAkabah, has secured both sides of the river from the incursions of the Bedawín, and given security to life and property. New villages have been built, and large areas of rich land which were formerly waste have been brought under cultivation. A railway now connects Jaffa with Jerusalem; another runs through the Haurán from Mezeiríb to Damascus, where it joins the line to Beirút; and a third, intended to connect Haifa with Damascus, is in course of construction.[1] Metalled roads have been made, and upon these wheeled transport has largely taken the place of the mule and camel. But the most interesting changes are those due to the efforts that have been made to establish European and Jewish agricultural colonies in the land. The first attempts, by Germans at Urtás in 1850, and by Americans at the same place in 1851, and near Jaffa in 1853 and 1866, failed. But in 1868 the German community of the "Temple" successfully founded colonies at Haifa and Jaffa, and afterwards at Sarona, north-east of Jaffa, and at Jerusalem. The community now numbers about 1200, and has its own schools and hospitals. Its members are engaged in trade, or in agricultural pursuits and the production of wine, or work as artisans. They have done much to promote the agricultural development of the country, and have introduced a higher standard of life, which is slowly but surely influencing the native peasantry. The Christian attempts at colonization attracted the attention of the Jews. In 1853 Sir Moses Montefiore purchased land near Jaffa for the use of the American colony; in 1870 the Alliance Israélite Universelle established an agricultural school for Jews near Jaffa; and in 1878 an abortive attempt was made to settle a colony of Jerusalem Jews at Mulebbis on the Jaffa–Náblus road. In 1881 and the following years the persecution of the Jews in Rumania and Russia led to emigration on a large scale, and many of the emigrants selected Palestine as their future home. Land was purchased, not always in suitable localities, and there was much suffering amongst the settlers from fever and ignorance of the country. Many died, and failure was almost certain, when Baron Edmond de Rothschild intervened with that financial assistance and intelligent direction without which there could be no measure of success.[2] His example was followed by the Alliance Israélite, the Jewish Colonization Association, the Chovevi Zion, and other societies, and numerous settlements had been established before the movement was checked by the action of the Porte in forbidding further immigration and the sale of land to Jews. At present there are more than twenty colonies, with about 5000 colonists, scattered over the country from the Merj ʿAyún to the vicinity of Ashdod. The land held exceeds 40,000 acres, and the whole of this has been brought under cultivation. In the face of obstacles created by local officials, crushing taxation, and the opposition of France and Russia, the colonization has been on the whole successful. The land has proved to be highly productive, and to respond readily to improved methods of agriculture; and under a better system of government the financial success of the colonies, which thus far has not been complete, would be assured. The influence of the colonies on the aspect and well-being of the country is marked. Forests of eucalyptus, extensive orchards, olive groves, vineyards, and cornfields have taken the place of arid waste lands; clusters of well-built houses are frequently seen; roads have been made; native landowners have adopted the agricultural methods of the Jews; industries have sprung up to meet the requirements of the colonies, and a great impetus has been given to the culture of silk, the manufacture of wine and perfumes, and the re-cultivation of the soil. How far the next generation will be able to resist the enervating tendency of the climate, and avoid the danger of assimilation with the natives, are questions that cannot be discussed here. Circassian colonies have been planted at Jerash, ʿAmmán, Kaisaríeh, and other places, where the colonists, although they have done irreparable damage to the ruins of the ancient cities, have introduced wheeled transport and improved methods of cultivation.

The Sultan, in pursuance of a scheme which had its origin about 1885, has taken up waste lands and purchased landed property throughout the Asiatic provinces of his empire. In Palestine he now holds as his private property (*arázi-i-seníye*) the whole of the Jordan valley south of the Sea of Galilee, and large estates in Wádi es-Surár and other places. These Crown properties, which are under an independent administration managed from Constantinople, serve as model farms, and have in some respects an influence for good. But they pay

[1] The construction of this line was suspended in 1901.

[2] In 1900 the Rothschild interest in the colonies was handed over to the Jewish Colonization Association.

no taxes to the State, and the officials attached to them act not only in the name but in the personal interests of the head of the State.

Accompanying, and partly consequent upon, the process of colonization there has been a change in the position of the peasantry who were formerly freeholders of the soil. In most of the fertile districts capitalists, to whom the peasant proprietors were hopelessly in debt, have foreclosed their mortgages, and the owners, obliged to give up their title-deeds, are now working as tenants at will (*sherík el-hawa*) on lands that had been handed down to them through many generations.

An interesting feature is the great increase in the number of monastic, missionary, educational, and philanthropic establishments. The scene of nearly every event connected with New Testament history has been localized, the site purchased, and a commemorative chapel and monastery erected. There has also been great missionary activity on the part of all the Churches, and latterly the Russians have sought to gain influence by subsidizing Greek Orthodox schools in which Russian is taught, by opening schools in the villages and seminaries in the towns, and by sending promising students to complete their education in Russia. The object of this propaganda is, apparently, to form a national Arab Church, looking to Russia for protection, and to weaken the position now held in Turkey by the Greek Orthodox Church. Amongst the philanthropic establishments none are more worthy of notice than the hospitals founded at Jerusalem, Nazareth, Tiberias, and other places by English and Scottish societies. As a result of this activity on the part of the Greek, Protestant, Roman Catholic, and Russian Churches, Palestine is now covered with churches, chapels, monasteries, nunneries, hospices, and hospitals, and filled with clergy, monks, nuns, and pilgrims, as it has not been since the fall of the Latin kingdom. The old theory that all Roman Catholic institutions in the Levant should be under French protection has been abandoned. In Egypt they are now under Austrian protection, and in Palestine, since the German emperor's visit in 1898, all German Roman Catholic subjects and institutions are under German protection.

The trade and prosperity are to a large extent derived from the various religious interests centred in the land. There has been a large import of building material, and general trade has increased; but although this has benefited Europeans and the upper and educated classes amongst the natives, the condition of the peasants is perhaps worse than it was before the inrush of Europeans commenced. There are no trustworthy statistics of the population. There has been a large increase since 1880 in the number of Europeans and Jews, but the native population apparently has been stationary, and in some districts even seems to have decreased.

Exploration.—Since 1885 important surveys, covering Jaulán and parts of Haurán, and Gilead, have been made by Schumacher; excavations have been carried out for the Palestine Exploration Fund by Petrie, Bliss, and Macalister at Tell el-Hesi (Lachish), Jerusalem, Tell es-Safi, and other sites; the Sea of Galilee has been examined by Barrois; and Petra, with parts of Moab and Edom, has been surveyed by Brünnow. The results of the excavations show generally that an advanced state of civilization, sometimes under Mycenaean, sometimes under Egyptian influence, existed in the country during the pre-Israelite period.

Palestine, a city of Texas, U.S.A., capital of Anderson county. It is on the International and Great Northern Railroad, in the eastern part of the state, at an altitude of 495 feet. It is in an agricultural and forested region, and has varied manufactures. Population (1880), 2997; (1890), 5838; (1900), 8297, of whom 356 were foreign-born and 2872 were negroes.

Palfrey, John Gorham (1796–1881), American historian, was born in Boston, Massachusetts, 2nd May 1796. He graduated at Harvard, 1815, and became a Unitarian minister, being pastor of the Brattle Square church, Boston, 1818–31. He was professor of sacred literature in the Harvard divinity school, 1831–39. Entering political life, he was secretary of state of Massachusetts, 1844–47; member of Congress, 1847–49; and postmaster of Boston, 1861–67. During his public career he was an earnest abolitionist. As a writer he edited the *North American Review*, 1836–43, and produced Biblical, sermonic, apologetic, and grammatical works now forgotten; but he is best known by a solid, rather than rhetorically interesting, *History of New England* to the revolutionary war, in five volumes, of which the first appeared in 1859 and the last posthumously in 1890. He died at Cambridge, Massachusetts, 26th April 1881.

Palghat, a town of British India, in the Malabar district of Madras, on the Madras Railway, 74 miles east of Beypur. Population (1881), 36,339; (1891), 39,367; municipal income (1897–98), Rs.65,850. It is a busy centre of trade with the western coast. The Basel Protestant mission has quarters here. The municipality manages the Victoria Jubilee College, with 67 students in 1896–97. There are two high schools with 481 pupils, two printing-presses, a reading-room, and a law library.

Palgrave, Francis Turner (1824–1897), English critic and poet, eldest son of Sir Francis Palgrave, the historian, was born at Great Yarmouth, 28th September 1824. His brothers, WILLIAM GIFFORD, traveller, author, and colonial official (1826–1888), and Sir REGINALD F. D. (1829– ——), who was Clerk of the House of Commons from 1886 to 1900, also had distinguished careers. At fourteen Francis was sent to Charterhouse; and in 1843, having in the meanwhile travelled extensively in Italy and other parts of the Continent, he proceeded to Oxford, having won a scholarship at Balliol. In 1846 he interrupted his university career to serve as assistant private secretary to Gladstone, but returned to Oxford the next year, and took a first-class in Literæ Humaniores. From 1847 to 1862 he was fellow of Exeter College, and in 1849, in which year began his long friendship with Tennyson, was appointed examiner in the Education Department at Whitehall, afterwards becoming assistant secretary. In 1850 he accepted the vice-principalship of Kneller Hall Training College. He married, in 1862, Cecil Grenville Milnes, daughter of James Milnes-Gaskell. In 1884 he resigned his position at the Education Department, and in the following year was elected professor of poetry at Oxford. He died in London, 24th October 1897, and was buried in the cemetery on Barnes Common. Palgrave published both criticism and poetry, but his work as a critic was by far the more important. Indeed, considering his admirable sense of the qualities and differentiations of true poetry, it is strange that he should have been content with the cold formality of much of his own verse. His *Visions of England* (1880–81) contains the last of his work in metre; it has dignity and lucidity, but little of the "natural magic" which the greatest of his predecessors in the Oxford chair considered rightly to be the test of inspiration. His lyrics were mildly delicate, but quite without lyrical fervour. On the other hand, his criticism was always marked by fine and sensitive tact, quick intuitive perception, and generally sound judgment. His *Handbook to the Fine Arts Collection, International Exhibition, 1862*, and his *Essays on Art* (1866), though not free from dogmatism and over-emphasis, were sincere contributions to art criticism, full of striking judgments strikingly expressed. His *Landscape in Poetry* (1897) showed wide knowledge and critical appreciation of one of the most attractive aspects of poetic interpretation. But Palgrave's principal contribution to the development of literary taste was contained in his *Golden Treasury of English Songs and Lyrics* (1861), an anthology of the best poetry in the language constructed upon a plan sound and spacious, and followed out with a delicacy of feeling which could scarcely be surpassed. The influence of this treasure-house of poetry, with the standards which it set up to taste and selection, has been incalculable. Palgrave followed it with a *Treasury of Sacred Song* (1889), and a second series of the *Golden Treasury* (1897); but in neither of these was quite the same exquisiteness of judgment preserved. (A. WA.)

Palit. See MALAY PENINSULA.

Pallanza, an industrial town and summer and winter resort of the province of Novara, Piedmont, Italy, occupying a position of great natural beauty, on a promontory on the west side of Lago Maggiore, with a semicircle of mountains behind and the lake and Borromean Islands in front, 62 miles north of Novara (56 by rail to Gravellona on the Simplon Railway). The annual mean temperature is 55° Fahr.; January, 37·1°; July, 74°. There is a fine botanical garden. There are cotton, silk, and jute manufactures, saw-mills and turnery shops, and a school of design. Population (1900), 3500.

Palma, capital of the province of Baleares, in the island of Majorca, the largest of the Balearic Isles, in the most northern part of the bay of the same name. It has a seminary founded in 1700, a depot of archives since the 14th century, schools of fine arts and museums of paintings, a nautical school, an institute, many primary schools, and a school for training teachers of both sexes. There are fine public buildings, and most of the streets have been improved with new houses in striking contrast with interesting old residences and palaces of the local nobility. Palma has a thriving trade in agricultural products, wine, oil, almonds, fruit, vegetables, silk, and food-stuffs, as well as live stock. There are manufactures of alcohol, liqueurs, chocolate, starch, sugar, preserves, flour, soap, leather, earthenware, glass, matches, paper, linen, woollen goods, and rugs. The port has been so much improved that large merchant steamers can enter and remain in even rough weather, and foreign war-vessels often visit the port. Population (1887), 61,052; (1897), 62,525.

Palmer, a town of Hampden county, Massachusetts, U.S.A. It has an area of 25 square miles of hill country, and is situated south-west of the centre of the state. The village of Palmer is on the Chicopee river, and on the Boston and Albany and the Central Vermont railways, at an altitude of 332 feet. It is irregular in plan, and has varied manufactures, consisting in part of cotton and woollen goods, iron and steel goods of various sorts, and carpets. Population (1880), 5504; (1890), 6520; (1900), 7801, of whom 2780 were foreign-born.

Palmer, John McCauley (1817–1900), American politician, was born at Eagle Creek, Ky., on 13th September 1817. In 1831 his family removed to Illinois, where he rose to some prominence as a Democrat. On the slavery question he joined the Republican party at its foundation. During the war he served in the Western armies, and rose to the rank of major-general. From 1868 to 1872 he was governor of Illinois, but joined the Liberal Republican movement in the latter year. As governor he resented strongly the assumption of police authority by General Sheridan and the federal troops at the time of the great Chicago fire (October 1872). In 1891 he was elected to the United States Senate by the Democrats, and served one term. Upon the adoption of the free-silver platform, and the nomination of Bryan by the Democratic Convention in 1896, General Palmer was nominated for the Presidency by the "Gold Democrats," but failed to receive any electoral votes. He then lived in retirement till his death, 25th September 1900.

Palmi, a town of the province of Reggio, Calabria, Italy, 26 miles north by east of Reggio on the west coast railway to Naples, standing halfway up the slope of Mount Elia, 450 feet above sea-level. It has olive-oil presses, and fishing for tunny and sword-fish. The town was almost entirely rebuilt after the earthquake of 1783. Population (1881), 9705; (1899), 15,500.

Palmyra Island. See POLYNESIA.

Palo Alto, a town of Santa Clara county, California, U.S.A., on the west side of Santa Clara valley, between two of the coast ranges, on the coast division of the Southern Pacific Railway, 34 miles nearly south of San Francisco. Its site is perfectly level and plan strictly regular. It has a water-supply pumped from artesian wells, and a good sewer system. It is the railway station for Leland Stanford Jr. University, which is $1\frac{1}{2}$ miles south-west. The name of the town was derived from a solitary redwood, standing near the railway track on the outskirts of the town. Population (1900), 1658.

Paludan-Müller, Frederik (1809–1876), the most distinguished of the recent poets of Denmark, was the third son of Jens Paludan-Müller, from 1830 to 1845 bishop of Aarhus. He was born at Kjerteminde in Fünen, on the 7th of February 1809. In 1819 his father was transferred to Odense, and the future poet began to attend the Latin school there. He went to Copenhagen as a student in 1828. After several efforts, he attracted general attention in 1833 by *The Dancing Girl*, a poetical narrative embroidered with charming melody and colour. Paludan-Müller was accepted by criticism without a struggle, and few writers have ever excited less hostility than he. He was, however, not entirely well inspired in his lyrical drama of *Amor and Psyche* in 1834, and his next productions were too vividly influenced by Byron. From 1838 to 1840 Paludan-Müller was making the grand tour in Europe, and his genius greatly expanded. In Italy he wrote *Venus*, a lyrical poem of extreme beauty, a hymn to the majesty of Eros. In 1841 he began to publish a great work on which he had long been engaged, and which he did not conclude until 1848; this was *Adam Homo*, a narrative epic, satirical, modern, and descriptive, into which Paludan-Müller wove all his variegated impressions of Denmark and of love. This remains the typical classic of Danish poetical literature. While this virile work was in slow progress the poet was engaged in shorter and more exquisite productions. In 1844 he was absolutely in flower, for he completed three enchanting idyls, *The Dryad's Wedding*, *Tithonus*, and *The Death of Abel*, each separate, and each one of the poet's most characteristic and most highly finished compositions. In *Tithonus*, perhaps, the genius of Paludan-Müller reaches its most personal expression. From 1850 a certain decline in the poet's physical powers became manifest, and he wrote less. His majestic drama of *Kalanus* belongs to 1854. Then for seven years he kept silence. *Paradise* (1861) bears evidence of malady, both physical and mental. Paludan-Müller wrote considerably after this, but never recovered his early raptures, except in the very latest of all his poems, the enchanting welcome to death, called *Adonis* (1874). After long ill-health, he died at Copenhagen on the 27th of December 1876. He was a poetic artist of the finest order, perhaps the greatest purely plastic poet that the North has seen. (E. G.)

Pamiers, chief town of arrondissement, department of Ariège, France, 12 miles north of Foix, on the railway from Toulouse to Ax-les-Thermes. It has a communal college, consultative chamber of arts and manufactures, and a hospital. Iron and steel of excellent quality, sheet-iron, iron-ware, chains, and carriage springs are among the products of its important metallurgical industries. It has also paper and saw mills and tanneries, and commerce in grain, flour, fodder, fruit, and vegetables. Population (1891), 8166; (1901), 9409.

Pamirs.—Since 1875 the Pamirs have probably been the best explored region in High Asia. Not only have many travellers of many nationalities directed their steps towards the Bam-i-dunya ("the Roof the World") in search of adventure or of scientific information, but the Government surveys of Russia and India have met in these high altitudes, and there effected a connexion which will help to solve many of the geodetic problems which surround the superficial survey of Asia. Since Wood first discovered a source of the Oxus in Lake Victoria in 1837, and left us a somewhat erroneous conception of the physiography of the Pamirs, with a legacy of political dispute arising therefrom, the gradual approach of Russia from the north has stimulated the processes of exploration from the side of India, until conflicting political interests have been set at rest by the discovery that no serious dispute is worth maintaining about those bleak, wind-swept, glacial regions, which are blocked by snow for half the year, and offer no right of way to more than the passing traveller at any time. Native explorers from India first began to be busy in the Pamirs about 1860, and continued their investigations for the following fifteen years. In 1874 the mission of Sir D. Forsyth to Yarkand led to the first systematic geographical exploitation of the Pamir country, and native attachés of the mission subsequently extended their researches into Turkestan. In 1885 Ney Elias made his famous journey across the Pamirs from east to west, identifying the Rang Kul as the Dragon Lake of Chinese geographers—a distinction which has also been claimed by some geographers for Lake Victoria. Then Lockhart and Woodthorpe, in 1886, passed along the Wakhan tributary of the Oxus from its head to Ishkashim in Badakshan, and completed an enduring record of most excellent geographical research. Bonvalot in 1887, Littledale in 1888, Cumberland, Bower, and Dauvergne, followed by Younghusband in succeeding years, extending to 1890; Dunmore in 1892, and Sven Hedin in 1894–95, have all contributed more or less to Pamir geography; but the honours of successful inquiry in those high altitudes still fall to Curzon, whose researches in 1894 led to a singularly clear and comprehensive description of Pamir physiography, as well as to the best map compilation that till then had existed. Meanwhile Russian explorers and Russian topographers had been equally busy from the north. The great soldier Skobeleff was probably the first European to visit the great Kara Kul. He was followed by scientific missions systematically organized by the Russian Government. In 1883 Putiata's mission started south. Grombchefski was hard at work from 1888 to 1892. Yanoff began again in 1891, after a short spell of rest, and has left his mark as a permanent record in the valley of Sarhad (or Wakhan), between the Baroghel pass and Bozai Gumbaz. Finally, in 1895, the Russian mission under General Schveikofski met the British mission under General Gerard on the banks of Victoria Lake, and from that point to the Chinese frontier eastward demarcated the line which thereafter was to divide Russian from British interests in highest Asia. Since then other travellers have visited the Pamirs, but the junction of the Russian and British surveys (the latter based on triangulation carried across the Hindu Kush from India) disposes of any further claim to the honours of geographical exploration (see Asia).

Pamir conformation.

Our estimate of the extent of Pamir conformation depends much on the significance of the word Pamir. If we accept the Persian derivation of the term (which is advanced by Curzon as being perhaps the most plausible), *pai-mir*, or "the foot of mountain peaks," we have a definition which is by no means an inapt illustration of the actual facts of configuration. It has been too often assumed that the plateau of Tibet and the uplands of the Pamirs are analogous in physiography, and that they merge into each other. This is hardly the case. Littledale points out (vol. vii., *R.G.S. Journal*) that the high-level valleys of glacial formation which distinguish the Pamirs, which are never very wide, and which are separated from each other by bands of mountain formation, with crests rounded by the action of the ice-cap and troughs filled with beds of detritus and alluvium, have no real counterpart in the Chang or plains of Tibet. The latter are 2000 feet higher; they are intersected by narrow ranges, and are drained by no rivers of importance. They form a region of salt lakes and stagnant marshes, relieved by wide flat spaces of open plateau country. The absence of any vegetation beyond grass or scrub is a striking feature common to both Pamir and Chang, and it is a remarkable fact that, from the Pamirs to eastern Tibet, a traveller may pass through 30 degrees of longitude without meeting with any vegetable growth "higher than an umbrella"; but there the resemblance ceases, and the physical conformation of mountain and valley to the east and to the west of the upper sources of the Zarafshan is radically distinct.

The axis, or backbone, of Pamir formation is the great meridional mountain chain of Sarikol—the ancient Taurus of tradition and history—on which stands the highest peak north of the Himalaya, the Muztagh Ata (25,000 feet). This chain divides off the high-level sources of the Oxus on the west from the streams which sweep downwards into the Turkestan depression of Kashgar on the east. There are the true Pamirs (*i.e.*, valleys reaching up in long slopes to the foot of mountain peaks) on either side, and the Pamirs on the west differ in some essential respects from those of the east. On the west the following are generally recognized as distinct Pamirs: (1) the Great Pamir, of which the dominant feature is Lake Victoria; (2) the Little Pamir, separated from the Great Pamir on the north by what is now known as the Nicolas range; (3) the Pamir-i-Wakhan, which is the narrow trough of the Wakhan tributary of the Oxus, the term Pamir applying to its upper reaches only; (4) the Alichur—the Pamir of the Yeshil Kul and Gund-dara—immediately to the north of the Great Pamir; (5) the Sarez Pamir, which forms the valley of the Murghab river, which has here found its way round the eastern head of the Great Pamir, and the Alichur from the Little Pamir, and now makes westwards for the Oxus. This branch was considered by many geographers as the main Oxus stream, and Lake Chakmaktin, at its head, was by them regarded as the Oxus source. At the foot of the Sarez Pamir stands the most advanced Russian outpost of Murghabi. To the north-east of the Alichur are the Rang Kul and the Kara Kul (or Kargosh) Pamirs. Rang Kul Lake occupies a central basin or depression; but the Kara Kul drains away north-eastwards through the Sarikol (as the latter, bending westwards, merges into the Trans-Alai) to Kashgar and the Turkestan plains. Similar characteristics distinguish all these Pamirs. They are hemmed in and separated by snow-capped mountain peaks and ridges, which are seamed with glaciers terminating in moraines and shingle slopes at the base of the foot-hills. Long sweeps of grassy upland bestrewn with boulders lead from the stream beds up to the snow-fields, yellow, grey, or vivid green, according to the season and the measure of sunlight, fold upon fold in interminable succession, their bleak monotony being only relieved by the grace of flowers for a short space during the summer months.

The Pamirs.

To the east of the Sarikol chain is the Taghdumbash Pamir, which claims many of the characteristics of the western Pamirs at its upper or western extremity, where the Karachukar, which drains it, is a comparatively small stream. But where the Karachukar, joining forces with the Khunjerab, stretches out northwards for a comparatively straight run to Tashkurghan, dividing asunder the two parallel ranges of Sarikol and Kandar, which together form the Sarikol chain, the appellation Pamir can hardly be maintained. This is the richest portion of the Sarikol province. Here are stone-built houses collected in scattered detachments, with a spread of cultivation reaching down to the river. Here are watermills and many permanent appliances of civilization suited to the lower altitude (11,500 feet, the average height of the upper Pamirs being about 13,000), and here we are no longer near the sources of the river at the foot of the mountain peaks. One other so-called Pamir exists to the east of Sarikol, separated therefrom by the eastern range (the Kandar) of the Sarikol, which is known as Mariom or Mariong. But this Pamir is situated nowhere near the sources of the Zarafshan or Raskam river, which it borders, and possesses little in common with the Pamirs of the west. The Mariom Pamir defines the western extremity of the Kuen Lun, which stretches eastwards for 250 miles before it becomes the political boundary of northern Tibet.

The Muztagh chain and Karakoram extension.

The Muztagh chain, which holds within its grasp the mightiest system of glaciers in the world, forms a junction with the Sarikol at the head of the Taghdumbash, where also another great system (that of the Hindu Kush) has its eastern roots. The political boundary between the extreme north of the Kashmir dependencies and the extreme south of Chinese Turkestan is carried by the Zarafshan or Raskam river, which runs parallel to the Muztagh at its northern foot (its valley dividing the Muztagh from the Kuen Lun) to a point in about 79° 20′ E., where it is transferred to the watershed of the Kuen Lun. Within the limits of these partially explored highlands, lying between the Pamirs and the Tibetan table-land, exact geographical definition is impossible. But we may follow Godwin-Austen in accepting the main drain of the Muztagh as merging into the central mountain system of the Tibetan Chang, its axis being defined and divided by the transverse stream of the Shyok at its westward bend, whilst the Karakoram range, in which the Shyok rises, is a subsidiary northern branch. The pass over the Karakoram (18,500 feet) is the most formidable obstacle on the main trade route between Leh and Kashgar.

The Taghdumbash Pamir.

The Taghdumbash Pamir occupies a geographical position of some political significance. One important pass (the Beyik, 15,100 feet) leads from the Russian Pamirs into Sarikol across its northern border. A second pass (the Wakhjir, 16,150 feet) connects the head of the Wakhan valley of Afghanistan with the Sarikol province across its western head, whilst a third (the Kilik, 15,600 feet) leads into the head of the Hunza river and opens a difficult and dangerous route to Gilgit. The Taghdumbash is claimed both by China and Kunjut (or Hunza), and there is consequently an open boundary question at this corner of the Pamirs.

Boundary between Russia and Afghanistan.

From Lake Victoria of the Great Pamir the northern boundary of that extended strip of Afghanistan which reaches out to the head of the Taghdumbash from Badakshan north of the Hindu Kush is to be traced, westwards, in the Victoria Lake affluent of the Oxus; and eastwards, on the Nicolas range, dividing the Great and Little Pamirs, till it overlooks a point on the Aksu (or Murghab) river in about 74° 40′ E. Here it diverges southwards to the Sarikol chain, north of Taghdumbash. This eastward extension was laid down by the Pamir Boundary Commission of 1895. All the head of the Little Pamir with the Wakhan valley is consequently Afghan territory, but no military posts have been established so far. The Alichur, Rang Kul, Kargosh (Kara Kul), and Sarez are Russian Pamirs. The Mariom Pamir is Chinese.

Glacial sources of the Oxus.

The Wakhan glaciers under the Wakhjir water-parting, Lake Chakmaktin near the sources of the Aksu, and Victoria Lake of the Great Pamir have all been claimed as indicating the true source of the Oxus. But detailed examination of their hydrographical conditions proves that neither of the two lakes, Victoria (13,400 feet) or Chakmaktin (13,020 feet), can justly be regarded as sources, both of them being derived from the same mighty system of glacial snow-fields on the summit of the Nicolas range. Both may be regarded as incidents in the course of glacial streams (incidents which are diminishing in volume day by day), rather than original springs or sources. The same glacial beds of the Nicolas range send down tributary waters to the Panja or Wakhan river, below its junction with the ice stream from Wakhjir, and thus it becomes impossible to decide whether the glaciers of the Wakhjir or the glaciers of Nicolas should be regarded as effecting the most important contribution to the main stream. There is evidence also that glacial moraine formations from time to time may have largely affected the catchment area of these tributary streams. It would be as rash to assert that from Victoria Lake no waters could ever have issued with an eastward flow as it would be to state that from Chakmaktin none ever flow westwards. The measure of the veracity of Chines pilgrims and geographers in the early centuries of our era must not be balanced on such points as these.

Population and ethnography.

There is no evidence that the Pamirs were ever the support of permanent settlements. The few mud-built buildings which once existed at Chakmaktin and at Lungar only decide recent occupation which could hardly have possessed a permanent character, and the few shrines and domed tombs which are scattered here and there about the empty desolation of the Pamir slopes are all of them of recent construction. The nomadic population which seeks pasturage during the summer months in these dreary altitudes is entirely Kirghiz, and we may take it for granted that it will soon be entirely Russian. The non-Russian population during the summer of 1895 could not have amounted to more than a few hundred souls—occupying a few encampments in the Little Pamir and in the Taghdumbash. The total population of the Russian Pamirs has been reckoned at 250 "kibitkas," or 1500 souls. There is no ethnographical distinction to be traced between the Kirghiz of the Alichur Pamir and the Kirghiz of the Taghdumbash.

The Kirghiz are Sunni Mahommedans by faith, but amongst them there are curious survivals of an ancient ritual of which the origin is to be traced to those Nestorian Christian communities of Central Asia which existed in the Middle Ages. A Christian bishopric existed at Yarkand in Marco Polo's time, and is supposed to have survived for another century (1350). The last Gurkhan of the Kara Khitay empire in the early part of the 13th century (the legendary Prester John) was a member of a Christian tribe called Naiman, which is one of the four chief tribal divisions mentioned by Ney Elias. The Naiman tribe claim kinship with the Kipchaks. It is curious that the same survival of Christian ceremonial should be found amongst the Sarikoli, a Shiah people of Aryan descent akin to the Tajiks of Badakshan, as may be traced amongst the Kirghiz. The discoveries of Christian symbols in the southern towns of Chinese Turkestan by Sven Hedin may throw further light upon this interesting question.

Evidences of the survival of Christian symbols.

The total area of the Pamir country may be estimated as about 150 miles long by 150 miles broad, of which about one-tenth is grass pasture land and the rest mountainous. All of it once formed part of the ancient kingdom of Bolor, itself a survival of the yet more ancient empire of the Yuchi, Tokharistan; and across it, in spite of its bleak inhospitality, there have been one or two recognized trade routes from east to west throughout all ages. The most important commercially was that which passed north-west *viâ* Tashkurghan and Rang Kul, from Chinese Turkestan to the khanates north of the Oxus; but the route *viâ* Tashkurghan and Lake Victoria to Badakshan was also well trodden. The great pilgrim route of Buddhist days was that which connects the ancient Buddhist cities of the Takla Makan in Chinese Turkestan with Chitral (Kashkar), by the Baroghel Pass across the Hindu Kush. This was but one link in a chain of devout peregrination which stretched from China to India, and which included every intervening Buddhist centre of note which existed in the early centuries of our era.

Area of the Pamirs.

Trade routes.

For six or seven months of the year (November to April) the Pamirs are covered with snow, the lakes are frozen, and the passes nearly impracticable. The mean temperature during the month of January recorded by Russian observers at the Murghabi—or Pamirski—post is $-13°$ F. In July this rises to 62° F., the elevation of the station being 12,150 feet. During the spring and summer months the prevalence of fierce cutting winds, which are shaped by the conformation of the valleys into blasts as through a funnel, following the strike of the valleys either up or down, makes travelling painful and existence in camp most unpleasant. In the absence of wind the summer atmosphere is often bright and exhilarating, but there is a constant tendency to sudden squalls of wind and rain, which pass as quickly as they gather. The most settled record of the Pamir Boundary Commission of 1895 lasted from the 19th of August to the 11th of September, the maximum temperature being recorded at 77° on the 21st August at Kizil Robat (12,570 feet); and yet on the 16th August snow had fallen to the depth of 6 inches and the Beyik Pass was blocked. There were indications that monsoon influences extended as far north at least as the Great Pamir, and a definite analogy was established between the record of barometric pressure on the Pamirs and that of the outer ranges of the Himalaya.

Climate of the Pamirs.

(T. H. H*.)

Pampa, a territory in the centre of the Argentine Republic, bounded on the N. by Cordoba, San Luis, and Mendoza, on the S. by the territory of Rio Negro, on the E. by Buenos Aires, and on the W. by Mendoza and the territory of Neuquen. Official area at the census of 1895, 56,320 square miles; population, 25,914. It is divided into fifteen departments. The capital, General Acha, has a population of about 1500. In 1895 there were 530,162 head of cattle, 232,489 head of horses, and 5,295,177 head of sheep in the territory.

Pamplona, capital of the province and ancient kingdom of Navarre, Spain, on the Arga. Population, 26,656 in 1887, and 29,753 in 1897. Modern detached forts have been erected. The imposing forts on the peak of San Cristobal and on Miravalles Hill command the approach of Pamplona in view of a French invasion, exactly as the fort of San Marcos, the entrenched camp of Choritogueta, and the fort of Guadalupe near Fuentarabia sweep the approaches to Irun and San Sebastian in Guipuzcoa. Part of the old outworks of Pamplona has been demolished, and suburbs are springing up near the walls and bastions. In the new part of the town are many industries, including cloth, linen stuffs, flour, soap, leather, cards, paper, earthenware, iron, and nails. The fairs are the centre of a trade in agricultural products and live stock, especially in July, when the Navarrese flock to their provincial capital for the patron saint's day, San Firmin. The town is well provided with schools for both sexes, and has an institute, normal schools, and a seminary, hospitals, and fine municipal buildings, kept in order, like their roads and streets, by the autonomous provincial council and municipality. The interior of the walled town has preserved its old-world aspect.

Pana, a city of Christian county, Illinois, U.S.A., near the centre of the state, on the Baltimore and Ohio South-Western, the Cleveland, Cincinnati, Chicago, and St Louis, and the Illinois Central railways, at an altitude of 697 feet. Its site is the level prairie, and its plan is fairly regular. It is in a coal region, and it has some trade and manufactures. Population (1880), 3009; (1890), 5077; (1900), 5530, of whom 727 were foreign-born.

Panama, the chief town of the department of the same name in the republic of Colombia, South America, situated at the upper extremity of the Gulf of Panama. La Boca dock at the Pacific terminus of the canal, three miles from the city, was completed in 1898. Its wharf, 1000 feet in length, can be approached by large steamers, which formerly had to anchor off Flamenco Island and load and unload from small vessels. The city is well laid out, and possesses beautiful squares, parks, and promenades. Among modern buildings are the hospital erected at the expense of the Canal Company, and the Grand Hotel. In October 1899 plans were prepared for a new aqueduct to supply the city with water. The chief exports are hides, deerskins, mother-of-pearl shells, and ivory; the imports include all kinds of dress goods, hardware, furniture, drugs, perfumery, &c. There is a line of steamers from Panama to San Francisco, and also lines south to Valparaiso. Over 200 vessels enter the port annually, with a total tonnage of over 250,000. (For the canal, see CANALS.) Population about 25,000.

Panch Mahals (= Five Districts), a district of British India, in the Gujarat division of Bombay. It includes the ancient Hindu capital of Champaner, now a ruin, and the hill sanatorium of Pawagarh. The administrative headquarters are at Godhra.

Area, 1613 square miles; population (1881), 255,479; (1891), 313,417; (1901), 261,870; showing an increase of 23 per cent. between 1881 and 1891, but a decrease of 16·4 per cent. between 1891 and 1901; average density, 162 persons per square mile. The land revenue is Rs.3,28,000, the incidence of assessment being just over R.1 per acre; cultivated area (1897–98), 357,099 acres, of which 2471 were irrigated from wells, &c., including 175 from Government canals; number of police, 699; children at school (1897–98), 5560, being 2·17 per cent. of the total population; registered death-rate (1897), 20 per thousand. The principal crops are inferior grain, rice, pulse, and oil-seeds; there are manufactures of lac bracelets and lacquered toys. Both portions of the district are now crossed by the branch of the Bombay and Baroda Railway from Anand, through Godhra and Dohad, to Rutlam; and a chord line from Godhra to Baroda city is projected. The district suffered very severely from the famine of 1899–1900.

Panderma, the ancient *Panormus*, a town of Asia Minor, situated on the south shore of the Sea of Marmora, near the site of Cyzicus. It has a trade in cereals, cotton, opium, and boracite. Its population comprises 4000 Moslems and 2000 Christians.

Pandharpur, a town of British India, in the Sholapur district of Bombay, on the right bank of the river Bhima, 38 miles west of Sholapur town. Population (1881), 16,910; (1891), 19,953. Pandharpur is the most popular place of pilgrimage in the Deccan. Three assemblages are held annually. The municipal high school had 101 pupils in 1896–97, and there is also an industrial school. There are two printing-presses, each issuing a vernacular newspaper. In 1900 a light railway was constructed from Barsi Road, 32 miles, partly as a famine relief work, which it is proposed to extend 20 miles farther to Sangola.

Panipat, a town of British India, in the Karnal district of the Punjab, near the old right bank of the Jumna, 53 miles north of Delhi by rail. Population (1881), 25,022; (1891), 27,547; municipal income (1897–98), Rs.24,475. It is a centre of trade, and has manufactures of cotton cloth, metal-ware, and glass. There are a municipal school, and two factories for ginning and pressing cotton. The neighbourhood, which was the scene of three historic battles, is now a favourite manœuvring-ground for British camps of instruction.

Panna, or PUNNA, a native state of Central India, in the Bundelkhand agency. Area, 2568 square miles; population (1881), 227,306; (1891), 239,333, showing an increase of 5 per cent.; average density, 93 persons per square mile.

Estimated revenue, Rs.50,00,000; tribute, Rs.9950. The chief, whose title is maharaja, is a rajput of the Bundela clan, descended from Chhatar Sal, the champion of the independence of Bundelkhand in the 18th century. The late maharaja died in 1898, leaving an only son, Madho Singh. In 1902 this son was found guilty by a special commission on the charge of poisoning his uncle. The diamond mines, for which the state was formerly famous, are no longer profitable. The state suffered severely during the famine of 1896–97. There are no railways, but one or two good roads.

The town of PANNA is 62 miles south of Banda. Population (1881), 14,676; (1891), 14,705. The town is well laid out, with some handsome stone buildings, and has a high school.

Pannonhalma (MONS PANNONIAE, MONS SANCTI MARTINI), or GYÖR SZENT MARTON (German, *Martinsberg*), a famous abbey in Hungary, 11 miles south-east of Raab. Charlemagne built the first chapel, and the well-known Benedictine abbey dates from the time of King St Stephen, and still possesses the original deed (1001). The Benedictines have played no small part in Hungarian history. The Tatars could not take the well-fortified convent, nor could the Turks hold it for more than four years. The present building is a block of palaces, containing also a beautiful cathedral. In the convent there are a seminary for priests, a normal school, a gymnasium, and a library of 120,000 volumes, and precious archives. From its tower eleven counties can be seen. On the same hill stands one of the monuments erected in 1896 in commemoration of the thousand years' existence of the Hungarian state. The chief abbot has the rank of a bishop, and in spiritual matters is subordinated immediately to the Roman curia. The chief abbey, with its daughter abbeys and a few parishes, forms a separate ecclesiastical district, and the chief abbot is member of the Upper House of the Hungarian Parliament. Many of the chief abbots were celebrated men. Claudius Vaszary, the present cardinal archbishop of Esztergom and primate of Hungary, was a dignitary here.

Pantin, a town in the arrondissement of St Denis, department of Seine, France, ½ mile east of the fortifications of Paris by rail, on the canal d'Ourcq. The construction of steam engines, boilers, railway waggons, electric bells, glass, and perfumery, and the operations of dye-works, forges, foundries, distilleries, and saw-mills represent some of the varied branches of its industrial activity. Population (1891), 21,761; (1901), 29,646.

Panton, a township of Spain in the province of Lugo, in a mountainous district, watered by the rivers Sil and Cabe. Live stock is extensively reared, and large quantities of wheat, wine, oats, and potatoes are produced. The industries are distilling and linen manufacture. Population (1887), 11,552; (1897), 12,492.

Papenburg, a town of Prussia, province of Hanover, 27 miles by rail south by west of Emden, and near the right bank of the Ems, with which it is connected by a canal 5 miles long. It is a Dutch-looking place, built in 1675. It is, next after Emden, the most prosperous port of the province; was cleared by 631 vessels of 64,294 tons in 1900; and the trade is growing steadily. The canal is to be deepened to 17–18 feet, whilst new locks (300 feet long, 57 feet wide, and 18 feet deep) will connect the town with the Dortmund–Ems canal. The industries include shipbuilding, oil and glass mills, metal (nickel) and moss-litter factories. There is a school of navigation. Population (1885), 6916; (1900), 7611.

Paper may best be described as a more or less thin tissue composed of any fibrous material, whose individual fibres, first separated by mechanical action, are then deposited and felted together on wire cloth while suspended in water. The main constituent in the structure of all plants is the vegetable fibre or cellulose, which forms the casing or walls of the different cells, being the woody portion of the plant freed from all foreign substances, which forms, so to speak, the skeleton of vegetable fibre to the amount of 75 to 78 per cent. Its forms and combinations are extremely varied, but it always consists of the same chemical elements, carbon, hydrogen, and oxygen, and in the same proportions. The glutinous, resinous, silicious, and other intercellular matters surrounding the cells together constitute the perfect plant, and it is the object of the paper-maker to eliminate these impurities, and to produce the fibre as pure and as strong as possible. Flax, hemp, and cotton rags, having already undergone a process of manufacture, consist of almost pure fibres with the addition of fatty and colouring matters which can be got rid of by simple boiling under a low pressure of steam with a weak alkaline solution; but the substitutes for rags, such as esparto, wood, straw, &c., being used as they come from the soil, contain all the intercellular matter in its original form, which has to be dissolved by strong chemical treatment under a high temperature. The vegetable fibre or cellulose, being of a tougher and stronger nature, is untouched by the action of caustic soda (which is the chemical generally employed for the purpose), unless the treatment be carried too far, whilst animal fibres or other organic matters are rendered soluble or destroyed by it. The cellulose, after its resolution by chemical treatment, is still impregnated with insoluble colouring matters, which have to be eliminated or destroyed by treatment with a solution of chlorine or bleaching powder. The object of the paper-maker in treating any one particular fibre is to carry the action of the dissolving and bleaching agents just so far as to obtain the fibre as free from impurities and as white in colour as is necessary for the kind of paper he wishes to make from it. The usefulness of a plant for a good white paper depends upon the strength and elasticity of its fibres, upon the proportion of cellular tissue contained in them, and upon the ease with which this can be freed from the encrusting and intercellular matters.

Treatment of rags.

Rags arrive at the mill from the rag merchants, either roughly sorted into grades or mixed in quality and material, and the first process is to free them from sand, dust, and other impurities. To effect this they are usually passed in bulk through an ordinary revolving duster. They are then sorted into grades to suit the paper manufactured, and cut to a workable size about 4 inches square. For the best work, hand cutting, done by women, is still preferred, but it is expensive, and good machines have now been designed to perform the work. After further thrashing and dusting the rags are ready for boiling, the object of which is not only to get rid of the dirt still remaining in the rags, and to remove some of the colouring matter, but also to decompose a particular glutinous substance which would impair the flexibility of the fibres and render them too

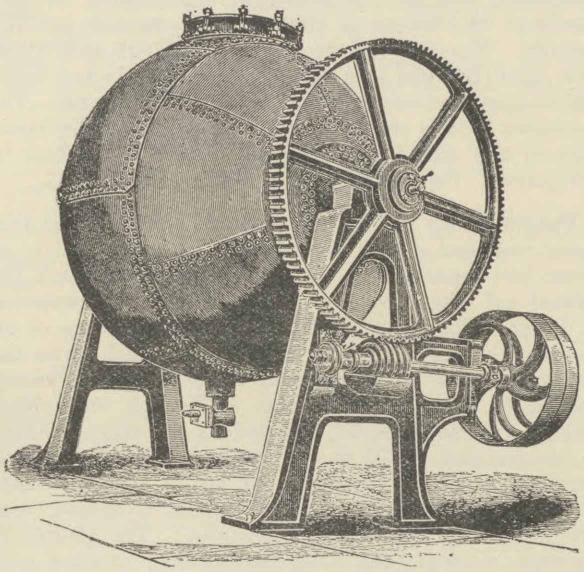

Fig. 1.—Revolving Spherical Rag Boiler.

harsh and stiff for readily making into paper. Various forms of vessels are used for boiling, but usually they are made to revolve by means of suitable gearing, and are either cylindrical or spherical (Fig. 1). In these the rags are boiled with an alkaline solution under a low steam pressure for six to twelve hours, according to the quality. The next step is that of washing and "breaking in," which takes place in an engine called the "breaker." (For description and illustration, see *Ency. Brit.* vol. xviii. p. 220.)

Esparto.

In treating esparto, the use of which for paper-making purposes is almost entirely confined to Great Britain, the object is to free it from all encrusting and intercellular matter. To effect this it is digested with a strong solution of caustic soda under a high temperature, in boilers which are almost invariably stationary. The most usual form is that known as Sinclair's patent (Fig. 2). This boiler is constructed of wrought-iron or steel plates, and holds from 2½ to 3 tons of grass. It is charged through the opening at the top A, and the boiled material taken out from a door B at the side; the grass rests on a false bottom of perforated plates C, through which the liquor drains, and by means of two "vomiting" pipes D, D, at the sides of the boiler connecting the space at the bottom with a similar space at the top, a continuous circulation of steam and liquor is maintained through the grass. The steam pressure is kept up to 35 to 40 ℔ per square inch for about three or four hours; then the strong liquor or lye, which contains all the resinous and intercellular matters of the esparto grass dissolved by the action of the caustic soda, is run off and stored in suitable tanks for subsequent recovery of the soda, while the grass is taken to the "potcher" or washing engine. In construction and working this is similar to the breaking engine used for rags: in it the grass is reduced to pulp, and washed for about twenty minutes to free it from the last traces of soda liquor remaining after the partial washing in the boiler. As soon as the wash water is running clear and free from colouring matter, it is shut off, and the necessary quantity of a solution of bleaching powder, or chlorine (averaging about 6 to 8 per cent. on the raw material), is run into the potcher, and the contents are heated by steam to a temperature of about 90° Fahr. After about four to six hours the bleaching is complete, the drum-washer is let down, fresh water run into the potcher, and the grass washed to free it from all traces of chlorine, an operation generally assisted by the use of a little antichlor. The esparto, as shipped in bales from the Spanish or African fields, is mixed with a certain quantity of roots, weeds, and other impurities unavoidable in the process of plucking; and as most of these do not boil or bleach as rapidly as the esparto, they would, if not taken out in the pulp, show up in the finished paper as specks and spots, and destroy its value. To get rid of them the esparto pulp when washed and bleached is run from the potcher into storage chests, from which it is pumped over a long narrow serpentine settling-table or "sand-table," made of wood and fitted with divisions or "weirs," behind which the heavy impurities or weeds fall to the bottom and are caught. The pulp is next passed over what is known as a "presse-pâte" (Fig. 3) or "half-stuff" machine, very similar to the wet end of a paper machine, consisting of strainers fitted with coarse-cut strainer plates, a short wire, and a pair of couch and press rolls. The pulp is drawn through the strainers by suction, which keep back the finer impurities which have passed the sand-table, and then flows on to the wire-cloth in the form of a thick web of pulp. After passing through the couch and press rolls, the pulp leaves the machine with about 70 per cent. of moisture, and is ready for the beating engine, the first operation of paper-making proper. This is the general and usual process, though various modifications are introduced in different mills and for different purposes.

Most kinds of straw can be utilized for making into paper, the varieties generally used being rye, oat, wheat, and barley; of these, the two former are the most important, as they give the largest yield in fibre. Germany and France are the two principal users of straw, which closely resembles esparto in its chemical constitution, and is reduced to pulp by a somewhat similar process.

Wood.

Scandinavia, Germany, the United States, and Canada are the countries which mainly use wood as a material for paper-making, owing to their possession of large forest areas. They also export large quantities of wood-pulp to other countries. The timbers chiefly used for the manufacture of wood-pulp are the spruces, pines, and poplars of various kinds. In Europe the Scotch fir (*Pinus sylvestris*), the spruce (*Picea excelsa*), the poplar (*Populus alba*), and the aspen (*Populus tremulo*) are the timbers principally employed; and in America the black spruce (*Picea nigra*), the hemlock (*Tsuga Canadensis*), the poplar (*Populus grandidentata*), and the aspen (*Populus tremuloides*). There are two kinds of wood-pulp prepared for paper manufacture, one prepared mechanically and the other chemically. The former is obtained by disintegrating the wood entirely by means of machinery without the use of chemicals, and is, as may readily be understood, a very inferior pulp, only used in the cheapest sorts, for news papers, &c. In the manufacture of chemical wood-pulp very great advances and improvements have been made since 1880, and the consumption of timber of various kinds for this purpose has enormously increased, so that wood-pulp has grown to be one of the most important fibres for paper-making purposes. There are two methods in use, known respectively as the soda or alkaline process and the sulphite or acid process, according as soda or sulphur (or rather sulphurous acid) forms the base of

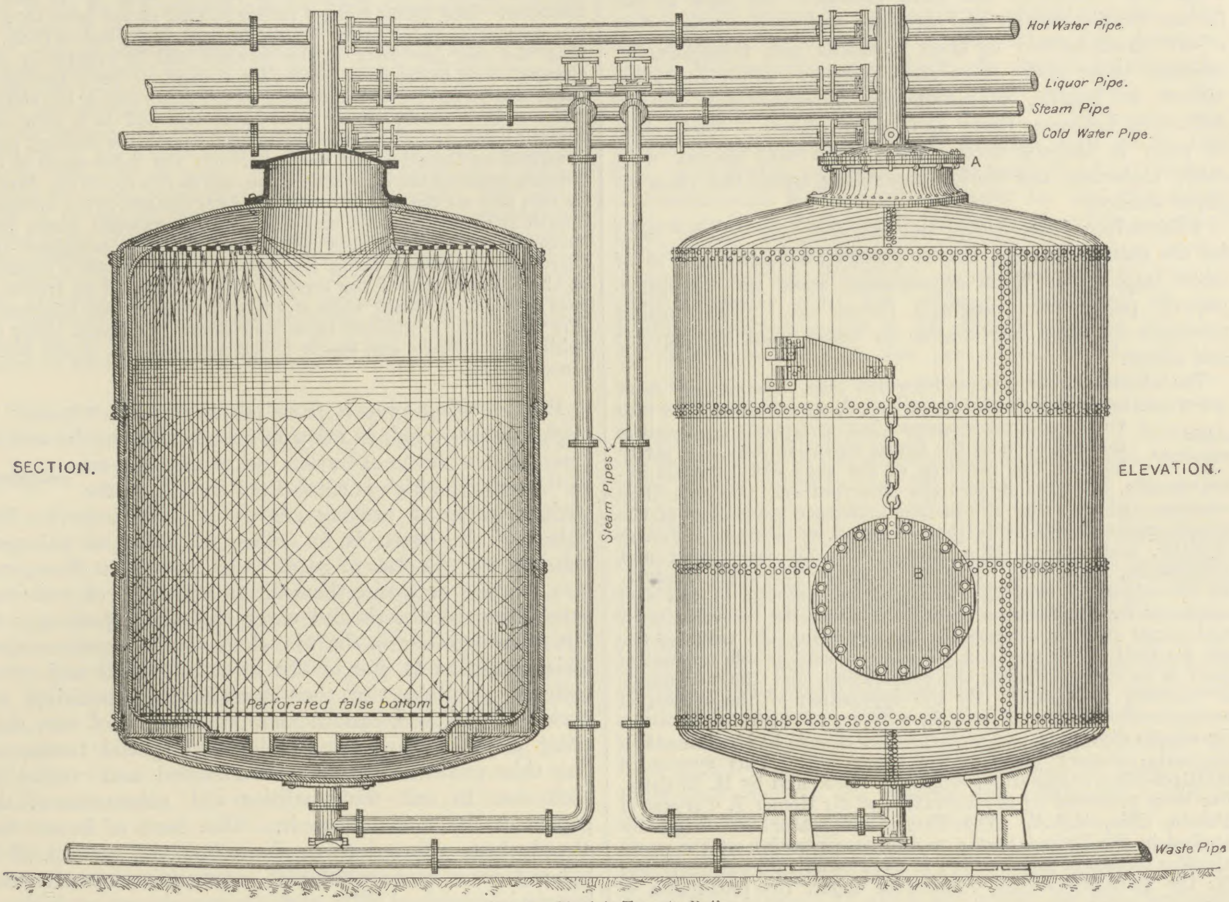

Fig. 2.—Sinclair Esparto Boiler.

the reagent employed. Trees of medium age are usually selected, varying from seventy to eighty years' growth, and running from 8 to 12 inches in diameter. They are felled in winter, and arrive at the mill in the form of logs about four feet long. After being freed from bark, and the knots taken out by suitable machinery, the logs are cut into small cubical chips about $\frac{1}{2}$ to $\frac{3}{4}$ inch in size by a revolving cutter. The chips are then bruised by passing them between two heavy iron rolls, to allow the boiling solution thoroughly to penetrate them, and are conveyed to the boilers over a screen of coarse wire-cloth, which separates out the fine sawdust as well as any dirt or sand.

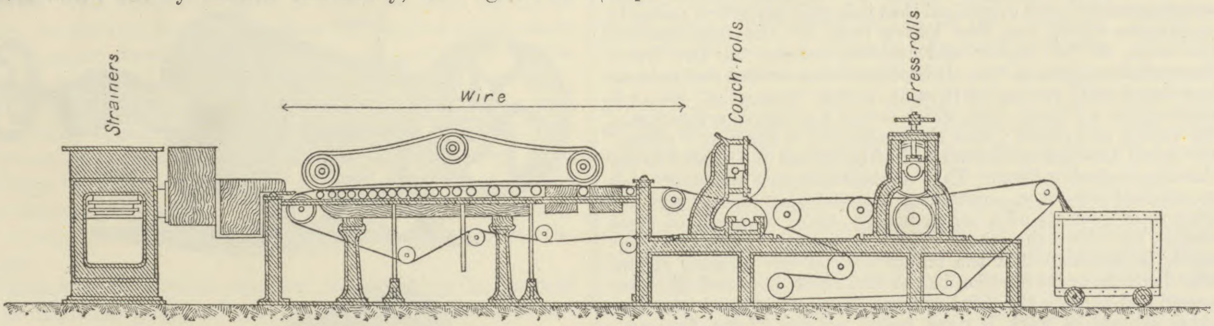

Fig. 3.—"Presse-Pâte," or Half-stuff Machine.

In the soda process the wood is boiled in large revolving or upright stationary boilers for about seven or eight hours, in a similar manner to esparto and straw, though it requires much severer treatment. The steam pressure varies from 90 ℔ to as much as 150 ℔ per square inch, and the amount of soda required is about 16 per cent. of Na_2O, estimated on the barked and cleaned wood. The essential feature of the sulphite process is the employment of a solution of sulphurous acid combined with a certain amount of base, either magnesia or lime. As the acid reaction of the bi-sulphite solution would attack any exposed ironwork with which it comes in contact, it is necessary that the boilers in all cases should be lined with lead. The type of boiler employed varies according to the process adopted. The principal patents connected with the sulphite process are those of Tilghman, Ekman, Francke, Ritter-Kellner, Mitscherlich, and Partington. The subsequent operations, in both the acid and alkaline processes, of washing, bleaching, and straining the pulp, are all very similar to those described for esparto, and require no further particular description. Wood-pulp produced by the sulphite process differs in a marked degree from that made by the soda process: the fibre in the former case is harsher and stronger, and papers made from it are characterized by their hardness and transparency, whereas those made from soda pulp are softer and more mellow in handle, corresponding in some way to the difference between linen and cotton fibres. Each class of pulp is largely used, both alone and mixed with other materials, the choice depending upon the class of paper desired.

Fibres like jute, hemp, manila, &c., are chiefly used for the manufacture of coarse papers where strength is of more importance than appearance, such as wrapping-papers, paper for telegraph forms, &c. The boiling processes for them are similar to those used for esparto and straw.

Soda recovery. The alkaline liquors or lyes in which rags, esparto, and other paper-making materials had been boiled, were formerly run into the nearest water-course; but now, partly because it is insisted upon by the Rivers Pollution Acts, and partly because the recovery of the soda can be made remunerative, all these liquors are preserved and the soda they contain utilized. One of the best and most economical of the simple recovery plants is that invented by Porion, a French distiller, and named after him. (See, for description and illustration, *Ency. Brit.* vol. xviii. p. 226.) It is open, however, to the objection that the whole of the sulphur in the coal employed for the furnaces finds its way into the recovered soda, and forms sulphur compounds, thus reducing the value of the ash for boiling purposes; in addition, a considerable amount of soda is volatilized during the evaporation, and the percentage of recovery is reduced. By the application of the system of multiple-effect evaporation to the recovery of waste liquors these drawbacks disappear, and an important change has been made in the soda-recovery plant of the paper-mill. This system of multiple-effect evaporation, originally introduced by M. Rillieux, has been perfected by the invention of Mr Homer T. Yaryan, of Toledo, Ohio, U.S.A. The Yaryan evaporator was originally applied in the United States to the concentration of the waste alkaline liquors of paper-mills; it then came into extensive use for the manufacture and refining of sugar, the production of glucose, and a variety of other purposes. The principle of multiple-effect evaporation is to utilize the latent heat of a vapour given off from a liquid under a certain pressure to vaporize a further quantity of the liquid under a pressure maintained by mechanical means below that of the first. The essential feature which distinguishes the Yaryan evaporator consists in the boiling of the liquor to be treated while it is passing through a series of tubes, which constitute a coil and are heated externally by steam or vapour. The quantity of liquor entering the coil is so controlled that it is only permitted partially to fill the tubes, and thus leaves room for the instantaneous liberation of the vapour and its free escape. As the liquor descends from tube to tube, it becomes concentrated and reduced in volume until ultimately it passes into a "separator," where it impinges on a plate or disc, which causes a complete separation of the vapour and liquid; each then passes on to the next "effect," the liquid through the second coil of tubes and the vapour to the chamber enclosing them. This combination of a series of tubes or coil, and separator, constitutes a vessel or "effect," and the evaporator consists of a series, usually three or more, of these vessels, one above the other. The vital feature, it will be understood, is therefore that the latent heat of the original steam, after performing its function in the first effect, is passed on to the second and then to the third or more effects, in each of which an equal amount of work is done before passing to the final condenser, where a vacuum is maintained. Thus, if the total temperature be divided three times, the result is a triple effect; if four times, a quadruple effect. Taking an evaporation of 10 ℔ of water per pound of coal, a single-effect apparatus will evaporate 10 ℔ of water, a double-effect 20 ℔, a triple-effect 30 ℔, and so on. The liquor to be concentrated is pumped from the storage tanks to the top or first effect of the Yaryan apparatus through a series of multiple-effect heaters, corresponding to the number of effects in the machine, by means of which the liquor is heated to as near the boiling-point as possible of the liquor in the tubes of the first effect. Live steam is introduced into the chamber surrounding the tubes of the first effect, and from the separator of the last effect the concentrated liquor is pumped to the incinerator. Any form of incinerating hearth can be used in conjunction with the multiple-effect evaporator, but one very suitable to the continuous work of, and the high degree of concentration produced by, the Yaryan machine is that known as the Warren rotary furnace. This consists of a revolving iron cylinder lined with brick, about 12 feet long by 10 feet in diameter. The lining being 6 inches thicker at the inlet than at the discharge, the interior of the furnace is conical in form, so that the ash gradually works forward and is eventually discharged fully burnt into trucks for storage, or on a travelling band, and so carried automatically to the dissolving or lixiviating tanks. The strong liquor runs in at one end in a slow continuous stream; by the rotation of the hearth the burning mass is carried up the sides and drops through the flame again to the bottom, much in the same manner as rags do in a revolving duster. In this way all the labour required to stir the ash of the ordinary hearth is dispensed with, and the burning material comes continuously in close contact with the flame, a complete and thorough combustion being the result. The fire-box is situated at the delivery end of the furnace, and is mounted on trucks so that it can be run back when cleaning or repairing the brickwork. The waste heat is utilized in raising steam in a steam boiler set behind the furnace, and finally in heating the weak liquor before concentration.

Beating. Paper-making proper, from prepared pulp, whether of rags, esparto, wood, or other raw material, may be said to commence with the operation technically known as "beating," which is carried out in one of the various forms of beating engine or "Holländer." The object of the beater is to reduce the fibres to a length suitable for the class of paper to be made from them, and also to beat or bruise them into a stiff pulp of sufficient consistency to absorb and carry the water necessary to felt them together on the wire-cloth of the paper-machine. This operation is one of the most important and most delicate processes in the manufacture, requiring experience, skill, and careful manipulation. Not only does every class of fibre demand its own special treatment, but this treatment has to be modified and varied in each case to suit the qualities and substances of the papers to be made from it. One form of beater has already been referred to in *Ency. Brit.* vol. xviii. p. 220; but engines of quite a different construction are now used largely in American mills, and also to some extent in Great Britain. These are known as "refiners," and the most important forms are the Jordan and Kingsland beaters (so called from the names of the inventors), or modifications of them.

The first (Fig. 4) consists of a conical plug or roll fixed on a shaft and revolving at a high rate of speed within an outer casing

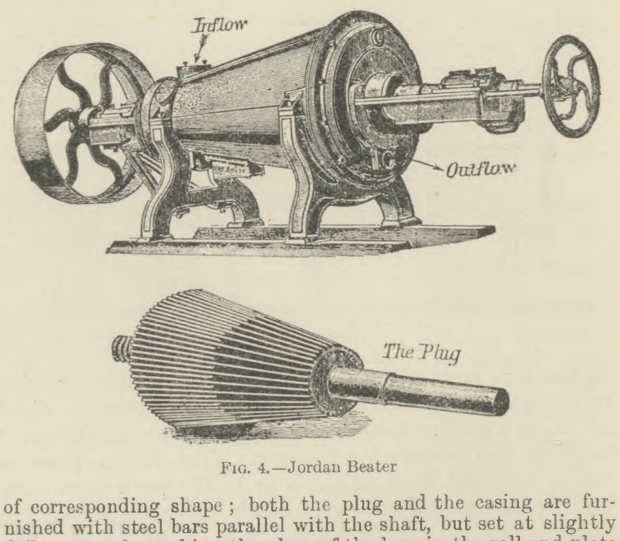

Fig. 4.—Jordan Beater

of corresponding shape; both the plug and the casing are furnished with steel bars parallel with the shaft, but set at slightly different angles, taking the place of the bars in the roll and plate of the ordinary beater. This conical plug or roll can be moved in either direction parallel to its axis, and by this means the cutting action of the two sets of bars can be increased or reduced. The pulp flows into the top of the beater at the smaller end of the cone through a box provided with an arrangement for regulating the flow, and passes out through an opening in the casing at the other end. The roll or plug revolves at from 350 to 400 revolutions per minute, and requires a power to drive it of from 25 to 40 h.p. according to the work done, and one engine is capable of passing as much as 1000 lb weight of dry pulp per hour. The Kingsland beater consists of a circular box or casing, on both inside faces of which are fixed a number of knives or bars of steel or bronze; inside the case is a revolving disc of metal fitted on both sides with corresponding and similar bars. The contact between the revolving and stationary bars can be regulated, as in the Jordan engine, to give the required amount of beating action on the pulp. The refiner is essentially a finishing process as an adjunct to the beating process proper. The advantages to be derived from its use are twofold, viz., a considerable saving in the time occupied in beating, and the production of a more uniformly and more evenly divided pulp, particularly where a mixture of different fibres is used. By the use of the refiner the time occupied in the beater can be reduced by nearly one-half, the half-beaten pulp passing through the refiner from the beater on its way to the paper-machine. It is not, however, generally employed for the best kinds of paper.

Sizing, &c. During the operation of beating various materials and chemicals are added to the pulp for the purposes of sizing, loading, colouring, &c. Papers for writing and most of those for printing purposes must be rendered non-absorbent of ink or other liquid applied to them, or they would partake of the nature of blotting-paper. To effect this some form of animal or vegetable size or glue must be applied to the paper, either as a coating on the finished web or sheet, or mixed with the pulp in the beating-engine. The latter, which is known as "engine-sizing," consists in filling up the interstices of the fibres with a chemical precipitate of finely divided rosin, which, when dried and heated on the cylinders of the paper-machine, possesses the property of being with difficulty wetted with water. Except in the very best qualities of paper, it is usual to add to the pulp a certain quantity of a cheap loading material, such as china-clay or kaolin, or pearl-hardening, a chemically precipitated form of sulphate of lime. The addition of such loading material to a moderate extent, say 10 to 15 per cent., is not entirely in the nature of an adulterant, as it serves to close up the pores of the paper, and for ordinary writing, printing, and lithographic papers renders the material softer, enabling it to take a much better and more even surface or glaze. But if added in excess it is detrimental to the strength and hardness of the sheet. Most materials, however well bleached, have a more or less yellowish tinge; to correct this, and produce the desired white shade in the paper, certain quantities of red and blue in the form of pigments or dyes must be added to the pulp. The blues usually employed are ultramarine, smalts, and the aniline blues, while the red dyes are generally preparations of either cochineal or the aniline dyes. In addition to these two colours, others are required in the manufacture of papers of different tints, and with one or two exceptions they must be mixed with the pulp in the beater.

Paper machine. There are two distinct processes of producing the finished paper from the pulp, known respectively as "hand-made" and "machine-made." Hand-made paper, except for certain of the best classes, has been almost superseded by machine-made, the expense of manufacture and consequent high price rendering it too costly for ordinary use; the entire process on the machine occupies at most a few minutes, which in the ordinary state of the weather could not be done by hand in less than a week. The paper-machine consists essentially of an endless mould of fine wire-cloth, on which the pulp flows and on which a continuous sheet of paper is formed; the sheet then passes through a series of rolls and over a number of steam-heated cylinders until it is dry. It need not be further described here, as details and illustrations may be found in the article in the ninth edition of this work (vol. xviii.), where also the other remaining processes of glazing, cutting, and sheeting are noticed. Paper-machines are now usually driven by two separate steam engines. The first, running at a constant speed, drives the strainers, pumps, shake motion, &c., while the second, working the paper-machine proper, varies in speed according to the rate at which it requires to be driven. The power consumed by the two engines will average from 40 to 100 h.p. The drying cylinders of the paper-machine form a convenient and economical condenser for the two steam engines, and it is customary to exhaust the driving engines into the drying cylinders and utilize the latent heat in the steam for drying the paper, supplementing the supply when necessary with live steam. The speed of the machine has frequently to be altered while in motion. An alteration of a few feet per minute can be effected by changing the driving speed of the steam engine governor; for a greater change, the machine must be stopped and other driving wheels substituted. Arrangements are made in the driving gear by which the various parts of the machine can be slightly altered in speed relatively to one another, to allow for the varying contraction or expansion of the paper web for different kinds and thicknesses of paper. The average speed of a paper-machine on fine writing-papers of medium weight is from 60 to 90 feet per minute; but for printing-papers, newspapers, &c., the machine is driven from 120 up to as much as 300 and 400 feet per minute. The width of machines varies greatly in different mills, from about 60 inches to as much as 150 inches wide. Mills running on higher classes of papers as a rule use narrow machines, as these make a closer and more even sheet of paper than wider ones; but for the cheaper and commoner qualities the wide machines are in vogue, as the cost of labour, &c., per ton of paper turned out is considerably reduced. The weight of paper that a machine can produce will of course depend upon its width and speed, and the thickness of the web of paper; on fine writing-papers an average machine will make from 20 to 40 tons per week, while for common printing and news papers the weekly output will amount to as much as 50 or 70 tons.

Standards of quality. With the enormously increased production of paper and the great reduction in price within recent years, due to the growing demand for cheap literature and publications, it has been found that the "science" of paper-making has scarcely advanced with the same rapid strides as the art itself. Although a sheet of paper made to-day differs but little as a fabric from the papers of earlier epochs, the introduction of new and cheaper forms of vegetable fibres and the auxiliary methods of treating them up to the point of putting them together as a sheet of paper have caused a great change in the quality, strength, and lasting power of the manufactured article. The undue introduction of excessive quantities of mechanical or ground wood-pulp in the period 1870–80 into the cheaper qualities of printing-papers, particularly in Germany, first drew attention to this matter, since it was noticed that books printed on paper in which much of this material had been used soon began to discolour and turn brown where exposed to the air or light, and after a time the paper became brittle. This important question began to be scientifically investigated in Germany about the year 1885 by the Imperial Testing Institution in Berlin. A scheme of testing papers has been formulated and officially adopted by which the chemical and physical properties of different papers are compared and brought to numerical expression. The result of these investigations has been the fixing of certain standards of quality for papers intended for different purposes. These qualities are grouped and defined under such heads as:—

Strength, expressed in terms of the weight or strain which the paper will support;

Elasticity and texture, measured by elongation under strain and resistance to crumpling or rubbing;

Bulk, expressed in the precise terms of specific gravity or weight per unit of volume.

Of not less importance are the qualities which belong to paper as a chemical substance or mixture, which are: (1) Its actual composition; (2) the liability to change under whatever conditions of storage and use it may be subjected to. For all papers that are to be used for any permanent purpose these physical and chemical qualities must come more and more into practical consideration, and ultimately rank as regulating the consumption and production of papers. For fuller information on this subject the reader is referred to the *Mitteilungen der Königlichen Versuchs-Anstalt*, Berlin, 1885 and onwards; and to the report of the committee of the Society of Arts on the "Deterioration of Paper," London, 1898.

British Paper-trade.—The *Directory of Paper-makers* for 1899 shows that in England and Wales there were 206 makers, employing 441 machines; in Scotland, 59 makers and 114 machines; in Ireland, 8 makers and 12 machines. These figures include 31 makers of hand-made paper, using 154 vats, in England; and 2 makers, 4 vats, in Scotland. A rough estimate of the amount of capital embarked in the industry may be formed on the basis that average mills would represent from £20,000 to £30,000 per machine. The following figures, abstracted from the Board of Trade returns for the year 1899, give the amounts and values of the imports and exports of paper and paper-making materials for Great Britain:—

Article.	Imports.		Exports.	
	Weight.	Value.	Weight.	Value.
	Cwts.	£	Cwts.	£
Paper and boards	5,307,079	3,724,254	71,757	929,370
	Tons.		Tons.	
Rags	20,617	174,661	65,041	341,749
Esparto	207,604	806,354	...	...
Wood-pulp—				
Chemical	196,926	1,441,809	...	...
Mechanical	218,180	547,897	...	...

Paraguay, an inland republican state of South America, lying between 20° 16′ 14″ and 26° 31′ S. and 54° 37′ and 62° W. It is bounded by the territories of the Argentine, Brazilian, and Bolivian republics, but the frontier line towards Bolivia has not yet been definitely fixed. The river Paraguay, running from north to south, divides the territory of the republic into two sections, the eastern section, or Paraguay Oriental, being the more important. The country as a whole is not well known. Outside the valley which stretches from Asuncion, the capital, to Villa Encarnacion, and away from certain frequented roads leading to the *yerbales*, there are few routes familiar to travellers. The western region, called the Gran Chaco, is to a large extent unexplored. The area comprised within the limits of the republic is estimated at about 97,700 square miles. According to the census of 1900, the population numbered 635,571, including an estimate of 80,000 for the Indians of the Chaco. The great majority of the inhabitants are of Indian descent, with very slight traces of foreign blood in their veins. Civilization has not made much progress, and the quaint habits and customs of the people have little similarity to those in the more advanced neighbouring republics. By nature the country people are gentle and patient, merry and smiling. As a general rule the Paraguayans are indolent, especially the men. Climatic conditions obviate the necessity of any superfluity of clothing. A cotton chemise, and a white *manta* wrapped in Moorish fashion over head and body, constitute the dress of the women; a cotton shirt and trousers that of the men. Boots and shoes are worn only by the upper classes. The common language of the country is Guarani, although in a few districts Tupi is spoken. The country people as a rule understand a little Spanish, if living near any trading centre. In 1893 a group of Australians, imbued with Socialistic tendencies, obtained a concession of 30 square leagues of land—about 135,000 acres—from the Paraguayan Government, and a number of immigrants from Australia settled on this tract. These colonists laboured under the condition that all property should be held in common. "New Australia" did not, however, prove a success. Disputes arose, and in the following year the project was abandoned, the land reverting to the Government. Thirty of the colonists with their families, in all ninety-three persons, agreed to stay and found a new settlement to be called "San Cosme." This experiment has succeeded somewhat better than the first, the settlers gaining a living by growing fruit and vegetables and occasionally working for wages when occasion offers. Another colony was founded with 150 Sicilian families, but this is by no means in a satisfactory condition. Immigration is small and does not increase. In 1892 there were only 539 immigrants; in 1897, 197; in 1898, 337; in 1899, 340; and in 1900, 170. The towns are few, small, and backward. Asuncion, the capital, with about 24,000 inhabitants, has neither water nor drainage works, and the streets are lighted with kerosene lamps placed at long intervals apart. Other towns are Concepcion, with 6000 inhabitants; Villa Rica, with 8000; San Pedro and Villa del Pilar, with 4000 each; and Villa Encarnacion, with 3000. The municipalities are all poor, and unable to bear further taxation for public works.

Administration.—The country is divided into 84 departments, grouped into 24 political districts, and the political constitution of 1870 is still in force. For the administration of justice there is a High Court, with lower tribunals and local magistrates accredited with judicial powers. The criminal courts are inefficient and dilatory, and crime as a rule is most inadequately punished. The death penalty nominally exists, but is rarely carried out. The civil courts are corrupt, and most tedious in procedure. The civil and criminal codes of Argentina, with a few modifications, have been adopted by Paraguay. The police system can hardly be said to extend beyond the cities, the expense of providing proper protection for life and property in the country districts being beyond the resources of the Government.

Religion and Instruction.—The Paraguayans adhere to the tenets of the Roman Catholic religion, implanted among them by the Jesuit missionaries in the 16th century, but they understand very little about religious principles. Education is in a most backward and neglected condition. Compulsory attendance at the schools for all children is nominally the law, but is never enforced. According to the official returns, there are 358 public and private elementary schools, with a staff of 680 teachers and 23,000 enrolled pupils. The actual attendance of children, however, does not exceed 12,000. The selection of the teaching staff is made without any regard to the capabilities of the applicants; salaries are on a very low scale, and frequently many months in arrear. At Asuncion a national college has been established with a staff of 15 professors, and 205 students were enrolled in 1898. The educational value of the college is not great. There are also an agricultural school, supported by the State; a school of arts and sciences, founded by the Sicilian friars; and a seminary.

Defence.—The army consists of 1 battalion of infantry, containing 1000 men; 2 squadrons of cavalry, with 1500 men; and 1 battery of artillery, with 750 men; total, 3250 men. There is also a national guard which may be called out in any emergency. Every Paraguayan between the ages of 20 and 50 is bound to serve. The republic has 1 gunboat with 4 guns, and 2 steam launches.

Finance.—The financial situation of the Paraguayan Government has been a source of anxiety for many years. In 1885, after interest had been unpaid for 11 years on bonds amounting to £1,505,400, an agreement was made for the issue of new scrip to the value of £850,000 in quittance of all claims for capital and arrears of interest, certain public lands being also ceded to the bondholders as compensation for their losses. In 1892 the Government again defaulted, and in 1895 an arrangement was made for a reduction of the rate of interest, for the funding of the arrears, and for the creation of a sinking fund. The Government were unable to meet their obligations under the new contract, and in 1898 the outstanding amount had risen to £994,600 sterling. Provision has now been made for the service of this foreign debt, and the authorities have been able regularly to meet the service of the coupons. Besides the London debt, there are many other claims on Paraguay. The national obligations are briefly set forth in the following statement as they stood at the end of 1898, gold debts being converted at the rate of $5 to the £, and the currency debts at the rate of $40 to the £.

Gold Debts—		
London debt		£994,640
Brazilian debt		1,792,037
Arrears of interest		183,256
Argentine debt		2,026,727
Arrears of interest		657,957
Argentine National Bank		8,517
General bonds		500,000
Paraguayan Central Railway Company		429,471
Total gold		£6,592,605
Currency Debts—		
Notes in circulation	$9,875,000	£246,875
Internal bonds	702,093	17,552
Floating debt	567,258	14,181
Total currency	$11,144,351	£278,608
Total debt		£6,871,213

The revenue of the republic is derived mainly from import duties, and the most important branches of expenditure are the salaries of public officials, the army, public instruction, and debt. The receipts and expenditure in 1891 and in each of the years 1896–99 were as follows:—

Years.	Receipts.	Expenditure.	Receipts.	Expenditure.
	$ Currency.	$ Currency.		
1891	1,647,717	2,485,203	£41,190	£62,130
1896	5,832,867	6,526,518	145,820	163,160
1897	4,200,009	6,852,334	105,000	171,308
1898	8,977,299	8,441,275	224,430	211,032
1899	9,866,000	8,122,139	246,650	203,054

The conversions in this statement are only approximate, the currency dollar being taken at 6d. for each of the years. The import and export duties in 1899 amounted to $7,996,440, and various taxes and contributions to $1,869,560. The estimated revenue for 1900 was $8,065,781, and expenditure $8,122,179, or, approximately, £201,640 and £203,050.

Industry.—The principal industries of the republic are the cultivation and preparation of *yerba maté* (Paraguayan tea), cattle-farming, fruit-growing, tobacco-planting, and timber-cutting. *Yerba maté*, classified as *Ilex paraguayensis*, is a shrub. The leaves are stripped, withered, rolled, and sorted, then packed in sacks and exported to Argentina for sale. This Paraguayan tea is used in place of the ordinary tea or coffee in many parts of South America. Medical experts state that the beverage infused from the leaves has a stimulating effect, and is also slightly diuretic. The total amount exported from Paraguay in 1896 was 5141 tons; in 1897 the total was 6548 tons; and in 1898, 7000 tons. The value of the yerba exported in 1899 was £97,360. The majority of the *yerbales* (tea plantations) were formerly the property of the national Government, but of late years private enterprise has stepped in and bought or leased the plantations. An important feature about *yerba maté* is the small expense necessary for its production, and the cheap rate, notwithstanding the high tariff on its importation, at which it can be placed on the Argentine market as compared with ordinary tea or Brazilian coffee.

The cattle industry comes next in importance. The number of animals is said to exceed 2,500,000, but exact figures are unobtainable. Hitherto the surplus stock has only found an outlet in the demands for local consumption, or for the value of the hides for export. The animals are small, but Durham and Hereford bulls are being introduced from Argentina to improve and enlarge the breed. The increase in the herds of recent years has caused the owners of *saladero* establishments in Argentina and Uruguay to try the working of factories in Paraguay for the preparation of *tasajo* (jerked beef) and the manufacture of extract of meat—the first for the Brazilian and Cuban markets, the latter for European consumption. The number of horses is estimated at 300,000; donkeys, 20,000; yaks, 10,000; pigs, 50,000; and sheep and goats, 240,000. Both grasses and climate are against sheep-farming on a large scale.

The fruit trade is confined to the exportation of oranges and pine-apples to the Buenos Aires, Rosario, and Montevidean markets. The orange groves are uncultivated, but yield abundantly. The demand for oranges is so large in Argentina that a ready sale could be found for a much larger quantity than is now exported. Both climate and soil in Paraguay could be turned to useful purpose for the cultivation of many tropical fruits and vegetables for sale in Argentina, and already some attempts are being made to develop a trade in this direction. Tobacco, although of inferior quality, is grown to a considerable extent, the total production for 1900 being about 280 tons, about one-eighth of which was exported. This industry might be largely increased in value if more attention were devoted to cultivation and curing.

The forests are a source of wealth as yet scarcely touched, and abound in such valuable timbers as quebracho, cedar, curupey, lapacho, and urundey. The difficulty and cost of transport at present block the development of this industry. In Buenos Aires, where the demand for lumber is constantly increasing, it is found cheaper to import from North America or Europe, a distance of 6000 miles, rather than from Paraguay, less than 1000 miles distant. In order to remove this anomalous condition of affairs, it is necessary that the great waterway formed by the Rio de la Plata, the Parana, and the Paraguay should be properly utilized.

The development of the agricultural and pastoral industries is encouraged, and land is assigned to colonists by the Government. In 1897 there were seven agricultural settlements, with altogether about 10,000 acres under cultivation. The climate is enervating, and otherwise there is no great inducement for European emigrants to go to Paraguay, since the best portion of the national lands is already in the hands of private individuals. During the year 1899 the Anglo-Paraguayan Land Company, the owners of the land ceded to the bondholders, sold 11 leagues (51,600 acres) at prices varying from £250 to £1000 per league.

Commerce.—The commercial situation of Paraguay has improved somewhat in consequence of the investment of some small amounts of foreign capital in industrial enterprise. The principal articles imported are textiles, hardware, wines, rice, flour, canned goods, and general provisions; the exports are *yerba maté*, hides, wood, oranges, hair, tobacco. Most of the trade is with Buenos Aires or Montevideo, direct dealing with Europe being the exception. The values since 1895 have been:—

	1895.	1896.	1897.	1898.	1899.	1900.
Imports	£492,010	£557,260	£440,690	£521,700	£429,570	£367,724
Exports	424,290	409,660	430,320	492,660	404,210	412,858

The textiles are mostly of British origin; the wines are from France. A promising trade was done with the adjoining Brazilian state of Matto Grosso for some time, under the terms of a treaty allowing free trade with that province of Brazil. In 1898, however, this arrangement with the Brazilian Government was rescinded, and business between Paraguay and Matto Grosso came to an end.

Whilst the commerce of Paraguay is extremely limited, it is, on the whole, fairly sound, and promises to increase in volume.

Communications.—There are two lines of passenger steamers plying between the port of Asuncion and Rio de la Plata, each of which runs one steamer weekly. There is also a fortnightly service of the Brazilian Lloyd's boats (cargo only) between Montevideo and Corumba, calling at Buenos Aires and Asuncion. In 1898, 418 ocean-going vessels and 750 coasting vessels entered at the port of Asuncion, and 408 ocean-going and 706 coasting vessels cleared. There are some fairly good waggon roads, and the Government appropriates annually a considerable sum for their extension. The transport of heavy goods is effected by bullock carts of antiquated type. In the capital there are half a dozen public vehicles and three private carriages. The only railway undertaking is that of the Paraguay Central Railway Company. The total length of line open to traffic is 156 miles. An extension has been projected for some years, but the failure of the Government to pay the guaranteed interest on the capital of the company has hitherto prevented the accomplishment of the work. A steam tramway connects Asuncion with San Lorenzo, 20 miles distant, and horse tramways run through the streets of the capital. In 1900 the railway carried 624,741 passengers and 75,503 tons of goods; the receipts being \$1,568,037 (or about £39,200), and the working expenses about 79 per cent. The tramway carried 870,546 passengers in 1899.

Post and Telegraph.—Paraguay entered the Universal Postal Union in 1884. In 1899 there were 139 post offices in the country, and in the same year 1,254,864 pieces of mail matter were handled. Four telegraph lines, of a total length of about 485 miles, connect Asuncion with other towns, and a submarine cable line puts the republic in communication with the rest of the world by way of Corrientes. In 1899 the inland telegrams numbered 18,925, and the international, 39,458. Telephone services are in operation at Asuncion and at Concepcion.

Money and Credit.—There are three banking companies, one of which in 1898 paid a dividend at the rate of 18 per cent. on a capital of \$1,000,000 currency. The capital invested in works for the development of the resources of the country is mostly foreign. The three British companies (railway, tramway, and land) have invested altogether about £1,430,000; a Belgian syndicate, working *yerbales*, cattle ranches, &c., £60,000; and a French company, for miscellaneous investments, £72,000. The money invested in private trading concerns probably amounts to about £1,000,000.

The money in circulation at the end of 1900 consisted almost entirely of \$12,000,000 paper (£300,000). The gold dollar (4 shillings) in 1900 was at a premium averaging over 800 per cent.

Weights and Measures.—The metric system is officially adopted, but the weights in common use are the *tonelada* (2025 lb), the *quintal* (101·4 lb), the *arroba* (25·35 lb), the *libra* (1·014 lb), and the *onza* (·0616 lb). The unit for liquid measure is the *cuarta* (·1665 gallon); that for dry measure, the *almud* (·66 bushel). The land measure is the *legua* (2·689 miles).

(W. W. R.; I. P. A. R.)

Recent Political History.—The modern political history of Paraguay dates from the death of Don Francisco Lopez in 1870. Succeeding his father, Don Carlos Lopez, as President in 1862, he made no pretence of governing the country according to the constitution of 1844, but arrogated to himself absolutely autocratic powers. In 1864 a dispute arose between Lopez and the Brazilian Government. The Paraguayan dictator, in order to enforce his demands, marched an army through Argentine territory for the purpose of invading the southern provinces of Brazil, and occupied the town of Uruguayana in Rio Grande do Sul. This act induced the Governments of Brazil, Uruguay, and Argentina to combine for the purpose of suppressing Lopez, whose aggressive behaviour and ambitious policy constituted a constant menace to the three countries. The invasion of Paraguay then took place, and a struggle involving an enormous sacrifice of life and treasure lasted for five years, only coming to a close when the Paraguayan forces were totally defeated and Lopez was killed at the battle of Aquidaban on 1st March 1870. During this warfare every male Paraguayan capable of bearing arms was forced into the fighting ranks, whole regiments being formed of boys of from 12 to 15 years of age. Nor were the women spared: they were used as beasts of burden to carry ammunition and stores, and when no longer capable of work were left to die by the roadside or ruthlessly murdered to avoid any ill consequences occurring from their capture by the enemy. When the war broke out, the population of Paraguay was 1,337,439 souls; when hostilities ceased the total number of inhabitants was 221,079 persons—28,746 men, 106,254 women above 15 years of age, and 86,079 children. Lopez was merciless in his treatment of his own people, and any attempt to evade military service was punished by death, as also was any evidence of hesitation to face the enemy. When gradually the Paraguayans were forced to retreat, the dictator ordered every town and village passed through to be razed to the ground, and every living animal for which no use could be found to be slaughtered. When the end came the country and people were in a state of absolute prostration.

After the death of Lopez, the Government was administered by a triumvirate consisting of Cirilo Rivarola, Carlos Loizaga, and José Diaz de Bedoza. In November 1870 a new constitution was formulated. The executive power was vested in the hands of a President elected by Congress for a term of four years, and assisted by five responsible ministers—namely, Interior, Finance, War and Marine, Worship and Instruction, and Foreign Affairs. Provision was also made for a Vice-President to act in case of the absence, death, resignation, or inability of the President. The legislative authority was to be exercised by a Congress consisting of two chambers, the Senate and the Chamber of Deputies, elected by the people, in the proportion of one senator for every 12,000 inhabitants and one deputy for every 6000, although in certain thinly populated districts a lesser number was required. The constitution provided that senators and deputies should receive an annual stipend of 1000 gold dollars. The choice for President of the republic fell upon Señor Cirilo Rivarola, and he was declared duly elected. The constitution of 1870 is still in force, but the majority of the Paraguayans have never availed themselves of the privilege of voting accorded to them. This inauguration of new political conditions did not mean, however, that all was plain sailing for the men in charge of Paraguayan destinies. The policy of Brazil had for many years leaned towards the annexation of Paraguay, in order that the Paraguay river might become the boundary to the south-west of the Brazilian empire. President Rivarola found himself thwarted in all directions by Brazilian intrigues, and in little more than a year after his election he resigned office, and was succeeded by the Vice-President, Señor Salvador Jovellanos. President Rivarola had aroused some strong hostile feelings during his tenure of power, and was shortly afterwards assassinated. President Jovellanos completed the term of office for which Rivarola had been originally selected, and in 1874 President Gill was chosen to succeed him. Brazilian intrigues were now once more set afoot, and the opposition to this policy, combined with the introduction of certain reform measures and the suppression of many flagrant abuses, resulted in a conspiracy against the President and his assassination in 1875. Vice-President Uriarte then assumed the Presidency, and served the remainder of the term. In 1878 Señor Baredo was elected, but died suddenly shortly afterwards, Vice-President Saguier succeeding to power. A conspiracy aided by the military element overthrew Saguier in 1881, and Congress then nominated General Caballero to hold office. He filled the position until 1886, when Congress elected Señor Escobar to the Presidency for the ensuing four years. The next chief magistrate was Señor Gonzalez, who made himself unpopular with the prominent politicians of Asuncion, and was eventually deposed in the beginning of 1894. The story of the conspiracy against him is an apt illustration of some South

American political methods. The malcontents approached the principal military officers, who gave promises of assistance to any movement against the President. Two deputies were then nominated to interview President Gonzalez and inform him that he would be required immediately to abdicate his office and leave the country. They went to Government House and found Señor Gonzalez in his office. Presenting their revolvers at his head, the deputies delivered the message with which they were charged. The President made no resistance, and was marched as a prisoner to the military barracks. The following day Señor Gonzalez was placed on board a steamer bound for Buenos Aires, and instructed not to return to Paraguay if he had any respect for his personal safety. Vice-President Moriñigo fulfilled the duties of President for the few months remaining of the term for which Señor Gonzalez had been elected, and in November 1894 was succeeded by Señor J. B. Egusquiza, who had been duly nominated by Congress. No noteworthy occurrences marked his term of office, with the exception of a dispute with Bolivia on the question of the boundary, and the rupture of official relations with Uruguay. The Uruguayan minister, in a despatch to his Government, had expressed the opinion that the Bolivian claim was just and reasonable. This despatch was, unfortunately, made public while the minister was absent from Asuncion. On his return to that city the hostile demonstrations against him were so strong that he was unable to land from his steamer. He went back to Montevideo; the formal rupture of relations then took place. Señor Aceval was nominated to the Presidency in 1898.

The dense ignorance of the mass of the people renders difficult the application of any political measures for the improvement of the general condition of the inhabitants. The constant penury of the Government is a further bar to legislation for the improvement of the educational system, the establishment of a more effective police force, or the carrying out of any important public works. Projects have been mooted from time to time for the entry of Paraguay into the Argentine Confederation or the Brazilian Union, but the idea has not been acceptable to the majority of the politicians who control the national destinies. The military element is always a stumbling-block in the way of any genuine political reform, such a policy virtually signifying the extinction of the power of the army to influence political events. The majority of the population care very little about the composition of the Government as long as taxation is not made too onerous and the men are not impressed for military service. (C. E. A.)

Paraguay River. See PLATA, RIO DE LA.

Parahyba do Norte, an Atlantic state of Brazil, situated between 6° 15′ and 7° 50′ S. and 34° 45′ and 38° 5′ W. Area, 28,854 square miles. Population in 1872, 382,587; in 1890, 497,000. It is bounded on the E. by the Atlantic, on the N. by the state of Rio Grande do Norte, on the W. by that of Ceará, and on the S. by that of Pernambuco. Capital, Parahyba, 10,000 inhabitants, with seven churches, a treasury, and other public buildings; the port, distant 30 kilometres, is called Cabedelo. Other towns are Arêa, Bananeiras, Cajazeiras, Campina Grande, Guarabira, Mamanguape, Pombal Souza, and Itabaiana.

Paramaribo, the administrative and commercial capital of Dutch Guiana, on the Surinam, at a point where the river is navigable for ships of 16 feet draught. The town covers an area of 1976 acres, and is divided into six inner and two outer quarters, and had in 1852 a population of only 6000, the fifth part of that of the colony (30,000). In 1900 its population amounted to 31,427, nearly one-half of the population of Dutch Guiana. A large number of the inhabitants of the colony have therefore withdrawn from the rural districts to the town, whose population is a conglomerate of different nations and religions. For statistics of trade and navigation, &c., see GUIANA, DUTCH.

Paraná. See PLATA, RIO DE LA.

Paraná, a city of the Argentine Republic, capital of the province of Entre Rios, on the river Paraná, nearly opposite to Santa Fé, about 240 miles north-west, in direct line, of Buenos Aires, situated in 31° 43′ S. and 60° 31′ W. It is the terminus of the provincial railway system, connecting with Concepcion in Uruguay. Various tramways run through the city. There is an important trade in lime; cereals are exported. At Bajada Grande, near Paraná, a magnificent wharf with all appliances for quick handling of ships' cargoes has been constructed. Paraná was the capital of the republic from 1852 to 1861. Population (1895), 24,261.

Paraná, a state of Brazil, between 22° 45′ and 26° 29′ S. and 47° 55′ and 55° 3′ W., bounded on the N. by São Paulo, on the W. by Matto Grosso and the Argentine Republic, on the S. by Santa Catharina, and on the E. by São Paulo and the Atlantic. Area, 85,453 square miles. Population in 1872, 126,722; in 1890, 626,722. The capital, Curitiba, has a population of about 20,000. Other towns are Paranaguá (8000), Ponta Grossa (7000), Castro (4000), Antonina (4000), Rio Negro (3000), Palmeira (2500), Campo Largo, Morretes, São José dos Pinhaes and Lapa, each with about 2000. There is a railway from Paranaguá to Curitiba. The principal article of export is *maté*, or Paraguay tea. Nearly the whole population is in the eastern half. Over 56,000 of the inhabitants are foreigners, and 60,000 foreign-born.

Paranagua, a town of Brazil, in the state of Paraná, of which it is the principal port. Population, about 8000. A railway connects the town with Curitiba. The principal article of export is *maté*, or Paraguay tea. The value of the foreign goods imported in 1893 was $264,868 (gold). In 1896 about 475 vessels of 243,000 tons visited this port, and in 1897, 431 vessels of 222,514 tons. A line of steamers runs directly between Paranagua and Hamburg.

Parasitic Diseases. See PATHOLOGY.

Parchim, a town of Germany, grand-duchy of Mecklenburg-Schwerin, 23 miles south-east of Schwerin. It was the birthplace of Field-Marshal Moltke (1800–1891), to whom a monument was erected in 1876. It is an ancient place, with town walls, a Gothic town hall, a couple of interesting churches (one 13th century, the other 14th century), a synagogue, and a mineral spring. Population (1885), 9726; (1900), 10,170.

Pardo Bazán, Emilia (1851– ——), Spanish author, was born at La Coruña, Spain, on 16th September 1851. Married in her eighteenth year to Sr D. José Quiroga, a Galician country gentleman, she interested herself in politics, and is believed to have taken an active part in the subterranean campaign against Amadeo of Savoy and, later, against the republic. In 1876 she came into notice as the successful competitor for a literary prize offered by the municipality of Oviedo, the subject of her essay being the Benedictine monk, Benito Jerónimo Feijóo, a figure of importance in the Spanish literature of the 18th century, and one of the glories of the province of Galicia. This was followed by a series of articles inserted in *La Ciencia Cristiana*, a magazine of the purest orthodoxy, edited by Juan

M. Orti y Lara. At this period the Sra Pardo Bazán, who has persistently published under her maiden name, was considered as a light among the Carlist party, and therefore as an aggressive Ultramontane. There is some reason for thinking that she has modified her earlier views concerning religious and civil policy, and in literature her progress is easily traced. Her first novel, *Pascual López* (1879), is a simple exercise in fantasy of no remarkable promise, though it contains good descriptive passages of the romantic type. It was followed by the much more striking story, *Un Viaje de Novios* (1881), in which a discreet attempt was made to introduce into Spain the methods of French realism, then at the height of its fashion. The book caused a sensation among the literary cliques, and this sensation was increased by the appearance of another naturalistic tale, *La Tribuna* (1885), wherein the influence of M. Zola and his school is unmistakable. Meanwhile, the writer's reply to her critics was issued under the title of *La Cuestión palpitante* (1883), a clever piece of rhetoric, but of no special value as regards criticism or dialectics. The naturalistic scenes of *El Cisne de Vilamorta* (1885) are more numerous, more pronounced, than in any of its predecessors, though the authoress shrinks from the logical application of her theories by supplying a romantic and inappropriate ending. Probably the best of Sra Pardo Bazán's work is embodied in *Los Pazos de Ulloa* (1886), the painfully exact history of a decadent aristocratic family, as notable for its portraits of types like Nucha and Julián as for its creation of characters like those of the political bravos, Barbacana and Trampeta. Yet perhaps its most abiding merit lies in its delightful pictures of country life, its poetic realization of Galician scenery set down in an elaborate, highly-coloured style, which, if not always academically correct, is invariably effective. A sequel, with the significant title of *La Madre Naturaleza* (1887), marks a further advance in the path of naturalism, and henceforward the Sra Pardo Bazán was universally recognized as one of the chiefs of the new naturalistic movement in Spain. The title was confirmed by the publication of *Insolación* and *Morriña*, both issued in 1889. In this year her reputation as a novelist reached its highest point. Her later stories, *La Cristiana* (1890), *La Prueba* (1890), *Cuentos de Amor* (1894), and *Arco Iris* (1895), though not wanting in simple charm, have failed to interest or to please. It might almost seem as though her mission was ended; but her energy has led her to seek success in literary criticism, in verse, in books of travel, in lectures, and in polemics. To this ambitious versatility we owe her biography of St Francis of Assisi, her sketches of the teachers of the Renaissance, her examination of the Russian novel, her speculations on Columbus, her discussion of John Stuart Mill's theories concerning the political position of women. These essays are executed with spirit and vigour, and they are interesting as the expression of a very individual temperament, as examples of popular exposition. *Los Pazos de Ulloa* and *La Madre Naturaleza* will outlive them, for both are characteristic products of an important movement.

Pardubitz, the chief town of a government district in Bohemia, Austria, 12½ miles south by west of Königgrätz. Population, including suburbs (1890), 12,367; (1900), 17,029 (estimated at 97 per cent. Czech, 3 per cent. German; 95·5 per cent. Catholic, 3 per cent. Jewish, and 1 per cent. Protestant). The Gothic chapel of the old chateau was restored in 1880, and a new town hall completed in 1894.

Parenzo, a seaport town in Istria, Austria, the seat of the Provincial Diet and an episcopal see. Population (1890), 8485; (1900), 9962, mostly Italian and Catholic. It is a station of the Austrian Lloyd Steamship Company. The principal resource of the inhabitants is fishing, shipbuilding, and seafaring pursuits. The trade is chiefly in wine, timber, and fish. It has extensive mulberry plantations.

Paris, a city of Illinois, U.S.A., capital of Edgar county. It is at the intersection of the Vandalia line and the Cleveland, Cincinnati, Chicago, and St Louis Railway, in the eastern part of the state, at an altitude of 700 feet. It has a level site and is regular in plan. It is in a rich farming region, and has a large trade. Population (1880), 4373; (1890), 4996; (1900), 6105, of whom 179 were foreign-born and 277 negroes.

PARIS.

PARIS, the capital of France, is situated on both banks of the Seine, 124 miles from its mouth, and 211 miles south-south-east of London, in 48° 50′ 49″ N. and 2° 20′ 15″ E. Its central position has always facilitated its commercial relations. The general character of its climate, somewhat continental in winter and oceanic in summer, has been more and more closely observed since the three observatories at different heights on the Eiffel Tower were added in 1889 to the old-established ones of Parc St Maur and Montsouris. The observatory at the Tour St Jacques, in the very centre of the city, and since 1896 a municipal establishment, is of special interest on account of the study made there of the transparency and purity of the air. There are barely 100 days in the year when the air is very clear. Generally the city is covered by a mantle of floating mists, possibly 1500 feet in thickness, which are chiefly brought by south-west winds. During the prevalence of north-easterly winds the sky is most obscured, since on that side lies the greatest number of factories with smoking chimneys. A chemical analysis of the air—taken in the first instance from Montsouris, on the outskirts, in the second from the centre of the city—shows that the former yields only 8 bacteria per cubic foot, whilst the latter yields as many as 200. To the hard winters mentioned in the ninth edition of the *Ency. Brit.* must be added those of 1890–91 (when for twenty days the Seine drifted large quantities of ice, and the frost lasted, almost without a break, for eighty days, from the end of November 1890 to the 15th of February 1891) and 1895 (when the Seine, during the whole month of February, a very late date for such great cold, either bore drifted ice or was frozen across).

Since 1840 Paris has been completely surrounded by a wall, which since 1860 has served also as the limit for the collection of municipal customs dues (*octroi*). Proposals are constantly being brought forward to demolish this wall—which, with its talus, is encircled by a broad and deep ditch—either entirely or at least from the Point du Jour, where the Seine intersects the wall below the city, to Pantin, so as to extend the limits of the city as far as the Seine, which runs almost parallel with the wall for that distance. The forts of St Jamme and of Aigremont, which the ninth edition indicates to the west of St Germain-en-Laye, had in 1902 not yet been built. On the other hand, those of Champigny and Sucy-en-Brie have been erected (between the forts of Villiers-sur-Marne and Villeneuve St Georges), commanding the mouth of the Marne and the battlefields of the 30th of November and the 2nd of December 1870. The Rue du Quatre

MAP OF PARIS.

Septembre, which unites the Place de l'Opéra to that of la Bourse, is now prolonged, under the name of Rue Réaumur, from the Bourse to the Square du Temple near the Place de la République, and runs parallel with the Grands

Boulevards through the busiest and most bustling part of the city. The business quarters of the east have been intersected by the Avenue de la République, between the place of that name and the cemetery of Père la Chaise. The Avenue Parmentier runs from the St Louis Hospital to the Place Voltaire, and the Avenue Ledru Rollin from the latter place to the Pont d'Austerlitz. On the Place de la Nation, where the statues of Philippe Auguste and St Louis already stand on high columns at the entrance to the Cours de Vincennes, the Triumph of the Republic, by Dalou, has been erected. Two new iron bridges for vehicles and pedestrians cross the Seine. The bridge Alexandre III., commemorating the Franco-Russian Alliance, connects the Esplanade des Invalides on the left bank with the Champs Elysées on the right; and the Pont Mirabeau, between the bridges of Grenelle and Point du Jour, unites the increasingly populous districts of Auteuil (right bank) and Grenelle (left bank). In addition a skew bridge, between the footbridge of Passy and the Grenelle bridge, carries the new line of railway from the Gare St Lazare to the Champ de Mars. The banks of the Seine, especially in the part below the city, have been further regulated by additional landing-stages, largely provided to meet the requirements of the Exhibition of 1900, the buildings of which extended along the river for a considerable distance. An important port has been designed at Ivry, just above the city on the left bank, at which the railway from Orleans terminates.

The district of Passy has more and more come to be a fashionable suburb, and a new quarter has sprung up near la Muette, on the former site of the municipal conservatories (*serres de la ville*), which have been transferred to the Parc aux Princes, on the southern boundary of the Bois de Boulogne. Here, in a number of nurseries, all the trees for the plantations of the town are grown. At the entrance to the Bois de Vincennes from the Avenue Daumesnil is a collection of different varieties of ornamental trees. The Bois de Boulogne, which has been devoted for some time to various sports (skating, pigeon-shooting, &c.), is now the headquarters of the Racing Club, which, however, has for its object the promotion of all sports. On the site of the Palais de l'Industrie, built in the Champs Elysées for the Exhibition of 1855, two Palais des Beaux Arts have arisen, built for the Exhibition of 1900, but designed to survive it. It is between these two edifices that the Avenue Nicolas II. passes, which opens upon the bridge Alexandre III., connecting the palace of the Elysée with the Hôtel des Invalides. The old church of St Geneviève, no longer used as a church, serves as a Pantheon for the burial of citizens to whom such honour is assigned. President Sadi Carnot, his grandfather Lazare Carnot, Victor Hugo, and others, lie in its vaults. The inner walls of the building are decorated with frescoes by eminent artists illustrating the history of St Geneviève, Jeanne d'Arc, and St Louis.

The only notable church built since 1875 is that of the Sacré Cœur, on the heights of Montmartre. This church is a national votive offering, decreed by the Constituent Assembly in 1871 and paid for by private subscriptions and collections. It was begun in 1876, but the ground not being solid enough for the first foundations, new and deeper ones, with pits 108 feet in depth, were made. The edifice is in Roman style, with a Byzantine dome 197 feet high, surmounted by a tower 263 feet high. Dominating Paris in every direction, it is one of the most colossal and also one of the most unsightly public monuments of modern times. It has a formidable bell called the Savoyarde, which is 10 feet high and 31 feet in circumference. This bell was a gift of four parishes in Savoy; it cost 65,500 francs, and was rung for the first time on 20th November 1895.

The Sorbonne has been completed. Its large, luxurious amphitheatres, and the spacious quarters of the University of Paris and of the faculties of science and literature form a striking contrast to the old and narrow quarters in which these institutions were formerly situated. The École de Médecine is being completed, the École de Droit considerably enlarged, and the Lycée Louis le Grand rebuilt. All these new buildings have greatly altered the appearance of the old Quartier Latin. Monuments have been raised to Francis Garnier, the hero of Tongking, on the Carrefour de l'Observatoire; Guy de Maupassant, the novelist, in the Parc Monceau; Alphand, the celebrated engineer, who for forty years has carried out the improvement of modern Paris, at the entrance to the Bois de Boulogne; and Charcot, the great doctor, opposite the hosital which he made famous, in the Place de la Salpêtrière. A monument to the chemist Lavoisier has been raised in the Place de la Madeleine, and a statue of Jeanne d'Arc, by Paul Dubois, in the Place St Augustin. The Opéra Comique, destroyed by fire (23rd February 1887), has been rebuilt on the old site in the Boulevard des Italiens. The house in which it found temporary accommodation in the Place du Châtelet has been rented by Sarah Bernhardt, the great tragédienne. The Théâtre Antoine has acquired a certain reputation for the audacity and originality of the pieces played there. A new hippodrome has been erected at Montmartre.

Population and vital statistics.

The population of Paris numbered 2,269,023 in 1881, 2,424,705 in 1891, and 2,660,559 in 1901, showing an increase of 6·8 per cent. between 1881 and 1891, and of 9·7 per cent. between 1891 and 1901.

The population shows an increasing tendency to spread out over the north-west region, in the districts of Passy and Auteuil; but the most populous quarters are still those of the centre and the north, particularly the Bonne-Nouvelle district. The Marbœuf quarter, just off the Champs Elysées, was entirely laid out between 1880 and 1885. Since 1870 the houses have always been built several storeys. In the rich quarters, Passy excepted, there are now scarcely any one-storey houses. The simple explanation is that formerly land was cheap, and the owner, having only a small capital, found it advantageous to construct his dwelling with materials of inferior quality, which could not support the weight of more than one storey, and to-day it is not possible to add other storeys to these light constructions. But since 1875 land, particularly in the north-west districts, has almost quadrupled in price, so that owners now find it to their interest to construct vast blocks of flats five or six storeys high, the rentals being thus proportionate to the capital invested in the land. In 1875 there were 66,850 houses and factories in Paris, representing rents to the value of 417,500,000 francs. In 1897 there were 75,000 houses, the rents of which aggregated 785,000,000; and a comparison of these totals is a sufficient demonstration of what we have just said, namely, that if the number of houses has increased in relatively small proportions (about 400 a year), on the other hand the rents of the houses have almost doubled. Here is another total: the approximate value of all the buildings in Paris, except some 400 belonging to the State, calculated at the price they would fetch, is now fourteen milliard francs, or £560,000,000, instead of seven and a half milliard francs in 1875. An interesting movement was begun in 1875 by MM. Müller and Cacheux, who were the first to have constructed upon 500,000 metres of land several hundred houses on the principle of building companies. The press giving its aid to this social and philanthropic enterprise, the result was the formation of the Working-men's Lodgings Company, of Passy-Auteuil, and of the Philanthropic Association, founded with a generous gift from M. Michel Heine, which began by constructing three houses of several storeys, each divided into small lodgings and rented at a price that would yield 3½ per cent. on the capital. The net income from these houses was devoted to the construction of similar dwellings. As the result of a congress held after the close of the Exhibition of 1889, a Cheap Lodgings Association was formed. Finally, the law of 30th November 1894 conferred certain advantages upon builders of small lodgings. In 1897 there were 810,468 premises used as dwellings, and 303,328 used for commercial or industrial purposes. Factories occupied 23,159 sites. The value of the total rental of these various properties was estimated at £31,400,000, and their marketable value at £440,000,000.

On comparing the following tables with those given in the ninth edition of the *Ency. Brit.*, it will be seen that the population is deserting the centre for the suburbs:—

Arrondissements.	Population present on the 29th March 1896.	Variation since 1881.	Population per acre.
Louvre	66,133	−9,257	140
Bourse	66,784	−9,610	275
Temple	87,335	−6,919	304
Hôtel de Ville	97,674	−6,086	249
Panthéon	115,947	+1,503	188
Luxembourg	100,692	+2,957	192
Palais-Bourbon	97,832	+14,505	98
Elysée	102,003	+12,999	108
Opéra	119,985	−2,911	228
St Laurent	153,785	−6,024	216
Popincourt	222,009	+12,763	249

As to the civil condition of the population, there were in 1891, amongst 2,424,705 inhabitants, 1,165,576 men, of whom 628,765 were single, 480,642 married, 51,885 widowers, 4284 divorced. In the same year women numbered 1,259,129, of whom 604,382 were single, 490,073 married, 158,533 widowed, 6141 divorced. The birth-rate is low—on an average 61,000 births per annum, or 25 per thousand inhabitants. The death-rate also is low, 55,000 to 58,000 deaths per annum, averaging 22 to 23 deaths per thousand inhabitants. This is accounted for by the fact that Paris is pre-eminently a town of adults, as the following table, referring to the year 1891, shows:—

Ages from		Ages from	
0 to 4 years	150,490	55 to 59 years	102,263
5 ,, 9 ,,	155,933	60 ,, 64 ,,	80,434
10 ,, 14 ,,	154,084	65 ,, 69 ,,	54,580
15 ,, 19 ,,	196,018	70 ,, 74 ,,	33,895
20 ,, 24 ,,	230,984	75 ,, 79 ,,	17,808
25 ,, 29 ,,	272,087	80 ,, 84 ,,	7,333
30 ,, 34 ,,	256,058	85 ,, 89 ,,	2,360
35 ,, 39 ,,	220,088	90 ,, 94 ,,	557
40 ,, 44 ,,	188,171	95 ,, 99 ,,	124
45 ,, 49 ,,	161,914	100 and over	9
50 ,, 54 ,,	132,102	Ages unknown	7,513

In these circumstances there is nothing remarkable in the annual number of marriages in Paris, 23,000, a high marriage-rate for the total number of inhabitants, but a low one compared with the number of marriageable persons.

A large number of the inhabitants (on an average 636 out of every 1000) are not Parisians by birth. In 1891 there were 2,196,627 of French parentage, 47,116 naturalized and 180,962 foreigners. Most of the latter belong to the following nationalities:—Belgians, 44,817; Germans, 26,863; Swiss, 24,786; Italians, 21,125; Luxembourgers, 13,157; English, 12,727; Russians, 9284; Americans, 4237; Austrians, 4387; Dutch, 4205; Spaniards, 4115. The Belgians, Germans, and Italians, mostly artisans, live chiefly in the industrial districts in the north and east of the city. The English and Americans, on the other hand, congregate in the wealthy districts of the Champs Elysées and Passy.

Occupations. The census of 1891 divided the population according to occupation as follows:—

(1) *Agriculture.*—Total number of persons engaged in agricultural pursuits, 8158, of whom 1767 were proprietors cultivating their own land, 384 farmers, 5861 horticulturists, 146 foresters.

(2) *Industries.*—Total number of persons employed, 1,071,254, of whom there were engaged in textile industries, 32,929; in mining and quarrying, 767; metallurgical industries, 2999; the manufacture of metal goods, 117,656; leather industry, 28,992; wood industry, 36,546; pottery, 8656; chemical industries, 13,814; building trade, 171,414; lighting, 8533; furnishing, 60,509; clothing and the toilette, 395,491; food supply, 46,665; industries connected with the sciences, arts, and literature, 76,625; watchmakers, jewellers, makers of *objets d'art*, &c., 67,015; State industries (manufacturers of carpets and tobacco), 2643.

(3) *Carrying Trade.*—Total number of persons employed, 138,690, of whom there were engaged in the building of ships, 218; in sea transport, 657; on canals and rivers, 2143; inland transport and towage on canals, 1039; making and repairing roads and bridges, 10,587; transport by railway, 40,600; street porters and messengers, 7442; carriers, 17,936; drivers of vehicles, 43,792; postmen and telegraph messengers, 14,276.

(4) *Commerce.*—Total number of persons employed, 560,066, among whom stockbrokers and bankers numbered 30,873; brokers, commission agents, or wholesale merchants, 30,955; keepers of hotels, coffee-houses, and public-houses, 120,296; retail provision dealers, 91,462; furniture dealers, 12,441; clothiers, 42,782; various, 231,257.

(5) *Army, Navy, and Police.*—Total number of persons employed, 42,926, of whom there were in the land force, 22,204; in the sea force, 1953 (the *infanterie de marine* is no longer actually represented in Paris); gendarmerie, 4360; police, 14,409.

(6) *Administration.*—Total number of persons employed, 37,798, of whom 17,978 were State officials, and 19,820 departmental and communal officials.

(7) *Liberal Professions.*—Total number of persons, 157,788, among whom members of the secular Catholic clergy numbered 2725; those belonging to Catholic religious communities, 6638, and to other religions, 829; while there were 3473 magistrates, 7268 barristers, 6926 legal officers, and 2995 solicitors; 9550 doctors, 719 veterinary surgeons, 8806 pharmaceutical chemists, 2648 dentists, 2108 midwives, and 5218 hospital assistants; 12,982 public lecturers and teachers, 10,807 private teachers, and 7276 teachers of accomplishments; 9847 *savants* or literary men, 20,352 civil engineers and architects, 3003 photographers, 5595 musicians, 20,654 sculptors, painters, and engravers, and 7369 lyric and dramatic artistes.

(8) Besides the above, there were 102,902 landed proprietors other than agricultural, 137,751 independent persons (*rentiers*), 12,910 pension-holders and retired persons living on their incomes, and 155,162 persons without definite occupation or unclassified.

Wages. The Chamber of Commerce has attempted to tabulate the alteration in the average daily wage in various trades between 1853 and 1892, as follows:—

	1853.	1892.		1853.	1892.
	Francs.	Francs.		Francs.	Francs.
Jewellers	4·25	7·50	Plumbers	4	6
Butchers	4·50	6	Bookbinders	3·50	5·50
Bakers	5	7	Ornamental Sculptors	4	7
Brewers	3·50	5	Locksmiths	4	6·50
Coachbuilders	4	6	Tailors	3	5
Hatters	4	6·50	Upholsterers	4	5
Coalheavers	3	5	Diggers	3	5
Carpenters	5	8·50	Turners (wood)	4	5
Wheelwrights	4	6	Turners (metal)	5	7

House painters	4	8	Boot-stitchers	2·50	3
Hairdressers	2	3			

Municipal budget. The municipal debt of Paris has greatly increased since 1860, owing to the extensive works undertaken in widening streets, improving sanitation, facilitating traffic, building schools, extending the system of aqueducts, and drainage. The budget of 1895 allowed the sum of £4,371,440 for interest on and amortization of the debt. The following are the chief items of expenditure for the year 1900:—

Municipal debt	£4,519,037
Prefecture of police and republican guard	1,446,051
Poor relief	1,269,620
Education	1,213,082
Streets and roads	1,018,717
Public walks, plantation, and lighting	541,277
Central administration	411,680
Collection of municipal customs dues (*octroi*)	463,974
Waterworks and drainage	471,027
Management of public works (salaries and material)	237,654
Architecture and fine arts	135,480

To sum up, the total budget of expenditure amounted to £12,848,870 on account of ordinary expenditure, £89,340 of extraordinary expenditure due to the debt, while £248,000 was applied to the liquidation of expenses incurred in previous years.

The principal items of revenue in 1900 were:—

Municipal customs dues (*octroi*)	£6,651,774
Direct contributions	1,400,528
Income from water and canals	826,339
Markets, market-places, and slaughter-houses	533,310

Gas rates	£625,604
Government subsidy and receipts of the prefecture of police	488,532
Revenues from public vehicles	368,773
Contributory taxes towards paving and cleaning streets	205,118
Revenue for public instruction (legacies, &c.)	183,504
Stands in public places	211,234
Burial and cemetery dues	136,786
Government subsidy towards the paving of the town	176,000
Night-soil and sewage	182,630
Householders' street-cleaning tax (*taxe de balayage*)	138,040

The chief items in the *octroi* in 1897 were :—

Beverages	£2,691,133
Eatables	1,370,944
Oil	684,473
Fuel	567,229

As a result of efforts to reform these taxes, since 1st January 1901 no *octroi* have been levied on wine, beer, and cider (all classed as hygienic drinks), but the duty on alcohol has been increased, and now about 4 francs 30 centimes is paid on each litre of alcohol that enters Paris.

On 1st January 1898 the length of public streets bordered with trees was 162 miles ; unplanted, 445 miles (86,333 trees and 8024 seats). The area unbuilt over covered 4090 acres. On the 1st of January 1898 the stone paving covered 1495 acres, metalled roadways 343 acres, asphalt 94 acres, wood pavement 286 acres, earthen roadways 7 acres. The number of wheeled vehicles of all kinds, carts and carriages, automobiles and bicycles, goes on steadily increasing. Pedestrians would be endangered at the principal cross-roads if policemen were not stationed to interrupt now the one and now the other stream of traffic. Refuges in the centre of the widest public thoroughfares have become more numerous, and facilitate the crossing of pedestrians. The Place de l'Opéra is traversed by 60,000 vehicles, 70,000 horses, and 400,000 foot passengers during certain hours of the day. Through the Rue de Rivoli, on the other hand, 43,000 vehicles and 53,000 horses pass partly by night with consignments for the central markets. Steamers ply on the Seine from Charenton to Auteuil, others in connexion with them running as far up as Ablon and down to Suresnes. Thus more than a hundred boats, accommodating from 225 to 400 persons, convey an increasing number of passengers, 13,080,000 in 1880 ; 21,000,000 in 1890 ; 24,931,879 in 1897. Tramways are more and more replacing the old lines of omnibus (though new 'bus routes still continue to be opened) and mechanical traction of various kinds tends to supersede the use of horses on the tram-lines. In 1894 the General Omnibus Company carried on its different routes (tramway and other) 227,868,392 passengers, other companies carrying 60,384,560. In 1897 the General Omnibus Company carried 256,000,000, and other companies 62,000,000. The General Omnibus Company owned in 1897 16,000 horses, and circulated 1130 vehicles daily, which covered daily a distance equal to two and a half times the circumference of the earth. Railway traffic round Paris has for many years been provided by the Chemin de Fer de Ceinture, which has thirty stations along the length of the rampart or near it. In 1897 there were 27,507,797 travellers between stations other than those from Paris to Auteuil, while for those latter there were 23,711,512 passengers. Very frequent circular trains leave the station of St Lazare, running west, south, east, north, and finally again west to their terminus at Courcelles, from which they return to St Lazare by the reverse route. Another service following the same course leaves the Gare du Nord. Several years ago the line between Paris, Sceaux, and Limours was extended from the Place Denfert-Rochereau, south of the city, to the Place de Medicis, near the Luxembourg. This line will be prolonged inwards from the Place de Medicis to the Place St Michel, there to join the new inner line of the Paris–Orléans Railway, running into the heart of the city. This is continued along the Seine from the Quai d'Austerlitz as far as the Quai d'Orsay, opposite the Tuileries. A new western line, taking a new route from Paris (Meudon) to Versailles (making, with the old lines known as the "right bank" and "left bank" lines, three distinct railways) has its terminus at the Esplanade des Invalides. It is to be placed in connexion with the circular railway from St Lazare. The Champ de Mars is connected with the Gare St Lazare by a line which accompanies at some distance the Ceinture Railway between St Lazare and Passy, traversing the latter quarter through a tunnel which opens opposite the skew bridge above mentioned, crossing by which it reaches Grenelle. Finally it has been decided to provide Paris with a metropolitan railway. The above-mentioned lines (that of the Champ de Mars excepted) are termed *lignes de pénétration*, and serve to facilitate communication between the city and outlying districts. The Metropolitan, on the contrary, is to be purely urban and to serve only the inner traffic of the city. Although its rolling stock will be able to pass over the rails of the main line, which are on the same gauge, the latter will not be able to make use of the Metropolitan lines on account of the decorative structures of the latter being provided with a moulding which does not permit them to do so. The Metropolitan will connect Parisian stations on different lines, but a train coming from Marseilles or Bordeaux will be unable to pass over its rails *en route* for Calais or Havre unless it be composed of Metropolitan carriages. The Metropolitan runs from the Porte de Vincennes to the Arc de Triomphe de l'Étoile, whence it forks towards the Porte Maillot and the Porte Dauphine, both at the entrance to the Bois de Boulogne, and also towards the Trocadero. The working of the Porte de Vincennes–Port Maillot line has so far been very successful. A circular line follows the old outer boulevards (until 1860 the wall of Paris). A third line is to connect Porte Maillot with Ménilmontant on the north of the city, and a fourth to cross the city from north to south from the Porte de Clignancourt to that of Orléans. Short lines are to unite the Boulevard de Strasbourg with the Pont d'Austerlitz and the Cours de Vincennes with the Porte d'Italie. The combined length of all these lines will be 40 miles, 70 per cent. of which will run underground, 16 per cent. over viaducts, and 14 per cent. through cuttings. The cost of construction and the purchase of material is estimated at £6,600,000. The traction is electric.

Traffic: vehicles.

Traffic: railways.

The following table shows the number of passengers arriving at and departing from the various main stations in 1897 :—

Station.	État.	Nord.	Est and Vincennes.	Ouest.	Orléans and Sceaux.	Paris-Lyons-Mediterranean.
Arrivals	99,058	9,966,000	13,894,627	24,088,495	4,475,531	3,754,821
Departures	96,853	10,080,000	14,063,085	24,406,612	4,533,451	3,446,436

In all, then — apart from the Circle Railway — 56,278,532 passengers arrived in Paris, and 56,626,437 left. (Passengers travelling with season tickets or free passes have not been included.) The companies have been obliged to extend their stations. The Gare d'Orléans has, as already noted, been removed to the Quai d'Orsay in the centre of Paris. The Gare St Lazare has been rebuilt and considerably enlarged ; the Gare de Lyon is also undergoing reconstruction. The Gare de l'Est and the Gare Montparnasse are being greatly extended. The terminus of the railway du Nord is being enlarged to accommodate an increased number of lines. The road railways running into Paris must also be mentioned, also one from Paris to St Germain which has its terminus in the Place de l'Étoile, and one from Arpajon, the trains running on which stop by day in the Rue de Medicis, near the Luxembourg, but at night run up to the central markets.

The goods traffic has not increased at the same rate as the passenger traffic. The following table shows in tons the quantity of goods that entered and left Paris in 1897 :—

Station.	État.	Nord.	Est and Vincennes.	Ouest.	Orléans.	Paris-Lyons-Mediterranean.
Entered	57,568	2,052,218	828,602	1,438,244	766,527	1,006,288
Left	28,767	506,759	311,559	694,086	345,465	511,357

Thus, in all, the main lines brought in 6,149,447 tons and carried out 2,397,993 tons. (The figures for the Est et Vincennes and Orléans et Sceaux lines give the tonnage carried by goods train only.)

Water-supply.

A new aqueduct, 62 miles long, carries the waters of the Avre, drawn off near Verneuil, in the department of Eure, to the reservoir at Montretout beyond St Cloud on the left bank of the Seine, 334 feet above sea-level. New supplies acquired by the city in the Loing and Lunain basins are about to be added to those of the Vanne, which come from an adjoining district. The average daily supply from various sources during 1897 was as follows :—

Source.	Dhuis.	Vanne.	Avre.	Ourcq.	Seine.	Marne.	Artesian Wells, &c.
Cubic feet.	741,720	3,724,494	3,781,288	4,753,188	3,499,611	2,717,591	223,681

Thus each inhabitant may consume, on an average, 63 gallons (22 of which are spring water) in twenty-four hours. Actually the daily consumption per head in 1894 was only 45 gallons ; in London it was only 40 gallons. To guard against the dearth which might arise in times of augmented consumption and diminished supply, improved filters have been fitted up for the purpose of purifying the river water. An Anderson filter, which purifies 706,397 cubic feet of water in twenty-four hours, was established in 1896 at St Maur on the Marne. The water is distributed throughout the city by two systems: the low pressure, carrying the river water for use in the streets, courts, and industrial premises; the high pressure, taking the spring water to the various floors of buildings, and supplying pumps, Wallace fountains, and (on 1st January 1898) 6170 fire-plugs. On the same date the total length of pipes was 1493 miles. The water arrives in all cases from two different directions, so that in case of accident the interruptions of the supply may be reduced to a minimum.

Drainage. Great changes have been made in the drainage of Paris owing to the underground operations necessitated by the construction of the Orléans and Metropolitan railways. The chief improvement has consisted in keeping the Seine (except in certain cases of exceptional pressure, such as sudden and violent storms) free from sewage water, which is now utilized on sewage farms. The main sewers converge at Clichy, on the right bank of the Seine, where a powerful elevator forces the sewage partly across the bridge, partly through a tunnel acting as a syphon below the river-level, to the left bank. Thence part of the sewage is distributed over the estate of Gennevilliers, from which it returns purified, after having fertilized the plots, to the Seine. At Colombes a second elevator drives the surplus unused sewage to the hills above Argenteuil (right bank). A third elevator at Pierrelaye distributes another portion on the hills of Méry. The remainder is employed to water the Parc d'Achères (left bank), the irrigation fields of Carrières-sous-Poissy (right bank), and finally those of Mureaux, opposite Meulan. New works are undertaken as the sewage increases and as its value is better realized by the agricultural classes. The rent of an acre of land at Gennevilliers has now risen to nearly £10. Certain parts of Paris lie too low for their drains to run into the main sewers. Special elevators are required to raise the sewage of the districts of Bercy, Javel, and the Cité. The quantity of sewage carried through the drains will be enormously increased when the scheme of drainage by means of sewers, which would clear all the water-closets of all the houses in this manner, is completed. In 1896 only 8800 premises employed this system. Since then the administration has decided to apply it to all the houses of certain streets indicated from year to year, and on 1st January 1898 it was in use in 12,475 dwellings. But owners resist this claim, which presses heavily upon them, because the town is as yet unable to furnish them with the water necessary for the scheme. On 1st January 1898 there were still 58,430 cess-pools, 15,028 movable buckets, and 29,207 tinettes.

Lighting. The consumption of gas in Paris increases but slowly since the extension of the electric lighting system. The annual consumption is from 10,000,000,000 to 11,000,000,000 cubic feet of gas. Six different companies have obtained concessions from the city authorities for the electric lighting of prescribed sections for a period of eighteen years. These concessions do not confer a monopoly, but are simply authorizations. The city has retained the management of the municipal electrical works under the central markets (Halles Centrales). The difficulties introduced into the administration by these arrangements have left Paris far behind many lesser towns in its application of the system of electric lighting.

Public health. The *services d'hygiène* of the city have developed rapidly. The Conseil d'Hygiène et de Salubrité of the department of the Seine, composed of 24 members nominated by the prefect of police and 17 members called to it in virtue of their office, has published since 1895 an account of its bi-monthly meetings. It inquired into and reported upon six hundred cases in 1896. To it are referred such questions as the sources from which to obtain drinking-water for the town, the sanitary measures to be taken during important works, the work connected with the main sewers for the cleaning of the Seine and the utilization of the sewage water, the health of workpeople employed in factories, the sanitary condition of the occupants of schools and prisons, questions relating to the disinfection of infected districts, the heating of public vehicles and dwellings, the conveyance of infected persons, night shelters, &c. Since 1892 the *service des épidémies* has been active, inquiring into the origin of these scourges and seeking to arrest their progress. It is this body that receives the compulsory declarations of doctors on the subject of contagious affections under their treatment. Special vehicles are now set apart for the conveyance of persons suffering from contagious diseases, whereas formerly public vehicles which had carried such persons were afterwards used, without undergoing disinfection, to convey healthy persons. Special municipal hot chambers disinfect all personal belongings believed to be infected, while houses are attended to by special disinfectors. A laboratory has been fitted up for the diagnosing of certain complaints (diphtheria and typhoid fever, for example) which cannot be identified without scientific tests. A central sanitary association has been formed and has commenced the registration of every house, entering against the name of each all information as to its sanitary condition. This association will be the chief auxiliary of the commission, long established, on insanitary dwellings, which issues orders for landlords to execute, voluntarily or under compulsion, any repairs or alterations which it deems necessary.

Education. The old *salles d'asile* are now called *écoles maternelles.* In 1897 there were 153 such schools belonging to the municipality, with 53,888 scholars; 23 *laïques privées* (that is, voluntary schools taught by lay mistresses) with 1284 scholars; and 41 *congréganistes* (that is, voluntary schools taught by *religieuses*) with 8162 scholars. The children are divided into three classes according to age, from 2 years to 3½, from 3½ years to 5, from 5 years to 7. Seventeen *écoles enfantines*, exclusively managed, as are the *écoles maternelles*, by women teachers, serve as a link between the latter schools and the *écoles primaires*, of which there are 392 public with 156,070 scholars, 562 *laïques privées* with 29,347 scholars, and 230 *congréganistes* with 56,276 scholars. Every year the city continues to open fresh groups of schools either to replace or complete old ones, and to the six upper *écoles primaires* for boys (Chaptal, Turgot, Lavoisier, Colbert, J. B. Say, Arago) have been added two for girls (Sophie Germain founded in 1882, Edgard Quinet in 1892). The capital invested in the building of the 153 public *écoles maternelles* and the 392 public *écoles primaires* must be close on £9,000,000. The *cantines scolaires* annually disburse £28,000 in providing the children with hot dinners. The *caisses des écoles* give assistance to indigent children; the *classes de garde* retain some children beyond ordinary school hours, and the *classes de vacances* beyond the duration of the ordinary scholastic course. For several years a certain number of children have been sent to spend a few days at school colonies or in travelling, but notwithstanding the progress in the secularization of municipal schools, there are in every parish free *écoles primaires* conducted by religious societies. Of these 57 are conducted by Christian Brothers, 76 by nuns. The *écoles professionnelles*—Diderot, Germain Pilon, Bernard Palissy—train apprentices in the application of the fine arts to industries; the École Boulle trains cabinet-makers, and the École Estienne trains in all processes connected with the production of a book. The Municipal School of Physics and Chemistry imparts both theoretical and (specially) practical knowledge of these sciences. Six *écoles ménagères* train girls in the duties and employments of their sex. The number of State *lycées* giving secondary education has been increased. Louis le Grand has been divided into two distinct establishments—Louis le Grand and Montaigne, the former including the higher classes, the second the lower classes, corresponding to the *grand* and *petit* Condorcet. St Louis specially prepares for the great scientific schools. Henri IV., Charlemagne, Janson de Sailly, Buffon, Voltaire, Carnot (formerly the *école Monge*), Lakanal (at Sceaux), and Michelet (at Vanves) share with Stanilas (under church management) and the municipal Collège Rollin, the education of students in classics and modern subjects, the latter especially in reference to commerce and its practical application. In all these establishments the number of day pupils is increasing, that of boarders decreasing. There are now five *lycées* in which girls can receive secondary education: Fénélon, Racine, Molière, Lamartine, and Victor Hugo. The five faculties of medicine, law, science, literature, and Protestant theology, and the higher school of pharmacy form the body of faculties, the association of which has taken the name of the University of Paris. This university has acquired corporate rights which allow of its receiving gifts. At the Sorbonne (seat of the university) there is also established the École des Chartes. The faculty of Roman Catholic theology no longer depends upon the State. This course is given at the independent Roman Catholic University, which includes also faculties of science, literature, and law. But no university except that of the State can confer a degree. The city of Paris, besides founding special chairs at the Sorbonne, has opened special courses at the Hôtel de Ville. The Agricultural Institute, now installed in a separate building from that of the Conservatoire des Arts et Métiers, has developed greatly. The Pasteur Institute not only treats patients threatened with hydrophobia and prepares serums which successfully combat certain diseases, but gives a course of biological chemistry in connexion with the faculty of science. The École du Louvre imparts such practical instruction as can be drawn from collections and museums. The École Coloniale prepares colonial officials, teaches natives from French colonies, and trains pupils for colonial life.

Churches. Paris has 70 Roman Catholic churches, without reckoning the chapels attached to the Invalides and the Sorbonne or those of the religious orders, which have services mostly open to the public. The Reformed or Calvinist Church has 17 places of worship, and the Lutherans or Confession of Augsburg, the adherents of which are mainly Alsatians, have 10. The Jews have 4 synagogues. The priests, pastors, and rabbis of these four bodies receive stipends from the State. The Protestant Free Church, a secession from the Reformed Church, has 4 congregations; and French Protestantism also comprises 1 Swedenborgian, 2 Methodist, and 3 Baptist communities. The English-speaking colonies have 3 Anglican churches, 1 Scottish, 1 Wesleyan, 1 Independent, 2 American Episcopal, 1 American

Presbyterian, and 1 Roman Catholic. The other foreign colonies have a United Greek, a Russian, an Armenian, a Spanish, a German Lutheran, and a Swedish Protestant church. The mission founded in 1872 by the late Dr R. W. McAll, chiefly supported by American and British subscriptions, has 17 stations, and the Salvation Army 8. No religious census has been taken in France since 1872.

Galleries and museums. The old Salle des États at the Louvre has received a Rubens collection, which was opened at the same time as fourteen rooms containing pictures of the Dutch school. This necessitated a general rearrangement of the Louvre, and the artistic collections of the town of Paris have been installed in the small palace of the Champs Élysées. The Musée Historique de l'Armée has been set up at the Invalides; the museum of the town of Paris, called the Musée Carnavalet, has been completely remodelled, and the town library established at the Hôtel Le Pelletier St Fargeau, Rue de Sévigné. The Musée des Arts Décoratifs still awaits its installation in the pavillon de Marsan, in the Tuileries. The Musée Guimet, near the Trocadero, contains a collection of objects illustrative of the religions of the Far East. The Musée Cernuschi, bequeathed to the town, consists chiefly of Japanese and Chinese collections; the Grandidier collection at the Louvre includes Chinese and Oriental articles. The Musée Galliéra contains very fine tapestry belonging to the town of Paris.

Charity. The sum dispensed in public charity in 1896 amounted to £1,473,345, about two-thirds of which was appropriated by the medical department, the remaining third to outdoor relief. In that year 511,880 persons in Paris received public charity. The hospitals provided 26,294 beds, and 110,000 patients were treated in their own homes; 48,000 paupers and 73,000 indigent persons received assistance, the number of charity children being 48,000. The cost of public charity has considerably increased, having risen from £1,000,000 to £1,500,000 since 1880 without a proportionate increase in the population during that period. The sum of £360,000 is devoted to the maintenance of charity children or those deserted by their parents. Several new societies have devoted themselves to the protection of abandoned children, to the suppression of begging, to finding work for the unemployed, and to the reformation of prisoners. The Society for the Protection of Deserted and Criminal Children has assisted thousands of children. Other associations attend to the treatment of consumptives and sick children.

Hospitals. Several new hospitals have been built. Amongst them may be named the Bichat, for important surgical operations; Hérold, Broussais, chiefly for epidemic cases; and Boucicaut, founded by the liberality of the founder of the Bon Marché establishment. On the other hand, the military hospital of Gros Caillou has been demolished to make way for a new quarter.

Pawnbroking. The Mont de Piété, which formerly lent only upon the pledging of portable property, has for several years made loans to the bearer of certain financial securities quoted on the Bourse. There is now no limit fixed to the magnitude of transactions on the former security, but on the latter not more than £20 can be lent. The number of loans continues to decline. In 1897, 1,155,564 securities to the value of £1,315,215 were pledged, 1,026,271 to the value of £1,208,553 were cleared, 729,205 to the value of £916,678 were renewed, and 129,442 to the value of £88,563 were sold.

Banks. The amount of the deposits at the Caisse d'Épargne, or savings bank, of Paris continuing to increase (in 1895 it reached the sum of £6,400,000), the rate of interest on deposits has been reduced from 3 per cent. to $2\frac{3}{4}$ per cent., and the maximum deposit permitted to each depositor has been reduced from £80 to £60. Beyond this sum the surplus is employed in the purchase of *rentes* (stock) on behalf of the depositor. The deposits were thus reduced to £6,098,386 at the end of 1896, and to £5,906,377 at the end of 1897. The National Savings Bank, which transacts its operations at the various State post offices, in 1895 had 2,280,000 depositors and £28,000,000 in deposits. One quarter of its transactions took place within Paris. In the same proportion Paris was concerned in the business done by the National Office for Old Age Pensions, which in 1894 paid out £1,328,673 to 196,987 annuitants. The interest paid when the association was founded in 1852 was 5 per cent.; since 1894 it has fallen to $3\frac{1}{2}$ per cent. The privilege of issuing bank notes enjoyed by the Bank of France has been extended from 1897 to 1920. The maximum issue has been fixed at 5,000,000,000 francs, or £200,000,000. The bank can now discount the stock of the agricultural syndicates, and has a branch in the capital of each department and in numerous other commercial centres, in addition to sub-offices which yearly increase in number; all its officials must be French. The circulation of bank notes in 1897 amounted in value to £151,361,227. (See also the article BANKING.)

Justice. The Court of Appeal now consists of seven civil chambers, besides one for preliminary proceedings and one for appeal from the correctional police. The prisons of Mazas, Ste Pélagie, and La Grande Roquette have been closed, demolished, and replaced by the new prison of Fresnes-les-Rungis. This establishment covers 50 acres. The prisoners, kept in solitary confinement, are divided into three groups: those undergoing short sentences, those sentenced to hard labour while awaiting transference to their final place of detention or to sentences over a year, and sick prisoners occupying the central infirmary of the prison. The Petite Roquette (occupied by children) is also to be demolished, and to be replaced by the agricultural and horticultural colony of Montesson. Paris is to retain only the Conciergerie and depot of the Prefecture of Police, both within the walls of the Palais de Justice, and the prison of La Santé, which will receive prisoners awaiting trial and political prisoners.

Cremation. The only crematorium in France has been built at Père la Chaise, for the cremation of those who have expressed a desire for it and for the destruction of human remains from the dissecting rooms.

Fire. The fire brigade (*sapeurs-pompiers*) is a regiment of the army, consisting of 2 battalions and 12 companies, the War Office sharing the control of it with the Prefect of Police and the Minister of the Interior. It consists of 52 officers, 185 non-commissioned officers, 291 corporals, and 1225 privates. It is composed of volunteer conscripts who have been brought up to the building trades. They have a dark blue uniform, with a gilt helmet. Like soldiers in the regular army, they serve three years, but may re-enlist for seven years. They have nightly duties at the theatres, and may be engaged for private entertainments. There are 24 stations, each provided with 4 engines, 2 vans, a fire-escape, and a steam pump. There are 184 horses, the property of a contractor. There are 6928 fire-plugs, placed at intervals of 100 metres, and the pressure at most of these is sufficient to dispense with pumps; but formerly, when the water supply was less perfect, by-standers had to be impressed to pass the buckets from hand to hand. There were in 1901, besides 1544 chimney fires and 436 false alarms, 1422 calls, but only 23 of these were serious fires. The aggregate damage was 5,927,000 francs, but in the previous year the burning down of the Comédie Française had raised the total to 10,346,000 francs. The cost of the force in 1901 was 2,729,000 francs, besides 892,000 francs supplementary expense for plant, repairs, and rebuilding. The charge falls on the Paris municipality. In recognition of the unquestionable efficiency and courage of the force, President Loubet, at the Longchamps review of the 14th July 1902, affixed to its flag the cross of the Legion of Honour.

Markets. The 2,511,955 inhabitants of the city consumed in 1896, 352,021 tons 8 cwt. of bread; 123,362,426 gallons of wine and spirits; 171,043 tons 9 cwt. of meat; 26,737 tons 14 cwt. of fish; 27,724 tons 4 cwt. of poultry and game; 491,799,240 eggs; 20,199 tons of butter; 8572 tons 8 cwt. of oysters; 667 tons 8 cwt. of cheese; 1207 tons 15 cwt. of early fruits and vegetables (only the fish and early produce arriving at the central markets are reckoned; those arriving elsewhere escape computation). The Marché de la Villette continues to be the great centre for the supply of cattle, and its abattoir is still the principal one in the city. But on the left bank of the Seine the abattoirs of Grenelle, Villejuif, and les Fourneaux have been replaced by that of Morillons, which occupies an area of 25 acres near the station of the Brittany Railway. The corn trade is still carried on at the old corn-market (*halle aux blés*) transformed into the *bourse du commerce*, flour dealers meeting in the district between the Louvre and St Germain l'auxerrois. For several years manual labour has been the subject of supply and demand at the Labour Exchange (*bourse du travail*).

Shipping. The following are the general results of the navigation statistics of the Seine for 1898: entrances, 5,202,700 tons; traffic clearances, 1,689,000 tons; transit, 1,397,800 tons; local, 641,300; total, 8,930,800 tons. Detailed results for 1897 are given in the following table:—

Entrances.		Clearances.		Transit.		Total Movement.
Lower Seine.	Upper Seine.	Towards the Lower Seine.	Towards the Upper Seine.	Towards the Lower Seine.	Towards the Upper Seine.	
Tons. 1,066,026	Tons. 1,735,149	Tons. 612,120	Tons. 713,171	Tons. 957,118	Tons. 987,608	Tons. 6,071,192

Navigation of the Canals in 1897.

Ourcq Canal.		St Denis Canal.		St Martin's Canal.		Total for the three Canals.
Up.	Down.	Up.	Down.	Up.	Down.	
Tons. 97,685	Tons. 525,148	Tons. 1,400,497	Tons. 399,171	Tons. 763,537	Tons. 351,447	Tons. 3,537,485

The *postal department* of Paris was served in 1897 by 98 offices (exclusive of the great central office), 96 of which were telegraph offices; there were also 48 auxiliary offices managed by shopkeepers, &c. These sub-offices continue to increase in number, as also do the letter-boxes, of which there are no less than 2000. The circulation of letters for specified years is shown by the following tables:—

Post office, &c.

Year.	Prepaid Letters.	Unpaid Letters.
1886	49,193,000	478,000
1890	57,930,000	473,000
1895	67,011,000	467,918
1897	67,352,348	460,075

There were also despatched from Paris in 1897, 15,264,000 post-cards, price 10 centimes; 3,127,400 letter-cards, price 15 centimes; 53,110 cards, reply prepaid, price 20 centimes; 19,580 foreign letter-cards, price 25 centimes; 502,055 registered letters for Paris, 4,492,315 registered letters for France, 770,472 registered foreign letters, 862,424 registered packets for France, 410,160 registered foreign packets; 85,299 letters containing money orders for Paris, 1,059,700 letters containing money orders for France, and 260,027 for abroad; 31,556 boxes containing money orders for Paris, and 408,002 for France.

Year.	French Money Orders.		International Money Orders.		Amounts re-covered.	Un-recovered.
	Issued.	Paid.	Issued.	Paid.		
1887	£3,388,000	£5,424,000	£452,000	£680,000	£212,000	£148,000
1894	4,024,000	6,688,000	428,000	728,000	476,000	272,000
1897	4,174,040	6,794,510	461,090	817,510	306,523	154,683

The following table shows the number of newspapers sent by post in specified years to addresses (*a*) in the department of the Seine, (*b*) in other departments or abroad:—

	Political and Periodical Journals.		Non-political Periodicals.	
Year.	Department of the Seine.	Other Depts. or Foreign Countries.	Department of the Seine.	Other Depts. or Foreign Countries.
1887	18,000,000	104,000,000	17,000,000	40,000,000
1890	20,000,000	112,000,000	18,000,000	48,000,000
1895	22,216,000	119,000,000	22,300,000	52,913,815
1897	22,774,812	120,992,934	22,974,945	53,475,201

In the *parcel post* department 4,508,277 packages were received in Paris from places in France, 735,783 from abroad; 16,232,742 were despatched from Paris into the provinces, 1,834,314 abroad. The receipts of the Paris post office amounted in 1887 to £2,320,000, in 1894 to £2,600,000. The *personnel* of the service on the 31st December 1896 consisted of 211 higher officials, 1696 clerks, 271 women assistants, 2972 letter-carriers. It employed 300 horses, 120 drivers, 35 two-horse vans, 53 one-horse vans, 59 tilburys, 37 factors' omnibuses. Cyclists carry special collections to the railway stations. Automobiles have been employed in collecting the contents of letter-boxes.

In connexion with the *telegraph* service of Paris there are 104 offices. The telegraphic circulation is tabulated thus (numbers in thousands):—

Year.	Despatched to			Received from		
	Paris.	The Provinces.	Abroad.	Paris.	The Provinces.	Abroad.
1886	3168	3394	1244	3168	3337	959
1890	4058	7551	1487	4058	7722	1170
1895	4490	8563	1591	4490	8817	1250
1897	4692	8967	1374	4692	9035	1063

To this number must be added the telegrams passing through Paris, which in 1886 numbered 16,798,000; in 1897, 25,402,000. A large number of the messages sent in Paris for delivery within the city are forwarded through pneumatic tubes. In 1886 the number so despatched was 3,095,997; in 1897, 4,410,400. The staff consisted on the 31st December 1896 of 24 higher officials, 1220 clerks, and 839 women assistants.

The *telephone* service, like the postal and telegraph services monopolized by the State, consists of a central office communicating with eleven divisional offices, to which subscribers in various districts come for connexion. The public can make use of telephone boxes in the post, telegraph, and telephone offices, and in certain railway stations. The time allowed for conversation is usually fixed at five minutes. The rate of charge varies according as the communication is exchanged with Paris or beyond, and the distance from the inner office. Telephonic messages can be conveyed, if desired, from the receiving office to specified addresses. Conversations are most frequent between Paris and, among foreign towns, Brussels, London, and Geneva. In France, Rouen, Havre, Lille, Lyons, Marseilles, and Reims are the towns that most frequently communicate with the capital. On the 31st December 1896 the telephone staff comprised four higher officials, 230 clerks, 1401 women assistants, 148 under-officials. The network of telephones increases continuously, and about 2500 new subscribers are added every year.

Exhibitions, &c.

The International Exhibitions which may be said to follow one another periodically in Paris (1855, 1867, 1878, 1889, 1900) offer a means of reviewing the progress made during the intervals between them in the various branches of art and industry, especially as each Exhibition carries out a programme vaster than that of its predecessor. Thus, whilst the 1855 Exhibition concerned itself only with contemporary art and industry, that of 1867 told the story of their development. In 1878 the Rue des Nations reproduced in Paris a monument of every foreign country with its local colour. In 1889 the Rue du Caire enabled one to live for a time in that celebrated capital. But these, after all, were but temporary shows, designed for the entertainment of crowds. The progress of greatest importance demonstrated in 1889 was that made in the art of construction in iron, as illustrated by two notable examples—the Eiffel Tower, the most gigantic tower of the whole world, 990 feet high, and the Gallery of Machinery, with its boldly designed girders (remarkable for their immense span). Glass buildings are features of the time; and in place of the flat and uniform *façades* which border the boulevards opened during the Second Empire, contemporary architects build carved and sculptured *façades*, with ledges and projections. And notwithstanding the heavy cost of the disasters of 1870, several important public buildings have been erected since—the Opéra, the Tuileries, the new Sorbonne, the schools of medicine and law, the general post office, central telephone office, the galleries of the natural history museum, the Opéra Comique, amongst others. Several *lycées* and hospitals and numerous schools have been either built or enlarged; the railway stations are magnificent structures; among bank buildings those of the Crédit Lyonnais may be quoted as models of their kind, and several handsome new museums have been opened, mainly by private individuals who see in such foundations the best means of safeguarding the future of their collections. Dwelling-houses, too, are much more intelligently arranged than those of older date, and are fitted with all the latest improvements devised by science for the comfort of man. (G. Ms.)

Parisian Events since 1875.—After the adoption of the Constitution of 1875, the first important political event in Paris was the dissolution of the Chamber of Deputies, pronounced by the Senate on 19th June 1877, at the request of Marshal MacMahon, then President of the Republic. The elections that followed this act gave a large majority to the Republicans. The Universal Exhibition of 1878, destined to show Europe that France had recovered her material prosperity and moral power, attracted a large concourse, but the different sovereigns abstained. The number of admissions was about 13,000,000. A grand fête, full of gaiety and enthusiasm, was held on 30th June. This was the first public rejoicing since the war. Marshal MacMahon resigned the Presidency in 1879, and was succeeded by M. Jules Grévy. The terrible winter of 1879–80 was the severest of the century; the Seine, entirely frozen, resembled a sea of ice. The 14th of July, the anniversary of the taking of the Bastille, was adopted as the French national holiday, and celebrated for the first time in 1880. A grand military review was held in the Bois de Boulogne, at which President Grévy distributed flags to all the regiments of the army. On 17th March 1881 a national loan of a thousand million francs was issued for the purpose of executing important public works. This loan was covered fifteen times, Paris alone subscribing for ten thousand millions. At the time of the legislative elections, on 21st August and 4th September 1881, several tumults occurred in the Belleville district. Gambetta, who was a candidate in the two wards of that district, vainly tried to address the electors.

The great orator died in the following year, on the 31st of December, from the effects of an accident, and his funeral, celebrated in Paris at the expense of the State, was attended by an immense gathering. A slight Legitimist agitation followed Gambetta's death. An unfortunate event occurred on 29th September 1883, the day when the king of Spain, Alphonso XII., returned from his visit to Berlin, where he had reviewed the 15th regiment of Prussian Uhlans, of which he was the honorary colonel. The cries of "Down with the Uhlan!" with which he was greeted by the Paris crowd, gave rise to serious diplomatic incidents. On 26th May 1885 the following decree was rendered: "The Pantheon is restored to its primitive and legal destination. The remains of the great men who have merited national recognition will be disposed therein." But it was only on 4th August 1899 that the ashes of Lazare Carnot, Hoche, Marceau, Latour d'Auvergne, and Baudin were solemnly transported to the Pantheon. Victor Hugo's funeral was celebrated on 1st June 1885, and by an urgency vote they were made national obsequies. It was decided that the corpse should be exposed one day and one night under the Arc de Triomphe, veiled with an immense crape. A few days before, upon the occasion of the anniversary of the fall of the Commune, a tumultuous political manifestation had been made in front of the tomb of the Communists buried in Père Lachaise cemetery.

M. Jules Grévy was re-elected President of the French Republic in 1885. The following year the Monarchists renewed their political demonstrations; the most important one was the reception given by the Count of Paris at the Galliera mansion on the occasion of the marriage of his daughter with the King of Portugal. The Count of Paris had invited to this reception all the foreign ambassadors, and some disturbance having taken place, the Chamber of Deputies, on 11th June 1886, voted a law interdicting sojourn upon French territory to the Orleanist and Bonapartist pretenders to the throne of France, and also to their direct heirs. At that epoch Paris was in a state of agitation and discontent, and various catastrophes occurred. First of all came the disastrous bankruptcy of a large financial concern called the Union Générale; then the scandal concerning the traffic in decorations, in which M. Wilson, son-in-law of M. Jules Grévy, was compromised, and which eventually led to the resignation of the President; finally, the deplorable Panama affair profoundly enervated the Parisians, and made them feel the necessity of shouting for a military master, some adventurer who would promise them a revenge. All this led to Boulangism. It was by wild acclamations and frantic shouts that General Boulanger was greeted, first at the review of the army on the 14th of July, then two days later at the opening of the Military Club, afterwards at the Winter Circus, where the Patriots' League held a mass meeting under the presidency of Paul Déroulède, and finally, on 8th July, at an immense demonstration at the Lyons railway station, when "le brav' Général" left Paris to take command of the 13th army corps at Clermont Ferrand. Popular refrains were sung in the streets in the midst of immense excitement on 27th January 1889 at the time of the election of General Boulanger as deputy for the Seine department. A majority of 80,000 votes had invested him with an immense moral authority, and he appeared as though elected as the candidate of the entire country; but he lacked the necessary audacity to complete his triumph, and the Government having decided to prosecute him for conspiracy against the security of the State, before the Senate acting as a High Court of Justice, he fled with his accomplices, Rochefort and Dillon. All three were condemned by default, on 14th August, to imprisonment in a fortified enclosure.

Other events had also troubled this astonishing interlude of Boulangism. On 23rd February 1887 a terrible fire destroyed the Opéra Comique during a performance, and a great many of the audience perished in the flames. The first performance of *Lohengrin*, which took place at the Eden Theatre on 1st May 1887, was also the cause of street rioting. In 1888 there were several strikes. That of the day labourers, which lasted more than a month, occasioned violent scenes, owing to the sudden death of Émile Eudes, a Communist, while he was speaking in favour of the strike at a public meeting. On 2nd December there were manifestations in memory of Baudin, a representative of the people, killed upon the barricades in 1851 while fighting in the defence of the Republic. But a calm finally came, and then the Parisians thought only of celebrating the centenary of the Revolution of 1789 by a universal exhibition. This Exhibition contained a profusion of marvels such as had never before been seen, and indicated what enormous industrial progress had been accomplished. Sadi Carnot, who had succeeded M. Jules Grévy as President of the Republic on 3rd December 1887, officially opened the Exhibition on 6th May 1889. Numerous fêtes were held in the grounds while the exhibition lasted. The Eiffel Tower and the illuminated fountains enraptured the crowd of visitors, while the Rue du Caire, with its Egyptian donkey-drivers, obtained a prodigious success. Most of the nations were represented at this Exhibition. Germany alone confined her co-operation to the display of some paintings. The Shah of Persia, in honour of whom splendid fêtes were organized, and the King of Greece, the Prince of Wales, the Lord Mayor of London, several Russian grand dukes, Annamite, Tunisian, Moorish, Egyptian, and African princes, successively visited the Exhibition. There were 30,000,000 visitors. On the 18th of August a banquet was offered in the Palais de l'Industrie by the Paris Municipal Council to all the mayors in France, and 15,000 of these officials were present.

In 1890 the duke of Orleans, having attained his majority, came to Paris to draw for military service with the young conscripts of his class. He was arrested, and placed, first in the Conciergerie, and later in the prison at Clairvaux, but was released after a few months' incarceration. The following years were remarkable for more strikes and several demonstrations by the students, which led in 1893 to conflicts with the police, in one of which a student was killed. On the 17th of October an enthusiastic welcome was extended to Admiral Avellan and the Russian sailors upon their arrival in Paris. It was about this time that dynamite began to be used by the Anarchists. After Ravachol, who commenced the sinister exploits of the "propaganda by acts," it was Vaillant that threw a bomb into the "Temple of the Laws" on 9th December 1893, and wounded forty-six deputies. Then there was a succession of these attacks during the two following months, for Ravachol and Vaillant had found emulators. Henry scattered fright and death among the peaceable customers of a brasserie, while bombs were thrown into the doorways and staircases of houses inhabited by wealthy people. Upon the steps of the Madeleine Church, Parvels, who was already the author of two dynamite plots, was struck down by the destructive machine that he was about to throw into the body of the church. Laurent Tailhade himself, who had celebrated with his pen the beauty of Vaillant's gesture, was subsequently wounded by dynamite thrown into the Café Foy, where he was lunching. Finally came the attack on President Carnot, who, on 24th June 1894, fell at Lyons under the blow of the Italian anarchist Caserio's dagger. His funeral was celebrated at Paris on 1st July. M. Casimir-Perier, elected President of the Republic on the preceding day, followed the procession on foot. He resigned office on 15th January 1895, and on the 17th M. Félix Faure was chosen as his successor.

The visit of the Emperor and Empress of Russia, on the 5th, 6th, and 7th of October 1896, was celebrated by incomparable fêtes. The Rue de la Paix was decorated with ropes and sails, stretched across the street like the rigging of a vast vessel, in honour of the Russian sailors. Nothing could be seen anywhere except flags, cockades, and badges formed of the colours of the two friendly nations. In the evening there were open-air balls, with farandoles and orchestras at all the street corners. Popular enthusiasm was again manifested on 31st August, when President Faure returned from his visit to the Russian court. On 4th May 1897 the terrible conflagration at the Charity Bazaar in the Rue Jean Goujon threw into mourning one hundred and forty families of the nobility or the aristocracy of Paris, and spread sorrow among the class always considerate in its benevolence. Then all minds were again troubled and disturbances occurred in the streets for more than two years over the Dreyfus case, dividing the French people into two camps. Certain newspapers kept up the agitation, which was the cause of numerous prosecutions.

Félix Faure died suddenly on the 18th of February 1899. The very day of his funeral, Paul Déroulède and Marcel Habert tried to make a *coup d'état* by urging General Roget to lead his troops, which had formed part of the guard of honour at the obsequies, against the Élysée. Immediately arrested and put on trial, Déroulède and Habert were acquitted by a timorous jury.

M. Émile Loubet, President of the Senate, was chosen as successor to M. Félix Faure. Upon his return to Paris from the Versailles Congress, where he had been elected President of the French Republic, he was greeted by hisses and cries of "Panama!" cries in no wise justifiable. Some time afterwards, Jules Guérin, by a desperate resistance against a summons of the police to give himself up, made the public believe for two months in the existence of an impregnable fortress in the Rue Chabrol, in the very centre of Paris. On the 4th of June there was a great scandal at the Auteuil Races, which President Loubet had been, according to custom, invited to attend. He was insulted and struck by Baron de Christiani, who was encouraged by the young royalists of the "Œillets Blancs" Association. A week later, the extraordinary and excessive police measures taken to prevent a disturbance at the Grand Prix occasioned the downfall of the Dupuy ministry. M. Waldeck-Rousseau then formed a cabinet, himself becoming President of the Council. The new premier immediately took energetic measures against the enemies of the Republic. Compromising documents found in various domiciliary searches made among the Monarchists and Nationalists formed the basis of prosecutions before the High Court of Justice. The trial resulted in the condemnation of Jules Guérin to a term of imprisonment, and the banishment of Paul Déroulède, Marcel Habert, André Buffet, and the Marquis de Lur Saluces, thereby ridding France of all these promoters of disorder, and opening a new era of peace, which lasted throughout the Universal Exhibition of 1900. This Exhibition covered an enormous space, including the slope of the Trocadéro, the Champ de Mars, the Esplanade of the Invalides, and both sides of the Seine bordered by the Rue de Paris and the Rue des Nations. Seen from the new Alexandre III. bridge, the spectacle was as fairy-like as a stage setting. Close beside, at the left, were the palaces of the different nations, each one showing its characteristic architecture, and all being of an astonishing diversity. To the right were the pavilion of the city of Paris and the enormous greenhouses, and in the distance Old Paris, so picturesquely constructed by Robida. In short, exotic edifices and scintillating cupolas arose with unparalleled profusion, creating in the heart of Paris a veritable city of dreams and illusion. The most distant countries sent their art treasures or the marvels of their industry. The number of visitors was 51,000,000, and the personages of mark included the Shah of Persia, the King of Sweden, the King of the Belgians, and the King of Greece, all of whom were successively the guests of France. On the 22nd of September 22,000 mayors accepted the invitation to the banquet offered in their honour by President Loubet, and thus solemnly affirmed their Republican faith. This admirably organized banquet was spread in the Tuileries Gardens. The Exhibition of 1900, a brilliant epilogue of the closing century, was a grand manifestation of universal concord, of the union of peoples by art, science, industry, all branches of human genius. (DE B.)

Paris, a city of Texas, U.S.A., capital of Lamar county. It is in the north-eastern part of the state, on the Gulf, Colorado, and Santa Fé, the St Louis and San Francisco, the Texas and Pacific, and the Texas Midland railways, at an altitude of 563 feet. It is in a grain and cotton region, for which it is a collecting and distributing point, and has a large trade and some manufactures. Population (1880), 3980; (1890), 8254; (1900), 9358, of whom 182 were foreign-born and 3061 negroes.

Paris, Louis Philippe Albert d'Orléans, COMTE DE (1838–1894), son of the Duc d'Orléans, the eldest son of King Louis Philippe, was born on 24th August 1838. His mother was the Princess Helen of Mecklenburg-Schwerin, a Protestant. By the death of his father through a carriage accident in 1842, the count, who was then only four years of age, became heir-apparent to the French throne. On the deposition of Louis Philippe in 1848, the Duchess of Orléans struggled to secure the succession to her son, and bore him through an excited populace to the Chamber of Deputies. The Chamber itself was soon invaded, however, and the Republic proclaimed. The Orleanists were driven into exile, and the duchess proceeded with her two sons, the Comte de Paris and the Duc de Chartres, first to Eisenach in Saxony, and then to Claremont in Surrey. At the latter place the count's education was conducted by his mother. He was reared in the Roman Catholic faith, and received his first communion at the hands of Cardinal Wiseman in 1850. After his mother's death in 1858, the count made a long foreign tour. In 1861 he and his brother accompanied their uncle, the Prince de Joinville, to the United States. During the campaign on the Potomac the brothers were attached to the staff of General McClellan. In April 1862 the count took part in the siege of Yorktown, and was present at the battle of Williamsburg on 5th May. He was also with McClellan at the battle of Fair Oaks, and was personally engaged in the sanguinary encounter at Gaines Mill on the 27th of June. When difficulties arose between France and the United States with regard to the affairs of Mexico, the Orléans princes withdrew from the American army and returned to Europe, paying a visit to President Lincoln before embarking. During the winter of 1862–63 the count took a special interest in the organization of the Lancashire Cotton Famine Fund, and contributed an article to the *Revue des Deux Mondes* entitled "Christmas Week in Lancashire." On 30th May 1864 he married his cousin, the Princess

Marie Isabelle, daughter of the Duc de Montpensier, and his son and heir, the Duc d'Orléans, was born at York House, Twickenham, in 1869. The count was refused permission to serve in the Franco-Prussian war, but after the fall of Napoleon III. he returned to France. Abstaining from putting himself forward, he lived quietly on his estates, which had been restored to him by a vote of the Assembly. He gave considerable study to social questions, and the relations between capital and labour, and published a valuable little work on trades unions. In August 1873 there was an important political conference at Frohsdorf, the result of which was that a fusion was effected, by which the Comte de Paris agreed to waive his claims to the throne in favour of those of the Comte de Chambord. By the death of the latter in 1883 the count became undisputed head of the House of Bourbon; but the old Legitimists did not hail him with much enthusiasm, nor did the count show any disposition to push his claims. The popularity of the Orleans family, however, was shown on the occasion of the marriage of the Comte de Paris's eldest daughter with the Duke of Braganza, son of the King of Portugal, in May 1886. This so alarmed the French Government that it led to a new law of expulsion, by which direct claimants to the French throne and their heirs were banished from France. The Comte de Paris again retired to England, taking up his abode at Sheen House, near Richmond Park. Here he devoted his leisure to his favourite studies. In addition to his work *Les Associations Ouvrières en Angleterre*, which was published in 1869 and translated into English, the count edited the letters of his father, and published at intervals in eight volumes his *Histoire de la Guerre Civile en Amérique.* In his later years the count seriously compromised the prospects of the Royalist party by the relations into which he entered with General Boulanger. He died 8th September 1894.

Parker, Joseph (1830–——), English Congregational minister, was born at Hexham-on-Tyne, 9th April 1830, his father being a stone-cutter. In 1852 he attended classes at University College, London. Ordained (1853) to the career of a Congregational pastor, he was called to Banbury, where he worked from 1853 to 1858, and then to Manchester, where in 1868 he published *Ecce Deus* (a reply to *Ecce Homo*); but in 1869 he came to London, and became minister of the Poultney Chapel in Holborn, in substitution for which afterwards the great City Temple was built in 1874, by his exertions, at a cost of £70,000. He became famous as a vigorous, stirring, and original preacher on conservative theological lines. In 1880 he visited the United States, where he was compared with Henry Ward Beecher, who had just died; and Parker was expected at the moment to take his place, but he returned to England with the degree of D.D. from Chicago University. In 1889 he issued *The People's Prayer-book*, and in 1885 began the publication of *The People's Bible* (in 25 vols.), a series of discourses which came out at intervals up to 1895. Among his other works may be mentioned *City Temple Sermons* (1869–70), *The Inner Life of Christ* (1881), *Apostolic Life* (1884), *My Life and Teaching* (1889), *A Preacher's Life* (1899), and some autobiographical sketches of ministerial life, *Springdale Abbey* (1869) and *Tyne Chylde* (1883). Dr Parker shared for many years with Mr Spurgeon the reputation of being the most impressive Dissenting preacher in England. He became chairman of the London Congregational Board and of the Congregational Union. He married twice, first in 1851, and secondly in 1864, and the death of his second wife in 1898 deprived him of a devoted helper.

Parkersburg, a city of West Virginia, U.S.A., capital of Wood county, on the west bank of the Ohio river, at the mouth of the Little Kanawha river, in the western part of the state, at an altitude of 616 feet. Next to Wheeling it is the largest city in West Virginia. It has four railways, the Baltimore and Ohio, the Baltimore and Ohio South-Western, the Little Kanawha, and the Ohio River. It has a large trade, both by rail and river. It is in a coal, oil, and natural gas region, and contains the shops of the Ohio River Railway, oil refineries, iron-works, lumber-mills, &c. Population (1890), 8408; (1900), 11,703, of whom 515 were foreign-born and 783 negroes.

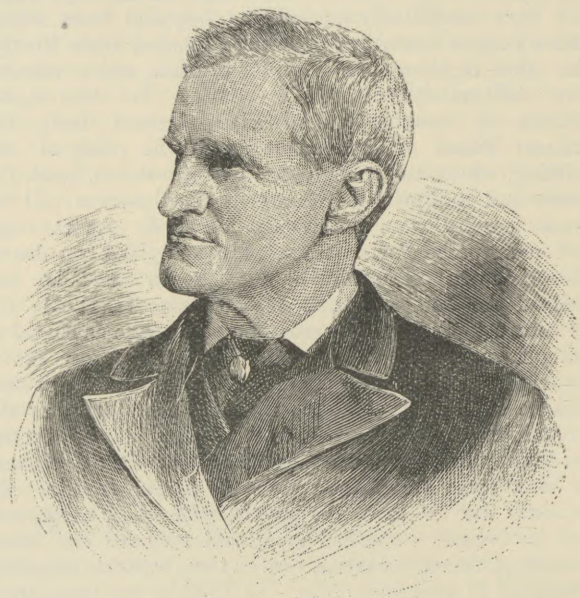
Parkes, Sir Harry Smith (1828–1885), English diplomatist, son of Harry Parkes, the founder of the firm of Parkes, Otway and Co., ironmasters, was born at Birchills Hall, near Walsall in Staffordshire, in 1828. When but four years old his mother died, and in the following year his father was killed in a carriage accident. Being thus left an orphan, he found a home with his uncle, a retired naval officer, at Birmingham. He received his early education at a boarding-school at Balsall Heath, and afterwards at King Edward's Grammar School. In 1837 his uncle died, and in 1841 he sailed for Macao in China, to take up his residence at the house of his cousin, Mrs Gutzlaff. At this time what was known as the "Opium War" had broken out, and Parkes eagerly prepared himself to take part in the events which were passing around him by diligently applying himself to the study of Chinese. In this pursuit he was fortunate to have the help and supervision of Dr Gutzlaff and John Robert Morrison, secretary and interpreter to Sir Henry Pottinger. Under these congenial influences he made rapid progress, and in 1842 he received his first appointment in the consular service. Fortunately for him, he was privileged to accompany Sir Henry Pottinger in his expedition up the Yangtse-kiang to Nanking, and after having taken part in the capture of Chinkiang and the surrender of Nanking, he witnessed the signing of the treaty on board the *Cornwallis* in August 1842. By this treaty the five ports of Canton, Amoy, Foochow, Ningpo, and Shanghai were opened to trade. After short residences at Canton and the newly opened Amoy, Parkes was appointed to the consulate at Foochow. Here he served under Mr (afterwards Sir) Rutherford Alcock, who was one of the few Englishmen who knew how to manage the Chinese. Though the war was over, the people were still hostile to foreigners, and it was only by the exercise of strong pressure that Alcock and his young interpreter were able to protect themselves and their countrymen from the assaults of the natives. In 1846 he was transferred with Alcock to Shanghai, which was even then beginning to show signs of developing into the place of importance which it has since become. In 1849 he returned to England on leave, and after visiting the Continent and doing some hard work for the Foreign Office, he returned to China in 1851. After a short stay at Amoy he was transferred to Canton as interpreter, and there he was first brought into contact with Commissioner Yeh, whose insolence and obstinacy led up to the second China war. Yeh had now met a man of even greater determination and power than himself, and when, as a climax to many outrages, Yeh seized the British lorcha *Arrow* and made prisoners of her crew, Parkes at once closed with his enemy. In response to a strongly-worded despatch from Parkes, Sir John Bowring placed matters in the hands of the admiral, who took Canton and, with Parkes's personal help, made a prisoner of Yeh. As the city was to be held, an allied commission was appointed to govern it, consisting of two Englishmen, of whom one was Parkes, and a French naval officer. Being the only one of the three who had any experience of the Chinese character, the burden of the work fell upon Parkes, who virtually governed this city of a million inhabitants for three years. Meanwhile the treacherous attack at Taku upon Sir Frederick Bruce, who was on his way to Peking to exchange the ratifications of the treaty concluded in 1858, led to a renewal of hostilities in the north, and Parkes was ordered up to serve as interpreter and adviser to Lord Elgin. In pursuance of these duties he went in advance of the army to the city of Tungchow, near Peking, to arrange a meeting between Lord Elgin and the Chinese commissioners who had been appointed to draw up the preliminaries of peace. While thus engaged he, Mr (afterwards Lord) Loch, Mr de Norman, Lord Elgin's secretary of legation, Mr Bowlby, the *Times* correspondent, and others, were treacherously taken prisoners. Parkes and Loch were carried off to the prison of the Board of Punishments at Peking, where they were separately herded with the lowest class of criminals. After ten days' confinement in this den of iniquity they were removed to a temple in the city, where they were comfortably housed and fed, and from which, after a further detention, they were granted their liberty. The other captives were not so fortunate, and a number were deliberately tortured to death. For this signal instance of treachery Lord Elgin burned down the Summer Palace of the emperor, and the ruins of this building, which have since been left unrestored, mark the horror and indignation with which this baseness and inhuman cruelty were universally regarded. At the conclusion of peace Parkes returned to England on leave, when he was made K.C.B. for his services; he had received the Companionship of the Order in 1860. On his return to China he served for a short time as consul at Shanghai, and was then appointed minister in Japan (1865). For eighteen years he held this post, and throughout that time he strenuously used his influence in support of the Liberal party of Japan, whose first object was to abolish the native feudal system of government and to substitute for it a more enlightened form of administration. So earnestly did he throw in his lot with these reformers, that he became a marked man, and incurred the bitter hostility of the reactionaries, who on three separate occasions attempted to assassinate him. In 1882 he was transferred to Peking, where, with his usual energy, he worked for the good of his country; and although in conducting negotiations he had many serious contentions with the mandarins, he retained throughout their respect and regard. While in Peking his health failed, and he died of malarial fever on the 21st of March 1885. In 1856 Sir H. (then Mr) Parkes married Miss Fanny Plumer, who died in 1879. (R. K. D.)

Parkes, Sir Henry (1815–1896), Australian statesman, was born at Stoneleigh, in Warwickshire, on 27th May 1815. The son of parents in very humble circumstances, he received only a rudimentary education, and at an early age was obliged to earn his living as a common labourer. Failing to make his way in England, he emigrated to Australia in 1839, and after a time settled in Sydney as an ivory-turner. Conscious of his great powers, he worked unremittingly to repair the deficiencies of his education, and developed a genuine taste for literature, and a gift for versification which won the approval of so severe a judge as Tennyson. His first volume of poems was published in 1842, under the title of *Stolen Moments.* He now began to take an active part in politics, and soon showed himself the wielder of an incisive style as a leader-writer, and a popular orator of unrivalled influence. He took a prominent part in the movement against the transportation of convicts, and in 1849 started the *Empire* newspaper to inculcate his policy of attacking abuses while remaining loyal to the Crown. The paper at once made its mark, but owing to financial difficulties ceased to appear in 1858. One of the reforms for which Parkes fought most strenuously was the full introduction of responsible government. He was triumphantly returned to the Legislative Council under the old constitution as member for Sydney, and on the establishment of a legislative assembly in 1856 was returned for East Sydney. In the debates on the new constitution he successfully attacked the proposal to create a hereditary Upper House, but vainly endeavoured to exclude the principle of nomination. His parliamentary career was twice interrupted by pecuniary embarrassments; indeed, he never acquired the art of making money, and in spite of a public subscription raised in 1887, died in absolute penury. He was elected for East Sydney in 1859 at the first general election under the new electoral Act, and sat till 1861, when he was sent to England as a commissioner for promoting emigration. He made a prolonged stay in England, and described his impressions in a series of letters to the *Sydney Morning Herald*, some of which were reprinted in 1869 under the title of *Australian Views of England.* He returned to Australia in 1863, and, re-entering the Assembly, became colonial secretary in the Martin ministry from 1866 to 1868. He succeeded in passing the Public Schools Act of 1866, which for the first time instituted an efficient system of primary education in the colony; but the Roman Catholic and Anglican communities, holding that the position of the denominational schools was menaced, displayed a bitter hostility to Parkes which survived the passing of the Bill. His great chance came in 1872, when the Martin ministry resigned on the question of the sum payable by Victoria in lieu of border duties. Parkes, who during his visit to England had fallen deeply under the influence of Cobden, had persistently advocated free-trade as a remedy for the financial distress of the colony. He now became prime minister and colonial secretary; and rising to the height of his opportunity, he not only removed the cause of dispute by throwing the colony open to trade, but made Sydney the chief port on the continent. It was due solely to his influence that New South Wales for many years alone of the Australian colonies adhered to a free-trade policy. He held office till 1875, and on the fall of the Robertson ministry again became premier and colonial secretary from March till August 1877. At the end of this year he was made K.C.M.G. Finding that the state of parties did not allow of the existence of a stable ministry, he formed a coalition with Sir John Robertson, and became premier and colonial secretary for the third time from December 1878 to January 1883. This administration was distinguished by a wide programme of social legislation, including temperance and employers' liability Acts, and reform of education and of the electoral law. In 1882 and in 1883–84 he paid prolonged visits to England. Already distinguished among Australian statesmen for breadth of outlook and passionate devotion to the Empire, he returned with those qualities enhanced. For a time he found himself almost in a position of isolation, but in 1887 the disastrous policy of protection adopted by his successors brought him again into office. His free-trade policy was once more successful. Other important measures of his administration were the reform of the civil service, the prohibition of Chinese immigration, and the Railways and Public Works Acts. He fell from office in January 1889, but in the following March became for the fifth time premier and colonial secretary. The remainder of his life was chiefly devoted to the question of Australian federation. He had from his early days been an advocate of this idea; but that inability to recognize the merits of his opponents, which, combined with excessive self-esteem, formed the chief defect of his character, prevented his co-operating in subsequent attempts at federation. The Federal Convention at Melbourne in 1890 was mainly his work; and he presided over the Convention at Sydney in 1891, and was chiefly responsible for the draft constitution there carried. Defeated in October 1891 on his refusal to accept an eight hours' day for coal-miners, he remained in opposition for the rest of his career, sacrificing even free-trade in the hope of smoothing the path of federation. He died at Sydney on 27th April 1896; but though he did not live to see the realization of his efforts, he may justly be called the Father of the Australian Commonwealth. He published, in addition to the works already named and numerous volumes of verse, a collection of speeches on the *Federal Government of Australia* (1890), and an autobiography, *Fifty Years in the making of Australian History* (1892). (H. SY.)

Parkman, Francis (1823–1893), American historian, was born in Boston, 16th September 1823. His great-grandfather, Ebenezer Parkman, a graduate of Harvard in 1741, was for nearly sixty years minister of the Congregational Church in Westborough, and was noted for his devotion to the study of history. One of this good clergyman's sons, Samuel Parkman, became an eminent merchant in Boston, and exhibited much skill in horticulture. Samuel's son, Francis Parkman, a graduate of Harvard in 1807, was one of the most eminent of the Boston clergymen, a pupil and friend of Channing, and noted among Unitarians for a broadly tolerant disposition. This Doctor Parkman, a man of rare sagacity and exquisite humour, was the father of Francis Parkman, the historian. His mother was a descendant of the celebrated John Cotton. She was the daughter of Nathaniel Hall of Medford, member of a family which was represented in the convention that framed the constitution of Massachusetts in 1780.

Francis Parkman was the eldest of her six children. As a boy, his health was delicate, so that it was thought best for him to spend much of his time at his grandfather Hall's home in Medford rather than in the city. That home was situated on the border of the Middlesex Fells, a rough and rocky woodland, 4000 acres in extent, as wild and savage in many places as the primeval forest. The place is within 8 miles of Boston, and it may be doubted if anywhere else can be found another such magnificent piece of wilderness so near to a great city. There young Parkman spent his leisure hours in collecting eggs, insects, and reptiles, trapping squirrels and woodchucks, and shooting birds with arrows. This breezy life saved him from the artificial stupidity which is too often superinduced in boys by their school training. At the age of fourteen Parkman began to show a strong taste for literary composition. In 1841, while a student at Harvard, he made a rough journey of exploration in the woods of northern New Hampshire, where he had a taste of adventure slightly spiced with hardship. About this time he made up his mind to write a history of the last French war in America, which ended in the conquest of Canada, and some time afterwards he enlarged the plan so as to include the whole course of the American conflict between France and Great Britain; or, to use his own words, "The history of the American forest; for this was the light in which I regarded it. My theme fascinated me, and I was haunted with wilderness images day and night." The way in which true genius works could not be more happily described. In the course of 1842 an attack of illness led to his making a journey in Italy, where he spent some time in a monastery belonging to one of the strictest of all the monastic orders, the Passionists, brethren addicted to wearing hair shirts and scourging themselves without mercy. In the young historian's eyes these good brethren were of much value as living and breathing historic material. In 1844 he graduated at Harvard with high rank.

He now made up his mind to study the real wilderness in its gloom and vastness, and to meet face to face the dusky warriors of the Stone Age. To-day such a thing can hardly be done within the United States, for nowhere does the primitive wilderness exist save here and there in shreds and patches. So recently as the middle of the 19th century, however, it covered the western half of the continent, and could be reached by a journey of 1600 or 1700 miles from Boston to the plains of Nebraska. Parkman had become an adept in woodcraft and a dead shot with the rifle, and could do such things with horses, tame or wild, as civilized people never see done except in a circus. In company with his friend and class-mate, Mr



Francis Parkman.

Quincy Shaw, he passed several months with the Ogillalah band of Sioux. Knowledge, intrepidity, and tact carried Parkman through these experiences unscathed, and good luck kept him clear of encounters with hostile Indians, in which these qualities might not have sufficed to avert destruction. It was a very important experience in relation to his life work. This outdoor life, however, did not suffice to recruit Parkman's health, and by 1848, when he began writing *The Conspiracy of Pontiac*, he had reached a truly pitiable condition. The trouble seems to have been some form of nervous exhaustion, accompanied with such hypersensitiveness of the eyes that it was impossible to keep them open except in a dark room. Against these difficulties he struggled with characteristic obstinacy. He invented a machine which so supported his hand that he could write legibly with closed eyes. Books and documents were read aloud to him, while notes were made by him with eyes shut, and were afterwards deciphered and read aloud to him till he had mastered them. After half an hour his strength would give out, and in these circumstances his rate of composition for a long time averaged scarcely six lines a day. The superb historical monograph composed under such difficulties was published in 1851. It had but a small sale, as the American public was then too ignorant to feel much interest in American history.

Undeterred by this inhospitable reception, Parkman took up at the beginning his great work on *France and England in the New World*, to which the book just mentioned was in reality the sequel. This work obliged him to trace out, collect, arrange, and digest a great mass of incongruous material scattered on both sides of the Atlantic, a large portion of which was in manuscript, and required much tedious exploration and the employment of trained copyists. This work involved several journeys to Europe, and was performed with a thoroughness approaching finality. In 1865 the first volume of the great work appeared, under the title of *Pioneers of France in the New World;* and then seven-and-twenty years more elapsed before the final volumes came out in 1892. Nowhere can we find a better illustration of the French critic's definition of a great life—a thought conceived in youth, and realized in later years. After the *Pioneers* the sequence is *The Jesuits in North America, La Salle and the Discovery of the Great West, The Old Régime in Canada, Frontenac and New France and Louis XIV., Montcalm and Wolfe, A Half Century of Conflict.* As one obstacle after another was surmounted, as one grand division of the work after another became an accomplished fact, the effect upon Parkman's condition seems to have been bracing, and he acquired fresh impetus as he approached the goal. There can be little doubt that his physical condition was much improved by his habit of cultivating plants in garden and conservatory. He was a horticulturist of profound attainments, and himself originated several new varieties of flowers. His work in this department made him an enthusiastic adherent of the views of Darwin. He was professor of horticulture in the Agricultural School of Harvard in 1871–72, and published a few books on the subject of gardening. He died at Jamaica Plain, near Boston, on 8th November 1893.

The significance of Parkman's work consists partly in the success with which he has depicted the North American Indians, those belated children of the Stone Age, who have been so persistently misunderstood alike by romancers, such as Cooper, and by detractors like Dr Palfrey. Parkman was the first great literary author who really understood the Indian's character and motives. Against this savage background of the forest Parkman shows the rise, progress, and dramatic termination of the colossal struggle between France and Great Britain for colonial empire. With true philosophic insight he shows that France failed in the struggle not because of any inferiority in the ability and character of the men to whom the work was entrusted, but chiefly by reason of her despotic and protective régime. There is no more eloquent commentary upon the wholesome results of British self-government than is to be found in Parkman's book. But while the author deals with history philosophically, he does not, like Buckle, hurl at the reader's head huge generalizations, or, like Carlyle, preach him into somnolence. With all its manifold instructiveness, his book is a narrative as entertaining as those of Macaulay or Froude. In judicial impartiality Parkman may be compared with Gardiner, and for depth and accuracy of learning, with Bishop Stubbs. Take him for all in all, he is incomparably the greatest historian that America has produced. (J. Fi.)

Parla Kimedi, a town of British India, in the Ganjam district of Madras. Population (1881), 10,812; (1891), 16,379; municipal income (1897–98), Rs. 13,600. It is the residence of a raja, who claims descent from the ancient kings of Orissa. His estate covers an area of 764 square miles, and pays a revenue of £8782 out of an estimated income of £53,274. He maintains a college, with 32 students in 1896–97; a high school, with 302 pupils; a printing-press, issuing an English newspaper; and two libraries. A steam tramway of 2 feet gauge, for 25 miles, has been sanctioned.

Parliament.—*Procedure.*—The change in the character of the House of Commons since 1832 has rendered necessary important changes in its rules of procedure. No fewer than seventeen committees made recommendations for the improvement of procedure between that date and 1902, but until the forms of the House were openly utilized to delay the progress of Government business the changes made were comparatively insignificant. They were necessitated by the increased volume of business with which the reformed Parliaments had to deal, and by the gradual transfer to Government of the whole work of controversial legislation. They consisted in (1) the discontinuance of superfluous forms, questions, and amendments; (2) restrictions of debates upon questions of form; (3) improved arrangements for the distribution of business; (4) the delegation of some of the minor functions of the House to committees and officers of the House; and (5) increased publicity in the proceedings of the House.

Irish obstruction.

With the entry of Mr Parnell and his Irish Nationalist followers into Parliament (1875–1880) a new era began in the history of the House of Commons. Parnell's professed object was to discredit that assembly, and, by demonstrating its insufficiency to deal with the affairs of the United Kingdom, to prove the necessity of Home Rule for Ireland. His tactics were to oppose all business of whatever kind, and at all hours. The Speaker could only administer the rules as they stood. They had been evolved out of the experience of centuries, during which the House had been on the whole homogeneous, and, however much members might differ in politics, they were wholly loyal to the historic assembly to which they had been elected, and were, moreover, answerable to the public opinion of their fellow-countrymen. But it was to public opinion in Ireland, not in England, that Mr Parnell looked for support, and so far were his efforts to discredit the House of Commons from exciting resentment there, that they gained for him a popularity unrivalled since the days of O'Connell. In one sense, indeed, his tactics were justified by their success, for after ten years' persistence in this novel method of opposition he succeeded in convincing one of the great political parties that the Irish claims could no longer be safely resisted, for the reason, among others, that "Ireland blocked the way" to British legislative reforms. It was not until February 1880 that the House so far overcame its reluctance to restrict liberty of discussion as to pass, in its earliest form, the rule dealing with "order in debate." It provided that whenever a member was named by the Speaker or Chairman as "disregarding the authority of the Chair, or abusing the rules of the House by persistently and wilfully obstructing the rules of the House," a motion might be made, to be decided without amendment or debate, for his suspension from the service of the House during the remainder of the sitting; and that if the same member should be suspended three times in one session, his suspension on the third occasion should continue for a week, and until a motion had been made upon which it should be decided, at one sitting, by the House, whether the suspension should then cease or not. The general election, which took place two months later, restored Mr Gladstone to power and to the leadership of the House. Mr Parnell returned to Parliament with a more numerous following, and resumed his former tactics. In January 1881 the Protection of Persons and Property (Ireland) Bill was introduced. For twenty-two hours Parnell fought the motion giving precedence to the Bill, and for four sittings its introduction. The fourth sitting lasted forty-one hours. Then Mr Speaker Brand intervened, and declined to call on any other member who might rise to address the House, because repeated dilatory motions had been supported by small minorities in opposition to the general sense of the House. He added: "A crisis has thus arisen which demands the prompt interposition of the Chair and of the House. The usual rules have proved powerless to ensure orderly and effective debate. An important measure, recommended by her Majesty nearly a month since, and declared to be urgent in the interests of the State by a decisive majority, is being arrested by the action of an inconsiderable minority, the members of which have resorted to those modes of obstruction which have been recognized by the House as a parliamentary offence. The dignity, the credit, and the authority of this House are seriously threatened, and it is necessary they should be vindicated. . . . Future measures for ensuring orderly debate I must leave to the judgment of the House. But the House must either assume more effectual control over its debates, or entrust greater powers to the Chair." The Speaker then put the question, which was carried by an overwhelming majority. Then followed the decisive struggle. Mr Gladstone gave notice for the next day (3rd February) of an urgency rule, which ordered, "That if the House shall resolve by a majority of three to one that the state of public business is urgent, the whole power of the House to make rules shall be and remain with the Speaker until he shall declare that the state of public business is no longer urgent." On the next day a scene of great disorder ended in the suspension of the Nationalist members, at first singly, and afterwards in groups. The urgency rule was then passed without further difficulty, and the House proceeded to resolve, "That the state of public business is urgent." The Speaker laid upon the table rules of sufficient stringency, and while they remained in force progress in public business was possible. During this session the Speaker had to intervene on points of order 935 times, and the Chairman of Committees 939 times; so that, allowing only five minutes on each occasion, the wrangling between the Chair and members occupied 150 hours.

The events of the session of 1881 and the direct appeal of the Speaker to the House proved the necessity of changes in the rules of procedure more drastic than had hitherto been proposed. Accordingly, in the first week of the session of 1882 Mr Gladstone laid his proposals on the table, and in moving the first resolution on 20th February, he reviewed, in an eloquent speech, the history of the Standing Orders. It was his opinion, on general grounds, that the House should settle its own procedure, but he showed that the numerous committees which, since 1832, had sat on the subject, had failed for the most part to carry their recommendations into effect from the lack of the requisite "propelling power," and he expressed his regret that the concentration of this power in the hands of the Government had rendered it necessary that they should undertake a task not properly theirs. He noted two main features in the history of the case: (1) the constantly increasing labours of the House, and (2) its constantly decreasing power to despatch its duties; and while he declared that "the fundamental change which has occurred is owing to the passing of the first great Reform Bill," he pointed out that the strain had not become intolerable till the development in recent years of obstructive tactics. He defined obstruction as "the disposition either of the minority of the House, or of individuals, to resist the prevailing will of the House otherwise than by argument," and reached the conclusion that the only remedy for a state of things by which the dignity and efficiency of the House were alike compromised, was the adoption in a carefully guarded form of the process known on the Continent as the "clôture." He explained that in his early years the House was virtually possessed of a closing power, because it was possessed of a means of sufficiently making known its inclinations; and to those inclinations uniform deference was paid by members, but that since this moral sanction had ceased to be operative, it was necessary to substitute for it a written law. The power to close debate had been of necessity assumed by almost all the European and American assemblies, the conduct of whose members was shaped by no traditional considerations; and the entry into Parliament of a body of men to whom the traditions of the House were as nothing, made it necessary for the House of Commons to follow this example. He proposed, therefore, that when it appeared to the Speaker, or to the Chairman of Committees, during any debate to be the evident sense of the House, or of the committee, that the question be now put, he might so inform the House, and that thereupon on a motion being made, "That the question be now put," the question under discussion should be forthwith put from the Chair, and decided in the affirmative if supported by more than 200 members, or, when less than 40 members had voted against it, by more than 100 members. This resolution was vehemently contested by the Opposition, who denounced it as an unprecedented interference with the liberty of debate, but was eventually carried in the autumn session of the same year, after a discussion extending over nineteen sittings.

The closure.

On 20th November the Standing Order of 28th February 1880, providing for the suspension of members who persistently and wilfully obstructed the business of the House or disregarded the authority of the Chair, was amended by the increase of the penalty to suspension on the first occasion for one week, on the second occasion for a fortnight, and on the third, or any subsequent occasion, for a month. The other rules, framed with a view to freeing the wheels of the parliamentary machine, and for the most part identical with the regulations adopted by Mr Speaker Brand under the urgency resolution of 1881, were carried in the course of the autumn session, and became Standing Orders on 27th November.

Mr Gladstone's closure rule verified neither the hopes of its supporters nor the fears of its opponents. It was not put into operation until 20th February 1885, when the Speaker's declaration of the evident sense of the House was ratified by a majority of 207—a margin of but seven votes over the necessary quorum. It was clear that no Speaker was likely to run the risk of a rebuff by again assuming the initiative unless in the face of extreme urgency, and, in fact, the rule was enforced twice only during the five years of its existence.

In 1887 the Conservative Government, before the introduction of a new Coercion Bill for Ireland, gave efficiency to the rule by an important amendment. They proposed that any member during a debate might claim to move, "That the question be now put," and that with the consent of the Chair this question should be put forthwith, and decided without amendment or debate. Thus the initiative was transferred from the Speaker to the House. Mr Gladstone objected strongly to this alteration, chiefly on the ground that it would throw an unfair burden of responsibility upon the Speaker, who would now have to decide on a question of opinion, whereas under the old rule he was only called upon to determine a question of evident fact. The alternative most generally advocated by the Opposition was the automatic closure by a bare majority at the end of each sitting, an arrangement by which the Chair would be relieved from an invidious responsibility; but it was pointed out that under such a system the length of debates would not vary with the importance of the questions debated. After fourteen sittings the closure rule was passed on 18th March and made a Standing Order.

In the next session, on 28th February 1888, the rule was yet further strengthened by the reduction of the majority necessary for its enforcement from 200 to 100. No further alteration was made up to 1902, so that the rule in its present form stands as follows:—

That, after a question has been proposed, a member rising in his place may claim to move, "That the question be now put," and, unless it shall appear to the Chair that such motion is an abuse of the rules of the House, or an infringement of the rights of the minority, the question, "That the question be now put," shall be put forthwith, and decided without amendment or debate.

When the motion "That the question be now put" has been carried, and the question consequent thereon has been decided, any further motion may be made (the assent of the Chair as aforesaid not having been withheld), which may be requisite to bring to a decision any question already proposed from the Chair; and also if a clause be then under consideration, a motion may be made (the assent of the Chair as aforesaid not having been withheld), "That the question 'That certain words of the clause defined in the motion stand part of the clause,' or 'That the clause stand part of, or be added to, the Bill,' be now put." Such motions shall be put forthwith, and decided without amendment or debate.

That questions for the closure of debate shall be decided in the affirmative, if, when a division be taken, it appears by the numbers declared from the Chair that not less than one hundred members voted in the majority in support of the motion.

The closure, originally brought into being to defeat the tactics of obstruction in special emergencies, has now become a part of parliamentary routine. The modern practice of retarding the progress of Government measures by amendments moved to every line, has unhappily been adopted by both the great political parties when in Opposition, and has led on two occasions to the forcing through Parliament by means of the process known as the "guillotine" of important Bills, most of the clauses in which had been undiscussed. On 17th June 1887, after prolonged debates on the Crimes Bill in committee, clause 6 only having been reached, the remaining 14 clauses were put without discussion, and the Bill was reported in accordance with previous notice. This precedent was followed by Mr Gladstone in 1893, when many of the clauses of the Home Rule Bill were carried through committee and on report by the same machinery. Thus to the Conservatives must be imputed the invention of this irrational method of legislation, to their opponents the use of it to carry a great constitutional innovation to which the majority of English and Scottish representatives were opposed.

The "guillotine."

The principle of closure has been extended to the debates on Supply. The old rule, that the redress of grievances should precede the granting of money, dating from a time when the minister of the Crown was so far from commanding the confidence of the majority in the House of Commons that he was the chief object of their attacks, nevertheless continued to govern the proceedings of the House in relation to Supply without much resultant inconvenience, until the period when the new methods adopted by the Irish Nationalist party created a new situation. Until 1872 it continued to be possible to discuss any subject by an amendment to the motion for going into Supply. In that year a resolution was passed limiting the amendments to matters relevant to the class of estimates about to be considered, and these relevant amendments were further restricted to the first day on which it was proposed to go into committee. This resolution was continued in 1873, but was allowed to drop in 1874. It was revived in a modified form in 1876, but was again allowed to drop in 1877. In 1879, on the recommendation of the Northcote committee, it was provided in a Sessional Order that whenever the committees of Supply or of Ways and Means stood as the first order on a Monday, the Speaker should leave the chair without question put, except on first going into committee on the Army, Navy, and Civil Service estimates respectively. In 1882 Thursday was added to Monday for the purposes of the Order, and, some further exceptions having been made to the operation of the rule, it became a Standing Order. The conditions, however, under which the estimates were voted remained unsatisfactory. The most useful function of the Opposition is the exposure of abuses in the various departments of administration, and this can best be performed upon the estimates. But ministers, occupied with their legislative proposals, were irresistibly tempted to postpone the consideration of the estimates until the last weeks of the session, when they were hurried through thin Houses, the members of which were impatient to be gone. In order to meet this abuse, and to distribute with some regard to the comparative importance of the subjects discussed the limited time which it was possible to allot to the estimates, Mr Balfour in 1896 proposed and carried a Sessional Order for the closure of Supply. By this, Supply, unimpeded by any dilatory motion, was to be the first order of the day on every Friday. A maximum of twenty-three days was to be given to its consideration, of which the last three alone might be taken after 5th August. On the last but one of the allotted days at 10 o'clock the Chairman was to put the outstanding votes, and on the last day the Speaker at the same hour was to put the remaining questions necessary to complete the reports of Supply. During the course of the session Mr Balfour consulted the leaders both of the Liberal and of the Nationalist Oppositions as to the estimates which they desired to discuss, and those were placed first on the paper on the succeeding Fridays. This Order was renewed in successive sessions until 1901, when an alteration was made in it by which logic was sacrificed to expediency. Year after year, when the closure of Supply came on, many hours were spent in the division lobby owing to the necessity under the order of a decision on every vote separately. In 1901 Mr Balfour so altered the resolution that the question was put, not with respect to each vote, but to each class of votes in the Civil Service estimates, and to the total amounts of the outstanding votes in the Army, Navy, and Revenue estimates. It is in this form that the Order was carried in the earlier session of 1902, with the view of making it a Standing Order.

Supply rule.

The appointment of standing committees, competent to represent the general opinion of the House, and aided by members appointed specially to serve in regard to particular Bills, was suggested by Sir Erskine May in his evidence before the Northcote committee of 1878. Effect was given to this suggestion by the resolutions of November and December 1882, when two standing committees were appointed for the consideration of all Bills relating to law and courts of justice and of trade, which might, by order of the House, be referred to them. In accordance with these resolutions the standing committees were set up in the session of 1883. The Criminal Procedure Bill was referred to the standing committee on law, and the Bankruptcy Bill to the standing committee on trade. In the latter instance the experiment proved a success, but the Criminal Procedure Bill was withdrawn. Between 1883 and 1888 the standing committees were not reconstituted. By 1886 it had become clear to most of the opponents of Home Rule that some alternative scheme of delegation to relieve the labours of Parliament was necessary to their position. Accordingly, the Hartington committee of 1886 made in their report a recommendation which, had it been adopted, would have

Standing committees.

revolutionized parliamentary procedure. They advised that the whole House should be divided at the commencement of the session into four standing committees, twenty members being a quorum in each, and that to these committees every public Bill, after the second reading, should be referred, except those originating in the committee of Ways and Means. This suggestion did not recommend itself to the House, but in 1888 the resolutions of 1882 were revived, and, after trade had been defined to include agriculture and fishing, they were made Standing Orders.

As constituted in 1902, these committees consisted of not less than sixty nor more than eighty members, nominated by the committee of selection, who have regard to the classes of Bills committed to such committees, to the composition of the House, and to the qualifications of the members selected; and who have power to discharge members from time to time, and to appoint others in their place. The quorum of each committee is twenty. The committee of selection have also power to add fifteen members to a standing committee in respect of any particular Bill. Bills reported from the standing committees are proceeded with as if they had been reported from committees of the whole House. The system of standing committees has worked well on the whole. At first it was understood that controversial Bills were not to be referred to them, but there has been a tendency to dispense with this limitation.

Time of business.

Important alterations have been made in the time-table of the House of Commons in recent years. The Standing Order of February 1879, under which no opposed business, except money Bills, Bills to which no notice of opposition had been given, and proceedings under any Act of Parliament, might be taken after 12.30 A.M., was amended in 1882, by exempting from the operation of the Order motions for leave to bring in Bills, and Bills which had passed through committee of the whole House. By the Standing Order of 24th February 1888 the House resolved to meet at 3 o'clock, instead of at 4, on every Monday, Tuesday, Thursday, and Friday. The sittings, under the Order, continued till midnight, when the business then under consideration was interrupted, and no further opposed business was taken. At 1 o'clock the Speaker adjourned the House without question put. On Wednesdays, when the House met at 12, the interruption of business was at 5.30 P.M., and the House stood adjourned at 6. Closure might be moved at the interruption of business, on the question then under consideration, and on the questions consequent thereon. Bills originating in committee of Ways and Means, and proceedings under any Act of Parliament, were exempted from the provisions of this Order.

The sittings of the House continued to be regulated by the Standing Order of 1888 until May 1902, when further important changes were made. The chief inconvenience experienced under the Order of 1888 was the frequent postponement of the orders of the day by the unexpected intervention of motions for adjournment or of private business. A main object of the amended rule was to give certainty to members as to the business to be taken at any particular sitting. Thursday was substituted for Friday as the day on which Supply is to be taken, with the additional proviso that no business other than the business of Supply may be taken before 12 o'clock on that night, and Friday took the place of Wednesday for the morning sittings. It was further ordered that the House shall meet every Monday, Tuesday, Wednesday, and Thursday, at 2 o'clock for an afternoon sitting, and at 9 o'clock for an evening sitting. The afternoon sittings last till 7.30, when the Speaker adjourns the House without question put. The 12 o'clock rule of 1888 holds good for the evening sittings. No alteration has been made in the hours of the morning sittings. To secure the afternoon sittings from interruption, it has been ordered that all private business not disposed of by 2.15 shall be postponed until such time as the Chairman of Ways and Means may determine, and that motions for adjournment for the discussion of a "definite matter of urgent public importance" shall stand over until the evening sitting of the same day, when they take precedence of private business. These motions for adjournment, in accordance with the Standing Order of November 1882, must be made after the questions asked at the commencement of public business have been disposed of. The member who proposes to make such a motion must obtain the acquiescence of the Speaker in his claim that the question he wishes to discuss is a definite matter of urgent public importance, and also the support of at least forty members, signified by their rising in their places on the Speaker's invitation. Another change in procedure introduced in 1902 relates to questions addressed to ministers. These questions are now taken at 2.15 P.M., and may be asked until 2.55, when, with the exception of questions unanswered owing to the absence of the minister addressed, or those of an urgent nature which have not appeared upon the paper, they give way to the business of the House. But the most important change is contained in the following provisions:—

> Any member who desires an oral answer to his question may distinguish it by an asterisk, but notice of any such question must appear at latest on the notice paper circulated on the day before that on which an answer is desired.
>
> If any member does not distinguish his question by an asterisk, or if he, or any other member deputed by him, is not present to ask it, or if it is not reached by five minutes before 3 of the clock, the minister to whom it is addressed shall cause an answer to be printed and circulated with the votes, unless the member has signified his desire to postpone the question.

This rule worked well, and much time was saved for public business.

The consequences of the rise of obstruction and of the 12 o'clock rule, together with the mandate of the electors, having combined to place in the Government all the motive power of the House of Commons, it had followed of necessity that in successive sessions ministers had taken by resolution most of the time at the disposal of that assembly. To this allocation of time a formal sanction was given by the Order of 11th April 1902. Government business now enjoys precedence at every sitting except the evening sitting on Tuesday and Wednesday, and the sitting on Friday. After Easter it has precedence at the evening sittings on Tuesday, and after Whitsuntide at all evening sittings, and at all Friday sittings except the sittings on the third and fourth Fridays after Whitsunday. At the evening sittings allocated to private members, notices of motion take precedence of the orders of the day. It is therefore only on Fridays before Whitsuntide and on two Fridays subsequently that the Bills introduced by private members can now be discussed.

Suspension of members.

On 5th March 1901 certain Irish Nationalist members refused to leave the House for a division on a motion for closure moved by Mr Balfour. They were thereupon suspended for wilfully obstructing the business of the House, and as they declined to withdraw, the Speaker was obliged to direct the Serjeant-at-Arms to cause them to be removed by force. Action had to be taken to preclude the recurrence of so scandalous a scene. On 7th March, at the instance of Mr Balfour, a paragraph was added to the Standing Order of 1882 relating to order in debate, to the effect that in cases where recourse to force had been found necessary to compel any member, or members acting jointly, to obey the direction of the Speaker, such member or members shall thereupon, and without further question put, be suspended from the House during the remainder of the session. It was proposed still further to increase the several periods of suspension for disregarding the authority of the Chair—on the first occasion so as to last for 20 days on which the House sits, on the second occasion for 40 days, and on the third or any subsequent occasion for 80 days. The amendments embodying this alteration were proposed in February 1902, but their further consideration was postponed till the autumn session.

History.—The Reform Act of 1884 was ultimately carried with the goodwill of both the great political parties. The Conservatives resisted Mr Gladstone's attempt to carry a great extension of the franchise before he had disclosed his scheme of redistribution, and the Bill was thrown out by the House of Lords in August 1884. But after a conference of Mr Gladstone with Lord Salisbury, to whom the whole scheme was confided, an agreement was reached, and the Bill was passed in the autumn session. In the following session (1885) the Redistribution Act was passed.

A uniform household and lodger franchise was established in counties and boroughs. If a dwelling was held as part payment for service, the occupier was not deprived of his vote because his home was the property of his master. The obligation was thrown on the overseers of ascertaining whether any other man besides the owner was entitled to be registered as an inhabitant occupier, and the owner was bound to supply the overseers with the information. The Registration Acts were otherwise widely amended. Polling-places were multiplied, so that little time need be lost in recording a vote. These and other beneficial changes went a long way towards giving a vote to every one who had a decent home. By the Redistribution of Seats Act, 1885, all boroughs with less than 15,000 inhabitants ceased to return a member. These small towns were merged into their counties, and the counties were subdivided into a great number of single-member constituencies, so that the inhabitants of the disfranchised boroughs voted for the member for the division of the county in which they were situated. Boroughs with less than 50,000 inhabitants returning two members were in future to return only one, and towns of over 100,000 were divided into separate constituencies, and received additional members in proportion to their population. The members for the City of London were reduced to two, but Greater London, including Croydon, returned sixty. Divided Liverpool returned nine, Glasgow seven, Edinburgh, Dublin, and Belfast each four, and so on. Six additional seats were given to England and twelve to Scotland, so that, allowing for a diminution by disfranchisement for corruption, the numbers of the House of Commons were raised to 670 members.

The most noteworthy effect from a constitutional standpoint of the successive Reform Acts has been the gain in power, of the executive on the one hand and of the electorate on the other, at the expense of the House of Commons. Before 1832 the functions of ministers were mainly administrative, and Parliament was able to deal much as it pleased with their rare legislative proposals without thereby depriving them of office. Moreover, since before that date ministers were, generally speaking, in fact as well as in theory appointed by the king, while the general confidence of the majority in the House of Commons followed the confidence, not of the electorate, but of the Crown, that House was able on occasions to exercise an effective control over foreign policy. Pitt, after 1784, was defeated several times on foreign and domestic issues, yet his resignation was neither expected nor desired. In 1788, when the regency of the prince of Wales appeared probable, and again in 1812, it was generally assumed that it would be in his power to dismiss his father's ministers and to maintain the Whigs in office without dissolving Parliament. This system, while it gave to ministers security of tenure, left much effective freedom of action to the House of Commons. But the Reform Act of 1832 introduced a new order of things. In 1835 the result of a general election was for the first time the direct cause of a change of ministry, and in 1841 a House of Commons was elected for the express purpose of bringing a particular statesman into power. The electorate voted for Sir Robert Peel, and it would have been as impossible for the House then elected to deny him their support as it would be for the college of electors in the United States to exercise their private judgment in the selection of a President. The Premier now derives his power neither from the Crown, nor from Parliament, but from the electorate, and to the electorate he is able to appeal if deserted by his majority. Unless it is prepared to drive him from the office in which it was elected to support him, that majority will not venture to defeat, or even seriously to modify, his legislative proposals, or to pass any censure on his foreign policy, for all such action is now held to be equivalent to a vote of no confidence. From the passing of the Reform Act of 1867 down to 1900 (with a single exception due to the lowering of the franchise and the redistribution of seats) the electorate voted alternately for the rival party leaders, and it was the function of the Houses elected for that purpose to pass the measures and to endorse the general policy with which those leaders were respectively identified. The Cabinet tends to become an executive committee acting on behalf of the electorate, charged to make certain changes in the law, pledged to govern the country in accordance with certain general principles ascertained beforehand, and removable only after a dissolution. This change of system has greatly added to the power of the Cabinet, because the control to which they were subject when dependent on the House of Commons was constant and immediate, whereas it is only at long intervals of time that they have to settle accounts with the electorate. On the other hand, the virtual identification of the electorate with the nation by the successive extensions of the franchise has added immensely to its power, the chief remaining limitations of which are supplied by the Septennial Act and the non-payment of members. The House of Lords restricts the action rather of the House of Commons than of the electorate, for the acquiescence of the Upper House in the decision of the electors, when they have been appealed to on a specific point at issue between the two Houses, has been affirmed in principle by Lord Salisbury, and may now be regarded as a constitutional convention.

Between 1885 and 1902 there was no further change in the constitution of either House of Parliament. But the frequent differences between the two Houses during the Parliament of 1880–85, culminating in the postponement by the Upper House of the Reform Bill, caused the status of that House to be much discussed during the general election of 1885, and proposals for its "mending or ending" to be freely canvassed on Radical platforms. On 5th March 1886 Mr Labouchere moved a resolution in the House of Commons condemning the hereditary principle. This was resisted by Mr Gladstone, then Prime Minister, on the ground that he had never supported an abstract resolution unless he was prepared to follow it up by action, and that the time for this had not arrived. On a division the motion was negatived by 202 votes against 166. The question of the constitution of the

House of Lords was much agitated in 1888. The Conservatives were again in power, but many of them thought that it would be prudent to forestall by a moderate reform the more drastic remedies now openly advocated by their opponents. On the other hand, Radicals were disposed to resist all changes involving the maintenance of the hereditary principle, lest they should thereby strengthen the House of Lords. On 9th March Mr Labouchere again moved his resolution in the House of Commons. Mr W. H. Smith, the leader of the House, in resisting the motion, admitted that some changes were desirable, and agreed with a previous speaker that it was by the Conservatives that such changes ought to be effected. On 19th March in the same year Lord Rosebery, in the House of Lords, moved for a select committee to inquire into the subject. He took the opportunity to explain his own plan of reform. While he did not wish to abolish the hereditary principle, he desired that no peer, outside the Royal family, should be a member of the House by right of birth alone. To the representatives of the Peers he proposed to add other men who had achieved distinction in a public career. He attached a high importance to the existence of a second chamber. His motion was negatived by 97 votes against 50. On 26th April Lord Dunraven withdrew a Bill for the reform of the House of Lords on the promise of the Government to deal with the matter, and on 18th June Lord Salisbury fulfilled this pledge. He introduced a Bill on that day to provide for the creation of a limited number of life peers and for the exclusion of unworthy members from the House. Under this measure a maximum of five life-peerages in any one year might be created, but the total number was never to exceed fifty. In respect of three out of these five life-peers the choice of the Crown was restricted to judges, generals, admirals, ambassadors, privy councillors, and ex-governors of colonies. The two additional life-peers were to be appointed in regard to some special qualification to be stated in the message to the House announcing the intention of the Crown to make the appointment. Power was also to be given to the House to expel members for the period of the current Parliament by an address to the Crown praying that their writs of summons might be cancelled. The Bill was read a second time on 10th July, but it met with a cold reception and was dropped. The only outcome of all that was written and said in this year was that in 1889, after the report of a select committee set up in 1888, the Lords made a few changes in their Standing Orders, among which the order establishing a quorum of thirty in divisions and those for the constitution of standing committees were the most important.

The Parliament which met at Westminster in August 1892 was more democratic in its tendencies than any of its predecessors. At the beginning of the session of 1893, in the course of which the Home Rule Bill was passed by the House of Commons, Government Bills were introduced for quinquennial parliaments, for the amendment of registration, and for the limitation of each elector to a single vote. The introduction of these Bills served merely as a declaration of Government policy, and they were not further pressed. On 24th March a resolution in favour of payment of members was carried by 276 votes against 229, and again in 1895 by 176 to 158. But the rejection of the Home Rule Bill by the House of Lords, with the apparent acquiescence of the country, combined with the retirement of Mr Gladstone to weaken the influence of this House of Commons, and small importance was attached to its abstract resolutions. In the ensuing session of 1894 an amendment to the Address condemning the hereditary principle was moved by Mr Labouchere, and carried by 147 to 145. The Government, however, holding that this was not the way in which a great question should be raised, withdrew the Address, and carried another without the insertion. In his last public utterance Mr Gladstone directed the attention of his party to the reform of the House of Lords, and Lord Rosebery endeavoured to concentrate on such a policy the energies of his supporters at the general election. But the result of the dissolution of 1895, showing, as it did, that on the chief political issue of the day the electorate had agreed with the House of Lords, and had disagreed with the House of Commons, greatly strengthened the Upper House, and after that date the subject was but little discussed. The House of Lords claims the right to resist changes made by the House of Commons until the will of the people has been definitely declared, and its defenders contend that its ultimate dependence on the electorate, now generally acknowledged, renders the freedom from ministerial control secured to it by its constitution a national safeguard.

The transfer of all real legislative power from the House of Commons, as such, to the Government has been completed since 1888 by the working of the 12 o'clock rule. The new position of ministers after the Reform Act, when they gradually became, as it were, the mandatories of the electorate, inaugurated the change. Sir Charles Wood, speaking in 1855, remarked that in 1828 "changes in our laws were proposed by independent members and carried, not as party questions, by the combined action of both sides of the House. Now," he added, "when an independent member brings forward a subject, it is not to propose himself a measure, but to call to it the attention of the Government. Our defects as legislators, which is *not* our business, damage us as administrators, which *is* our business." In 1825 a private member was able to carry through the House of Commons a measure so bitterly contested as Catholic Emancipation, and though this could not have been done after 1832, it was still, for another half century, possible for private members to surmount the opposition to Bills of less importance. But when a limit was fixed to the time during which opposed business might be taken, and when Government became accustomed to monopolize nearly all the time within that limit, controversial legislation initiated by private members became impossible. A resolute minority, however inconsiderable numerically, can stop the progress of any private member's Bill. The Deceased Wife's Sister Bill won the first place in the ballot in the session of 1902. It was read a second time by a majority of more than two to one on the first Wednesday of the session available for private members' Bills, but, though more favourably circumstanced than any other Bill not introduced by the Government, it made no further progress. Thus the separation of the legislative from the executive power accomplished, after long struggles, by the early parliaments has practically ceased to exist.

Procedure in Foreign Legislative Assemblies.—The average time occupied by a single sitting of the House of Commons is at least double that found necessary by any other European assembly. The usual length of a sitting in each of the French chambers is from four to five hours, from 2 P.M. to about 6.30 P.M. The German Reichstag meets at 1 P.M., and sits on an average for four hours. The Austrian Reichsrath sits from 11 A.M. till about 4 P.M. The Italian Senate sits from 3.30 P.M. till about 6.30 P.M., and the Chamber of Deputies from 2 till about 6 P.M. In the United States, on the other hand, the sittings are even longer than at Westminster. Thus, the House of Representatives meets at 11 A.M., the Senate at noon, and both Houses often sit till late at night. The ordinary method of taking divisions which obtains in the Parliaments of France, Germany, Italy, Austria, and the United States is *par assis et levé*. Members in favour of a motion rise in their places, while those opposed to it remain sitting. This method is more expeditious than that in use at Westminster, the process usually occupying only five minutes, but it must be remembered that in most foreign Chambers members sit in a rising half-circle round the presidential chair, and it is consequently easier for the president to take the opinion of the House in this way than it would be for the Speaker in the existing House of Commons. When the president is in doubt as to the result obtained by *assis et levé*, or at the request of a group of members varying in number in the different assemblies, or, finally, on certain specified occasions, such as the final passing of a Bill, recourse is had to other methods of taking a vote: *e.g.*, in France, to the public ballot; in Austria and Italy, to the roll-call or the ballot; in Germany, to ballot, or to a process resembling that of the British Parliament; and in the United States to the roll-call. In the Senate of the United States divisions are always taken by the roll-call. The number of members necessary to form a quorum is in most assemblies much larger than at Westminster. In the American House of Representatives and in the German Reichstag a quorum consists of an absolute majority of the whole House; in the Austrian Reichsrath, of one hundred members. It is possible that an increase in the quorum of the House of Commons, at present consisting of forty members, might tend to shorten the length of its sittings.

Foreign assemblies, as a rule, meet in the autumn and rise in the early summer. In March 1890 a resolution moved by Sir George Trevelyan, proposing that the House of Commons should in this respect follow their example, was negatived by a majority of only four votes (173 to 169). The French Chamber of Deputies sits on an average about 125 days in the year, and the Senate about 90 days; there are some 86 working days in the session of the German Reichstag; the Italian Chamber sits about 140 days in the year; and the Austrian Lower House about 150 days. The power to suspend the sitting in cases of grave disorder is everywhere possessed by presidents of foreign legislative assemblies. This power was given to the Speaker of the House of Commons on 17th February 1902 by a sessional order which it was proposed to make a Standing Order. In the French and other assemblies Bills do not lapse at a prorogation. Proposals have often been made to introduce this practice into British procedure. A committee, presided over by Mr Goschen, was appointed in 1890 to inquire into the subject. In their report they postulated three principles: (1) That it was desirable to increase the power of the House of Commons to deal with long controversial measures; (2) That it was desirable to shorten the length of sessions; (3) That it was *not* desirable, so long as any alternative remained, to increase the stringency of the closing power. From these principles they deduced the necessity of freeing Parliament in certain cases from the obligation of repeating in two successive sessions the same debate upon the same questions. This report was adopted by a majority of 11 to 9, Mr Gladstone and his Liberal colleagues constituting the minority. Mr Gladstone drew up a counter report, in which he summarized his objections to the proposal. These were in substance: (1) That the advantage of altering the scope of a Bill in a new session would be lost; (2) That the motions at the end of a session for suspending Bills would waste more time than would be economized by the suspensions; (3) That the powers of closure already possessed by the House rendered the change unnecessary; and (4) That the House of Lords might, by a similar Standing Order, assume an unlimited power of postponing Bills passed by the House of Commons. No steps were taken to give effect to the recommendations of the committee. (A. J. S. M.; F. C. H.)

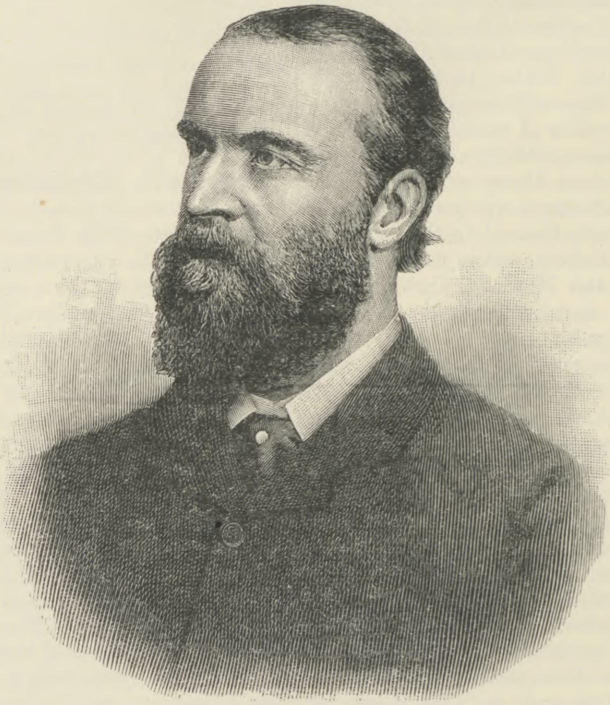
Parma, a town, episcopal see, and capital of the province of Parma, Emilia, Italy, between the Apennines and the Po, 55 miles north-west of Bologna by rail. The university, which was attended by 550 students, with 42 professors, in 1898, and has faculties of law, medicine, and natural science, possesses an observatory and natural science collections, amongst the latter being the Eritrean Zoological Museum. Parma has three theatres, in addition to the ruined Farnese Theatre. It also possesses an officers' school, which is adorned with frescoes by A. Caracci; a royal college, a royal school of music, an agricultural institute, and a technical school. Statues to Garibaldi (1893), Victor Emmanuel (1893), Correggio (1872), and Parmegianino (1879) adorn the town. From archæological discoveries it would appear that the ancient Gallic town was preceded by an Etruscan, and this again by a prehistoric settlement of the Bronze Age, the dwellings of which rested upon piles. Population (1881), 44,492; (1901), 49,370.

Parnell, Charles Stewart (1846–1891), Irish Nationalist leader, was born at Avondale, county Wicklow, on 27th June 1846. His father was John Henry Parnell, a country gentleman of strong Nationalist and Liberal sympathies, who married in 1834 Delia Tudor, daughter of Commodore Charles Stewart of the United States navy. The Parnell family was of English origin, and more than one of its members attained civic note at Congleton in Cheshire under the Stuarts and during the Commonwealth. Among them was Thomas Parnell, who migrated to Ireland after the Restoration. He had two sons, Thomas Parnell the poet and John Parnell, who became an Irish judge. From the latter Charles Stewart Parnell was lineally descended in the fifth generation. Sir John Parnell, Chancellor of the Exchequer in Grattan's Parliament, and one of O'Connell's lieutenants in the Parliament of the United Kingdom, was the grandson of Parnell the judge. The estate of Avondale was settled on him by a friend and bequeathed by him to his youngest son William (grandfather of Charles Stewart Parnell). His eldest son was imbecile. His second son was Sir Henry Parnell, a noted politician and financier in the early part of the 19th century. Sir Henry Parnell moved the resolution which displaced Wellington's Government in 1830. He held office under Grey and Melbourne, and after being raised to the peerage as Baron Congleton, he died by his own hand in 1842. William Parnell was no active politician, though he was a keen student of Irish politics, with a strong leaning towards the popular side, and in 1805 he published a pamphlet entitled "Thoughts on the Causes of Popular Discontents," which was favourably noticed by Sydney Smith in the *Edinburgh Review*. Thus by birth and ancestry, and especially by the influence of his mother, who inherited a hatred of England from her father, Charles Stewart Parnell was, as it were, dedicated to the Irish national cause. He was of English extraction, land-owner, and a Protestant. Educated at private schools in England and at Magdalene College, Cambridge, his temperament and demeanour were singularly un-Irish on the surface—reserved, cold, repellent, and unemotional; and yet no man was ever less English in his political sympathies, methods, and aims. He appears to have been rather turbulent as a school-boy, contentious, insubordinate, and not over-scrupulous. He had few friends, and was not popular with his companions. He was fond of cricket and devoted to mathematics, but had little taste for other studies or other games. He was subject to somnambulism, and liable to severe fits of depression—facts which, taken in connexion with the existence of mental affliction among his ancestors, with his love of solitude and mystery, and his invincible superstitions about omens, numbers, and the like, may perhaps suggest that his own mental equilibrium was not always stable. He was as little at home in an English school or an English university as he was afterwards in the House of Commons. "These English," he said to his brother at school, "despise us because we are Irish; but we must stand up to them. That's the way to treat an Englishman—stand up to him."

Parnell was not an active politician in his early years. He found salvation as a Nationalist and even as a potential rebel over the execution of the "Manchester Martyrs" in 1867, but it was not until some years afterwards that he resolved to enter Parliament. In the meanwhile he paid a lengthened visit to the United States. At the general election of 1874 he desired to stand for the county of Wicklow, of which he was high sheriff at the time. The Lord-Lieutenant declined to relieve him of his disqualifying office, and his brother John stood in his place, but was unsuccessful at the poll. Shortly afterwards a bye-election occurred in Dublin, owing to Colonel Taylor having accepted office in the Disraeli Government, and Parnell resolved to oppose him as a supporter of Isaac Butt, but was heavily beaten. He was, however, elected for Meath in the spring of 1875.

Butt had scrupulously respected the dignity of Parliament and the traditions and courtesy of debate. He looked very coldly on the method of "obstruction"—a method invented by certain members of the Conservative party in opposition to the first Gladstone Administration. Parnell, however, entered Parliament as a virtual rebel who knew that physical force was of no avail, but believed that political exasperation might attain the desired results. It would consolidate the national feeling of Ireland, and might convince the party of physical force that by giving him their covert support he could achieve in the senate what they could never achieve in the field. It was not for nothing that Mr Gladstone had declared that the Manchester murder and the Clerkenwell outrage had "drawn the attention of the people of Great Britain to the Irish question." Parnell resolved to make obstruction in Parliament do the work of outrage in the country, to set the church-bell ringing—to borrow Mr Gladstone's metaphor—and to keep it ringing in season and out of season in the ears of the House of Commons. He did not choose to condemn outrages to gratify the Pharisaism of English members of Parliament. He courted the alliance of the physical force party, and he had to pay the price for it. He invented and encouraged "boycotting," and did not discourage outrage. When a supporter in America offered him twenty-five dollars, "five for bread and twenty for lead," he accepted the gift, and he subsequently told the story on at least one Irish platform. In the course of the negotiations in 1882, which resulted in what was known as the Kilmainham Treaty, he wrote to Captain O'Shea: "If the arrears question be settled upon the lines indicated by us, I have every confidence that the exertions we should be able to make strenuously and unremittingly would be effective in stopping outrages and intimidation of all kinds." This is at least an admission that he had, or could place, his hand on the stop-valve, even if it be not open to the gloss placed on it by Captain O'Shea in a conversation repeated in the House of Commons by Mr Forster, "that the conspiracy which has been used to get up boycotting and outrage will now be used to put them down."

In 1877 Parnell entered on an organized course of obstruction. He and Mr Joseph Gillis Biggar, one of his henchmen, were gradually joined by a small band of the more advanced Home Rulers, and occasionally assisted up to a certain point by one or two English members. Butt was practically deposed and worried into his grave. Shaw, a "transient and embarrassed phantom," was elected in his place, but Parnell became the real leader of a Nationalist party. The original Home Rule party was split in twain, and after the general election of 1880 the more moderate section of it ceased to exist. Obstruction in Parnell's hands was no mere weapon of delay and exasperation; it was a calculated policy, the initial stage of a campaign designed to show the malcontents in Ireland and their kinsmen in other lands that Butt's strictly constitutional methods were quite helpless, but that the parliamentary armoury still contained weapons which he could so handle as to convince the Irish people and even the Fenian and other physical force societies that the way to Irish legislative independence lay through the House of Commons. The Fenians were hard to convince, but in the autumn of 1877 Parnell persuaded the Home Rule Confederation of Great Britain (an association founded by Butt, but largely supported by Fenians) to depose Butt from its presidency and to elect himself in his place. He defined his attitude quite clearly in a speech delivered in New York early in 1880:—"A true revolutionary movement in Ireland should, in my opinion, partake both of a constitutional and illegal character. It should be both an open and a secret organization, using the constitution for its own purposes, but also taking advantage of its secret combination." Parnell's opportunity came with the general election of 1880, which displaced the Conservative Government of Lord Beaconsfield and restored Mr Gladstone to power with a majority strong enough at the outset to overpower the Opposition, even should the latter be reinforced by the whole of Parnell's contingent. Distress was acute in Ireland, and famine was imminent. Ministers had taken measures to relieve the situation before the dissolution was announced, but Lord Beaconsfield had warned the country that there was a danger ahead in Ireland "in its ultimate results scarcely less disastrous



CHARLES STEWART PARNELL.
(From a photograph by William Lawrence, Dublin.)

than pestilence and famine. . . . A portion of its population is attempting to sever the constitutional tie which unites it to Great Britain in that bond which has favoured the power and prosperity of both. It is to be hoped that all men of light and leading will resist this destructive doctrine." The Liberal party and its leaders retorted that they were as strongly opposed to Home Rule as their opponents, but Lord Beaconsfield's manifesto undoubtedly had the effect of alienating the Irish vote in the English constituencies from the Tory party and throwing it on the side of the Liberal candidates. This was Parnell's deliberate policy. He would have no alliance with either English party. He would support each in turn with a sole regard to the balance of political power in Parliament and a fixed determination to hold it in his own hands if he could. From the time that he became its leader the Home Rule party sat together in the House of Commons and always on the Opposition side. Even when Mr Gladstone had formed a Home Rule Government in 1886 and introduced a Home Rule Bill, Parnell declined to follow the precedent set by O'Connell, who crossed the House with his followers and took his place on the ministerial side under the second Government of Lord Melbourne.

In the Government formed by Mr Gladstone in 1880 Lord Cowper became viceroy and Mr W. E. Forster chief secretary for Ireland. The outlook was gloomy enough, but the Gladstone Government do not seem to have anticipated, as Peel anticipated in 1841, that Ireland would be their difficulty. Yet the Land League had been formed by Mr Michael Davitt and others in the autumn of 1879 for the purpose of agrarian agitation, and Parnell after some hesitation had given it his sanction. He visited the United States at the close of 1879. It was then and there that the "new departure"—the alliance of the open and the secret organizations — was confirmed and consolidated. Parnell obtained the countenance and support of the Clan-na-Gael, a revolutionary organization of the American-Irish, and the Land League began to absorb all the more violent spirits in Ireland, though the Fenian brotherhood still held officially aloof from it. As soon as the general election was announced Parnell returned to Ireland in order to direct the campaign in person. Though he had supported the Liberals at the election, he soon found himself in conflict with a Government which could neither tolerate disturbance nor countenance a Nationalist agitation, and he entered on the struggle with forces organized, with money in his chest, and with a definite but still undeveloped plan of action. The prevailing distress increased and outrages began to multiply. A fresh Relief Bill was introduced by the Government, and in order to stave off a measure to prevent evictions introduced by the Irish party, Mr Forster consented to add a clause to the Relief Bill for giving compensation in certain circumstances to tenants evicted for non-payment of rent. This clause was afterwards embodied in a separate measure known as the Compensation for Disturbance Bill, which after a stormy career in the House of Commons was summarily rejected by the House of Lords.

The whole Irish question was once more opened up in its more dangerous and more exasperating form. It became clear that the land question — supposed to have been settled by Mr Gladstone's Act of 1870—would have to be reconsidered in all its bearings, and a commission was appointed for the purpose. In Ireland things went from bad to worse. Evictions increased and outrages were multiplied. Intimidation and boycotting were rampant. As the winter wore on, Mr Forster persuaded his colleagues that exceptional measures were needed. An abortive prosecution of Parnell and some of his leading colleagues had by this time intensified the situation. Parliament was summoned early, and a Coercion Bill for one year, practically suspending the Habeas Corpus Act and allowing the arrest of suspects at the discretion of the Government, was introduced, to be followed shortly by an Arms Bill. Parnell regarded the measure as a declaration of war, and met it in that spirit. Its discussion was doggedly obstructed at every stage, and on one occasion the debate was only brought to a close, after lasting for forty-one hours, by the Speaker's claiming to interpret the general sense of the House and resolving to put the question without further discussion. The rules of procedure were then amended afresh in a very drastic sense, and as soon as the Bill was passed Mr Gladstone introduced a new Land Bill, which occupied the greater part of the session. Parnell accepted it with many reserves. He could not ignore its concessions, and was not disposed to undervalue them, but he had to make it clear to the revolutionary party, whose support was indispensable, that he regarded it only as a payment on account, even from the agrarian point of view, and no payment at all from the national point of view. Accordingly the Land League at his instigation determined to "test" the Act by advising tenants in general to refrain from taking their cases into court until certain cases selected by the Land League had been decided. The Government treated this policy, which was certainly not designed to make the Act work freely and beneficially, as a deliberate attempt to intercept its benefits and to keep the Irish people in subjection to the Land League; and on this and other grounds—notably the attitude of the League and its leaders towards crime and outrage—Parnell was arrested under the Coercion Act and lodged in Kilmainham gaol (17th October 1881).

Parnell in prison at once became more powerful for evil than he had ever been, either for good or for evil, outside. He may have known that the policy of Mr Forster was little favoured by several of his colleagues, and he probably calculated that the detention of large numbers of suspects without cause assigned and without trial would sooner or later create opposition in England. Mr Forster had assured his colleagues and the House of Commons that the power of arbitrary arrest would enable the police to lay their hands on the chief agents of disturbance, and it was Parnell's policy to show that so long as the grievances of the Irish tenants remained unredressed no number of arrests could either check the tide of outrage or restore the country to tranquillity. Several of his leading colleagues followed him into captivity at Kilmainham, and the Land League was dissolved, its treasurer, Patrick Egan, escaping to Paris and carrying with him its books and accounts. Before it was formally suppressed the League had issued a manifesto, signed by Parnell and several of his fellow-prisoners, calling upon the tenants to pay no rents until the Government had restored the constitutional rights of the people. Discouraged by the priests, the No-Rent manifesto had little effect, but it embittered the struggle and exasperated the temper of the people on both sides of the Irish Channel.

Lord Cowper and Mr Forster were compelled to ask for a renewal of the Coercion Act with enlarged powers. But there were members of the Cabinet who had only accepted it with reluctance, and were now convinced not only that it had failed, but that it could never succeed. A *modus vivendi* was desired on both sides. Parnell was tired of imprisonment and solicitous for his ascendancy in Ireland; Mr Gladstone was impatient of failure. Negotiations were set on foot through the agency of Captain O'Shea—at that time and for long afterwards a firm political and personal friend of Parnell, but ultimately his accuser in the Divorce Court—and after a somewhat intricate course they resulted in what was known as the Kilmainham Treaty. As a consequence of this informal agreement, Parnell and two of his friends were to be released at once, the understanding being, as Mr Gladstone stated in a letter to Lord Cowper, "that Parnell and his friends are ready to abandon 'No Rent' formally, and to declare against outrage energetically, intimidation included, if and when the Government announce a satisfactory plan for dealing with arrears." Parnell's own version of the understanding has been quoted above. It also included a hope that the Government would allow the Coercion Act to lapse and govern the country by the same laws as in England. Parnell and his friends were released, and Lord Cowper and Mr Forster at once resigned.

The Phœnix Park murders (7th May 1882) followed (see IRELAND: *History*). Parnell was prostrated by this catastrophe. In a public manifesto to the Irish people he declared that "no act has ever been perpetrated in our country, during the exciting struggle for social and political rights of the past fifty years, that has so stained the name of hospitable Ireland as this cowardly and unprovoked assassination of a friendly stranger." Privately to his own friends and to Mr Gladstone he expressed his desire to withdraw from public life. There were those who believed that nevertheless he was privy to the Invincible conspiracy. There is some *primâ facie* foundation for this belief in the indifference he had always displayed towards crime and outrage when crime and outrage could be made to serve his purpose; in his equivocal relation to the more violent and unscrupulous forms of Irish sedition, and in the fact that Byrne, an official of the Land League, was in collusion with the Invincibles, that the knives with which the murder was done had been concealed at the offices of the Land League in London, and had been conveyed to Dublin by Byrne's wife. But the maxim *is fecit cui prodest* disallows these suspicions. Parnell gained nothing by the murders, and seemed for a time to have lost everything. A new Crimes Bill was introduced and made operative for a period of three years. A régime of renewed coercion was maintained by Lord Spencer and Mr (afterwards Sir George) Trevelyan, who had succeeded Lord Frederick Cavendish in the office of Chief Secretary; Ireland was tortured for three years by the necessary severity of its administration, and England was exasperated by a succession of dynamite outrages organized chiefly in America, which Parnell was powerless to prevent. The Phœnix Park murders did more than any other incident of his time and career to frustrate Parnell's policy and render Home Rule impossible. He had denounced the murders; forthwith the Irish revolutionaries began to suspect him as a mere Whig and time-server. He had connived at other crimes, and seemed to the majority of Englishmen to be a reckless and unscrupulous conspirator, the friend of murderers and assassins.

For more than two years after the Phœnix Park murders Parnell's influence in Parliament, and even in Ireland, was only intermittently and not very energetically exerted. His health was indifferent, his absences from the House of Commons were frequent and mysterious, and he had already formed those relations with Mrs O'Shea which were ultimately to bring him to the Divorce Court. The Phœnix Park murderers were arrested and brought to justice early in 1883. Mr Forster seized the opportunity to deliver a scathing indictment of Parnell in the House of Commons. In an almost contemptuous reply Parnell repudiated the charges in general terms, disavowed all sympathy with dynamite outrages, their authors, and abettors—the only occasion on which he ever did so—declined to plead in detail before an English tribunal, and declared that he sought only the approbation of the Irish people. This last was shortly afterwards manifested in the form of a subscription known as the "Parnell Tribute," which quickly reached the amount of £37,000, and was presented to Parnell, partly for the liquidation of debts he was known to have contracted, but mainly in recognition of his public services. The Irish National League, a successor to the suppressed Land League, was founded in the autumn of 1882 at a meeting over which Parnell presided, but he looked on it at first with little favour, and its action was largely paralysed by the operation of the Crimes Act and the vigorous administration of Lord Spencer.

The Crimes Act, passed in 1882, was to expire in 1885, but the Government of Mr Gladstone was in no position to renew it as it stood. In May notice was given for its partial renewal, subject to changes more of form than of substance. The second reading was fixed for 10th June. On 8th June Parnell, with thirty-nine of his followers, voted with the Opposition against the Budget, and defeated the Government by a majority of 264 votes to 252. Mr Gladstone forthwith resigned. Lord Salisbury undertook to form a Government, and Lord Carnarvon became viceroy. The session was rapidly brought to an end with a view to the dissolution rendered necessary by the Franchise Act passed in 1884—a measure which was certain to increase the number of Parnell's adherents in Parliament. It seems probable that Parnell had convinced himself before he resolved to join forces with the Opposition that a Conservative Government would not renew the Crimes Act. At any rate, no attempt to renew it was made by the new Government, which showed itself strangely complaisant towards Parnell and his followers by consenting to an inquiry, which Lord Spencer and his colleagues had steadfastly refused, into certain matters connected with recent agrarian murders and their punishment. Moreover, Lord Carnarvon, the new viceroy, was known to Parnell and to some others among the Irish leaders to be not unfavourable to some form of Home Rule if due regard were paid to imperial unity and security. He sought and obtained a personal interview with Parnell, explicitly declared that he was speaking for himself alone, heard Parnell's views, expounded his own, and forthwith reported what had taken place to the Prime Minister. In the result the new Cabinet refused to move in the direction apparently desired by Lord Carnarvon.

Parnell opened the electoral campaign with a speech in Dublin, in which he pronounced unequivocally in favour of self-government for Ireland, and expressed his confident hope "that it may not be necessary for us in the new Parliament to devote our attention to subsidiary measures, and that it may be possible for us to have a programme and a platform with only one plank, and that one plank National Independence." This was startling to English ears. The Press denounced Parnell; Lord Hartington (afterwards the Duke of Devonshire) protested against so fatal and mischievous a programme; Mr Chamberlain repudiated it with even greater emphasis. Meanwhile Mr Gladstone was slowly convincing himself that the passing of the Franchise Act had made it the duty of English statesmen and English party leaders to give a respectful hearing to the Irish National demand, and to consider how far it could be satisfied subject to the governing principle of "maintaining the supremacy of the Crown, the unity of the Empire, and all the authority of Parliament necessary for the conservation of the unity." This was the position he took up in the Hawarden Manifesto issued in September before the general election of 1885. Speaking later at Newport in October, Lord Salisbury treated the Irish leader with unwonted deference and respect, as though he were willing to parley with him, though he repudiated the analogy of Austria and Hungary as indicating a possible solution of the Irish problem in a federal sense. Parnell, however, took no notice of the Newport speech, and waited for Mr Gladstone to declare himself more fully in Midlothian. But in this he was disappointed. Mr Gladstone went no farther than he had gone at Hawarden, and he implored the electorate to give him a majority independent of the Irish vote. Subsequently Parnell invited him in a public speech to declare his policy and to sketch the constitution he would give to Ireland subject to the limitations he had insisted on. To this Mr Gladstone replied, "through the same confidential channel," that he could not consider the Irish demand before it had been constitutionally formulated, and that, not being in an official position, he could not usurp the functions of a Government. The reply to this was the issue of a manifesto to the Irish electors of Great Britain violently denouncing the Liberal party and directing all Irish Nationalists to give their votes to the Tories. In these circumstances the general election was fought, and resulted in the return of 335 Liberals, four of whom were classed as "independent," 249 Conservatives, and 86 followers of Parnell.

Mr Gladstone had now ascertained the strength of the Irish demand, but was left absolutely dependent on the votes of those who represented it. Through Mr Arthur Balfour he made informal overtures to Lord Salisbury proffering his own support in case the Prime Minister should be disposed to consider the Irish demand in a "just and liberal spirit"; but he received no encouragement. Towards the close of the year it became known through various channels that he himself was considering the matter and had advanced as far as accepting the principle of an Irish Parliament in Dublin for the transaction of Irish affairs. Before the end of January Lord Salisbury's Government was defeated on the Address, the Opposition including the full strength of the Irish party. Mr Gladstone once more became Prime Minister, with Mr John Morley (an old Home Ruler) as Chief Secretary, and Mr Chamberlain provisionally included in the Cabinet. Lord Hartington, Mr Bright, and some other Liberal chiefs, however, declined to join him.

Mr Gladstone's return to power at the head of an Administration conditionally committed to Home Rule marks the culminating point of Parnell's influence on English politics and English parties. The history of the Home Rule Government and of the Home Rule Bill introduced by it is narrated under IRELAND and ENGLAND: *History*. It must suffice to say here, that after the defeat of the Home Rule Ministry in 1886, Parnell associated himself more closely with the Liberal Opposition. At the same time he withdrew himself largely from active interposition in current parliamentary affairs, and relaxed his control over the action and policy of his followers in Ireland. He entered occasionally into London society—where in certain quarters he was now a welcome guest—but in general he lived apart, often concealing his whereabouts and giving no address but the House of Commons, answering no letters, and seldom fulfilling engagements. He seems to have thought that Home Rule being now in the keeping of an English party, it was time to show that he had in him the qualities of a statesman as well as those of a revolutionary and a rebel. His influence on the remedial legislation proposed by the Unionist Government for Ireland was considerable, and he seldom missed an opportunity of making it felt. It more than once happened to him to find measures, which had been contemptuously rejected when he had proposed them, ultimately adopted by the Government; and it may be that the comparative tranquillity which Ireland enjoyed at the close of the 19th century was due quite as much to legislation inspired and recommended by himself as to the disintegration of his following which ensued upon his appearance in the Divorce Court and long survived his death. No sooner was Lord Salisbury's new Government installed in office in 1886, than Parnell introduced a comprehensive Tenants' Relief Bill. The Government would have none of it, though in the following session they adopted and carried many of its leading provisions. Its rejection was followed by renewed agitation in Ireland, in which Parnell took no part. He was ill—"dangerously ill," he said himself at the time—and some of his more hot-headed followers devised the famous "Plan of Campaign," on which he was never consulted and which never had his approval. Ireland was once more thrown into a turmoil of agitation, turbulence, and crime, and the Unionist Government, which had hoped to be able to govern the country by means of the ordinary law, was compelled to resort to severe repressive measures and fresh coercive legislation. Mr Balfour became Chief Secretary, and early in the session of 1887 the new measure was introduced and carried. Parnell took no very prominent part in resisting it. In the course of the spring *The Times* had begun publishing a series of articles entitled "Parnellism and Crime," on lines following Mr Forster's indictment of Parnell in 1883, though with much greater detail of circumstance and accusation. Some of the charges were undoubtedly well founded, some were exaggerated, some were merely the colourable fictions of political prepossession, pronounced to be not proven by the special commission which ultimately inquired into them. One of the articles, which appeared on 18th April, was accompanied by the facsimile of a letter purporting to be signed but not written by Parnell, in which he apologized for his attitude on the Phœnix Park murders, and specially excused the murder of Mr Burke. On the same evening, in the House of Commons, Parnell declared the letter to be a forgery, and denied that he had ever written any letter to the same effect. He was not believed, and the second reading of the Crimes Act followed. Later in the session the attention of the House was again called to the subject, and it was invited by Sir Charles Lewis, an Ulster member and a bitter antagonist of the Nationalists, to declare the charges of *The Times* a breach of privilege. The Government met this proposal by an offer to pay the expenses of a libel action against *The Times* to be brought on behalf of the Irish members incriminated. This offer was refused. Mr Gladstone then proposed that a select committee should inquire into the charges, including the letter attributed to Parnell, and to this Parnell assented. But the Government rejected the proposal. For the rest, Parnell continued to maintain for the most part an attitude of moderation, reserve, and retreat, though he more than once came forward to protest against the harshness of the Irish administration and to plead for further remedial legislation. In July 1888 he announced that Mr Cecil Rhodes had sent him a sum of £10,000 in support of the Home Rule movement, subject to the condition that the Irish representation should be retained in the House of Commons in any future measure dealing with the question. About the same time the question of "Parnellism and Crime" again became acute. Mr F. H. O'Donnell, an ex-M.P. and former member of the Irish party, brought an action against *The Times* for libel. His case was a weak one, and a verdict was obtained by the defendants. But in the course of the proceedings the Attorney-General, counsel for *The Times*, affirmed the readiness of his clients to establish all the charges advanced, including the genuineness of the letter which Parnell had declared to be a forgery. Parnell once more invited the House of Commons to refer this particular issue—that of the letter—to a select committee. This was again refused; but after some hesitation the Government resolved to appoint by Act of Parliament a special commission, composed of three judges of the High Court, to inquire into all the charges advanced by *The Times*. This led to what was in substance, though not perhaps in judicial form, the most remarkable State trial of the 19th century. The commission began to sit in September 1888, and issued its report in February 1890. It heard evidence of immense volume and variety, and the speech of Sir Charles Russell in defence was afterwards published in a bulky volume. Parnell gave evidence at great length, with much composure and some cynicism. On the whole he produced a not unfavourable impression, though some of his statements might seem to justify Mr Gladstone's opinion that he was not a man of exact veracity. The report of the commission was a very voluminous document, and was very variously interpreted by different parties to the controversy. Their conclusions may be left to speak for themselves:—

"I. We find that the respondent members of Parliament collectively were not members of a conspiracy having for its object to establish the absolute independence of Ireland, but we find that some of them, together with Mr Davitt, established and joined in the Land League organization with the intention, by its means, to bring about the absolute independence of Ireland as a separate nation.

"II. We find that the respondents did enter into a conspiracy, by a system of coercion and intimidation, to promote an agrarian agitation against the payment of agricultural rents, for the purpose of impoverishing and expelling from the country the Irish landlords, who were styled 'the English garrison.'

"III. We find that the charge that 'when on certain occasions they thought it politic to denounce, and did denounce, certain crimes in public, they afterwards led their supporters to believe such denunciations were not sincere,' is not established. We entirely acquit Mr Parnell and the other respondents of the charge of insincerity in their denunciation of the Phœnix Park murders, and find that the 'facsimile' letter, on which this charge was chiefly based as against Mr Parnell, is a forgery.

"IV. We find that the respondents did disseminate the *Irish World* and other newspapers tending to incite to sedition and the commission of other crime.

"V. We find that the respondents did not directly incite persons to the commission of crime other than intimidation, but that they did incite to intimidation, and that the consequence of that incitement was that crime and outrage were committed by the persons incited. We find that it has not been proved that the respondents made payments for the purpose of inciting persons to commit crime.

"VI. We find, as to the allegation that the respondents did nothing to prevent crime, and expressed no *bonâ fide* disapproval, that some of the respondents, and in particular Mr Davitt, did express *bonâ fide* disapproval of crime and outrage, but that the respondents did not denounce the system of intimidation that led to crime and outrage, but persisted in it with knowledge of its effect.

"VII. We find that the respondents did defend persons charged with agrarian crime, and supported their families; but that it has not been proved that they subscribed to testimonials for, or were intimately associated with, notorious criminals, or that they made payments to procure the escape of criminals from justice.

"VIII. We find, as to the allegation that the respondents made payments to compensate persons who had been injured in the commission of crime, that they did make such payments.

"IX. As to the allegation that the respondents invited the assistance and co-operation of, and accepted subscriptions of money from, known advocates of crime and the use of dynamite, we find that the respondents did invite the assistance and co-operation of, and accepted subscriptions of money from, Patrick Ford, a known advocate of crime and the use of dynamite; but that it has not been proved that the respondents, or any of them, knew that the Clan-na-Gael controlled the League, or was collecting money for the Parliamentary Fund. It has been proved that the respondents invited and obtained the assistance and co-operation of the Physical Force Party in America, including the Clan-na-Gael, and in order to obtain that assistance abstained from repudiating or condemning the action of that party."

The specific charges brought against Parnell personally were thus dealt with by the commissioners:—

"(*a*) That at the time of the Kilmainham negotiations Mr Parnell knew that Sheridan and Boyton had been organizing outrage, and therefore wished to use them to put down outrage.

"We find that this charge has not been proved.

"(*b*) That Mr Parnell was intimate with the leading Invincibles; that he probably learned from them what they were about when he was released on *parole* in April 1882; and that he recognized the Phœnix Park murders as their handiwork.

"We find that there is no foundation for this charge. We have already stated that the Invincibles were not a branch of the Land League.

"(*c*) That Mr Parnell on 23rd January 1883, by an opportune remittance, enabled F. Byrne to escape from justice to France.

"We find that Mr Parnell did not make any remittance to enable F. Byrne to escape from justice."

The case of the *facsimile* letter alleged to have been written by Parnell broke down altogether. It was proved to be a forgery. It had been purchased with other documents from one Pigott, a needy and disreputable Irish journalist, who afterwards tried to blackmail Archbishop Walsh by offering, in a letter which was produced in court, to confess its forgery. Mercilessly cross-examined by Sir Charles Russell on this letter to the archbishop, Pigott broke down utterly. Before the commission sat again he fled to Madrid, and there blew his brains out. He had confessed the forgery to Mr Labouchere in the presence of Mr G. A. Sala, but did not stay to be cross-examined on his confession. The Attorney-General withdrew the letter on behalf of *The Times*, and the commission pronounced it to be a forgery. Shortly after the letter had been withdrawn, Parnell filed an action against *The Times* for libel, claiming damages to the amount of £100,000. The action was compromised without going into court by a payment of £5000.

Practically, the damaging effect of some of the findings of the commission was neutralized by Parnell's triumphant vindication in the matter of the *facsimile* letter and of the darker charges levelled at him. Parties remained of the same opinion as before: the Unionists still holding that Parnell was steeped to the lips in treason, if not in crime; while the Home Rulers made abundance of capital out of his personal vindication, and sought to excuse the incriminating findings of the commission by the historic antecedents of the Nationalist cause and party. The failure to produce the books and papers of the Land League was overlooked, and little importance was attached by partisans to the fact that in spite of this default (leaving unexplained the manner in which over £100,000 had been expended), the commissioners "found that the respondents did make payments to compensate persons who had been injured in the commission of crime." Parnell and his colleagues were accepted as allies worthy of the confidence of an English party; they were made much of in Gladstonian Liberal society; and towards the close of 1889, before the commission had reported, but some months after the forged letter had been withdrawn, Parnell visited Hawarden to confer with Mr Gladstone on the measure of Home Rule to be introduced by the latter should he again be restored to power. What occurred at this conference was afterwards disclosed by Parnell, but Mr Gladstone vehemently denied the accuracy of his statements on the subject.

But Parnell's fall was at hand. In December 1889 Captain O'Shea filed a petition for divorce on the ground of his wife's adultery with Parnell. Parnell's intimacy with Mrs O'Shea had begun in 1881, though at what date it became a guilty one is not in evidence. Captain O'Shea had in that year challenged him to a duel, but was pacified by the explanations of Mrs O'Shea. It is known that Captain O'Shea had been Parnell's confidential agent in the negotiation of the Kilmainham Treaty, and in 1885 Parnell had strained his personal authority to the utmost to secure

Captain O'Shea's return for Galway, and had quelled a formidable revolt among some of his most influential followers in doing so. It is not known why Captain O'Shea, who, if not blind to a matter of notoriety, must have been complaisant in 1885, became vindictive in 1889. No defence being offered, a decree of divorce was pronounced, and in June 1891 Parnell and Mrs O'Shea were married.

At first the Irish party determined to stand by Parnell. The decree was pronounced on 17th November 1890. On the 20th a great meeting of his political friends and supporters was held in Dublin, and a resolution that in all political matters Parnell possessed the confidence of the Irish nation was carried by acclamation. But the Irish party reckoned without its English allies. The "Nonconformist conscience," which had swallowed the report of the commission, was shocked by the decree of the Divorce Court. At a meeting of the National Liberal Federation held at Sheffield on 21st November, Mr John Morley was privately but firmly given to understand that the Nonconformists would insist on Parnell's resignation. Parliament was to meet on the 25th. Mr Gladstone tried to convey to Parnell privately his conviction that unless Parnell retired the cause of Home Rule was lost. But the message never reached Parnell. Mr Gladstone then requested Mr John Morley to see Parnell; but he could not be found. Finally, on the 24th, Mr Gladstone wrote to Mr Morley the famous and fatal letter, in which he declared his conviction "that, notwithstanding the splendid services rendered by Mr Parnell to his country, his continuance at the present moment in the leadership would be disastrous in the highest degree to the cause of Ireland," and that "the continuance I speak of would not only place many hearty and effective friends of the Irish cause in a position of great embarrassment, but would render my retention of the leadership of the Liberal party, based as it has been mainly upon the presentation of the Irish cause, almost a nullity." This letter was not published until after the Irish parliamentary party had met in the House of Commons and re-elected Parnell as its chairman without a dissentient voice. But its publication was a thunder-clap. A few days later Parnell was requested by a majority of the party to convene a fresh meeting. It took place in Committee Room No. 15, which became historic by the occasion, and after several days of angry recrimination and passionate discussion, during which Parnell, who occupied the chair, scornfully refused to put to the vote a resolution for his own deposition, 45 members retired to another room and there declared his leadership at an end. The remainder, twenty-six in number, stood by him. The party was thus divided into Parnellites and anti-Parnellites, and the schism was not healed until several years after Parnell's death.

This was practically the end of Parnell's political career in England. The scene of operations was transferred to Ireland, and there Parnell fought incessantly a bitter and a losing fight, which ended only with his death. He declared that Ireland could never achieve her emancipation by force, and that if she was to achieve it by constitutional methods, it could only be through the agency of a united Nationalist party rigidly eschewing alliance with any English party. This was the policy he proclaimed in a manifesto issued before the opening of the sittings in Committee Room No. 15, and with this policy, when deserted by the bulk of his former followers, he appealed to the Fenians in Ireland—"the hillside men," as Mr Davitt, who had abandoned him early in the crisis, contemptuously called them. The Fenians rallied to his side, giving him their votes and their support, but they were no match for the Church, which had declared against him. An attempt at reconciliation was made in the spring, at what was known as "the Boulogne negotiations," where Mr William O'Brien endeavoured to arrange an understanding; but it came to nothing in the end. Probably Parnell was never very anxious for its success. He seems to have regarded the situation as fatally compromised by the extent to which his former followers were committed to an English alliance, and he probably saw that the only way to recover his lost position was to build up a new independent party. He knew well enough that this would take time—five years was the shortest period he allowed himself—but before many months were passed he was dead. The life he led, the agonies he endured, the labours he undertook from the beginning of 1891, travelling weekly to Ireland and intoxicating himself with the atmosphere of passionate nationalism in which he moved, would have broken down a much stronger man. He who had been the most impassive of men became restless, nervous, almost distracted at times, unwilling to be alone, strange in his ways and demeanour. He visited Ireland for the last time late in September, and the last public meeting he attended was on the 27th of that month. The next day he sent for his friend Dr Kenny, who found him suffering from acute rheumatism and general debility. He left Ireland on the 30th, promising to return on the following Saturday week. He did return on that day, but it was in his coffin. He took to his bed shortly after his return to his home at Brighton, and on 6th October he died. His remains were conveyed to Dublin, and on Sunday, 11th October, they were laid to rest in the presence of a vast assemblage of the Irish people in Glasnevin Cemetery, not far from the grave of O'Connell.

The principal materials for a biography of Parnell and the history of the Parnellite movement are to be found in *Hansard's Parliamentary Debates*, 1875–91; in the *Annual Register* for the same period; in the *Report of the Special Commission* issued in 1890; in *The Life of Charles Stewart Parnell*, by R. Barry O'Brien; in *The Parnellite Movement*, by T. P. O'Connor, M.P.; and in a copious biography of Parnell contributed by an anonymous but well-informed writer to the *Dictionary of National Biography*, vol. xliii. (J. R. T.)

Paropamisus. See Herat.

Parramatta, a town of Australia, New South Wales, on the Parramatta river, in the county of Cumberland, 14 miles west of Sydney by rail. It is the oldest town in all Australia, and round it the first grain of the colony was grown. It is now noted for its orangeries and orchards. The mean rainfall (15 years) is 38·95 inches. Population (1891), 11,677; (1901), 12,560.

Parry, Sir Charles Hubert Hastings, Bart., English musical composer (1848-——), the second son of Thomas Gambier Parry, of Highnam Court, Gloucester, was born at Bournemouth, 27th February 1848. He was educated at Malvern, Twyford, near Winchester, Eton (from 1861), and Exeter College, Oxford. While still at Eton he wrote music, two anthems being published in 1865; a service in D was dedicated to Sir John Stainer. He took the degree of Mus.B. at Oxford at the age of eighteen, and that of B.A. in 1870; he then left Oxford for London, where in the following year he entered Lloyd's, abandoning business for art soon afterwards. He studied successively with H. H. Pierson (at Stuttgart), Sterndale Bennett, and Macfarren; but the man to whom the most important part of his artistic development was due was Mr Edward Dannreuther, at whose private concerts his chamber compositions were frequently performed. Among the larger works of this early period must be mentioned an overture, *Guillem de Cabestanh*

(Crystal Palace, 1879), a pianoforte concerto in F sharp minor, played by Dannreuther at the Crystal Palace and Richter Concerts in 1880, and his first choral work, the *Scenes from Prometheus Unbound*, produced at the Gloucester Festival, 1880. These, like a symphony in G, given at the Birmingham Festival of 1882, were distinctly caviare to the general; the ideas seemed strange even to educated hearers, who were further confused by the intricacy of their treatment. It was not until Shirley's ode, *The Glories of our Blood and State*, was brought out at Gloucester, 1883, and the *Partita* for violin and pianoforte was published about the same time, that Parry's importance came to be realized. With his sublime eight-part setting of Milton's *Blest Pair of Sirens* (Bach Choir, 1887) began a fine series of compositions to sacred or semi-sacred words. In *Judith* (Birmingham, 1888), the *Ode on St Cecilia's Day* (Leeds, 1889), *L'Allegro ed il Penseroso* (Norwich, 1890), *De Profundis* (Hereford, 1891), *The Lotus Eaters* (Cambridge, 1892), *Job* (Gloucester, 1892), *King Saul* (Birmingham, 1894), *Invocation to Music* (Leeds, 1895), *Magnificat* (Hereford, 1897), *A Song of Darkness and Light* (Gloucester, 1898), and *Te Deum* (Hereford, 1900), are revealed the highest qualities of music. Skill in piling up climax after climax, and command of every choral resource, are the technical qualities most prominent in these works; but in his orchestral compositions, such as the three later symphonies, in F, C, and E minor, in two suites, one for strings alone, and above all in his *Symphonic Variations* (1897), he shows himself a master of the orchestra, and his experiments in modification of the conventional classical forms, such as appear in the work last named, or in the *Nineteen Variations for Pianoforte Solo*, are always successful. His music to *The Birds* of Aristophanes (Cambridge, 1883) and *The Frogs* (Oxford, 1892) are striking examples of humour in music; and that to *Agamemnon* (Cambridge, 1900) is among the most impressive compositions of the kind. His chamber music, exquisite part songs, and solo songs maintain the high standard of his greater works. At the opening of the Royal College of Music in 1883 he was appointed professor of composition and of musical history, and in 1894, on the retirement of Sir George Grove, Parry succeeded him as principal. He was appointed Choragus of Oxford University in 1883, succeeding Stainer in the professorship of the University in 1900. He received the honorary degree of Mus.D. at Cambridge 1883, Oxford 1884, Dublin 1891; and was knighted in 1898. Outside the domain of creative music, Parry's work for the art has been of the greatest importance: as a contributor of many of the most important articles on musical forms, &c., in Grove's dictionary, his literary work first attracted attention; in his *Studies of Great Composers* musical biography was treated, almost for the first time, in a really enlightened and enlightening way; and his *Art of Music* is a splendid monument of musical literature, in which the theory of evolution is applied to musical history with wonderful skill and success.

Parsons, a city of Labette county, Kansas, U.S.A. It is situated at the intersection of the Kansas City, Fort Scott and Memphis, and the Missouri, Kansas, and Texas railways, in the south-eastern part of the state, at an altitude of 900 feet. Its site is level and its plan regular. It is in a rich farming country, and has a large trade. It contains railway offices and works, foundries and furniture factories. Population (1880), 4199; (1890), 6736; (1900), 7682, of whom 378 were foreign-born and 807 negroes.

Partabgarh, or PRATAPGARH, a district of British India, in the Fyzabad division of Oudh. The administrative headquarters are at Bela. Area, 1439 square miles; population (1881), 847,047; (1891), 910,895; (1901), 891,095, showing an increase of nearly 8 per cent. between 1881 and 1891, but a decrease of 2·2 per cent. between 1891 and 1901; average density, 619 persons per square mile, or almost one person to every acre in a tract that is entirely rural.

The land revenue and rates are Rs.10,71,800, the incidence of assessment being R.1 : 5 : 3 per acre; cultivated area (1896–97), 463,808 acres, of which 273,848 were irrigated from wells and tanks; number of police, 730; vernacular schools, 132, with 5225 pupils; registered death-rate (1897), 42 per thousand. The principal crops are rice, pulse, barley, sugar-cane, opium, and indigo. There are 47 indigo factories, with an out-turn valued at Rs.1,46,000. The district is traversed by the branch of the Oudh and Rohilkhand railway from Rae Bareli to Benares, which was opened in 1898. There are no Government canals. It manufactures sugar, and has a hemp-pressing factory.

Partabgarh, or PERTABGARH, a native state of India, in the Rajputana agency. Area, 959 square miles; population (1881), 79,298; (1891), 87,975; (1901), 52,029, showing an increase of 11 per cent. between 1881 and 1891, but a decrease of 40·9 between 1891 and 1901; average density, 54 persons per square mile; revenue (1896–97), Rs.4,01,387. A metalled road has been opened from PARTABGARH town to Mandesaur, on the Rajputana railway, 19 miles. The mint was closed in 1897. The town has a population of 13,000.

Partap [or PERTAB] **Singh, Sir** (1844-——), native Indian soldier and statesman, belonging to the Rathor rajputs of the Jodha class, was born in 1844, being the son of Maharaja Takht Singh, ruler of Marwar (or Jodhpur). In 1878 and again in 1879 he was chief minister of Jodhpur. In the following year he accompanied the British mission to Afghanistan, and on his return he resumed his duties as chief minister, carrying out many judicious reforms and administering Jodhpur with remarkable success. He visited England to take part in the celebration of the 1887 Jubilee of Queen Victoria's reign. His high soldierly instincts induced him to offer his services when war broke out on the north-western frontier of India, and he served on the staffs of Sir William Lockhart and General Elles in the Tirah and Momand expeditions beyond the Punjab border in the campaigns of 1897–98. He was slightly wounded, and he was mentioned in despatches, being promoted to the rank of full colonel for his services. He is reputed to be one of the keenest sportsmen and the best riders that even Rajputana has produced. When it was decided to send a force from India to China in 1900 to relieve the foreign embassies besieged in Peking, Sir Partap Singh at once offered the services of the Jodhpur Lancers, and himself proceeded with them to the seat of military operations. His father rendered good services to the British Government in the Mutiny, and Partap Singh always esteemed it a point of honour and a matter of filial duty to identify the famous state of Jodhpur with the British Government in times of trouble or foreign war. He cherished the memory of the protection given by the East India Company in 1818, when Jodhpur had suffered from internal dissension and the ravages of the Marathas, and was taken into subordinate alliance with the British on terms honourable to both parties. In social matters the Maharaja favoured the party of moderate reform, but it was as a rajput soldier and a loyal prince that he was most distinguished. No prince in India has ever won so many proofs of public estimation from the British Government and English society as Sir Partap Singh. From Queen Victoria he received the honour of knighthood and the decorations of the Bath and the Star of India; from King Edward VII. the distinction of "aide-de-camp"; from the

War Office the rank of colonel in the King's army; and from the University of Cambridge the degree of LL.D. From his own state of Jodhpur he obtained the title of Maharaja-Dhiraj. In 1901 he succeeded to the rulership of the state of Idar.

Parthenay, chief town of arrondissement, department of Deux-Sèvres, France, 25 miles north-north-east of Niort, on railway from Paris to Bordeaux. The town is picturesquely situated on a promontory overlooking the Thouet, and still retains considerable portions of its 13th-century ramparts, with large round towers, offering, next to Aigues-Mortes, the finest example of the fortifications of that period. Amongst ancient buildings of interest are the church of Ste Croix, of the 12th century, restored 1885, and with 15th-century belfry; the church of St Laurent, also restored in modern times, but portions of whose walls date from the 11th century; a ruined portal of Notre Dame de la Couldre, with beautiful sculpture and two equestrian statues; and 1 mile south-west of the town the ancient church of Parthenay-le-Vieux. The manufacture of knitted woollen goods and wool-spinning are the principal local industries. Population (1881), 3899; (1891), 5361; (1901), 6426.

Partick, a police burgh in the parish of Govan, Lanarkshire, Scotland, on the north bank of the Clyde, adjoining and continuous with Glasgow. Since 1850 it has grown from a village to be a large and wealthy residential quarter of Greater Glasgow. Five shipbuilding yards are situated in the burgh, which contains also the industries of paper-staining, flour-milling, hydraulic-machine making, weighing-machine making, brass-founding, and galvanizing. It has a town hall and a Victoria public park (1887). Partick forms the major part of the Partick division of Lanarkshire, which returns a member to Parliament. The municipality maintains a separate police force and a fire brigade, but uses Glasgow gas and water. One of the public schools has a secondary department. Area, 1006 acres. Population (1891), 36,538; (1901), 54,274.

Partnership.—In 1890 the Partnership Act of that year was passed to declare and amend the law of partnership; the Act came into operation on 1st January 1891. With one important exception (§ 23), it applies to the whole United Kingdom. It is not a complete code of partnership law; it contains no provisions regulating the administration of partnership assets in the event of death or bankruptcy, and is silent on the subject of goodwill. The existing rules of equity and common law continue in force, except so far as they are inconsistent with the express provisions of the Act. The article on Partnership in the ninth edition of this work contains a short account of the state of the law before the Act. The decisions which established that law show the principles which underlie the Act, and will be found useful as illustrations of its application and guides to its interpretation when its language is obscure. On all points specifically dealt with by the Act it is now the one binding authority. The Act has made no important changes in the law, except in respect of the mode of making a partner's share of the partnership assets available for payment of his separate debts. This change does not affect Scotland. The Act is divided into the four main divisions mentioned below.

I. *Nature of Partnership.*—Partnership is defined to be the "relation which subsists between persons carrying on a business in common with a view of profit." From this definition corporations and companies, such as joint-stock companies and cost-book mining companies, which differ from ordinary partnerships in many important respects, are expressly excluded. The Act also contains several subsidiary rules for determining the existence of a partnership. These rules are of a fragmentary nature, and for the most part are expressed in a negative form; they have not introduced any change in the law. Co-ownership of property does not of itself create a partnership, nor does the sharing of gross returns. The sharing of profits, though not of itself sufficient to create a partnership, is *primâ facie* evidence of one. This means that if all that is known is that two persons are sharing profits, the inference is that such persons are partners; but if the participation in profits is only one amongst other circumstances, all the circumstances must be considered, and the participation in profits must not be treated as raising a presumption of partnership, which has to be rebutted. To illustrate the rule that persons may share profits without being partners, the Act gives statutory expression to the decision in *Cox* v. *Hickman* (1860, 8 House of Lords Cases, 268), viz., that the receipt by a person of a debt or other fixed sum by instalments, or otherwise, out of the accruing profits of a business does not of itself make him a partner; and it re-enacts with some slight modification the repealed provisions of Bovill's Act (28 and 29 Vict. c. 86). Whenever the question of partnership or no partnership arises, it must not be forgotten (though this is not stated in the Act) that partnership is a relation arising out of a contract; regard must be paid to the true contract and intention of the parties as appearing from the whole facts of the case. If a partnership be the legal consequence of the true agreement, the parties thereto will be partners, though they may have intended to avoid this consequence (*Adam* v. *Newbigging*, 1888, L.R. 13 App. Cas. 315). Partners are called collectively a "firm"; the name under which they carry on business is called the firm name. Under English law the firm is not a corporation, nor is it recognized as distinct from the members composing it; any change amongst them destroys the identity of the firm. In Scotland a firm is a legal person distinct from its members, but each partner can be compelled to pay its debts.

II. *Relations of Partners to Persons dealing with them.*—Every partner is an agent of the firm and of his co-partners for the purpose of the partnership business; if a partner does an act for carrying on the partnership business in the usual way in which businesses of a like kind are carried on—in other words, if he acts within his apparent authority—he thereby *primâ facie* binds his firm. The partners may by agreement between themselves restrict the power of any of their number to bind the firm. If there be such an agreement, no act done in contravention of it is binding on the firm with respect to persons who have notice of the agreement. Such an agreement does not affect persons who have no notice of it, unless indeed they do not know or believe the person with whom they are dealing to be a partner; in that case he has neither real, nor, so far as they are concerned, apparent authority to bind his firm, and his firm will not be bound. If a partner does an act, *e.g.*, pledges the credit of the firm, for a purpose apparently not connected with the firm's ordinary course of business, he is not acting in pursuance of his apparent authority, and whatever liability he may personally incur, his partners will not be bound unless he had in fact authority from them.

Apart from any general rule of law relating to the execution of deeds or negotiable instruments, a firm and all the partners will be bound by any act relating to the business of the firm, and done in the firm name, or in any other manner showing an intention to bind the firm, by any person thereto authorized. An admission or representation by a partner, acting within his apparent authority, is evidence against his firm. Notice to an acting partner of any matter relating to the partnership affairs is, apart from fraud, notice to his firm.

A firm is liable for loss or injury caused to any person not a partner, or for any penalty incurred by any wrongful act or omission of a partner acting in the ordinary course of the partnership business, or with the authority of his co-partners; the extent of the firm's liability is the same as that of the individual partner. The firm is also liable to make good the loss (*a*) where one partner, acting within his apparent authority, receives money or property of a third person and misapplies it; and (*b*) where a firm in the course of its business receives money or property of a third person, and such money or property while in the custody of the firm is misapplied by a partner. It is not sufficient, in order to fix innocent partners with liability for the misapplication of money belonging to a third party, merely to show that such money was employed in the business of the partnership, otherwise all the members of a firm would in all cases be liable to those beneficially interested therein for trust money improperly employed in this manner by one partner. This is not the case. To fix the other partners with liability, notice of the breach of trust must be brought home to them individually.

The liability of partners for the debts and obligations of their firm arising *ex contractu*, is joint, and in Scotland several also; the estate of a deceased partner is also severally liable in a due course of administration, but subject, in England or Ireland, to the prior payment of his separate debt. The liability of partners for the obligations of their firm arising *ex delicto*, is joint and several.

The authority of a partner to bind his co-partners commences with the partnership. A person therefore who enters into a partnership does not thereby become liable to the creditors of his partners for anything done before he became a partner. But a partner who retires from a firm does not thereby cease to be liable for debts or obligations incurred before his retirement. He may be discharged from existing liabilities by an agreement to that effect between himself and the members of the firm as newly constituted and the creditors. This agreement may be either express or inferred as a fact from the course of dealing between the creditors and the new firm. The other ways in which a partner may be freed from partnership liabilities incurred before his retirement are not peculiar to partnership liabilities, and are not therefore dealt with by the Partnership Act.

A continuing guaranty given to a firm, or in respect of the transactions of a firm, is, in the absence of agreement to the contrary, revoked as to the future by a change in the firm. The reason is that such a change destroys its identity.

Any person, not a partner in the firm, who represents himself, (or, as the phrase is, "holds himself out") or knowingly suffers himself to be represented, as a partner, is liable as a partner to any person who has given credit to the firm on the faith of the representation. The representation may be by words spoken or written, or by conduct. The liability will attach, although the person who makes the representation does not know that the person who has acted on it knew of it. The continued use of a deceased partner's name does not impose liability on his estate.

III. *Relations of Partners to one another.*—The mutual rights and duties of partners depend upon the agreement between them. Many of these rights and duties are stated in the Partnership Act; but, whether stated in the Act or ascertained by agreement, they may be varied by the consent of all the partners; such consent may be express or inferred from conduct. Subject to any agreement, partners share equally in the capital and profits of their business, and must contribute equally to losses, whether of capital or otherwise; they are entitled to be indemnified by their firm against liabilities incurred in the proper and ordinary conduct of the partnership business, and for anything necessarily done for its preservation; they are entitled to interest at 5 per cent. on their advances to the firm, but not on their capital. Every partner may take part in the management of the partnership business, but no partner is entitled to remuneration for so doing. The majority can bind the minority in ordinary matters connected with the partnership business, but cannot change its nature nor expel a partner, unless expressly authorized so to do. No partner may be introduced into the firm without the consent of all the partners. The partnership books must be kept at the principal place of business, and every partner may inspect and copy them. Partners must render to each other true accounts and full information of all things affecting the partnership. A partner may not make use of anything belonging to his firm for his private purposes, nor may he compete with it in business. If he does so he must account to his firm for any profit he may make.

Partners may agree what shall and what shall not be partnership property, and can by agreement convert partnership property into the separate property of the individual partners, and *vice versâ*. Subject to any such agreement, all property originally brought into the partnership stock, or acquired on account of the firm or for the purposes and in the course of its business, is declared by the Act to be partnership property. Property bought with money of the firm is *primâ facie* bought on account of the firm. Partnership property must be applied exclusively for partnership purposes and in accordance with the partnership agreement. Co-owners of land may be partners in the profits of the land without the land being partnership property; if such co-owners purchase other lands out of the profits, these lands will also belong to them (in the absence of any agreement to the contrary) as co-owners and not as partners. The legal estate in partnership land devolves according to the general law, but in trust for the persons beneficially interested therein. As between partners, and as between the heirs of a deceased partner and his executors or administrators, such land is treated as personal or movable estate, unless a contrary intention appears.

When no fixed term has been agreed upon for the duration of the partnership, it is at will, and may be determined by notice at any time by any partner. If a partnership for a fixed term is continued after the term has expired without any express new agreement, the rights and duties of the partners remain as before, so far as they are consistent with a partnership at will.

A partner may assign his share in the partnership either absolutely or by way of mortgage. The assignee does not become a partner; during the continuance of the partnership he has the right to receive the share of profits to which his assignor would have been entitled, but he has no right to interfere in the partnership business, or to require any accounts of the partnership transactions, or to inspect the partnership books. On a dissolution he is entitled to receive the share of the partnership assets to which his assignor is entitled as between himself and his partners, and for this purpose to an account as from the date of dissolution.

Since the Act came into operation no writ of execution may issue in England or Ireland against any partnership property, except on a judgment against the firm. If in either of these countries a judgment creditor of a partner wishes to enforce his judgment against that partner's share in the partnership, he must obtain an order of court charging such share with payment of his debt and interest. The court may appoint a receiver of the partner's share, and may order a sale of such share. If a sale be ordered the other partners may buy the share; they may also at any time redeem the charge. The mode of making a partner's share liable for his separate debts in Scotland has not been altered by the Act.

IV. *Dissolution of Partnership.*—A partnership for a fixed term, or for a single adventure, is dissolved by the expiration of the term or the termination of the adventure. A partnership for an undefined time is dissolved by notice of dissolution, which may be given at any time by any partner. The death or bankruptcy of any partner dissolves the partnership as between all its members. If a partner suffers his share in the partnership to be charged under the Act for his separate debts, his partners may dissolve the partnership. The foregoing rules are subject to any agreement there may be between the partners. A partnership is in every case dissolved by any event which makes the partnership or its business unlawful. The court may order a dissolution in any of the following cases, viz.:—When a partner is found lunatic or is of permanently unsound mind, or otherwise permanently incapable of performing his duties as a partner; when a partner has been guilty of conduct calculated to injure the partnership business, or wilfully or persistently breaks the partnership agreement, or so conducts himself in partnership matters that it is not reasonably practicable for his partners to carry on business with him; when the partnership can only be carried on at a loss; and lastly, whenever a dissolution appears to the court to be just and equitable. The Act is silent as to the effect of the assignment by a partner of his share in the partnership as a cause of dissolution; probably it is now no more than a circumstance enabling the court, if it thinks fit, to grant a dissolution on the ground that it is just and equitable to do so. A dissolution usually is not complete as against persons who are not partners, until notice of it has been given; until then such persons may treat all apparent partners as still members of the firm. Consequently, if notice is not given when it is necessary, a partner may be made liable for partnership debts contracted after he ceased to be a partner. Notice is not necessary to protect the estate of a dead or bankrupt partner from partnership debts contracted after his death or bankruptcy; nor is notice necessary when a person not known to be a partner leaves a firm. If a person not generally known to be a partner is known to be so to certain individuals, notice must be given to them. Notice in the *Gazette* is sufficient as regards all persons who were not previously customers of the firm; notice in fact must be given to old customers. On a dissolution, or the retirement of a partner, any partner may notify the fact and require his co-partners to concur in doing so.

After a dissolution, the authority of each partner (unless he be a bankrupt) to bind the firm, and the other rights and obligations of the partners, continue so far as may be necessary to wind up the partnership affairs and to complete unfinished transactions. The partners are entitled to have the partnership property applied in payment of the debts of the firm, and to have any surplus divided between them. Before a partner can receive any part of the surplus, he must make good whatever may be due from him as a partner to the firm. To enforce these rights, any partner or his representatives may apply to the court to wind up the partnership business. It was well established before the Act, and is still law, that in the absence of special agreement the right of each partner is to have the partnership property—including the goodwill of its business, if it be saleable—realized by a sale. The value of the goodwill depends largely on the right of the seller to compete with the purchaser after the sale. The Act makes no mention of goodwill, but the rights of a seller in this respect were fully discussed in the House of Lords in *Trego* v. *Hunt* (L.R. 1896, App. Cas. 7). In the absence of special agreement, the seller may set up business in competition with, and in the immediate neighbourhood of, the purchaser, and advertise his business and deal with his former customers, but may not represent himself as carrying on his former business, nor canvass his former customers. The purchaser may advertise himself as carrying on the former business, canvass its customers, and trade under the old name, unless that name is or contains the name of the vendor, and the purchaser by using it without qualification would expose the vendor to the liability of being sued as a partner in the business. If, on a dissolution or change in the constitution of a firm, the goodwill belongs under the partnership agreement exclusively to one or more of the partners, the partner who is not entitled to the goodwill has the rights of a seller, and those to whom the goodwill belongs have the rights of a purchaser.

When a partner has paid a premium on entering into a partnership for a fixed term, and the partnership is determined before the expiration of the term, the court may, except in certain cases, order a return of the premium or of some part of it. In the absence of fraud or misrepresentation, the court cannot make such an order when the partnership was at will, or, being for a fixed term, has been terminated by death or by reason of the misconduct of the partner who paid the premium; nor can it do so if terms of dissolution have been agreed upon, and the agreement makes no provision for the return of premium. When the court makes an order it usually orders the return of so much of the premium as bears the same proportion to the whole as the actual bears to the agreed duration of the partnership.

When a person is induced by the fraud or misrepresentation of others to become a partner with them, the court will rescind the contract at his instance (*Adam* v. *Newbigging*, 1888, R. 13 App. Cas. 308). Inasmuch as such a person is under the same liability to third parties for liabilities of the firm incurred before rescission as he would have been under had the contract been valid, he is entitled on the rescission to be indemnified by the person guilty of the fraud or making the representation against these liabilities. He is also entitled, without prejudice to any other rights, to receive out of the surplus assets of the partnership, after satisfying the partnership liabilities, any money he may have paid as a premium or contributed as capital, and to stand in the place of the creditors of the firm for any payments made by him in respect of the partnership liabilities.

If a partner ceases to be a member of a firm, and his former partners continue to carry on business with the partnership assets without any final settlement of accounts, he, or, if he be dead, his estate, is, in the absence of agreement, entitled to such part of the subsequent profits as can be attributed to the use of his share of the partnership assets, or, if he or his representatives prefer it, to interest at 5 per cent. on the amount of his share. If his former partners have by agreement an option to purchase his share, and exercise the option and comply with its terms, he is not entitled to any further or other share in profits than that given him by the agreement. If, however, his former partners, assuming to exercise such an option, do not comply with its terms, they are liable to account for subsequent profits or interest to the extent mentioned above. Subject to any agreement between the partners, the amount due from the surviving or continuing partners to an outgoing partner, or the representatives of a deceased partner, in respect of his share in the partnership, is a debt accruing at the date of the dissolution or death.

In the absence of any special agreement on a final settlement of accounts between partners, losses (including losses of capital) are paid first out of profits, next out of capital, and lastly by the partners in the proportions in which they share profits. The assets of the firm, including all sums contributed to make up losses of capital, are applied in paying the debts and liabilities of the firm to persons who are not partners; then in paying to each partner rateably what is due from the firm to him, first for advances and next in respect of capital; and the ultimate residue (if any) is divisible among the partners in the proportion in which profits are divisible.

See Sir NATHANIEL LINDLEY. *A Treatise on the Law of Partnership*, 6th edition. London, 1893.—Sir FREDERICK POLLOCK. *A Digest of the Law of Partnership, incorporating the Partnership Act, 1890*, 6th edition. London, 1895.—Also article on "Partnership" in the *Encyclopædia of the Laws of England*, to the publishers of which (Messrs Sweet and Maxwell, Limited, London, and Messrs W. Green and Sons, Edinburgh) the writer's thanks are due. (W. B. L.)

The following points in United States law may be added. An ordinary partnership between miners for working a mine is not dissolved by the death of one of the partners, nor by the transfer by one of his interest in the concern. Contract is not deemed the basis of the relation between the partners, but rather a common property and co-operation in its exploitation (Parsons, *Principles of Partnership*, sect. 15). A corporation cannot become a partner in any mercantile adventure, unless specially authorized by charter or general statute. If it could, the management of its affairs would no longer be exclusively in the hands of its directors, to whom the law has entrusted it. Hence, corporations cannot associate for the formation of a "trust" to be managed by the associated partners. (S. E. B.)

Pasadena, a city of Los Angeles county, California, U.S.A., at the base of the San Gabriel Mountains, in southern California, at an altitude of 827 feet. It is 9 miles north-east of Los Angeles, with which it is connected by lines of steam and trolley cars. It is on the Southern Pacific and the Southern California (Atchison, Topeka, and Santa Fé) railways. Its site is level, its plan regular. It has an excellent water-supply, and is well sewered. The surrounding country is to a large extent highly cultivated, producing sub-tropical fruits in great variety and quantity. Pasadena is noted for its mild, soft climate, especially in winter, and for the beauty of its surroundings, with the San Gabriel range rising to the north, and southwards the beautiful valley, rendered fruitful by hundreds of artesian wells and irrigation ditches. On these accounts it has become a very popular winter resort, especially for consumptives. The Mount Low railway, partly trolley, partly cable, ascends the San Gabriel range from this point. Population (1880), 391; (1890), 4882; (1900), 9117, of whom 1278 were foreign-born and 336 coloured, including 218 negroes.

Pasages, a town and seaport of Spain, province of Guipuzcoa, 10 miles from the mouth of the river Urumen, with a station on the railway from the French frontier to Madrid. This seaport, of which the population was only 1744 in 1887 and 2501 in 1897, has developed very considerably in importance since 1890. The town only consisted until 1875 of two comparatively unimportant but picturesque groups of houses or "carrios." Vessels find a good anchorage in 30 feet of water in the centre of the land-locked bay and near the quays built along the shore opposite. An attempt has been made to dredge the bay and turn it into a port of refuge and emporium of trade. On the peak of San Marcos is the modern fortress erected to command all the approaches to San Sebastian and Pasages. The new town of Pasages contains liqueur factories, cellars for the preparation of wines, the famed "coupage" of the product of the French vineyards with strongly alcoholic Navarre and Aragon wines or alcohol now manufactured in Spain on a large scale. In 1897, 41,500 tons of British coal were landed at Pasages. Forty British vessels entered and cleared in the same year.

Pas-de-Calais, a department on the northern coast of France, bordering on the English Channel.

Area, 2606 square miles. From 819,022 in 1881 the population increased to 949,968 in 1901. Births in 1899, 28,384, of which 2994 were illegitimate; deaths, 19,119; marriages, 7809. There were in 1896, 1785 schools, with 158,000 pupils, the illiterate constituting 7 per cent. of the population. The area under cultivation measured (1896) 1,531,400 acres, of which 1,230,060 acres were plough-land. Wheat, which, relatively to its size, this department grows in considerably more than average quantity, returned in 1899 the value of £2,040,000; rye, £136,000; barley, £192,000; oats, £1,360,000; potatoes, £441,000; mangold-wurzel, £245,000; garden-poppy, £68,000; beetroot, £1,208,000; tobacco, £78,000; apples, £44,000. The live stock comprised in 1899, 76,480 horses, 220,540 cattle, 217,650 sheep, 164,780 pigs, and 23,460 goats. The production of milk amounted (1899) to the value of £1,680,000. Pas-de-Calais surpasses all the other departments of France in the abundance and extent of its coalfields. In 1898 it produced not less than 12,800,000 metric tons of fuel, valued at £5,000,000, nearly half of the total output of France. Yet the industry in metals is much less active in this department than in Nord. Its production in 1898 amounted to 90,000 metric tons of cast-iron and 63,000 tons of steel, which, with the other minerals added, were valued at £995,000. The sugar refineries yielded in 1898, 1,820,000 cwt., and the distilleries 7,200,000 gallons of alcohol. Calais (population, 59,793 in 1901) is celebrated for its lace. Spinning is likewise a source of revenue to the department. Arras, the capital, had 25,813 inhabitants in 1901, and Boulogne 49,083 in the same year.

Pasewalk, a town of Prussia, province of Pomerania, 26 miles west-north-west of Stettin by rail. It is an old and historically interesting town, having been frequently burnt and sacked in the 17th and 18th centuries. A bronze statue was erected to the Emperor Frederick III. in 1895. It manufactures tobacco, beer, and iron, and has various mills. Population (1885), 9514; (1900), 10,300.

Pasig, a town on the Pasig river, near the Laguna de Bay, Luzon, Philippine Islands. It was almost completely destroyed by fire in 1899 during the insurrection, but has since been rebuilt, and was made the capital of the province of Manila in June 1901. It is an important commercial centre for the whole lake region, as its inhabitants are largely engaged in transporting the products of the neighbouring towns to Manila. Large quantities of fresh-water fish are taken in the shallow waters of the marshes. Although built on low ground, the town is fairly healthy. The language is Tagalog. Population, 22,000.

Passaglia, Carlo (1812–1887), Roman Catholic divine, was born at Lucca on 2nd May 1812. Passaglia was soon destined for the priesthood, and was placed under the care of the Jesuit body at the age of fifteen. He became successively Doctor in Mathematics, Philosophy, and Theology in the University of Rome. In 1844 he was made professor in the Collegio Romano, the well-known Jesuit college in Rome. In 1845 he took the vows as a member of the Jesuit order. In 1848, during the expulsion of the Jesuits from Rome which followed on the revolutionary troubles in the Italian peninsula, he paid a brief visit to England. On his return to Italy he founded, with the assistance of Father Curci and Robert Tapparelli d'Azeglio, the celebrated organ of the Jesuit order entitled the *Civiltá Cattolica*. In 1854 came the decision of the Roman Church on the long-debated question of the Immaculate Conception of the Virgin. Into the agitation for the promulgation of this dogma Passaglia threw himself with great eagerness, and by so doing recommended himself strongly to the then Pope, Pius IX. But his favour with the Pope was of short duration. In 1859, when the war between Austria and France (the first step towards the unification of Italy) broke out, Passaglia espoused the popular side. He took refuge at Turin, and under the influence of Cavour he wrote an *Epistola ad Episcopos Catholicos pro causa Italica*, in which, like Liverani before him, he boldly attacked the temporal power of the Pope. For this he was expelled from the order of Jesuits, his book was put on the *Index*, and his figure struck out, by the Pope's order, from a picture painted to commemorate the proclamation of the Dogma of the Immaculate Conception. A refuge from the anger of the Pope was afforded him in the Casa Cavour, of Turin, the house in which Cavour was born. There he laboured for Italian unity with indomitable energy in the north of Italy, in conjunction with Cardinal d'Andrea in the south, and he collected the signatures of 9000 priests to an address to the Pope in opposition to the temporal power, and in favour of abandoning all resistance to the union of Italy under a king of the House of Savoy. He and the 9000 priests were excommunicated on 6th October 1862. Passaglia disregarded his excommunication, and continued his work as professor of moral philosophy at Turin, to which he had been appointed in 1861, and commenced a series of Advent addresses in the church of San Carlo at Milan. But on arriving in order to preach his second sermon, he found himself met by an inhibition on the part of Mgr Caccia, the administrator of the archdiocese of Milan. Elected deputy in the Italian Parliament, he still advocated strongly the cause of Italian independence, and at a later period wrote a defence of the rights of the Episcopate under the title of *La causa di sua eminenza il Cardinale d'Andrea*. He also (1864) wrote against Renan's *Vie de Jésus*. The later years of his life were spent in obscurity. Eight days before his death he endeavoured to be reconciled to the Pope, and made a full retractation. He died at Turin, 12th March 1887. (J. J. L*.)

Passaic, a city of Passaic county, New Jersey, U.S.A., on the west bank of the Passaic river, in the north-eastern part of the state, at an altitude of 100 feet. Its site is hilly and its plan irregular. It is divided into four wards, and has a water-supply derived from Passaic river above the falls. In 1900 it contained 185 manufacturing establishments, employing 7102 hands, and having a capital of $23,279,421 and an output valued at $14,031,254. To some extent it serves as a residence suburb to New York. Population (1880), 6532; (1890), 13,028; (1900), 27,777, of whom 12,900 were foreign-born and 443 negroes. There were 9274 persons of school age (5 to 20 years). Of 7552 males, 21 years of age and over, 1011 were illiterate (unable to write).

Passau, a town and episcopal see of Bavaria, Germany, district of Lower Bavaria, on both banks of the Danube, at the confluence of the rivers Inn and Ilz, 74 miles by rail south-east of Ratisbon. The towers of the cathedral were finished in 1896–98. The church of St Gertrude, in Innstadt, restored in 1888; the votive church (1564), restored in 1864; the pilgrimage church of Our Lady of Succour; and St John's Hospital church, with its wood carvings, are all noteworthy. The town hall was enlarged in 1888–93. Two scholastic institutes of the English Sisters, an agricultural school, a textile school, and a theological seminary are the chief educational institutions. Population (1885), 15,583; (1900), 17,988.

Pastel.—Since 1870 there has been a revival of the art of pastel, the result of a better understanding and appreciation on the part of the public. Grimm's denunciation of it to Diderot—"every one is agreed that pastel is unworthy the notice of a great painter"—which for many years found general acceptance, is now seen to have been based on ignorance of the virtues of the method. Artists have always recognized its beauties, but the prejudice and indifference of the public and even of "connoisseurs" had up to recent years rendered fruitless their efforts to restore its practice. It was thought that "coloured chalks," as it used to be called, promised nothing but sketches of an ephemeral kind, so fragile that they were at the mercy of every chance blow or every touch of dampness. The fact is, that with care no greater than is accorded to every work of art, pastel properly used is not more perishable than the oil-painting or the water-colour. Damp will affect it seriously, but so also will it ruin the water-colour; and violence is to be feared for the oil-picture not less than for the pastel. Moreover, pastel possesses advantages that can be claimed by neither oil-painting nor water-colour. That is to say, if pictures in these three mediums be hung side by side for a hundred years in a fair light and in a dry place, the oil-painting will have darkened and most probably have cracked; the water-colour will have faded; but the pastel will remain as bright, fresh, and pure as the day it was painted. If Time and Varnish, which Hogarth and Millais declared the two greatest of the old masters, will do nothing to "improve" a pastel, neither will they ruin it; so that the pastel-painter, having no adventitious assistance to hope for, or to fear, must secure at once the utmost of which his method is capable.

The advantages of pastel are threefold: those of working, those of results, and those of permanence. The artist has at his command, without necessity of mixing his colours, every hue to be found in nature, so that freshness and luminosity can always be secured without fear of that loss of brilliancy commonly attendant on the mixing of colour on the palette. Moreover, the fact of pastel being dry permits the artist to leave his work and take it up again as he may choose; and he is free from many of the technical troubles and anxieties natural to oil and water-colour painting. Applied with knowledge, pastel, which has been likened for delicacy of beauty to "the coloured dust upon the velvet of butterflies' wings," will not fall off. It can, if desired—though this is hardly necessary or even desirable—be "fixed," most commonly by a *fixatif*. If intending so to treat his work, the artist must paint in a somewhat lighter key, as the effect of the fixing medium is slightly to lower the general tone. But whether it be fixed or left unfixed, the unfettered artist who employs pastel has been enabled to enjoy the advantages it offers of rapidity, spontaneity, directness, adaptability, and variety—conveniences to be sought for in vain in other colour mediums.

The inherent qualities of pastel are those of charm, of subtlety, softness, and exquisite depths of tone, unsurpassable harmonies and unique freshness of colour, sweetness, delicacy, mystery—all the virtues sought for by the artist of daintiness and refinement. Pastel-painting is essentially, therefore, the art of the colourist. Now, these very qualities suggest its limitations. Although it is unfair to relegate it—as fashion has foolishly done for so long—to the bunch of pretty triflings which Carlyle called "Pompadourisms," we must recognize that a medium which suggests the bloom upon the peach is not proper to be employed for rendering "grand," or even *genre* subjects, or for the covering of large surfaces of canvas. It is inappropriate to the painting of classic compositions.

although in point of fact it has been so used, not without success. It is best adapted to the rendering of still life, of landscape, and of portraiture. But in these cases it is not advisable to aim at that solidity which is the virtue of oil-painting, if only because oil can bring about a better result. The real reason is that, in securing solidity, pastel tends to forfeit that lightness and grace which constitute its especial charm and merit. Strength belongs to oil, tenderness and subtlety to pastel, together with freshness and elegance.

The pre-eminent technical advantage, in addition to those already mentioned, is the permanence of the tones. In water-colours there is an admixture of gum and glycerine which may attract moisture from the air; and, besides, the pigment is used in very thin washes. In oil-painting, not only does the oil darken with age, but sometimes draws oxygen from a pigment and changes its hue. In pastel the colour is put on without any moist admixture, and can be laid on thick. Moreover, the permanence may arise from the method of manufacture. In a very rare work, *The Excellency of the Pen and Pencil* (1668), a chapter on "how to make pastils" (*sic*) "of several colours, for drawing figure, landskip, architecture, &c., on blew paper," describes the manner of grinding up the pigments with grease. This used to be the secret of pastel—that every grain of colour was separately and securely locked up in grease, and so was rescued from any chemical change that might have come about through contact of the colours with one another or with the atmosphere. Thus, for example, if in water-colour indigo be mixed with Indian red (as for the painting of a sky), in course of time the indigo will be chased off the paper and a red sky be left. This is often seen in the works of the earlier water-colour painters. With pastel nothing of the kind could occur; and the works of Quentin Latour, Perroneau, Watteau, St Jean, and Chardin, in France, and Russell and Cotes, in England—to name no others—testify to the permanency of the colours. Some manufacturers nowadays employ gum as the binding medium; others beeswax (which at one time was more frequently used than it is at present); others, again, a very small proportion of tallow, and sometimes a little soap. But this introduction of binding medium is now adopted only in the case of certain colours. Whether the point or edge of the stick be used (as in pastel *drawing*), or the side of it, helped with the tips of the fingers (as in pastel *painting*), the result is equally permanent; and if, when the work is done, it be struck two or three times, and then touched up by hand-crayons, no dropping of colour from the paper will ever occur. The drawing is made on a grained paper that will hold the chalk, or on a specially manufactured toothed cloth. The crisp touches of the pastel can be placed side by side, or the "vibrations" which the artist seeks may be obtained by glazes and superposed tones.

The art of pastel, as M. Roger Ballu expressed it, "was slumbering a little," until in 1870 the Société des Pastellistes was founded in France and met with ready appreciation. With many artists it was a matter of "coloured chalks," as, for example, with Millet, Lhermitte, and Degas in France, and with Whistler in England. With the majority the full possibilities were seized, and a great number of artists abroad then practised the art for the sake of colour, among whom may be mentioned Adrien Moreau, A. Besnard, Émile Lévy, Machard, Pointelin, Georges Picard, Iwill, René Billotte, and Lévy-Dhurmer, in France; in Belgium, Émile Wauters (who has produced a great series of life-sized portraits of amazing strength, vitality, and completeness) and Fernand Khnopff; in Italy, C. Laurenti, P. Fragiacomo, and the late Giovanni Segantini; in Holland, Josselin de Jong; in Germany, F. von Lenbach, Max Liebermann, and Franz Stück; and in Norway, Fritz Thaulow.

In England the revival of pastel dates from 1880, when the first exhibition of the Pastel Society was held in the Grosvenor Gallery. The exhibition was a *succès d'estime*, but after a while the society languished until, in 1899, it was reconstituted, and obtained the adhesion of many of the most distinguished artists practising in the country, as well as of a score of eminent foreign painters. In that year, and since, it has held exhibitions of a high order, and intelligent public appreciation has been directed to the work of the most noteworthy contributors. Among these are E. A. Abbey, R.A., M'Lure Hamilton, J. M. Swan, A.R.A., J. Lorimer, R.S.A., A. Peppercorn, Anning Bell, J. J. Shannon, A.R.A., James Guthrie, H. Brabazon, Walter Crane, Melton Fisher, Edward Stott, S. J. Solomon, A.R.A., and W. Rothenstein.

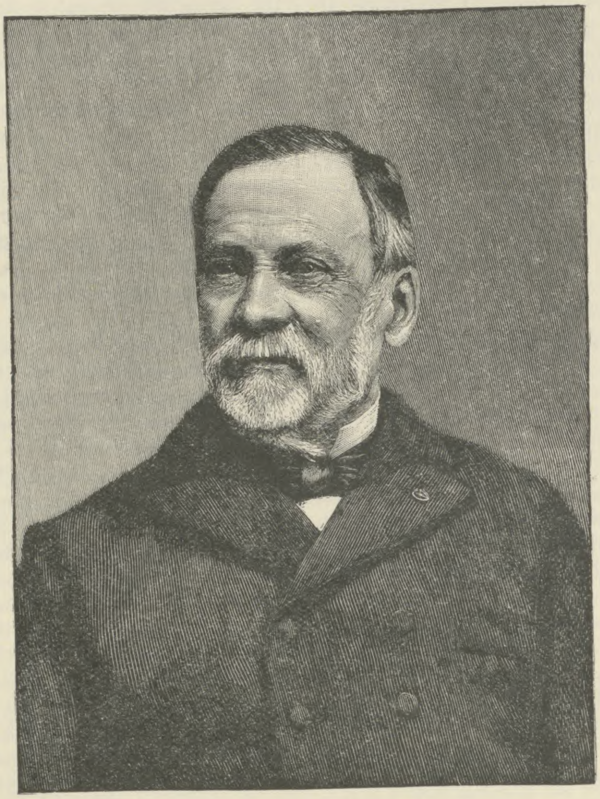
Pasteur, Louis (1822–1895), French chemist, was born, on 27th December 1822, at Dôle, Franche Comté, where his father carried on the business of a tanner. Shortly afterwards the family Pasteur removed to Arbois, where Louis attended the école primaire, and later the "collège" of that place. Here he apparently did not especially distinguish himself, belonging to the class of "bons ordinaires." Fortunately at Arbois he came under the influence of an excellent teacher in the person of the director of the "collège," who must have discerned in the quiet boy the germs of greatness, as he constantly spoke to him of his future career at the École Normale in Paris. In October 1838 Louis was sent with a friend to the metropolis, to a school in the Quartier Latin, preparatory to the École Normale. But he did not remain long in Paris, for, being a nervous and excitable boy, his health broke down, and he yearned for his home in Franche Comté. "If only I could smell the tannery once more," said he to his companion, "I should feel well." So home he went, though not for long, as his ambition was still to become a "normalien," and to this end he entered the Royal College of Besançon, "en attendant l'heureux jour où je serai admis à l'École Normale." Step by step he attained his end; in 1840 he won his "bachelier ès lettres," and shortly afterwards he received an appointment as assistant mathematical master in the college. Two years later he passed the examination for the "bacalaureat ès sciences" enabling him to become candidate for the École Normale. But here something (probably the examiner) was at fault, for a note was attached to Pasteur's diploma stating that he was only "mediocre" in chemistry. In those early days and early trials the dominant note of Pasteur's life was sounded. To his sisters he writes: "Ces trois choses, la volonté, le travail, le succès, se partagent toute l'existence humaine. La volonté ouvre la porte aux carrières brillantes et heureuses; le travail les franchit, et une fois arrivé au terme du voyage, le succès vient couronner l'œuvre." Throughout his life, and to the very end, "work" was his constant inspiration. On his deathbed he turned to the devoted pupils who watched over their master's last hours. "Où en êtes-vous?" he exclaimed, "Que faites-vous?" and ended by repeating his favourite words, "Il faut travailler."

The first incentive to his serious study of chemistry was given by hearing Dumas, the most celebrated chemist of the time, lecture at the Sorbonne; and ere long he broke new ground for himself, Balard having given him an opportunity for chemical work by appointing him to the post of laboratory assistant. A few words of explanation concerning Pasteur's first research are necessary to give the key to all his future work. What was the secret power which enabled him to bring under the domain of scientific laws phenomena of disease which had so far baffled human endeavour? It simply consisted in the application to the elucidation of these complex problems of the exact methods of chemical and physical research. Perhaps the most remarkable discovery of modern chemistry is the existence of compounds, which, whilst possessing an identical composition, are absolutely different bodies, judged of by their properties. The first of the numerous cases of isomerism now known was noted, but unexplained, by Berzelius. It was that of two tartaric acids, deposited from wine-lees. The different behaviour of these two acids to a ray of polarized light was subsequently observed by Biot. One possessed the power of turning the plane of the polarized ray to the right; the other possessed no rotary power. Still no explanation of this singular fact was forthcoming, and it was reserved for the young chemist from Franche Comté to solve a problem which had baffled the greatest chemists and physicists of the time. Pasteur proved that the inactivity of the one acid depended upon the fact that it was composed of two isomeric constituents: one the ordinary or dextro-rotary acid, and the other a new acid which possessed an equally powerful left-handed action. The veteran Biot, whose acquaintance Pasteur had made, was incredulous. He insisted on the repetition of the experiment in his presence; and when convinced of the truth of the explanation he exclaimed to the discoverer, "Mon cher enfant, j'ai tant aimé les sciences dans ma vie que cela me fait battre le cœur." Thus at one step Pasteur gained a place of honour among the chemists of the day, and was immediately appointed professor of chemistry at the Faculté of Science at Strasburg, where he soon afterwards married Mlle Laurent, who proved herself to be a true and noble helpmeet. Next he sought to prepare the inactive form of the acid by artificial means; and after great and long-continued labour he succeeded, and was led to the commencement of his classical researches on fermentation, by the observation that when the inactive acid was placed in contact with a special form of mould (*penicillium glaucum*) the right-handed acid alone was destroyed, the left-handed variety remaining unchanged. So well was his position as a leading man of science now established that in 1854 he was appointed professor of chemistry and dean of the Faculté des Sciences at Lille. In his inaugural address he used significant words, the truth of which was soon manifested in his case, "In the field of observation chance only favours those who are prepared." The diseases or sicknesses of beer and wine had from time immemorial baffled all attempts at cure. Pasteur one day visited a brewery containing both sound and unsound beer. He examined the yeasts under the microscope, and at once saw that the globules from the sound beer were nearly spherical, whilst those from the sour beer were elongated; and this led him to a discovery, the consequences of which have revolutionized chemical as well as biological science, inasmuch as it was the beginning of that wonderful series of experimental researches in which he proved conclusively that the notion of spontaneous generation is a chimera. Up to this time the phenomenon of fermentation was considered strange and obscure. Explanations had indeed been put forward by men as eminent as Berzelius and Liebig, but they lacked experimental foundation. This was given in the most complete degree by Pasteur. For he proved that the various changes occurring in the several processes of fermentation—as, for example, in the vinous, where alcohol is the chief product; in the acetous, where vinegar appears; and in the lactic, where milk turns sour—are invariably due to the presence and growth of minute organisms called ferments. Exclude every trace of these organisms, and no change occurs. Brewers' wort remains unchanged for years, milk keeps permanently sweet, and these and other complex liquids remain unaltered when freely exposed to air from which all these minute organisms are removed. "The chemical act of fermentation," writes Pasteur, "is essentially a correlative phenomenon of a vital act beginning and ending with it."



Louis Pasteur.
(From a photograph by Pierre Petit et Fils, Paris.)

But we may ask, as Pasteur did, why does beer or milk become sour on exposure to ordinary air? Are these invisible germs which cause fermentation always present in the atmosphere? or are they not generated from the organic, but the non-organized constituents of the fermentable liquid? In other words, are these organisms not spontaneously generated? The controversy on this question was waged with spirit on both sides; but in the end Pasteur came off victorious, and in a series of the most delicate and most intricate experimental researches he proved that when the atmospheric germs are absolutely excluded no changes take place. In the interior of the grape, in the healthy blood, no such germs exist; crush the grape, wound the flesh, and expose them to the ordinary air, then changes, either fermentative or putrefactive, run their course. But place the crushed fruit or the wounded animal under conditions which preclude the presence or destroy the life of the germ, and again no change takes place; the grape juice remains sweet and the wound clean. The application of these facts to surgical operations has, in the able hands of Lister, been productive of the most beneficent results, and has indeed revolutionized surgical practice.

Pasteur was now the acknowledged head of the greatest chemical movement of the time, the recipient of honours both from his own country and abroad, and installed at the École Normale in Paris in a dignified and important post. Not, however, was it without grave opposition from powerful friends in the Academy that Pasteur carried on his work. Biot—who loved and admired him as a son—publicly announced that his enterprise was chimerical and the problem insoluble; Dumas evidently thought so too, for he advised Pasteur not to spend more of his time on such a subject. Yet he persevered: "Travailler, travailler toujours" was his motto, and his patience was rewarded by results which have not merely rendered his name immortal, but have benefited humanity in a way and to a degree for which no one could have ventured to hope. To begin with a comparatively small, though not unimportant, matter, Pasteur's discoveries on fermentation inaugurated a new era in the brewing and wine-making industries. Empiricism, hitherto the only guide, if indeed a guide at all, was replaced by exact scientific knowledge; the connexion of each phenomenon with a controllable cause was established, and rule of thumb and quackery banished for ever by the free gift to the world of the results of his researches.

But his powers of patient research and of quick and exact observation were about to be put to a severe test. An epidemic of a fatal character had ruined the French silk producers. Dumas, a native of the Alais district, where the disease was rampant, urged Pasteur to undertake its investigation. Up to that time he had never seen a silkworm, and hesitated to attempt so difficult a task; but at the reiterated request of his friend he consented, and in June 1865 went to the south of France for the purpose of studying the disease on the spot. In September of the same year he was able to announce results which pointed to the means of securing immunity from the dreaded plague. The history of this research, of the gradual elimination of the unimportant conditions, of the recognition of those which controlled the disease, is one of the most fascinating chapters of scientific discovery. Suffice it here to say that careful experiment and accurate observation succeeded in ascertaining the cause of the disease and in preventing its recurrence, thus bringing back to prosperity the silk trade of France, with all that this entails. "There is no greater charm," says Pasteur, "for the investigator than to make new discoveries; but his pleasure is heightened when he sees that they have a direct application to practical life." Pasteur had the good fortune, and just reward, of seeing the results of his work applied to the benefit both of the human race and of the animal world. The starting-point of all his investigations in preventive medicine was the original observation of Jenner, that of vaccination, or the replacement of a slight disease for a serious one, by which the subject was rendered immune. But Jenner's discovery was up to recent times an isolated one, and it is to Pasteur that the world is indebted for the generalization of Jenner's discovery, and for the introduction of methods which have already worked wonders, and bid fair to render possible the preventive treatment of all infectious diseases. Just as each kind of fermentation possesses a definite organized ferment, so each disease is dependent on the presence of a distinct microbe; and just as the gardener can pick out and grow a given plant or vegetable, so the bacteriologist can (in most cases) eliminate the adventitious and grow the special organism—in other words, can obtain a pure cultivation which has the power of bringing about the special disease. But by a process of successive and continued artificial cultures under different conditions, the virus of the organism is found to become attenuated; and when this weakened virus is administered, only a slight attack of the disease occurs, but the animal is rendered immune from further attacks. The virus has become a vaccine. The first disease investigated by Pasteur was that of chicken cholera, an epidemic which destroyed 10 per cent. of the French fowls; after the application of the preventive method the death-rate was reduced to below 1 per cent. Next came the successful attempt to deal with the fatal cattle scourge known as anthrax. This is also caused by the presence of a microbe, of which the virus can also be attenuated, and by inoculation of this weakened virus the animal rendered immune. Many millions of sheep and oxen all over the world have thus been treated, and the rate of mortality reduced from 10 to less than 1 per cent. As to the money value of these discoveries, Huxley has given it as his opinion that it was sufficient to cover the whole cost of the war indemnity paid by France to Germany in 1870.

The most interesting of Pasteur's investigations in preventive and curative medicine remains to be told. It is no less than a cure for the dread disease of hydrophobia in man and of rabies in animals; and the interest of the achievement is not only that he successfully combated one of the most mysterious and most fell diseases to which man is subject, but also that this was accomplished in spite of the fact that the special microbe causing the disease has not been isolated. To begin with, Pasteur, in studying the malady in dogs, came to the conclusion that the virus had its seat in the nerve centres, and he proved that the injection of a portion of the matter of the spinal column of a rabid dog into the body of a healthy one produces in the latter with certainty the symptoms of rabies. The next step was to endeavour so to modify and weaken the virus as to enable it to be used as a preventive or as an antitoxin. This, after long and serious labour, he effected: the dog thus inoculated proved to be immune when bitten by a rabid animal. But this was not enough. Would the inoculation of the attenuated virus have a remedial effect on an animal already bitten? If so, it might be possible to save the lives of persons bitten by mad dogs. Here again experiment was successful. A number of dogs were inoculated, the same number were untreated, and both sets were bitten by rabid animals. All the treated dogs lived; all the untreated died from rabies. It was, however, one thing to experiment on dogs, and quite another to do so on human beings. Nevertheless Pasteur was bold enough to try. The trial was successful, and by doing so he earned the gratitude of the human race. Then the Institut Pasteur was founded. Thousands of people suffering from bites from rabid animals, from all lands, have been treated at this institute, and the death-rate from this most horrible of all diseases has been reduced to less than 1 per cent. Not only in Paris, but in many cities throughout the world, institutes on the model of the original one have been set up and are doing beneficent work, all arising from the genius and labours of one man. At the inauguration of the institute Pasteur closed his oration with the following words:—

"Two opposing laws seem to me now in contest. The one, a law of blood and death, opening out each day new modes of destruction, forces nations to be always ready for the battle. The other, a law of peace, work, and health, whose only aim is to deliver man from the calamities which beset him. The one seeks violent conquests, the other the relief of mankind. The one places a single life above all victories, the other sacrifices hundreds of thousands of lives to the ambition of a single individual. The law of which we are the instruments strives even through the carnage to cure the wounds due to the law of war. Treatment by our antiseptic methods may preserve the lives of thousands of soldiers. Which of these two laws will prevail? God only knows! But of this we may be sure, that science, in obeying the law of humanity, will always labour to enlarge the frontiers of life."

Rich in years and in honours, but simple-minded and affectionate as a child, this great benefactor to his species passed quietly away near St Cloud on 28th September 1895.

Mention need only be made of Pasteur's chief works, as follows:—*Études sur le vin* (1866), *Études sur le vinaigre* (1868), *Études sur la maladie des vers à soie* (1870), *Études sur la bière* (1876). He began the practice of inoculation for hydrophobia in 1885.

See *Vie de Pasteur*, par René Vallerey-Radot. Hachette. Paris, 1900. (H. E. R.)

Patagonia, the name given to that portion of South America which, to the east of the Andes, lies south of the Rio Negro (41° S.), and to the west of the Andes, south of the Chilian province of Chiloe (42° S.). The Chilian portion embraces the two provinces of Llanquihué and Magallanes. East of the Andes the Argentine portion of Patagonia is divided into four territories, viz. :—(1) Neuquen, 80,000 square miles approximately, with 9261 inhabitants in 1895, formed by a portion of the triangle situated to the west of the rivers Limay and Neuquen, between the northern shore of Lake Nahuel-Huapi (41° S.) and Rio Barrancas (37° S.); (2) Rio Negro, 44,000 square miles approximately, with a population of 14,517 in 1895, extending from the Atlantic to the Cordillera of the Andes, to the north of 42° S.; (3) Chubut, 95,000 square miles approximately, with a population of 3748 (1895), embracing the regions between 42° and 46° S.; and (4) that portion of the province of Santa Cruz which stretches from the last-named parallel as far south as the dividing line with Chile, and between Dungeness Point and the water-shed of the Cordillera, an area approximately of 106,000 square miles, with a population (1895) of 1058. The general character of the Argentine portion of Patagonia is for the most part a region of vast steppe-like plains rising in a succession of abrupt terraces about 300 feet at a time, and covered with an enormous bed of shingle almost bare of vegetation. This peculiar tract of shingle is of Tertiary marine origin, and has been designated by geologists the Patagonian formation. Beneath the shingle is a vast deposit of sands and clays of marine and lacustrine origin, and volcanic lavas and tuffs. In the hollows of the plains are ponds or lakes of brackish and fresh water. Towards the Andes the shingle gives place to porphyry, granite, and basalt lavas, animal life becomes more abundant and vegetation more luxuriant, acquiring the characteristics of the flora of the western coast, principally the beech and conifers.

Exploration.

Since 1880 explorations of a scientific character have been carried on in both the interior and coast regions of Patagonia by Moreno, Moyano, Rogers, Lista, Bertrand, Ziemiradzky, Steffen, Kruger, Stange, Hauthal, Wherti, Burckhardt, Nordenskiöld, Hatcher, and the surveyors of the Argentine and Chilian Boundary Commissions, and an appreciable modification of current ideas has been effected. Although the general character of the country is that of table-land, diversified by the beds of former lakes and rivers, the examination of the region close to the Cordillera has revealed striking features that give it a peculiar and interesting character.

Physiography.

Among the depressions by which the plateau is intersected transversely, the principal is the Hualichu, south of the Rio Negro, the Maquinchau and Balcheta (through which previously flowed the waters of Lake Nahuel-Huapi, which now feed the river Limay); others between the latter and the Chubut, Senguerr, Chico, Deseado; others between the Desire and the San Julian, now totally disappeared, the Shehuen depression, and those of Santa Cruz—Coile and Gallegos. Besides these transverse depressions (some of them marking lines of ancient inter-oceanic communication), there are others which were occupied by more or less extensive lakes, such as the Yagagtoo, Musters, and Colhue, and others situated to the south of Port Desire, in the centre of the country. Over the greater part of its surface the plateau is covered by a loose glacial, and in some parts fluvio-glacial, gravel, which barely supports the growth of herbage. Good pastures are found only on the watered lowlands, where bushes are more numerous, and where, by irrigation, extensive areas can be cultivated, and in the neighbourhood of the Andes, where are situated extensive tracts of land suitable for cultivation. In the central region volcanic eruptions, which have taken part in the formation of the plateau from the Tertiary period down to the present era, cover a large part with basaltic lava-caps; and in the western third more recent glacial deposits appear above the lava. There, in contact with folded Cretaceous rocks, uplifted by the Tertiary granite, erosion, caused principally by the sudden melting and retreat of the ice, aided by tectonic changes, has scooped out a deep longitudinal depression, which generally separates the plateau from the first lofty hills, the ridges generally called the Pre-Cordillera, while on the west of these there is a similar longitudinal depression all along the foot of the snowy Andean Cordillera. This latter depression contains the richest and most fertile land of Patagonia.

Geology.

The geological constitution is in accordance with the orographic physiognomy. The Tertiary plateau, flat on the east, gradually rising on the west, shows Upper Cretaceous caps at its base. First come Lower Cretaceous hills, raised by granite and dioritic rocks, undoubtedly of Tertiary origin, as in some cases these rocks have broken across the Tertiary beds, so rich in mammal remains; then follow, on the west, metamorphic schists of uncertain age; then quartzites appear, resting directly on the primitive granite and gneiss which form the axis of the Cordillera. Porphyritic rocks occur between the schists and the quartzites. These Upper Cretaceous and Tertiary deposits have revealed a most interesting vertebrate fauna. These, together with the discovery of the perfect cranium of a chelonian of the genus *Myolania*, which may be said to be almost identical with *Myolania oweni* of the Pleistocene age in Queensland, form an evident proof of the connexion between the Australian and South American continents. The Patagonian *Myolania* belongs to the Upper Chalk, having been found associated with remains of *Dinosauria*. Other specimens of the interesting fauna of Patagonia, belonging to the Middle Tertiary, are the gigantic wingless birds, exceeding in size any hitherto known, and the singular mammal *Pyrotherium*, also of very large dimensions. In the Tertiary marine formation a considerable number of cetaceans has been discovered. In deposits of much later date, formed when the physiognomy of the country did not differ materially from that of the present time, there have been discovered remains of pampean mammals, such as *Glyptodon* and *Macrauchenia*, and in a cave near Last Hope Inlet, a gigantic ground sloth (*Grypotherium listai*), an animal which lived contemporaneously with man, and whose skin, well preserved, showed that its extermination was undoubtedly very recent. With the remains of *Grypotherium* have been found those of the horse (*Onoshippidium*), which are known only from the lower pampas mud, and of the *Arctotherium*, which is found, although not in abundance, in even the most modern Pleistocene deposits in the pampas of Buenos Aires. It would not be surprising if this latter animal were still in existence, for footprints, which may be attributed to it, have been observed on the borders of the rivers Tamango and Pista, affluents of the Las Heras, which run through the eastern foot-hills of the Cordillera in 47° S. Glaciers occupy the valleys of the main chain and some of the lateral ridges of the Cordillera, and descend to lakes San Martin, Viedma, Argentino, Dickson, Hauthal, and Tyndall, strewing them with icebergs. Several of the high peaks are still active volcanoes, amongst which may be mentioned three that have not been definitely located, or are little known, viz., one which, according to the Indians, is situated to the west of Lake Dickson; the second is Fitzroy volcano; and the third lies about 47° 30′ S., and was observed from the sea by the Argentine vessel *Azopardo*. In Patagonia an immense ice-sheet extended to the east of the present Atlantic coast during the first ice age, at the close of the Tertiary epoch, while, during the second glacial age in modern times, the terminal moraines have generally stopped, 30 miles in the north and 50 miles in the south, east of the summit of the Cordillera. These ice-sheets, which scooped out the greater part of the longitudinal depressions, and appear to have rapidly retreated to the point where the glaciers now exist, did not, however, in their retirement fill up with their detritus the fjords of the Cordillera, for these are now occupied by deep lakes on the east, and on the west by the Pacific channels, some of which are as much as 250 fathoms in depth, and soundings taken in them show that the fjords are deeper in the vicinity of the mountains than to the west of the islands. In so far as its main characteristics are concerned, Patagonia seems to be a portion of the Antarctic continent, the permanence of which dates from very recent times, as is evidenced by the apparent recent emergence of the islets around Chiloe, and by the general character of the pampean formation. Some of the promontories of Chiloe are still called "huapi," the Araucanian equivalent for "islands"; and this may perhaps be accepted as perpetuating the recollection of the time when they actually were islands. They are composed of caps of shingle, with great, more or less rounded boulders, sand, and volcanic ashes, precisely of the same form as occurs on the Patagonian plateau. From an examination of the pampean formation it is evident that in recent times the land of the province of Buenos Aires extended farther to the east, and that the advance of the sea, and the salt-water deposits left by it when it retired, forming some of the lowlands which occur on the littoral and in the interior of the pampas, are much more recent phenomena; and certain caps of shingle, derived from rocks of a different class from those of the neighbouring hills, which are observed on the Atlantic coasts of the same province, and which increase in quantity and size towards the south, seem to indicate that the caps of shingle which now cover such a great part of the Patagonian territory recently extended farther to the east, over land which has now disappeared beneath the waves, from which it formerly emerged, while other marine deposits along the same coasts became converted into bays during the subsequent advance of the sea. There are besides, in the neighbourhood of the present coast, deposits of volcanic ashes, and the ocean throws up on its shores blocks of basaltic lava, which in all probability proceed from eruptions of submerged volcanoes now extinct. One fact, however, which apparently demonstrates with greater certainty the existence in recent times of land that is now lost, is the presence of remains of pampean mammals in Pleistocene deposits in the bay of San Julian and in Santa Cruz. The animals undoubtedly reached these localities from the east; it is not at all probable that they advanced from the north southwards across the plateau intersected at that time by great rivers and covered by the ice-sheet. With the exception of the discoveries at Last Hope Inlet, in close communication with the Atlantic valley of Gallegos, none of these remains have been discovered in the Andean regions.

On the upper plains of Neuquen territory thousands of cattle can be fed, and the forests around Lakes Traful and Nahuel-Huapi yield large quantities of valuable timber. The Neuquen river is not navigable, but as its waters are capable of being easily dammed in places, large stretches of land in its valley are utilized; but the lands on each side of its lower part are of little commercial value. As the Cordillera is approached the soil becomes more fertile, and suitable districts for the rearing of cattle and other agricultural purposes exist between the regions which surround the Tromen volcano and the first ridges of the Andes. Chosmalal, the capital of the territory, is situated in one of these valleys. More to the west is the mining region, as yet almost unexplored, but which contains deposits of gold, silver, copper, and lignite. In the centre of the territory, also in the neighbourhood of the mining districts, are the valleys of Norquin and Las Lajas, the general camp of the Argentine army in Patagonia, with excellent timber in the forest on the Andean slope. The regions of Las Lajas, Alumine, Pulmary, Rucachoroy, Quillen, Tromen, and Huechulafquen are extremely picturesque, being overlooked on the west by the snows of the Lonquimay, Villarica, Yaimas, Quetropillan and Lanin volcanoes, which are scored by deep ravines and their sides dotted with araucaria (*A. imbricata*) and an abundant crop of strawberries (*Fragaria chilensis*). The wide valleys occur near Rio Malleco, Lake Huechulafquen, the river Chimehuin, and Vega de Chapelco, near Lake Lacar, where are situated villages of some importance, such as Junin de los Andes and San Martin de los Andes. Close to these are the famous apple orchards supposed to have been planted by the Jesuits in the 17th and 18th centuries. These regions are drained by the river Collon-Cura, the principal affluent of the river Limay. Lake Lacar is now a contributary of the Pacific, its outlet having been changed to the west, owing to a passage having been opened through the Cordillera. To the south of the valley of the Chimehuin are the depressions of the rivers Caleufu and Traful, also tributaries of the Limay, which receive the waters of the eastern slope of the Cordillera and of Lakes Hermoso, Metiquina, Villarino, Falkner, Traful, and Tilohuehuen. Lakes Espejo and Carrentoso originally formed part of Lake Nahuel-Huapi, but now empty their waters into that lake by a narrow channel. The landscape around these lakes is very beautiful, and the forest very rich in timber.

Neuquen.

The Rio Negro runs along a wide transverse depression, now followed by the railway which goes to the confluence of the rivers Limay and Neuquen, and in this depression are several settlements, among them Viedma, the capital of the Rio Negro territory, Pringles, Conesa, Choele Choel and Roca. To the south of the Rio Negro the Patagonian plateau is intersected by the depressions of the Gualicho and Maquinchau, which in former times directed the waters of two great rivers (now disappeared) to San Antonio Bay, the first-named depression draining the network of the Collon-Cura and the second the Nahuel-Huapi lake system. To the south of the second of these valleys rises a volcanic plateau, with small craters perfectly preserved; and in the centre of the territory a longitudinal granite chain, with porphyritic trachitic rocks, runs southwards, being the end of the northern chains of central Argentina hidden under the Tertiary sandstone as far south as 38° S. This chain continues towards the centre of the Chubut territory, ending in porphyritic rocks at Atlas Point and Port Desire on the Atlantic coast. In the valleys and depressions amongst these rocks there are beautiful tracts of country, which are now beginning to be inhabited. In 42° S. there is a third broad transverse depression, apparently the bed of another great river, now perished, which carried to the Atlantic the waters of a portion of the eastern slope of the Andes, between 41° and 42° 30′ S. The soil of this depression close to the Atlantic, near the eruptive mountains of San Antonio, and of the central part is of relatively small value as pasturage, but towards the Cordillera the soil becomes richer and the scenery grand. The network of small lakes, *e.g.*, Hess, Fonck, Vidal Gormaz, Mascardi, Gutierrez, Guilielmo, Martin, and Steffen, survivals of a former extension of Lake Nahuel-Huapi, drain excellent districts, all alike picturesque, over the whole of the Valle Nuevo, which extends between Lake Nahuel-Huapi and Lake Puelo. In this region two recent breaches through the Andes carry off the waters of these eastern valleys to the Pacific.

Rio Negro.

Chubut territory presents the same characteristics as the Rio Negro territory. Rawson, the capital, is situated at the mouth of the river Chubut on the Atlantic (42° 30′ S.), and is connected by railway with Golfo Nuevo at Port Madrin. The town was founded in 1865 by a group of colonists from Wales, assisted by the Argentine Government; and its prosperity has led to the foundation of other important centres in the valley, such as Treleu and Gaiman. Here is the seat of the governor of the territory, and in 1895 the inhabitants of this part of the territory, composed principally of Argentines, Welsh, and Italians, numbered 2585. The valley has been irrigated and cultivated, and produces the best wheat of the Argentine Republic. At 75 miles from its mouth the river Chubut receives the Rio Chico del Chubut, which was formerly a considerable river, but is now diminished on account of the waters of the Rio Senguerr having ceased to feed it. The latter river is the outflow of Lakes La Plata and Fontana, and receives the waters of the rivers Tenca, Mayo, Chalia, and Guenguel. It is finally absorbed in Lakes Musters and Colhue, and from 1888 its flow into the Rio Chico grew gradually less and less, until in 1896 it ceased altogether. Between the Chubut and the Senguerr there are vast stretches of fertile land, spreading over the Andean region to the foot of the Cordillera and the lateral ridges of the Pre-Cordillera, and filling the basins of some desiccated lakes, which have been occupied since 1885, and farms and colonies founded upon them. The chief of these colonies is that of 16 de Octobre, formed in 1886, mainly by the inhabitants of Chubut colony, in the longitudinal valley which extends to the eastern foot of the Cordillera. In 1895 its population numbered 1164; they devote themselves to cattle-rearing and agriculture, for which some of the valleys are admirably adapted. Other rivers in this territory flow into the Pacific through breaches in the Cordillera, *e.g.*, the upper affluents of the Fetaleufu, Palena, and Rio Cisnes. The first is formed by the waters of the Cholila, Rivadavia, Fetalafquen, and other smaller lakes lying at the eastern foot of the main chain. To the north of these, and separated from them by an extensive moraine, lies Lake Epuyen, which empties into Lake Puelo and is the source of the river Puelo, which flows into the Pacific at Reloncavi Bay. Fetaleufu river also receives the Corinto river, which issues from the lateral cordon of the Andes and flows into the fluvio-glacial plains of Esquel through the valley of 16 de Octobre, which it also irrigates. The principal affluent of the Palena, the Carrenleufu, carries off the waters of Lake General Paz, situated on the eastern slope of the Cordillera. Rio Pico, an affluent of the same river and of the Rio Cisnes, receives nearly the whole of the waters of the extensive undulating plain which lies between the Rio Teka and the Rio Senguerr to the east of the Cordillera, whilst the remainder are carried away by the affluents of Rio Jehua, viz., the Cherque, Omkel, and Appeleg. This region, representing a pre-Glacial lacustrine basin, is being occupied by Argentine cattle-breeders. It likewise contains auriferous drifts, but these, like the auriferous deposits, veins of galena and lignite in the mountains farther west which flank the Cordillera, have not been properly investigated. At Lake Fontana there are auriferous drifts and lignite deposits which abound in fossil plants of the Cretaceous age. The Rio Senguerr, a river of considerable volume, but not navigable, flows out of this lake, and when it reaches the plain breaks up into a number of small channels. The valley of the Rio Verde, an affluent of the Senguerr, contains rich soil, and is the site of several prosperous Argentine farms. To the south of the Senguerr stretches the Patagonian plain in all its monotony, and there the continental watershed, which is distinct from and independent of the Cordillera, frequently changes, so that it is not possible to determine it with certainty. The streams which form the rivers Mayo and Chalia, affluents of the Senguerr, join the tributaries of the Rio Aisen, which flows into the Pacific, watering in its course extensive and valuable districts where colonization has been initiated by Argentine settlers. Colonies have also been formed in the basin of Lakes Musters and Colhue; and on the coasts near the Atlantic, between Bahia Camarones, Tilly Road, and the Gulf of Saint George, there are extensive farms.

Chubut.

The territory of Santa Cruz is arid along the Atlantic coast and in the central portion between 46° and 50° S. With the exception of certain valleys at Port Desire and in the transverse basins which occur as far south as Puerto San Julian, and which contain several cattle farms, few spots are capable of cultivation, the pastures being poor, water insufficient, and salt lagunas fairly numerous. Port Desire is the outlet for the produce of the Andean region situated between Lakes Buenos Aires and Pueyrredon. Into this inlet there flowed at the time of the conquest a voluminous river, which subsequently disappeared, but returned again to its ancient bed, owing to the river Fenix, one of its affluents, which

Santa Cruz.

had deviated to the west, regaining its original direction. Lake Buenos Aires, the largest lake in Patagonia, measuring 75 miles in length, poured its waters into the Atlantic even in post-Glacial times by means of the river Desire, and it is so depicted on the maps of the 17th and 18th centuries; and so too did Lake Pueyrredon, which, through the action of erosion, now empties itself westwards, through the river Las Heras, into the Calen inlet of the Pacific, in 48° S. Port San Julian, where Hernando de Magallanes wintered, has lately been colonized by cattle farmers, who are also pushing into the interior up the valley of a now extinct river which in comparatively recent times carried down to Port San Julian the waters of Lakes Volcan, Belgrano, Azara, Nansen, and of some other lakes which now drain into the river Mayer and so into Lake San Martin. The Rio Chico, which represents the large extinct river just mentioned, empties itself into Santa Cruz Bay a little to the south of San Julian, after receiving the Rio Shehuen, a former outlet of Lake San Martin and of Lake Viedma. The latter now sends its waters to Lake Argentino by the Rio Leona, while the waters of Lake San Martin pierce the Cordillera of the Andes and empty westwards into the southern arm of Calen inlet. The valleys of the Rio Chico throughout their whole extent, as well as those of Lake Shehuen, afford excellent grazing, and around Lakes Belgrano, Burmeister, and Rio Mayer and San Martin there are spots suitable for cultivation. In the Cretaceous hills which flank the Cordillera important lignite beds and deposits of mineral oils have been discovered. The Rio Santa Cruz, originally explored by Captain Fitzroy and Charles Darwin, is an important artery of communication between the regions bordering upon the Cordillera and the Atlantic. It has been ascended at various times in small craft to its source in Lake Argentino, and by the river Leona as far as Lake Viedma. Upon the southern border of Lake Argentino there are cattle-rearing settlements, as well as on the banks of the Rio Santa Cruz. In the bay an important trade centre has been established. But the present cattle region *par excellence* of Patagonia is the department of Rio Gallegos, the farms extending from the Atlantic to the Cordillera. Gallegos itself is an important business centre, which bids fair to rival the Chilian colony of Punta Arenas. The western region of this department, as well as the remainder of the Andean region, contains several lakes, the principal one being the picturesque Maravilla. The others, *e.g.*, Lakes Dickson, Nordenskiöld, Sarmiento, Paine, Hauthal, and Tyndall, are smaller. Glaciers come down to as far as the waters of the first two of these lakes, and the waters of the whole series are received by the Rio Serrano, which passes through the Cordillera from the east, by means of a narrow breach, to Last Hope Inlet. Owing to the produce of the cattle farms established there, the working of coal in the neighbourhood, and the export of timber from the surrounding forests, the town of Punta Arenas is in a flourishing condition. Its population numbers about 4000. But the colonization of the western (Chilian) coast has failed, principally owing to the adverse climatic conditions of the Cordillera in those latitudes.

Magallanes. In the extreme south (Magallanes) the existence of fossils and other features in the Cordillera similar to those in the more northern Andes gives support to the supposition that the upheaval of at least a portion of this territory took place at a very modern epoch; there is also additional evidence of this in the fact that the country at the present day differs from that depicted by the early navigators. The recent volcanic eruptions in this territory extend from 41° S. up to the straits in the same zone, Mount Aymond being the principal crater.

Natives. The natives of Patagonia are nearly extinct. Here and there one may find a Tehuelchian or Gennaken encampment, but natives of pure race are now very scarce, and the two races all told probably do not number more than 100 male individuals. The remaining population is composed of Araucanians, a mixture of the Tehuelches and Gennaken. But these are not the only type of people who have dwelt in Patagonia. The ancient burial-places have yielded the bones of other races quite distinct from the present inhabitants, some of them having greatly resembled the primitive types which are met with more to the north, in the Argentine Chaco and in Brazil; while others, again, strongly resembled certain of the Pacific races, in that they possessed ethnic characteristics which have not been observed elsewhere in South America. Among these remains every type of artificial deformity of the skull hitherto known has been found, while at the present time the natives only practise the occipital deformation which is so common among the western tribes of America.

Communications. Patagonia has ceased to be isolated from the rest of America, and the influx of population has led to navigation being established on the Rio Negro, on Lake Nahuel-Huapi, and on the Rio Santa Cruz; and communication is regularly maintained on the first-named river as far as the confluence of the Limay and the Neuquen, to which point also the railway reaches. The telegraph extends to Chosmalal, the capital of Neuquen territory, and to San Martin de los Andes on the west and to Bahia Camarones, near 46° S., and is being extended to the colony of 16 de Octobre and to Cape Virgenes, at the eastern entrance of Magellan Strait. As already mentioned, a small railway connects Puerto Madrin in Golfo Nuevo with Rawson. Between Buenos Aires and the principal ports of the Atlantic coast as far as Punta Arenas and Tierra del Fuego a monthly service of steamers exists, and surveys have been commenced for the laying of light railways between the port of San Antonio on the Atlantic coast to San Martin and Junin de los Andes, Nahuel-Huapi, and 16 de Octobre; also from Tilly Road in Saint George Gulf to Lake Buenos Aires and 16 de Octobre, and from Rio Gallegos up to the slope of the Cordillera. Various other parts are in communication by roads. Surveys for utilizing the waters of Lakes Nahuel-Huapi and Argentino for the irrigation of land near the Rio Negro and the Santa Cruz were made in 1898.

Patel, Framjee Nasarwanjee (1804–1894), Parsee merchant and philanthropist, was born in 1804, and had a sound vernacular education, with a smattering of English received during a short period of study in the then solitary English school in Bombay. At the age of fifteen he entered upon a business career, and its pursuit proved so congenial that by 1827 he had worked his way to a partnership in the firm of Frith, Bomanjee, and Co. The Parsees of those days evinced a great aptitude for commerce, and their simple manner of life, frugal habits, business capacity, and strict honesty made them desirable coadjutors with the mercantile firms which by that time had opened a regular and growing business with England. Banking facilities being then exceedingly scanty, such Parsees as had any capital at command acted as bankers and brokers to the rising English firms. Patel's experience enabled him in a few years to raise the status of his compatriots to the higher level of independent merchants, and he founded in 1844 a business house under the name of Wallace and Co., in which he was himself a partner with the English members of the firm. When he retired in 1858 he had amassed a large competence, and in the following year he established a firm on the same lines under the style of Framjee, Sands and Co., of which the members were some of his sons, together with English partners. This system of partnership with English merchants was a landmark in the business history of the Parsees, though it has not been much developed owing to the preference of the younger men for professional and official pursuits. The improvement effected in the commercial status of the Parsees in Bombay is none the less to the credit of Framjee Nasarwanjee Patel. It was, however, not so much for his success as a merchant, as for his spirit and liberality as an educationist, reformer, and philanthropist, that his name is notable in the annals of western India. He entered on his civic labours in 1837, and in all public movements figured prominently as an accredited representative of his community. As a pioneer of education, both for boys and girls, his example inspired the younger men of his time, like Dadabhoy Naoroji, formerly member of the Imperial Parliament for East Finsbury, and the late Naoroji Fardoonjee and Sorabjee Shapurjee Bengallee. When Mountstuart Elphinstone, during his governorship, conceived the idea of concentrating the literary and educational activity which had arisen from isolated efforts on the part of men who had themselves been brought into contact with Western culture, among his chief collaborators were Framjee Cowasjee Banajee and Framjee Patel. To their initiative was due the establishment of the Elphinstone Institution, which comprised a high school and, after some years, a college, which continue to hold foremost rank among the similar academies since established in western India. But Mr Patel's most remarkable public service was performed in connexion with the Parsee Law Association, of which he was president. Since their exodus from Persia the domestic affairs of the Parsees had been in a very unsettled state. Matrimonial obligations and the rights of succession in cases of intestacy had fallen into hopeless confusion, and the adjudication of disputes in relation thereto was effected by certain elders of the community, who had neither the knowledge and help of fixed principles to guide their judgments, nor any authority to enforce their decisions. The case of *Ardesir Cursetjee* v. *Peeroxebai*, which came up on appeal before the Privy Council in England, brought to light the strange fact that even the Supreme Court of Bombay had no jurisdiction over matrimonial and ecclesiastic disputes among Parsees. This state of lawlessness was recognized by that community as intolerable, and the agitation which ensued thereupon led to the appointment of a commission, of which the distinguished jurist Sir Joseph Arnould was the president and Mr Framjee Patel the chief Parsee member. The Parsee Law Association, under the guidance of Mr Patel and Mr Sorabjee Bengallee, rendered invaluable help to the commission, and their joint efforts resulted in the passing by the Government of India of the Parsee Marriage and Divorce Act and the Parsee Intestate Succession Act (15 and 21 of 1865). These Acts form the charter of matrimonial and ecclesiastical status for the Parsees. At the time of his death in 1894, at the ripe age of nearly ninety years, Mr Framjee Patel was the most revered and best beloved of the distinguished natives of India, having during an eventful public life extending over sixty years worked in co-operation with three generations of the most prominent of his compatriots to better the condition of their country. During that period Framjee Patel was *primus inter pares* among a succession of enlightened and public-spirited Parsees, who, under the guidance and encouragement of men like the Rev. Dr John Wilson, Sir Bartle Frere, and Sir George Birdwood, brought about the regeneration of the old civilization of western India by British methods. He thus fully justified the term applied to him by the last-named, in the dedication to him of his work on the old records of the India Office, of "the Nestor of the Parsees." His family surname refers to the title of Patel, that is, "Mayor," of Bombay, conferred on its founder for services rendered to the English in 1692. (M. M. BH.)

Patents (see also LETTERS PATENT).—In this article patents for inventions alone are considered. Few material alterations in the English law have been made since the article Patents in the ninth edition of this work was published, and the account there given of the subject-matter of valid letters patent, and of legal proceedings for the infringement and revocation of patents, is still substantially correct. But the following points deserve notice.

(i.) *Exhibitions.*—The exhibition of an invention at an industrial or international exhibition certified as such by the Board of Trade, or the publication of any description of the invention during the period of the holding of the exhibition, or its use for the purpose of the exhibition in the place where it is held, or during the period of the exhibition by any person elsewhere, without the privity or consent of the inventor, is not to prejudice the right of the inventor or of his legal personal representative to apply for and obtain a patent, or the validity of any patent granted on the application, provided that two conditions are complied with, viz., (*a*) the exhibitor must, before exhibiting the invention, give the Comptroller-General a prescribed notice of his intention to do so; and (*b*) the application for the patent must be made before or within six months from the date of the opening of the exhibition (Patents Act, 1883). The Patents Act, 1886, enables the Sovereign, by Order in Council, to extend the provision above mentioned to industrial and international exhibitions held out of the United Kingdom.

(ii.) *Prior Publication.*—Whereas "user" in public is sufficient prior publication to invalidate a subsequent patent for the invention so used, publication in books, &c., will not be a bar to novelty unless its effect is to make the invention actually a part of public knowledge; and in dealing with alleged anticipations by patents that have never come into general use the courts will not invalidate a subsequent patent unless a person of ordinary knowledge of the subject, on having the alleged anticipation brought under his notice, would at once perceive, understand, and be able practically to apply the invention without making experiments or seeking for further information.

(iii.) *Variance or Disconformity.*—Since the introduction of the patent specification, it has been necessary that an invention protected by patent should be accurately described by the inventor. Formerly, when the condition on which letters patent issued was that the patentee should file a specification completely describing the nature of his invention within a certain time after the grant, the function of giving the necessary preliminary information on the subject was to some extent discharged by the title; at any rate, the validity of the grant was liable to be objected to on the ground of the title being too general. Under the present law the task of preliminary disclosure falls to the provisional specification, introduced by the Patent Law Amendment Act, 1852, and continued by the Patents Act of 1883, although a patentee may, under the latter statute, dispense with a provisional specification if he thinks proper to file a complete one in the first instance. Where, however, these two specifications are filed, it becomes of vital moment to an inventor that the true relation between them should be maintained. That relation, as settled by recent cases, may be stated thus: It is the duty and the office of the provisional specification to declare the nature of the invention in general terms. The function of the complete specification subsequently filed is to explain the invention in detail, and to show how it is to be carried out. The object of the provisional specification is to secure immediate protection, and to enable a patentee to work at and improve his invention without the risk of his patent being invalidated by premature publication. He is therefore entitled to embody in his complete specification any improved method of working his invention which he may discover in the interval; and he is indeed bound to do so, since the price that a man who desires a patent has to pay to the public for the privilege is that he should make a full disclosure of his invention in his complete specification. But there is a limit to what the patentee may do in this respect. He must not describe in his complete specification an invention different from that declared in the provisional. If he falls into this error there is said to be a "variance" or "disconformity" between the two specifications, and the patent will be bad. The Patents Act, 1883, § 9, made it the duty of the examiners of the Patent Office to consider the question of disconformity between specifications on applications for patents, and it was thought at one time that if the Comptroller-General accepted a patent after the examiner had reported on it, there could no longer be any objection on the ground of disconformity. But this view has been rejected, and disconformity is still a good answer to an action for infringement and makes a patent void.

(iv.) *Compulsory Licences.*—For about fifteen years the provisions introduced into the Patents Act, 1883, for the compulsory licensing of patents under the authority of the Board of Trade, remained practically a dead letter. Up to the end of 1887 there had been only one informal application, which was by leave withdrawn. In 1888 there was also one application. Probably the fact that the compulsory licence provisions did not apply to patents granted, or applications pending, before the Patents Act, 1883, came into operation, may account for this circumstance. There have been several cases since 1897. It may be noted at this point that by English patent law a patentee is not obliged to bring his invention into practice within a specified time (compulsory working, or *exploitation*): there is no preliminary examination into, or guarantee of, novelty by the Patent Office; and a patentee is not prohibited from importing into the country articles manufactured under his patent abroad. The law is different, as will be seen by reference to the headings (x.) and (xi.) *infra*, in many British colonies and foreign countries. With reference to preliminary examination in England, however, it should be added that the Board of Trade recently appointed a strong committee, with Sir Edward Fry as its chairman and Lord Alverstone and Mr Fletcher Moulton, K.C., among its members, to inquire into and report upon, *inter alia*, the question whether any, and, if so, what, additional powers should be given to the Patent Office to (*a*) control, (*b*) impose conditions on, or (*c*) otherwise limit the issue of letters patent in respect of inventions which are obviously old, or which the information recorded in the office shows to have been previously protected by letters patent in Great Britain.

(v.) *Legal Remedies.*—Several additional forms of legal proceedings in connexion with patents should be noted. (*a*) At common law a person who, alleging that he has a patent, threatens his rivals in trade, is liable to an action for damages, but the plaintiff cannot succeed without showing that the threats were made maliciously. (*b*) The Patents Act, 1883, provides another remedy—what is known as "the threats action" (see sec. 32). The statute makes the good faith of the patentee threatening legal proceedings no answer to an action brought against him by any person aggrieved by his threats if the acts complained of are not in fact an infringement of the patent, and if the patentee fails with due diligence to commence and prosecute an action for infringement. (*c*) The point has recently been raised whether a patentee threatening legal proceedings for infringement could not be sued under section 4 of the Statute of Monopolies, which gives to any person "hindered, grieved, disturbed or disquieted . . . by occasion or pretext of any monopoly or letters patent," a right to treble damages.

(vi.) *Extent and Construction.*—The patent when sealed is to have effect in the United Kingdom and the Isle of Man. The present Act, unlike the Patent Law Amendment Act of 1852, does not extend the monopoly to the Channel Islands. The statutory form of letters patent for inventions provides that "These our letters patent shall be construed in the most beneficial sense for the advantage of the said patentee." It is now settled, however, after considerable judicial discussion, that a specification should be subjected neither to what was once called a "benevolent" construction nor to a strict one, but that the language should be construed according to its ordinary meaning.

(vii.) *Fees.*—By an order of the Board of Trade which came into operation on 1st October 1892, the following important reductions in the renewal fees payable on patents were made. Before the expiration of the 4th year from the date of the patent, £5 instead of £10; of the 5th year, £6 instead of £10; of the 6th year, £7 instead of £10; of the 7th year, £8 instead of £10; of the 8th year, £9 instead of £15; of the 10th year, £11 instead of £20; of the 11th year, £12 instead of £20; of the 12th year, £13 instead of £20; and of the 13th year, £14 instead of £20. The preliminary fees amounting to £4 were left untouched by the order, the result of which was to reduce the entire cost of a patent from £154 to £99.

(viii.) *Business.*—A new Patent Office has been constructed in London on the site of the old buildings, the frontage extending from Southampton Buildings into Staple Inn. The number of applications for patents, which sprang from 5993 in 1883 to 17,110 in 1884, culminated in a total of 30,952 for the year 1892, since which date a steady decline has set in. The number of patents sealed on application for a given year shows less variation, the minimum being 8775 for 1885 against 14,465 for 1897. The proportion of seals to applications varied from 46 to 50 per cent. during 1890–1900. The receipts from patent fees in 1899 were £202,977, against a total expenditure of £123,216. The latter sum includes £24,118 expended chiefly on the new office.

The official publications of the Patent Office deserve some notice, as, in the absence of official investigation into novelty, the onus of search rests with the applicant or his agent. The procedure has been greatly simplified by the publication, on a uniform system and at a low rate (1s. per volume), of illustrated abridgments of specifications. From 1877 practically to date the searcher obtains a chronological digest of all specifications falling within a given class. To these classes there is a reference index, known as the "abridgment class and index key," which at once directs the searcher to his proper class and index heading. The periods already issued in volume form are 1877–83, 1884–88, 1889–92, 1893–96. The series for 1897–1900 was issued sheet by sheet to subscribers. The first sheets of a similar series for 1867–76 have also been published, while it is proposed to reissue on similar lines abridgments of all specifications filed since the initiation of the English patent system.

(ix.) *Patent Agents.*—The position of patent agents is now regulated by statute. By the Patents Act, 1888, it was provided that no person should, after 1st July 1889, be entitled to describe himself (and whoever does so knowingly incurs liability to a maximum penalty of £20) as a patent agent whether by advertisement, description on his place of business, or otherwise, without being registered as such in pursuance of the Act. But the Act preserves the right to registration of every person who, to the satisfaction of the Board of Trade, shows that he had been *bonâ fide* practising as a patent agent before it passed. The Board of Trade is empowered by this statute to make from time to time general rules for the purpose of carrying out its provisions, and by rules issued in 1889, and reissued in 1891, the Board of Trade delegated to the Institute of Patent Agents (which obtained a royal charter in 1891) the care of the register of patent agents and the duty of holding the necessary examinations for entrance into the profession.

(x.) *India and the British Colonies* [see also (vi.) and (xii.)].—Little more can be attempted under the present heading or the following one—(xi.) *Foreign Patent Laws*—than to touch upon a few distinctive features, such as duration, fees, preliminary examination into novelty, &c.

Australian States.—In New South Wales the regulating Act is No. 19 of 1899. It amends the law on a variety of matters, provides for the appointment of an examiner of patents, and is practically a transcript of the provisions of the Imperial Patents Act, 1883, as to amendment of specifications, disclaimers, and revocation of patents. It appears that there may be a preliminary examination as to novelty (see §§ 5 (1) and 22). The duration is not less than 7 nor more than 14 years. In Queensland the Patents Acts are No. 13 of 1884, No. 5 of 1886, and No. 8 of 1890. The provisions of these statutes closely follow the Imperial legislation on the subject. But there is a preliminary examination as to novelty (see No. 5 of 1886). In South Australia the latest Act is No. 421 of 1887. A preliminary examination as to novelty may be ordered (see No. 78 of 1877). Patent law is now regulated in Victoria by No. 1123 of 1890, which is modelled on the English Acts. There is a preliminary examination as to novelty. The fees payable before the expiration of the 3rd and 7th years are now respectively reduced from £15 and £20 to a sum in each case of £2 10s. In West Australia the governing Acts are now No. 5 of 1888, No. 15 of 1892, and No. 4 of 1894. There is apparently no preliminary examination as to novelty. The general provisions are similar to those of the English statutes. The renewal fees are prescribed by the Patent Rules 1898, and amount to a sum of £5 before the end of the 4th year and £10 before the end of the 7th year from the date of the patent. See also *New Zealand* and *Tasmania*.

Bahama Islands.—The law is regulated by the following Acts of the colony:—52 Vict. c. 23, 53 Vict. c. 2, and 54 Vict. c. 12. Duration of patent 7 years, with power in governor to renew for another 7 years, and thereafter for a third period of 7 years. The fees are £3 on filing specification, £10 for second renewal, and £20 for third. Apparently there is no preliminary examination as to novelty.

Barbados.—Cp. Acts of Colony of 12th December 1883 and No. 37 of 1892–93. Duration of patent 7 years, with possible extensions for two further periods of 7 years each, but no more. Fees are £3 6s. 8d. on filing specification, £10 for second renewal, and £20 for third. No preliminary examination as to novelty.

Bermuda.—There is apparently no statutory patent law in this colony.

British Guiana.—The law is still regulated by ordinance No. 1 of 1861. It may be noted in addition that there is no preliminary examination for novelty.

British Honduras.—The law of 10th September 1862 has been re-enacted with slight modifications (see supplement to *Patent Laws of the World*, No. 4). There is no examination as to novelty.

British India.—The law is now governed by Act 5 of 1888, which applies to the whole of British India. Duration of patent is 14 years. A preliminary examination into novelty might apparently be ordered. The following taxes are payable:—Annual sums of Rs.50 from the 4th to the 8th year, and of Rs.100 from the 8th to the 13th year of the term.

British New Guinea.—The Queensland Patents Acts, No. 13 of 1884 and No. 5 of 1886, have been adopted. See British New Guinea Ordinance No. 6 of 1889, Schedule A.

British North Borneo.—Straits Settlements law (No. 12 of 1871), adopted by Patents Proclamation 1887 (No. 1 of 1887).

Canada.—Patent legislation belongs exclusively to the Dominion Parliament [B.N.A. Act, 1867, § 91 (22)]. The existing Acts are c. 61 of 1886; 55 and 56 Vict. c. 24, and 56 Vict. c. 34. The duration of the patent is 18 years. At the time of application the applicant may pay the full fee required for that term (viz., 60 dollars) or the partial fee required for the term of 6 years (20 dollars) or for the term of 12 years (40 dollars). If a partial fee only is paid, the amount is stated in the patent, and the patent ceases at the end of the term covered by such partial payment, unless before the expiration of such term the patentee pays the fee required for the further term of 6 or 12 years, viz., 20 dollars in the former case and 40 in the latter. There is a preliminary examination into novelty by examiners, with an appeal from the decision of the Commissioner of Patents to the Governor in Council. The patent is void unless it is worked in Canada within 2 years, or if after the expiration of 12 months, or any authorized extension of either of these periods, the patentee imports the invention into Canada.

Cape of Good Hope.—The law is still regulated by Act No. 17 of 1860. There is no preliminary examination into novelty, and the Act contains no provisions for compulsory working, or as to the importation of patented articles from abroad.

Ceylon.—The law is now regulated by Act 16 of 1892. The duration of the patent is 14 years, with power vested in the governor in council to grant extensions of 7 and 14 years. There is no preliminary examination as to novelty, and there are no provisions as to compulsory working or the importation of patented articles from abroad. The renewal fees are Rs.50 annually from before the expiration of the 4th to before the expiration of the 8th year from the filing of the specification, and Rs.100 annually from before the expiration of the 9th to before the expiration of the 13th year. See also No. 6 of 1897.

Channel Islands.—These are not now included in grant of letters patent. See form of grant, schedule I., Form D, Patents Act, 1883.

Falkland Islands.—No regulations exist.

Fiji Islands.—The law depends on ordinances No. 3 of 1879 and 7 of 1882, and Order of 29th December 1890. The duration of the patent is 14 years. There is no preliminary examination, and there are no provisions as to compulsory working or importation from abroad. The patent is not subject to any payment after issue. A fee of 5 guineas is payable on deposit of petition and specification. The fee for provisional protection is 5 guineas; on obtaining letters patent the applicant pays 10 guineas.

Gambia.—No regulations exist. An ordinance practically identical with that of the Gold Coast is being adopted.

Gibraltar.—There is no patent law in Gibraltar, but special ordinances are sometimes passed extending the privileges of British patentees to the dependency for the unexpired residues of the original terms. See as examples No. 5 of 1890, No. 1 of 1896, and No. 1 of 1898.

Gold Coast.—The law is now regulated by ordinance No. 1 of 1900, which closely resembles the Imperial Act.

Hong Kong.—The law is regulated by ordinance No. 2 of 1892. The inventor or assignee of any invention patented in England may obtain protection in the colony for the unexpired residue of the original term. If the English patent is extended by the advice of the Judicial Committee, an extension of the colonial patent may be obtained, or a new patent granted for the extended period. A fee of 25 dollars is payable on grant of patent, and another fee of the same amount on grant of extension or original letters in lieu of extension. There is no preliminary examination, and there are no provisions as to compulsory working or importation from abroad.

Jamaica.—The law is still in substance governed by c. 30 of 1857. But under ordinance No. 15 of 1891 the stamp duty on letters patent is now £2 instead of £6 10s., and there is no longer any fee payable on the reference to the Attorney-General. There is no preliminary examination as to novelty, and there are no provisions as to importation from abroad.

Lagos.—No regulations exist, but an ordinance practically identical with that of the Gold Coast is being adopted.

Leeward Islands.—The principal Acts still are No. 12 of 1876 and No. 16 of 1878. There is no preliminary examination into novelty, and there are no provisions as to compulsory working or importation from abroad. A retrospective power of granting extensions of time for any Act or payment is conferred on the governor in council by No. 2 of 1891.

Malta.—The law is governed by ordinance No. xi. of 1899, the duration of the patent is 14 years. There is no express provision for a preliminary examination into novelty. Provision is made for compulsory assignation or licence, where the invention has not been put into use within 12 months subsequent to the grant or its working has been suspended for 12 months continuously. The annual fees are £5 before the expiration of the 4th year from the date of the patent; £6 before the expiration of the 5th; £7 and £8 respectively before the expiration of the 6th and 7th years; £9 and £10 before the expiration of the 8th and 9th; and from £11 to £14 before the expiration of the 10th, 11th, 12th, and 13th years.

Mauritius.—The law is still regulated by ordinance No. 16 of 1875. There is no preliminary examination as to novelty, and there are no provisions for compulsory working or importation from abroad.

Natal.—The law is still regulated by No. 4 of 1870. But certain details of practice are amended by No. 2 of 1895. There is no preliminary examination as to novelty, and there are no provisions as to compulsory working or importation from abroad.

Newfoundland.—The law is contained in the Consolidated Statutes, Title xii. c. 109. There is no preliminary examination into novelty. In addition to the office fees, the patentee is required to deposit with the Colonial Secretary the sum of 25 dollars, to be paid by him to the Receiver-General for the use of the colony.

New Zealand.—The law now depends on No. 12 of 1889, amended in details by No. 8 of 1897. The duration of a patent is 14 years. There is no preliminary examination as to novelty, and there are no provisions as to compulsory working or importation from abroad. The following fees are payable:—£2 on obtaining letters patent, £5 before the expiration of the 4th year, and £10 before the expiration of the 7th.

St Helena.—The law is regulated by ordinance No. 3 of 1872. The grantee of an English patent, or his representatives, can have the grant extended to the colony. All cases of doubt and difficulty not provided for by the laws of the colony are governed by the law in force in England. A fee of one guinea is payable on filing copy of letters patent and specification with the registrar of the Supreme Court.

Sierra Leone.—No special regulations exist, but an ordinance practically identical with that of the Gold Coast is being adopted.

Straits Settlements.—The law is prescribed by ordinance No. 12

of 1871. The duration of a patent is 14 years. There is no preliminary examination as to novelty, and there are no provisions as to compulsory working or importation from abroad. There is a stamp duty of 50 dollars on the petition. No renewal fees are payable.

Tasmania.—The law is now regulated by Act No. 6 of 1893. The duration of the patent is 14 years. There is no preliminary examination as to novelty (but see § 110), and there are no provisions as to compulsory working or importation from abroad. The fees payable are £2 on obtaining patent, £15 at or before the expiration of the 3rd year, and £20 at or before the expiration of the 7th.

Trinidad and Tobago.—The law is regulated by ordinance No. 10 of 1900. The duration of the patent is 14 years. There is no preliminary examination into novelty, and there are no provisions as to compulsory working or importation from abroad. A fee of £10 is payable on application for a patent.

Turks and Caicos Islands.—The law of Jamaica has been extended to these islands by No. 7 of 1897. See supplement to *Patent Laws of the World*, No. 3.

Windward Islands.—In the Windward Islands other than Barbados, viz., Grenada, St Lucia, and St Vincent, patents for invention were granted until recently only by special ordinances. See, *e.g.*, St Lucia, ordinance No. 41 of 1875 (Tooth's patent). A stamp duty of £10 was payable in this island on letters patent for inventions (No. 6 of 1881, schedule). But ordinances based on the Imperial Act have now been passed, St Vincent (No. 5 of 1898), Grenada (No. 4 of 1898), and St Lucia (No. 14 of 1899).

(xi.) *Foreign Patent Laws.*—For the text of these see *Patent Laws of the World*, ed. 1899. But the following are the essential facts.

Algeria.—French law applied by decree of 5th June 1850.

Argentine Republic.—The law of 11th October 1864 is still in force. There is no provision as to importation from abroad.

Austria.—A new law (11th January 1897) came into force on 1st January 1899. The principal changes introduced by this measure are these: There is now a strict preliminary examination into novelty. The term of the patent is now fixed at 15 years, and besides an application fee of 10 florins, there are annual fees rising from 20 florins for the first year to 340 florins for the fifteenth. The period for compulsory working is raised from 1 year to 3 years from the date of the publication of the grant of the patent in the patent journal. Provision is made for the conversion of patents under the old law of 15th August 1852 (extended to Hungary by law of 27th June 1878, and to Bosnia and Herzegovina by law of 20th December 1879) into patents under the new law.

Belgium.—The law is still governed by the law of 24th May 1854. Patents are granted, as in France, without guarantee of novelty.

Bolivia.—The patent law depends on a law of 8th May 1858. The duration of the grant is in the case of a patent of invention not less than 10 nor more than 15 years; in the case of an imported invention, 3 years if its establishment requires an outlay of 25,000 dollars, if it reaches 50,000 dollars, 6 years, and if 100,000 or more, 10 years. The novelty neither of patents for invention nor of patents for imported inventions is guaranteed. The patent lapses unless the invention is put into complete practice within a year and a day from the date of the privilege, unless the omission is excused by justifiable causes according to law.

Brazil.—Patents are granted under the law of 14th October 1882. The patent lapses unless the invention is brought into effective use within 3 years from the date of the grant, or if such use is suspended for more than a year, except by reason of *force majeure* admitted by Government to be a sufficient excuse. Besides expenses and fees, patents of invention are subject to an annual and progressive tax, commencing at 20 dollars and increasing at the rate of 10 dollars a year. The patents issued are without guarantee of novelty or utility.

Chile.—The law is regulated by the law of 9th September 1840, decree of 1st August 1851, and laws of 25th July 1872, 20th January 1883, and 20th January 1888. There is a preliminary examination as to novelty and utility. Though the duration of a patent does not ordinarily exceed 10 years, the term may be extended to 20 years by the President of the Republic, if the report of the experts on the nature and importance of the invention seem to justify it. There are no provisions as to importation from abroad.

Colombia.—Patents are granted under law No. 35 of 1869. The term varies from 5 to 20 years at the option of the applicant. There is no preliminary examination as to novelty, and there is no provision as to importation from abroad. A patent for a new industry is void when such industry is idle for a whole year, unless inevitable circumstances have intervened. An applicant pays a sum of 10 pesos, which is forfeited if the patent is refused, and taken in part payment of the patent fee if it is granted. The patent tax is from 5 to 10 pesos a year for every year of the privilege.

Congo.—Patents are issued under a law of 29th October 1886 and a decree of 30th October 1886. They are of three kinds, patents of invention, of importation, and of improvement. There is no preliminary examination as to novelty, and the patent expressly mentions that the grant is made without guarantee. The term of a patent of invention is 20 years. A patent of importation or of improvement expires in the former case with the foreign, in the latter with the principal patent. Patents of improvement are not liable to any tax; on other patents a payment of 100 francs is required. There are no provisions as to compulsory working or prohibiting the importation of patented articles.

Costa Rica.—Prior to 26th June 1896, applications for patents had to be made to the Constitutional Congress. The matter is now dealt with by a law of the above-mentioned date. The duration of the term is 20 years. There is apparently no preliminary examination into novelty. The period for compulsory working is 2 years, and a patent which ceases to be worked during any 3 consecutive years becomes public property.

Denmark.—Patents are now granted under a law of 28th March 1894. The duration of the patent is 15 years, and no extension can be granted. There is a preliminary examination into novelty. The patent may, on terms, be appropriated by the State if the public interest demands it. The period for compulsory working is 3 years, and the patent will also lapse if the exercise of the invention is discontinued for more than a year. The patent commission may release the patentee from the obligation of manufacturing the patented article in Denmark, if satisfied that the cost of such manufacture would be unreasonable, on condition that the patented article is always kept on sale in Denmark. The tax is an annual fee of 25 kroner for the first 3 years, 50 kroner for the next 3, 100 for the following 3; then for 3 years 200 kroner yearly, and for the last 3, 300 kroner yearly.

Ecuador.—Patents are granted under a law of 18th October 1880. The provisions are identical with those given for Bolivia.

Finland.—The law is regulated by ordinances of 21st January 1898. The term of the patent is 15 years. There is a preliminary examination into novelty. The period for compulsory working is 3 years, the penalty for non-compliance being an obligation on the part of the patentee to grant compulsory licences. The tax consists of annual fees, commencing with the second year of the patent, and of the following amounts:—20 marks yearly for the 2nd and 3rd years; 40 marks from the 4th to and including the 6th year; 50 marks from the 7th to and including the 9th; 60 marks from the 10th to and including the 12th year; and 70 marks from the 13th to and including the 15th.

France.—The law is still regulated by the law of 5th July 1844. The following additional points should be noted:—The term of a patent of invention is 5, or 10, or 15 years, at the option of the patentee. Every such patent is subject to the following taxes, payable by annual instalments of 100 francs:—500 francs for a patent of 5 years, 1000 francs for a patent of 10 years, and 1500 francs for a patent of 15 years. A tax of 20 francs is payable on application for a patent of addition. Patents of addition are not subject to annual taxes. There is no preliminary examination as to novelty. A patentee is not obliged to mark patented articles as such, but, if he does, the words *Sans Garantie du Gouvernement*, or the initial letters of these words—S. G. D. G.—must be added, under liability to a penalty for omission of from 50 francs to 1000 francs. The provisions as to compulsory working (*exploitation*) are in the main so interpreted as to strike only at voluntary and calculated inactivity. The law of 5th July 1844 is applied to the French colonies by a decree of 21st October 1848, and as to French Indo-China, see decree of 24th June 1893.

Germany.—Patents (the law as to which is not affected by the new civil code) are granted under a law of 7th April 1891. The duration of the patent is 15 years. There is a strict preliminary examination into novelty. The period for compulsory working is 3 years, but it is sufficient if the patentee has done everything that is necessary to ensure the carrying out of the invention. A tax of 30 marks has to be paid before the grant. In addition to this there has to be paid at the commencement of the second and every following year of the term a tax amounting to 50 marks for the first year and increasing by 50 marks every subsequent year.

Greece.—No special patent law apparently exists. A private Act is required, which can be introduced by a deputy and is treated like any other Bill.

Guatemala.—Patents are granted under the law of 21st May 1886 and a decree of 17th December 1897. The term of the patent ranges from 5 to 15 years. An annual tax of 30 pesos is payable. The period of compulsory working is 1 year, and abandonment of working for a year forfeits the patent. There is apparently a preliminary examination as to novelty (see Art. 16 of the decree of 17th December 1897), but there is no prohibition of the importation of patented articles.

Hawaiian Islands.—Patents were issued till recently under the civil code (§§ 255, 256) and a law of 29th August 1884, which were not at first affected by the annexation of the islands by the United States. There was a preliminary examination as to novelty. The maximum duration of the patent was 10 years. On application a fee of 5 dollars was payable, the Commissioner of Patents received 20 dollars for his examination, and a fee of 5 dollars was payable when the patent was issued. No further payments. Now the United States law applies.

Honduras.—No. 177 of 10th March 1898. Term not to exceed 20 years. Annual tax 5 to 10 *silver* pesos; in the case of foreigners 10 to 50 *gold* pesos.

Hungary.—The law in force is that of 7th July 1895. The duration of the patent is 15 years. The period for compulsory working is ordinarily 3 years. The annual taxes range from 40 kroner for the 1st year to 500 for the 15th.

Italy.—The law is still governed by that of 31st January 1864, extending the Sardinian law of 30th October 1859 to the whole kingdom. There is no preliminary examination into novelty, and there is no provision prohibiting the importation of patented articles. Patents are subject (i.) to a proportional tax of as many times 10 lire as the years for which the patent is applied for, and (ii.) to an annual tax of 40 lire for the first 3 years; 65 lire for the following 3; 90 lire for the 7th, 8th, and 9th; 115 lire for the 10th and 11th; and 140 lire for the remaining 3 years.

Japan.—Patents are issued under an Act which came into operation on 16th July 1899. The law as to subject-matter resembles that of England and the United States. The term of a patent is 15 years from the date of registration. The patent may be annulled if the patentee has not worked his invention within 3 years from the date of the certificate of grant, or if, having discontinued such use for 3 years, he has refused a reasonable request by a third party for an assignment or a licence. An applicant not domiciled in the empire must appoint within 6 months a duly qualified agent by power of attorney. There is apparently a preliminary examination into novelty. The patent owner must affix his mark to the patent. The fees are calculated on a gradually ascending scale.

Liberia.—Patents are issued under a law of 23rd December 1864. The maximum term is 20 years. There is a preliminary examination as to novelty. A sum of 25 or 50 dollars is payable on application, according as the applicant is a citizen or an alien. An invention patented by an alien must be put in practical operation within 3 years. There is no prohibition of the importation of patented articles.

Luxembourg (law of 30th June 1880).—The term of the patent is 15 years. There is no preliminary examination as to novelty, and the importation of patented articles is not prohibited. An annual and progressive tax, commencing at 10 francs and increasing by 10 francs annually, is payable in advance. The period for compulsory working is 3 years, and after the expiration of that period compulsory licences may be ordered.

Mexico (laws of 7th June 1890 and 2nd June 1896).—The duration of a patent is 20 years, with possible extension for another 5 years. There is no preliminary examination as to novelty or utility. There are apparently no provisions as to compulsory working (but compulsory licences may be ordered) or prohibiting the importation of patented articles. The tax ranges from 50 to 150 dollars. The patentee must also at the end of each 5 years of the grant, in order to keep the patent in force for another 5 years, pay 50 pesos at the end of the first 5 years, 75 pesos at the end of 10 years, and at the end of 15 years, 100 pesos.

Nicaragua.—Patents were, as a general rule, until recently, granted only by special Act of Congress. But see now supplement 720, No. 15, *Patent Laws of the World*.

Norway (law of 10th June 1885).—The term of the patent is 15 years. There is a preliminary examination into novelty. The invention must be worked within 3 years, and the working must not be discontinued for a year on pain of forfeiture. For each patent an annual tax is payable amounting to 10 crowns for the second year and increasing by 5 crowns each year.

Orange River Colony, formerly *The Orange Free State.*—Up to the outbreak of war in 1899 the law was regulated by ordinance No. 10 of 1888. The term of a patent was 14 years. No preliminary examination as to novelty. Compulsory licences might be obtained. No prohibition of the importation of patented articles. The fee for signing and sealing the patent was not less than £10 nor more than £50. Taxes of £5 and £10 were payable before or at the expiration of the 3rd and 7th years of the term respectively.

Peru (law of 28th January 1869 and law of 3rd January 1896).—The maximum term of the patent is 10 years, and the tax is an annual sum of 100 dollars. There is no preliminary examination into novelty. The period for compulsory working is 2 years, and the importation of patented articles from abroad (except models of machinery whose introduction is authorized by the Government) is prohibited.

Portugal (law of 15th December 1894).—The maximum term is 15 years. The patent tax is 3000 reis, payable in advance, for each year of the term for which the privilege is granted or renewed. There is no preliminary examination into novelty. The period for compulsory working is 2 years, and discontinuance of working for any 2 years at a stretch forfeits the patent unless the inaction can be justified. The importation of patented articles from abroad is not prohibited.

Russia (law of 20th May 1896).—The maximum term is 15 years; the tax ranges from 15 roubles for the 1st year to 400 roubles for the 15th. There is apparently (see Arts. 3 and 13) a preliminary examination into novelty, but none into utility. The period for compulsory working is 5 years. There is no prohibition of importation of patented articles.

Spain.—Patents are still issued under the law of 30th July 1878. There is no preliminary examination as to novelty, and the importation of patented articles is not prohibited.

Sweden (law of 16th May 1884).—The term is 15 years. The annual tax is 25 crowns for the 2nd, 3rd, 4th, and 5th years; 50 crowns for each of the following 5 years; and 75 crowns for each of the remaining 5 years. There is a preliminary examination as to novelty, the period for compulsory working is 3 years, and discontinuance during any entire year entails forfeiture. There is no prohibition of the importation of patented articles.

Switzerland (laws of 29th November 1888 and 23rd March 1893).—The term of the patent is 15 years. There is an annual and progressive tax, rising from 20 francs for the 1st year by an annual increase of 10 francs up to 160 francs for the 15th. There is no preliminary examination as to novelty. The patent is forfeited if the invention has not been carried into practice by the end of the 3rd year, or if patented articles are imported from abroad, while at the same time the proprietor has refused applications on equitable terms for Swiss licences. Patented articles must be marked with the Federal cross and the number of the patent.

Transvaal Colony, formerly *The South African Republic.*—At the outbreak of war in 1899 law No. 10 of 1898 was in force. Patents were granted on payment of prescribed fees ranging from £20 up to £200, according to duration, for periods of 3, 5, 8, and 11 years.

Tunis (law of 22nd Rabia-et-Tani, 1306; 26th December 1888).—The term is either 5 years (fee 500 piastres) or 10 years (fee 1000 piastres) or 15 years (fee 1500 piastres). There is no preliminary examination as to novelty. The period for compulsory working is 2 years, and two consecutive years' discontinuance of such working, unless justified, forfeits the patent. So also does the importation of patented articles, but the introduction may be authorized (i.) of models of machines, and (ii.) of articles, made abroad, intended for public exhibitions or for trials.

Turkey.—Patents are still granted under the law of 2nd March 1880. There is no preliminary examination as to novelty, and a patentee who mentions his title as such without adding the words "without guarantee of Government," is liable to a maximum penalty of 45 Turkish pounds.

United States.—The American law may be considered at greater length. The Federal Constitution empowered Congress "to promote the progress of science and useful arts by securing for limited times to . . . inventors the exclusive right to their . . . discoveries." The existing American patent law is based on a series of Acts of Congress passed in virtue of this provision in the constitution, and on the judicial interpretation of these statutes. Between American and English patent law there is, as will appear in the course of this sketch, a considerable degree of similarity. The fact is not surprising when it is remembered that the Statute of Monopolies (21 Jam. I. c. 3) was, except in limiting the maximum duration of letters patent for inventions at fourteen years, only declaratory of the common law, and therefore formed part of the original common law of America. The English and American patent systems further agree in this, that they contain no provision as to compulsory working, and no prohibition of the importation of patented articles. But there are important differences between the two systems, not merely in points of detail, but in matters affecting the theory and practical working of the law. In England the consideration for the grant of a patent has all along been mainly the benefit which the public derives from the introduction of a new manufacture. In America greater emphasis is placed on the right of an inventor to have his merits rewarded. Again, under the Statute of Monopolies an inventor's exclusive privilege arises only in regard to inventions not known or used at the date of the grant, although it should be observed that under the modern Patents Acts the date of a patent, once granted, relates back to the date of the application. In the United States, on the other hand, the right is conferred on inventors to an exclusive privilege in such inventions as were not known or used before their discovery by the patentees. The practical bearing of this difference is explained in an admirable note on "The Statute of Monopolies" in *Ruling Cases, sub tit.* "Patent" (vol. xx. p. 5):—"It shifts the point of view in the important question of novelty. Many good American inventions have been given away in England by the premature publication in America of the inventor's proceedings. He is interviewed, and an article in the New York *Sun*, or some other paper, in due time finds its way

American law and procedure.

to England. This does no harm in America; on the contrary, it is good evidence of the date of the actual invention. But it is fatal to a subsequent application in England."

Certain other differences between English and American patent law (such as the less generous provision by the former than by the latter for disclaimers, the preliminary examination into novelty in American law, and the statutory right of patentees whose inventions are used by the Government to fair compensation) owe their origin to the fact that in England a patent is, in legal contemplation, a grant made by "the especial grace" of the sovereign, whereas in American legislation it is treated as a right.

The definition of patentability in American law is contained in section 4886 of the Revised Statutes of the United States as amended by an Act of 3rd March 1897. In the following passage the amendments are indicated by italics:—

"Any person who has invented or discovered any new and useful art, machine, manufacture or composition of matter, or any new and useful improvement thereof, not known or used by others in this country *before his invention or discovery thereof*, and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof *or more than two years prior to his application*, and not in public use or on sale for more than two years prior to his application, unless the same is proved to have been abandoned, may, upon payment of the fees required by law and other due proceedings had, obtain a patent therefor."

The effect of the two amendments made by the Act of 1897 should first be noted: (i.) The old law failed to state at what time the invention should be known or used by others in America so as to bar a patent; whether before the application or before the invention. This ambiguity is removed by the use of the words "before his invention or discovery thereof." (ii.) Under the old law a foreign patentee could take out a patent in America for the same invention at any time during the life of the foreign patent, provided it had not been in use in America more than two years prior to his application, unless anticipated by a prior invention or publication. The words "or more than two years prior to his application," merely give the same force to a foreign patent or publication that had previously been given to prior use. An invention to be patentable must, according to American law, be both novel and useful. Utility may be evidence of novelty and *vice versâ*, and commercial success is relevant evidence of utility. As in England, a bare principle is not patentable. A "process" is included under the words "useful art" in the above definition of patentability, and is good subject-matter for a patent when the term is used to represent a practical method of producing a beneficial result or effect. The word "machine" in the definition includes every mechanical device or combination of devices for producing certain results. Such a device or combination is patentable when it possesses utility and novelty, and produces either a new result or an old result in a better form.

Under the law of 1790, which was exclusively American in spirit, the duty of granting letters patent for inventions was discharged by the Secretary of State, the Secretary of War, and the Attorney-General, or any two of them. The law from 1793 to 1836 was exclusively English in spirit, and during that period the duty fell to the Secretary of State, subject to the Attorney-General's approval. It was in 1837 that the marked divergence between the English and American patent system began. In that year the patent business of the United States had attained to such dimensions that the powers and duties of the Secretary of State in regard to patents were transferred to a sub-department of the State department known as the Patent Office. The American Patent Office consists of a Commissioner of Patents, one assistant commissioner, and three examiners-in-chief, who are appointed by the President of the United States with the advice and consent of the Senate; and also of other examiners, and a staff of officers, clerks, and employés, appointed by the Secretary of the Interior on the nomination of the Commissioner of Patents. The Commissioner of Patents, under the direction of the Secretary of the Interior, is charged with the superintendence or performance of all duties respecting the grant and issue of patents, and has the control and custody of all books, records, papers, &c., belonging to the Patent Office. He is authorized to make, from time to time, regulations not inconsistent with law, for the conduct of proceedings in the Patent Office, and prepares an annual report which is laid before Congress, and which is framed on the same lines as that of the Comptroller-General in England. "He is the final judge, so far as the Patent Office is concerned, of all controverted questions arising in the office, and in granting or withholding patents he is not bound by the decisions of his inferiors" (Robinson on *Patents*, vol. i. p. 84). The examiners-in-chief are required to be persons of competent legal knowledge and ability. Their duties are:—On the written petition of inventors to revise and determine upon the validity of the adverse decisions of subordinate examiners, upon applications for patents, and for reissues of patents, and in interference cases, and, when required by the Commissioner of Patents, to hear and report upon claims for extension, and to do such other similar work as he may assign to them. The Patent Office publishes an *Official Gazette* corresponding to the English *Patent Office Illustrated Journal*, and discharges similar functions to those of the English Patent Office in regard to the public dissemination of information as to patented inventions. The number of original applications for patents in the period covered by the report of the Commissioner of Patents for 1898–99 was 35,352; the number of patents granted was 23,550; the receipts amounted to $1,209,554, the expenditure to $1,148,663, leaving a surplus of $60,891.

The first step in the procedure to obtain a patent is the lodging by the inventor at the Patent Office of a written application, together with a specification or particular written description of his invention, and a claim distinctly pointing out and claiming what he alleges to be his invention or discovery. The specification and claim are signed by the inventor and attested by two witnesses. Drawings, specimens of ingredients, and models may be required to be furnished. On the filing of each original application for a patent, a fee of fifteen dollars is payable. The applicant is required to verify his claim to the invention on oath, taken, if he resides within the United States, before any person authorized by American law to administer oaths; if he resides in a foreign country, before any diplomatic or commercial agent of the United States, or any notary public of the foreign country in which the applicant may be. The Commissioner of Patents then causes an examination to be made into the novelty of the invention, and if the result is satisfactory the patent issues. On the issuing of each original patent, a fee of twenty dollars is payable. A patent is issued in the name of the United States of America and under the seal of the Patent Office. It consists of a short title or description of the invention or discovery, correctly indicating its nature and design, and a grant to the patentee, his heirs and assigns. Patents, it may be observed in passing, may be granted and issued or reissued to the assignee of the inventor or discoverer, and every patent or any interest in it is assignable, the assignment being recorded in the Patent Office, for the term of seventeen years of the exclusive right to make use of and vend the invention or discovery throughout the United States and the territories thereof. The rights of property in patents granted in Cuba, Porto Rico, the Philippines, and other ceded territory under Spanish law, are to be respected in those territories as if that law were still in force there. A patent is dated as of a day not later than six months from the time at which it was passed, and if the fee is not paid within that time the patent is withheld. No fewer than 4021 patents were withheld, in the period covered by the report of the Commissioner of Patents for 1898–99, for non-payment of fees. In case, however, the issue of a patent has been prevented by a failure to pay the fee within the prescribed period, the application may be renewed within two years after the allowance of the original application. But the applicant has no right to damages for any use of the invention in the interval, and on the hearing of the renewed application abandonment may be considered as a question of fact. So far we have followed the procedure to obtain a patent where its course is uninterrupted. A double form of interruption is, however, possible. A claim for a patent may be rejected on the ground of want of novelty in the alleged invention. In this case, the fact of the rejection, together with the reasons for it, is communicated to the applicant by the commissioner; and if he persists in his claim, a re-examination is ordered. Or, again, an application may appear to the commissioner to interfere with a pending application,[1] or with any expired patent. In these circumstances, he gives notice to the applicant, and directs the primary examiner to proceed to determine the question of priority of invention. This interruption of the course of the proceedings to obtain a patent is called an "interference." In either of the cases above mentioned an appeal lies, on payment of a fee of ten dollars, from the primary examiner to the board of examiners-in-chief, and, on payment of a fee of twenty dollars, from the examiners-in-chief to the commissioner in person. An applicant for a patent, but not a party to an interference, may appeal from the decision of the commissioner to the Supreme Court of the District of Columbia sitting in *banc*. In interference cases the appeal lies to the District of Columbia Court of Appeals. There is an ultimate right of appeal, in cases involving the validity of a patent, to the Supreme Court of the United States. Patents are obtainable by Bill in equity, although the Commissioner of Patents (or, on appeal, the Supreme Court of the District of Columbia) may have refused them. The circuit courts of the United States have original jurisdiction in all patent suits. Appellate jurisdiction is vested in the circuit court of appeals; and on the certificate of that court, or by *certiorari*, an appeal may be brought to the Supreme Court of the United States.

[1] A citizen of the United States, or an alien who has within the preceding twelve months given notice of his intention to become one, may, by filing in the Patent Office a "caveat," the fee for which is ten dollars, secure for himself notice of possibly conflicting applications.

Section 4887 of the Revised Statutes provides that:—

"No person *otherwise entitled thereto* shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid by reason of its having been first patented or caused to be patented *by the inventor or his legal representatives or assigns* in a foreign country, *unless the application for the said foreign patent was filed more than seven months prior to the filing of the application in this country, in which case no patent shall be granted in this country.*"

The words italicized in the above section were added by an Amending Act of 3rd March 1897. In its original form the section provided that no person should be debarred from receiving a patent because the invention was first patented in a foreign country, whether he was otherwise entitled to the patent or not. The words "otherwise entitled to" merely postulate that no other bar to the issue of the patent shall exist. The words "by the inventor or his legal representatives or assigns" safeguard the inventor to some extent against fraud by third parties; while the provision requiring the application in the United States to be filed within seven months of the filing of the foreign patent is intended to carry out the provisions of the International Convention. It should be noted that the duration of an American patent for an invention already patented abroad is no longer limited by that of the prior foreign patent, but is granted for 17 years from the date of issue.

Patented articles are required to be marked as such, either by the word "patented," together with the day and the year the patent was granted, being affixed to them, or, when from the character of the article this cannot be done, by fixing to it, on the package containing one or more of such articles, a label containing the like notice; and in any suit for infringement by a party failing so to mark, no damages shall be recovered by the plaintiff, except on proof that the defendant was duly notified of the infringement, and continued after such notice to make, use, or vend the article so patented. A penalty of not less than 100 dollars is attached to falsely marking or labelling articles as patented.

When through inadvertence, accident, or mistake, and without fraudulent or deceptive intention, a patentee has claimed more than he is entitled to, his patent is valid for all that part which is truly and justly his own; provided this is a material or substantial part of the thing patented, and the patentee or his heirs or assigns, on payment of the prescribed fee (ten dollars), disclaim the surplusage. The disclaimer must be in writing, and attested by one or more witnesses; it is recorded in the Patent Office, and is thereafter considered a part of the original specification. But no disclaimer affects any action pending at the time of its being filed, except so far as may relate to the question of unreasonable neglect or delay in filing it.

In the same circumstances, or where a patent is inoperative or invalid by reason of a defective or insufficient specification, the patentee may surrender his patent, and the Commissioner of Patents may, on the application of the patentee and on payment of a fee of 30 dollars, issue a new patent in accordance with the amended specification.

Uruguay (law of 12th November 1885).—The term is 3, 6, or 9 years, at the option of the applicant. There is an annual tax of 25 dollars for every year of the privilege. The invention must be worked within a time fixed by the executive, and the working must not be discontinued for a year, on pain of forfeiture. There is no preliminary examination as to novelty.

Venezuela (law of 19th March 1900).—The term is 5, 10, or 15 years. The tax is 250 francs (bolivars) a year if the patent is for an invention or discovery, and 200 francs (bolivars) a year if it relates to an improved process. There is no preliminary examination as to novelty. The invention must be worked within the period fixed by the grant, and a year's discontinuance, unless the inaction is justified, entails forfeiture.

(xii.) *International Patents.*—The International Convention for the protection of industrial property was signed at Paris on 20th March 1883; the necessary ratifications were exchanged on 6th June 1884, and the Convention came into force a month later. Provision was made by sections 103 and 104 of the Patents Act, 1883, for carrying out the Convention in Great Britain by Orders in Council, applying it from time to time to (*a*) British possessions whose legislatures had made satisfactory arrangements for the protection of inventions patented in Great Britain; (*b*) foreign states with which the Sovereign had made arrangements for the mutual protection of inventions.

(*a*) The following is a list of the Orders in Council issued under the first category and now in force applying the provisions of the Patents Act, 1883, § 103, to British possessions:—

State.	Date of Order in Council.
New Zealand	February 8, 1890.
Queensland	September 17, 1885.
Tasmania	April 30, 1894.
West Australia	May 11, 1895.

(*b*) The following is a list of the Orders in Council issued under the second category and now in force applying the provisions of the Act of 1883, § 103, to foreign states:—

Foreign State.	Date of Order in Council.
Belgium	June 26, 1884.
Brazil	June 26, 1884.
Denmark (including the Faroe Islands)	November 20, 1894.
Dominican Republic	October 21, 1890.
France	June 26, 1884.
Italy	June 26, 1884.
Japan	October 7, 1899.
Mexico	May 28, 1889.
Netherlands	June 26, 1884.
,, (East Indian Colonies)	November 17, 1888.
,, (Curaçoa and Surinam)	May 17, 1890.
Paraguay	September 24, 1886.
Portugal	June 26, 1884.
Servia	June 26, 1884.
Spain	June 26, 1884.
Sweden and Norway	July 9, 1885.
Switzerland	June 26, 1884.
Tunis	June 26, 1884.
United States	July 12, 1887.
Uruguay	September 24, 1886.

Under the powers of the Foreign Jurisdiction Act, 1890, penalties have been imposed on British subjects committing offences against the Patents, &c., Acts, 1883–88, and the Orders in Council issued thereunder, in Africa, East Africa, Morocco, Persia, Persian coast, and Zanzibar.

An International Bureau in connexion with the Convention has been established at Bern, where an official monthly periodical, *La Propriété Industrielle*, is published. Conferences were held under the Convention at Rome in April and May 1886, and at Madrid in April 1890. At the latter conference an important article was adopted, under which it is left to each country to define and apply "compulsory working" (*exploitation*) for the purposes of the Convention in the sense that it chooses. In the year 1898 there were 264 applications in Great Britain for patents under the Convention.

Pater, Walter Horatio (1839–1894), English man of letters, was born at Shadwell, 4th August 1839. He was the second son of Richard Glode Pater, a medical man, of Dutch extraction, born in New York. Richard Pater moved to Shadwell early in the century, and continued to practise there among the poorer classes. He died while his son Walter was yet an infant, and the family then moved to Enfield, where the children were brought up.

In 1853 Walter Pater was sent to King's School, Canterbury, where he was early impressed by the æsthetic beauties of the cathedral. These associations remained with him through life. As a schoolboy he read *Modern Painters*, and was attracted to the study of art, but he did not make any conspicuous mark in school studies, and showed no signs of the literary taste which he was afterwards to develop. His progress was always gradual. He gained a school exhibition, however, with which he proceeded in 1858 to Queen's College, Oxford. His undergraduate life was unusually uneventful; he was a shy, "reading man," making few friends. Jowett, however, was struck by his promise, and volunteered to give him private tuition. But Pater's class was a disappointment, and he only took a second in Literæ Humaniores in 1862. After taking his degree he settled in Oxford and read with private pupils. As a boy he had cherished the idea of entering the Anglican Church, but, under the influence of his Oxford reading, his faith in Christianity became shaken, and by the time he took his degree he had thoughts of graduating as a Unitarian minister. This project, too, he resigned; and when, in 1864, he was elected to a fellowship at Brasenose, he had settled down easily into a university career. But it was no part of his ambition to sink into academic torpor. With the assumption of his duties as fellow the sphere of his interests widened rapidly; he became acutely interested in literature, and even began to write articles and criticisms himself. The first of these to be printed was a brief essay upon Coleridge, which he contributed in 1866 to the *Westminster Review*. A few months later (January 1867) appeared in the same review his now well-known essay on Winckelmann, the first expression of his idealism. In the following year his study of "Æsthetic Poetry" appeared in the *Fortnightly Review*, to be succeeded by essays on Lionardo da Vinci, Sandro Botticelli, Pico della Mirandula, and Michelangelo. These, with other studies of the same kind, were in 1878 collected in his *Studies in the History of the Renaissance*. Pater was now the centre of a small but very interesting circle in Oxford. Such men as cherished æsthetic tastes were naturally drawn to him; and, though always retiring and, in a sense, remote in manner, he was continually spreading his influence, not only in the university, but among men of letters in London and elsewhere. The little body of Pre-Raphaelites were among his friends, and by the time that *Marius the Epicurean* appeared he had quite a following of disciples to hail it as a gospel. This fine and polished work, the chief of all his contributions to literature, was published early in 1885. In it Pater displays, with perfected fulness and loving elaboration, his ideal of the æsthetic life, his cult of beauty as opposed to bare asceticism, and his theory of the stimulating effect of the pursuit of beauty as an ideal of its own. In 1887 he published *Imaginary Portraits*, a series of essays in philosophic fiction; in 1889, *Appreciations, with an Essay on Style*; in 1893, *Plato and Platonism*; and in 1894, *The Child in the House*. His *Greek Studies* and his *Miscellaneous Studies* were collected posthumously in 1895; his posthumous romance of *Gaston de Latour* in 1896; and his *Essays from the "Guardian"* were privately printed in 1897. A collected edition of Pater's works was issued in 1901. Pater changed his residence from time to time, living sometimes at Kensington and in different parts of Oxford; but the centre of his work and influence was always his rooms at Brasenose. Here he laboured, with a wonderful particularity of care and choice, upon perfecting the expression of his theory of life and art. He wrote with difficulty, correcting and recorrecting with imperturbable assiduity. His mind, moreover, returned to the religious fervour of his youth, and those who knew him best believed that had he lived longer he would have resumed his boyish intention of taking holy orders. He was cut off, however, in the prime of his powers. Seized with rheumatic fever, he rallied, and sank again, dying on the staircase of his house, in his sister's arms, on the morning of Monday, 30th July 1894. Pater's nature was so contemplative, and in a way so centred upon reflection, that he never perhaps gave full utterance to his individuality. His peculiar literary style, too, burnished like the surface of hard metal, was too austerely magnificent to be always persuasive. Since his death, Pater has exercised a remarkable and a growing influence, although this must always be restricted to those who have themselves something of his own love for beauty and the beautiful phrase. But the cumulative richness and sonorous depth of his language harmonized intimately with his deep and earnest philosophy of life; and those who can sympathize with a nervous idealism will always find inspiration in his sincere and sustained desire to "burn with a hard, gem-like flame," and to live in harmony with the highest. (A. WA.)
