There are difficulties in the way of applying the resonance theory to the perception of noises. Noises have pitch, and also each noise has a special character; if so, if the noise is analysed into its constituents, why is it that it seems impossible to analyse a noise, or to perceive any musical element in it? Helmholtz assumed that a sound is noisy when the wave is irregular in rhythm, and he suggested that the crista and macula acustica, structures that exist not in the cochlea but in the vestibule, have to do with the perception of noise. These structures, however, are concerned rather in the sense of the perception of equilibrium than of sound (see *Semicircular Canals*). Gray is also of opinion that evidence supports the view that the ear detects difference of phase, which was denied by Helmholtz. Comparing the perception of sound with that of touch, he advances a modification of the resonance theory which appears to meet some of the objections that may be urged against it as it was enunciated by Helmholtz.

Sensitiveness of the ear.

Various physicists have attempted to measure the sensitiveness of the ear by estimating the amplitude of the molecular movements necessary to call forth the feeblest audible sound. Thus Töpler and Boltzmann, on data founded on experiments with organ pipes, state that the ear is affected by vibrations of molecules of the air not more in amplitude than ·0004 mm. at the ear, or 0·1 of the wave-length of green light, and that the energy of such a vibration on the drum-head is not more than $\frac{1}{543}$ billionth kilog., or $\frac{1}{17}$th of that produced upon an equal surface of the retina by a single candle at the same distance (*Ann. d. Phys. u. Chem.*, Leipzig, 1870, Bd. cxli. S. 321). Lord Rayleigh, by two other methods, arrived at the conclusion "that the streams of energy required to influence the eye and ear are of the same order of magnitude." He estimated the amplitude of the movement of the aërial particles, with a sound just audible, as less than the ten-millionth of a centimetre, and the energy emitted when the sound was first becoming audible, at 42·1 ergs. per second. He also states that in considering the amplitude or condensation in progressive aërial waves, at a distance of 27·4 metres from a tuning-fork, the maximum condensation was $= 6{\cdot}0 \times 10^{-9}$ cm., a result showing "that the ear is able to recognize the addition or subtraction of densities far less than those to be found in our highest vacua" (*Proc. Roy. Soc.*, 1877, vol. xxvi. p. 248; *Lond. Edin. and Dub. Phil. Mag.*, 1894, vol. xxxviii. p. 366).

Binaural audition.

Hearing with two ears does not affect the quality of sounds, but it must to some extent affect the intensity with which sounds are perceived. We hear a sound louder with two ears than with one, and there can be no doubt that by having two ears we are enabled to judge of the direction of sound with more accuracy than if we used only one ear. Our judgment as to the direction of sounds is formed mainly from the different degrees of intensity with which they are heard by two ears. Lord Rayleigh states that diffraction of the sound-waves will occur as they pass round the head to the ear farthest from the source of sound; thus partial tones will reach the two ears with different intensities, and thus quality of tone may be affected (*Trans. Music. Soc.*, London, 1876). Silvanus P. Thompson advocates a similar view, and he shows that the direction of a complex tone can be more accurately determined than the direction of a simple tone, especially if it be of low pitch (*Phil. Mag.*, 1882).

The Sense of Equilibrium.—By this term is meant the sense, or series of sensations, by which we have a feeling of security in standing, walking, and indeed in all the movements by which the body is carried through space. Such a feeling of security is necessary both for maintaining any posture, such as standing, or for performing any movement. If this feeling is absent or uncertain, or if there are contradictory sensations, then definite muscular movements are inefficiently or irregularly performed, and the body may stagger or fall. When we stand erect on a firm surface, like a floor, there is a feeling of resistance, due to nervous impulses reaching the brain from the soles of the feet and from the muscles of the limbs and trunk. In walking or running, these feelings of resistance seem to precede and guide the muscular movements necessary for the next step. If these are absent or perverted or deficient, as is the case in the disease known as locomotor ataxia, then, although there is no loss of the power of voluntary movement, the patient staggers in walking, especially if he is not allowed to look at his feet, or if he is blindfolded. He misses the guiding sensations that come from the limbs; and with perhaps the feeling that he is walking on a soft substance, offering little or no resistance, he cannot avoid staggering, and his muscular movements become fitful and irregular. Such a condition may be artificially brought about by washing the soles of the feet with chloroform or ether. And it has been observed to exist partially after extensive destruction of the skin of the soles of the feet by burns or scalds. This shows that tactile impulses from the skin take a share in generating the guiding sensation. In the disease above mentioned, however, tactile impressions may be nearly normal, but the guiding sensation is weak and inefficient, owing to the absence of impulses from the muscles. The disease is known to depend on morbid changes in the posterior columns of the spinal cord, by which impulses are not freely transmitted upwards to the brain. These facts point to the existence of impulses coming from the muscles and tendons. It is now known that there exist in both end-organs in the shape of peculiar spindles, in the substance of muscle, and of little rosettes or coils or loops of nerve fibres in close proximity to tendons. The transmission of such impulses gives rise to what is termed the *muscular sense*, and the guiding sensation which precedes co-ordinated muscular movements largely depends on these impulses. Thus from the limbs streams of nervous impulses pass to the sensorium from the skin and from muscles and tendons; these may or may not arouse consciousness, but they guide or evoke muscular movements of a co-ordinated character, more especially of the limbs.

In animals whose limbs are not adapted for delicate touch nor for the performance of complicated movements, such as some mammals and birds and fishes, the guiding sensations seem to depend largely on the sense of vision. This sense in man, instead of assisting, sometimes disturbs the guiding sensation. It is true that in locomotor ataxia visual sensations may take the place of the tactile and muscular sensations that are absent, and the man can walk without staggering if he is allowed to look at the floor, and especially if he is guided by either longitudinal or transverse straight lines. On the other hand, the acrobat on the wire-rope dare not trust his visual sensations in the maintenance of his equilibrium. He usually keeps his eyes fixed on one point instead of allowing them to wander to objects below him, and his muscular movements are regulated by the impulses that come from the skin and muscles of his limbs. The feeling of insecurity probably arises from a conception of height, and also from a knowledge, the result of experience, that by no muscular movements can a man avoid a catastrophe if he should fall. A bird, on the other hand, depends largely on visual impressions, and it knows by experience that if launched into the air from a height it can fly. Here, probably, is an explanation of the large size of the eyes of birds. Cover the head, as in hooding a falcon, and the bird seems to be deprived of the power of voluntary movement. Little effect will be produced if we attempt to restrain the movements of a cat by covering its eyes. A fish also is readily deprived of the power of motion if its eyes are covered. But both in the bird and in the fish tactile and muscular impressions, especially the latter, come into play in the mechanism of equilibrium. In flight the large-winged birds, especially in soaring, can feel the most delicate wind-pressures, both as regards direction and force, and they adapt the position of their body so as to catch the pressure at the most efficient angle. The same is true of the fish, especially of the flat-fishes. In these animals, and in mammals generally, the sense of equilibrium depends, then, on streams of tactile, muscular, and visual impressions pouring in on the sensorium, and calling forth appropriate muscular movements. It has also been suggested that nervous impulses coming from the abdominal viscera may take part in the mechanism. The presence in the mesentery of felines (cats, &c.) of large numbers of Pacinian corpuscles, which are believed to be modified tactile bodies, favours this supposition. Such animals are remarkable for the delicacy of all these muscular movements, especially those of balancing and leaping.

Semi-circular canals.

There is still another channel by which nervous impulses may reach the sensorium and play their part in the sense of equilibrium, namely, from the semicircular canals, a portion of the internal ear. We have already learned (under *Hearing*) that the appreciation of sound is in reality an appreciation of variations of pressure. We have also seen that the labyrinth consists of the vestibule, the cochlea, and the semicircular canals. There can be no doubt that the cochlea has to do with the reception of sound-waves (variations of pressure) that constitute musical tones. This it accomplishes by the structures in the ductus cochlearis. In the vestibule we find two sacs, the saccule next to and communicating with the ductus cochlearis, and the utricle communicating with the semicircular canals. The base of the stapes communicates pressures to the utricle. The membranous portion of the semicircular canals consists of a tube, dilated at one end into a swelling or pouch, termed the ampulla, and each end communicates freely with the utricle. It is important to note that on the posterior wall of both the saccule and of the utricle there is a ridge or crest, termed in each case the macula acustica, bearing a highly specialized epithelium, and that a similar structure exists in each ampulla. This would suggest that all three structures have to do with hearing; but, on the other hand, there is experimental evidence that the utricle and the canals may transmit impressions that have to do with equilibrium. Pressure of the base of the stapes is exerted on the utricle. This will compress the fluid in that cavity, and tend to drive the fluid into the semicircular canals that communicate with that cavity by five openings. Each canal is surrounded by a thin layer of perilymph, so that it may yield a little to this pressure, and exert a certain pull or pressure on the nerve-endings in each ampulla. Thus nervous impulses may be generated in the ampullæ which are primarily excited at the base of the stapes.

The three semicircular canals lie in the three directions in space, and it has been suggested that they have to do with our appreciation of the direction of sound. But our appreciation of sound is very inaccurate: we look with the eyes for the source of the sound, and instinctively direct the ears or the head, or both, in the direction from which the sound appears to proceed. But the relationship of the canals on the two sides must have some physiological significance. Thus (1) the six canals are sensibly parallel, two and two; or (2) the two horizontal canals are in the same plane, while the superior canal on one side is nearly parallel with the posterior canal of the other. These facts point to the two sets of canals and ampullæ acting as one organ, in a manner analogous to the action of two retinæ for single vision (Crum-Brown, *Nature*, London, 1878, p. 449; also M'Kendrick's *Physiology*, vol. ii. p. 694).

We have next to consider how the canals may possibly act in connexion with the sense of equilibrium. So long ago as 1820, Purkinje (*Med. Jahrb.*, Wien, 1820, Bd. vi.) studied the well-known vertigo that follows rapid rotation of the body in the erect position on a vertical axis. On stopping the rotation there is a sense of rotation in the opposite direction, and this may occur even when the eyes are closed. Purkinje noticed that the position of the imaginary axis of rotation depends on the axis around which the head revolves (M'Kendrick, *op. cit.* vol. ii. p. 701). In 1828 Flourens discovered that injury to the canals causes disturbance of equilibrium and loss of co-ordination, and that sections of the canals produce a rotatory movement of a kind corresponding to the canal that had been divided. Thus division of a membranous canal causes rotatory movements round an axis at right angles to the plane of the divided canal. The body of the animal always moves in the direction of the cut canal (Flourens, *Comptes Rendus*, 11th August 1828, p. 5). Many other observers have corroborated these experiments. Goltz was the first who clearly formulated the conditions necessary for equilibration. He put the matter thus:—(1) A central co-ordinating organ—in the brain; (2) centripetal fibres, with their peripheral terminations—in the ampullæ; and (3) centrifugal fibres, with their terminal organs—in the muscular mechanisms. A lesion of any one of these portions of the mechanism causes loss or impairment of balancing (Goltz, *Archiv f. d. ges. Physiol.*, Bonn, Bd. iii. S. 172). Cyon also investigated the subject, and arrived at the following conclusions:—(1) To maintain equilibrium, we must have an accurate notion of the position of the head in space; (2) the function of the semicircular canals is to communicate impressions that give an accurate representation of this position—each canal having a relation to one of the dimensions of space; (3) disturbance of equilibrium follows section; (4) involuntary movements following section are due to abnormal excitations; (5) abnormal movements occurring a few days after the operation are caused by irritation of the cerebellum (Cyon, *Recherches expérimentales sur les fonctions des canaux semi-circulaires*, Thèse, 1878).

On theoretical considerations of a physical character, Mach, Crum-Brown, and Breuer have advanced theories based on the idea of the canals being organs for sensations of acceleration of movement, or for the sense of rotation (Mach, *Grundlinien der Lehre von den Bewegungsempfendungen*, Leipzig, 1875; Crum-Brown, *Journ. of Physiol. Lond.* vol. viii.; Breuer, *Jahrb. d. Gesellsch. d. Artze*, Wien, 1874–75). Mach first pointed out that Purkinje's phenomena, already alluded to, were in all probability related to the semicircular canals. "He showed that when the body is moved in space, in a straight line, we are not conscious of the velocity of motion, but of variations in this velocity. Similarly, if a body is rotated round a vertical axis, we perceive only angular acceleration and not angular velocity. The sensations produced by angular acceleration last longer than the acceleration itself, and the position of the head during the movements enables us to determine direction" (Schäfer's *Text-Book of Physiology*; article *Hearing*, by author, vol. ii. p. 1200). Both Mach and Goltz state that varying pressures of the fluid in the canals produced by angular rotation produce sensations of movement (always in a direction opposite to the rotation of the body), and that these, in turn, cause the vertigo of Purkinje and the phenomena of Flourens. Mach, Crum-Brown, and Breuer advance hydrodynamical theories—that is to say, they assume that the fluids move in the canals—and the two latter differ from Mach only in details. Goltz, on the other hand, supports a hydrostatical theory—that is to say, he assumes that the phenomena can be accounted for by varying pressures. Crum-Brown differs from Mach and Breuer as follows:—(1) In attributing movement or variation of pressure not merely to the endolymph, but also to the walls of the membranous canals and to the surrounding perilymph; and (2) in regarding the two labyrinths as one organ, all the six canals being required to form a true conception of the rotating motion of the head. He sums up the matter thus: "We have two ways in which a relative motion can occur between the endolymph and the walls of the cavity containing it—(1) When the head begins to move, here the walls leave the fluid behind; (2) when the head stops, here the fluid flows on. In both cases the sensation of rotation is felt. In the first this sensation corresponds to a real rotation, in the second it does not, but in both it corresponds to a real acceleration (positive or negative) of rotation, using the word acceleration in its technical kinematical sense" (Crum-Brown, *Nature*, London, 1878; review of Cyon's Thesis, *loc. cit.*).

Cyon states that the semicircular canals only indirectly assist in giving a notion of spatial relations. "He holds that knowledge of the position of bodies in space depends on nervous impulses coming from the contracting ocular muscles; that the oculomotor centres are in intimate physiological relationship with the centres receiving impulses from the nerves of the semicircular canals; and that the oculomotor centres, thus excited, produce the movements of the eyeballs, which then determine our notions of spatial relations" (Schäfer's *Text-Book*, *loc. cit.* vol. ii. p. 1203). These views are supported by experiments of Lee on dog-fish. When the fish is passively rotated round different axes there are compensating movements of the eyes and fins. "It was observed that if the fish were rotated in the plane of one of the canals, exactly the same movements of the eyes and fins occurred as were produced by experimental operation and stimulation of the ampulla of that canal" (Lee, *Journ. Physiol.*, Camb. and London, vol. xvii. p. 192). Sewall, in 1883, carried out experiments on young sharks and skates, and concluded that there was not sufficient evidence to connect the canals, and indeed the labyrinth, with the sense of equilibrium (Sewall, *Journ. Physiol.*, Camb. and Lond., vol. iv. p. 339). Lee returned to the subject in 1894, and, after numerous experiments on dog-fish, in which the canals or the auditory nerves were divided, obtained strong evidence that the ampullæ contain sense-organs connected with the sense of equilibrium (Lee, *Journ. Physiol.*, Camb. and London, 1894, vol. xv.).

It has been found by physicians and aurists that disease or injury of the canals, occurring rapidly, produces giddiness, staggering, nystagmus (a peculiar twitching movement of the muscles of the eyeballs), vomiting, noises in the ear, and more or less deafness. It is said, however, that if pathological changes come on slowly, so that the canals and vestibule are converted into a solid mass, none of these symptoms may occur. On the whole, the evidence is in favour of the view that from the semicircular canals nervous impulses are transmitted, which, co-ordinated with impulses coming from the visual organs, from the muscles, and from the skin, form the bases of these guiding sensations on which the sense of equilibrium depends. These impulses may not reach the level of consciousness, but they call into action co-ordinated mechanisms by which complicated muscular movements are effected. (J. G. M.)

Physiology of Development. See EMBRYOLOGY.

Physiology of Plants.—The great development of research into the vital phenomena of living organisms, which was a conspicuous feature of the scientific work of the last three decades of the 19th century, has tended to establish and develop the view that physiology should not be divided into two distinct sections, animal and vegetable, but that it exhibits an essential unity, and comprehends the study of all living protoplasm, whether the organisms under observation are simple or complex, and whatever is the nature of the differentiation exhibited by them. The so-called *vegetable physiology*, at the beginning of that period, was in arrear of *animal*, and particularly of *human*, physiology, the study of the latter being followed by many more observers, and from its relative degree of advancement being the more capable of rapid development. It was fully recognized by its followers that the dominating influence in the structure and working of the body was the protoplasm, and the division of labour which it exhibited, with the accompanying or resulting differentiation into various tissues, was the special subject of investigation. Many who followed the study of vegetable structure did not at that time give an equal prominence to this view. The early histological researches of botanists led them to the recognition of the vegetable cell, and the leading writers in the middle of the 19th century pointed out the probable identity of Von Mohl's "protoplasm" with the "sarcode" of zoologists. They laid great stress on the nitrogenous nature of protoplasm, and noted that it preceded the formation of the cell-membrane. But by the ordinary student of thirty years later their work was to some extent overlooked, and the *cell-wall* assumed a prominence to which it was not entitled. The study of the *differentiation* of protoplasm was at that time seldom undertaken, and no particular attention was paid either to fixing it, to enable staining methods to be accurately applied to it, or to studying the action of chemical reagents upon it. It is only comparatively recently that the methods of histological investigation used by animal physiologists have been carefully and systematically applied to the study of the vegetable organisms. They have, however, been attended with wonderful results, and have revolutionized the whole study of vegetable structure. They have emphasized the statements of Von Mohl, Cohn, and other writers alluded to, that the protoplasm is here also the dominant factor of the body, and that all the peculiarities of the cell-wall can only be interpreted in the light of the needs of the living substance.

The Nature of the Organization of the Plant, and the Relations of the Cell-Membrane and the Protoplasm.—This view of the structure of the plant and this method of investigation lead us to a greatly modified conception of its organization, and afford more completely an explanation of the peculiarities of form found in the vegetable kingdom.

The study of simple organisms, many of which consist of nothing but a little mass of protoplasm, exhibiting a very rudimentary degree of differentiation, so far as our methods enable us to determine any at all, shows that the duties of existence can be discharged in the absence of any cell-wall. Those organisms which possess the latter are a little higher in the scale of life than those which remain unclothed by it, but a comparison of the behaviour of the two quickly enables us to say that the membrane is of but secondary importance, and that for those which possess it, it is nothing more than a protective covering for the living substance. Its physical properties, permeability by water, extensibility and elasticity, receive their interpretation in the needs of the latter. We come, accordingly, to regard it as practically an exoskeleton, and its functions as distinctly subordinate to those of the protoplasm which it clothes. If we pass a little higher up the scale of life, we meet with forms consisting of two or more cells, each of which contains a similar minute mass of living substance. A study of them shows that each is practically independent of the others; in fact, the connexion between them is so slight that they can separate and each become free without the slightest disadvantage to another. So long as they are connected together mechanically, they have apparently the power of influencing one another in various ways, and of passing liquid or gaseous materials from one to another. The conjoined organism is, in fact, a colony or association of the protoplasmic units, though each unit retains its independence. When we pass, again, from these to examine more bulky, and consequently more complex, plants, we find that the differences which can be observed between them and the simple lowly forms are capable of being referred to the increased number of the protoplasmic units and the consequent enlarged bulk of the mass or colony. Every plant is thus found to be composed of a number of these protoplasmic units, or, as they may preferably be termed, *protoplasts*, all of which are at first exactly alike in appearance and in properties. This is evident in the case of such plants as have a body consisting of filaments or plates of cells, and is little less conspicuous in those whose mass is but small, though the cells are evidently capable of computation in three dimensions. It does not at first appear to be the same with the bulkier plants, such as the ordinary green herbs, shrubs, or trees, but a study of their early development indicates that they do not at the outset differ in any way from the simple undifferentiated forms. Each commences its existence as a simple naked protoplast, in the embryo-sac or the archegonium, as the case may be. After the curious fusion with another similar protoplast, which constitutes what we call fertilization, the next stage in complexity already noted may be observed, the protoplasm becoming clothed by a cell-membrane. Very soon the single cell gives rise to a chain of cells, and this in turn to a cell mass, the individual units of which are at first quite uniform. With increase of number, however, and consequently enlargement of bulk in the colony, differentiation becomes compulsory. The requirements of the several protoplasts must be met by supplies from without, and, as many of them are deep seated, varieties of need arise, so that various members of the colony are set apart for special duties, masses of them being devoted to the discharge of one function, others to that of another, and so on. Such limitations of the powers and properties of the individuals have for their object the well-being of the community of which those individuals are constituents.

Physiological and Morphological Differentiation.—The first indication of this differentiation in the vegetative body of the plant can be seen not only in the terrestrial green plants which have been particularly referred to, but also in the bulkier sea-weeds. It is an extension of the first differentiation which was observable in the simple protoplasts first discussed, the formation, that is, of a protective covering. *Fucus* and its allies, which form conspicuous members of the larger Algæ, have their external cells much smaller, more closely put together, and generally much denser, than the rest of their tissue. In the lowly as well as the higher green plants we have evidence of specialization of the external protoplasts for the same purpose, which takes various shapes and shows different degrees of completeness, culminating in the elaborate barks which clothe our forest trees.

The second prominent differentiation which presents itself takes the form of a provision to supply the living substance with water. This is a primal necessity of the protoplast, and every cell gives evidence of its need by adopting one of the various ways in which such need is supplied. What little differentiation can be found to exist in the protoplasm of the simple unicellular organism shows the importance of an adequate water supply, and, indeed, the dependence of life upon it. The naked cells which have been alluded to live in water, and call therefore for no differentiation in connexion with this necessity; but those which are surrounded by a cell-wall always develop within themselves a *vacuole* or cavity which occupies the greater part of their interior, and the hydrostatic pressure of whose contents keeps the protoplasm in contact with the membrane, setting up a condition of turgidity.

The need for a constant supply of water is partly based upon the constitution of protoplasm, so far as we know it. The apparently structureless substance is saturated with it; and if once a cell is completely dried, even at a low temperature, in the enormous majority of cases its life is gone, and restoration of water fails to enable it to recover. Besides this intimate relationship, however, we can point to other features of the necessity for a constantly renewed water supply. The protoplasm derives its food from substances in solution in the water; the various waste products which are incident to its life are excreted into it, and so removed from the sphere of its activity. The raw materials from which the food is constructed are absorbed from the exterior in solution in water, and the latter is the medium through which the gaseous constituents necessary for life reach the protoplasm. Moreover, growth is essentially dependent upon water supply. There is little wonder, then, that in a colony of protoplasts such as constitute a large plant, a considerable degree of differentiation is evident, bearing upon the question of water supply. Certain cells of the exterior are set apart for absorption of water from the soil, this being the source from which supplies are derived. Others are devoted to the work of carrying it to the protoplasts situated in the interior and at the extremities of the plant, a *conducting system* of considerable complexity being the result.

Other collections of cells are in many cases set apart for giving rigidity and strength to the mass of the plant. It is evident that as the latter increases in bulk, more and more attention must be paid to the dangers of uprooting by winds and storms. Various mechanisms have been adopted in different cases, some connected with the subterranean and others with the sub-aërial portions of the plant. Another kind of differentiation in such a cell-mass as we are dealing with is the setting apart of particular groups of cells for various metabolic purposes. We have the formation of numerous mechanisms which have arisen in connexion with the question of food supply, which may not only involve particular cells, but also lead to differentiation in the protoplasm of those cells, as in the development of the chloroplastids of the leaves and other green parts.

The inter-relations of the members of a large colony of protoplasts such as constitute a tree, demand much adjustment. Relations with the exterior are continually changing, and the needs of different regions of the interior are continually varying, from time to time. Two features which are essentially protoplasmic assume a great importance when we consider these relations. They are the power of receiving impressions or stimuli from the exterior, and of communicating with each other, with the view of co-ordinating a suitable response. We have nothing structural which corresponds to the former of these. In this matter, differentiation has proceeded very differently in animals and plants respectively, no nerves or sense organs being structurally recognizable. Communication between the various protoplasts of the colony is, however, carried on by means of fine protoplasmic threads, which are continuous through the cell-walls.

All the peculiarities of structure which we encounter consequently support the view with which we started, that the protoplasm of the plant is the dominant factor in vegetable structure, and that there need be but one subject of physiology, which must embrace the behaviour of protoplasm wherever found. There can be no doubt that there is no fundamental difference between the living substance of animals and plants, for many forms exist which cannot be referred with certainty to either kingdom. Free-swimming organisms without cell-membranes exist in both, and from them series of forms can be traced in both directions. Cellulose, the material of which vegetable cell-walls are almost universally composed, at any rate in their early condition, is known to occur, though only seldom, among animal organisms. Such forms as *Volvox* and the group of the *Myxomycetes* have been continually referred to both kingdoms, and their true systematic position is still a subject of controversy. All physiology, consequently, must be based upon the identity of the protoplasm of all living beings.

This method of study has to a large extent modified our ideas of the relative importance of the parts of such an organism as a large tree. The interest with which we regard the latter no longer turns upon the details of the structure of its trunk, limbs, and roots, to which the living substance of the more superficial parts was subordinated. Instead of regarding these as only ministering to the construction of the bulky portions, the living protoplasts take the first place as the essential portion of the tree, and all the other features are important mainly as ministering to their individual well-being and to their multiplication. The latter feature is the *growth* of the tree, the well-being of the protoplasts is its *life* and *health*. The interest passes from the bulky dense interior, with the elaborate features of its cell-walls, to the superficial parts, where its life is in evidence. We see herein the reason for the great subdivision of the body, with its finely cut twigs and their ultimate expansions, the leaves, and we recognize that this subdivision is only an expression of the need to place the living substance in direct relationship with the environment. The formation and gradually increasing thickness of its bark are explained by the continually increasing need of adequate protection to the living cortex, under the strain of the increasing framework which the enormous multiplication of its living protoplasts demands, and the development of which leads to continual rupture of the exterior. The increasing development of the wood as the tree grows older is largely due to the demands for the conduction of water and mineral matters dissolved in it, which are made by the increased number of leaves which from year to year it bears, and which must each be put into communication with the central mass by the formation of new vascular bundles. Similar considerations apply to the peculiar features of the root-system. All these points of structure can only be correctly interpreted after a consideration of the needs of the individual protoplasts, and of the large colony of which they are members.

Gaseous Interchanges and their Mechanism.—Another feature of the construction of the plant has in recent years come into greater prominence than was formerly the case. The organism is largely dependent for its vital processes upon gaseous interchanges. It must receive a large constituent of what ultimately becomes its food from the air which surrounds it, and it must also take in from the same source the oxygen of its respiratory processes. On the other hand, the aërial environment presents considerable danger to the young and tender parts, where the protoplasts are most exposed to extremes of heat, cold, wet, &c. These must in some way be harmonized. No doubt the primary object of the cell-wall of even the humblest protoplast is protection, and this too is the meaning of the coarser tegumentary structures of a bulkier plant. These vary considerably in completeness with its age; in its younger parts the outer cell-wall undergoes the change known as *cuticularization*, the material being changed both in chemical composition and in physical properties. The corky layers which take so prominent a share in the formation of the bark are similarly modified and subserve the same purpose. But these protective layers are in the main impermeable by gases and by either liquid or vapour, and prevent the access of either to the protoplasts which need them. Investigations carried out by Blackman, and by Brown and Escombe, have shown clearly that the view put forward by Boussingault, that such absorption of gases takes place through the cuticular covering of the younger parts of the plant, is erroneous and can no longer be supported. The difficulty is solved by the provision of a complete system of minute intercellular spaces which form a continuous series of delicate canals between the cells, extending throughout the whole substance of the plant. Every protoplast, except in the very young regions, has part of its surface abutting on these, so that its wall is accessible to the gases necessary for its vital processes. There is no need for cuticularization here, as the external dangerous influences do not reach the interior, and the processes of absorption which Boussingault attributed to the external cuticularized cells can take place freely through the delicate cell-walls of the interior, saturated as these are with water. This system of channels is in communication with the outer atmosphere through numerous small apertures, known as *stomata*, which are abundant upon the leaves and young twigs, and gaseous interchange between the plant and the air is by their assistance rendered constant and safe. This system of intercellular spaces, extending throughout the plant, constitutes a reservoir, charged with an atmosphere which differs somewhat in its composition from the external air, its gaseous constituents varying from time to time and from place to place, in consequence of the interchanges between itself and the protoplasts. It constitutes practically the exterior environment of the protoplasts, though it is ramifying through the interior of the plant.

The importance of this provision in the case of aquatic vascular plants of sturdy bulk is even greater than in that of terrestrial organisms, as their environment offers considerable obstacles to the renewal of the air in their interior. They are without stomata on their submerged portions, and the entry of gases can only take place by diffusion from the water through their external cells, which are not cuticularized. Those which are only partially submerged bear stomata on their exposed portions, so that their environment approximates towards that of a terrestrial plant, but the communication even in their case is much less easy and complete, so that they need a much larger reservoir of air in their interior. This is secured by the development of much larger intercellular spaces, amounting to lacunæ or passages of very considerable size, which are found ramifying in different ways in their interior.

Transpiration.—In the case of terrestrial plants, the continual renewal of the water contained in the vacuoles of the protoplasts demands a copious and continuous evaporation. This serves a double purpose, bringing up from the soil continually a supply of the soluble mineral matters necessary for their metabolic processes, which only enter the plant in solutions of extreme dilution, and at the same time keeping the plant cool by the process of evaporation. The latter function has been found to be of extreme importance in the case of plants exposed to the direct access of the sun's rays, the heat of which would rapidly cause the death of the protoplasts were it not employed in the evaporation of the water. Brown and Escombe have shown that the amount of solar energy taken up by a green leaf may often be fifty times as much as it can utilize in the constructive processes of which it is the seat. If the heat were allowed to accumulate in the leaf unchecked, they have computed that its temperature would rise during bright sunshine at the rate of more than 12° C. per minute, with of course very rapidly fatal results. What is not used in the constructive processes is employed in the evaporation of the water, the leaf being thus kept cool. Whether the leaf is brightly or only moderately illuminated, the same relative proportions of the total energy absorbed are devoted to the purposes of composition and construction respectively. This large evaporation, which constitutes the so-called *transpiration* of plants, takes place not into the external air but into this same intercellular space system, being possible only through the delicate cell-walls upon which it abuts, as the external coating, whether bark, cork, or cuticle, is impermeable by watery vapour. The latter ultimately reaches the external air by diffusion through the stomata, whose dimensions vary in proportion as the amount of water in the epidermal cells becomes greater or less.

Mechanism and Function of Stomata.—It is not quite exact to speak of either the gaseous interchanges or the transpiration as taking place through the stomata. The entry of gases into, and exit from, the cells, as well as the actual exhalation of watery vapour from the latter, take place in the intercellular space system of which the stomata are the outlets. The opening and closing of the stomata is the result of variation in the turgidity of their guard cells, which is immediately affected by the condition of turgidity of the cells of the epidermis contiguous to them. The amount of watery vapour in the air passing through a stoma has no effect upon it, as the surfaces of the guard cells abutting on the air chamber are strongly cuticularized, and therefore impermeable. The only way in which their turgidity is modified is by the entry of water into them from the contiguous cells of the general epidermis and its subsequent withdrawal through the same channel. This opening and closing of the stomata must be looked upon as having a direct bearing only on the emission of watery vapour. There is a distinct advantage in the regulation of this escape, and the mechanism is directly connected with the greater or smaller quantity of water in the plant, and especially in its epidermal cells. This power of varying the area of the apertures by which gases enter the internal reservoirs is not advantageous to the gaseous interchanges—indeed, it may be directly the reverse. It may lead to an incipient asphyxiation, as the supply of oxygen may be greatly interfered with and the escape of carbon dioxide may be almost stopped. It may at other times lead to great difficulties in the supply of the gaseous constituents which are used in the manufacture of food. The importance of transpiration is, however, so great, that these risks must be run.

Nature of the Food of Plants.—The recognition of the fundamental identity of the living substance in animals and plants has directed attention to the manner in which plants are nourished, and especially to the exact nature of their food. The idea was till recently currently accepted, that anything which plants absorbed from without, and which went to build up their organic substance, or to supply them with energy, or to exert some beneficial influence upon their metabolism, constituted their *food*. Now, as the materials which plants absorb are carbon dioxide from the air, and various inorganic compounds from the soil, together with water, it is clear that if this view is correct, vegetable protoplasm must be fed in a very different way from animal, and on very different materials. A study of the whole vegetable kingdom, however, throws considerable doubt upon the theory that the compounds absorbed are in the strict sense to be called food. Fungal and phanerogamic parasites can make no use of such substances as carbon dioxide, but draw elaborated products from the bodies of their hosts. Those Fungi which are saprophytic can only live when supplied with organic compounds of some complexity, which they derive from decomposing animal or vegetable matter. Even in the higher flowering plants, in which the processes of the absorption of substances from the environment has been most fully studied, there is a stage in their life in which the nutritive processes approximate very closely to those of the group last mentioned. When the young sporophyte first begins its independent life—when, that is, it exists in the form of the embryo in the seed—its living substance has no power of utilizing the simple inorganic compounds spoken of. Its nutritive pabulum is supplied to it in the shape of certain complex organic substances which have been stored in some part or other of the seed, sometimes even in its own tissues, by the parent plant from which it springs. When the tuber of a potato begins to germinate, the shoots which it puts out derive their food from the accumulated store of nutritive material which has been laid up in the cells of the tuber. If we examine the seat of active growth in a young root or twig, we find that the cells in which the organic substance, the protoplasm, of the plant is being formed and increased, are not supplied with carbon dioxide and mineral matter, but with such elaborated material as sugar and proteid substances, or others closely allied to them.

Identity of the Food of Animals and Plants.—It is evidently to the actual seats of consumption of food, and of consequent nutrition and increase of living substance, that we should turn when we wish to inquire what are the nutritive materials of plants. If we go back to the first instance cited, the embryo in the seed and its development during germination, we can ascertain what is necessary for its life by inquiring what are the materials which are deposited in the seed, and which become exhausted by consumption as growth and development proceed. We find them to consist of representatives of the great classes of food-stuffs on which animal protoplasm is nourished, and whose presence renders seeds such valuable material for animal consumption. They are mainly carbohydrates such as starch and sugar, proteids in the form of globulins or albumoses, and in many cases fats and oils, while certain other bodies of similar nutritive value are less widely distributed.

The differences between the nutritive processes of the animal and the plant are not therefore fundamental, as they were formerly held to be. The general vegetable protoplasm has not the capacity of being nourished by inorganic substances which are denied to the living substance of the animal world. Differences connected with the mode of supply of nutritive material do exist, but they are mainly correlated with the structure of the organisms, which makes the method of absorption different. The cell-walls of plants render the entry of solid material into the organism impossible. The food must enter in solution in order to pass the walls. Moreover, the stationary habit of plants, and the almost total absence of locomotion, makes it impossible for them to seek their food.

The Special Apparatus of Plants for constructing Food.—The explanation of the apparent difference of food supply is very simple. Plants are furnished with a constructive mechanism by which they are enabled to fabricate the food on which they live from the inorganic, gaseous, and liquid matters which they absorb. The fact of such absorption does not render these substances food; they are taken in not as food, but as raw materials to be subjected to the action of this constructive mechanism, and by it to be converted into substances that can nourish protoplasm, both vegetable and animal. It is sometimes forgotten, when discussing questions of animal nutrition, that all the food materials of all living organisms are prepared originally from inorganic substances in exactly the same way, in exactly the same place, and by the same machinery, which is the *chlorophyll apparatus* of the vegetable kingdom. A consideration of these facts emphasizes still more fully the view with which we set out, that all living substance is fundamentally the same, though differentiated both anatomically and physiologically in many directions and in different degrees. All is nourished alike on materials originally prepared by a mechanism attached to the higher vegetable organism, and capable of being dissociated, in theory at least, from its own special means of nutrition, if by the latter term we understand the appropriation by the protoplasm of the materials so constructed.

The possession of this mechanism, which we have alluded to as the chlorophyll apparatus, is limited to those plants which are green, or which have green portions, the colour, of course, being the inherent colour of the mechanism itself. The latter is especially charged with the duty of manufacturing carbohydrates, its action in the formation of proteids being not completely understood. The construction of the latter apparently depends upon a supply of carbohydrate material, together with other constituents, so that indirectly, at least, the chlorophyll apparatus is concerned in their preparation. The formation of fats is still less understood. It appears to be a function of protoplasm itself under certain conditions of nutrition, and therefore removed a little farther from the influence of the chlorophyll machinery.

The story of the construction processes is not, however, complete until we have considered also the groups of plants which contain no chlorophyll apparatus. We have evidence in the case of many of these that the power of construction is not entirely absent from them. Fungi can live, thrive, and grow in nutritive media which contain carbohydrates, together with certain salts of ammonia, but which are free from proteids. As we have seen strong reasons to believe that their protoplasm is like that of animals, and therefore incapable of being nourished by inorganic compounds of nitrogen, we must surmise their possession of a mechanism which can construct proteids if supplied with these nitrogen compounds, together with sugar. We have no apparent differentiation of such a mechanism, and its existence must remain for the present only as a probability, although a strong one. It must exist in the green plant side by side with the chlorophyll apparatus; indeed, this is probable from the fact that a good deal of evidence points to the leaves as the seat of proteid construction. It may be that this power is a particular differentiation of a physiological kind in all vegetable protoplasm, or in that of certain cells. The idea of an identity of protoplasm does not involve a denial of special powers developed in it in different situations, and the possession of such a power by the vegetable cell is not more striking than the location of powers of co-ordination and thought in the protoplasm of cells of the human brain.

The normal green plant is seen thus to be in possession of a complete machinery for the manufacture of its own food. The process of manufacture of carbohydrates, in which are primarily concerned the carbon dioxide of the air and the water of the soil, has been generally spoken of as the *assimilation of carbon dioxide*, a term which the more recent work on the true nature of the food shows to be misleading, and which has already been abandoned by many writers. The carbon dioxide is not *assimilated* by the protoplasm, but is built up into carbohydrates by the chlorophyll apparatus. As the latter is only active under the influence of the radiant energy of light, the term *photosynthesis* has been suggested, to replace the older one.

Photosynthesis.—Though the actual details of this process have been studied by many observers of late years, little substantial progress has been made in ascertaining what they are. The general position has been slightly changed, the appearance of starch in the chlorophyll apparatus bearing now a slightly different interpretation from that formerly in vogue. Its very prompt appearance as soon as the apparatus became active led to the opinion that the work of the latter was only complete when the starch was formed. It appears more likely that the ultimate product is not starch but *sugar*, though what particular sugar is still a matter of controversy. The appearance of the starch is interpreted as the sign of a surplus manufacture: what is produced beyond the immediate requirements of the cell being converted into the insoluble form of starch by the plastids of the chlorophyll apparatus, and so withdrawn from the sphere of action, thereby enabling the construction of further quantities of sugar to take place. Starch, indeed, wherever it appears in the plant, seems to be a reserve store of carbohydrate material deposited where it is found for longer or shorter periods till it is needed for consumption. The readiness with which it is converted into sugar fits it especially for that duty.

Very little progress has been made in the investigation of the stages by which sugar is constructed. The view brought forward originally by Baeyer, that the first step is the decomposition of carbon dioxide into carbon monoxide and oxygen, while water is simultaneously split up into hydrogen and oxygen, and that this is at once followed by the union of the carbon monoxide and hydrogen to form formaldehyde, has only been slightly modified. There is no evidence that carbon monoxide is ever produced; indeed, there are strong reasons for disbelieving that it is. Formaldehyde has been said to be present in leaves during photosynthesis, and certain Algæ have been found capable of forming nutritive substances and storing starch in their cells when supplied with a compound of this body and sodium-hydrogen-sulphite. The evidence for its formation in the ordinary course of photosynthesis is not, however, very strong. The course of photosynthesis has been with tolerable certainty found to lead to the construction of sugar, and the general opinion has been that the sugar is a simple hexose such as glucose, $C_6H_{12}O_6$. Brown and Morris in 1892 advanced strong reasons for thinking that cane sugar, $C_{12}H_{22}O_{11}$, is the first carbohydrate synthesized, and that the hexoses found in the plant result from the decompositions of this. The whole story of the different sugars existing in the plant—their relations, and their several functions—requires renewed investigation.

Symbiosis. — Though green plants thus possess a very complete mechanism for the manufacture of their different food-stuffs, it is not always exercised to the fullest extent. Many of them are known to supplement it, and some almost entirely to replace it, by absorbing the food they need in a fully prepared condition from their environment. It may be that they procure it from decomposing organic matter in the soil, or they may get it by absorption from other plants to which they attach themselves, or they may in rare cases obtain it by preying upon insect life. The power of green plants, not even specialized in any of these directions, to absorb certain carbohydrates, particularly sugars, from the soil was demonstrated by Acton in 1889. Similar observations have been made in the case of various compounds of nitrogen, though these have not been so complex as the proteids. It was formerly the custom to regard as parasites all those plants which inserted roots or root-like organs into the tissues of other plants and absorbed the contents of the latter. The most conspicuous case, perhaps, of all these is the mistletoe, which flourishes luxuriantly upon the apple, the poplar, and other trees. Bonnier has drawn attention to the fact that the mistletoe in its turn, remaining green in the winter, contributes food material to its host when the latter has lost its leaves. The relationship thus existing he showed to be mutually beneficial, each at one time or another supplying the necessities of the other. Such a relationship is known as *symbiosis*, and the large majority of the cases of so-called parasitism among green plants can be referred to it. Bonnier showed that the same relationship could be proved in the cases of such plants as the rattle (*Rhinanthus*), the eye-bright (*Euphrasia*), and other members of the Natural Orders *Scrophulariaceæ* and *Santalaceæ*, which effect a union between their roots and the roots of other plants growing near them. The union taking place underground, while the bulk of both partners in the symbiosis rises into the air, renders the association a little difficult to see, but there is no doubt that the plants in question do afford each other assistance, forming, as it were, a kind of partnership. The most pronounced case of parasitism, that of *Cuscuta*, the dodder, which infests particularly clover fields, appears to differ only in degree from those mentioned, for the plant, bare of leaves as it is, yet contains a little chlorophyll. The advantages it can offer to its host are, however, infinitesimal when compared with the injury it does it. Many other cases of symbiosis have been investigated with some completeness, especially those in which lower plants than the Phanerogams are concerned. The relations of the Alga and the Fungus, which have formed a close associationship in the structure known as the Lichen, were established many years ago. Since about 1880 our knowledge of the species which can enter into such relationships has been materially extended, and the fungal constituents of the Lichens are known to include *Basidiomycetes* as well as *Ascomycetes*.

Mycorhizas.—The most interesting cases, however, in which Fungi form symbiotic relationships with green plants have been discovered in connexion with forest trees. The roots of many of the latter, while growing freely in the soil, are found to be surrounded with a dense feltwork of fungal mycelium, which sometimes forms a mass of considerable size. The plants showing it are not all forest trees, but include also some Pteridophytes and some of the prothallia of the Ferns, Club-mosses, Liverworts, and Horsetails. The true nature of the relationship was first recognized by Pfeffer in 1877, but few cases were known till recent years. Very complete examination, however, has now been made of many instances, and the name *mycorhiza* has been given to the symbiotic union. Two classes are recognized. In the first, which are called *ectotropic*, the fungal filaments form a thick felt or sheath round the root, either completely enclosing it or leaving the apex free. They seldom penetrate the living cells, though they do so in a few cases. The root-hairs penetrate between masses of the hyphæ of the Fungus. This type of mycorhiza is found among the Poplars, Oaks, and Fir trees. The other type is called *endotropic*. The fungal filaments either penetrate the epidermis of the root, or enter it from the stem and ramify in the interior. Some make their way through the cells of the outer part of the cortex towards the root-tip, and form a mycelium or feltwork of hyphæ, which generally occupies two or three layers of cells. From this branches pass into the middle region of the cortex and ramify through the interior half of its cells. They often cause a considerable hypertrophy of the tissue. From the outer cortical mycelium, again, branches pass through the epidermis and grow out in the soil. In such cases the roots of the plants are usually found spreading in soils which contain a large amount of humus, or decaying vegetable matter. The organic compounds of the latter are absorbed by the protruding fungal filaments, which take the place of root-hairs, the tree ceasing to develop the latter. The food so absorbed passes to the outer cortical mycelium, and from this to the inner hyphæ, which appear to be the organs of the interchange of substance, for they are attracted to the neighbourhood of the nuclei of the cells, which they enter, and in which they form agglomerations of interwoven filaments. The prothalli of the Pteridophytes, which form similar symbioses, show a somewhat different mode of arrangement, the Fungi occupying the external or the lower layers of the thalloid body.

The discovery of the widespread occurrence of this mycorhizal symbiosis must be held to be one of the most important results of research upon the nutritive processes of plants during the closing decade of the 19th century. Among green plants the symbionts include Conifers, Orchids, Heaths, Oaks, Poplars, and Beeches, though all do not derive equal advantages from the association. *Monotropas* afford an extreme case of it, having lost their chlorophyll almost entirely, and come to depend upon the Fungi for their nutriment. The fungal constituents vary considerably. Each species of green plant may form a mycorhiza with two or three different Fungi, and a single species of Fungus may enter into symbiosis with several green plants. The Fungi that have been discovered taking part in the union include *Eurotium*, *Pythium*, *Boletus*, *Agaricus*, *Lactarius*, *Penicillium*, and many others of less frequent occurrence. All the known species belong to the *Oomycetes*, the *Pyrenomycetes*, the *Hymenomycetes*, or the *Gasteromycetes*. The habit of forming mycorhizas is found more frequently in warm climates than cold; indeed, the percentage of the flora exhibiting this peculiarity seems to increase with a certain regularity from the Arctic Circle to the Equator.

Fixation of Nitrogen.—Another, and perhaps an even more important, instance of symbiotic association has come to the front during the same period. It is an alliance between the plants of the Natural Order *Leguminosæ* and certain bacterium-like forms which find a home within the tissues of their roots. The importance of the symbiosis can only be understood by considering the relationship in which plants stand with regard to the free nitrogen of the air. Long ago the view that this gas might be the source of the combined nitrogen found in different forms within the plant, was critically examined, particularly by Boussingault, and later by Lawes and Gilbert and by Pugh, and it was ascertained to be erroneous, the plants only taking nitrogen into their substance when it is presented to their roots in the form of nitrates of various metals, or compounds of ammonia. Many writers in recent years, among whom may be named especially Hellriegel and Wilfarth, Lawes and Gilbert, and Schlœsing and Laurent, have shown that the Leguminosæ as a group form conspicuous exceptions to this rule. While they are quite capable of taking up nitrates from the soil where and so long as these are present, they can grow and thrive in soil which contains no combined nitrogen at all, deriving their supplies of this element in these cases from the air. The phenomena have been the subject of very careful and critical examination for many years, and may be regarded as satisfactorily established. The power of fixing atmospheric nitrogen by the higher plants seems to be confined to this solitary group, though it has been stated by various observers with more or less emphasis that it is shared by others. Frank has claimed to have found oats, buckbeans, spurry, turnips, mustard, potatoes, and Norway maples exercising it; Nobbe and others have imputed its possession to *Elæagnus*. There is little direct evidence pointing to this extension of the power, and many experimenters directly contradict the statements of Frank.

The power exercised by the Leguminosæ is associated with the presence of curious tubercular swellings upon their roots, which are developed at a very early age, as they are cultivated in ordinary soil. If experimental plants are grown in sterilized soil, these swellings do not appear, and the plant can then use no atmospheric nitrogen. The swellings have been found to be due to a curious hypertrophy of the tissue of the part, the cells being filled with an immense number of minute bacterium-like organisms of V, X, or Y shape. The development of these structures has been studied by many observers, both in England and on the continent of Europe. They appear to be present in large numbers in the soil, and to infect the Leguminous plant by attacking its root-hairs. One of these hairs can be seen to be penetrated at a particular spot, and the entering body is then found to grow along the length of the hair till it reaches the cortex of the root. It has the appearance of a delicate tube which has granular contents, and is provided with an apex that appears to be open. The wall of the tube is very thin and delicate, and does not seem to be composed of cellulose or any modification of it. Careful staining shows that the granular substance of the interior really consists of a large number of delicate rod-like bodies. As the tube grows down the hair it maintains its own independence, and does not fuse with the contents of the root-hair, whose protoplasm remains quite distinct and separate. After making its way into the interior, the intruder sets up a considerable hypertrophy of the tissue, causing the formation of a tubercle, which soon shows a certain differentiation, branches of the vascular bundles of the root being supplied to it. The rod-like bodies from the interior of the tube, which has considerable resemblance to the zooglœa of many Bacteria, are liberated into the interior of the cells of the tubercle and fill it, increasing by a process of branching and fission. When this stage is reached, the invading tubes and their ramifications frequently disappear, leaving the cells full of the bacterioids, as they have been called. When the root dies later, such of these as remain are discharged into the soil, and are then ready to infect new plants. In some cases the zooglœa thread or tube has not been seen, the organism consisting entirely of the bacterioids.

This peculiar relationship suggests at once a symbiosis, the Fungus gaining its nutriment mainly or entirely from the green plant, while the latter in some way or other is able to utilize the free nitrogen of the air. The exact way in which the utilization or *fixation* of the nitrogen is effected remains undecided. Two views are still receiving certain support, though the second of them appears the more probable. These are: (1) That the green plant is so stimulated by the symbiotic association which leads to the hypertrophy, that it is able to fix the nitrogen or cause it to enter into combination. (2) That the fixation of the gas is carried out by the fungal organism either in the soil or in the plant, and the nitrogenous substance so produced is absorbed by the organism, which is in turn consumed by the green plant. Certain evidence which supports this view will be referred to later.

Whichever opinion is held on this point, there seems no room for doubt that the fixation of the nitrogen is concerned only with the root, and that the green leaves take no part in it. The nodules, in particular, appear to play the important part in the process. Marshall Ward has directed attention to several points of their structure which bear out this view. They are supplied with a regular system of conducting vascular bundles communicating with those of the roots. Their cells during the period of incubation of the symbiotic organism are abundantly supplied with starch. The cells in which the fungoid organism is vigorously flourishing are exceedingly active, showing large size, brilliant nuclei, protoplasm, and vacuole, all of which give signs of intense metabolic activity. The sap in these active tissues is alkaline, which has been interpreted as being in accordance with Lœw's suggestion that the living protoplasm in presence of an alkali and free nitrogen can build up ammonium nitrate, or some similar body. It is, however, at present entirely unknown what substances are formed at the expense of the atmospheric nitrogen.

The idea that the atmospheric nitrogen is gradually being made use of by plants, although it is clearly not easily or commonly utilized, has been growing steadily. Besides the phenomena of the symbiosis just discussed, certain experiments tend to show that we have a constant fixation of this gas in the soil by various Bacteria. Researches which have been carried out since 1885 by

Berthelot, Andrée, Laurent, and Schlœsing, and more recently by Kossowitsch, seem to establish the fact, though the details of the process remain undiscovered. Berthelot imputes it to the action of several species of soil Bacteria and Fungi, including the Bacterium of the Leguminosæ, when the latter is cultivated free from its ordinary host. Laurent and Schlœsing affirm that the free nitrogen of the air can be fixed by a number of humble green plants, principally lowly green Algæ. They must be exposed freely to light and air during the process, or they fail to effect it. Frank has stated that *Penicillium cladiosporioides* can flourish in a medium to which no nitrogen but that of the atmosphere has access. Kossowitsch claims to have proved that fixation of nitrogen takes place under the influence of a symbiosis of certain Algæ and soil Bacteria, the process being much facilitated by the presence of sugar. The Algæ include *Nostoc, Cystococcus, Cylindrospermum*, and a few other forms. In the symbiosis the Algæ are supplied with nitrogen by the bacteria, and in turn they construct carbohydrate material, part of which goes to the microbes. This is supported by the fact that if the mixed culture is placed in the light there is a greater fixation than when it is left in darkness. If there is a plentiful supply of carbon dioxide, more nitrogen is fixed.

Nitrification and Denitrification in the Soil.—Another aspect of the nitrogen question has been the subject of much investigation and controversy since 1877. The round of changes which nitrogenous organic matter undergoes in the soil, and how it is ultimately made use of again by plants, presents some curious features. We have seen that when nitrogenous matter is present in the condition of humus, some plants can absorb it by their roots or by the aid of mycorhizas. But the changes in it in the usual course of nature are much more profound than these. It becomes in the soil the prey of various microbes. Ammonia appears immediately as a product of the disruption of the nitrogen-containing organic molecule. Later, oxidation processes take place, and the ammonia gives rise to nitrates, which are absorbed by plants. These two processes go on successively rather than simultaneously, so that it is only towards the end of the decomposition of the organic matter that nitrification of the ammonia which is formed is set up. In this process of nitrification we can distinguish two phases, first the formation of nitrites, and secondly their oxidation to nitrates. The researches of Warington in England and Winogradsky on the Continent have satisfactorily shown that two distinct organisms are concerned in it, and that probably more than one species of each exists. One of them, comprising the genera *Nitrosomonas* and *Nitrosococcus*, has the power of oxidizing salts of ammonium to the condition of compounds of nitrous acid. When in a pure culture this stage has been reached, no further oxidation takes place. The oxidation of the nitrites into nitrates is effected by another organism, much smaller than the first. The name *Nitrobacter* has been given to this genus, most of our knowledge of which is due to the researches of Winogradsky.

The two kinds of organism are usually both present in the same soil, those of the second type immediately oxidizing the nitrites which those of the first form from ammonium salts. The *Nitrobacter* forms not only cannot oxidize the latter bodies, but they are very injuriously affected by the presence of free ammonia. When cultivated upon a suitable nutritive material in the laboratory, the organism was killed by the presence of ·015 per cent. of this gas, and seriously inconvenienced by one-third as much. Except in this respect, however, the two classes show great similarity. A very interesting peculiarity attaching to them is their distaste for organic nutriment. They can be cultivated most readily on masses of gelatinous silica impregnated with the appropriate compounds of nitrogen, and their growth takes place most copiously in the absence of light. They need a little carbonate in the nutrient material, and the source of the carbon which is found in the increased bulk of the plant is partly that and partly the carbon dioxide of the air.

We have in these plants a power which appears special to them, in the possession of some mechanism for the construction of organic substance which differs essentially from the chlorophyll apparatus of green plants, and yet brings about substantially similar results. The steps by which this carbon dioxide is built up into a compound capable of being assimilated by the protoplasm of the cells, are not known. The energy for the purpose appears to be supplied by the oxidation of the molecules containing nitrogen, so that it is dependent upon such oxidation taking place. Winogradsky has investigated this point with great care, and he has come to the conclusion that about 35 milligrammes of nitrogen are oxidized for each milligramme of carbon absorbed and fixed.

Deposition and Digestion of Reserve Materials in Plants and Animals.—As we have seen, the tendency of recent research is to prove the identity of the mode of nutrition of vegetable and animal organisms. The material on which they feed is of the same description, and its treatment in the body is precisely similar. In both groups we find the presence of nutritive material in two forms, one specially fitted for transport, the other for storage. In the plant the intermittent processes of its manufacture from the raw materials absorbed lead to the accumulation of a constantly increasing surplus, which is continuously being removed from the seats of its construction and deposited for longer or shorter periods in other parts of the structure, usually near the regions at which its ultimate consumption will take place. We have the deposition of starch, aleurone grains, amorphous proteids, fats, &c. &c., in the neighbourhood of growing points, cambium rings, and phellogens; also the more prolonged storage in tubers, seeds, and other reproductive bodies. Turning to the animal, we meet with similar provisions in the storage of glycogen in the liver and other parts, of fat in various internal regions, and so on. In both we find the reserve of food, so far as it is in excess of immediate need, existing in two conditions, the one suitable for transport, the other for storage, and we see continually the transformation of the one into the other. The formation of the storage form at the expense of the travelling stream is due to the activity of some protoplasmic structure—it may be a plastid or the general protoplasm of the cell—and is a process of secretion. The converse process is one of a true digestion, which deserves the name no less because it is intracellular. We find processes of digestion strictly comparable to those of the alimentary canal of an animal in the case of the insectivorous *Nepenthes, Drosera*, and other similar plants, and in the saprophytic Fungi. Those which now concern us recall the utilization of the glycogen of the liver, the stored fats and proteids of other parts of the animal body, being like them intracellular.

Enzymes.—The agents which effect the digestive changes in plants have been studied with much care. They have been found to be mainly enzymes, which are in many cases identical with those of animal origin. A vast number of them have been discovered and investigated, and the majority call for a brief notice. Their number, indeed, renders it necessary to classify them, and rather to look at groups of them than to examine them one by one. They are usually classified according to the materials on which they work, and we may here notice especially four principal groups, the members of which take part in the digestion of reserve materials as well as in the processes of external digestion. These decompose respectively carbohydrates, glucosides, proteids, and fats or oils. The action of the enzyme in nearly every case is one of hydration, the body acted on being made to take up water and to undergo a subsequent decomposition.

Among those which act on carbohydrates the most important are: the two varieties of *diastase*, which convert starch into maltose or malt sugar; *inulase*, which forms fructose from inulin; *invertase*, which converts cane sugar into glucose (grape sugar) and fructose; *glucase* or *maltase*, which produces grape sugar from maltose; and *cytase*, which hydrolyses cellulose. Another enzyme which does not appear to be concerned with digestion so directly as the others is *pectase*, which forms vegetable jelly from pectic substances occurring in the cell-wall.

The enzymes which act upon glucosides are many; the best known are *emulsin* and *myrosin*, which split up respectively *amygdalin*, the special glucoside of certain plants of the *Rosaceæ*; and *sinigrin*, which has a wide distribution among those of the *Cruciferæ*. Others of less frequent occurrence are *erythrozym*, *rhamnase*, and *gaultherase*.

The proteolytic enzymes, or those which digest proteids, are usually divided into two groups, which are represented by the *pepsin* of the stomach of the higher animals and the *trypsin* of their pancreatic juice. The differences between them have recently been shown to be of degree rather than of kind. It is not quite certain whether a pepsin exists in plants, but many trypsins have been discovered. Among them we have the *papäin* of the Papaw fruit (*Carica Papaya*), the *bromelin* of the Pine-apple, and the enzymes present in many germinating seeds, in the seedlings of several plants, and in other parts. Another enzyme, *rennet*, which in the animal body is proteolytic, is frequently met with in plants, but its function has not been ascertained.

The digestion of fat or oil has not been adequately investigated, but its decomposition in germinating seeds has been found to be due to an enzyme, which has been called *lipase*. It splits it into a fatty acid and glycerine, but seems to have no further action. The details of the further transformations have not yet been completely followed.

Oxidases.—Another class of enzymes has been discovered in both animals and plants, but they do not apparently take any part in digestion. They set up a process of oxidation in the substances which they attack, and have consequently been named *oxidases*. Very little is known about them.

In many cases the digestion of reserve food materials is effected by the direct action of the protoplasm, without the intervention of enzymes. This property of living substance can be proved in the case of the cells of the higher plants, but it is especially prominent in many of the more lowly organisms, such as the *Bacteria*. The processes of putrefaction may be alluded to as affording an instance of such a power in the vegetable organisms. At the same time, it must be remembered that the secretion of enzymes by Bacteria is of widespread occurrence.

Supply and Distribution of Energy in Plants.—Since about 1880 considerable attention has been directed to the question of the supply, distribution, and expenditure of energy in the vegetable kingdom. This is an extremely important question, since the supply of energy to the animal world has been found to depend entirely upon the vegetable one. The supply of energy to the several protoplasts which make up the body of a plant is as necessary as is the transport to them of the food they need; indeed, the two things are inseparably connected. The source of energy which is the only one accessible to the ordinary plant as a whole is the radiant energy of the rays of the sun, and its absorption is mainly due to the properties of chlorophyll. This colouring matter, as shown by its absorption spectrum, picks out of the ordinary beam of light a large proportion of its red and blue rays, together with some of the green and yellow. This energy is obtained especially by the chloroplastids, and part of it is at once devoted to the construction of carbohydrate material, being thus turned from the kinetic to the potential condition. The other constructive processes, which are dependent partly upon the oxidation of the carbohydrates so formed, and therefore upon an expenditure of part of such energy, also mark the storage of energy in the potential form. Indeed, the construction of protoplasm itself indicates the same thing. Thus even in these constructive processes there occurs a constant passage of energy backwards and forwards from the kinetic to the potential condition, and *vice versâ*. The outcome of the whole round of changes, however, is the fixation of a certain part of the radiant energy absorbed by the chlorophyll. The rays of the visible spectrum do not supply all the energy which the plant obtains. It has been suggested by several botanists, with considerable plausibility, that the ultra-violet or chemical rays can be absorbed and utilized by the protoplasm without the intervention of any pigment such as chlorophyll. There is some evidence pointing to the existence of this power in the cells of the higher plants. Again, we have evidence of the power of plants to avail themselves of the heat rays. There is no doubt a direct interchange of heat between the plant and the air, which in many cases results in a gain of heat by the plant. Indeed, the tendency to absorb heat in this way, either from the air or directly from the sunlight, has already been pointed out as a danger which needs to be averted by transpiration.

There is probably but little transformation of one form of kinetic energy into another in the plant. It has been suggested that the red pigment *anthocyan*, which is found very commonly in young developing shoots, petioles, and midribs, effects a conversion of light rays into heating ones, so facilitating the metabolic processes of the plant. This is, however, rather a matter of speculation. The various electrical phenomena of plants also are obscure.

Certain plants possess another source of energy which is common to them and the animal world. This is the absorption of elaborated compounds from their environment, by whose decomposition the potential energy expended in their construction can be liberated. Such a source is commonly met with among the Fungi, the insectivorous plants, and such of the higher plants as have a saprophytic habit. This source is not, however, anything new, for the elaborated compounds so absorbed have been primarily constructed by other plants through the mechanism which has just been described.

The question of the distribution of this stored energy to the separate protoplasts of the plant can be seen to be the same problem as the distribution of the food. The material and the energy go together, the decomposition of the one in the cell setting free the other, which is used at once in the vital processes of the cell, being in fact largely employed in constructing protoplasm or storing various products. The actual liberation in any cell is only very gradual, and generally takes the form of heat. The metabolic changes in the cells, however, concern other decompositions side by side with those which involve the building up of protoplasm from the products on which it feeds. So long as food is supplied, the living substance is the seat of transformations which are continually proceeding, being partially decomposed, and again constructed, the new food being incorporated into it. The changes involve a continual liberation of energy, which in most cases is caused by the respiration of the protoplasm and the oxidation of the substances it contains. The need of the protoplasm for oxygen has already been spoken of: in its absence death soon supervenes, respiration being stopped. Respiration, indeed, is the expression of the liberation of the potential energy of the protoplasm itself. It is not certain how far substances in the protoplasm are directly oxidized without entering into the composition of the living substance, though this appears to take place. Even their oxidation, however, is effected by the protoplasm acting as an oxygen carrier.

The supply of oxygen to a plant is thus seen to be as directly connected with the utilization of the energy of a cell as is that of food concerned in its nutrition. If the access of oxygen to a protoplast is interfered with, its normal respiration soon ceases, but frequently other changes supervene. The partial asphyxiation or suffocation stimulates the protoplasm to set up a new and perhaps supplementary series of decompositions, which result in the liberation of energy just as do those of the respiratory process. One of the constant features of respiration, the exhalation of carbon dioxide, can still be observed. This comes in almost all such cases from the decomposition of sugar, which is split up by the protoplasm into alcohol and carbon dioxide. Such decompositions are now generally spoken of as *anaërobic* respiration. The decomposition of the complex molecule of the sugar liberates a certain amount of energy, as can be seen from the study of the fermentation set up by yeast, which is a process of this kind, in that it is intensified by the absence of oxygen. The liberated energy takes the form of heat, which raises the temperature of the fermenting wort. It has been ascertained that in many cases this decomposition is effected by the secretion of an enzyme, which has been termed *zymase.* This body has been prepared from active yeast, and from fruits and other parts which have been kept for some time in the absence of oxygen. The protoplasm appears to be able also to bring about the change without secreting any enzyme.

The Ascent of Water in Trees.—Little advance has been made in the solution of the problem of the ascent of water in tall trees. About 1880 two views were held by different botanists: one was that the water travels in the woody cell-walls of the vascular bundles, mainly under the action of the forces of root-pressure and transpiration, and that the cavities of the vessels contain only air. The other was that the vessels are not empty, but that the water travels in their cavities, which contain columns of water in the course of which are large bubbles of air. On this view the water flows upwards under the influence of variations of pressure and tension in the vessels. Neither hypothesis is satisfactory, and others have been advanced to supplement them, which have more or less weight. Westermaier and Godlewski put forward the view that the living cells of the medullary rays of the wood, by a species of osmosis, act as a kind of pumping apparatus, by the aid of which the water is lifted to the top of the tree, a series of pumping-stations being formed. Though this at first met with some acceptance, Strasburger showed that the action goes on in long lengths of stem the cells of which had been killed by poison or by the action of heat. More recently, Dixon and Joly in Dublin and Askenasy in Germany have suggested the action of another force. They have shown that columns of water of very small diameter can so resist tensile strain that they can be lifted bodily instead of flowing along the channel. They suggest that the forces causing the movement are complex, and draw particular attention to the pull upwards in consequence of disturbances in the leaves. In these we have (1) the evaporation from the damp delicate cell-walls into the intercellular spaces; (2) the imbibition by the cell-wall of water from the vacuole; (3) osmotic action, consequent upon the subsequent increased concentration of the cell sap, drawing water from the wood cells or vessels which abut upon the leaf parenchyma. They do not, of course, deny the co-operation of the other forces which have been suggested, except so far as these are inconsistent with the motion of the water in the form of separate columns rather than a flowing stream. This view requires the existence of certain anatomical arrangements to secure the isolation of the separate columns, and cannot be said to be fully established.

Nervous System of Plants.—Researches made upon the relationship of plants to their environment have been marked by definite results. In this direction, also, there has been a closer approximation of the plant to the animal. The indications of definite sense organs by which particular stimulations were appreciated, or which were said to be the seats of particular irritabilities, had been suggested by 1880, and a few cases were established. It had been shown that the root-tip is sensitive to watery vapour, and turns towards it as growth goes on. This fact has been confirmed and our knowledge of such phenomena extended. The root-tip has been shown to be sensitive to many forms of stimulation. The growing apex of some stems has been shown to have the power of appreciating light, and many parts have been proved to be capable of receiving impressions of contact, or of responding to chemical stimulation. The effect of these various forms of stimulation has been found to be the production of a purposeful response, generally taking the form of a movement of some part of the plant, which is usually situated at some distance from the sensitive part. We have evidence, indeed, of a rudimentary nervous system in which such parts play the *rôle* of organs of special sense, which are clearly differentiated physiologically though not anatomically. The conduction of such stimulation to parts removed some distance from the sense organ suggests paths of transmission comparable to those which transmit nervous impulses in animals. Again, the degree of differentiation is very slight anatomically, but delicate protoplasmic threads have been shown to extend through all cell-walls, connecting together all the protoplasts of a plant. These may well serve as conductors of nervous impulses. The nervous mechanism thus formed is very rudimentary, but in an organism the conditions of whose life render locomotion impossible great elaboration would seem superfluous. There is, however, very great delicacy of perception or appreciation on the part of the sense organ, stimuli being responded to which are quite incapable of impressing themselves upon the most highly differentiated animal.

The power of response is seen most easily in the case of young growing organs, and the parts which show the motor mechanism are mainly the young growing cells. We do not find their behaviour like that of the motor mechanism of an animal. The active contraction of muscular tissue has no counterpart in the plant. The peculiarity of the protoplasm in almost every cell is that it is especially active in the regulation of its permeability by water. Under different conditions it can retain it more strongly or allow it to escape more freely. This regulation of turgor is as characteristic of vegetable protoplasm as contraction is of muscle. The response to the stimulus takes the form of increasing the permeability of particular cells of the growing structures, and so modifying the degree of the turgidity that is the precursor of growth in them. The extent of the area affected and of the variation in the turgor depends upon many circumstances, but we have no doubt that in the process of modifying its own permeability by some molecular change we have the counterpart of muscular contractibility.

Organic Rhythm.—It is a remarkable fact that during the process of growth we meet with rhythmic variation of such turgidity. The existence of rhythm of this kind has been observed and studied with some completeness. It is the immediate cause of the phenomena of circumnutation, each cell of the circumnutating organ showing a rhythmic enlargement and decrease of its dimensions, due to the admission of more and less water into its interior. The restraint of the protoplasm changes gradually and rhythmically. The sequence of the phases of the rhythm of the various cells are co-ordinated to produce the movement. Nor is it only in growing organs that the rhythm can be observed, for many plants exhibit it during a much longer period than that of growth. It is easy to realize how such a rhythm can be modified by the reception of stimuli, and can consequently serve as the basis for the movement of the stimulated organ. This rhythmic affection of vegetable protoplasm can be observed in very many of its functions. What have been described as "periodicities," such as the daily variations of root-pressure, afford familiar instances of it. It reminds us of a similar property of animal protoplasm which finds its expression in the rhythmic beat of the heart and other phenomena.

Piacenza (in French *Plaisance*), a fortified town, bishop's see, and capital of the province of Piacenza, Emilia, Italy, on the right bank of the Po, just below the confluence of the Trebbia, 91 miles north-west of Bologna by rail. The public library contains 120,000 volumes, valuable MSS., and numismatic and other collections, amongst them the "finds" of the ancient *Velleia*, 6 miles to the east, which was overthrown by a landslip in 370. Piacenza has an arsenal, a technical school, an arts school, and various industries—iron and brass works, foundries, silk-throwing, manufactures of cardboard boxes, casks and tubs, and hosiery, flour-mills, and printing. It is also an important administrative and military station. Population (1881), 34,987; (1900), 36,064.

Piano.—Since 1885, when the article PIANOFORTE in vol. xix. of this work was published, and the Inventions and Music Exhibition at South Kensington took place, there are few changes of piano structure to record, such as were conspicuous in the interval which had followed the Paris Exhibition of 1867, with the exception of one in metal framing which will be described later. Since 1885 the American system of a metal plate in one casting, and cross- or over-stringing by which the spun bass strings cross the longer steel diagonally, has become general in Europe with the exception of France, where musical taste has remained constant to the older wooden structure and parallel stringing throughout. The greater tenacity of the modern cast-steel wire favours a very much higher tension, and consequent easier production of the higher partials of the notes, permitting a *sostenuto* unknown to Beethoven, Schumann, or Chopin. While in 1862 the highest tension of a concert grand piano worked out at sixteen tons, since 1885 thirty tons has been recorded. Generally speaking, the rise in tension may be expressed musically by the interval of a minor third, to the great advantage of the standing in tune. First shown by the late Henry Steinway in the London Exhibition of 1862, this altered construction attracted extraordinary attention at Paris in 1867, and determined the German direction of manufacture and a few years later the English. What is now particularly noticeable wherever pianos are made, is the higher average of excellence attained in making, as well as in piano-playing. Naturally the artistic quality, the personal note, characterizes all first-class instruments, and permits that liberty of choice which appertains to a true conception of art.

Structural changes.

Much attention has been given of late years to the touch of pianos, to make it less tiring for the modern manipulator, especially since, in 1885–86, Anton Rubinstein went through the herculean feat of seven historical recitals, played consecutively in the capital cities and principal musical centres of Europe. For even this stupendous player a light touch was indispensable. In the competition for power, piano-makers had been gradually increasing the weight of touch to be overcome by the finger, until, to obtain the faintest pianissimo from middle C, at the front edge of the key, from three to four ounces was a not uncommon weight. The Broadwood grand piano which Chopin used for his recitals in London and Manchester in 1848 an instrument that has never been repaired or altered, shows the resistance he required: the middle C sounds at two ounces and a half, and to that weight piano-makers have returned, regarding two ounces and three-quarters as a possible maximum. Owing to the greater substance of the hammers in the bass, the touch will always be heavier in that department, and lighter in the treble from the lesser weight. The shorter leverage of the black keys has of course to be adjusted in balancing to the longer white, the so-called natural, keys. When the player touches the keys farther back, the leverage is proportionately shortened and the weight increased, and there is also an ascending scale in the weight of the player's blow up to the fortissimo sought for. The sum of the aggregate force expended by a pianist in a recital of an hour and a half's duration, if calculated, would be astonishing.

The one important structural change in pianos referred to has been the rejection of support given by metal bars or struts between the metal plate to which the strings are hitched and the wrestplank wherein the tuning-pins are inserted. These bars (see PIANOFORTE, vol. xix.) formed part of William Allen's invention, brought forward by Stodart in 1820, and were first employed for rigidity in place of compensation by the Paris Érards two years later, Broadwood in London introducing about that time the fixed metal plate. The patent, No. 1231, for the barless or open-scale piano, taken out in London in 1888 by H. J. Tschudi Broadwood, is remarkable for simplification of design as well as other qualities.

The increase of resonance.

The problem of resonance—with stringed keyboard instruments, the reinforcement or amplification of sound—has, from the days of the lute- and spinet-makers, been empirical. With lute, guitar, and viol or violin the sound-box comes in, combining in the instrument the distinct properties of string and enclosed air or wind. With the spinet, harpsichord, and piano we have to do chiefly with the plate of elastic wood, to amplify the initial sound of the strings; and the old plan of a thin plate of spruce, put in slightly convex and with an under-barring of wood for tension, has absorbed the attention of piano-makers. The violin belly, with its bass bar and sound post, has relation to it; but the recent invention of the Stroh violin has shown us that the initial string vibrations may be passed through a bridge, be concentrated, and adequately transferred to an aluminium disc not much larger than half a crown. The piano, with its numerous strings, cannot be so reduced, but the reinforcement problem is open to another solution, tentative it is true, but a possible rival. The "Gladiator" soundboard is the invention of Albert Schulz, late director of the piano manufactory of Ritmüller und Söhn of Göttingen. Dr Moser's name has been associated with the inventor's

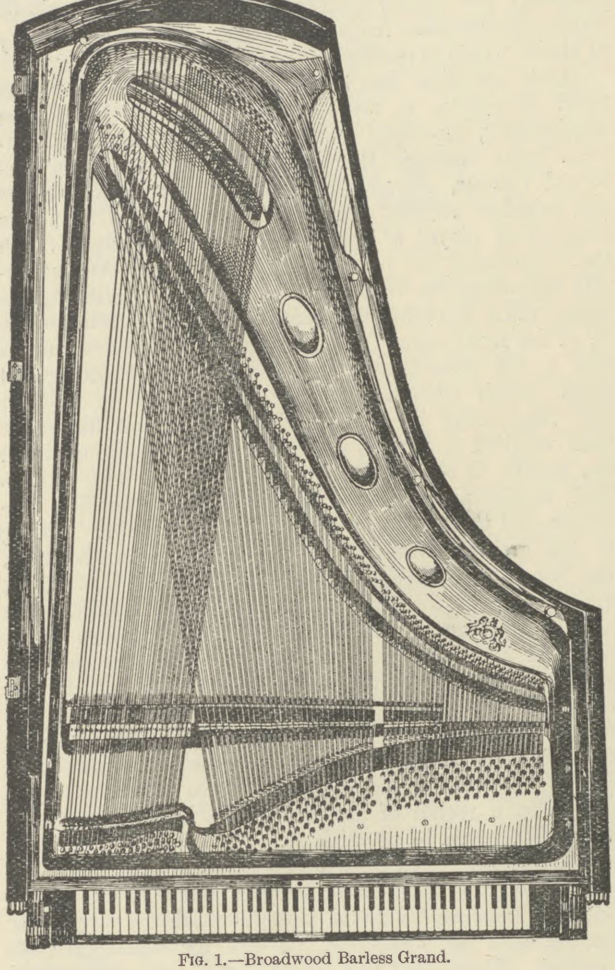

FIG. 1.—Broadwood Barless Grand.

in the English patent. In the "Gladiator" two slabs of wood, with grain of opposed direction to give the necessary tension, are glued together, and the whole system of belly bars is done away with. There is a thinning round the edge, to facilitate promptness of speech. As we are still feeling our way towards an accurate and comprehensive statement of resonance, this invention is one claiming scientific interest, as well as being of possible practical importance.

Repetition.

To return to the touch. The desirability of what is called repetition—that the jack or sticker, which from the depression of the key delivers the blow that raises the hammer to the strings, should never be far away from the notch or nose which receives the impulse—is as much an object of consideration with piano-makers now as it has been since Sebastian Érard began those experiments in 1808 which ended in his famous "double escapement" action. The principle of this grand action, like that of Wornum patented for upright pianos in 1826, has become general. But Joseph Henry Cary in 1853 (patent No. 2283) invented a simple contrivance for repetition in all pianos, neglected at the time, and subsequently repatented and disputed over by others, which has only been preserved in the records of the Patent Office, while the inventor has left no other mark. But the utility of the invention has come to light. It is increasingly used in the actions of upright pianos, and, in combination with the old English grand action (vol. xix. p. 74, Fig. 24), is successfully competing with the Érard action proper, and the simplified Herz-Érard, of late years so very generally employed.

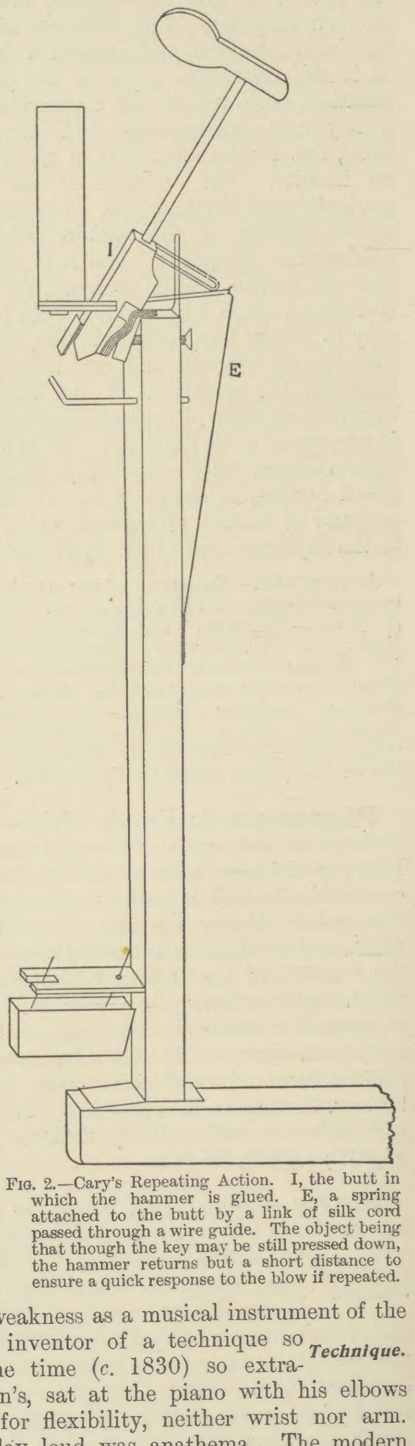

FIG. 2.—Cary's Repeating Action. I, the butt in which the hammer is glued. E, a spring attached to the butt by a link of silk cord passed through a wire guide. The object being that though the key may be still pressed down, the hammer returns but a short distance to ensure a quick response to the blow if repeated.

Technique.

There has been a great change in the freer technique of piano-playing, partly favoured by the development of piano-making, but reacting and obliging the piano-makers to keep their attention incessantly alive to the aim and requirements of the players. It is true that the genius of Beethoven dominates a technique that has become obsolete, and so completely that the adequate performance of his piano works still gives to the sense as well as the intellect the highest pleasure, but his annotations to Cramer's *Studies*, as preserved by Schindler, betray the close touch of the clavichord-player and the student of C. P. E. Bach's *Essay on Clavichord-Playing*, as well as the weakness as a musical instrument of the early piano. The inventor of a technique so original, and at the time (*c.* 1830) so extraordinary, as Chopin's, sat at the piano with his elbows immovable, using, for flexibility, neither wrist nor arm. With Chopin, to play loud was anathema. The modern free style of playing comes from Czerny—whom Beethoven despised as having no legato (*Bildung*),—through Liszt to the Rubinsteins, and to the splendidly equipped performers of our time, to whom the pedal has become indispensable for cantabile and effect.

These great performers are, however, rivalled technically by the recent extraordinary invasion of the American automatic piano-players—the Angelus, Pianola, Apollo, Cecilian, and other varieties of the same idea. The use of the perforated roll acts by means of the ingenious and indeed faultless application of pneumatic leverage to the ordinary piano, doing duty for the pianist's fingers; and it is made possible to play louder or softer, faster or slower, by mechanical arrangement. Such an instrument lacks the player's touch, which is as personal and indispensable for sympathy as the singer's voice or violinist's bow. Still, to a violinist, it is a benefit to have a correct coadjutor in a Beethoven or Brahms sonata with one of these handy companions, just as it is to a singer to have always at command the accompaniments to his or her repertory. The Apollo has the addition of a useful transposing apparatus—an aid, however, that, though often tried, has never yet been adopted; it is possibly too disturbing to the musician's ear. The mechanical tuning-pin is an analogous experiment which comes regularly under notice as the years go by, to be as persistently rejected. The most practical of these tuning inventions was the Alibert, shown in the Inventions Exhibition, 1885. Here, pressure upon the strings above the wrestplank bridge modified their tension after a first rough adjustment to pitch had been effected.

Mechanical playing.

The perforated music-sheet, a mechanism common to piano-playing attachments as well as self-playing pianos, first appears in a French patent, 1842. A United States patent for a keyboard piano-player was issued to E. D. Bootman, 18th December 1860, and the first pneumatic keyboard piano-player was patented in France in 1863 by M. Fourneaux. Between 1879 and 1902 a total of 55 patents had been issued in the States. The first complete automatic piano-player ready for performance was the Angelus (No. 24799, 1897). The specification is from a communication to the British Patent Office by Edward Hollingworth White, of Meriden, New Haven, Connecticut, U.S.A. There is a pneumatic chest, fulcrum bar, finger levers, bellows, and pedals. The whole apparatus is contained in a portable cabinet mounted upon castors, so as to be conveniently moved about a room. The finger levers or key strikers correspond with a considerable portion of the manual keys or clavier of a piano. Thus the automatic piano-player comprises a portable cabinet provided with bellows and operating pedals, a pneumatic actuating mechanism, a tracker adjusted for the use of a perforated music-sheet, a pneumatic motor and winding-roll mechanism to propel the music-sheet, and a series of finger levers operated by the pneumatic mechanism, so projecting as to overhang the piano keyboard and play upon it, with rockers or levers for depressing the piano pedals. Subsequently the apparatus was made capable of accelerating or retarding the tempo at the will of the operator. A roll of music, twelve inches wide and varying in length according to the composition, can be placed in position promptly, and when exhausted can be returned upon its original roll by a simple stop, altogether a triumph of mechanical adjustment. The Pianola followed in 1898, the Apollo 1900. The difference of all these clever contrivances is not conspicuous to the amateur.

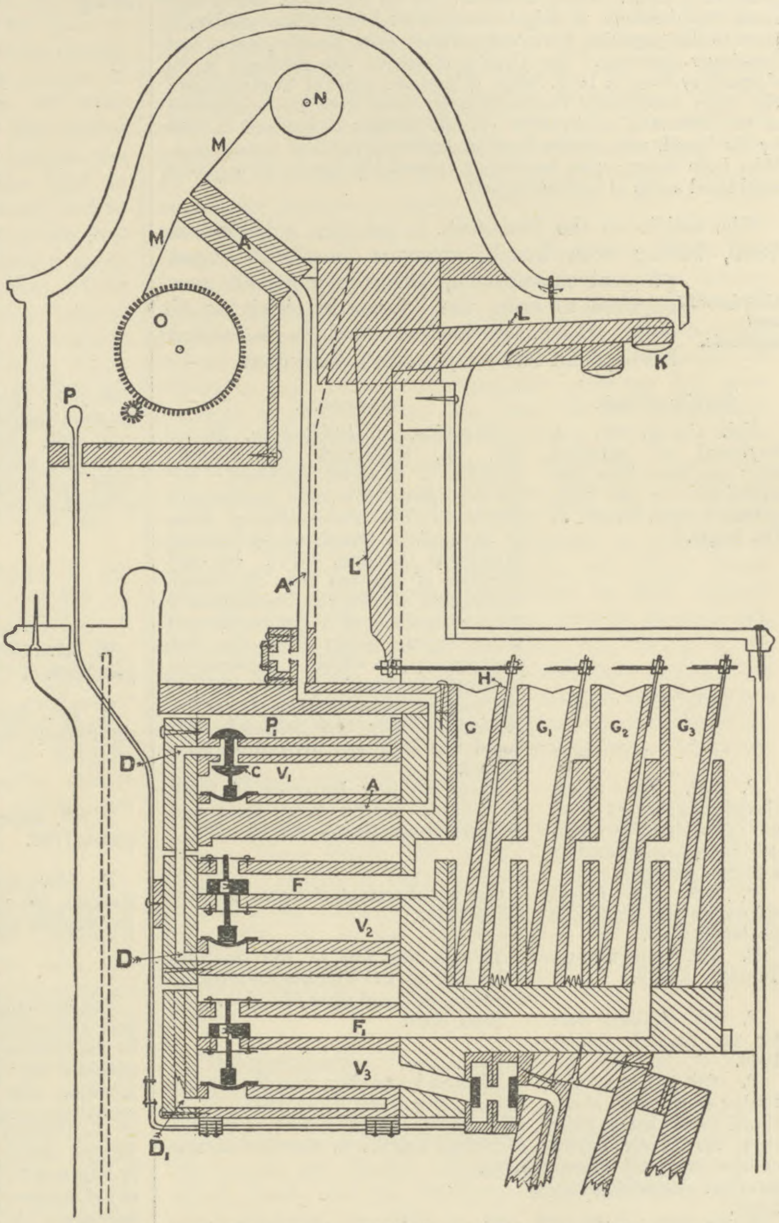

Fig. 3.—Sectional plan of Pianola. MM is the perforated paper, carried on a roll N, and wound upon another roll O by the action of a pneumatic motor. When a perforation comes opposite the orifice of A, the suction bellows in the base of the machine, worked from a treadle by the player's feet, draw in a puff of air which passes along A to the mushroom valve C. The chamber V_1, being in connexion with the suction bellows, is at less than atmospheric pressure, and the result of the air arriving along A is that C rises from its seat. Thereupon communication is opened from the chamber P_1, which is at atmospheric pressure, along the channel D to a second valve E, the chamber above which, V_2, is also under suction. Hence E also rises and opens a way from V_2 by the passage F to the collapsing bellows G; the air-pressure in these being thus reduced, the back H moves to the left, communicating its motion through the lever L to the finger K, which strikes the key of the piano. Similar mechanism, including a mushroom-valve, a secondary pneumatic-valve (of which another may be seen at E_1 in connexion with the passage F_1), and collapsing bellows, as at G_1, G_2, G_3, are provided corresponding to each note of the piano. The time is altered by regulating the suction on the pneumatic motor which unwinds the perforated roll, so that it runs more quickly or slowly as desired. Changes in loudness are attained by means of a handle, P, operating on valves, which increase or diminish the suction in the bellows G, G_1, &c., and therefore the force with which they collapse.

While these allied inventions have had to do with a substitute for touch and the necessity for the persevering acquirement of a difficult technique, another, the Virgil Practice Clavier, so called after the inventor, Mr Almon Kincaid Virgil, an American music teacher, is intended to shorten the period of study by doing away with tone, so that the finger technique is acquired mechanically and unmusically, while value of tone, reading, expression, whatever we understand by musical production exciting our receptivity through the ear, is delayed until the player's hand is formed and considerably developed. The opinion of some of the very greatest pianists is brought forward as approving of the system; in the work, for instance, of Vladimir de Pachmann, whose technique was formed long before the Virgil Clavier came to Europe. Bearing in mind that the minimum weight of the touch of a concert piano is not likely to exceed three and a half ounces, it is hardly likely that these skilled performers use this dumb keyboard with the graduated weight advised for advancing pupils, namely, from five to eight ounces. It is allowed that the lightest possible touch may be used at first. One high recommendation certainly remains after all that may be said regarding Mr Virgil's invention: that it is practically silent, almost noiseless, the up and down clicks that mark the duration of finger attachment being alone audible, a boon to the unwilling hearers of ordinary piano practice, scales, and five-finger exercises. Mr Virgil's invention was produced in its elementary form in 1872, when it bore the name of Techniphone; the more satisfactory Practice Clavier dates from the completion of the invention, about 1890. It was brought to England in 1895 by Mr Virgil, who, assisted by an American pupil of great talent, Miss Julie Geyer, made his theory extensively known by a widely conducted series of lecture-recitals.

The dumb keyboard.

The article on the Pianoforte in vol. xix., published in 1885, having been based, wherever practicable, upon personal examination, few corrections are now required to bring the information in it up to date. Some are, however, due to the record having been less complete then than now.

Corrigenda and addenda.

Earlier Article.	*Corrections.*
Vol. xix. p. 65^{a}. A keyboard of balanced keys may have been first introduced in the little portable organ known as the Regal.	Vitruvius, *de Architectura*, lib. x. cap. xi., translated by Newton, describes a balanced keyboard; but the key apparatus is more particularly shown in *The Pneumatics of Hero of Alexandria*, translated by Bennett Woodcroft (London, 1851). In confirmation of this has been the recent remarkable discovery at Carthage of a terra-cotta model of a Hydraulikon or water organ, dating from the 2nd century A.D., in which a presumably balanced keyboard, if not two, of eighteen or nineteen keys, is shown. It seems likely the balanced keyboard was lost, and afterwards reinvented.
P. 66^{b}. The oldest clavichords extant have no more than two tangents to a note, formed by a pair of strings.	There are now instances of small clavichords having three keys and tangents to one pair of strings.
P. 68^{a}. The oldest spinet we can point out (is dated) 1523.	One was shown at Bologna in 1888 dated 1480.
P. 68^{b}. Spinetta Tavola. Fig. 9.	This is now one of the treasures belonging to the Victoria and Albert Museum, S. Kensington, London.
P. 68^{b}. Earliest date for an English spinet, 1668.	Read 1664.
P. 69^{b}. From the tuning of Handel's clavichord we are led to infer that the nearer halves of the two cut sharps were the chromatic semitones.	We now know they were the further halves; the nearer being employed for the major thirds below, *i.e.*, the dominant fourths to the next natural keys.
P. 69^{a}. Thomas Hitchcock, for whom we have a date 1703.	We have also an early date for him, 1664.
P. 69^{b}. There is an existing example, dating as early as 1526, with the bass keys carried out in long measure.	This date should be 1626—unfortunately this interesting keyboard has been altered by a restorer.
P. 69^{b}. Cristofori . . . the single keyboard.	In the harpsichord Cristofori made for Prince Ferdinand dei Medici in 1702, recently acquired by Mr Stearns, of Detroit, and presented by him to the University of Michigan, U.S.A., there are three keyboards, thus arranged: 1st, highest keyboard, octave string only; 2nd, middle, octave and first unison; 3rd, lowest, both unisons. A harpsichord similarly designed with three keyboards, inscribed Vincentius Sodi Florentinus, Anno Domini 1779, has been presented by Mrs John Crosby Brown to the Metropolitan Museum, New York.
P. 70^{a}. Hans Ruckers . . . we may not withhold from him the credit of introducing the octave string.	The octave string was already in use when Hans Ruckers began his work. The harpsichord as known throughout the 18th century, with piano upper and forte lower keyboard, was the invention of Hans Ruckers' grandson, Jean Ruckers' nephew, Jan Couchet, about 1640. Before that time the double keyboards in Flemish harpsichords were merely a transposing expedient, to change the pitch a fourth, from plagal to authentic and *vice versâ*, while using the same groups of keys. Fortunately there is a harpsichord existing with double keyboards unaltered, date 1638, belonging to Sir Bernhard Samuelson, formerly in the possession of the late Mr Spence, of Florence, made by Jean Ruckers, the keyboards being in their original position. It was not so much invention as beauty of tone which made the Ruckers' harpsichords famous.
P. 70^{b}. Handel had a Ruckers harpsichord.	It is now in Buckingham Palace.
P. 70^{b}. Two pedals were also used, the left-hand one a combination of a unison and lute.	This pedal, with the "machine" stop, reduced the upper keyboard to the lute register, the plectra of which acted upon the strings near the wrest-plank bridge only; the lower keyboard to the second unison. Releasing the machine stop and quitting the pedal restores the first unison on both keyboards and the octave on the lower.
P. 71^{b}. Cristofori pianoforte of 1720.	Is now in the Metropolitan Museum, New York, the gift of Mrs John Crosby Brown.
P. 72^{a}. Frederici upright piano, dated 1745.	An earlier upright grand piano has been discovered by Signor Ponsicchi, of Florence, made by Domenico del Mela, in 1739. The action is an adaptation of Cristofori's.
P. 72^{b}. Zumpe's square piano, 1766.	Fétis narrates that he began the study of the piano on a square piano made by Zumpe in 1762.
P. 73^{b}. Americus Backers, the inventor of the English action.	Backers' "Original Forte Piano" was played at the Thatched House in St James's Street, London, in 1773. Ponsicchi has found a Backers grand piano at Pistoia, dated that year.

The invention of the piano by Cristofori, and he alone, is now past discussion. What is still required to satisfy curiosity would be the discovery of a Fort Bien, or Frederici square piano, said to antedate by a year or two Zumpe's invention of the instrument in London. Also the "old movement" for the long or grand pianos, sometimes quoted in the Broadwood day-books of the last quarter of the 18th century with reference to replacement by the Backers English action. The store or lumber rooms of old country houses in England have produced many interesting and valuable examples of old keyboard instruments. The particular interest of the "old movement" is to see if it was Cristofori's, like the three Silbermann pianos at Potsdam. (A. J. H.)

Piatra, a town in Rumania (Moldavia), on the left bank of the river Bistritza, chief town of the district of Neamtz. It is the seat of a court of first instance, contains seven Orthodox churches, one Roman Catholic church, one Armenian church, and two synagogues. The town is connected with the railway system by a branch line from Bacau. The chief trade is timber and wine, and three fairs are held annually. There are several monasteries in the neighbourhood, namely, those of Bistritza, Bissericani, Pangaratzi, Bulhalmitza, Vinetori, and Almas. Population (1895), 18,000; (1901), 17,391.

Piatti, Carlo Alfredo, Italian violoncellist (1822–1901), born at Bergamo, 8th January 1822, was the son of a violinist and became a pupil at the Conservatorio of Milan. At the age of twelve he appeared at a school concert, and from 1838 onwards he journeyed over Europe, playing with extraordinary success in all the important cities of the Continent. In 1844 he appeared before the London public at a Philharmonic Concert; and in 1859, on the foundation of the Popular Concerts, he took up the work with which he was most intimately connected for thirty-nine seasons, retaining until 1897 the post of first violoncello at these famous chamber concerts, during the latter half of each series. His purely classical style of interpreting the music of the great composers, his wide musical sympathies, and his general culture and charm would have ensured him a high position even without the marvellously finished technical skill, which was kept so wonderfully under control that difficulties seemed not to exist for him. In 1894 the fiftieth anniversary of his first appearance in London was celebrated by a reception given in honour of him and his lifelong friend Joachim, whose first appearance in England was made in the same year as his own. He retired from public life, owing to a severe illness, in 1897, and from that time till his death, which occurred at Bergamo on 19th July 1901, he divided his time between his native town and Cadenabbia. As a composer he attained a wide popularity with his songs, in a popular and graceful style; he did excellent work as an editor; and he was, moreover, an enthusiastic collector and musical antiquary. (J. A. F. M.)

Piauhy, a state of Brazil, situated between 2° 45′ and 11° 40′ S. and 40° 5′ and 48° 40′ W., bounded on the N. by the Atlantic, on the W. by Maranhão, on the S. by Bahia, and on the E. by Ceara and Pernambuco. Area, 116,218 square miles. Population (1890), 267,610. The capital is Therezina; and other towns are Amarante (12,000), Parnahyba (10,000), Barras, and União. The foreign trade is carried on through Tutoyo, the port of Parnahyba. The exports, valued at about £100,000 a-year, consist of hides, cotton, and rubber.

Pickering, Edward Charles (1846-——), American physicist and astronomer, was born in Boston on 19th July 1846. He graduated in 1865 at the Lawrence School of Harvard University, where for the next two years he was a teacher of mathematics. Subsequently he became professor of physics at the Massachusetts Institute of Technology, and in 1876 he was appointed professor of astronomy and director of the Harvard College Observatory. Under his direction the operations of this observatory, founded in 1840, have been enormously extended. In 1877 he decided to devote one of the telescopes of the observatory to stellar photometry, a field of research at that time very little explored, and after an exhaustive trial of various forms of photometers, he devised one, the meridian photometer (see PHOTOMETRY, STELLAR), which seemed to be free from most of the sources of error to which previous methods had been liable. With the first instrument of this kind, having objectives of 1·5 inch aperture, he measured the brightness of 4260 stars, including all stars down to the 6th magnitude between the North Pole and −30° declination. Encouraged by this success, and with the object of reaching fainter stars, Professor Pickering constructed another instrument of the same pattern, but of larger dimensions, and with this more than a million observations have been made. The first important work undertaken with it was a revision of the magnitudes given in the Bonn *Durchmusterung*. On the completion of this, Professor Pickering decided to undertake the survey of the southern hemisphere. An expedition, under the direction of Professor S. I. Bailey, was accordingly despatched, and the meridian photometer erected successively in three different elevated positions on the slopes of the Andes. The third of these was Arequipa, at which a permanent branch of the Harvard Observatory is now located. The magnitudes of nearly 8000 southern stars were determined, including 1428 stars of the 6th magnitude and brighter, and the *Harvard Photometry* thus extended to the whole visible heavens. The instrument was then returned to Cambridge (U.S.A.), where the former work was revised and the survey extended so as to include all stars of magnitude 7·5 down to −40° declination, after which it was once more sent back to Arequipa for further observations of the southern stars. In 1886 the widow of the late Professor Henry Draper, one of the pioneers of stellar spectroscopy, made a liberal provision for carrying on spectroscopic investigations at Harvard College in memory of her husband. With Professor Pickering's usual comprehensiveness, the inquiry was so arranged as to cover the whole sky; and with four telescopes,—two at Cambridge for the northern hemisphere, and two at Arequipa in Peru for the southern,—to which a fine 24-inch photographic telescope has more recently been added, no less than 75,000 photographs had been obtained up to the beginning of 1901. These investigations have yielded many important discoveries, not only of new stars, and of large numbers of variable stars, but also of a wholly new class of double stars which are so close together that no telescope in existence is capable of dividing the components, but whose binary character is revealed by peculiarities in their spectra. The important conclusion has been already derived that the majority of the stars in the Milky Way belong to one special type; and, in Professor Pickering's opinion, the fact that the spectra of the stars may be arranged in a sequence merging by insensible degrees one into the other, is evidence of a unity of plan governing the construction of all parts of the visible universe.

Pictou, seaport, port of entry, and capital of Pictou county, Nova Scotia, 90 miles north-east by north of Halifax. It has a good harbour and railway facilities, churches, an excellent academy, and several valuable industries. It is the shipping port for the adjacent coal mines. For 1901 the exports were $187,214, and imports $249,748. Population (1891), 2998; (1901), 3235.

Piedmont, a territorial division of northern Italy. It embraces the four provinces of Alessandria, Cuneo, Novara, and Turin, and has an area of 11,340 sq. miles, with a population of 3,070,250 (1881), and 3,326,311 (1901). The people are chiefly engaged in agriculture, growing wheat, maize, and rice, chestnuts, wine, and hemp, and in the reeling and throwing of silk, and in the manufacture of cottons, woollens, and clothing. The Piedmontese dialect has been rather strongly influenced by French. The more important towns are Turin, Pinerolo, Carmagnola, Novara, Vercelli, Biella, Alessandria, Asti, Casale Monferrato, Cuneo, Mondovì, Savigliano, and Brà. There are numerous summer resorts in the Alpine valleys, *e.g.*, Baveno, Valdieri, Varallo, Ceresole, Pallanza, and several others in the vicinity of Biella.

Pierson, Henry Hugo (properly HENRY HUGH PEARSON), English composer (1815–1873), son of the Rev. Dr Pearson of St John's College, Oxford, where he was born in 1815; his father afterwards became dean of Salisbury. Pierson was educated at Harrow and Trinity College, Cambridge, and was at first intended for the career of medicine. His musical powers were too strong to be repressed, and after receiving instruction from Attwood and concert piano is not likely to exceed three and a half ounces, it is hardly likely that these skilled performers use this dumb keyboard with the graduated weight advised for advancing pupils, namely, from five to eight ounces. It is allowed that the lightest possible touch may be used at first. One high recommendation certainly remains after all that may be said regarding Mr Virgil's invention: that it is practically silent, almost noiseless, the up and down clicks that mark the duration of finger attachment being alone audible, a boon to the unwilling hearers of ordinary piano practice, scales, and five-finger exercises. Mr Virgil's invention was produced in its elementary form in 1872, when it bore the name of Techniphone; the more satisfactory Practice Clavier dates from the completion of the invention, about 1890. It was brought to England in 1895 by Mr Virgil, who, assisted by an American pupil of great talent, Miss Julie Geyer, made his theory extensively known by a widely conducted series of lecture-recitals.

The dumb keyboard.

Corrigenda and addenda.

The article on the Pianoforte in vol. xix., published in 1885, having been based, wherever practicable, upon personal examination, few corrections are now required to bring the information in it up to date. Some are, however, due to the record having been less complete then than now.

Earlier Article.	*Corrections.*
Vol. xix. p. 65a. A keyboard of balanced keys may have been first introduced in the little portable organ known as the Regal.	Vitruvius, *de Architectura*, lib. x. cap. xi., translated by Newton, describes a balanced keyboard; but the key apparatus is more particularly shown in *The Pneumatics of Hero of Alexandria*, translated by Bennett Woodcroft (London, 1851). In confirmation of this has been the recent remarkable discovery at Carthage of a terra-cotta model of a Hydraulikon or water organ, dating from the 2nd century A.D., in which a presumably balanced keyboard, if not two, of eighteen or nineteen keys, is shown. It seems likely the balanced keyboard was lost, and afterwards reinvented.
P. 66b. The oldest clavichords extant have no more than two tangents to a note, formed by a pair of strings.	There are now instances of small clavichords having three keys and tangents to one pair of strings.
P. 68a. The oldest spinet we can point out (is dated) 1523.	One was shown at Bologna in 1888 dated 1480.
P. 68b. Spinetta Tavola. Fig. 9.	This is now one of the treasures belonging to the Victoria and Albert Museum, S. Kensington, London.
P. 68b. Earliest date for an English spinet, 1668.	Read 1664.
P. 69b. From the tuning of Handel's clavichord we are led to infer that the nearer halves of the two cut sharps were the chromatic semitones.	We now know they were the further halves; the nearer being employed for the major thirds below, *i.e.*, the dominant fourths to the next natural keys.
P. 69a. Thomas Hitchcock, for whom we have a date 1703.	We have also an early date for him, 1664.
P. 69b. There is an existing example, dating as early as 1526, with the bass keys carried out in long measure.	This date should be 1626—unfortunately this interesting keyboard has been altered by a restorer.
P. 69b. Cristofori . . . the single keyboard.	In the harpsichord Cristofori made for Prince Ferdinand dei Medici in 1702, recently acquired by Mr Stearns, of Detroit, and presented by him to the University of Michigan, U.S.A., there are three keyboards, thus arranged: 1st, highest keyboard, octave string only; 2nd, middle, octave and first unison; 3rd, lowest, both unisons. A harpsichord similarly designed with three keyboards, inscribed Vincentius Sodi Florentinus, Anno Domini 1779, has been presented by Mrs John Crosby Brown to the Metropolitan Museum, New York.
P. 70a. Hans Ruckers . . . we may not withhold from him the credit of introducing the octave string.	The octave string was already in use when Hans Ruckers began his work. The harpsichord as known throughout the 18th century, with piano upper and forte lower keyboard, was the invention of Hans Ruckers' grandson, Jean Ruckers' nephew, Jan Couchet, about 1640. Before that time the double keyboards in Flemish harpsichords were merely a transposing expedient, to change the pitch a fourth, from plagal to authentic and *vice versâ*, while using the same groups of keys. Fortunately there is a harpsichord existing with double keyboards unaltered, date 1638, belonging to Sir Bernhard Samuelson, formerly in the possession of the late Mr Spence, of Florence, made by Jean Ruckers, the keyboards being in their original position. It was not so much invention as beauty of tone which made the Ruckers' harpsichords famous.
P. 70b. Handel had a Ruckers harpsichord.	It is now in Buckingham Palace.
P. 70b. Two pedals were also used, the left-hand one a combination of a unison and lute.	This pedal, with the "machine" stop, reduced the upper keyboard to the lute register, the plectra of which acted upon the strings near the wrest-plank bridge only; the lower keyboard to the second unison. Releasing the machine stop and quitting the pedal restores the first unison on both keyboards and the octave on the lower.
P. 71b. Cristofori pianoforte of 1720.	Is now in the Metropolitan Museum, New York, the gift of Mrs John Crosby Brown.
P. 72a. Frederici upright piano, dated 1745.	An earlier upright grand piano has been discovered by Signor Ponsicchi, of Florence, made by Domenico del Mela, in 1739. The action is an adaptation of Cristofori's.
P. 72b. Zumpe's square piano, 1766.	Fétis narrates that he began the study of the piano on a square piano made by Zumpe in 1762.
P. 73b. Americus Backers, the inventor of the English action.	Backers' "Original Forte Piano" was played at the Thatched House in St James's Street, London, in 1773. Ponsicchi has found a Backers grand piano at Pistoia, dated that year.

The invention of the piano by Cristofori, and he alone, is now past discussion. What is still required to satisfy curiosity would be the discovery of a Fort Bien, or Frederici square piano, said to antedate by a year or two Zumpe's invention of the instrument in London. Also the "old movement" for the long or grand pianos, sometimes quoted in the Broadwood day-books of the last quarter of the 18th century with reference to replacement by the Backers English action. The store or lumber rooms of old country houses in England have produced many interesting and valuable examples of old keyboard instruments. The particular interest of the "old movement" is to see if it was Cristofori's, like the three Silbermann pianos at Potsdam. (A. J. H.)

Pierson, Henry Hugo (properly HENRY HUGH PEARSON), English composer (1815–1873), son of the Rev. Dr Pearson of St John's College, Oxford, where he was born in 1815; his father afterwards became dean of Salisbury. Pierson was educated at Harrow and Trinity College, Cambridge, and was at first intended for the career of medicine. His musical powers were too strong to be repressed, and after receiving instruction from Attwood and

A. T. Corfe, he went in 1839 to Germany to study under C. H. Rink, Tomaschek, and Reissiger. He was elected Reid Professor of Music in Edinburgh in 1844; but, owing to a disagreement with the authorities concerning the original intentions of the founder of the chair, he resigned in the following year, and definitely adopted Germany as his country about the same time, making the change in his names noted above. His two operas, *Leila* (Hamburg, 1848) and *Contarini* (Hamburg, 1872), have not retained their hold upon the German public as his music to *Faust* has done, a work which, until quite recently, was frequently associated with Goethe's drama. He was never recognized in England as he was in Germany, for the most important part of his career fell in the period of the Mendelssohn fashion, when not to imitate that master was to court disaster, and not to admire his methods and mannerisms was to ensure neglect. His most important work was the oratorio *Jerusalem*, produced at the Norwich Festival of 1852, and subsequently given in London (Sacred Harmonic Society, 1853) and Würzburg (1862). For the Norwich Festival (at one of the meetings a selection from his *Faust* music was given with success) he began an oratorio, *Hezekiah*, in 1869; it was not finished, but was given in a fragmentary condition at the festival of that year. These two large works and a number of Pierson's songs, as well as the three overtures played at the Crystal Palace, reveal undeniable originality and a wealth of melodic ideas. His critics were right in pronouncing him weak in contrapuntal skill, and his music no doubt was sadly wanting in outline and coherence; but in a more favourable atmosphere and in more fortunate conditions his great natural gifts might have been turned to better artistic account, and have made a more lasting mark upon the art of his time. He died at Leipzig, 28th January 1873, and was buried at Sonning, Berks, of which parish his brother, Canon Pearson, was rector. (J. A. F. M.)

Pietermaritzburg, capital of Natal, South Africa, situated about 40 miles north by west of Durban by rail, at an elevation of 2200 feet above the level of the sea. The town was laid out by the Boers in 1839, and takes its name from their leaders, Pieter Retief and Gert Maritz. In 1898 the population was 24,535, comprising 14,015 Europeans, 6967 natives, and 3553 Indians. The town compares favourably, as regards health and climate, with any other in South Africa. The mean temperature for the year is 64·9°, for February 71·8°, for July 55·7°. Its town hall, destroyed by fire in 1898, has been rebuilt, and there are handsome Government and Parliament buildings. The town is well lit by electricity. An extensive park, botanical gardens, and good swimming-baths are attractive features.

Pigeon Post.—Ever since the time of King Solomon, historical examples can be found of the use of pigeons to carry messages, but their extended use in modern times dates from the siege of Paris in the Franco-Prussian war of 1870–71. For a trustworthy system of communication by means of these birds, it is generally recognized that careful organization and preliminary training must first be established; but, in spite of the absence of all such arrangements, it was found possible to send a hundred and fifty thousand official messages, and a million private ones, into Paris during the siege. Soon afterwards numerous private societies were established for keeping pigeons of this class in all important European countries; and, in time, various governments recognized the importance of the subject, and established systems of communication for military purposes by pigeon post. When the possibility of using the birds between military fortresses had been thoroughly tested, attention was turned to their use for naval purposes, to send messages between coast stations and ships at sea; and at the present date most great Powers propose to employ them both for naval and military purposes. They are also found of great use by news agencies and private individuals. Governments have in several countries established lofts of their own. Laws have been passed making the destruction of such pigeons a serious offence; premiums to stimulate efficiency have been offered to private societies, and rewards given for destruction of birds of prey. It has also been found of great importance to establish registration of all birds. In order to hinder the efficiency of the systems of foreign countries, difficulties have been placed in the way of the importation of their birds for training, and in a few cases falcons have been specially trained to interrupt the service in war time.

Results of experiments differ very much, according to the conditions under which they were undertaken, and it is therefore impossible to lay down any rigid rules as to what pigeons can or cannot do, but it is possible to arrive at a general idea of what may be expected in average cases. Birds employed for such work in Great Britain are usually known as homing pigeons. The best are bred in Belgium, where private societies and owners are very numerous, much encouragement is given, and many races are organized. The Belgian homers are crossed with local breeds in various countries, with successful results. The best sort of bird to suit climatic conditions is soon arrived at, the pigeons best adapted for rough weather being somewhat heavier and slower than those employed in countries where atmospheric conditions are more favourable. A homing pigeon is trained to take a message to the loft where he was bred, or to which he was moved before he had seen the outside of any other loft. Old birds that have been brought up elsewhere are sometimes kept in lofts for breeding purposes, but these are not allowed outside, or they will probably find their way to their original home, if within a reasonable distance. Various methods have been adopted for carrying the messages. One of the most usual is to place the paper inside a quill, which is then sealed at both ends and attached to a tail feather by means of wire, one of the firmest feathers being selected if during the moulting season. Another way is to wrap the paper round the bird's leg and fix it with an elastic band, or it may be fixed to a strong wing feather. In order to reduce the weight carried, the assistance of photography may be resorted to. Messages sent to Paris in the 1870 war were photographed on films, each of which took over 2000, and in this way as many as 40,000 messages were in one case carried by a single bird. On receipt of the films in Paris they were enlarged on a magic lantern screen, copied out, and sent to their destinations. Opinions differ very widely as to the distance which birds can be relied upon to cover, and all estimates must necessarily depend upon local and temporary conditions. For lofts or land communication, perhaps 150 miles apart may be taken as a distance that should not be exceeded, although with specially picked birds messages could no doubt be sent for double this distance with but a small percentage of loss in favourable weather, and with special training even this can be considerably exceeded. For communication between ships and the coast the results of experiments differ very widely indeed. For absolutely safe work perhaps 50 miles may be taken, though successful results have been obtained up to 300. In cases where the home of the pigeon moves about, as with the headquarters of a field army or of a ship at sea, success cannot be expected excepting at ranges not exceeding a few miles—certainly not over 20. Atmospheric conditions must be studied on all occasions, as they very materially affect the results. A large proportion of the birds will be lost in foggy weather, and they fly only during the period of daylight. Should the distance to be covered be considerable, they should not be sent off in the evening, but at a time that will enable them to reach their home by daylight at their average speed. Stormy weather interferes very seriously with their flight. For these reasons, also, it is very difficult to lay down any rule about the average speed at which the messages will be carried. Whilst speeds of about 60 miles an hour are sometimes attained, the average could not be placed at over 30 miles an hour under fairly favourable conditions.

The training of young birds is commenced during the first year by taking them out in closed receptacles and releasing them at gradually increasing distances from their loft, allowing intervals of rest for several days between each flight. About 100 miles may be expected of them during the first season, and this distance increased in subsequent years. The best results are obtained by training a bird always to fly in the same general direction for the season. If intended to be kept away from their loft for a long time, they should be placed in a dark room with no look-out, and the cocks and hens should be separated. When the young are being brought up, only one of the parent birds is taken out at a time. Each brood consists of two eggs, on which both parents sit in turn, the cock only for a few hours in the middle of the day. A loft for homing pigeons should be on a commanding site. It is best made in the shape of a large room, which should be protected from vermin, suitably subdivided, and provided with drinking troughs, rock salt, and crushed mortar for the bird's use. It should also be fitted with a sufficient number of nests about 2 feet long, 20 inches in breadth and height. Arrangements should be made for allowing the pigeons to fly out daily for exercise; and they should be trained to re-enter the loft through bolting wires which open inwards only into a small chamber, to which an electric arrangement may be fitted so as to sound a bell and warn the owner of the arrival of a bird. This chamber can be shut off from the loft, if required, to facilitate the capture of birds returning with messages. Marks showing to what club and to what loft each bird belongs are usually stamped on wing feathers, and when quite young a metal ring showing the date of hatching is usually placed on the leg by passing it over the foot. The food of birds in training consists of vetch, beans, maize, peas, broken rice, and millet, in various proportions, according to the country, climate, and season of the year, the daily allowance for each bird being about 40 grammes weight. Young birds may be fed on rice in the husk and bread.

The question of the homing instinct, which enables pigeons of certain classes to find their way home over such great distances, is a study of much interest, and their method of determining the true direction is still a matter of surmise. At all times their culture provides an interesting recreation, and numerous societies exist for the organization of races, and for encouraging their further development.

(G. G. A.)

Pigments.—It is convenient to distinguish between pigments and paints, the latter being prepared from the former by the addition of a vehicle or medium. Nor are pigments and dyes identical, although there are cases in which the same colouring matter which yields a dye or stain may give rise to a pigment. A pigment is, in fact, a substance which is insoluble in the vehicle with which it is mixed to make a paint, while a dye is soluble. Pigments exhibit various degrees of transparency and opacity, and ought to possess such qualities as these: ease in working, chemical indifference to each other and, generally, to the vehicles employed, also stability under exposure to light and air. As a rule, it is desirable that pigments should not be seriously affected in hue by the vehicle; at all events, whatever change does occur ought to admit of calculation. In the case of oil colours it should be remembered that a thorough drying of the paint is preferable to the formation of a surface-skin, and that a few pigments, notably white lead, possess properties conducing to this desirable result. It is scarcely necessary to add to these general observations concerning pigments that their artistic value depends primarily upon the nature and amount of the optical sensation which they are competent to produce.

Sources. Although the number of available pigments is great, the number of chemical elements which enter into their composition is not large. Very many richly-coloured compounds cannot be employed because they lack the properties of insolubility, inertness, and stability. Pigments are drawn from various sources. Some are natural, some artificial; some are inorganic, some organic; some are elements, some mixtures, some compounds. It is not unusual to arrange them into two groups, *substantive* and *adjective*. Amongst the members of the former group such a pigment as vermilion, where each particle is homogeneous, may be cited as an example. Amongst the adjective pigments rose-madder may be named, for each particle consists of a colourless base on which a colouring matter (alizarin) has been thrown. Most of the inorganic pigments, whether natural or artificial, belong to the substantive group; while there are many organic pigments, notably those of artificial origin, which are of adjective character. The following table presents a summary classification of pigments according to their source or origin:—

Mineral pigments .	Natural; as terre verte.
	Artificial; as aureolin.
Organic pigments .	Animal; as carmine.
	Vegetable; as madder-lake.
	Artificial; as alizarin-orange.

Preparation. A variety of processes are in use in order to fit natural coloured substances for employment as pigments. The first step is, in many cases, to select or "pick over" the raw material, rejecting whatever impurities may weaken or injure the characteristic hue of the product. It is occasionally necessary to treat the finely-ground substance with water by the method of elutriation or washing-over; the wash-waters will then deposit, on standing, various grades of the coloured body required. With rare exceptions native pigments need careful grinding, either by means of a muller on a slab or by edge rollers, or horizontal mill-stones, or special machines. The substance is usually ground in spirits of turpentine, or alcohol, or water; oil-paints are of course finally ground in a drying-oil, such as linseed oil or poppy oil; water-colours require gum-water, or gum-water and glycerin if they are to be "moist" paints. In the case of all pigments, whether mineral or organic, whether natural or artificial, it is of the highest importance to make sure that they are free from saline matters soluble in water. Such salts are removed by thorough washing with distilled water. A treatment of this kind is essential in the case of a large number of pigments formed by chemical reactions in the "wet way." Characteristic examples are furnished by Prussian blue, viridian, and lakes. Sometimes it is necessary to remove dangerous impurities by solvents other than water, such as carbon bisulphide, which is used to extract free sulphur from cadmium yellow. Mention may here be made of another kind of preparative treatment which is adopted with some pigments: they are subjected to the action of heat—moderate in some cases, strong in others. Thus a few substances, such as ivory black and yellow ochre, which in ordinary circumstances contain much non-essential moisture, before they are ground in oil may with advantage be gently dried at a temperature not above that of boiling water. Again, there are pigments, such as Prussian brown, light red, and burnt sienna, which owe their hues to a process of actual calcination, the first of these being thus made from Prussian blue, the second from yellow ochre, and the third from raw sienna. The pigments known as burnt carmine and burnt madder are prepared at a much lower temperature, and ought to be described as roasted rather than as burnt.

Adulteration. The substitution of one pigment for another is rarely practised, but it is not so unusual to find that a costly substance has received an admixture of something cheaper, and that an inferior grade of a genuine pigment has had its hue exalted or enhanced by some unlawful or dangerous addition. In fact, these two kinds of sophistication are often associated. Thus vermilion is adulterated with red lead, with red antimony sulphide, or with baryta white and lead sulphate, and then the hue of the mixture is restored to the proper pitch by the introduction of one of the powerful but fugitive colouring matters from coal-tar known as eosin. Amongst other adulterations which may be named here are the addition of chrome-yellow (lead chromate) to yellow ochre, of green ultramarine to terre verte, and of indigo to ivory black; this last mixture being a substitute for vine-black, the natural blue-black. The detection of the above-named sophistications is by no means difficult even in the hands of persons unacquainted with chemical manipulation, but it needs a trained analyst when quantitative results are required. If we are dealing with an oil-colour, the first step is to remove the oil by means of a solvent, such, for example, as ether. The residual pigment is then allowed to dry, and the dry powder submitted to the appropriate physical and chemical tests. Thus a suspected vermilion, having been freed from oil, is heated in a small hard glass bulb-tube: it should prove practically volatile, leaving a mere trace of residue. In this particular case the presence of a red hue in the ether-extract affords evidence of adulteration with an organic colouring matter, such as eosin. Then, again, we may detect the presence in yellow ochre of lead chromate by pouring a little sulphuretted hydrogen water and dilute hydrochloric acid upon one portion of the dry pigment, and boiling another portion with dilute sulphuric acid and some alcohol: in the former experiment blackening will occur, in the latter the liquid part of the mixture will acquire a greenish tint. So also green ultramarine may be recognized in adulterated terre verte by the addition of dilute hydrochloric acid, which destroys the colour of the adulterant and causes an abundant evolution of the evil-smelling hydrosulphuric acid gas. Moreover, nothing is easier than the recognition of indigo in vine or charcoal-black, for the dry powder, heated in a glass tube, gives off purple vapours of indigo, which condense in the cooler part of the tube into a blackish sublimate.

A word must be said here as to the adulteration of white lead, and the examination of this most important pigment. The best variety of white lead or flake white contains two molecules of lead carbonate to one of lead hydrate, and is wholly soluble in dilute nitric acid, while barium sulphate, its most frequent adulterant, is wholly insoluble. China-clay and lead sulphate will also remain undissolved; but whitening or chalk cannot be detected in this way—indeed, the thorough examination of white lead, not only for sophistications but also for correspondence with the best type in composition, cannot be carried out save by a skilled analyst.

Classification.

One of the most instructive ways of arranging pigments is based on their chemical composition. With the ordinary pigments nine groups may be constituted, seven of these being fairly well defined, but the eighth and ninth having a somewhat miscellaneous character. The groups of Elements, Oxides, Sulphides, Hydrates, Carbonates, and Silicates present this characteristic, namely, that each member of any one group is without action upon the other members of the group; any two or more may therefore be mixed together without fear of mutual injury. The same statement may be made with reference to the various inorganic salts of Group VIII. and to the organic compounds of Group IX., although in this large final group there are two pigments containing copper (verdigris and emerald green) which must be regarded with suspicion. The inertness of the members of the same group towards each other may be explained in the majority of cases by the following consideration. An oxide does not act upon an oxide, nor does a sulphide affect a sulphide, because all the pigment oxides have taken up their full complement of oxygen, and can neither give nor lose this element to similar oxides; so also with sulphur in the sulphides. A few details regarding the several members of the nine groups are now offered:—

Group I.—*Elements.*—All the black pigments in ordinary use—ivory black, lamp black, charcoal black, Indian ink, and graphite—consist of or contain carbon, an element not liable to change; the last-named pigment, which is less correctly termed black lead and plumbago, is a special form of carbon of peculiarly unalterable character. The metallic pigments, gold, silver, aluminium, and platinum, belong here; of these, silver alone is easily susceptible of change, tarnishing by absorption of sulphur.

Group II.—*Oxides.*—The oxides have generally been formed at a high temperature and are not easily amenable to physical or chemical change; they are, moreover, not liable to affect other pigments, being practically inert, red lead only being an exception. The oxides include zinc white, green oxide of chromium, burnt umber (oxides of Fe and Mn), cobalt green ($CoO,nZnO$), cobalt blue (CoO,nAl_2O_3), cœruleum ($CoO,nSnO_2$), Venetian red, light red, Indian red, and burnt sienna (all chiefly composed of Fe_2O_3), and red lead (Pb_3O_4).

Group III.—*Sulphides.*—Some of the members of this group are liable to contain free sulphur, and some may give up this element to the metallic bases of other pigments. Thus cadmium yellow blackens emerald green, producing copper sulphide. Another pigment of this group, vermilion, is prone to a molecular change whereby the red form passes, without chemical alteration, into the black variety. This change, frequent in water-colour drawings, is scarcely observable in works painted in oil. The sulphides comprise cadmium yellow (CdS), king's yellow (As_2S_2), realgar (As_2S_3), antimony red (Sb_2S_3), and vermilion (HgS). It is convenient to give places in the same group to the various kinds of ultramarine, blue, green, red, violet, and native, for in all of them a part of the sulphur present occurs in the form of a sulphide. It may be stated that the sulphides of arsenic and antimony just named are dangerous and changeable pigments not suited for artistic painting.

Group IV.—*Hydrates or Hydroxides.*—Several native earths belong here, notably yellow ochre, raw umber, raw sienna, and Cappagh brown. These substances owe their colours mainly to hydrates and oxides of iron and of manganese, but the presence of a colourless body such as white clay or barium sulphate is usual with the paler pigments. A false yellow ochre from Cyprus is really a basic ferric sulphate, and does not properly belong to this group. Besides the yellow and brown pigments, there is a magnificent deep green pigment in this group, known as emerald oxide of chromium or viridian. The blue copper preparation which goes under the name of *bleu lumière* and mountain blue, a very unstable pigment, is also essentially a hydrate, though by no means pure. It should be stated that all the earthy or native hydrates belonging to this group contain water in two states, namely, hygroscopic or loosely-attached, and constitutional. Before grinding them in oil, the reduction in the amount of the hygroscopic moisture by means of a current of dry air or a gentle warmth often improves the hue and working quality of these pigments.

Group V.—*Carbonates.*—There is but one really important member of this group, namely, the old and typical variety of white lead ($2PbCO_3$, PbH_2O_2). Like green verditer ($2CuCO_3$, CuH_2O_2), and blue verditer ($CuCO_3$, CuH_2O_2), it is not a simple carbonate, but contains a hydrate or hydroxide as well. Purified chalk or whitening ($CaCO_3$) belongs here also.

Group VI.—*Silicates.*—Terre verte, which is a natural green ochre containing a silicate of iron, potassium, and magnesium, and one other silicate, smalt, an artificial glass containing a silicate of cobalt and potassium, constitute this small group. However, some of the ochreous earths contain silicates of iron, manganese, and aluminium, as well as hydrates of the two former metals, and so have some claim to be ranked with the silicates.

Group VII.—*Chromates.*—These salts are rich in oxygen. When in contact with some of the more alterable organic pigments belonging to Group IX., the chromates may lose oxygen, acquiring a somewhat greenish or greyish hue, owing to the formation of the lower or green oxide of chromium. The chromates cannot be trusted as pigments. The yellow chromates, those of barium, strontium, zinc, and lead, are represented by the general formula $M''CrO_4$; chrome red is basic, and is Pb_2CrO_5.

Group VIII.—*Various Inorganic Salts.*—This group is intended to receive a number of pigments which are solitary, or almost solitary, examples of various classes of salts. There is one cobalti-nitrite, aureolin ($K_6Co_212NO_2$, associated with one or more molecules of water), called sometimes cobalt yellow; one antimonate, that of lead, the true Naples yellow; one tungstate, that of chromium, known as tungsten green; a metaphosphate of manganese, which goes under the name of Nürnberg or manganese violet; and several mixed cobalt compounds containing arsenates and phosphates of that metal, and represented by cobalt violet and Thénard's blue. Two sulphates also belong here, namely, baryta white ($BaSO_4$) and lead sulphate ($PbSO_4$); also Schweinfurt green, a basic copper arsenite. It is obvious that of the members of so miscellaneous a group of pigments no general characteristics can be predicated. But it may be stated that the two sulphates, the tungstate, and the cobalt compounds are practically inert and unalterable, while the copper arsenite and the lead antimonate are sensitive to the action of sulphur and of sulphides. The cobaltinitrite, aureolin, cannot be safely mixed with some of the organic pigments belonging to the next and last group.

Group IX.—*Organic Compounds.*—Most of the members of this large and unwieldy group of pigments possess this character in common, proneness to oxidation and consequent deterioration in the presence of light, moisture, and air. Such oxidation is accelerated by the action of some of the highly oxidized pigments belonging to other groups, such as the chromates of Group VII. and aureolin of Group VIII., this action being particularly marked in the case of the yellow lakes, the cochineal lakes, and indigo. There are two pigments consisting of copper salts in this group. They are verdigris—both the blue-green and the green varieties being basic copper acetates—and the pigment known in England as emerald-green, which is a basic cupric aceto-arsenite. These copper pigments present the usual sensitiveness to the attack of sulphur which distinguishes compounds of this metal, and cannot therefore be safely mixed with the members of Group III., and more particularly with the cadmium colours. About nine members of Group IX. may be regarded as substantive pigments. These include Indian yellow (mainly magnesium and calcium euxanthates), gamboge, sap green, indigo, Prussian blue, bitumen or asphalt, bistre, sepia, and the bituminous variety of Vandyck brown. The adjective pigments include a great variety of lakes where different kinds of colouring matters of more or less acid character have been thrown upon a base, generally of colourless aluminium hydrate, aluminium phosphate, stannous hydrate, stannic oxide, baryta, or lime; sometimes coloured bases containing such metals as copper, chromium, manganese, or iron are introduced in small quantities. The colouring matters used are both natural and artificial. Amongst the former may be named Indian lake, from the resinous exudation produced in certain trees by the attacks of *Coccus lacca;* carmine, crimson, and purple lake, from the colouring matter obtained from the cochineal insect, *Coccus cacti;* rose-madder and the madder-lakes, from the alizarin and allied bodies derived from the root of the ordinary madder plant *Rubia tinctorum;* and yellow lakes, from quercitron bark (*Quercus tinctoria*), and from Persian and Avignon berries (species of *Rhamnus* or Buckthorn). The lakes derived from alkanet root, archil, Brazil wood, and red sanders wood are of very small interest and value. The same judgment may be pronounced upon the large number of artificial lakes which owe their colours to coal-tar derivatives, with the single exception of the important class of pigments obtained from artificial alizarin and from its congeners and derivatives. Of these, alizarin itself ($C_{14}H_6O_2(OH)_2$), in its purest state and associated with alumina and a little lime, yields those pigments which possess a pink or rosy hue. When purpurin ($C_{14}H_5O_2(OH)_3$) and its isomers, anthrapurpurin and flavopurpurin, are present, the red hue is more pronounced, and may even tend towards a golden colour, or, when some copper or iron or manganese is introduced, may become decidedly brown. Many of the alizarin crimsons sold as paints are not made from alizarin itself, but from the sulphonic acids of alizarin. These lakes present a wide range of hues. Another derivative of alizarin, known as β-nitro-alizarin, yields a rich orange lake, to which such names as pure orange, orange madder, and marigold have been applied.

Stability.—Some notion of the relative stability of pigments will have been derived from the remarks already made under "Classification." But as permanence is of no less importance than chromatic quality in the case of pigments used in the fine art of painting, to which the present article is mainly devoted, further particulars concerning certain selected pigments may profitably be given here. The judgments formed have been derived from direct experiments and from the study of old paintings and drawings. It will be convenient, for the practical purpose in view, to revert to the familiar arrangement according to hue. Beginning, then, with white pigments, these three may be named as useful: white lead, Freeman's white, zinc white. As an oil-colour, white lead of the old type is generally the best to use, but among water-colours its place must be taken by zinc white in the condensed form known as Chinese white. Zinc white, in spite of the qualities which recommend its use in oil, namely, the fact of its being not only unaffected by sulphur, but odourless and non-poisonous, lacks toughness as an oil-paint, and has a tendency to scale. Freeman's white, which consists essentially of lead sulphate, is the best substitute for white lead yet devised. The small percentages of zinc white and baryta white which it contains are not to be regarded as adulterations, for they greatly increase its *body*, and though of less specific gravity than lead sulphate, actually raise the weight per cubic foot of the dry pigment. Out of a dozen or more familiar yellow paints, a selection may be made of these six: yellow ochre, raw sienna, mars orange, cadmium yellow, aureolin, and baryta yellow. Concerning two of these, cadmium yellow and aureolin, the following recent observations may be set down. There is but one sulphide of cadmium, CdS, but this compound exists in two forms, which in some measure correspond to the two modifications of mercuric and antimonious sulphides. One of these forms is yellow and the other reddish orange. When sulphuretted hydrogen is sent into a weak, cold, and neutral solution of a cadmium salt, the sulphide which separates is pale and yellow—the orange variety is obtained from a strong, hot, and acid solution. The pale variety is more prone to change than the darker one; but as oil-colours both forms are sufficiently stable for use, provided they are pure. The value of aureolin as a pigment depends much upon its mode of preparation. A new variety of bright yellow hue was described by Adie and Wood in 1900, and is represented by the formula $K_2NaCo(NO_2)_6,H_2O$; it seems likely to prove an excellent and permanent pigment. Of red pigments, six claim special mention. These are vermilion, light red, Venetian red, Indian red, red ochre, and the red lakes derived from madder or alizarin. Vermilion is stable in oils, but as a water-colour paint is prone to change, under exposure to strong light, into the black modification of mercuric sulphide. The iron-reds named above, whether natural or artificial, are quite permanent, but so much cannot be said of the various madder-paints. They are of far greater stability under exposure to light than any other red organic pigments, and are absolutely necessary to the artist. It must be noted that those madder and alizarin lakes which contain an element of yellow and brown are less stable than those of a crimson hue. Five green pigments may be recommended, namely, viridian, or the emerald oxide of chromium, the ordinary green oxide, cobalt green, green ultramarine, and terre verte. Except for minor decorative work, where permanence is of secondary moment, one is obliged to exclude from the palette emerald green, green verditer, verdigris, sap-green, and the numerous preparations which owe their colour to mixtures of Prussian blue and chrome yellow, and are sold under the names of green vermilion, chrome green, Brunswick green, and so on. All these pigments usually contain much barium sulphate. Similarly, amongst blue pigments, ultramarine, cobalt blue, and cœruleum may be retained, while smalt, indigo, and all the copper blues should be rejected. Prussian blue, or the mixture of this pigment with a white base which is usually called Antwerp blue, can scarcely be spared, but care should be taken to choose a sample containing no potassium compounds. Cœruleum, which may be described as cobalt stannate, presents the peculiarity of appearing a greenish blue in artificial light, not a purplish blue like that of ordinary cobalt blue. Cobalt violet is a sound pigment, while manganese metaphosphate or Nürnberg violet is said not to be safe in oil. Mars violet, an artificially prepared ferric oxide, is dull in hue but permanent. Passing on to brown pigments, it is matter for regret that there are no permanent colours possessing the artistic capacities of asphalt, madder brown, and the old bituminous Vandyke brown. Cappagh brown, burnt sienna, and raw and burnt umber may be employed safely. Little need be said as to the selection of black pigments, for all are permanent. The soot from burning acetylene, which has recently been introduced, forms a black pigment of remarkable intensity.

Uses.—Hitherto pigments have been considered chiefly in relation to the requirements of the painter of pictures, whose aim it is to translate ideas of colour and of light and shade into a concrete and permanent form. In many merely decorative arts, such as the manufacture of wall-papers and the painting of woodwork and of iron, the pigments available are in one direction, that of cost, more restricted, but, on the other hand, many alterable or weak pigments are commonly employed. In paints intended for the protection of ironwork, the nature of the pigment introduced is a matter of great moment, for red lead, zinc white, and white lead are found to exert a strong protective influence, which is not observed in the case of the vast majority of pigments. There are a number of other uses besides those just named for which special pigments, or, more precisely, special paints, are employed. Amongst such preparations may be named luminous paints, anti-fouling paints, metallic paints, damp-proof paints, and asbestos and other fire-proof paints.

Pilibhit, a town and district of British India, in the Rohilkhand division of the North-West Provinces. The town is situated on the left bank of the Deoha river; railway station, 34 miles north-east of Bareilly. Population (1881), 29,721; (1891), 33,799. The municipal income in 1897–98 was Rs.42,535, more than half derived from octroi; incidence of taxation, 11 annas per head; registered death-rate (1897), 89·7 per thousand. It was made the headquarters of a district in 1879, and has considerable trade in country produce, manufactures of sugar, a high school, and a printing-press. The district of Pilibhit has an area of 1372 square miles; population (1881), 451,601; (1891), 485,366; (1901), 470,689, showing an increase of 7 per cent. between 1881 and 1891, as compared with a decrease of 8 per cent. in the previous nine years, and a decrease of 3 per cent. between 1891 and 1901; average density, 342 persons per square mile. The land revenue and rates were Rs.8,12,749, the incidence of assessment being Rs.2 per acre; cultivated area (1896–97), 375,640 acres, of which 73,805 were irrigated from wells, &c., including 15,595 from Government canals; number of police, 1419; vernacular schools, 78, with 3170 pupils; registered death-rate (1897), 45·3 per thousand. The principal crops are rice, pulses, wheat, and sugar-cane. The Lucknow–Bareilly section of the Oudh and Rohilkhand Railway runs through the district, a portion of which is watered by the Rohilkhand canals.

Pillau, a seaport town of Prussia, province of East Prussia, on the spit of sand (*nehrung*) which separates the Frisches Haff from the Baltic, on the north side of the entrance channel, and 29 miles by rail west by south of Königsberg. It is fortified and has a harbour, which serves as the outer port of Königsberg, and to some extent also of Elbing and Braunsberg. A new navigable channel was in 1900–01 constructed across the Frisches Haff from Pillau to Königsberg. Shipbuilding, sail-making, fishing, and the working of amber are carried on. Population (1895), 3192; (1900), 2993.

Pilots.—The name of pilot is applied either to a particular officer serving on board a ship during the course of a voyage and having the charge of the helm and the ship's route, or to a person taken on board at a particular place for the purpose of conducting a ship through a river, road, or channel, or from or into a port. The latter kind is the only one to which the term is now applied either in British or foreign countries. In England, formerly, pilots were subject to the jurisdiction of the Lord High Admiral; and in the 16th century there are many instances of the Admiralty Court dealing with pilots disciplinarily as well as civilly holding them liable in damages to owners of ships lost or damaged by their negligence.

For some considerable time throughout the United Kingdom the appointment and control of pilots have been in the hands of numerous societies or corporations established at the various ports by charter or Act of Parliament, such as the Trinity Houses of Deptford Strond (London), Kingston-upon-Hull, Newcastle-on-Tyne, and Leith, and the Society of Cinque Ports Pilots and Court of Lodemanage (now extinct). These societies had jurisdiction over the pilots exercising their employment within the limits of such ports, and in many cases made it compulsory for ships resorting thither to employ them. By degrees the London Trinity House acquired a leading position, which was confirmed and extended by the general Pilotage Acts passed in the 18th and 19th centuries, with the object of introducing a uniform system throughout the realm. At the present day the United Kingdom is divided into districts for the purpose of pilotage jurisdiction. The (London) Trinity House has jurisdiction over the London district, which extends from Orfordness to Dungeness, and comprises the Thames and Medway up to London and Rochester bridges; the English Channel district, comprising the sea between Dungeness and the Isle of Wight; and the Trinity outport districts, which include any pilotage districts for the appointment of pilots within which no particular provision is made by Act of Parliament or charter, and the number of which, according to a parliamentary return of 1899, is 40, all English and Welsh. There are 66 other districts, within which other pilotage authorities have jurisdiction.

Authorities.

The present general pilotage law is contained in the Merchant Shipping Act of 1894. Pilotage authorities are defined as bodies or persons authorized to appoint or license pilots, or to fix and alter rates of pilotage, or to exercise any jurisdiction in respect of pilotage. They are subject to the control of the Board of Trade as the supreme mercantile marine authority. Those bodies, however, which existed at the time of the passing of the Act retain their powers and jurisdiction, so far as is consistent with it. The Board has power to appoint a new pilotage authority in any area where there is none, and to include a new area where there is none within an already existing one (but in either case pilotage cannot be made compulsory), or to transfer pilotage jurisdiction over a port other than that where the pilotage authority for that port resides, from that pilotage authority to the harbour or other local authority for that port, or to the Trinity House, or to a new authority; and the Board has all powers necessary to effectuate such transfer and constitute the new authority. The Board may also, by provisional order (which requires parliamentary confirmation), provide for the representation of pilots or shipowners on the pilotage authority of any district, and the exemption of ships from compulsory pilotage in any district. Where pilotage is not compulsory, and the power of obtaining pilotage licences unrestricted, the Board can in the same way give the pilotage authority powers with respect to licences, amount of pilotage rates, and the like. Pilotage authorities may, by by-laws under the Act (which require confirmation by Order in Council), exempt wholly or partly any ships or classes of ships from compulsory pilotage, and regulate the means of obtaining licences, and the amount of pilotage rates, subject to a maximum limit. They must make yearly returns to the Board of Trade of their by-laws, the names, ages, and services of their licensed pilots, the rates of pilotage, the amounts received for pilotage and their receipts and expenditure; and if they fail to do so, the Board may suspend their authority, which is then exercised by the Trinity House.

Law.

The statute also provides generally for the qualifications of pilots. A "qualified" pilot is one duly licensed by a pilotage authority to conduct ships to which he does not belong. On his appointment he receives a licence, which is registered with the chief officer of customs at the nearest place to the pilot's residence, and must be delivered up by the pilot whenever required by the licensing pilotage authority. On his death this licence must be returned to that authority. Pilotage dues are recoverable summarily from the owner, master, or consignees of the ship, after a written demand for them has been made. A pilot may not be taken beyond the limits of his district without his consent, and if so taken he is entitled to a fixed daily sum in addition to the dues; if he cannot board the ship, and leads her from his boat, he is entitled to the same dues as if he were on board; and he must be truly informed of the ship's draught of water. An unqualified pilot may in any pilotage district take charge of a ship without subjecting himself or his employer to any penalty, where no qualified pilot has offered himself, or where a ship is in distress, or in circumstances where the master must take the best assistance he can, or for the purpose of changing the moorings of any ship in port on docking or undocking her; but after a qualified pilot has offered himself any unqualified pilot continuing in charge, or any master continuing him in charge of the ship, is liable to a penalty. A qualified pilot may not be directly or indirectly interested in licensed premises or in the selling of dutiable goods, or in the unnecessary supply of gear or stores to a ship for his personal gain or for the gain of any other person. He can be punished for quitting a ship before the completion of his duty without the consent of the master, refusing or delaying to perform his duty without reasonable cause when required by lawful authority, lending his licence, acting as pilot when suspended or when intoxicated, and any pilot who through wilful breach of or neglect of duty, or by reason of his drunkenness, endangers ship, life, or limb, is guilty of a misdemeanour and liable to suspension or dismissal; but the pilot has an appeal in cases of fines over £2, of suspension or dismissal, suspension or revocation of his licence, or the application of a pilotage fund to which he has contributed. This appeal lies in England to a county court judge having jurisdiction over the port where he is licensed, or a metropolitan police magistrate or stipendiary magistrate with the like power; in Scotland to a sheriff; in Ireland to a county court judge, chairman of quarter sessions, recorder, or magistrate. Pilotage certificates may also be granted by pilotage authorities, available within their districts, to masters and mates of ships; and the holder of such a certificate may pilot any ship in respect of which it is available without incurring any penalty for not employing a qualified pilot.

Qualifications.

The statute further makes special regulation for Trinity House pilots. Every such pilot, on his appointment, must execute a bond for £100 conditioned for due observance of the Trinity House regulations and by-laws, and thereupon he is not liable for neglect or want of skill to anybody beyond the penalty of the bond and the amount payable to him for pilotage on the voyage on which he was engaged at the time of his so becoming liable. The licence may be revoked or suspended by the Trinity House when it thinks fit; it only continues in force for a year, and the Trinity House has absolute discretion whether it shall be renewed or not.

Pilot boats and signals.

A pilot boat is approved and licensed by the district pilotage authority who appoints or removes the master thereof. In order to be easily recognized, she has printed on her stern in legible white letters the name of her owner and her port, and on her bows the number of her licence; the remainder of the boat is usually black. The pilot flag is a red and white horizontal flag of a comparatively large size, and is flown from a conspicuous position. When the flag is flown from a merchant vessel, it indicates that a licensed pilot is on board, or that the master or mate holds a certificate entitling him to pilot the ship. By Order in Council of 1900, on and after the 1st day of January 1901 the signals for a pilot displayed together or separately are to be:—In daytime, there is (1) hoisted at the fore the Union Jack having round it a white border, one-fifth of the breadth of the flag; (2) the international code pilotage signal indicated by P.T.; (3) the international code flag S., with or without the code pennant; (4) the distant signal consisting of a cone pointing upwards, having above it two balls or shapes resembling balls. By night, (1) the pyrotechnic light commonly known as a blue light, every fifteen seconds; (2) a bright white light, flashed or shown at short or frequent intervals just above the bulwarks for about a minute or two.

Compulsory pilotage.

Pilotage in British waters may be either compulsory or free for all or certain classes of ships. From the parliamentary pilotage return of 1899, it appears that it is compulsory in 64 districts of the United Kingdom (of which two-thirds are the Trinity House districts), free in 32, free and compulsory in 8, while in 3 cases (Berwick, Dingwall, and Coleraine) no particulars are given. British warships in British waters are not compelled to employ a pilot, the navigating officer becoming the pilot under the direction of the captain. If a pilot be employed, the captain and navigating officer are not relieved from responsibility. They supervise the pilot, and should, if necessary, remove him from the ship. In the majority of foreign ports British warships are exempted from employing pilots, but the Suez Canal and the ports of France are exceptions. The Merchant Shipping Act continues the compulsory employment of pilots in all districts where it was already compulsory, and also the already existing exemptions; and there is no power in any pilotage authority or the Board of Trade to increase the area of compulsory pilotage, though there is to diminish it. Compulsion is enforced by a provision in the Act, that within a district where compulsory pilotage exists, the master of an unexempted ship who pilots her himself without holding the necessary certificate, after a qualified pilot has offered or signalled to take charge of the ship, shall be liable for each offence to a fine of double the amount of the pilotage dues demandable for the conduct of the ship. The exemptions from compulsory pilotage still existing in British territorial waters are as follows:—Ships or vessels with British registers trading to Norway or the Cattegat or the Baltic (except vessels on voyages between any port in Sweden or Norway and the port of London), or round the North Cape, or into the White Sea on their inward or outward voyages whether coming up by North or South Channels; any constant British traders inwards from ports between Boulogne inclusive and the Baltic coming up by North Channel, and any British ships or vessels trading to ports between the same limits on their outward passages and when coming up by the South Channels; Irish traders using the navigation of the Thames and Medway; ships engaged in the regular coasting trade of the kingdom; ships or vessels wholly laden with stone produced in the Channel Islands and Isle of Man and brought thence; ships or vessels not exceeding 60 tons, whether British or belonging to a foreign country specified by Order in Council; ships within the limits of the port or place to which they belong, if this is not a place particularly provided for by Act of Parliament or charter as regards the appointment of pilots; ships passing through the limits of any pilotage district in their voyages from one port to another port, and not being bound to any port or place within such limits or anchoring therein, but not including ships loading or discharging at any place situate within the district, or at any place situate above the district on the same river or its tributaries. Ships whose masters or mates are owners or part-owners of them, and living at Dover, Deal, or the Isle of Thanet, may be piloted by them from any of these places up and down the Thames or Medway, or into or out of any place or port within the jurisdiction of the Cinque Ports. The following ships in the London district and Trinity outport districts are also exempt when not carrying passengers, namely: ships employed in the coasting trade of the United Kingdom; ships of not more than 60 tons burden; ships trading to or from any port in Great Britain within the above districts to or from the port of Brest in France, and any port in Europe (which does not include the United Kingdom) north and east of Brest, or to the Channel Islands or Isle of Man; and ships navigating within the limits of the port to which they belong. The port to or from which the ship must be "trading" in this provision has been interpreted by the decisions to mean the port where the cargo is substantially discharged or loaded respectively; and the word "coaster" similarly has been held to apply only to a vessel carrying to one port of the United Kingdom a cargo which has been taken in at another. Every ship carrying passengers between any place in the British Islands and any other place so situate must carry a compulsory pilot, unless her master or mate have a pilotage certificate. The effect in law of the ship (British or foreign) being in charge of a compulsory pilot under the Act is that her owner and master are not answerable to any person whatever for any loss or damage occasioned by the fault or incapacity of any qualified pilot acting in charge of such ship within any district where the employment of such pilot is compulsory by law. In order to take advantage of this privilege, the shipowner must show (1) that a properly qualified pilot was acting in charge of the ship; there are, however, various kinds of qualified pilots—the qualified pilot who is always capable of acting, and the qualified pilot who is liable to be superseded if a better can be obtained; (2) that that charge was compulsory; the pilot, however, need not be compulsorily employed at the place where the accident happened, so long as he is compulsorily employed within the district where it happens; (3) that it was solely the pilot's fault or incapacity which caused the damage. Similarly, under the Harbours, Piers, and Docks Clauses Act, the owner of a vessel is not liable for damage done thereby to docks or piers when she is in charge of a duly licensed pilot.

This statutory exemption of a ship in charge of a compulsory pilot from any liability for her negligent navigation by that pilot, is only declaratory of the common law of England, and is based on the principle that the pilot is a State official put in charge of a ship, and is not the servant of the shipowner so as to make him liable for his negligence; and a British court gives the same effect to any foreign or colonial law which makes it compulsory on shipowners to put a pilot in charge of their ship when within their jurisdiction. Most foreign codes, however, while agreeing with English law in making the presence of a pilot on board compulsory, differ from it in not putting him in charge of the ship; and in this case the defence of compulsory pilotage cannot be pleaded successfully in British courts. Judicial decisions have established that French, Suez Canal, Danube, and Dutch pilots are not compulsory pilots in the British sense of the word, being only advisers of the master, or "living charts." But if the pilot is put in charge by the foreign or colonial law, although that law expressly provides that in spite of the owner surrendering the charge of the ship to him the owner shall still remain liable, a British court will hold the owner free from liability, on the ground that to make any person liable for a tort committed abroad, the act complained of must be wrongful not only according to the foreign law but also by English law. This consequence which English law attaches to the employment of a compulsory pilot has been much criticized in recent times, and it would seem that the foreign view is much more satisfactory, in regarding the pilot merely as the adviser and not the superior of the master. Moreover, the adoption of the foreign law on this point would restore the old general maritime law. The policy of the law was at one time inclined to extend this principle of compulsory pilotage, on the ground that it was for the benefit of commerce and the safety of seamen's lives, but it now restricts it within as narrow limits as possible, *e.g.*, the presence of a compulsory pilot on board a tow who is directing the navigation of a tug does not protect the tug-owner from liability for negligent navigation. As already pointed out, pilotage authorities have no power to extend its scope.

A pilot who is compulsorily in charge of a ship under English law has supreme control over her navigation, superseding the master for the time being; and if she is a tow he has also control of the navigation of her tug. The judicial decisions establish that it is within his province to decide whether the ship shall get under way, the proper time and place for her to anchor, the way of carrying her anchor, the proper orders for the helm, her rate of speed, and whether the statutory rules of navigation shall be complied with; and the master and crew must not interfere with his control, and only remain liable for the proper execution of the pilot's orders and the trim and general efficiency as to lookout, &c., of the ship. The master, however, is bound to supersede the pilot in case of his intoxication or manifest incapacity, and to interfere if there is a clear and plain prospect of danger to the ship in following the pilot's directions, *e.g.*, getting under way in a thick fog. A pilot taken voluntarily, and not by compulsion of law, is considered as the servant of the shipowner, and as such renders him liable for his acts of negligence towards third parties. He does not, it seems, supersede the master in the control of the ship, but only advises him. The Admiralty and the Board of Trade and the Trinity House all take the view that the captain or master is bound to keep a vigilant eye on the navigation of the vessel by the pilot, and insist on all proper precautions being taken. For the purposes of a policy of marine insurance a ship is not seaworthy without a pilot in compulsory pilotage waters; and where there is no legal compulsion to have one, but the locality requires navigation by a person having local knowledge, it has been said that a ship must take a pilot, certainly when leaving a port, and probably on entering a port if a pilot is available.

A pilot can sue for his pilotage fee at common law or in Admiralty (*q.v.*), in the latter case provided that the contract was made and the work done not within the body of a county; but he has a summary remedy by statute which is of easier application. He cannot be sued in Admiralty for damage done by a collision caused by his negligence (*e.g.*, on the Admiralty side of a county court having Admiralty jurisdiction); but he can be made liable at common law or in the Admiralty Division of the High Court, although in the case of a Trinity House pilot his liability is limited to the amount of his bond and pilotage fee then being earned (see above); but the court has refused to join him as a defendant to an action *in rem* brought against the ship of which he had the charge. A pilotage authority cannot be made liable for the negligent navigation of a ship by a pilot which it has licensed, for he is not its servant, though it has been held liable for the negligence of a person not licensed by it as a pilot, but employed by it for wages to pilot ships into a harbour under its jurisdiction, itself taking the pilotage dues and applying them for harbour purposes. A pilot is not in common employment with the master and crew of a ship, and can recover for any injury done him by their negligence. He may be entitled to claim salvage from a ship of which he has charge, if the services he renders are beyond the scope of his pilotage contract, either from the outset or owing to supervening circumstances, but not otherwise, whether he is on board her or leading her from his boat. (See SALVAGE.)

United States pilotage laws are regulated by the respective states according to Congress. If the waters are the boundary between two states, a duly licensed pilot of either state may be employed, but no discrimination can be made in the rates of pilotage between vessels of different states. In the *German Empire* the pilotage laws are very complicated. In the majority of the maritime states each one has its own regulations and laws. In *Prussia* there are Government pilots who enter the service as apprentices, and are placed under a department of state. In *France* the general organization of pilots is regulated by the Statute on Pilots of the 12th December 1806, and the pilotage regulations for each port are made by the Minister of Marine at the request of his local representative and the Chamber of Commerce. French pilots are exempt from military service.

(G. G. P*.; J. W. D.)

Piloty, Karl von (1826–1886), German painter, was born at Munich, 1st October 1826. Under the guidance of his father, Ferdinand Piloty (*d.* 1844), who enjoyed a great reputation as a lithographer in that city, young Piloty acquired in early life an insight into the principles of art. In 1840 he was admitted as a student of the Munich Academy, where he became a zealous pupil of the artists Schorn and Schnorr. After a journey to Belgium, France, and England, undertaken for the purpose of visiting the galleries in those countries, he commenced work as a painter of *genre* pictures, and in 1853 produced a work, "Die Amme" (The Wet Nurse), which, on account of its originality of style, caused a considerable sensation in Germany at the time. But he soon forsook this branch of painting in favour of historical subjects, and produced in 1854 for King Maximilian II. an historical painting representing "The Adhesion of Maximilian I. to the Catholic League in 1609." This picture has been variously criticized, but on the whole opinion inclines to regard it as being somewhat superficial and theatrical in tone, whilst it strongly betrayed the influence of the Belgian school of colourists. It was succeeded by "Seni at the Dead Body of Wallenstein" (1855), which gained for the young painter the membership of the Munich Academy, where he succeeded Schorn (his brother-in-law) as professor. Among other well-known works by Piloty are the "Battle of the White Mountain near Prague," "Nero Dancing upon the Ruins of Rome" (1861), "Godfrey of Bouillon on a Pilgrimage to the Holy Land" (1861), "Galileo in Prison" (1864), and "The Death of Alexander the Great" (unfinished), his last great work. He also executed a number of mural paintings for the royal palace in Munich. For Baron von Schach he painted the justly celebrated "Discovery of America." In 1874 he was appointed keeper of the Munich Academy, being afterwards ennobled by the king of Bavaria. Piloty was the foremost representative of the realistic school in Germany: he strove to represent nature to the minutest details. He was a most successful teacher, and among his more famous pupils may be mentioned Makart, Lenbach, Defregger, Max, and Grützner. He died at Munich on the 21st of July 1886.

Pilsen (Czech, *Plzeň*), the second town of Bohemia, Austria, at the confluence of the Mies and Radbusa, 52 miles west-south-west of Prague. Population (1890), of the town proper, 9778, including suburbs 50,221; (1900), 68,292, including the garrison of 2259 men. In 1880 the Czech and German elements were nearly equal, but it is now estimated that about 84 per cent. are Czech, 16 per cent. German; 94 per cent. Catholic, 5 per cent. Jewish, and 1 per cent. Protestant. Of all Bohemian towns, with the exception of the four suburbs of Prague, Pilsen shows the largest increase of population since 1857, when it had 14,269 inhabitants. As in Prague, there are separate educational establishments for the two nationalities, including gymnasia, *real* schools, commercial and trade academies, training colleges, &c. A joint-stock company was formed in 1893 for the manufacture of the staple product of the town, the celebrated Pilsen beer. In that year the two largest breweries produced 808,600 hectolitres of beer, over four times the entire quantity produced in the 'eighties. Other branches of industry comprise manufactures of malt, of iron and metal wares (including bell-founding and wire-drawing), of carts and waggons, and explosives, and the preparation of marble, granite, mill-stones, &c., together with steam corn and saw mills.

Pinar del Rio, capital of Pinar del Rio, the easternmost province of Cuba, 97 miles south-west by west of Havana. The town has rail connexion with Havana, and is the centre of the tobacco industry of the Vuelta Abajo region. Population (1899), 8880.

Pind Dadan Khan, a town of British India, in the Jhelum district of the Punjab, situated in 32° 35′ N. and 73° 5′ E., near the right bank of the river Jhelum, and a station on the salt mine branch of the North-Western Railway. Population (1881), 16,724; (1891), 15,055; municipal income (1897–98), Rs.30,381. It is an important centre of trade, and its manufactures include boats, brass-ware, pottery, embroidered scarves, and riding-whips. There is a municipal school.

Pine Bluff, a city of Arkansas, U.S.A., capital of Jefferson county, on the Arkansas, at an altitude of 216 feet. It is in one of the richest cotton regions of the country, and is on the St Louis, Iron Mountain, and Southern, the St Louis South-Western, and the Pine Bluff and Arkansas River railways. It has a large trade in cotton, and has cotton compresses, cotton-seed oil mills, planing mills, flour mills, and car works. Population (1880), 3203; (1890), 9952; (1900), 11,496, of whom 359 were foreign-born and 5771 negroes.

Piotrków, a province in the west of Russian Poland, with an area of 4729 square miles. Geologically it represents a continuation of Upper Silesia, and is built up of Upper Carboniferous deposits, containing near Bendzin a layer of coal, 265 square miles in extent, of which only one-fifth is worked. Permian and Jurassic deposits, containing zinc ores, as also lignite and limonite iron ores, overlie the Carboniferous. The surface forms a series of heights, from 1000 to 1580 above sea-level, intersected by ravines, and stretching from south-west to north-east. The province is watered by the Warta and the Pilica, and was formerly covered by thick forests. It was colonized by Mazurs and Poles (Veliko- and Malo-Polyans). The domiciled population numbered 1,409,044 in 1897, of whom 707,272 were women, and 509,699 lived in towns. Most of the inhabitants are Poles, the rest being Jews (189,000) and Germans (162,500). The province is divided into eight districts, of which the chief towns are Piotrków (see below), Bendzin (21,190), Brzeziny (7669), Czenstochowo (45,130), Łask (4238), Łódź (315,209), Nowo

Radom (12,407), and Rawa (6471). Pabianice has 26,900 inhabitants, Zgerż 19,124, and Tomaszew 21,041. Educational institutions are comparatively numerous and efficient. Although the soil is not fertile, agriculture is the main occupation of the people, and nearly 1,440,000 quarters of various cereals and 2,165,000 quarters of potatoes are grown annually, the latter chiefly for the distilleries. The average crops of 1895–99 were: wheat, 568,000 cwt.; rye, 3,154,000; oats, 1,254,000; all cereals, 5,941,000; and potatoes, 11,724,000 cwt. Cattle-breeding is extensively carried on, and in 1897 there were 123,130 horses, 251,050 horned cattle, and 220,000 sheep. Weaving as a domestic industry gave employment in 1897 to 8920 workers, and yielded a return of £460,000. Small furniture works and forges are widely scattered amongst the villages. Coal-mining gives occupation to 13,500 workers, and 3,230,000 tons are extracted annually. Iron ore was extracted in 1898 from 44 mines (1630 workers), and there were 9 iron works (6250 workers), employing 79 steam engines, and showing a return of 125,000 tons of pig iron and 100,000 tons of iron rails and iron-ware. Textile industries have rapidly developed, the towns of Łódź Pabianice, Zgreż, and Bendzin all being important manufacturing centres. The chief industries are cotton-spinning, cotton-printing, dyeing, and the manufacture of woollen cloth, silks, and jute. They employ 150,000 workers, and the value of their yearly output reaches £15,000,000. Granica and Sosnowice are two of the chief custom-houses in Russia, and the annual trade of the province is estimated at £12,000,000. (P. A. K.)

Piotrków, capital of the above government, situated 90 miles by rail south-west of Warsaw, on the railway to Vienna. It is a well-kept town, with numerous gardens. Its factories (agricultural machinery works, flour-mills, saw-mills, tanneries) are unimportant. Population (1882), 23,050; (1897), 30,372.

Piqua, a city of Miami county, Ohio, U.S.A., on the Miami river, the Miami and Erie Canal, and the Cincinnati, Hamilton and Dayton, and the Pittsburg, Cincinnati, Chicago, and St Louis railways, at an altitude of 865 feet. It contains varied manufactures, especially of agricultural implements, furniture, waggons, tin-plate, and woollen goods. Population (1890), 9090; (1900), 12,172, of whom 901 were foreign-born and 487 negroes.

Pirano, a seaport town in the crownland of Istria, Austria, situated at the point of a small peninsula, a few miles south of Trieste. In addition to viticulture and the cultivation of the olive, its principal resources are shipbuilding, fishing, the manufacture of chemicals, and the evaporation of sea-salt, of which some 50,000 tons are annually produced. Its port is entered and cleared by an aggregate of about 7500 vessels of 442,000 tons annually, mostly coasting vessels. Pirano is celebrated for the victory of the Venetians over the fleet of the Emperor Frederick I. in 1177. Population (1900), 13,339.

Pirna, a town of Germany, on the Elbe, 11 miles by rail south-east of the town, and in the circle of Dresden, kingdom of Saxony. It has several educational institutions, amongst them a girls' higher-grade school, a girls' industrial school, a commercial school, and a seminary for teachers. Population (1890), 13,852; (1900), 18,295.

Pirot, during the Turkish rule known as *Shehr-Koey*, a Servian town, 12½ miles from the Bulgarian frontier at Tsaribrod, on the railway line between Nish and Sofia. It has a mediæval fortress, believed to have been built on the site of the Roman fortress *Quimedava*, on the military road leading from Old Naissus to Philippopolis. The town is of great strategical importance, for which reason the Russian plenipotentiaries at the Berlin Congress (1878) stubbornly tried to include it within the Bulgarian frontier, while Austria and some other Powers insisted that it should be given to Servia. In the war between Servia and Bulgaria in 1885 the Bulgarians occupied and held it until the conclusion of peace. It is the seat of the prefecture for the whole district, with a tribunal, several schools, and a custom-house. A regiment of infantry, with several batteries, is stationed permanently in Pirot, the neighbourhood of which has since 1886 been strengthened by modern fortifications. It is the only really industrial town in Servia, having numerous small factories for the manufacture of thin cloth (*shayak*), woollen braid (*gaytan*), and especially carpets. Its carpets have a great reputation in the Balkan Peninsula for their quaint designs, durability, and freshness of colour. Population (1900), 10,421.

Pisa, a town, archiepiscopal see, and capital of the province of Pisa, Tuscany, Italy, on the Arno, 7 miles from the sea and 49 miles west of Florence by rail. It still retains its ancient walls, 6¼ miles in circuit, and is defended by a citadel on the south-west. The principal streets run alongside the river, and are lined with fine buildings. Besides the cathedral, the baptistery, and the leaning tower, the city possesses several notable churches, as the Renaissance church of the Tuscan order of St Stephen, built in 1562 from plans by Vasari; San Niccolo, with a four-storeyed tower (1230), built by Niccola Pisano, and the tomb of John of Swabia, the parricide; Santa Caterina (1262); Santa Maria della Spina, in the Italo-Gothic style, built in 1230 and restored in 1872; San Sepolchro, erected in 1150 by Diotisalvi; San Francesco, with frescoes by Taddeo Gaddi; and the basilica of San Michele (1018). Amongst the secular buildings may be mentioned the royal palace; the archiepiscopal palace; the palace of the order of St Stephen, built by Niccola Pisano and reconstructed by Vasari; the Upezzinghi (formerly Lanfreducci) palace, built of Carrara marble in 1590; the Lanfranchi, Agostini, and other palaces; the university (1472); a large hospital (1258); and fine market halls. There are statues to Cosimo I. (by Francavilla), Archduke Leopold, and Ferdinand I. The city possesses also an academy of the fine arts, with a gallery of paintings; and the university a library of 120,000 volumes, a natural history museum, botanical garden, and agricultural schools. The university, founded in 1338, has faculties of law, medicine, mathematics, and philosophy and literature. In 1898 it was attended by 1087 students and had 56 professors. There are also numerous other educational institutions, including the school of the Chamber of Commerce and a technical school. The most important industry is the manufacture of cottons. In the vicinity of the city are the royal stud-farm (horses and dromedaries) of Cascine di San Rossore, and the mineral baths of San Giuliano, alkaline-ferruginous, with temperature 91·4° to 105·8° Fahr. Population (1881), 42,779; (1900), 61,279.

Pisciculture (Marine).—The extent and efficiency of sea-fishing operations in British waters greatly increased during the last decade of the 19th century, but the quantity of fish landed by no means increased in equal proportion, and in the case of certain kinds actually decreased. The average price of fish, especially of soles and turbot, advanced considerably, and it can be proved that the supply at any rate of ground fish on the more accessible grounds, which have been exploited for the longest time, has materially diminished. In the drift-net fisheries the development of the industry and the diminution in the supply have not hitherto been so conspicuous. The fecundity of fish being so great, it is often supposed that adequate protection of the young would be sufficient to maintain the supply of adults. But in cases where the capture of the commercially valuable adult fish is very extensive and persistent, the number of mature individuals surviving to breed may diminish every season, in spite of the protection of the young, and thus in every season there may be fewer young to be protected.

We may specially consider, in reference to this point, the trawl fishery in the North Sea, where the steam trawler, with the large otter trawl, extending 90 or 100 feet at the mouth, is so enormously more efficient than the old sailing trawler with the beam trawl of 40 or 50 feet. The most definite evidence on this question is supplied by Dr Fulton's account of the results of experiments made by the Scottish Fishery Board (*Fourteenth Annual Report*, p. 128). That authority prohibited trawling for ten years in the Firth of Forth and St Andrews Bay, and throughout that time took careful observations of the abundance of fish both in the closed areas and the open areas adjacent to them. Dr Fulton, after careful discussion of the results, shows that in spite of the closure a decrease took place, both in the closed and the open areas, in some of the most important flat-fishes, namely, plaice and lemon soles. Dr Fulton points out that the plaice and lemon sole spawn in the open off-shore areas and not in the closed, and concludes that the diminution was due to the capture of so many adult mature fish in the open areas by the trawlers. Exception was taken to Dr Fulton's evidence by Professor M'Intosh; but Mr Garstang, after re-examining it, finds that, though Dr Fulton's discussion of the statistics was open to certain objections, his conclusions are nevertheless correct. Dr Fulton thinks that protection of the off-shore spawning-grounds is the method most likely to increase the supply of fish. But the question arises whether it is practicable to close off-shore areas to trawling or other kinds of fishing. The Scottish Fishery Board has now for some years closed the whole of the Moray Firth, which includes spawning-grounds as well as inshore grounds; but this closure applies only to British subjects, and is not therefore complete, as foreign vessels can and do trawl there, a state of things which it is difficult to justify.

Artificial Propagation.—The conclusion that the chief cause of the diminution in the supply of fish is the excessive destruction of the mature adults, is a strong argument in favour of the necessity of artificial propagation. But in spite of the efforts which have been made since 1890, it is by no means certain that a practically successful system of artificial propagation has yet been devised. The practice hitherto followed is to obtain a large number of fertilized eggs, to keep them in appropriate apparatus until they are hatched, and then to liberate the fry in the sea. The number of eggs produced by a single female fish is very large, as will be seen from the following list of average numbers:—

Plaice	300,000	Haddock	500,000
Lemon dab	500,000	Whiting	100,000
Sole	500,000	Cod	3,000,000
Turbot	8,000,000	Ling	20,000,000

The number varies according to the size of the individual fish, as well as according to the species; but a very large number of eggs can be obtained from a small number of mature fish, and if the number of valuable fish produced bore any considerable proportion to the number of eggs which can be obtained, the results of artificial propagation would be very important. The fertilization of the spawn is very easily effected. The eggs are collected either by stripping them from the mature adult immediately after capture, or by keeping the adults alive until they are ready to spawn, and then stripping them, or by keeping them in reservoirs of sea water and allowing them to spawn of their own accord. In the two former cases a little milt is allowed to fall from a male fish into a vessel containing sea water, and the eggs are pressed from the female fish into the same vessel. With few exceptions, the eggs of commercially valuable marine fishes are buoyant in sea water and free; those of the herring and of the American winter flounder, however, are heavy and adhesive.

The United States Fish Commission possesses two marine hatcheries, one at Gloucester and one at Wood's Hole, both in Massachusetts. In the winter of 1897–98 the following results were obtained:—

Gloucester	160 million eggs yielded	96 millions of	cod fry.
,,	7 ,, ,,	4 ,,	pollack fry.
Wood's Hole	153 ,, ,,	105 ,,	cod fry.
,,	57 ,, ,,	39 ,,	winter-flounder fry.

The Government of Newfoundland possesses a hatchery at Dildo Island, in Trinity Bay. This establishment is under the direction of Mr Adolf Nielsen, Superintendent of Fisheries, and is devoted entirely to the propagation of cod. The total output of fry since the commencement of operations has been as follows:—

1890	17 millions.	1894	221 millions.
1891	39 ,,	1895	188 ,,
1892	165 ,,	1896	186 ,,
1893	201 ,,		

The annual average, therefore, has been over 145 millions. In 1896 the number of cod eggs placed in the hatching apparatus was 233 millions, so that the proportion lost in the process of development was 20 per cent. In 1890, we are informed, the loss was 49·4 per cent., and therefore a great improvement has been effected.

The first important marine hatchery established in Europe was that of Captain Dannevig at Flödevig, near Arendal, on the south coast of Norway. This also deals almost exclusively with cod eggs. The total numbers hatched annually have been as follows:—

1891	193½ millions.	1894	100 millions.
1892	208 ,,	1895	85 ,,
1893	240 ,,	1896	327 ,,

Of these fry about 15 millions have been liberated on the average every year in Christiania Fjord; the rest have been put into the sea near Arendal.

In Britain the Scottish Fishery Board has maintained a marine fish hatchery since the year 1894. Until 1899 this establishment was situated at Dunbar; it has since been removed to the Bay of Nigg, near Aberdeen. Its resources have been devoted principally to plaice, the fry of which have been hatched in numbers varying from 11 millions to 38 millions per annum. In the years 1895 and 1896 a few million fry of cod, lemon dabs (*Pl. microcephalus*), and turbot were hatched. In the earlier years the fry were all liberated in the sea near Dunbar, but in recent years all the plaice fry were put into upper Loch Fyne, in order that more definite evidence might be obtained concerning the effect of the introduction of artificially hatched fry on the subsequent supply of adult fish. The efficiency of the arrangements in the Dunbar hatchery, which has been under the management of Mr Harald Dannevig, a son of Captain Dannevig, is proved by the fact that the loss of eggs during hatching operations was only 10·7 per cent. for a whole season.

A small hatchery has been established by the Lancashire Sea Fisheries Committee at Piel, on the shore of Morecambe Bay. In the year 1899 over 3 million fry were produced and liberated. These consisted principally of cod fry; of plaice there were 364,000, of haddock 340,000, and of flounder a few thousands.

Hatching Apparatus.—In the United States and in Newfoundland the apparatus generally used for hatching buoyant ova is the M'Donald automatic tidal box. This apparatus is made of wood, and consists of water-tight compartments each 2½ feet by 1½ foot in area, and 18 inches deep. In each compartment fits an egg-box, the bottom of which consists of linen scrim. The outflow pipe is in the form of a siphon, so that the outflow is intermittent, and the level of the water in the box rises and falls alternately. Water is admitted through the side of the egg-box. These arrangements are supposed to keep the eggs in constant motion. In the Dannevig apparatus, which is used in England and Norway, the egg-boxes are only 1 foot square, and are hinged by one side to the sides of the water-tight compartments. The apparatus is fixed in a slanting position and water flows from one compartment into the egg-box below, the overflow being continuous, not intermittent. Usually the egg-boxes are moved at intervals by a mechanical arrangement, to keep the eggs in motion. This apparatus has proved very successful.

Results of Artificial Propagation.—Very little satisfactory evidence, of a statistical kind, of the results of artificial propagation has been published. The following figures, given by Captain Dannevig for Christiania Fjord, are probably the most important yet produced:—

Year.	Number of Cod caught.	Millions of Fry planted.
1892	44,013	10
1893	50,322	20
1894	65,212	—
1895	65,753	12
1896	70,414	18
1897	70,898	15
1898	81,367	15
1899	78,760	15

During the period covered by the above figures the great cod fisheries of the north of Norway showed considerable fluctuations, but no general increase.

As there seems no reason at all to suppose that artificially-hatched fry are in any way inferior to those produced naturally, a certain proportion of the millions of fry planted must develop into fish of marketable size. The only questions, therefore, to be considered are: (1) What is the magnitude of the results produced by operations of the method and extent indicated above? (2) Does the value of possible result exceed the cost of the operations? (3) What improvements can be suggested in the mode of operation?

If the fry placed in a certain area, such as Christiania Fjord, were the only fry of the species in that area, there would be no doubt that the fish caught were the result of artificial propagation. But in order to be convinced that an increase in the fish caught is due to artificial operations, we ought to be able to compare the number of fry introduced with the number naturally produced. We may do this either by comparing parent fish in the two cases, or the eggs and fry in the two cases. Supposing every egg hatched into living fry, the fifteen millions of fry placed by Dannevig in Christiania Fjord would be the produce of only about five mature female cod. Supposing that only one-tenth of the eggs are hatched in the sea, the same number of fry would be the produce of fifty female cod. The question therefore arises whether the addition of fifty mature female cod, with a suitable number of males, each year would double the cod supply in Christiania Fjord. It is at any rate evident that artificial propagation on the scale on which it has hitherto been carried on cannot possibly check to any considerable extent the diminution of great sea fisheries. For example, it has been calculated that four million mature female plaice were landed in a year at Grimsby alone. The greatest number of plaice fry produced by the Scottish hatchery was thirty-eight millions. Taking the number of eggs produced by one plaice at only 200,000, and supposing only one-tenth to hatch in the sea, the produce of the hatchery represents 1900 female plaice in the sea; so that the work of the hatchery is equivalent to returning to the sea one female plaice out of every 2000 killed at Grimsby, leaving the plaice landed at other ports out of consideration.

As an instance of the comparison of artificially and naturally produced fry, the following may be given. Mr Williamson (*Report* of Scottish Fishery Board for 1898) estimated, from a number of tow-net collections made at definite intervals, that 483 millions of plaice eggs were naturally produced in Loch Fyne in one spawning season. The number of artificially-hatched fry added was 19 millions. As the plaice eggs in the loch were in all stages of development, the loss before hatching could not be very high. Supposing only 100 million fry were naturally hatched in the loch, the increase in the supply of plaice due to artificial hatching would be only 19 per cent. However, even a small percentage added to the produce of a valuable fishery may be worth a good deal of money, and it is interesting to consider whether it is possible to compare the cost of hatcheries with the value of results.

The working of the hatchery at Dildo, Newfoundland, in 1896, is stated to have cost £200 a year. Captain Dannevig states that his hatchery has produced 2163 millions of fry in ten years, at a cost of £485 a year, but he does not say whether the value of the fishery has been increased by that amount. With regard to shad-hatching in the United States, it is stated (U.S. Fish Commission *Report* for 1898, published 1899) that the value to the fishermen of the shad caught in 1880 was $995,790, in 1896 $1,656,711, an increase of $660,921, while the total expenditure in the year 1896–97, for shad-hatching alone, was only $15,726. The total appropriation for the Commission from the U.S. Treasury in 1898 was $462,076 = £92,415; for propagation alone, $132,500, or £26,500.

Rearing of Fry.—The development of the fish in the egg up to the moment of hatching takes but a short time, namely, from three or four days up to about three weeks, according to temperature and the kind of fish. The development of the hatched fry up to the perfect condition in which it resembles its parents takes from six weeks to three months. There can be no doubt that most destruction occurs during this stage, both because it is longer than the egg stage and because the young fish have to seek their own food. The fry also have more enemies than the eggs or older fish. It would therefore be advantageous to rear the fry through the larval stage before putting them into the sea. Such rearing has generally been found very difficult, but experience indicates that the two chief conditions of success are: (1) to feed the larvæ *before* the yolk has all been absorbed; (2) to move the larvæ artificially in the water. Fish larvæ and other pelagic creatures seem to require the stimulus of considerable agitation in the water to keep them in vigour. In 1886 Dannevig turned out 500,000 cod larvæ into a closed reservoir 43 yards long by 20 yards in breadth and 5 yards in greatest depth. Some of these lived for two years; but his object was merely to prove that they would develop into perfect cod, not to rear them before they were put into the sea. In 1896 Harald Dannevig reared plaice larvæ at Dunbar in a large glass carboy, changing the water twice a day: when six weeks old they had nearly completed their transformation and had taken to lying on the bottom. If the fry are not reared to the fully-developed condition, it is open to question whether it would not be equally beneficial to put the fertilized eggs directly into the sea, instead of hatching them. The process of hatching absorbs a large proportion of the cost of artificial propagation, and it is not certain that the protection of the eggs alone is worth the expense.

Pisek, the chief town of a government district in Bohemia, Austria, on the Woltawa, 24 miles west by south of Tabor. Population (1890), including suburbs, 10,950; (1900), 13,574, including garrison of 935; mostly Czech and Catholic. Feldspar, quartz, and granite are quarried in the environs.

Pistoja, a town and episcopal see of the province of Florence, Tuscany, Italy, 21 miles north-west of Florence on the railway to Bologna. It is surrounded by a wall pierced by five gates and further defended by a citadel. Its institutions embrace a medical institute, a natural history museum, an academy of sciences, and two small libraries. Its varied industries include iron and steel works, manufactures of glass, silk, macaroni, woollens, olive oil, ropes, paper, and vehicles. Population (1881), 30,951; (1899), 32,000.

Pitcairn Island, the most southerly island of the Low Archipelago, in the eastern Pacific Ocean, in 25° 3′ S. and 130° 6′ W. It became known as the home of the mutineers of the *Bounty*, of whom the present inhabitants are for the most part descendants by Tahitian wives. Described in past travels as the denizens of an earthly Paradise, they seem to have fallen sadly from their high estate. There has been a gradual disappearance of trees, which has affected the climate and caused droughts, and though there is still much fertile soil left in the valleys and on the hills in the interior, the energy to make use of it is lacking. Recent accounts describe the people as "lax in morals" and "weak in intellect"; as "degenerating"; "unless something is speedily done to alter their condition they will probably drift into hopeless imbecility." Intermarrying has brought about its natural results, and the want of intellect among the young is reported to be appalling. There would appear, however, to be some reason to believe that these accounts have been unduly pessimistic, for later report is of a much more favourable character. Nevertheless the population is diminishing. In 1901 it was 126. Meat, except goat's flesh and chicken, is unknown. The island is overrun by chickens, which unfortunately the islanders do not appreciate. Tea, coffee, tobacco, and spirituous liquors are never tasted. There is an annual election of a governing body of seven, who elect their chairman. The island has now been placed under the jurisdiction of the High Commissioner of the Western Pacfic. It has been proposed to remove the people *en masse* to Fiji, Tahiti, or Norfolk Island, but the mischief may be remedied by the opening up of a frequent communication with Tahiti.

The Parliamentary Papers C. 9148, *Correspondence relating to the Condition of the Pitcairn Islanders*, 1899, and Cd. 754, *Further Correspondence, &c.*, 1901, should be consulted. (H. E. EG.)

Pitch, Musical.—The pitch of a musical sound is aurally defined by its absolute position in the scale and by its relative position with regard to other musical sounds. It is precisely defined by a vibration number recording the frequency of the pulsations of a tense string, a column of air, or other vibrator, in a second of time. In Great Britain and America the complete vibration to and fro (swing both ways of a pendulum) is taken as the unit; elsewhere the vibration in one direction only (swing one way of the pendulum). The only official standard is the French, dating from 1859, preserved by a tuning-fork vibrating 870·9 (double vib. 435·45) at a temperature of 15° Centigrade (59° Fahr.) in a second. The vibration number stated in the edict establishing the Diapason Normal is 870 (435), which for comparison will be here adhered to. The natural basis for a standard musical pitch is the voice, particularly the male voice, which has been of greater importance historically. There is no reason to suppose the human voice has varied, during the period of which we have evidence, more than other physical attributes. The only difference to be reckoned with may be in recent tendencies of solo vocalists to sing for effect, and so to extend the compass of the voice upwards. Otherwise we may assume no disturbing alteration has taken place for more than 2000 years in its position and extent. Vibrations increase in rapidity as a note rises, and decrease as it falls. Any note may be a pitch note; for orchestras custom has settled upon a^1 in the treble clef, for organs and pianos in Great Britain c^2, and for modern brass instruments b flat^1.

We are not without a clue to the pitch usual in the classic Greek and Alexandrian ages: the vocal octave to which the lyre was adapted was noted as from e to e^1. As in choruses baritone and low tenor singers always prevail, d–d^1, at French or at medium pitch, would really be the Greek singing octave; we may therefore regard it as a tone lower than that to which we are accustomed. But to sing the lower Greek modes in or near the vocal octave it was necessary to transpose (μεταβολή) a fourth upwards, which is effected in modern notation by a flat placed upon the b line of the staff; thus modulating from our major key of C to that of F. This transposition has had, as we shall see, much to do with the history of our subject, ultimately influencing the ecclesiastical chant and lasting until the 17th century of our era. It does not appear from any evidence that the keyboards—when there were more than one—of the early organs were arranged for transposition, but it is certain that the Flemish harpsichords to 1650 were made with double keyboards to accommodate it, as the writer has proved elsewhere (*History of the Pianoforte*, Novello, London, 1897). But a positive identity of pitch cannot be claimed for any period of time, and certainly not for the early organs; the foot-rule of the organ-builder, which had to do with the lengths of the pipes, and which varied in every country and province, could easily cause a difference of a semitone. Scale and wind-pressure are also important factors. But with all these often opposed conditions, we find less variation than might be expected, the main and really important divergence being due to the necessity of transposition, which added a very high pitch to the primarily convenient low one.

The first to attempt to define pitch would seem to have been Arnold Schlick (*Musica ausgeteutscht und ausgezogen*, Heidelberg, 1511), who gives a measure, a line of $4\frac{7}{8}$ Rhenish inches, which, he says, multiplied sixteen times, should be the lowest F of a small organ. He gives no diameter or wind-pressure. The late Dr A. J. Ellis used this indication to have an organ pipe made which, with one-sixteenth diameter and a wind-pressure of $3\frac{1}{4}$ inches, at one-fourth Schlick's length, gave f^1 301·6, from which he derived a just major third of a^1 377, which would compare very well with an old Greek a^1. Schlick goes on to say the organ is to be suited to the choir and properly tuned for singing, that the singer may not be forced to sing too high or too low and the organist have to play chromatics, which is not handy for every one. Further, he says pitch cannot be exactly defined, because voices vary; he nevertheless gives the measure above mentioned for the low F, but if a larger organ is built to include the still lower C, then this C must be *of the same measurement*, the reason being that a greater part of Church music ends in "grambus," a word understood by Schlick's editor to mean the transposition of a fourth. The larger high-pitch organ will therefore be at a^1 502·6. The Halberstadt organ, about which so much has been written, was, according to Praetorius (*Syntagma Musicum*, Wölffenbüttel, 1618), built in 1361, and repaired or rebuilt 1495. He gives the longest pipe of this organ, B natural, as 31 Brunswick feet, and the circumference $3\frac{1}{2}$ feet. He further tells us this pitch was a tone, nearly a tone and a half, higher than a suitable church pitch (*Chorton*), for which he gives a diagram. Dr Ellis had pipes (now preserved in the Royal Institution, London) made to reproduce both these pitches at $3\frac{1}{4}$ inches wind-pressure. The Halberstadt pitch was found to be a^1 505·8; the *Chorton*, 424·2. Ellis used mean-tone temperament in calculating this lower pitch; but as he used just intonation for the Halberstadt, it seems preferable to substitute it for the *Chorton*, thus reducing it to a^1 422·8. Praetorius's *Cammerton*, or chamber pitch, formulated in his diagrams for voices and instruments, is, he says, a whole tone higher; equivalent, therefore, to a^1 475·65. Nearly all the German organs in his time were tuned to this higher pitch. Ellis offered the suggestion of a much higher pitch for this *Cammerton* in his lecture "On the History of Musical Pitch," read before the Society of Arts, London (*Journ. Soc. Arts*, 5th March 1880), but the writer is unable to accept it. The lower vibration number is justified by due consideration of the three divisions of the male voice, bass, tenor, and alto, as given by Praetorius, whose *Cammerton* very closely corresponds with Bernardt Schmidt's Durham organ, 1663–68, the original pitch of which has been proved by Professor Armes to have been a^1 474·1. The Halberstadt pitch is nearly a semitone higher, which again agrees with the statement of

Praetorius, and also Schlick's high C organ. Yet it would seem there had been a still higher pitch used in the old ecclesiastical music. Upon this interesting question Praetorius is confused and difficult to understand, but he never wavers about the transposition of a fourth. In one passage he distinctly says the old organ high pitch had been a whole tone above his *Cammerton*, with which we shall find his *Tertia minore* combines to make the required interval. The term "*Tertia minore*," or "*inferiore*," is used by Praetorius to describe a low pitch, often preferred in England and the Netherlands, in Italy, and in some parts of Germany. An organist, instead of transposing a whole tone down from the *Cammerton*, would for the *Tertia minore* have to transpose a minor third. A corroboration of this pitch is found in A. Silbermann's great organ in Strasburg minster (1713–16), the pitch of which, taken in 1880 and reduced to 59° Fahr. (as are all pitches in this article), is a^1 393·2. An old organ at Versailles (1789) was very near this example, a^1 395·8. Sir Frederick Gore Ouseley (*vide* Ellis's lecture) regarded the French *ton de chapelle* as being about a minor third below the Diapason Normal, a^1 435, and said that most of the untouched organs in the French cathedrals were at this low pitch. Strasburg was French territory in 1713, but Silbermann's organ is not quite a whole tone below. Ellis quotes an organ at Lille, a^1 374·2, but no other instance of the very low Schlick pitch is recorded, although trial of the French cathedral organs might perhaps result in the finding of examples. Ellis gives Dom Bédos (*L'Art du Facture d'orgues*, Paris, 1766) as authority for a mean tone a^1 376·6. To return to the *Tertia minore*. Dr R. Smith, of Cambridge, in 1759, had the organ of Trinity College, built by Bernhardt Schmidt, lowered a whole tone, to reduce it to certain Roman pitch pipes made about 1720. His determinations of pitch by a weighted wire are not trustworthy; Ellis thinks they are not safe within four or five vibrations per second, but gives a mean pitch for this organ, when altered, of a^1 395·2. St Michael's Church at Hamburg, built as late as 1762 and unaltered in 1880, had a 17th-century pitch, a^1 407·9. This is about a semitone below the Diapason Normal, and a just minor third lower than the St Jacobi organ in the same city (1688), measured by Herr Schmahl, a^1 489·2. What was remarkable in this organ was that it had one stop which was an equal minor third lower, a^1 411·4[1]. The difference of a minor third, or, as we shall see later, a whole tone, had replaced the earlier fourth. Sir Frederick Gore Ouseley's comparison of the church and chamber pitches of Orlando Gibbons (*vide* Ellis's lecture) clearly shows the minor third in Great Britain in the first half of the 17th century. But the narrowing continued. Bernhardt Schmidt, better known in England as Father Smith, was invited about 1660 to build the organ for the Chapel Royal, Whitehall. Two years later he built the organ in Durham Cathedral, a^1 474·1, difference a whole tone, and practically agreeing with the *Cammerton* of Praetorius. The Hampton Court organ of 1690 shows that Schmidt had further lowered his pitch a semitone, to a^1 441·7. What happened at Durham was that at some subsequent date the pipes were shifted up a semitone to bring the organ into conformity with this lower pitch, with which it is probable Schmidt's organs in St Paul's and the Temple, and also Trinity College, Cambridge, agreed. This lowering tendency towards the low church pitch, and the final adoption of the latter as a general mean pitch throughout the 18th century, was no doubt influenced by the introduction of the violin, which would not bear the high tension to which the lutes and viols had been strained. Harpsichords had long been preferred at the *Tertia minore*. The *Chorton* of Praetorius, a^1 422·8, is practically the same pitch as that of the fork the possession of which has been attributed to Handel, a^1 422·5. It is a very fair mean between G. Silbermann's 18th-century Dresden pitch, a^1 415, and the organs of Renatus Harris, a^1 428·7. Stein tuned Mozart's piano to a fork a^1 421·6, and the Broadwood pianos used at the London Philharmonic Society in its first concerts (1813) were tuned to a fork c^2 506·8, which gives a mean tone a^1 423·7.

According to Schindler (*Niederrheinische Musik-Zeitung*, 1855, Nos. 8 and 9) and the report of the French Commission, 1859, the rise in pitch began at the Congress of Vienna in 1816, the military bands being the cause. With the improvements in wind instruments this continued, as a more brilliant effect was gained. In 1823 Weber's *Euryanthe* is recorded as having been played in Vienna at a^1 437·5, and in 1834 Kreutzer's *Nachtlager* at a^1 440. The measurements are doubtful, but the upward tendency is clear. Scheibler, who was nothing less than trustworthy, owing to his simple and accurate Tonometer, has recorded pitches in Vienna about 1834 from a^1 433·9 to 440·2. About that time, or it may be a few years earlier, Sir George Smart established a fork for the Philharmonic Society, a^1 433·2. Forks intended for this vibration number, stamped "Philharmonic," were sold as late as 1846. But about that year the performing pitch of the Society had reached 452·5. Sir Michael Costa was the conductor 1846–54, and from his acceptance of that high pitch the fork became known as Costa's, and its inception was attributed to him, though on insufficient grounds. In 1874 a further rise in the fork to a^1 454 was instigated by Sir Charles Hallé. The British army is bound by His Majesty's Rules and Regulations to play at the Philharmonic pitch, and a fork tuned to a^1 452·5 in 1890 is preserved as the standard for the Military Training School at Kneller Hall. But the Philharmonic Society adopted the Diapason Normal in 1896, and the military bands have not gone with it. In point of fact, they are gradually going higher, and the brass bands, which are so important in the North of England and in Wales, are not behind them.

It was the irrepressible upward tendency that caused the French Government in 1859, acting with the advice of Halévy, Meyerbeer, Auber, Ambroise Thomas, and Rossini, to establish by law the *Diapason Normal*. Other countries have gradually followed, and, with few exceptions, the low pitch derived from the Diapason Normal may be said to prevail throughout the musical world. Great Britain has been the last to fall in, but the predominance of the low pitch, introduced at Covent Garden Opera since 1880, is assured. The proprietors of Queen's Hall, London, did much for it when they undertook the alteration, at great expense, of their large concert organ, which had only just been erected. In 1896 the Philharmonic Society decided upon a performing pitch, ostensibly at 68° F., of a^1 439; and in 1899 Messrs Broadwood made a successful effort to get this vibration number accepted by their competitors in Great Britain. The high pitch remains only where there are large concert organs not yet lowered, and with the military and brass bands.

The consideration of temperature as affecting the use of a standard pitch was not attended to when the French Government issued its ordonnance. The 15° Centigrade attached to the description of the standard fork in Paris was intended for the definition and verification of the fork only. The alteration of the fork due to heat is scarcely perceptible, but wind instruments, and particularly the organ, rise almost proportionately to the increase in temperature of the surrounding air, because sound travels at an enhanced rate as the temperature rises. The coefficient of this rise is equivalent to half a vibration (0·5) per degree Fahr. per second. Mr D. J. Blaikley (*Essay on Musical Pitch*, Catalogue of the Royal Military Exhibition, Chelsea, 1890) and Mr Victor Mahillon (*Catalogue descriptif et analytique du Musée*, Bruxelles, troisième volume, appendice, 1900) have recorded their experience of wind instruments under changes of temperature. The French Commission, in establishing the Diapason Normal, should have chosen a temperature of 20° C. There would then have been less disturbance owing to the breath of the players and heat of the theatres or concert rooms. It would be a great advantage to get this higher grade generally adopted. It was proposed in the Stimm-Conferenz at Vienna in 1885, but not carried. Table III., showing orchestral pitches obtained in 1899, for the measurements of which the writer is responsible, prove how chimerical it is to hope for greater accuracy than is found between 435 and 440 vibrations a second for a^1, inasmuch as temperature must always be reckoned with.

Table I.

1495 to 1690. Pitch descending.	Authority.	V. at 59° F.
Halberstadt organ . . . 1495	Ellis	a^1 505·8
Arnold Schlick, Heidelberg 1511	Ellis	502·6
St Jacobi, Hamburg . . 1688–93	Schmahl	489·2
St Catharinen, Hamburg . 1543	Degenhardt . . .	480·8

Verified by A. J. Hipkins. But for Leipzig a comparison with the Gewandhaus Band may be sought. (A. J. H.)

Pitesci, or PITESTI, a small town in Rumania (Wallachia), situated on the right bank of the river Arges, and capital of the district of the same name. The branch railway to Curtea d'Arges leaves the main line at this point. Population (1900), 15,570.

Pithiviers, chief town of arrondissement, department of Loiret, 26 miles north-east of Orleans, on the railway to Malesherbes. The church of St Solomon is partly of the 12th century, and there are some remains of the ancient ramparts. Statues have been erected of the mathematician Poisson (*d.* 1840), and of the physician and agriculturist Duhamel de Monceau (1700–82), who introduced into his park at Monceau several hundred species of trees and shrubs previously unknown in France. The town is an important centre for saffron, the cultivation of which, originally introduced by the Jews of Avignon, was fostered by Louis XIV. Lark pies and almond cakes are noted comestibles. The shrine of St Solomon in the 9th, and that of St Gregory, an Armenian bishop, in the 10th century formed the nuclei of the town; and the donjon built at the end of the 10th century for Héloïse, lady of Pithiviers, from the design of Lanfroy, was one of the finest of the period. Population (1881), 4745; (1891), 5115; (1901), 6225.

Pitlochry, a village of Perthshire, Scotland, in the midst of charming Highland scenery, at the south end of the Pass of Killiecrankie and on the banks of the Tummel, 7½ miles south of Blair Athole and 28½ north-north-west by rail from Perth. It is a favourite summer resort and excursion centre for the Scottish Highlands. Amongst its immediate attractions may be mentioned the Loch and Falls of Tummel, Killiecrankie Pass, and a couple of hydropathics. The village is well sheltered, although standing 300 feet above sea-level. Population (1901), 1541.

Pitman, Sir Isaac (1813–1897), English phonographer, was born at Trowbridge, Wiltshire, 4th January 1813, and educated at the local grammar school. He started in life as a clerk in a cloth factory, a business with which his father also was connected; but in 1831 it was decided that he should become a schoolmaster, and for this purpose he was sent for training to the Normal College of the British and Foreign School Society in London. Between 1832 and 1839 he held masterships at Barton-on-Humber and Wotton-under-Edge, and from 1839 to 1843 he conducted a private school of his own at Bath. In 1829 he took up Taylor's system of shorthand, and from that time he became an enthusiast in developing the art of phonography. A detailed account of his own system (which he first expounded in 1837) is given under the article SHORTHAND (*Ency. Brit.* xxi. 838 *et seq.*). Pitman devoted himself to perfecting phonography and propagating its use, and established at Bath a Phonetic Institute and a *Phonetic Journal* for his purpose; he printed in shorthand a number of standard works, and his new book on phonography (1st ed., 1840) went through many editions. He was also an enthusiastic spelling reformer, and adopted a phonetic system which he tried to bring into general use. He was twice married, his first wife dying in 1857, and his second, whom he married in 1861, surviving him. In 1894 he was knighted, and on 22nd January 1897 he died at Bath. Sir Isaac Pitman's memory will live as the popularizer of shorthand at a time when the advance of the newspaper press and modern business methods were making it a matter of great commercial importance. His system adapted itself readily to the needs of journalism, and its use revolutionized the work of reporting. He was a non-smoker, a vegetarian, and a great advocate of temperance principles.

Pitt-Rivers, Augustus Henry Lane-Fox (1827–1900), English soldier and archæologist, son of W. A. Lane-Fox, was born 14th April 1827. It was not till 1880 that he assumed the name of Pitt-Rivers, on inheriting the Dorsetshire and Wiltshire estates of his great-uncle, the second Lord Rivers. Educated at Sandhurst, he received a commission in the Grenadier Guards in 1845, being captain 1850, lieut.-colonel 1857, colonel 1867, major-general 1877, and lieut.-general 1882. He served in the Crimean War, and was at the Alma and the siege of Sebastopol. His talent for experimental research was utilized in investigation into improvements of the army rifle, and he was largely responsible for starting the Hythe School of Musketry. It is not, however, for his military career, but for his work as an anthropologist and archæologist, that General Pitt-Rivers will be remembered. His interest in the evolution of the rifle early extended itself to other weapons and instruments in the history of man, and he became a collector of articles illustrating the development of human invention. His collection became famous, and, after being exhibited in 1874–75 at the Bethnal Green Museum, was presented in 1883 to the University of Oxford. When, in 1880, General Pitt-Rivers obtained possession of his great-uncle's estates—practically untouched by the excavator since they had been the battleground of the West Saxons, the Romans, the Britons—he devoted himself to exploring the rich field of research which they offered. His excavations round Rushmore discovered a mine of materials of the utmost interest and value; he founded a local museum to exhibit the results, and published several illustrated volumes recording them. As a scientific archæologist he was recognized as taking rank among the first. Oxford gave him the degree of D.C.L. in 1886; he was president of the Anthropological Institute, and F.R.S. He married, in 1853, Alice Margaret, daughter of the second Lord Stanley of Alderley, and had a numerous family; his second daughter became, in 1884, the wife of Sir John Lubbock (Lord Avebury). General Pitt-Rivers died at Rushmore, 4th May 1900.

Pittsburg, a city of Crawford county, Kansas, U.S.A., at the intersection of five trunk lines of railway, at an altitude of 934 feet. It has a level site and a regular plan, and is divided into four wards. It is in the lead and zinc region of south-eastern Kansas and south-western Missouri, and contains zinc smelting works. Population (1880), 624; (1890), 6697; (1900), 10,112, of whom 860 were foreign-born and 365 negroes.

Pittsburg.—Pittsburg, the second city in Pennsylvania and chief iron and steel manufacturing centre in the United States, situated at the junction of the Allegheny and Monongahela rivers, where they unite to form the Ohio river. The closing decades of the 19th century brought exceptional municipal and industrial growth. In 1880 the population within the city limits was 156,389, in 1890 it was 238,617, and in 1900 it was 321,616. The largest growth during the last decade of the century was in the manufacturing and residential suburbs outside the city limits. The total population for the entire industrial community of city and suburbs, estimated in 1885 at 325,000, was 450,000 in 1890, and in 1900 was estimated at 650,000. For several years the city enjoyed in natural gas a smokeless and extraordinarily cheap fuel. About 1890 the supply began to be inadequate to the demand, and the price rose to a level which confined its main use to household purposes, and manufacturers returned to the coal of western Pennsylvania. The cheques passing through the clearing-house in 1883 aggregated $497,653,962. In 1901 they aggregated $2,047,605,967, or more than four times as much. In the same period the production of iron and steel in the city and its neighbourhood increased sixfold. In 1901 there were 34 blast furnaces, producing 3,690,011 tons of pig iron, and (1899) 63 rolling mills and steel works, producing 4,134,917 tons of finished iron and steel. Of the entire production of the United States, the Pittsburg district in 1899 produced 24 per cent. of the pig iron, 34 per cent. of the Bessemer steel, 50 per cent. of the open-hearth steel, and 64 per cent. of the structural iron. Not only have existing works, such as the Carnegie Steel Company, the Westinghouse works, expanded until they are the largest in their respective lines in the world, but districts previously rural, such as Ford City, East Pittsburg, Glassport, Charleroi, and Davis Island City, have become manufacturing towns, so that the manufacturing district of Pittsburg has been extended 25 to 30 miles up the Allegheny and Monongahela, and 10 miles down the Ohio. Within this manufacturing district in 1900 there were 3300 manufacturing establishments of all kinds, employing 250,000 men, and having aggregate assets of $2,000,000,000. The total freight tonnage of the district for 1899 was 58,656,697, of which

5,683,120 tons were shipped by river. In 1901 Pittsburg received a new charter under the state law for the government of second-class cities. The government consists of two branches of councils, and a Recorder as executive, directing departments of public works, public safety, and public charities. Under it about $30,000,000 have been expended for city improvements of all kinds. Prior to 1890 Pittsburg had no parks, but it now contains Schenley Park, of 422 acres, the greater part of which was the gift of Mrs Mary E. Schenley; Highland Park, of 366 acres; and seven smaller parks aggregating 132 acres; and over a million dollars has been authorized for further park acquisitions. The County Court House of Allegheny county, which was completed in 1888, and cost about $2,500,000, is a splendid structure in the Romanesque style, designed by H. H. Richardson. Another very prominent municipal building is the Carnegie Institute, at the Schenley Park entrance, founded by Andrew Carnegie in 1894, and combining within one building a free library —which has branches throughout the city—an art gallery, a music hall, and a museum. On this foundation Andrew Carnegie has expended nearly $8,000,000, while his similar gifts to the suburban municipalities amount to $2,000,000 more. Schenley Park also contains a fine conservatory, the gift of Henry Phipps; and Highland Park contains zoological buildings, the gift of C. L. Magee. The total assessed valuation of real and personal property in the city in 1900 was $352,582,792; the net debt was $19,600,569. The income for the fiscal year, not including loans of $7,137,410, was $9,251,065; and the total expenditures, not including loans repaid, were $10,838,360. The amount of cash on hand at the end of the fiscal year was $7,449,751. Of the total population in 1900, 84,878 were foreign-born and 17,040 were negroes. Out of 96,563 adult males, 7933 were illiterate (unable to write), of whom 6419 were foreign-born and 1116 were negroes. The death-rate in 1890 was 20·1; in 1900 it was 20. (See Allegheny.)

Pittsfield, a city of Massachusetts, U.S.A., capital of Berkshire county, on the Housatonic river, at an altitude of 1013 feet. It has a large area, 43 square miles, situated mainly in the broad, level valley between the Hoosac and Taconic mountains. The densely-built portion is regularly laid out, has a water supply derived from Lake Ashley by gravity, and is divided into seven wards. It is on the main line of the Boston and Albany Railway, and on a branch of the New York, New Haven, and Hartford Railroad. The city has extensive manufactures of cotton and woollen goods, boots and shoes, and paper. Population (1890), 17,281; (1895), 20,461; (1900), 21,766, of whom 4344 were foreign-born and 277 negroes.

Pittston, a city of Luzerne county, Pennsylvania, U.S.A., on the north branch of the Susquehanna river, near the mouth of the Lackawanna, at an altitude of 571 feet. Its site is uneven, the street plan is irregular, and it is divided into eleven wards. It is on five railways, the Central of New Jersey, the Delaware and Hudson, the Delaware, Lackawanna, and Western, the Erie and Wyoming Valley, and the Lehigh Valley. It is in the anthracite coal region, and has a large coal traffic. Its manufactures are varied. Formerly a borough, it received a city charter in 1894. Population (1890), 10,302; (1900), 12,556, of whom 3394 were foreign-born.

Piura, the most northerly department of Peru; area, 13,931 square miles. Population (1896), 213,000. The principal towns of the department are Tumbez (3000), the most northerly port of Peru; Paita (5000), the port of Piura; and Piura, capital of the department (12,000)—all in provinces of the same names; Catacaos, in the province of Ayabaca; Sechura (8500); and Sullana (7000), in Huancabamba. In the eastern mountain district are the towns of Morropon (5000), Tambo Grande (8000), and Chulucanas (6000).

Pizzo, a seaport town of the province of Catanzaro, Calabria, Italy, 72 miles north-east of Reggio on the west coast railway from Naples, and 27 miles south-west of Catanzaro, on a steep cliff overlooking the Gulf of Santa Eufemia. It has an old castle, in which Joachim Murat, ex-king of Naples, was shot on 13th October 1815. The people engage in tunny- and coral-fishing, and carry on an active coasting trade. In 1897 the port was cleared by 350 vessels of 65,542 tons. In 1783 the town was almost destroyed by an earthquake. Population (1899), about 8500.

Plague.—The exhaustive article by Dr J. F. Payne in the ninth edition of this work brings the history of plague down to about 1880. Since then much has happened to enlarge our knowledge of the disease from every point of view. The most striking feature of the previous history, summarized by Dr Payne, is the gradual retrocession of plague from the West, after a series of exceedingly destructive outbreaks extending over several centuries, and its eventual disappearance from Europe. It appears to have come to a sudden end in one country after another, and to have been seen there no more. Those lying most to the west were the first to be freed from its presence, namely, England, Portugal, and Spain. From all these it finally disappeared about 1680, at the close of a period of pandemic prevalence. Northern and central Europe became free about 1714, and the south of France in 1722. The last outbreak in northern Russia occurred in 1770. After this, plague only appeared in the south-east of Europe, where in turn it gradually died away during the first half of the 19th century. In 1841 its long reign on this continent came to an end with an isolated outbreak in Turkey. From that time until quite recently it has been extinct, except in the East. The province of Astrakhan, where a very small and limited outbreak occurred in 1878, is politically in Europe, but geographically it belongs rather to Asia. And even in the East plague was confined to more or less clearly localized epidemics; it showed no power of pandemic diffusion. In short, if we regard the history of this disease as a whole, it appears to have lost such power from the time of the Great Plague of London in 1665, which was part of a pandemic wave, until the present day. There was not merely a gradual withdrawal Eastwards lasting nearly two hundred years, but the outbreaks which occurred during that period, violent as some of them were, showed a constantly diminishing power of diffusion and an increasing tendency to localization. The sudden reversal of that long process is therefore a very remarkable occurrence. Emerging from the remote endemic centres to which it had retreated, plague has once more taken its place among the zymotic diseases with which Western communities have to reckon, and that which has for more than a century been little more than a name and a tradition has become the familiar object of investigation, carried on with all the ardour and all the resources of modern science. In what follows an attempt will be made to summarize the facts and indicate the conclusions to be drawn from recent experience.

Diffusion.—At the outset it is characteristic of this subtle disorder that the present pandemic diffusion cannot be traced with certainty to a definite time or place of origin. Herein it differs notably from other exotic diseases liable to similar diffusion. For instance, the last visitation of cholera could be traced clearly and definitely to a point of origin in northern India in the spring of 1892, and could be followed thence step by step in its march Westwards. (See CHOLERA.) Similarly, though not with equal precision, the last wave of influenza was shown to have started from central Asia in the spring of 1889, to have travelled through Europe from east to west, to have been carried thence across the sea to America and the Antipodes, until it eventually invaded every inhabited part of the globe. (See INFLUENZA.) In both cases no doubt remains that the all-important means of dissemination is human intercourse. The movements of plague cannot be followed in the same way. With regard to origin, several endemic centres are now recognized in Asia and Africa, namely, (1) the district of Assyr in Arabia, on the eastern shore of the Red Sea; (2) parts of Mesopotamia and Persia; (3) the district of Garwhal and Kumaon in the North-West Provinces of India; (4) Yunnan in China; (5) East and Central Africa. All these are mentioned by Dr Payne, with the exception of the last, which was recently discovered by Dr Koch. It includes the district of Kisiba in German East Africa, and extends into Uganda. In applying the term "endemic centres" to these localities, no very precise meaning can be attached to the word. They are for the most part so remote, and the information about them so scanty, that our knowledge is largely guesswork. What we mean is that there is evidence to show that under various names a disease identical with plague has been more or less continuously prevalent for a number of years, but how long and how continuously is not known. Whether any of them are permanent homes of plague the evidence does not enable us to say. They seem, at any rate, to have harboured it since its disappearance from Europe, and probably further investigation would disclose a still wider prevalence. For instance, there are good reasons for believing that the island of Réunion has been subject, since 1840 or thereabouts, to outbreaks under the name of "lymphangite infectieuse," an elegant euphemism characteristically French. In all the countries named, plague appears to behave very much as it used to do in Europe from the time of the Black Death onwards. That is to say, there are periods of quiescence, with epidemic outbreaks which attract notice at irregular intervals. Taking up the story at the point where Dr Payne leaves off, we get the following list of countries in which plague is known to have been present in each year (Local Government Board's Reports, 1898–99–1900):—1880, Mesopotamia; 1881, Mesopotamia, Persia, and China; 1882, Persia and China; 1883, China; 1884, China and India (as *mahamari*); 1885, Persia; 1886, 1887, 1888, India (as *mahamari*); 1889, Arabia, Persia, and China; 1890, Arabia, Persia, and China; 1891, Arabia, China, and India (as *mahamari*); 1892, Mesopotamia, Persia, China, Russia (in central Asia); 1893, Arabia, China, Russia, and India (as *mahamari*); 1894, Arabia, China, and India (as *mahamari*); 1895, Arabia and China; 1896, Arabia, Asia Minor, China, Japan, Russia, and India (Bombay); 1897, Arabia, China, Japan, India, Russia, and East Africa; 1898, Arabia, Persia, China, Japan, Russia, East Africa, Madagascar, and Vienna; 1899, Arabia, Persia, China, Japan, Mesopotamia, East Africa, West Africa, Philippine Islands, Straits Settlements, Madagascar, Mauritius, Réunion, Egypt, European Russia, Portugal, Sandwich Islands, New Caledonia, Paraguay, Argentine, Brazil: 1900, to the foregoing should be added Turkey, Australia, California, Mexico, and Glasgow; and in 1901, South Africa.

This list is probably by no means exhaustive, but it sufficiently indicates in a summary fashion the extent of that wave of diffusion which set in during the closing years of the 19th century and is still in progress. It did not fully gather way till 1896, when plague appeared in Bombay, but our modern knowledge of the disease dates from 1894, when it attacked Hong Kong and first presented itself to accurate observation. From this point a more detailed account may be given. Plague was recognized at Hong Kong in May 1894, and there can be little doubt that it was imported from Canton, where a violent outbreak—said to have caused 100,000 deaths—was in progress a few months earlier, being part of an extensive wave of infection which is believed to have come originally out of the province of Yunnan, one of the recognized endemic centres, and to have invaded a large number of places in that part of China, including Pakhoi and other seaports. Hong Kong was severely affected, and has never since been entirely free from plague. In two intermediate years—1895 and 1897—very few cases were recorded, but more recently the epidemic has gathered force again. The following table gives the cases and deaths in each of the six years 1894–99:—

Year.	Cases.	Deaths.	Case Mortality.
1894	2833	2550	90 per cent.
1895	45	36	80 ,,
1896	1204	1078	89 ,,
1897	21	18	85 ,,
1898	1320	1175	89 ,,
1899	1486	1415	95 ,,
Total . .	6909	6272	90·7 per cent.

The excessively high rate of mortality is probably due in part to under-statement of the number of cases. Concealment is practised by the Chinese, who are chiefly attacked, and it is easier to conceal sickness than death. Plague appears to have been equally persistent and destructive on the mainland in southern China during the period indicated, but no accurate details are available. In 1897 the Portuguese settlements of Lappa and Macao were invaded. In addition to the provinces of Yunnan, Kwang-si, and Kwang-tung in southern China, plague is reported to have been present for several years in a district in Mongolia to the north of Peking, and distant about "twelve days' ride." More recently several localities in Mongolia and Manchuria have been affected. Formosa was attacked in 1896, and has suffered considerably in subsequent years; in 1899 the Japanese Government officially reported 2633 cases, with 1974 deaths. Japan itself has had a certain amount of imported plague, but not on a large scale. Speaking generally, the disease has persisted and spread in the Far East since 1894, but precise information is lacking, except with regard to Hong Kong.

In 1896 plague appeared in the city of Bombay. It was certainly present in August, but was not recognized until 23rd September, and the diagnosis was not bacteriologically confirmed until 13th October. This fact should be remembered when failure to recognize the disease on its first appearance occurs elsewhere. The origin of the Bombay invasion is shrouded in obscurity. It is not even known when or in what part of the city it began (Condon, *The Bombay Plague*). Several theories have been put forward, but it seems useless to discuss conjectures as to matters of fact in the absence of evidence. Importation by sea from China is the theory which has met with most acceptance. The native form of plague, known as *mahamari*, is confined to the southern slopes of the Himalaya. It is described by Dr Payne, whose account of plague in India begins with the epidemic of

1812–21, and may here be supplemented by some earlier references unearthed by the *Bombay Gazetteer* (vol. iv.). Ibn Batesta notices two destructive pestilences in the 14th century, and Ferishta one in 1443, which he calls *ta'un*, and describes as very unusual in India. At the end of the 16th century there was a pestilence following a prolonged famine, and in the 17th century two violent epidemics are recorded under the names *ta'un* and *wába*. In the second of these, which occurred in the Ahmedabad district of the Bombay Presidency in 1683–89, buboes are distinctly described. In the 18th century several pestilences are recorded without description. It is at least probable from these notes that even before the undoubted outbreak, which began in Cutch in 1812, India was no stranger to epidemic plague. To return to Bombay and 1896: the infection spread gradually and slowly at first, but during the first three months of 1897 not only was the town of Bombay severely affected, but district after district in the presidency was attacked, notably Poona, Karachi, Cutch Mandvi, Bhiwandi, and Daman. The number of cases and deaths reported in the presidency, exclusive of the city, in each year down to the end of 1899, was as follows:—

Year.	Cases.	Deaths.	Case Mortality.
1896	367	273	74·3 per cent.
1897	49,125	36,797	74·7 ,,
1898	90,506	68,061	75·2 ,,
1899	131,794	101,485	77·0 ,,
Total . .	271,792	206,616	75·8 per cent.

The corresponding figures for Bombay city are:—

Year.	Cases.	Deaths.	Case Mortality.
1896	2,530	1,801	71·1 per cent.
1897	11,963	10,232	85·7 ,,
1898	19,863	18,160	91·2 ,,
1899	19,484	15,830	81·3 ,,
Total . .	53,840	46,023	85·4 per cent.

The total for the presidency, including the city, in four years was 325,632 cases with 252,549 deaths in a population of 26,960,421 (census of 1891). The population of the city is 821,764, but during the earlier plague period large numbers fled, so that the foregoing figures do not give the true plague incidence according to population. Moreover, concealment was extensively practised, and there can be little doubt that the number of victims was really much greater than the official returns indicate. The most striking fact brought out by the tables given above is the large and steady increase year by year in the presidency, in spite of all efforts to arrest the spread of infection. It has gone on since 1899, and it has not been confined to Bombay, but has extended over the whole of India. In 1897 it had already penetrated to Rajputana, the Punjab, the North West Provinces, and the Central Provinces. In the following year Bengal, Madras, Haidarabad, and Mysore were invaded. Not all these provinces suffered alike, but on the whole plague steadily strengthened its hold on India generally, and hardly relaxed it in any part. The most noteworthy details available are as follow:—Calcutta, mortality, 192 in 1898, 2745 in 1899, 7449 in first half of 1900; Patna district, mortality in first half of 1900, 17,674; Punjab, mortality in 1898, 2049; Madras Presidency, mortality August 1898 to June 1900, 2892; Haidarabad, mortality in 1899, 4242; Mysore, mortality 1898–99, 15,597.

Out of China and India plague has caused no great mortality in any of the countries, enumerated above, in which it has appeared, with the exception perhaps of Arabia, about which very little is known. But some of the outbreaks are interesting for other reasons, and require notice. The first case is the singular occurrence of three deaths at Vienna in October 1898, undoubtedly occasioned by a laboratory accident. The earliest victim was an attendant named Barisch, employed in the pathological laboratory of the Vienna General Hospital, and told off to look after the animals and bacteriological apparatus devoted to the investigation of plague, cultures of which had been brought from India by the medical commissioners sent by the Royal Academy of Science in 1897. Barisch was drunk and out all night on 8th October; on 14th October he fell ill. Plague was suspected, but Dr Müller, who attended the man and had studied the disease in India, would not admit the diagnosis on clinical grounds, nor was it bacteriologically established until 19th October. Barisch died on 18th October. On the 20th one of the nurses, and on the 21st Dr Müller, fell ill. Both died of pneumonic plague, from which also Barisch had undoubtedly suffered. A second nurse and a sister of mercy had feverish attacks, but no further case occurred. Barisch was shown to have been careless in the performance of his duties, and to have disregarded instructions; and the inference is that he conveyed the infection to his mouth, and so to the lungs, from the bacteriological specimens or inoculated animals. The melancholy incident illustrates several points of interest: (1) the correctness of the bacterial theory of causation, and the identity of the *bacillus pestis* as the cause; (2) the infectious character of the pneumonic type of disease; (3) its high fatality; (4) the difficulty of diagnosis. The next occurrence of special interest is the appearance of plague in Portugal in 1899, after an absence of more than 200 years. Its origin is shrouded in obscurity. Oporto, the seat of the outbreak, had no connexion by sea with any place known to be infected, and all attempts to trace introduction ended in speculation or assumption. The most probable theory was that soldiers returning home from infected Portuguese possessions in the East brought it with them, but this does not explain the selection of Oporto and the escape of other places. The earliest cases, according to retrospective inquiry, occurred in June 1899; suspicions were aroused in July, but the diagnosis was not established until August. It was contended by some medical men that the disease had really been present long before; but this view was supported by no better evidence than the opinion held in the same quarters, but quite untenable, that it was not plague at all. The conclusion reached, after careful investigation by Dr Jorge, the medical officer of health, that the commencement really dated from June, is confirmed by the fact that about that time the riverside labourers, who were first affected, began to notice an illness among themselves sufficiently novel to attract their attention and that of an English shipowner, who from their description suspected plague. Through him the suspicion was conveyed to the *Medical Times and Gazette*, in which the suggestion of plague at Oporto was made before any public mention of it in the town itself. The outbreak never assumed large proportions. It gained ground by degrees until October, after which it declined, and eventually ceased in February 1900. No recrudescence has been officially announced. The number of cases recorded in a population of 150,000 was 310, with 114 deaths, representing a case mortality of 36·7 per cent. They were widely scattered about the town and outlying suburbs; but no further extension occurred, except some isolated cases at Braga, a town 35 miles distant, and one at Lisbon, in the person of the distinguished bacteriologist, Professor Camara Pestana, who contracted the disease in making a *post-mortem* at Oporto, and died in Lisbon. The only other appearance of plague in Europe in 1899 was on the Volga. Three places were affected, namely, Kolobovka and Krasnoyarsk, in the province of Astrakhan, and Samara, higher up the river. All three outbreaks were small and limited, and no further extension took place. A commission appointed by the Russian Government pronounced the disease to be undoubtedly plague, and it appears to have been very fatal. The origin was not ascertained.

The most interesting extensions of plague in 1900 were those in Australia and Glasgow. The following towns were affected in Australia:—Sydney, in New South Wales; Adelaide, in South Australia; Melbourne, in Victoria; Brisbane, Rockhampton, Townsville, Cairns, and Ipswich, in Queensland; Fremantle, Perth, and Coolgardie, in West Australia. In none of these, with the exception of Sydney, did plague obtain a serious hold. The total number of cases reported in Queensland was only 123, with 53 deaths. In Sydney there were 303 cases, with 103 deaths, a case mortality of 34 per cent. The infection is supposed to have been brought from Noumea, in New Caledonia, where it was present at the end of 1899; and the medical authorities believe that the first case, which occurred on 19th January, was recognized. The outbreak, which hardly reached epidemic proportions, lasted about six months. That in Glasgow was on a still smaller scale. It began, so far as could be ascertained, in August 1900, and during the two months it lasted there were 34 cases and 15 deaths. Once more the disease was not at first recognized, and its origin could not be traced. In 1901 plague invaded South Africa, and obtained a distinct footing both at Cape Town and Port Elizabeth. The total number of cases down to July was 760, with 362 deaths; the number of Europeans attacked was 196, with 68 deaths, the rest being natives, Malays, Indians, Chinese, and negroes. With regard to Great Britain, a few ship-borne cases have been dealt with at different ports from time to time since 1896, but except at Glasgow the disease has nowhere obtained a footing on land.

Causation.—Plague is a specific infectious fever, caused by the *bacillus pestis*, which was identified in 1894 by Kitasato, and subsequently, but independently, by Yersin. An account of the organism will be found under the heading of PATHOLOGY (*Parasitic Diseases*). It is found in the buboes in ordinary cases, in the blood in the so-called "septicæmic" cases, and in the sputum of pneumonic cases. It may also be present in the urine. *Post mortem* it is found in great abundance in the spleen and liver. Nothing is known of its natural history outside the body, but on cultivation it is apt to undergo numerous involution forms. Its presence in a patient is regarded as positive diagnostic proof of plague; but failure to find or to identify it does not possess an equal negative value, and should not be too readily accepted, for many instances are recorded in which expert observers have only succeeded in demonstrating its presence after repeated attempts. It is clear, from the extreme variations in the severity of the illness, that the resisting power of individuals varies greatly. According to the Plague Research Committee of Bombay, the predisposing causes are "those leading to a lower state of vitality," of which insufficient food is probably the most important. There is no evidence that age, sex, or race exercises a distinct predisposing influence. The largest incidence in Bombay was on young adults; but then they are more numerous and more exposed to infection, because they go about more, than the younger and the older. Similarly, the comparative immunity of Europeans in the East may be explained by their different conditions of life. It is doubtful whether the distinction drawn between *pestis minor* and *pestis major* (see Dr Payne's article) has a real ætiological basis. Very mild cases occurring in the course of an outbreak of typical plague may be explained by greater power of resistance in individuals, but the epidemic prevalence of a mild illness preceding the appearance of undoubted plague suggests some difference or modification of the exciting cause. "It is impossible," writes Sir Richard Thorne (Local Government Board Report, 1898–99), "to read the medical history of this disease in almost every part of the world without being impressed with the frequency with which recognized plague has been preceded by ailments of such slight severity, involving some bubonic enlargement of glands and some rise in body-temperature, as to mask the real nature of the malady." Considering the great importance of arresting the spread of infection at the outset, and the implicit reliance placed upon bacteriological criteria, the ætiology of such antecedent ailments deserves more attention than has hitherto been paid to it. Of course plague does not stand alone in this respect. Epidemic outbreaks of other diseases—for instance, cholera, diphtheria, and typhoid fever—are often preceded and followed by the prevalence of mild illness of an allied type; and the true significance of this fact is one of the most important problems in epidemiology. In plague, however, it is of special importance, on account of the peculiarly insidious manner in which this disease fastens itself upon a locality.

The path by which the bacillus enters the body has not been satisfactorily determined. In pneumonic cases it is presumed to enter by the air-passages, and in bubonic cases by the skin, through some abrasion or crack. The Bombay Plague Research Committee, whose experience is unequalled, say: "In a number of instances points of inoculation were found on the extremities of patients, from which plague cultures were obtained, and in these cases buboes were found above the point of inoculation. In the majority of instances, however, no local indication could be found marking the point at which the microbe was implanted." From the fact that bacilli are hardly ever found in the blood of bubonic cases, it may be inferred that they are arrested by the lymphatic glands next above the seat of inoculation, and that the fight—which is the illness—takes place largely in the bubo; in non-bubonic cases they are not so arrested, and the fight takes place in the general circulatory system, or in the lungs. As might be expected from these considerations, the bubonic type is very little infectious, while pneumonic cases are highly so, the patients no doubt charging the surrounding atmosphere by coughing. Whether infection can be introduced through the digestive tract by infected food is doubtful. The bacillus is non-resistant and easily killed by heat and germicide substances, particularly acids. Little is known of its toxic action; only a weak toxin has been obtained from cultures. Of the lower animals, mice, rats, guinea-pigs, rabbits, squirrels, and monkeys are susceptible to the bacillus; horses, cattle, sheep, goats, pigs, dogs, and cats are more or less resistant, but cats and dogs have been known to die of plague (Oporto, Daman, Cutch, and Poona). In the Great Plague of London they were believed to carry the infection, and were killed in vast numbers. The bacillus has been demonstrated in the bodies of fleas, flies, bugs, and ants.

Clinical Characters.—One of the results of recent observation is the classification of plague cases under three heads, which have already been mentioned several times: (1) bubonic, (2) pneumonic, (3) septicæmic. (The word "pesti-cæmic" is also used instead of "septicæmic," and though etymologically objectionable, it is otherwise better, as "septicæmic" already has a specific and quite different meaning.) It should be understood that this classification is a clinical one, and that the second and third varieties are just as much plague as the first. It is necessary to say this, because a misleading use of the word "bubonic" has given rise to the erroneous idea that true plague is necessarily bubonic, and that non-bubonic types are a different disease altogether. The word "plague"—or "pest," which is the name used in other languages—had originally a general meaning, and may have required qualifications when applied to this particular fever; but it has now become a specific label, and the prefix "bubonic" should be dropped. The illness varies within the widest limits, and exhibits all gradations of severity, from a mere indisposition, which may pass almost unnoticed, to an extreme violence, only equalled by the most violent forms of cholera. The mild cases are always bubonic; the other varieties are invariably severe, and almost always fatal. Incubation is generally from four to six days, but it has been observed as short as thirty-six hours and as long as ten days (Bombay Research Committee). Incubation, however, is so difficult a thing to determine that it is unwise to lay down any positive limit. As a rule the onset is sudden and well marked. The symptoms may be described under the headings given above. (1) Bubonic cases constitute fully three-fourths of the whole, and the symptoms may therefore be called typical. In a well-marked case there is usually an initial rigor—in children convulsions—followed by a rise of temperature, with vomiting, headache, giddiness, intolerance to light; pain in epigastrium, back, and limbs; sleeplessness, apathy, or delirium. The headache is described as splitting; delirium is of the busy type, like delirium tremens. The temperature varies greatly; it is not usually high on the first day—from 101° to 103°—and may even be normal, but sometimes it rises rapidly to 104° or 105° or even 107° F.; a fall of two or three degrees on the second or third day has frequently been observed. The eyes are red and injected; the tongue is somewhat swollen, and at first covered with a thin white fur, except at the tip and edges, but later it is dry, and the fur yellow or brownish. Prostration is marked. Constipation is the rule at first, but diarrhœa may be present, and is a bad sign. A characteristic symptom in severe cases is that the patient appears dazed and stupid, is thick in speech, and staggers. The condition has often been mistaken for intoxication. There is nothing, however, in all these symptoms positively distinctive of plague, unless it is already prevalent. The really pathognomonic sign is the appearance of buboes or inflamed glands, which happens early in the illness, usually on the second day; sometimes they are present from the outset, sometimes they cannot be detected before the third day, or even later. The commonest seat is the groin, and next to that the axilla; the cervical, submaxillary, and femoral glands are less frequently affected. Sometimes the buboes are multiple and on both sides, but more commonly they are unilateral. The pain is described as lancinating. If left, they usually suppurate and open outwards by sloughing of the skin, but they may subside spontaneously, or remain hard and indurated. Petechiæ occur over buboes or on the abdomen, but they are not very common, except in fatal cases, when they appear shortly before death. Boils and carbuncles are rare. (2) Pneumonic plague was observed and described in many of the old epidemics, and particularly by two medical men, Dr Gilder and Dr Whyte, in the outbreak in Kathiawar in 1816; but its precise significance was first recognized by Childe in Bombay. He demonstrated the presence of the bacilli in the sputa, and showed that the inflammation in the lungs was set up by primary plague infection. The pneumonia is usually lobular, the onset marked by rigors, with difficult and hurried breathing, cough, and expectoration. The prostration is great and the course of the illness rapid. The breathing becomes very hurried—forty to sixty respirations in the minute—and the face dusky. The expectoration soon becomes watery and profuse, with little whitish specks, which contain great quantities of bacilli. The temperature is high and irregular. The physical signs are those of broncho-pneumonia; œdema of the lungs soon supervenes, and death occurs in three or four days. (3) In septicæmic cases the symptoms are those of the bubonic type, but more severe and without buboes. Prostration and cerebral symptoms are particularly marked; the temperature rises rapidly and very high. The patient may die comatose within twenty-four hours, but more commonly death occurs on the second or third day. Recovery is very rare.

There is no reason for doubting that the disease described above is identical with the European plagues of the 14th and subsequent centuries. It does not differ from them in its clinical features more than epidemics of other diseases are apt to vary at different times, or more than can be accounted for by difference of handling. The swellings and discolorations of the skin which play so large a part in old descriptions would probably be equally striking now but for the surgical treatment of buboes. Similarly, the comparatively small destructiveness of modern plague, even in India, may be explained by the improved sanitary conditions and energetic measures dictated by modern knowledge. The case mortality still remains exceedingly high. The lowest recorded is 34 per cent. in Sydney, and the highest 95 per cent. at Hong Kong in 1899. During the first few weeks in Bombay it was calculated by Dr Viegas to be as high as 99 per cent. It is very much higher among Orientals than among Europeans. In the Bombay hospitals it was about 70 per cent. among the former, and between 30 and 40 per cent. among the latter, which was much the same as in Oporto, Sydney, and Cape Town. It appears, therefore, that plague is less fatal to Europeans than cholera. The average duration of fatal cases is five or six days; in the House of Correction at Byculla, where the exact period could be well observed, it was five and a half days. Patients who survive the tenth or twelfth day have a good chance of recovery. Convalescence is usually prolonged. Second attacks are rare, but have been known to occur.

Diagnosis.—When plague is prevalent in a locality, the diagnosis is easy in fairly well-marked cases of the bubonic type, but less so in the other varieties. When it is not prevalent the diagnosis is never easy, and in pneumonic and septicæmic cases it is impossible without bacteriological assistance. The earliest cases have hardly ever been even suspected at the time in any outbreak in a fresh locality. As the doctor who was called to the first cases in Glasgow said afterwards, "It never occurred to me that I was dealing with plague." It very seldom does occur to medical men in similar circumstances, and not infrequently they continue to believe the disease is something else after full proof of its nature has been furnished. This will show the difficulty of diagnosis when plague is a novelty. In these circumstances it may be taken at first for almost any fever, particularly typhoid, or for venereal disease or lymphangitis. In plague countries the diseases with which it is most liable to be confounded are malaria, relapsing fever, and typhus, or broncho-pneumonia in pneumonic cases.

Treatment.—The treatment of plague is still symptomatic. The points requiring most attention are the cerebral symptoms—headache, sleeplessness, delirium, &c.—and the state of the heart. Alcohol and cardiac stimulants may be required to prevent heart failure. Speaking generally, it is important to preserve strength and guard against collapse. Buboes should be treated on ordinary surgical principles. An antitoxic serum has been prepared from horses by the Institut Pasteur in France, but has not met with success. The results in India obtained by British and various foreign observers were uniformly unfavourable, and the verdict of the Research Committee (1900) was that the serum had "failed to influence favourably the mortality among those attacked." Success was somewhat noisily claimed for an improved method tried in Oporto, but the evidence is of little or no value. Of 142 cases treated, 21 died; while of 72 cases not treated, 46 died; but the former were all hospital patients, and included several convalescents and many cases of extreme mildness, whereas the non-serum cases were treated at home or not at all, some being only discovered when death had made further concealment impossible. Moreover, it is not known how many non-serum cases there really were to furnish the 46 deaths; 72 was the number notified, but an unknown number was concealed, which might entirely alter the proportions. Some light is thrown upon these curious statistics by the singular fact that the mortality was nearly twice as great among those serum cases which had the advantage of the treatment from the beginning, as it was among those treated at a later stage of their illness and therefore under less favourable conditions. There were 7 deaths in 31 full-serum cases, and only 14 deaths in 111 part-serum cases. The only possible conclusion is either that the serum had an injurious effect, or that the statistics are valueless. Another serum, prepared by Lustig and Galeotti, has not been successful.

Morbid Anatomy.—(1) Bubonic cases. A bubo is found to consist of a chain of enlarged glands, surrounded by a mass of engorged connective tissue, coagulated blood, and serum. Nearly all the lymphatic glands in the body are a little swollen, but the lymphatic vessels show little or no change. The spleen and liver are always enlarged, the former sometimes to twice or thrice its natural size. The lungs are engorged and œdematous, and often show hæmorrhages. The kidneys are enlarged and congested. The serous membranes show petechiæ and hæmorrhages. The right side of the heart is frequently dilated, with clots in the cavities. The heart muscle is normal, or soft and friable. The substance of the brain, spinal cord, and nerve trunks is normal, but the membranes are engorged. (2) Pneumonic cases. The lymphatic glands are hardly affected. There is general engorgement and œdema of the lungs, with pneumonic patches varying in size and irregularly distributed. (3) Septicæmic cases. Nearly all the lymphatic glands in the body are involved, and have a characteristic appearance. They are enlarged to the size of an almond, rounded, firm, and pink; there is some engorgement and œdema on section; the substance is rather soft, and can be scraped off with a knife. The surrounding tissue is not engorged or œdematous. The description of the other organs given under (1) applies also to (2) and (3).

Dissemination.—Given the bacillus, the questions arise, How is it disseminated? and What are the conditions that favour its propagation? Only a very imperfect answer can be given. The perpetual failure to trace introduction, even with approximate precision, shows how obscure and secret the movements of this poison are. Perhaps it is unscientific to assume introduction as a matter of course in all cases, but its appearance in places where it has been unknown for centuries, and in others where it has never been known at all, combined with the fact that seaports are the points of attack, is sufficient evidence to justify the assumption in general. That it is conveyed from person to person is an undoubted fact, proved by innumerable cases, and tacitly implied by the word "infectious," which is universally allowed. The sick are a source of danger and one means of dissemination, and, since the illness may be so slight as to pass unrecognized, an obviously insidious one. The ambulatory plague patient goes far to explain the spread of the disease without leaving any track. But there is evidence that persons may carry the infection and give it to others without being ill at all themselves. One such case occurred at Glasgow, and another at Oporto. In the Glasgow case the wife of a laundryman employed in handling plague linen contracted the disease. She was brought into connexion with it in no other way, and there can be no doubt that she took it from her husband, though he was not ill at all himself. The Oporto instance is still more conclusive. Two little girls had plague at Argoncilhe, a suburb some miles from Oporto, and were the only cases which occurred in that place. Their father was a riverside labourer, who lodged during the week in Oporto, but went home for Sunday. He was not ill, but several cases of plague occurred in the house in which he lodged. How the poison passes from one person to another is less clear. In pneumonic cases patients no doubt spread it around them by coughing, and others may take it up through the air-passages or the skin; but even then the range of infection is small, and such cases are comparatively rare. In the vast majority of cases the bacilli are in the lymphatic or the circulatory system, and aërial convection, even for a short distance, seems highly improbable. This view is borne out by the experience in hospitals and with "contacts," which goes to show that with reasonable care and under fair conditions the risk of infection from ordinary plague patients is very small. When persons live crowded together in close contact, and when they are careless with regard to discharges of all kinds from patients, the risk is obviously much increased. Discharges—vomited matters, sputa, urine, and fæces—are probably the media by which plague is chiefly spread from person to person. They also contaminate clothing, which thus becomes another means of dissemination capable of acting at a distance. This is the most probable explanation of the two cases of indirect infection related above. Failure to catch or induce plague from clothing that has been worn by plague patients proves nothing. Such clothing is not necessarily infectious; indeed, the probability is that it is not, unless contaminated by discharges. There is no evidence that merchandise and foodstuffs are means of dissemination, and a great deal of evidence against such a theory, but suspicion has sometimes fallen on bakers' shops. Then we come to the lower animals. Attention has been concentrated on rats, and some observers seem disposed to lay upon them the whole blame for the propagation and spread of plague, which is held to be essentially a rat-borne disease. This hypothesis is in advance of the evidence, and not consistent with some of the facts. The susceptibility of rats has been noted from remote times and in many countries, particularly in China, but it has never attracted so much attention as during the recent prevalence of plague. From one place after another a great mortality among rats was reported, and the broad fact that they do die of plague is incontestable. It is therefore easily intelligible that they may play an important part in multiplying and fixing the poison on a locality. How they convey it to man is less clear, for they seldom come in contact with human beings. They may conceivably infect articles of food, but the weight of the evidence is all against the conveyance of plague by ingestion. Fleas have been suggested; and that again is possible, for it has been shown that rat fleas will bite man, but it can hardly happen often enough to account for the incidence of plague. Equally doubtful is the part played by them in disseminating the disease to a distance. Mortality among rats is said to precede the appearance of human plague, but the evidence of this is always retrospective and of a very loose character. The proof that rats migrate in large numbers to great distances is still more unsatisfactory. We are told that "armies of rats" were seen migrating on sundry occasions; but we are not told who saw them, or what an "army of rats" is. Such rhetorical language condemns itself. The strongest evidence in favour of rat-borne plague yet produced is the experience at Sydney, where a careful investigation was made. The conclusion reached by Dr Tidswell is that "there was no ground for even a suspicion that our epidemic was being maintained by any process of direct contagion between man and man," but that rats were the carriers. This seems to prove too much. The inference is that infected rats are more dangerous to human beings than infected persons, although the latter manufacture the poison on a much larger scale and come into far closer contact. In Glasgow the experience was just the contrary. Personal connexion was traced in every case, and rats excluded; there was no mortality among them, and of 300 caught and examined none had plague (Chalmers). Similarly, at Oporto personal connexion was traced in all the earlier cases; there was no mortality among rats, and no evidence to connect them with the outbreak (Jorge). Again, a comparison between rat-infested and rat-free districts in Bombay showed a much higher incidence of plague in the latter. A campaign against rats in Bombay, by which 50,000 or 60,000 were killed in a short time, had no effect in checking the disease. Plague-rats have rarely been found in ships sailing from infected ports; and though millions of these animals must have been carried backwards and forwards from quay to quay between Hong Kong, Bombay, and the great European ports, they have not brought the disease ashore. The evidence, therefore, is conflicting on the subject. Perhaps a fair conclusion is that rats are one of the means of disseminating plague; but it can exist without them, and be spread by other agencies. According to the official history of plague in India (Nathan), rats are "certainly not so common a cause of infection as the sick person and his surroundings." Very little light has been thrown on the conditions which favour the prevalence of plague. We do not know why it has developed a diffusive activity of late years, nor why it has attacked some places and consistently passed by others, such as Singapore. The words "dirt" and "insanitary conditions" are much used, but such general terms explain nothing. Singapore, where plague has several times been introduced, but never taken hold, is probably quite as dirty and insanitary as Hong Kong, and it is pertinently remarked by the Bombay Research Committee that filth *per se* has but little influence, inasmuch as "there occurred in the House of Correction at Byculla, where cleanliness is brought as near to perfection as is attainable, an outbreak which exceeded in severity that in any of the filthy *chawls* and tenements around." Again, in Oporto there is an area which combines every possible sanitary defect—dense overcrowding, great poverty, no light, no air, no drainage, no scavenging, water brought in buckets. Plague got into this quarter, but did not spread there; on the other hand, it appeared in other and vastly superior parts of the town. Yet in at least one case neither the patient nor the "contacts" were removed, but were all shut up in one room with a sentry at the door and another in the street. The seasonal variations have been well marked and extremely regular in Bombay. The disease begins to be active in late autumn or the commencement of winter, and reaches its height in February or March, dying down in the summer. Mr Baldwin Latham has made an elaborate examination of the meteorological conditions, and more particularly of the vapour tension, from which he draws the conclusion that the seasonal variations are due to exhalation from the ground. His observations are original and worth attention. A simpler explanation is that the people live more indoors, and are so more exposed to infection during the plague season. The curve shows two rises, one at the beginning of winter, and the other at the commencement of the monsoon, and at both these times the people are driven indoors. A broad survey of the epidemiological facts suggests some general conclusions. The outbreaks fall into two well-defined groups: (1) those in which the disease is destructive and persistent, (2) those in which its effects are slight and transient. In the former the poison clearly fastens on the locality, and gradually increases its hold. The place is infected, not merely the people in it; for if they evacuate it, the disease soon ceases among them, and if they return in a short time, they are again attacked. Now the poison is contained, as we have already seen, in the discharges from patients, and in such infected localities the standing conditions and the habits of the people combine to retain the discharges on the premises. The floors, mostly of mud covered with dung, are fouled with spittle, vomit, and urine, and, being seldom or never cleaned out, foster a gradual accumulation of poison, to which infected rats and the concealment of illness contribute. These are just the conditions which prevailed in Europe in the old plague days. They do not prevail now in those "white countries" which have been invaded but have repelled the attack with comparative ease and little loss. It may be concluded, with some confidence, from experience and theory alike, that localities where they do not prevail may fail to keep plague out, but have very little to fear from it, except the disturbance of trade caused by the traditional terrors that still cling to the name.

Prevention.—The principles are the same as those which govern the prevention of other infectious diseases. "Sanitary cordons" and the like are obsolete. International procedure is supposed to be regulated by the Venice Convention of 1897, but that instrument has never been ratified, and it contains an optional clause, which allows countries to do as they please with their own frontiers. Except Great Britain and Germany, they all retain quarantine in a more or less stringent form at seaports. It is generally used as a system of local extortion imposed upon travellers and shipping. According to the Venice Convention, ships are divided into (1) healthy, (2) suspected, (3) infected. (1) Healthy are those free from plague throughout the voyage; (2) suspected, those in which plague has occurred, but no fresh case within twelve days; (3) infected, those in which plague has occurred within twelve days. Great Britain relies on medical inspection, removal of sick or suspected cases, and supervision of the healthy arriving on an infected ship; infected clothing is burnt and infected ships disinfected. The procedure is the same as for cholera, and it has been equally successful. Ships passing through the Suez Canal are subject to similar inspection; sick persons are landed at Moses Wells, and suspected ones detained. The risk of importing plague from India has been materially lessened by medical inspection of outward-bound ships at the principal ports. This has been very thoroughly carried out at Bombay with good results. In 1897 pilgrimages from India to the Hedjaz were prohibited. By the Venice Convention a number of articles of merchandise are classed as susceptible and liable to be refused admission, but the only ones which there is any reason to consider dangerous are used clothing and rags. A watch should be kept on rats at ports of arrival and on board ships from infected countries.

When plague is present in a place, the measures to be taken are the usual ones for dealing with infectious disease, with some additions. The sick and suspected should be removed in special ambulances to an isolation hospital, their soiled linen, &c., should be burnt, and the premises disinfected. Corrosive sublimate in an acid solution is the best disinfectant, but sulphuric acid, 1 in 250, is efficient and cheaper. Suspected cases should be bestowed in a special isolated building until the diagnosis is fully determined. "Contacts" should be kept under observation. Rats should be exterminated as far as possible. The greatest care should be taken in dealing with the hospital linen and discharges from patients. Hospital staffs should be kept apart. Inoculation with Haffkine's prophylactic fluid should be offered to all persons willing to avail themselves of it. It is especially desirable for hospital and ambulance staffs to be inoculated. This drug is prepared from sterilized cultures of plague bacillus. Inoculation is harmless, and the results obtained in India justify a favourable opinion of its protective efficacy. At Hubli, where nearly the whole population was inoculated between 11th May and 27th September 1898, the mean mortality among the inoculated was 1·3 per cent.; among the uninoculated 13·2 per cent. At Daman the mortality was—inoculated 1·6 per cent., uninoculated 24·6 per cent.; at Dharwar—inoculated 1·2 per cent., uninoculated 5·2 per cent. In all these cases the numbers dealt with were large and the test fair. For further statistics and details the reader is referred to *The Bombay Plague*, by Captain Condon (official, 1900). Inoculation protects against attack, and greatly modifies the illness when it fails to protect. How long the protection lasts has not been determined, but it appears to be several months at least. Evacuation of streets and whole villages has been adopted in India with marked success, but in Western countries so drastic a measure is hardly feasible and not likely to be required.

Recent experience goes to show that plague is an exceedingly difficult disease to keep out altogether, but a very easy one to control under fairly good local conditions, and even under bad ones provided that it is not allowed to implant itself firmly in a locality. When that happens, it is most difficult to eradicate or confine. Vigilance, therefore, on the part of medical men, and promptness on the part of the administrative authorities, are of the utmost importance. Backed by them, the foregoing measures may be relied upon with perfect confidence to dispose of plague quickly and effectually. Without them it is likely, in a favourable soil, to defy all measures.

Plainfield, a city of Union county, New Jersey, U.S.A., 24 miles from New York, of which it is in great measure a residential suburb, and with which it is connected by the Central of New Jersey Railroad. It is regularly and beautifully laid out on a level site commanded by hills on the north-west and south-east, is divided into four wards, and has all municipal improvements. Population (1890), 11,267; (1895), 13,629; (1900), 15,369, of whom 2733 were foreign-born and 1450 negroes.

Planarians.—In reviewing the work done by naturalists on this group of animals since the publication in 1885 of the article on them in the earlier volumes (ninth) edition of this Encyclopædia, it will be necessary not only to notice the discovery of new forms and the progress towards a fuller anatomical knowledge of the different phases of life, but also to inquire how far later investigation of this class (Turbellaria) has contributed to a solution of the pressing modern problems of comparative physiology. Lastly, the views which are held as to the affinities of the group will be discussed.

Anatomical Discovery.—Although there has been a steady stream of publications dealing with the descriptions of new forms of Polyclads, Triclads, and Rhabdocœls, the advance in taxonomic and morphological knowledge has been most marked in the case of two groups, the "Turbellaria Acœla" and the "Land Planarians." In the former the advance is a morphological one. Comparatively little is known of the specific variety of the Acœla, and no doubt there still exists a wealth of undescribed forms, as is shown by the discovery of such peculiar genera as *Polychœrus* (Mark, *Festschrift f. Leuckart*, p. 298), and the pelagic *Haplodiscus.* At present about a dozen species of Acœla are adequately known, and they have furnished the material for a monograph by von Graff (*Turbellaria Acœla*, Leipzig, 1891) which has shed a new light on many vexed questions, such as the nature of the "digestive parenchyma," the nervous system, and the relations of the Acœla to other Turbellaria.

Von Graff has shown that the parenchyma assumes a simple, an intermediate, and a complex grade of structure. The simple parenchyma is seen in *Monoporus.* It consists of a nucleated vacuolated syncytium, and contains active amœbocytes, which are probably the chief agents in digesting the food and in supplying it to the surrounding tissues. In *Amphicœrus* the walls of the vacuoles assume a firmer consistency and give more stability to the parenchyma, while in *Convoluta paradoxa* the syncytium is divisible into a central finely granular protoplasm and a peripheral cellular parenchyma. The former is presumably the digestive tract, while the latter is skeleto-trophic in nature, and, in addition to many unspecialized cells, contains the symbiotic brown structures, which are apparently unicellular algæ. In fact, the absence of a gut is more apparent than real, and the anatomical study of known Acœla leads to the conclusion that from a common central syncytial mass those tracts have been developed to which in higher Turbellaria we give the names endodermal gut and mesodermal parenchyma. The embryological study of the Acœla has thrown no clear light on this subject (see Georgovitch, *Arch. Zool. Exp.* ser. iii. vol. vii. p. 343).

Another great advance in the morphology of this interesting group has been the discovery of the nervous system. This was first made in a convincing manner by Delage (*Arch. Zool. Exp.* ser. ii. vol. iv. p. 199) in 1886, and the details of the system are pretty fully described by von Graff in his monograph. The "brain" is always placed anteriorly, and is composed of two pairs of ganglia. One of these supplies the otocyst and other sensory structures, and gives off the outer pair of longitudinal nerve tracts which course down the margin of the body. The other pair of cerebral ganglia gives off an ad-median and a lateral pair of tracts, and these form a small meshed plexus in the body-wall.

The appendix to von Graff's work on the Accela contains Haberlandt's account of the nature of the green cells in *Convoluta roscoffensis.* This animal when just hatched contains no green cells, and it is said to die unless it comes into contact with a green unicellular alga (Georgovitch, *loc. cit.*). These algæ form a definite assimilating tissue, and the *Convolutæ* adopt a plant-life mode of life. The nature of the brown, yellow, and purple structures in many other (holozoic) Accela is at present unknown. A peculiarity of this group which still holds good is the entire absence of any excretory system of "flame-cells," and of canaliculi in connexion with them.

It is to von Graff, again, that we owe the magnificent work (*Monographie d. Turbellaria*, 1899), dealing with the Land Planarians in a monographic and elaborately illustrated manner, the outcome of twenty-five years' unwearied devotion to the subject. The sections dealing with the nervous system, sense-organs, and reproduction are perhaps the most noteworthy. But the chapter and tables of distribution have the greatest general interest, since they form the first attempt on a sufficiently large scale seriously to consider the distribution of Land Planarians and the manner in which it has come to pass. One of the most salient facts is the division of the family Geoplanidæ into two closely related sections. Of these, one, the more primitive, inhabits South America; the other, Australia and New Zealand. Another striking conclusion is the contrast between Japan and the rest of the Palæarctic regions, and the almost complete restriction of the family Bipaliidæ to Madagascar, Ceylon, and Indo-Malaya (including Celebes).

Physiology.—The most noteworthy advance in recent zoology has been the broadening of its aims. Zoological science is no longer content merely to describe the anatomical facts of a group, to discriminate its members, and to determine its distribution and development. Such a collection of facts forms the basis for further investigation into the nature and influence of the factors which determine the development—sexual and asexual—of the individual; into the influence of the environment, organic and inorganic, intrinsic and extrinsic, in modifying metabolism and reproduction; into comparative physiology and phylogeny. At present it must be admitted that although planarians are very promising subjects for research on these questions, they have not been utilized by workers on the first two problems. We must therefore inquire what light research has thrown upon the organs of Planarians considered as structures for carrying out the functions of life. What indications have we as to the manner in which, *e.g.*, the muscles, nerves, secretory organs—as we know them in their highly differentiated character in Arthropoda, Annelida, and Mollusca—have arisen from the simple and yet multi-functional corresponding tissues of the lower Invertebrates? The evidence of Planarians on this question may be expected to be especially valuable, since there is reason for believing that they form a basal group, intermediate in a physiological sense between the Cœlenterates (including Ctenophores) and the segmented Chætopoda.

As an indication of the intermediate character of Planarians, reference may be made to the nervous system. In Cœlenterates this is composed of stellate ganglion-cells specially developed in relation to the musculature, whether ecto- or endodermic. These cells give off processes which serve partly to connect them *inter se* and with the muscles and skin. But these processes are equivalent. There are no distinct nerve-fibres. In the ganglion-cells and their processes there is no known differentiation of neurofibrillæ (Apathy, *Mitt. Zool. Stat. Neap.* vol. xii. pt. iv., 1897). Even in Ctenophores the grade of structure remains as we find it in medusæ or sea-anemones—simply a diffused plexus. In Chætopods, on the other hand, the nervous system never exhibits anastomosing ganglion-cells. There is a marked distinction between the central and the peripheral parts. The ganglion-cells are largely confined to the central nervous system, and their processes are of two kinds: nerve-fibres which form the peripheral system, and branching outgrowths (neuropile) confined to the core of the brain or cord. Neurofibrillæ are found both in the body of the cell and in its processes. A neuropile is established which seems to be the real seat of reflex action, the ganglion-cells becoming centres of trophic actions. The question now is, Does the nervous system of Planarians show how the differentiation of these elements of the nervous system in the higher invertebrate has taken place from the Cœlenterate ganglionic plexus? To some extent it may be said to do so, although we are not sufficiently acquainted with the minute structure of the ganglion-cells of Planarians to be able to state the origin of neuropile and neurofibrillæ. The planarian nervous system possesses scattered ganglion-cells along the course of the chief paired tracts—dorsal, lateral, and ventral—and large multi- and bi-polar cells occur peripherally in relation to the muscles and sensory organs (Monti, *Boll. Sci. Ann. Pavia*, vol. xviii. No. 24, 1897). In Triclads and Polyclads the brain is little more than a thickening due to the fusion of these tracts at the anterior end and on the ventral surface. There is no clear separation between central and peripheral portions. The gradual formation of neuropilar centres is seen in its inception. What is perhaps still more significant of the undifferentiated condition of the nervous system is its mode of reparation. A freshwater Planaria can be divided into a few or a great number of small pieces, and each of these will regenerate the organs of the entire animal, apparently so long as a small group of ganglion-cells is included in the severed part (Morgan, *Arch. f. Entwicklung*, vol. vii. p. 364, 1898). But the growth of the new ganglion-cells, as of some of the other tissues, is not due to a multiplication of pre-existing differentiated cells, but to certain elements of the "parenchyma" which have remained at an embryonic phase, and which in the severed portion give rise to new ganglion-cells. In some forms of Planarians asexual reproduction in this way is a normal physiological process.

This marked absence of "division of labour" in the planarian economy, as contrasted with the more complex and efficient mechanism of higher Invertebrates, is manifested by the other tissues, and in none more clearly than in the endoderm. In the Accela the first indication of a separation and transference of the many functions of this tissue becomes apparent. But even in Triclads the gut still plays many parts. It digests, absorbs, and circulates the food. It is partially a respiratory organ. It contains excretory products either in the form of granules or in "flame-cells" embedded in its walls (Gunda). There is some evidence (which requires confirmation) that the endoderm furnishes the ovaries and testes. Viewed from such a physiological standpoint, the Planarians exhibit little advance on the Cœlenterates, except in the presence of ducts (often of great complexity) belonging to the reproductive organs.

Affinities.—There remains for discussion the chief problem with reference to this group that morphology sets itself to solve: What are the affinities of Planarians? To this question there are at present two separate and irreconcilable answers. It is universally conceded that Planarians form a natural and homogeneous subdivision of the phylum Platyelmia. This being allowed, attempts have been made to solve the problem of the origin of this phylum in different ways, which may for convenience be distinguished as (1) the Trochophore hypothesis, (2) the Gastræa hypothesis. The view that this phylum is a degenerate outcome of more highly organized, segmented Annelids is not here discussed.

The Trochophore hypothesis is the oldest and most widely supported of these, but in its latest and most detailed form it is due to Hatschek (*Lehrbuch d. Zoologie*, 1891). Hatschek emphasizes the occurrence of the trochophore larva in many Invertebrate phyla (for example, Mollusca, Chætopoda, Polyzoa, and Rotifera), and believes it to represent, not the larva of a common ancestor, but the common ancestor itself of all invertebrates above the Planarians, the Echinoderms alone excepted; and a modification of this—the pro-trochula—is, Hatschek holds, to be considered as the point of meeting of flat-worms and all higher invertebrates. If we go farther, and inquire what this pro-trochula may be and how it arose, Hatschek's reply would be that it is a hypothetical organism represented by the stage in the development of the trochophore before the formation of the anus. How it arose is not clear. Kleinenberg (*Zeitsch. f. wiss. Zool.* vol. xliv. p. 1, 1887) held that the Trochophore was a modified form of Medusa, while Hatschek compared it to a hypothetical Ctenophore in which the gonads and excretory vessels had become separated from the stomach. And he considered that the apical sensory plate, the mesenchymatous musculature and ectodermic stomodæum were comparable structures in both Trochophore and Ctenophore. Hatschek concludes that Ctenophores, Platyelmia, and other Invertebrates (except Echinoderms) have a common ancestor which resembled a Trochophore larva. The ingenuity of zoologists has devised several variants of the Trochophore hypothesis. The Ctenophore hypothesis of Lang (1884), which has been extended by Willey (1896), reaches much the same conclusion, though with differences of detail (see Bourne in Lankester's *Treatise on Zoology*, vol. ii., 1900). In both cases the Polyclad Turbellaria are assumed to be ancestral to the remaining Planarians; but from von Graff's work on the Acœla there appears to be strong grounds for doubting the validity of such an assumption. Both hypotheses are suggestive speculations, and will remain so until we have some principles of embryology by which their real value may be gauged.

The Gastræa hypothesis has been propounded by von Graff on the basis of his study of the Turbellaria Acœla. "I find," he says (*Turbellaria Acœla*, p. 51), "that the remarkable creature discovered by F. E. Schultze, and described by him as *Trichoplax adhærens*, represents a precursor of the Acœla leading straight to the Gastræadæ." *Trichoplax* has hitherto only been found in the marine aquarium at Graz. It is a flattened amœbiform animal from 1·5 to 3 mm. in greatest length. Dorsally it is covered with a squamous epithelium, ventrally with ciliated columnar cells. Beneath this epidermis is a thin layer of circular muscle fibre. The central part of the body is composed of a jelly, secreted by mesenchymatous cells, and contains both dorso-ventral muscle elements and peculiar refringent corpuscles. Fission is the only mode of reproduction as yet known. No nervous system nor otolith has been found. The Gastræadæ from which von Graff derives this *Trichoplax*, and through it the Acœla, is an obscure group of heterogeneous and problematical members, and there is much doubt as to its validity. The parasitic Dicyemids and Orthonectids form the greater part of it; some writers add *Haliphysema* and *Physemaria*, which others consider to be aberrant sponges. The only character which these Gastræadæ have in common is a central core of nucleated tissue covered with an outer ciliated one. They may, in fact, be compared to planulæ.

A more intelligible conclusion on the view that the Acœla are the basal group of Planarians would be to consider them, as Sedgwick has done (*Text-Book of Zoology*, p. 212, 1898), as "connecting forms between large Infusoria and the higher animals, in which the endodermal protoplasm, though without a continuous cavity, is partly differentiated into a number of important organs." It seems to the present writer that this conception of the intimate relation of the endoderm to the parenchyma, and especially to the reproductive and nephridial organs, is a very promising one, and capable of considerable extension. The separation of the parenchyma from the endoderm may take place early in development, in the form of mesoblast-cells capable of secreting vast masses of a gelatinous or semi-fluid matrix forming the soft parenchyma analogous to the mesoglœa of Cœlenterates; and just as in Anthozoa and Ctenophora the reproductive function and the function of excretion are largely the work of the endoderm cells, so in Turbellaria the endoderm appears to give rise to the gonads (in Polyclads, Triclads, and Rhabdocœls), and to excrete in the form of granules the greater part of the solid waste products, while the fluid ones are swept out by the nephridial canals. Yet even these canals are often closely related to the endoderm cells, and Lang has shown in *Gunda* that the flame-cells may lie in, and form part of, the endoderm. If we further consider the gradual differentiation of the parenchyma in the Acœla, the conclusion seems probable that the endoderm in Turbellaria has by no means lost, or lost connexion with, the functions of reproduction and excretion; and that while it performs its characteristic work of digestion, it is still closely associated with the sexual and uropoietic properties which we connect with it in Cœlenterates. From the fact that the parenchyma (and its contained organs) may remain in connexion with the endoderm throughout life (Acœla), or separate at a late period (larva of *Stylochus pilidium*) or early in development (many Polyclads), we should expect to find, on a more extended basis of observation, that this cell-layer exhibits in the Turbellaria that gradual differentiation into a number of different organs to which Mr Sedgwick has alluded. If that proves to be the case, the attempt by Hatschek (*loc. cit.*), followed by Lankester (*Treatise on Zoology*, vol. ii., 1900), to claim the so-called "generative sacs" of Planarians as "cœlomic" in nature, and to include the Platyelmia among the Cœlomata (Cœlomocœla), must be given up. There are at present no facts to support it; and what facts there are as to the origin of reproductive and nephridial tissues seem to show that there is actually no cœlom at all, but that if it be desired to force the Platyelmia into the "Cœlomata," the branches of the gut itself will have to be considered as a virtual cœlom. For this there is no more justification than in the case of many Cœlenterates.

Authorities.—The literature on Planarians is conveniently summarized in the article "Flat-Worms" (*Cambridge Natural History*. Macmillan. 1896); and in *A Treatise on Zoology* (edited by E. Ray Lankester, F.R.S. Black. 1901). Part iv., "Platyhelmia and Mesogoa."—To these lists the following important papers should be added:—Hesse (*Zeit. Wiss. Zool.* vol. lxii. 1897. "On the Eyes of Planarians").—Dorler (*Ibid.* vol. lxviii. 1900. "On Certain Parasitic Rhabdocœls").—And Loeb (*Comparative Physiology of the Brain*. Murray. 1901. "On the Nervous System and Response to Stimulation").

(F. W. Ga.)

Planquette, Robert (1850– ——), French musical composer, was born in Paris, 31st July 1850, and was educated at the Conservatoire. While little more than a boy he wrote numerous songs and operettas for café concerts, and sprang into fame as the composer of *Les Cloches de Corneville* (Paris, 1877; London, 1878). In this popular work he showed a fertile if somewhat commonplace vein of melody, which won instant recognition. There is besides in his music a touch of romantic feeling, which, had he cared to cultivate it, would have placed him far above contemporary writers of *opéra bouffe*. Unfortunately, he did little but repeat the formula which originally brought him reputation. *Le Chevalier Gaston*, his next work, was produced in 1879 with little success. In 1880 came *Les Voltigeurs du 32me*, which had a long run in London in 1887 as *The Old Guard*, and *La Cantinière*, which was translated into English as *Nectarine*, though never produced. In 1882 Planquette's *Rip van*

Winkle was produced in London, being subsequently given in Paris as *Rip*, in both cases with remarkable success. The libretto, an adaptation by H. B. Farnie of Washington Irving's famous tale, brought out what was best in Planquette's talent. In *Rip van Winkle* there is a note of tenderness and even of pathos such as is rarely heard in works of this kind. In 1884 the phenomenon of an opera by a French composer being produced in London previously to being heard in Paris was repeated in *Nell Gwynne.* In this work Planquette reached the highest point of his achievement. His score was carefully written, and some of the concerted music was excellent. It suffered from being allied to a libretto of more than ordinary inanity and inconsequence. *Nell Gwynne* was tolerably successful in London, though it failed completely when produced in Paris as *La Princesse Colombine. Nell Gwynne* was followed by *La Crémaillère* (Paris, 1885), *Surcouf* (Paris, 1887; London, as *Paul Jones*, 1889), and *Captain Thérèse* (London, 1887). A change in popular taste banished French *opéra bouffe* from the London stage during the last decade of the 19th century, its place being taken by so-called musical comedy of home manufacture, and none of Planquette's later works found their way across the Channel. The most successful of his more recent productions have been *La Cocarde Tricolore* (Paris, 1892), *Le Talisman* (Paris, 1892), *Panurge* (Paris, 1895), and *Mam'zelle Quat'sous* (Paris, 1897). Planquette is more gifted naturally than any writer of *opéra bouffe* of his time. His melodies are always fluent, and often original, but the workmanship of many of his operas suffers from the fact that he appears to aim at nothing but popularity of the most transient description.

Plasencia, a town of Spain, province of Caceres, on the right bank of the river Jerte. It has some trade in agricultural products and live stock, and the local industries are unimportant. It is still interesting on account of its churches and convents, and as the highroad to the monastery of Yuste (St Just), where Charles V. retired and died. Population (1877), 7090; (1897), 8351.

Plate River, or Rio de la Plata, a funnel-shaped estuary, on the east side of South America, extending west-north-west from the sea about 170 miles. Its extreme breadth at its mouth is 138 miles. It narrows quickly to 57 miles at Montevideo, and at its head, where it receives the united Paraná and Uruguay rivers, its width is about 25 miles. Its northern or Uruguayan shore is somewhat elevated and rocky, while the southern or Buenos Airean shore is very low, and much of it has a *tosca* rock cap which gently dips under the river-bed. The whole estuary is very shallow, and in no place above Montevideo exceeds 36 feet in depth when the river is low. The bottom generally consists of enormous banks of sand covered with from 10 to 20 feet of water, and there is a continuous and intricate channel, of about 22 feet depth only, to within 14 miles of the port of Buenos Aires. The remaining distance has a depth of 18 feet in the uncertain channel. At times, however, the river is so low that for three or four days together carts can drive out a distance of three miles or more from the shore. Azara says that "in 1795 the water fell so much in a calm day, that for three leagues out the shore was exposed, remaining so a whole day." The Plata is simply the estuarine receptacle of two mighty streams, the *Uruguay* and *Paraná*, which drain the Plata basin. This has an area of 1,198,000 square miles, or over two and one-half times that of the Pacific slope of the Andes, and comprises the most fertile, healthiest, and best part of Brazil, a large portion of the Argentine Republic, the whole of Paraguay and south-eastern Bolivia, and most of Uruguay.

The Uruguay and affluents.

The Uruguay river has a length of about 1000 miles. Many small streams from the western slope of the Brazilian Serra do Mar unite, in about 27° 45′ S., to form this river, which then, in imposing volume, flows west-north-westwards, serving as the boundary between the states of Santa Catharina and Rio Grande do Sul, as far as 52° W., near which it receives a considerable tributary from the north, called the *Pepiri-guazú.* Throughout this section it is enriched by many minor streams, mostly from the highlands which cross the state of Rio Grande do Sul. Between 27° 58′ and 33° 34′ S. three important tributaries join it from the east—the *Ipui-guazú*, the *Ibicui*, and the *Negro*, the last being its main affluent. A few unimportant streams enter it from the Argentine provinces of Misiones, Corrientes, and Entre Rios, the *Gualeguaychú* being the largest.

The Pepiri-guazú was one of the limits between the possessions of Portugal and Spain. Its lower course is about 250 feet wide, but higher up it narrows to about 30 feet, and runs with great violence between high wooded banks. It is navigable for canoes for about 70 miles above its mouth, as far as its first fall. The Rio Negro has a delta of several large islands at its confluence with the Uruguay. Its head-waters are in the southern part of Rio Grande do Sul, but the main river belongs entirely to the state of Uruguay, which it cuts midway in its course from north-east to south-west. *En route* it receives a great number of copious affluents and waters a most inviting region. Its lower reaches are navigable for craft of moderate draught.

Course of the Uruguay.

From the time the Uruguay leaves the coast range of Brazil, it runs for a long distance through a beautiful, open, hilly country, but afterwards enters a forest belt of high lands. At the river Pepiri-guazú it turns suddenly to the south-west, and continues this course to its junction with the Paraná and Plata. Near Fray Bentos, 61 miles before reaching the Plata, it forms a great lake, about 56 miles long and from 4 to 6 miles wide. At Punta Gorda, where it debouches into the Plata, it is only 1 mile to 1½ mile wide, but is 90 feet deep. From the Pepiri-guazú junction its banks are high and covered with forest as far down as 27° 30′ S., where the river is 2300 feet wide and from 10 to 40 feet deep. Thence its course is through a smooth and generally open, but occasionally broken, country; but along the lower 100 miles of its eastern side there are picturesque hills, from 100 to 500 feet high, divided by many rivulets, which fertilize rich valleys beyond, while the Entre Rios margin is low, monotonous, and wooded. The Uruguay is much obstructed by rocky barriers. Four miles below its confluence with the Pepiri-guazú it has a cataract, about 8 miles long, with a total fall of 26 feet at low water. The river near the Pepiri-guazú is 1550 feet wide, but about 1½ mile before reaching the cataract its width is reduced to 600 feet. Along the cataract it is closed in between high precipitous walls of black rock only 70 feet apart. Above Punta Gorda, 212 miles, is the Salto Grande, which has a length of 15 miles of rapids, the greatest single fall being 12 feet, and the difference of level for the entire length of the reefs 25 feet. These cross the river diagonally, and during floods all, excepting a length of 1½ mile of them, are submerged. Nine miles below the Salto Grande is the Salto Chico, which bars navigation during six months of the year, but in flood-time may be passed in craft drawing 5 feet of water. The Uruguay can be navigated at all seasons by vessels of 4½ feet draught as far up as the Salto Chico, and of 14 feet up to Paysandú for a greater part of the year. Fray Bentos may be reached all the year round by any vessel that can ascend the Paraná. Above the navigable lower river there is launch and canoe navigation for many hundreds of miles upon the main artery and its branches, between the rapids which are met with from time to time. The Uruguay has its annual floods, due to the rains in its upper basin. They commence at the end of July and continue to November, attaining their maximum during September and October. At the narrow places the river rises as high as 30 feet, but its average rise is 16 feet. It flows almost for its entire course over a rocky bed, generally of red sandstone, at times very coarse and then again of extremely fine composition. Except in floods, it is a clear-water stream, and even at its highest level carries comparatively little silt.

The Paraná and its affluents.

The Paraná (the "Mother of the Sea" in Guarani) drains a vast area of southern Brazil. It is formed by the union of the *Rio Grande* and *Paranáhyba*, and is about 1600 miles long from its extreme source in Goyaz to its junction with the Paraguay, and thence 600 more to the Plata estuary. Its average width for the latter length is from 1 to 3 miles. Its Rio Grande branch descends from the slope of the Serra da Mantiqueira, in the region where the orographic system of Brazil culminates near the peak of Itatiaia-assú, almost in sight of Rio de Janeiro. It is about 680 miles long, but only navigable in the stretches between the many reefs, falls, and rapids which interrupt its regular flow. Among its numerous affluents, the principal one is the *Rio das Mortes*, rising in the Serra Mantiqueira. It is 180 miles long, with two sections, of a total of 120 miles, which are navigable for launches. The main branch of the Paraná, the Paranáhyba, rises in about 15° 30′ S., on the southern slopes of the Pyreneos mountains, and receives numerous tributaries before its confluence with the Rio Grande, near which it is barred by two cataracts. It drains a little-known region of Goyaz and western Minas Geraes, lying upon the immediate southern watershed of Brazil.

Besides these rivers, the Paraná has many long and powerful affluents from the Brazilian states of São Paulo and Paraná; but its western ones, limited by the Serra Cayapó and the highlands which border north-eastern Paraguay, are not of equal importance. Most of them, although obstructed by rapids, are navigable for launches and canoes. Among the eastern tributaries are the *Tiété*, the *Paraná-panema*, formerly known as the Anemby, and the *Iguazú*.

The *Tiété*, over 700 miles long, rises in the Serra Paranápicaba and flows in a north-west direction. With the river Pardo, it was the favourite route of the "Sertanistas"—explorers and raiders of Matto Grosso—although its course is broken by fifty-four rapids, and the lower river by two falls, the Avanhandava, 44 feet drop, and the Itapurá, 65 feet.

The *Paraná-panema* is about 600 miles long, and rises in a ramification of the Serra Paranápicaba which overlooks the Atlantic Ocean. Its general course is north-west. From the south it receives many important tributaries, and from the north about a score of affluents, all of small volume. It is navigable for a distance of only about 30 miles above its mouth, and for its whole course it has so many obstructions that it is useless for commercial purposes.

The *Iguazú*, also called the Rio Grande de Curutiba, has its sources on the slopes of the Serra do Mar of Brazil, and flows nearly west, through thick forests, along the line of 26° S. Its navigation is difficult even for small craft, as it is full of reefs, rapids, and cataracts. Sixteen miles above its mouth is the magnificent Salto del Iguazú, sometimes called the Victoria Fall, round which canoes have to be transported 37 miles before quiet water is reached again. Its mouth is about 800 feet wide, and the depth in mid-river 40 feet. The volume of water which the Iguazú receives from its four principal branches and numberless small streams is large; and as the great river tumbles 197 feet over the Iguazú fall into a wild gorge, the scene is of imposing grandeur. The width of the falls, measured along their crest or edge, is 2½ miles; part of the river takes two leaps of about 100 feet each, but a portion of it plunges down the whole depth in unbroken mass.

Course of the Paraná.

The Paraná, at a point 28 miles above the mouth of the Tiété, is interrupted by the falls of Urubupunga, but below these it has unobstructed navigation for about 400 miles, as far down as the falls of Guaira, in 24° 3′ S., where the river forms a lake 4½ miles long and 2½ wide, preparatory to breaching the Serra de Mbaracayú, which there disputes its right of way. It has torn a deep gorge through the mountains for a length of about 2 miles, where it is divided into several channels, filled with rapids and cataracts. It finally gathers its waters into a single volume, to plunge with frightful velocity through a long cañon only about 200 feet wide. From these so-called falls of Guaira, or "Sete Quedas," as far as its confluence with the Paraguay river, the Paraná has carved a narrow bed through an immense cap of red sandstone, along which it sometimes flows with great rapidity, occasionally being interrupted by dangerous narrows and rapids, where the banks in some places close in to a width of 450 to 600 feet, although the average is from 1200 to 1600 feet. At the south-east angle of Paraguay the Paraná is prevented from continuing its natural southern course to the river Uruguay by the highlands which cross the Argentine province of Misiones, and connect those of Rio Grande do Sul with the Caa-guazú range of Paraguay. Here, therefore, it is turned westwards; but before escaping from its great sandstone bed, it is obstructed by several reefs, notably at the rapids of Apipé, which are the last before it joins the placid Paraguay, 130 miles farther on. From the Apipé rapids there is a vast triangular space at the south-western corner of Paraguay but little above sea-level, consisting of low, sandy ground and morasses, at times flooded by the Paraguay river. This district, united to the equally enormous area occupied by the Yberá lagoon and its surrounding morasses, in the northern part of the Argentine province of Corrientes, was probably the delta of the Paraná river when it emptied into the ancient Pampean Sea. The Paraná is charged with but little silt in comparison with its much smaller affluent, the Paraguay, although in flood it carries a volume of water estimated to be ten times that of the latter stream, and its width along the northern sandstone border of the province of Corrientes is from 3 to 9 miles.

The Paraguay.

The river PARAGUAY, the main affluent of the Paraná, rises in Matto Grosso, in the vicinity of the town of Diamantino, about 14° 24′ S. It flows south-westwards, as far as Villa Maria, along the foot of the high plateau which divides it from the Cuyabá river to the east, and then, turning southwards, soon reaches the morass expansion of Xarayas, which it traverses for about 100 miles. A few miles below Villa Maria it receives an affluent from the north-west, the Jaurá, which has its source nearly in contact with the head-waters of the Guaporé branch of the river *Madeira*. The *Cuyabá*, which is known as the São Lourenço for 90 miles above its confluence with the Paraguay, has its sources in 13° 45′ S., almost in touch with those of the Tapajos branch of the Amazon. The Cuyabá flows past them at a right angle, from north-east to south-west, for a distance of 150 miles, and is only separated from them by the plateau-ridge of Trombador, which in places is not 3 miles wide. As it flows onwards it is enlarged by a great number of minor streams, especially from the north-west, until it reaches the spur of the great sandstone plateau, at the south-eastern point of which the town of Cuyabá is situated; thence it enters the upper margin of the vast, swampy, and inundated region between the rivers Paraguay and São Lourenço. Just below the point where it takes this latter name it is 700 feet wide. Above the town of Cuyabá it is from 150 to 400 feet wide, and may be navigated up stream by canoes for 150 miles; but there are many rapids. The town may be reached from the Paraguay river, at low water, by craft drawing 18 inches. According to the observations of Clauss, Cuyabá is only 660 feet above sea-level. From the junction of the São Lourenço (or Cuyabá) with the river Paraguay, the latter, now a great stream, moves sluggishly southwards, spreading its waters, in the rainy season, for hundreds of miles to the right and left, as far south as 20°, turning vast swamps into great lakes—in fact, temporarily restoring the region, for thousands of square miles, to its ancient lacustrine condition.

Lagoons of upper Paraguay

On the west side of the upper Paraguay, between about 17° 30′ and 19° S., are several large, shallow *lagunas* or lakes which receive the drainage of the southern slopes of the Chiquitos sierras, but represent mainly the south-west overflow of the vast morass of Xarayas. The principal of these lakes, naming them from north to south, are the Oberaba, the Gaiba, Mandioré, and the "Bahia" de Casares. The Oberaba is the largest; its margins are completely inundated at high water, and the surrounding lands, as far as the eye can see, are tree-covered swamps and creeks choked with aquatic plants. The Gaiba is connected with the river Paraguay by a short *caño* or canal, said to offer 7 feet depth of water in the channel. The total length of the lake, which is in two unequal divisions, is 11 miles; its greatest width is 5 miles, and its maximum depth 12 feet—all at low water. It has long shelving shores which prevent access to its margins, except with craft of extremely light draught of water. The northern division of the lake belongs entirely to Brazil, but the southern division, about two-thirds of its area is bisected from north to south by the boundary-line between Brazil and Bolivia, according to the treaty of 1867. It is in great part surrounded by high ground and hills, but its southern coast is swampy and flooded during the rainy season. The west shore is historic. Here, in 1543, the *conquistador*, Martinez de Irala, founded the "Puerto de los Reyes," with the hope that it might become the port for Peru; and from Lake Gaiba several expeditions, in Spanish colonial days, penetrated 500 miles across the Chaco to the frontier of the empire of the Incas. At the Puerto de los Reyes Bolivia laid out a town in December 1900, in the forlorn hope that the "Port" may serve as an outlet for that commercially suffocated country, there being no other equally good accessible point for Bolivia on the Paraguay river. West of, and almost in contact with, the Gaiba is the smaller *laguna* Gaiba-Merim. A little to the south of the Gaiba is the shallow and useless Mandioré lake, and it is probably connected with it by a *caño* choked with weeds. Still farther south is the lake called the "Bahia" de Casares (Puerto Suarez), 19° S. It is too shallow to navigate, except by craft drawing less than 3 feet of water. "Bahia" Negra, 20° 10′ S., is an irregular flooded region forming a group of large connected lakes on the west side of the Paraguay river. They take the drainage of the river Otuquis, through the sandy district in which it is lost in its unsuccessful effort to reach the Paraguay. As an outlet for the country to the west and north of it the Bahia Negra is valueless.

Affluents of the Paraguay.

South of the São Lourenço, the first river of importance which enters the Paraguay from the east is the *Taquary*, about 19° S. It rises in the Serra Cayapó, on the southern extension of the Matto Grosso tableland. It is a river famous in the history of the slave-raiders from São Paulo in the 16th century. South of this stream, about 50 miles, a considerable river, the *Mondego*, with many branches, draining a great area of extreme southern Matto Grosso, also flows into the Paraguay; and still farther south, near 21°, is the *Apá* tributary, which forms the boundary between Paraguay and

Brazilian Matto Grosso. From northern to southern Paraguay the western drainage slope sends numerous short streams to swell the Paraguay. From the west it has but few and very short tributaries until the river *Pilcomayo* is reached, the country being too flat and the soil too sandy and thirsty to allow any large amount of water to flow to the great river.

The Pilcomayo.

The PILCOMAYO is of more importance from its length than from its volume. It rises among the Bolivian Andes north of Potosi and north-west of Sucre, races down the mountains to their base, crosses the Chaco plains, and pours into the river Paraguay near Asuncion. Nor does it receive any branch of importance until it reaches about 21° S., where it is joined from the south-west by the river *Pelaya*, upon which Tupiza, the most southerly city of Bolivia, is situated. The Pelaya rises upon the lofty inter-Andean plateau, and, taking an easterly course, saws its way across the inland Andean range, turns northwards and then eastwards to unite with the Pilcomayo, which it is said at least to equal in volume. Just below the junction is the fall of Guarapetendi, 23 feet high. From this point to the mouth of the Pilcomayo the distance in a straight line is 480 miles, although by the curves of the river, which is extremely tortuous, it is about double that distance. According to Storm, who quotes Captain Baldrich, the river bifurcates at 21° 51′ S., but again becomes a single stream at 23° 43′, the right channel being the greater in volume. It is probable that between 23° and 24° S. it throws east-south-eastwards three great arms to the river Paraguay, the upper portions of which have yet to be explored, but the lower parts have been examined for 100 to 200 miles up from the Paraguay. Enumerating from north to south, they are called the Esperanza, the Montelindo, and the Macá. From 180 to 200 miles above its mouth the Pilcomayo filters through a vast swamp about 100 miles in diameter, through which there is no principal channel. This swamp, or perhaps shallow lagoon, is probably partly drained by the river Confuso, which reaches the Paraguay between the Pilcomayo and Macá. A northern branch of the Pilcomayo, the Fontana, the junction being at 24° 56′ S., is probably also a drainage outlet of the same great swamp.

For the first 100 miles below the fall of Guarapetendi the Pilcomayo is from 600 to 1000 feet wide, but it so distributes its waters through its many bifurcations, and loses so much from infiltration and in swamps, and by evaporation from the numerous lagoons it forms on either side of its course, that its channel is greatly contracted before it reaches the Paraguay. It is possible that its Montelindo outlet may be the main river. From Sucre to the Andean margin of the Chaco, a distance of about 350 miles by the river, the fall is at least 8000 feet—a sufficient indication that its upper course is useless for purposes of navigation. The statements made by explorers regarding the Pilcomayo are very confused. This is probably due to the wandering propensities of the river and the immense areas of country it overflows in flood-time.

The missionaries in 1556 first reported the existence of the Pilcomayo, which for a long period of time was known as the Araguay. The first definite information regarding its course was given by the expedition of Armenta y Zaráte, which descended its valley by land for a considerable distance in 1672. In 1721 Patiño and Rodriguez partially explored it, and since then numerous attempts have been made to test its navigability, all of which have been failures; and several of them have ended in disaster and loss of life, so that the Pilcomayo now has a sinister reputation.

The Bermejo.

The BERMEJO river flows parallel to the Pilcomayo, and enters the Paraguay a few miles above the junction of this with the Paraná. Its numerous sources are on the eastern frontage of the inland Andes, between the Bolivian town of Tarija and the Argentine city of Jujuy. Its most northerly tributary is the San Lorenzo, which, after being augmented by several small streams, takes the name of *Rio de Tarija*. This, running east, is in turn swollen by several affluents, and then taking a general south-easterly course, joins the Bermejo in 22° 50′ S. at a point called the Juntas de San Antonio. Thence, flowing southwards, the Bermejo is enriched by many tributaries from the Andean gorges, and finally, in 23° 50′ S., receives its main affluent, the San Francisco, from the south-west. The latter has its source in about 22° 30′ S., and, under the name of Rio Grande runs directly southwards, in a deep, mountain valley, as far as Jujuy. It then turns eastwards for 50 miles, and is then joined by the Lavayen from the south-west. These two streams form the *San Francisco*, which from their junction runs north-eastwards to the Bermejo. The average width of the San Francisco is about 400 feet; it is seldom over 2 feet deep, and has many shoals and sandbanks. From its junction with the latter stream the Bermejo flows south-eastwards to the Paraguay, with an average width in its main channel of about 650 feet, although narrowing at times to 160 and even 100. In its course, however, it bifurcates and ramifies into many channels, forming enormous islands, and frequently leaves old beds for new ones. During floods it inundates immense areas of the flat Chaco country, filling vast lagoons and swamps on both sides of the river, which at such times becomes of indefinable width.

Since the exploration of the Bermejo by Patiño in 1721, it has often been examined from its sources to its mouth, with a view to ascertain its navigability. Captain Page in 1854 and 1859 found it impracticable to ascend it over 135 miles, in the dry season, with a little steamer drawing 23 inches of water; but in flood-time, in December 1871, he succeeded, in 60 days, in reaching a point 720 miles from its mouth, in the steamer *Alpha*, 53 feet long and 30 inches draught. He afterwards penetrated another 100 miles up stream. The round voyage took a year, owing to the swift currents, shoals, quicksands, snags, and fallen trees.

The Salado.

The SALADO, about 250 miles south-west of and approximately parallel to the Bermejo, is the only great tributary which the Paraná receives from the west below its confluence with the Paraguay. Its extreme head-waters are in the Argentine province of Salta, and they drain a much broken Andean region lying between 24° and 26° 30′ S. The most westerly sources are the rivers Santa Maria and Calchaqui, which unite near the town of San Carlos and form the river Guáchipas, which flows north-eastwards until it meets the Rio Arias, which has collected in a single artery various small affluents from the north and west. Having received the Arias, the Guáchipas runs north-eastwards about 50 miles, and then it changes its name to the Juramento, which is retained until the river reaches the Chaco plains at the base of the foot-hills of the Andes. Here it becomes the Salado, a name it preserves for the remainder of its course. It joins the Paraná near Santa Fé, in 31° 39′ S. and 60° 40′ W. From the time the Salado leaves the foot-hills it lazily rambles across the plains in a south-easterly course, now in a single channel, then dividing into several branches and forming long islands, and again overflowing to the right and left into great lagoons and swamps, sometimes to a width of 60 miles. In the dry season it is a narrow, tortuous stream, full of shoals and snags. At all times it carries an immense quantity of floating vegetation and trunks of trees, which constantly fall from its crumbling banks. Explorers of the river, inclusive of Captain Page in 1855, claim that its lower half is navigable, but the many efforts which have been made to utilize it as a commercial route have all resulted in failure. The Salado occupies the south-western side of a very level depression 300 miles across from south-west to north-east, and only 240 feet above the sea. Along the north-east side of this depression runs the Rio Bermejo.

As the Pilcomayo, the Bermejo, and the Salado wander about the country, ever in search of new channels, they erode and tear away great quantities of the Pampean material, dissolve it into silt, and pour it into the Paraguay and Paraná rivers. The engineer Pelleschi estimates that "the soil annually subtracted from the territory of the Chaco by the Bermejo alone equals 6,400,000 cubic yards."

South of the Salado, the rivers *Saladillo*, *Primero* and *Segundo*, provide the water for the evaporation from the great inland lake Porongos. The *Tercero* and *Quarto* streams unite and empty into the Paraná near Rosario, with a considerable volume of water. The *Quinto*, with other small rivers, draining the southern spurs of the Cordoba range, are absorbed by the thirsty Pampean morass La Amarga.

South-easterly course of Paraná.

South of its confluence with the river Paraguay, the Paraná washes the western foot of a series of sandstone bluffs for 30 miles. Thence for 240 miles the bordering hills are about 80 feet high, but at Goya the country is almost on a level with the river. Near the boundary-line between Corrientes and Entre Rios the banks are very low on both sides of the river, and continue so for nearly 100 miles; but farther down, for 150 miles, the left bank is margined, as far as Diamante, by a range of hills from 125 to 160 feet high, at times boldly escarped. At Diamante they trend inland, south-eastwards, for about 50 miles, and probably once bordered an ancient channel of the river. From 31° 30′ S. to the head of the Plata estuary the western bank of the Paraná is a precipitous bluff of reddish clay, varying from 25 to 75 feet above mean river level. It is being gradually undermined, and tumbles into the water in great blocks, adding to the immense volume of silt which the river carries. According to Ramon Lista, "the lowest level of the Paraná is in October and November, and, save an occasional freshet, it remains stationary until the beginning of summer, when its waters commence to rise, reaching their maximum about the middle of February in the lower part of their course." The difference between low and high river is generally about 12 feet, depending upon the varying quantity of rains in Brazil and the melting of the Andean snows. Below its junction with the Paraguay the Paraná has an average current of $2\frac{1}{2}$ miles an hour, and the river varies in width from 1 to 3 miles at low water; but in floods it seems almost a continuous lake, broadening to 10 and 30 miles and burying many of its numerous islands and marginal swamps under a vast sheet of water, and obliterating its many parallel lateral channels and intricate systems of connecting canals.

In the middle Paraná, from the mouth of the Iguazú to the mouth of the Paraguay river, there are many islands, some of them large, rocky, and high above the river. From Paraguay to the city of Rosario, islands are numerous, many of them of great area; and again below Rosario they soon increase in number and size until the Plata estuary is reached. In the lower Paraná they are mostly covered with dense and beautiful vegetation, sometimes mingled with the bright crimson foliage of the Seibo tree. In flood-time the upper portion of the trees being out of water, they have the appearance of floating forests. Then the river often makes wild work with its banks, and builds up or sweeps away entire islands, leaving deep channels instead. Mouchez in 1857, searching for two islands, the position of which he had fixed in the previous year, found in their place 25 and 32 feet of water. The lower delta of the Paraná does not share in these phenomena; its islands and main channels appear more fixed. This probably is due to the less elevation attained by the waters in flood-time, and the numerous branches which distribute them into the Plata estuary. This must have extended, in a very recent geological period, inland from its present head to at least 32° S.; but the enormous quantity of silt which the Paraná receives from its Paraguay affluent, and from the tributaries which reach it from the Andes, has filled this length of about 220 miles with these muddy islands, which rest upon a sandy bed of great depth.

Islands of Paraná.

The frontage of the Paraná delta is 40 miles across, almost in a straight line from north to south. Through this the river finds its way to the Plata by eleven outlets, large and small, the two principal ones being the Paraná-guazú and the Paraná de las Palmas. The frontage is a line of marked regularity, due probably to the current of the Uruguay river, which cuts across its face and carries the silt to the south-west until it meets the outflow of the Paraná de las Palmas, which sweeps it south-east along the Buenos Aires shore.

Paraná delta.

The mean flow of the Mississippi river at New Orleans is 675,000 cubic feet per second, and its flood maximum about 1,000,000 feet. The minimum of the Plata past Buenos Aires is 534,000, the maximum 2,145,000. It may therefore be fairly assumed that the yearly discharge of the great North American river is not superior, and may be inferior, to that of the Plata.

The Paraná is navigable at all times as far up as the São Lourenço river by craft drawing 3 feet of water, and to within a few miles of Asuncion, the capital of Paraguay, by vessels drawing 9 feet. The city of Paraná may always be reached with a draught of 12, and Rosario with 15, feet of water.

The commercial development of the Plata basin may be conveniently illustrated by statistics for the year 1822, which marks the beginning of independent rule in its republics; for 1854, when the steamboat and the railway first began to play a part in this quarter of the world; and in 1898 and 1899, as indicating approximately the state of affairs at the end of the 19th century. In Buenos Aires, for example, the foreign trade (entered and cleared) in 1822 aggregated 107,170 tons; in 1854, 342,463 tons; and in 1899, 5,046,847 tons. The coasting and river trade of the same port increased from 150,741 tons in 1854 to 3,695,088 tons in 1899. But, taking into account all the Argentine ports, except those which lie to the south of the Plata, there was for the six years ending with 1899 an annual average of 14,000,000 for the overseas commerce and 11,000,000 tons for the river and coasting trade. On the other, or northern, bank of the stream the chief port is Montevideo; and its foreign commerce increased from an aggregate of 50,000 in 1822 to 150,000 tons in 1854 and to 4,069,870 tons in 1898, the river and coasting trade having increased from 50,000 tons in 1822 to 150,000 tons in 1854 and to 3,915,421 tons in 1898. The total foreign trade of the Plata valley thus increased from over 157,000 tons in 1822 to nearly 18,100,000 tons in 1898–99. (G. E. C.)

Commerce.

Plattsburg, a village of New York, U.S.A., capital of Clinton county, on the west shore of Lake Champlain, at the mouth of the Saranac river, at an altitude of 120 feet. It is on the Delaware and Hudson railroad, and is the terminus of the Chateaugay railroad. Its site is level and its plan regular. Its manufacturing establishments include saw-mills, pulp-mills, foundries, and machine shops. Population (1890), 7010; (1900), 8434, of whom 1053 were foreign-born.

Plattsmouth, a city of Nebraska, U.S.A., capital of Cass county, at the junction of the Platte and the Missouri rivers, at an altitude of 968 feet. The city has an irregular plan, with good water supply and sewer systems. It is upon the Burlington and Missouri River and the Missouri Pacific railways, has a large trade in grain and cattle, and has the works of the Burlington and Missouri River railroad. Population (1880), 4175; (1890), 8392; (1900), 4964, of whom 979 were foreign-born.

Plauen, a town of Germany, on the Weisse Elster, 21 miles south-west of the town and in the circle of Zwickau, kingdom of Saxony; stations on the Leipzig–Hof, Reichenbach–Eger, and Gera–Weischlitz railways. The seat of a commercial and industrial chamber, Plauen has 3 churches, a Methodist chapel, a gymnasium, a builders', an industrial, a commercial school, and other schools, and a seminary for teachers. Its industries include cotton, carded woollen, paper, twisting, embroidery, and other mills, many dye and bleaching works, leather, piano, iron safe, and other factories. Population (1880), 35,082; (1890), 47,007; (1900), 73,891.

Playfair, Lyon, 1st Baron (1818–1898), was born at Chunar, Bengal province, on 21st May 1818. He was sent to Europe by his father at an early age, and received his first education at St Andrews. Subsequently he studied medicine at Glasgow and Edinburgh. A short visit to India (in 1837–38) was followed by his return to Europe to study chemistry, which had always attracted him. This he did at University College, London, and afterwards under Liebig at Giessen, where he took his doctor's degree. At Liebig's request, Playfair translated into English the former's work on the *Chemistry of Agriculture*, and represented Liebig at a meeting of the British Association at Glasgow. The outcome of his studies was his engagement in 1841 as chemical manager of the Primrose print works at Clitheroe, a post which he held for rather more than a year. In 1843 he was elected hon. professor of chemistry to the Royal Institution of Manchester, and soon afterwards was appointed a member of the Royal Commission on the Health of Towns, a body whose investigations may be said to have laid the foundations of modern sanitation. In 1846 he was appointed chemist to the Geological Survey, and thenceforward was constantly employed by the public departments in matters of sanitary and chemical inspection. He had previously been offered, and had accepted, a professorship of chemistry at Toronto; but the representations of his friends, who had interested Sir Robert Peel in his favour, induced him to withdraw his acceptance and rely on the certainty of a career in England. The opportunity of his life came with the 1851 Exhibition, of which he was one of the Special Commissioners. For his services in this connexion he was made C.B., and his work had the additional advantage of bringing him into close personal connexion with the Prince Consort, who appointed him Gentleman Usher in his household. He was selected to appoint the jurors for the Exhibition of 1862, and was one of the English commissioners at the Paris Exhibition of 1855, and again in 1878. From 1856 to 1869 he was professor of chemistry at Edinburgh University, numbering among his pupils the present King and the late Duke of Edinburgh. In 1868 he was elected to represent the Universities of Edinburgh and St Andrews in Parliament, and retained his seat till 1885, from which date until 1892 he sat as member for Leeds. In 1873 he was made Postmaster-General, and in the following year, after the dissolution of Parliament, was applied to by the incoming Tory Government to preside over a Commission to inquire into the working of the Civil Service. Its report established a completely new system, which has ever since been officially known as the "Playfair scheme." The return of Mr Gladstone to power in 1880 afforded opportunity for Playfair to resume his interrupted parliamentary career, and from that time until 1883 he acted as Chairman of Committees during a period when the obstructive tactics of the Irish party were at their height. On his retirement from the post he was made K.C.B. As illustrative of the many interests which now divided his time, may be mentioned his strong advocacy of the Vaccination Acts; his efforts on behalf of the Tercentenary Commemoration of Edinburgh University in 1884; his presidency of the British Association in 1885; his appointment by Mr Gladstone in 1886 to the office of Vice-President of the Council; his advocacy of medical reform; and his work (as deputy-chairman of the Commissioners of the Great Exhibition) in connexion with Queen Victoria's Jubilee in 1887. In 1892 he was created Baron Playfair of St Andrews, and a little later was appointed Lord-in-Waiting to the Queen. In 1895 he was given the G.C.B. In spite of failing health, the last years of his life were full of activity, one of his latest public acts being his suggestion that Queen Victoria's Diamond Jubilee of 1897 should be commemorated by the completion of the South Kensington Museum. He died in London, after a short illness, on 29th May 1898, and was buried at St Andrews. He was three times married. He was the author of a number of papers on scientific and social topics, a selection from which he published in 1889 under the title of *Subjects of Social Welfare*. A memoir of him by Sir Wemyss Reid appeared in 1899. (R. F. S.)

Plevna, or Pleven, the chief town of a district in the principality of Bulgaria, situated 85 miles north-east of Sofia, on the Toutchinitza, an affluent of the Danube, and on the Sofia–Varna Railway (opened in 1899), where a branch line passes north, 25 miles to Sómavit on the Danube, where a new port has been formed. After the capture of the town by the Russians in 1877, it was forsaken almost entirely by the Turks, and most of the mosques have gone to ruin; but, peopled now mainly by Bulgarians, it has quite recovered its prosperity, and has a large commerce in cattle and wine. A recently introduced manufactory is that of safes. The ancient Turkish kanak is now used as the prefecture of the department. Numerous monuments have been erected by the Russians and Bulgarians to the memory of those killed during the struggles for its possession. Population (1900), 18,709.

Plimsoll, Samuel (1824–1898), British politician and social reformer, was born at Bristol on 10th February 1824. Leaving school at an early age, he became a clerk, and rose to be manager of a brewery in Yorkshire. In 1853 he endeavoured to set up a business of his own in London as a coal merchant. The venture proved a failure, and Plimsoll was reduced to destitution. He has himself related how for a time he lived in a common lodging-house on 7s. 9½d. a week. This experience had a profound influence on his career. He learnt to sympathize with the struggles of the poor; and when the success of his enterprise placed him in possession of a competence, he resolved to devote his leisure to the amelioration of their lot. His efforts were directed more especially against what were known as "coffin-ships"—unseaworthy and overloaded vessels, often heavily insured, in which an unscrupulous owner was allowed by the law of that time to risk the lives of his crew. Plimsoll entered Parliament as Liberal member for Derby in 1868, and endeavoured in vain to pass a Bill dealing with the subject. In 1872 he published a work entitled *Our Seamen*, the sincerity and deep feeling of which made a great impression throughout the country. Though many of its statements were shown to be exaggerated or unfounded, enough remained to prove the crying need for reform. Accordingly, on Plimsoll's motion in 1873, a Royal Commission was appointed, and in 1875 a Government Bill was introduced, which Plimsoll, though regarding it as inadequate, resolved to accept. On 22nd July, the Premier, Disraeli, announced that the Bill would be dropped. Plimsoll lost his self-control, applied the term "villains" to members of the House, and shook his fist in the Speaker's face. Disraeli moved that he be reprimanded, but on the suggestion of Lord Hartington agreed to adjourn the matter for a week to allow Plimsoll time for reflection. Eventually Plimsoll made an apology. The country, however, shared his view that the Bill had been stifled by the pressure of the shipowners, and the popular agitation forced the Government to pass a Bill, which in the following year was amended into the Merchant Shipping Act. This gave stringent powers of inspection to the Board of Trade, and made the old abuses impossible. The mark that indicates the limit to which a ship may be loaded is generally known as Plimsoll's mark. With the passage of this Act Plimsoll's work reached its climax. He was re-elected for Derby at the general election of 1880 by a great majority, but gave up his seat to Sir W. Harcourt, in the belief that the latter, as Home Secretary, could advance the sailors' interests more effectively than any private member. Though offered a seat by some thirty constituencies, he did not re-enter the House, and subsequently became estranged from the Liberal leaders by what he regarded as their breach of faith in neglecting the question of shipping reform. He held for some years the presidency of the Sailors' and Firemen's Union, raised a further agitation, marred by obvious exaggeration, about the horrors of the cattle ships, and visited the United States with the object, in which he proved successful, of securing the adoption of a less bitter tone towards England in the historical text-books used in American schools. He died at Folkestone on 3rd June 1898. (H. SY.)

Płock, a government of Russian Poland, bordering on Prussia, with an area of 4200 square miles, and in 1897 a population of 556,819, of whom 278,104 were women, and 99,821 lived in towns. It is divided into seven districts, of which the chief towns are Płock (*q.v.*), Ciechanow (10,664), Lipno (6753), Mława (13,449), Prasnysz (9136), Rypin (6040), and Sierpiec (8560). The standard of education is very low, and in 1896 the 443 schools were attended by only 13,749 boys and 5386 girls. Agriculture is the main occupation, the average annual yield of the crops from 1895 to 1899 being 1,141,000 cwt. of wheat, 3,252,000 cwt. of rye, 852,000 cwt. of oats, 405,000 cwt. of barley, 6,048,000 cwt. of all cereals, and 9,541,000 of potatoes; considerable quantities of grain are exported. Beetroot is also cultivated for the manufacture of sugar, and gardening and bee-keeping are extensively engaged in for industrial purposes. The live stock included in 1897, 90,000 horses, 213,000 horned cattle, and 393,000 sheep, chiefly of improved breeds. The aggregate output of the factories—chiefly sugar works—was valued at only £335,000.

Płock, the capital of the above government, situated on the right bank of the Vistula, 172 feet above its level, 32 miles from the Kutno Railway station. There is considerable navigation on the Vistula, grain, flour, wool, and beetroot being the chief items of export. Coal, naphtha, salt, and fish are imported. Population (1897), 27,073.

Ploesci, chief town of the district of Prahova, Rumania, situated 38 miles from Bucharest, at the entrance of the valley of the Prahova, in a region which is sufficiently indicated by its name Ploesci (*pluviena*, rainy). It is the headquarters of a military division and seat of a court of first instance, and has a lycée, a school of arts and crafts, and a commercial school, and is besides an important commercial centre, with numerous markets and fairs. It is likely to develop still further, as occupying one of the richest petroleum-bearing districts in Rumania. There is a large number of commercial and banking co-operative societies. It contains nineteen churches, comprising one Roman Catholic church and three synagogues, besides the Church of Our Lady, constructed in 1740 by Matthew Bassaraba. In the neighbourhood are the monasteries of Pargasoru, Crangulu, Peinlui, and Maigineni. Population (1900) 42,687.

Plumptre, Edward Hayes (1821–1891), English theologian and scholar, was born in London on 6th August 1821. Becoming scholar of University College, Oxford, he graduated with a double first-class in 1844, and in the same year was elected fellow of Brasenose College. He was ordained in 1847, and was shortly afterwards elected to the Chair of Pastoral Theology at King's College, London. In 1863 he was given a prebendal stall at St Paul's, and for the period from 1869 to 1874 was a member of the committee appointed by Convocation to revise the authorized version of the Old Testament. After successively holding the livings of Pluckley and Brickley in Kent, he was installed in 1881 as Dean of Wells. Dean Plumptre was a man of great versatility; he is known as the translator of the plays of Sophocles and Æschylus, and of the *Divina Commedia* of Dante. Among his contributions to theological literature may be mentioned *Exposition of the Epistles to the Seven Churches of Asia* (1877), *The Spirits in Prison* (1884), *The Book of Proverbs* (which he annotated in the *Speaker's Commentary*), the *First Three Gospels, the Acts, and the Second of Corinthians*, in Bishop Ellicott's *New Testament Commentary*, and *Life of Bishop Ken* (1886). He died on 1st February 1891.

Plymouth, a municipal, county (1888, extended 1896), and parliamentary borough, and seaport of Devonshire, England, 231 miles by rail west-south-west of London, on Plymouth Sound, which consists of the confluence of the estuary of the Tamar on the west with the estuary of the Plym on the east. With the township of Stonehouse and the borough of Devonport, Plymouth constitutes the aggregate "Three Towns." The municipal borough is distributed into 14 wards, under a mayor, 14 aldermen, 42 councillors, a recorder, town clerk, &c. Bounded on the S. by a line connecting Penlee and Wembury Point, the Sound is 3 miles long from north to south and 2½ to 3 miles broad, covering at high water 4500 acres. Its inlets into the land on the north are, from the east end westwards: (1) Catwater, 200 acres, with accommodation for 1000 vessels, anchorage chiefly for timber vessels and coal-hulks; it was in 1888 provided with a new wharf and hydraulic cranes, and a small breakwater is laid across its entrance. The depth varies from 18 to 24 feet, and in 1902 was increased throughout to the greater depth. (2) Sutton Pool, 90 feet wide at its entrance, with an area of 27 acres, a substantial jetty, and a graving beach 400 feet long. The Pool has been connected with the Great Western and South-Western railways. (3) Mill Bay. Outside its floating dock, 17 feet neaps, is the tidal basin of 35 acres; on its western side is an extension jetty. At low water it accommodates ships of 24 feet draught, free to arrive and discharge at any time. The graving dock, entered from the inner basin (13 acres), is 464 feet long by 92 feet wide, 80 feet width of entrance, and 22 feet depth of water at ordinary spring tides, as in the floating basin. (4) Stonehouse Pool, the anchorage more particularly of ships in the timber trade, and with 22 to 24 feet at low water. New quays have been constructed, and there are two discharging berths. (5) Hamoaze, 4 miles long from Mount Edgcumbe to Saltash, the thoroughly protected harbourage of his Majesty's ships "in ordinary." For 14 miles above Devonport the Tamar is navigable for small vessels. Till 1841 the Sound was exposed to the brunt of the south-western gales. In that year was completed, at a cost of 1½ million sterling, the Great Breakwater. It stretches, an isolated mole of stones, 2½ miles south of the Hoe, 360 feet wide at the base, sloping to 45 feet at the top, 1700 yards long, across the middle of the Sound, its two ends or cants bent inwards at an angle of 120 degrees; an outlying barrier which has since secured to the entire Sound the safety of a harbour. The open channels between breakwater and shore are on the west 4300 feet and on the east 2200 feet broad. A lighthouse stands at the west end of the breakwater, a pyramidal beacon at the east end. The school board has 13 ordinary schools, 3 cooking centres, 2 woodwork centres, &c.; and the municipal, science, art, and technical schools (1892) are attended by 800 students. Other new buildings are an Established church, the Marine Biological Laboratory (1888), the Armada Memorial (1888), a new Corn Exchange, the market, rebuilt, a new fishmarket, an ear and throat hospital, a new wing to the Devon and Cornwall Hospital, an endowed convalescent home, and the Mill Bay station of the Great Western Railway.

A highly important Government station, Plymouth is strongly fortified. On the north the chain of forts around the three towns, stretching in horse-shoe line from the river Tamar to the river Plym, is 14 miles long. The citadel at the east end of the Hoe commands the Catwater. Strong fortifications on Mount Wise command the entrance to Hamoaze. Just inside the breakwater is one of the strongest forts in the world. The channel to the east of the breakwater is further protected by a granite battery at Bovisand, north of which is a strong fort on Staddon Heights, and still farther north the forts of Bellevue and St Ann. The channel to the west of the breakwater is protected from the land by Cawsand Battery. Farther north, on the west side of the Sound, are Picklecombe Fort and Earl's Battery, Western King Fort and Eastern King Battery—the two latter on Stonehouse coast. Whitesand Bay, again, is guarded from the coast by Pollawny Battery and Tregantle Fort. Drake's Island is strongly fortified and garrisoned. The industries of Plymouth include large engineering and shipbuilding works; large exporting starch, blue, and black-lead factories; two soap factories, tanneries, distilleries, &c. There are three daily newspapers. The registered shipping at the port in 1900 was 323 vessels of 55,537 tons, against 345 of 28,087 tons in 1888. In 1900, 2903 vessels of 884,918 tons entered, as compared with 1231 of 480,525 tons in 1888. Clearances numbered 2902 vessels of 833,222 tons in 1900, as compared with 1116 of 433,983 tons in 1888. The total foreign and colonial imports in 1900 were valued at £1,573,049, against £1,416,282 in 1888. The total exports of merchandise of the United Kingdom in 1900 were £154,993, against £162,227 in 1888. Area, 2370 acres. Population (1891), 88,926; (1901), 107,509.

The township of Stonehouse, governed by an urban district council of 15 members, is a western continuation of Plymouth, separated by Stonehouse Pool from Devonport, in the parliamentary borough of which it is included. A bridge across the Pool connects Stonehouse with Devonport; higher up, Mill Bridge connects Stonehouse with Stoke Damerel. A naval and military depôt, Stonehouse contains the Royal William Victualling Yard (14 acres), the western part of which is appropriated to the naval ordnance department, with repairing shops, armoury, &c.; marine barracks, with accommodation for 1500 men; a naval hospital (24 acres); a town hall; and a theatre (1889), seating over 2000 persons. Area, 190 acres. Population (1881), 15,041; (1901), 15,108. (C. N.)

Plymouth, a town of Massachusetts, U.S.A., capital of Plymouth county, comprising 116 square miles of rolling country, dotted with ponds. The principal village bears the same name as the town, and is situated in the northern part, on Plymouth Harbour and on a branch of the New York, New Haven, and Hartford Railroad. It has an irregular plan, a good water supply and sewer systems, and varied manufactures. Population of the town (1890), 7314; (1895), 7957; (1900), 9592, of whom 2274 were foreign-born and 146 negroes.

Plymouth, a borough of Luzerne county, Pennsylvania, U.S.A., on the Susquehanna river, and on the Delaware, Lackawanna, and Western Railroad, at an altitude of 535 feet. It is in the anthracite coal region, and its industries are related to the mining and handling of coal. Population (1890), 9344; (1900), 13,649, of whom 4804 were foreign-born.

Pneumatic Despatch.—The system of pneumatic despatch tubes (for telegrams only) in use in the English Postal Department had in 1902 a total length of over 60 miles, laid underground, of which length 40 miles were in use in the London district. There are also short tubes, known as "house tubes," in use in most large offices; such tubes, which are worked either by power (in the case of the head offices) or by hand pumps, are from $1\frac{1}{2}$ to $2\frac{1}{4}$ inches in diameter, and are used for the purpose of conveying messages from one part of a telegraph instrument-room to another, or from the instrument-room to the public counter. The underground, or "street," tubes in London are chiefly $2\frac{1}{4}$ inches in diameter, but there are also a number of 3-inch tubes in use; those in the large provincial towns (Birmingham, Bradford, Cardiff, Glasgow, Grimsby, Liverpool, Manchester, Leeds, and Newcastle) are $2\frac{1}{4}$ inches in diameter, but in Dublin $1\frac{1}{2}$-inch tubes are employed. There are 50 street tubes in London, varying in length from 100 to 2000 yards (Central Office to the Houses of Parliament), and also 50 house tubes; the pumps for the whole system are worked by four 50-horse power steam-engines. At Cardiff and Leeds the pumps are driven by electric motors.

Carriers. The "carriers" in all cases have gutta-percha bodies and are covered with felt, the front of the carrier being provided with a buffer or piston formed of several discs of felt which exactly fit the tube; the messages are prevented from getting out of the carrier by the end being closed by an elastic band, which can be stretched sufficiently to allow the message forms to be put in. The 3-inch carriers will hold 75 ordinary message forms, the $2\frac{1}{4}$-inch carriers 25 forms, and the $1\frac{1}{2}$-inch carriers 20 forms. ***Tubes.*** The tubes are in all cases of lead, the $2\frac{1}{4}$-inch tubes weighing 8 lb per foot run and being made in lengths of 28 feet; they are enclosed in 3-inch cast-iron pipes made in lengths of 9 feet.

Great care is exercised in making the joints in the lead pipes. Before the tube is placed in its trench a strong chain is passed through it, and a polished steel mandrel, 6 inches long and slightly less in diameter than the diameter of the tube, is heated and attached to the chain, and pushed half its length into the end of the tube already laid; the new length of tube is then forced over the projecting end of the mandrel until the tube ends (which have been previously cut flat) butt perfectly together; an ordinary plumber's joint is then made. By this means the tube is made perfectly air-tight, and the mandrel keeps the surface of the tube under the joint as smooth as at any other part of its length. After the joint is completed, the mandrel is drawn out by the chain attached to it, the next length is drawn on, and the above process repeated. The tubes are laid about 2 feet below the surface of the ground.

The tubes radiate from the central to the branch offices, the principal offices having two tubes, one for "inward" and the other for "outward" traffic. At the smaller offices both the inward and outward traffic is carried on through one tube. ***Working.*** The carriers are propelled in one direction (from the central office) by "pressure," and drawn in the opposite direction by "vacuum," the standard pressure and vacuum being 10 lb and $6\frac{1}{2}$ lb per sq. in. respectively, which values give approximately the same speed.

The time of transit of a carrier through a tube when the air pressure does not exceed 20 lb per square inch is given very approximately by the empirical formula:

$$t = \cdot 00872\sqrt{\frac{l^3}{\mathrm{P}d}};$$

where l=length of tube in yards, d=diameter of tube in inches, P=effective air-pressure in pounds per square inch, t=transit time in seconds. For vacuum the formula is:

$$t = \frac{\cdot 00825}{1 - \cdot 234\sqrt{15\cdot 5 - \mathrm{P}_1}}\sqrt{\frac{l^3}{d}};$$

where P_1=effective vacuum in pounds per square inch.

The horse-power required to propel a carrier is approximately, for pressure—

$$\mathrm{H.P.} = (\cdot 574 + \cdot 0011\mathrm{P})\sqrt{\frac{\mathrm{P}^3 d^5}{l}};$$

for vacuum—

$$\mathrm{H.P.} = (5\cdot 187 - 1\cdot 214\sqrt{15\cdot 5 - \mathrm{P}_1})\mathrm{P}_1\sqrt{\frac{d^5}{l}}.$$

For a given transit time the actual horse-power required is much less in the case of vacuum than in the case of pressure working, owing to the density of the air column moved being much less: thus, for example, the transit time for 10 lb pressure is the same as for $6\frac{1}{2}$ lb vacuum, but the horse-power required in the two cases is as 1·83 to 1. A tube 1 mile long, $2\frac{1}{4}$ inches in diameter, and worked at 10 lb per square inch pressure, will have a transit time of $2\frac{1}{4}$ minutes, and will theoretically require 3·35 horse-power to be expended in working it, although actually 50 per cent. more horse-power than this must be allowed for, owing to losses through various causes. The transit time for a $2\frac{1}{4}$-inch tube is 16 per cent. more than for a 3-inch tube of the same length, when both are worked at the same pressure, but the horse-power required is 50 per cent. less; it is not advisable, therefore, to use a tube larger than is absolutely necessary to carry the volume of traffic required.

Despatching and receiving apparatus. The somewhat complicated pattern of "double sluice valve" originally used at the central stations has been superseded by a simpler form, known as the "D" box—so named from the shape of its cross section. This box is of cast iron, and is provided with a close-fitting, brass-framed, sliding lid with a glass panel. This lid fits air-tight, and closes the box after a carrier has been inserted into the mouth of the tube; the latter enters at one end of the box and is there bell-mouthed. A supply pipe, to which is connected a "3-way" cock, is joined on to the box and allows communication at will with either the "pressure" or "vacuum" mains, so that the apparatus becomes available for either sending (by pressure) or receiving (by vacuum) a carrier.

On the long tubes (over about 1000 yards) a modification of the "D" box in its simplest form is necessary; this modification consists in the addition of a "sluice" valve placed at a distance of about 9 inches (*i.e.*, rather more than the length of a carrier) from the mouth of the tube. This sluice valve, by means of an interlocking arrangement, is so connected with the sliding lid of the box that the lid cannot be moved to the open position unless the sluice valve has closed the tube, nor can the sluice valve be opened unless the sliding lid is closed. The object of this sluice valve is to prevent the back rush of air which would take place into the tube when the sliding lid is opened to take out a carrier immediately on the arrival of the latter; for although the vacuum may be turned off by the 3-way cock, yet, owing to the great length of the tube, equilibrium does not immediately take place in the latter, and the back rush of air into the vacuum when the lid is opened to extract the carrier will cause the latter to be driven back into the tube. The sluice also prevents a similar, but reverse, action from taking place when pressure working is being carried on. As a rule, only one carrier is despatched at a time, and no second carrier is inserted in the tube until the arrival of the first one at the farther end is automatically signalled (by an electric apparatus) to the despatching office. On some of the long tubes a carrier, when it passes the midway point on the tube, strikes a trigger and sends back an electrical signal indicating its passage; on the receipt of this signal a second carrier may be despatched. Recently a signalling apparatus which by a clock movement actuates an indicating hand and moves the latter to "tube clear" a certain definite time (30 to 40 seconds) after a carrier has been inserted in the tube, has been introduced. By this arrangement carriers can be despatched one after the other at comparatively short intervals of time, so that several carriers (separated by distinct intervals) may be travelling through the tube simultaneously. It is necessary that the carriers be separated by a definite interval, otherwise they tend to overtake one another and become jammed in the tube. Although the stoppage of a carrier in a tube is of exceedingly rare occurrence, it does occasionally take place, through picks being driven into the tube by workmen executing repairs to gas or water pipes, but the locality of such a stoppage is easily determined by a simple inspection along the route of the tube. In no case is any special means of testing for the locality from the central office found necessary.

Stoppages and leaks in tubes.

In America, tubes (of brass) up to 8 inches in diameter are in use for the despatch of letters. The system is that of Batcheller, and a total length of several miles is worked.

(H. R. K.)

Pneumatic Tools.—The term pneumatic tool is applied to a class of machine-shop appliances of recent origin, which have been developed chiefly in America, and, in the initial stages, in the railway repair and maintenance works of that country. This development was due to the prior existence in these works of means for compressing air. The air-brake is almost universally used on American railways, and in consequence numbers of the air-pumps which are fitted on the locomotives are always to be found in such works, either awaiting or having undergone repair. In these circumstances, when an apparently useful application of compressed air was devised, it became a simple matter to lay the necessary pipes and connect one of the pumps for trial. In many cases these pumps, in spite of their well-known low efficiency, were retained for a considerable time, several being combined in a battery; but when the economy of the new methods had been fully demonstrated, well-designed air compressors of a suitable and economical type were substituted, and are now considered a necessary part of the equipment of a well-organized American railway repair work. From such works the use of the tools has extended to other works, and especially to shipyards.

The machines may be roughly classified into small portable tools, guided largely by the hand, in which the effort exerted is small but fairly continuous, and larger stationary tools, in which a considerable effort is exerted, but intermittently only. All are alike in one particular—the aggregate of power consumed per hour is small. The work done by both classes is chiefly such as has hitherto been done directly by hand, although occasionally they displace other machines, which, however, are in most cases hand-driven. Sometimes, when only a small amount of work is to be done, pneumatic tools are brought to heavy pieces of material which were previously taken to fixed machines. The main sources of economy in the use of pneumatic tools are thus the substitution of mechanical for manual power, and the moving of a small portable machine to a heavy piece of work, instead of moving the work to a fixed machine. As is the fact with most applications of compressed air, the mechanical efficiency, considered as the ratio between input and output, is low, but, as in many other instances connected with applications of power, the commercial efficiency, measured by the cost of the work, is nevertheless high. The increase of output of a workman and his pneumatic tool over that of a workman using the old hand tools is so much greater than the increased cost due to the added expense of maintaining and operating the pneumatic plant, that the work is done at far less cost per unit. Moreover, the output of a given plant or workshop is largely increased, and the owners thereby secure the well-recognized economical advantages of production on a larger scale.

Perhaps the most important of these tools is the hammer (Fig. 1), which was the first to become of commercial importance. It is somewhat similar to the rock-drill, the chief difference, next to that of size, being the free-flying piston. In the rock-drill the piston carries the drilling-tool with it in its reciprocations, but in the hammer it does not. The shank of the tool—chisel, caulking-tool, or whatever it may be—projects slightly through the cylinder head, so that the free piston strikes it at each stroke, the action being precisely like that of a hand hammer. The motion is very rapid, 3600 blows per minute being delivered in the smaller sizes. Originally these tools were of small size only, suitable for holding in the hand, but larger ones are now made, with suitable frames and supports, intended chiefly for driving rivets. For some purposes a heavy blow is needed—a large number of light blows not being the equivalent of a smaller number of heavy blows. For these purposes a new type of hammer, to be held in the workman's hand, and called the long-stroke hammer, is an important development. The piston is heavier and the stroke is much longer than in the older type. This type is especially adapted to riveting, and it is in large use for that purpose on steam boilers, the hulls of ships, and the erection-work of bridges and steel-frame buildings. It can be used in many places in which the application of machines held in yokes or frames would be impossible. The range of application of pneumatic hammers is almost as wide as that of a hand hammer; they have even been used under water by divers working on wrecks. A recent application of the same principle is to be seen in the sand-rammers employed in making foundry moulds (Fig. 2).

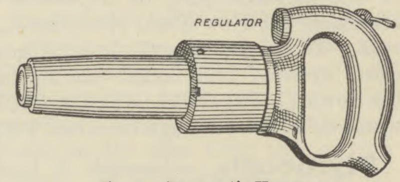

Fig. 1.—Pneumatic Hammer.

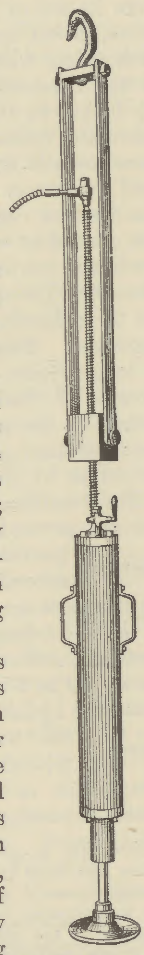

Fig. 2.—Pneumatic Sand-Rammer.

A second tool of similar importance is the rotary drill (Fig. 3). Originally this consisted of a small rotary engine with feeding mechanism for tools suitable for drilling or boring in iron or wood, but the wastefulness of such an arrangement led to the design of small reciprocating engines for the same purpose. For distinction these are called piston air drills, though, as the original construction drops out of use, the distinction in name will naturally be dropped also, the term rotary being probably retained. They are chiefly used where formerly the hand ratchet brace was relied upon. In all heavy machine work cases are of frequent occurrence in which holes are required in inaccessible places. In these the hand ratchet was formerly employed, as well as in those in which small holes, so located as to be easily accessible, were needed in large pieces. The operation of the hand ratchet is slow, laborious, and expensive, while the mere moving and fixing of heavy pieces in position under a stationary drilling machine may cost far more than the actual performance of the work. In both these cases the rotary air drill gives marked economy.

These motors are applied to a great variety of operations besides drilling. Reaming, tapping, expanding boiler tubes, grinding steam joints, sand-papering woodwork, and cleaning castings by their aid, are very common; and a recent application is to the driving of a special tool for the removal of flues from old boilers, an operation that was previously very tedious and expensive. The motors are also employed to drive portable boring-bars, crank pin and car journal turners, and, in emergency work, at night or on Sundays, to drive the standard machine tools of the machine shop.

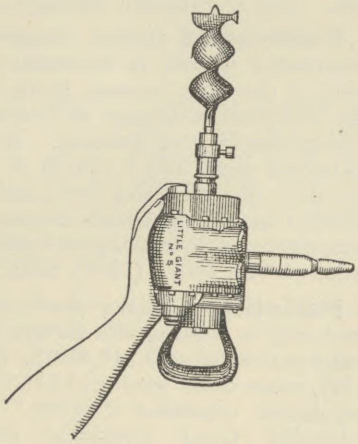

Fig. 3.—Pneumatic Rotary Drill.

Classed among pneumatic tools, perhaps not quite correctly, is the pneumatic hoist, which has come into very extensive use. A long cylinder of bored pipe hangs from the ceiling or from a trolley running on a tram rail attached to the ceiling. Within it is a piston, from which a long piston-rod depends. A simple hook for attaching a chain by which the load is slung, and a valve for admitting and discharging air to and from the lower end of the cylinder, complete the mechanism which has largely displaced the chain hoist. Where head-room is restricted, these hoists are often arranged to lie horizontally under the ceiling, and they are frequently applied to light swing-cranes for yard use. A modification of the device is the pneumatic jack, which is placed below the piece to be lifted, and operates directly. The jack is frequently mounted on wheels, for transporting the load.

Other pneumatic tools are of more restricted and special application. Of these are the stay-bolt cutter, which is simply a powerful pair of nippers, designed to remove by a single movement the surplus ends of locomotive stay-bolts—an operation which, when done by cold chisel and hand hammer, is laborious, and, moreover, tends to loosen the bolts in their holes. The painting machine for painting large surfaces simply atomizes the paint by a jet of air; it was first used on the buildings at the Chicago World's Fair of 1893. The mud-ring riveter is a special device for riveting the seam around the bottom of locomotive fire-boxes, and another special machine cuts the stay-bolts of old locomotive fire-boxes prior to removal. Among other appliances more or less related to the preceding are small presses for forcing work together; small forging and bending presses—commonly known as "bull-dozers"; furnaces for heating and expanding driving-wheel tyres; paint burners for the removal of old paint; cleaning machines for the renovation of the seats and cushions of railway carriages, the efficiency of which is remarkable; bell-ringers for the bells universally used as warning signals on American locomotives; track-sanders for blowing sand under locomotive driving-wheels; fire-kindlers for the use of oil fuel in place of wood in starting fires on locomotives; and sheep-shearers, which are widely adopted in Australia.

Very few trustworthy data of the comparative cost of work done in the old and new way have been published, and, indeed, exactness in such data is scarcely to be expected. The following are given on the authority of Mr Edward C. Schmidt, of the University of Illinois, U.S.A.:—

Tool.	General Character of Work.	Saving per cent. of Cost.
Pneumatic hammer	General foundry work—chipping	67 to 75
" "	Riveting on mud ring and fire-box	67
" "	Chipping flue sheet . . .	84
" "	Beading flues	75
" "	General boiler-shop work . .	60
" "	Cutting out broken fire-box stays	70
" "	Cutting off stay-bolt heads .	58
Riveter . . .	Boiler riveting	66
Drill . . .	Drilling saddles . . .	70
" . . .	In general machine-shop work .	75
" . . .	Drilling for stays . . .	50
" . . .	In general boiler-work shop .	75
" . . .	Facing steam pipes . . .	75
" . . .	Tapping for stays . . .	65
" . . .	Reaming crown sheet . .	70
Breast drill . .	General work	90
Stay-bolt nippers .	Cutting off stays . . .	73 to 90
Driving-box press .	Pressing brasses . . .	68
Paint sprayer . .	Painting box cars . . .	67
" " . .	Painting car trucks . . .	87
" burner . .	Cleaning of passenger cars . .	67
Sand blast . .	Cleaning tanks . . .	90
Air jet . . .	Cleaning cushions . . .	50

These figures relate to the saving at the tool, and do not include the fixed charges and cost of operating the air-compressor. In one work, from which many of these figures were taken, the decrease in the percentage of saving due to the cost of compressing the air was found to amount to about 15 per cent. at the most. Generalization in this respect is scarcely possible.

It is too early to speak with confidence of the ultimate place and importance of these appliances. Compared with the main equipment of a workshop, they are small and apparently insignificant, but it is quite possible that they may eventually be looked upon as the greatest contribution to the methods of machining iron and steel made during the closing decade of the 19th century. The mechanical talent embodied in many of them is of the first order. The hammers and rotary drills especially, whether considered from the standpoint of design or of execution and workmanship, are worthy of high praise. (F. A. H.)

Po, a river of North Italy, draining Piedmont, Lombardy, and the greater part of Emilia, also parts of Venetia.

In the first 21 miles of its course, down to Revello (west of Saluzzo), the Po descends no less than 5250 feet, or a fall of 47·3 : 1000, forming a very remarkable contrast to its fall lower down. From the confluence of the Ticino its fall is about 0·3 : 1000; from the beginning of the delta below Ferrara, 0·08 : 1000. At Turin it has an average width of 400 to 415 feet, a mean depth of 3½ to 5½ feet, and a velocity of 1 to 3 feet in the second. The mean depth from the confluence of the Ticino (altitude 217 feet) downwards is 6 to 15 feet. The river is embanked from Piacenza, and continuously from Cremona, the total length of the embankments exceeding 600 miles. Owing to its confinement between these high banks, and to the great amount of sedimentary matter which the river brings down with it, its bed has been gradually raised, so that in its lower course it is in many places above the level of the surrounding country. A result of confining the stream between its containing banks is the rapid growth of the delta. Lombardini calculated that the annual increase in the area of the Po delta during the period 1300 to 1600 amounted to 127 acres; but during the period 1600 to 1830 it rose to 324 acres. Dr Marinelli estimates that between the years 1823 and 1893 the annual increase has been at the average rate of 173 to 175 acres, and the total accretion at about 20 square miles; and the total area of inundated land north and south of the delta at nearly 60 square miles. He further estimates that the Po della Maestra advances 282 feet annually, the Po delle Tolle, 262 feet, the Po della Gnocca, 111½ feet, and the Po di Goro, 259 feet. All along its course from Chivasso (below Turin) down to the delta the river is connected with several of its tributaries by canals, and at the same time other canals connect the tributaries and carry off their waters and the waters of the Po for purely irrigation purposes. The river is navigable as far as Casale, above the junction of the Sesia, but navigation is attended with great risks, owing to the prevalence of shallows and sandbanks.

See G. Marinelli, in *Atti Inst. Veneto Sci.*, series 8, vol. viii. (1896–97); and "L'Accrescimento del Delta del Po nel Secolo XIX.," in *Riv. Geog. Ital.*, vol. v. (1898).

Pobêdonostsef, Constantine Petrovitch (1827–——), Russian jurist, state official, and writer on philosophical and literary subjects. Born in Moscow in 1827, he studied at the School of Law in St Petersburg, and entered the public service as an official in one of the Moscow departments of the Senate. From 1860 to 1865 he was professor of Russian civil law in the Moscow University, and was entrusted with the task of giving instruction in the theory of law and administration to the sons of Alexander II. In 1868 he became a Senator in St Petersburg, in 1872 a member of the Council of the Empire, and in 1880 Chief Procurator of the Holy Synod, an important post which forms the connecting link between the Russian Church and the Tsar. In all his professorial, administrative, and literary activity he always showed himself a consistent, uncompromising Conservative, and, unlike the majority of Russian Conservatives, he never shrank from expressing boldly his opinions. Consequently, in the so-called Liberal camp he was always denounced as an "obscurantist" and an enemy of progress. In the early years of the reign of Alexander II. (1855–81), when the great majority of his educated countrymen assumed that the duty of Russia was to replace her antiquated and barbarous institutions by the most liberal institutions of Western Europe, M. Pobêdonostsef maintained, though keeping aloof from the Slavophils, that these Occidental institutions were radically bad in themselves and totally inapplicable to Russia. Parliamentary methods of administration, modern judicial organization and procedure, trial by jury, freedom of the press, secular education,—these were among the principal objects of his aversion. Parliamentarism he considered the great curse of the time, because it handed over the mass of the population to the tender mercies of narrow-minded, egotistical, unscrupulous men who have learned the dangerous arts of sophistry and eloquence. In his opinion the modern courts of law were equally objectionable. Barristers were simply adepts in sophistry and logomachy, and juries were a motley, mixed herd, chosen at random and incapable of analysing facts or comprehending the duties of a judge. Still worse, if possible, was the periodical press, for it enabled any ignorant, worthless babbler to pose as a great authority on any conceivable subject. Fortunately these dangerous products of the spirit of Occidental rationalism find a counterpoise in popular *vis inertiæ*, and in the respect of the unsophisticated masses for the old respectable institutions which have developed slowly and automatically during the past centuries of the national life. Among the practical deductions drawn from these premisses is the necessity of preserving in the administration the autocratic power, and of fostering among the people the traditional veneration for the ritual of the National Church. These strange ideas and deductions may be regarded as the natural outcome of the peculiar intellectual condition of the Russian educated classes in the reign of Alexander II. Exaggerations naturally engender exaggerations in an opposite direction: as the ultra-Liberal ideas of that time found their extreme expression in Nihilism, so the ultra-Conservative tendencies culminated in the wildly reactionary doctrines of M. Pobêdonostsef. In the sphere of practical politics he exercised considerable influence by inspiring and encouraging the Russification policy of Alexander III. (1881–94), which found expression in an administrative Nationalist propaganda and led to a good deal of religious persecution. (See also RUSSIA, *History*.)

Podiebrad (Czech, *Poděbrad*), chief town of a government district in Bohemia, Austria, on the right bank of the Elbe, between Kolin and Nimburg. It was the birthplace of George of Podiebrad, the Calixtine or Utraquistic king of Bohemia. It contains the ruins of Podiebrad castle and a church of the 14th century. It has also a mineral spring (iron) and bathing establishment. There is an important trade in corn, and the manufactures comprise sugar, flour, and glass works and breweries. Population (1890), 4807; (1900), 5512.

Podolia, a frontier province of south-west Russia, bordering on Austria, with an area of 16,224 square miles, and a population of 2,242,650 in 1881, and 3,031,513 in 1897, when there were 1,514,753 women and the urban population numbered 220,596. In 1896 there were 2,152,629 Greek Orthodox, 17,648 Nonconformists, 241,742 Catholics, 4137 Lutherans, and 388,437 Jews. It is, after Moscow, the most densely inhabited government of Russia outside Poland. It is divided into twelve districts, the chief towns of which are Kamenets-Podolsk (34,483), the capital of the government, Balta (23,393), Bratslaff (4796), Gaysin (9393), Leticheff (8731), Litin (9428), Moghileff-on-Dniester (43,106), Novaya Ushitsa (5099), Olgopol (8098), Proskuroff (22,915), Vinnitsa (28,995), and Yampol (6709). Tulchin (11,217), Bar (10,614), and Khmelnik (11,215) are also worthy of notice. The sanitary service is fairly well organized by the *zemstvo* (provincial council), and in 1896 there were 1762 schools (exclusive of the Jewish *hedars*), attended by 74,283 boys and 14,500 girls. The chief occupations of the people are agriculture and gardening, both maintained at a high level. Only 12 per cent. of the surface is under forests, and less than 5 per cent. is uncultivable. The annual average yield from 1895 to 1899 of wheat was 10,019,000 cwt., of rye 6,279,000 cwt., of oats 1,963,000 cwt., of barley 3,117,000 cwt.; of all cereals, 29,180,000 cwt.; of potatoes, 6,950,000 cwt.; of beetroot and tobacco, 6250 cwt. Nearly 67,000 gallons of wine are obtained annually. Owing to the green crops, cattle-breeding is flourishing; in 1897 there were 501,860 horses, 665,500 horned cattle, and 829,000 sheep. Bee-keeping is an important industry (annual production about 6000 cwt. of honey). Factories—sugar factories, distilleries, flour mills, woollen mills, tanneries, potteries—give employment to nearly 29,000 persons, and have an annual output valued at about £4,000,000. There is considerable trade in grain, flour, sugar, spirits, leather, and wool, all of which are exported. Grain, timber, firewood, spirits, and fruit are shipped in great quantities down the Dniester, the annual movement of 28 river ports being over 100,000 tons loaded and unloaded. Large fairs are held at Yaronolintsy and Balta. (P. A. K.)

Poissy, a town, arrondissement of Versailles, department of Seine-et-Oise, France, 12 miles north-north-west of Versailles, on the railway from Paris to Havre. The church, supposed to have been built between 1125 and 1130, and restored in modern times under the direction of Viollet le Duc, is of special architectural interest, as affording one of the earliest and best examples of transition from the Roman to the ogival style. The bridge of Poissy, a very ancient foundation, has been widened and modernized, but of the mills, known as Queen Blanche's, which formerly bordered it, only one remains. A statue of the painter

Meissonier was erected in 1894. His house, on the site of an ancient monastery, is now occupied as an asylum for children. Poissy during six centuries supplied butchers' meat to Paris, but in 1867 the market was removed to the metropolis. A handsome fountain stands in the old market-place. Various branches of engineering and important iron foundries are the leading industries, and ragstone is quarried. Population (1881), 3990; (1901), 7406.

Poissy, the ancient *Pinciacum*, was the capital of the country of the Carnutes. In the time of Charlemagne it had a royal palace, where during the 9th century four national assemblies were held. Later it became a favourite residence of Blanche of Castille, and here her son, afterwards St Louis, was born in 1215. Philip the Fair gave the castle to the Dominicans, by whom it was completely transformed, and it was in the refectory of the abbey that the famous conference of Poissy between the Roman Catholics and Protestants took place in 1561.

Poitiers, capital of the department of Vienne, France, 206 miles south-west of Paris, on the railway from Paris to Bordeaux. The Palais des Facultés was enlarged in 1892–94. Near the Pont Joubert has been erected a colossal statue of Notre Dame des Dames. Population (1881), 29,304; (1901), 39,565.

Poker, a card game played by any number of players. It is usual to play with a full pack of fifty-two cards, but occasionally an écarté pack is used. Five cards are dealt to each player, whose object it is to obtain certain combinations of cards, the value of which depends on their infrequency. Each player has the option of exchanging any number of the cards dealt to him for an equal number from the undealt portion of the pack. The pool is started by the player on the dealer's left (called the *age*) depositing a fixed amount (called the *ante*). Every player who, after looking at his cards, decides to enter the game, must in his turn, beginning with the player to the left of the *age*, deposit an amount equal to twice the *ante*, except the *age*, who again deposits the same amount as the *ante*. An essential part of the game is that each player, at the time he makes any contribution to the pool, or signifies his intention to remain in, can make a *raise*, which obliges all the players to make an equal contribution to the pool, or to retire from the game. There is not, however, uniformity of custom; sometimes players are only allowed to make a *raise* after cards have been exchanged. After the draw the raising is started by the player on the left of the *age*. When all the players who remain in have seen the last *raise*, none of them making a further *raise*, the hands are shown, and the best hand takes the pool. The hands are valued in the following order:—1. Straight flush (all the five cards being of the same suit and in sequence). 2. Fours (four cards of the same rank and one other). 3. Full hands (three cards of one rank and two of another rank). 4. Flushes (the five cards being of the same suit, but not in sequence). 5. Straights (the five cards being in sequence, but not of the same suit). 6. Triplets (three cards of one rank and two of different ranks). 7. Two pairs. 8. One pair. 9. All other hands. When there are hands in the same class, the best is determined in the case of fours by the rank of the quartet; in the case of a full hand or a triplet, by the rank of the triplet; in case of two pairs, by the rank of the higher pair; in the case of a pair, by the rank of the pair; in other cases, by the rank of the highest card in the hand, and, if these are equal, by the rank of the second best card.

Advice to Players.—A scientific analysis of the rules of play is to some extent out of place, since scientific play is often one of the last things desired by the votaries of the game. Poker is indulged in for the sake of excitement. The opportunities of showing recklessness with regard to money have made it a favourite pastime with those who are proud of having money to lose, and consequently also with those who are desirous of winning it. In some circles it would be considered bad form to follow the correct methods of play.

The following table gives the probability of a player having dealt to him the various combinations:—

Description of Hand.	Number of Times in 2,598,960 Deals.	Number of Times in 1,000,000 Deals.
Straight flushes . .	40	15
Fours . . .	624	240
Full hands . .	3,744	1,441
Flushes . . .	5,108	1 965
Straights . . .	10,200	3,925
Triplets . . .	54,912	21,129
Two pairs . . .	123,552	47,539
One pair . . .	1,098,240	422,569
Inferior hands . .	1,302,540	501,177

This table, it should be noted, gives only the probabilities before the draw. The probabilities after the cards have been exchanged are dependent on the character of the play, which, in its turn, rightly depends on the number of players. It can, however, be approximately obtained by the use of the following proposition:—If the player exclusively aims at obtaining a given combination, he is equally likely to obtain it in any specified manner; or the probability that he will have dealt to him a particular part of the combination and then fill it, is the same as the probability that the whole of the combination will be dealt to him. For instance, take the case of a straight flush to the ace in hearts. The chance that the player will have ace, king, queen, knave, ten of hearts dealt to him, is the same as the chance that he will have a given four, ace, king, queen, knave (say) dealt to him, and obtain the ten in exchange for his fifth card, or that he will have ace, king, queen, dealt to him, and obtain the knave and ten in exchange. This is on the assumption that the player is striving exclusively for the given combination. If the player's rule is to keep any four in the hope of filling a straight flush, since there are five combinations of four cards, he would be five times as likely to obtain the combination after having had four of the cards dealt to him, as to have the whole of the five cards dealt to him at once. In a similar manner, a player is four times as likely to obtain four of a kind by taking in the fourth card to a triplet, as by having the four dealt to him originally; and six times as likely by taking in two cards to a pair. A disturbing element in the case is that there is a chance that the cards outside the combination may induce him to try for a different combination; still, the rule is sufficiently near the truth for practical use.

Whilst the game is one especially susceptible of mathematical treatment, most attempts to treat of it from a mathematical standpoint have been failures. The fault has been in ignoring the possibility of the other players modifying their play in order to oppose any fixed rule. A fixed rule, to be successful, must be such as to leave the other players frequently in doubt as to their play; whilst advantage must be taken of the possibility of their being frightened and led to abandon hands which would have won. Thus every rule of play must be tested as much by its effect on the other players as by its own apparent chance of succeeding. The following advice may be given with regard to the decision to play a hand. When a player has six players following him, he should stand on nothing less than a pair of aces; when he is followed by only one player, he can stand on a pair of fives; the gradations are fairly regular between these extremes. To oppose a player who has declared to stand, a second player should hold a rather better hand than would justify the first; except the *age*, who may stand on an equal or even an inferior hand.

The two objects of raising are to choke off better hands, and to win more by making the pool larger. With a moderately strong hand it is a mistake to raise, because only opposing hands, that would be beaten, will be choked off; and the hands that see the raise will generally be stronger hands, that will take the pool thus increased. With a strong hand, rather more than twice as rare as what he would expect to find against him, the player should raise the pool; and about half as frequently with a hand too weak to be shown. The most advantageous amount by which to raise is the amount which is already in the pool (if less than the limit). If it is worth raising the pool at all, it is worth raising as much as this. Making any distinction between the amount of *raises* will only give an observant adversary a hint as to the character of the hand.

The number of times that a player bluffs, *i.e.*, raises with a weak hand, should bear such a proportion to the number of times that he raises with a strong hand as to give a fair inducement to the opponent or opponents to see the raise. By seeing the raise, the opponent virtually bets the amount of the raise to the amount in the pool that the player is bluffing. The number of bluffs to the number of genuine raises ought to bear this same proportion. If the proportion of bluffs is greater, the opponent knows that it is worth seeing the raise, and bluffing will fail; if the proportion is less, he will not see the raise, and the pool will be less. In a similar way, the rule as to seeing the raise is connected with bluffing. If the player seldom sees a raise, the opponent will know that he can bluff successfully. If he sees a raise too often, the opponent will avoid bluffing, profiting by the increased value of the pool. By bluffing, a player virtually bets the amount of the raise to the amount in the pool that the opponent will not see the raise. This ought to represent the proportion of the number of times that the hands are abandoned to the times that the raises are seen.

By following correct rules of play, the player can with average luck avoid loss. Nearly the whole of the gain will be made by noticing where the other players follow wrong methods, and modifying one's own play in accordance.

Pola, the principal naval harbour and arsenal of the Austro-Hungarian Monarchy, situated near the southern extremity of the peninsula of Istria, on the Gulf of Venice. The extensive system of fortifications comprises forts and batteries at the adjoining coast village of Fasana, overlooking the channel of the same name, and on the Brionian Islands. Pola is, next to Trieste and Fiume, the most important mercantile harbour of the monarchy. It is an episcopal see. Population (1890), 38,937; (1900), 45,052, including a garrison of 7657.

Poland, Russian, a territory consisting of ten governments which formerly constituted the kingdom of Poland (*Tsaritvo Polskoye*), but now officially described as "governments on the Vistula" (*Privislyanskis Gubernii*), or occasionally as "territory on the Vistula" (*Privislyanskiy Krai*). It has a total area of 49,159 square miles, and its population, which was 7,319,980 in 1881, numbered 9,455,943 (4,764,007 men and 4,691,936 women) in January 1897, counting the domiciled population only, to which about 1,000,000 must be added if the total is to include the inhabitants (foreigners and natives) not living at their regular domicile at the date of the census. Omitting this last class, Poland, with 193 inhabitants per square mile, has a denser population than any other portion of the empire, the next to it being Moscow, with 189 inhabitants per square mile. Poland has thus a more considerable urban population than any other part of the Russian Empire. Twelve per cent. of the aggregate population is gathered in 117 towns, of which 32 have populations of over 10,000, the three largest being Warsaw (638,000), Łódz (315,000), and Lublin (50,000). Nearly one-half of the urban population are Jews, the great bulk of whom are artizans. The distribution of the population is shown in the following table:—

Governments.	Area, Square Miles.	Domiciled Population, 1897.	Urban Population.	Density per Square Mile.
Kalisz	4392	846,719	113,609	194
Kielce	3897	763,746	57,814	196
Lomża	4667	585,781	69,834	144
Lublin	6501	1,159,463	148,196	177
Piotrków	4729	1,409,044	509,699	297
Płock	4200	556,877	89,821	153
Radom	4769	820,363	94,318	171
Siedlce	5535	775,316	110,995	140
Suwałki	4846	604,945	73,308	127
Warsaw	5623	1,933,689	791,746	286
Total	49,159	9,455,943	2,059,340	193

Classified according to nationality and religion, it is estimated that there are about 6,630,000 Poles, 1,225,000 Jews, 1,050,000 Great and Little Russians, 300,000 Lithuanians and Zhmudes, and 250,000 Germans; and that some 75·2 per cent. are Roman Catholics, 14·1 per cent. Jews, 5·8 per cent. Protestants, and 4·9 per cent. of the Greek Orthodox Church. Of the non-domiciled population, nearly 100,000 are estimated to be foreigners, chiefly Germans.

Education.—There were in 1896, under the Ministry of Public Instruction, 3026 schools, with 3729 teachers and 206,973 pupils, while other schools and colleges numbered nearly 4000. The principal among these latter are the University of Warsaw, with 1114 students in 1899, at which instruction is now given in the Russian language; the Agricultural Institute at Nowa Alexandrya; and the Veterinary Institute and the Musical Conservatory at Warsaw. For secondary education there are 31 lyceums for boys and 19 for girls, 9 normal schools for teachers, 5 *realschulen*, 6 Catholic seminaries, and 1 polytechnic at Łódz. There are also a considerable number of smaller technical schools and private schools in the industrial regions. Nearly 70 newspapers were published in 1899, but the censorship is very rigorous.

Land Tenure and Agriculture.—In 1901 the village communities owned 40·9 per cent. of the total area; private owners, 50·3 per cent. (the bulk of which is owned by the nobles); the Crown and the Imperial Family, 6 per cent.; various institutions, 2·8 per cent. The holdings of the peasant families vary, generally speaking, from 13 to 30 acres. By a law of 1891 further subdivision is prohibited when the holding is less than 8·3 acres. Forests cover over 23 per cent. of the surface, or 7,357,000 acres, of which 2,130,400 acres belong to the Crown. Agriculture continues to stand at a higher level than in other Russian provinces. No less than 70 per cent. of the peasants' holdings, and 52 per cent. of the land owned by the landlords, is under crops, while 11 per cent. of the former and 8 per cent. of the latter is meadow land. In 1899, 12,538,000 acres were under crops, yielding 75,548,000 qrs. of rye, 55,392,000 qrs. of oats, 25,838,000 qrs. of wheat, 19,274,000 qrs. of barley, 264,826 qrs. of potatoes, and 1,955,350 tons of hay. After all local wants are supplied, there remains every year a surplus of about 3,500,000 qrs. of grain. Beet-root is largely grown for the manufacture of refined sugar, of which Poland produces more than the rest of Russia put together. The crop in 1898–99 was 838,000 tons, and the production of sugar 68,196 tons. Potatoes are largely grown for use in the distilleries.

Mining and Industries.—Mining and the iron industry have considerably developed in the governments of Piotrków and Radom. The output of coal was 4,025,000 tons in 1898; and in 1899 the output of pig-iron from the 36 private and 4 Crown ironworks was 310,400 tons, of steel 227,500 tons, of iron 71,800 tons, and of zinc 5650 tons. Some salt is extracted from springs in the government of Warsaw. Other industries are steadily progressing. In 1898 there were nearly 30,000 factories and workshops, employing some 250,000 workers of both sexes, the annual output being valued at about £25,000,000, while the total annual output of all industries, including mining and distilleries, was valued at £42,500,000. The districts of Łódz, Rawa, and Łask, in the government of Piotrków, and the provinces of Warsaw and Kalisz, are the main centres of industry. The yearly returns of the different branches of textile industries are: cottons, estimated at £6,000,000; woollens, £4,000,000; and linen and hemp goods, £1,700,000.

Trade.—With the extension of railways (1293 miles), the fairs have lost much of their importance, but their aggregate yearly returns are still estimated at £3,000,000. The chief fairs are held at Warsaw (wool and hemp), Łenczica, Skaryszew, Ciechanoviec, and Łowicz.

POLAR REGIONS.

I. Arctic Exploration.

After the synchronous observations during the years 1882–83, the next important Arctic work was the crossing of the great glacier forming the interior of Greenland by Nansen and Peary. Dr Nansen, with six companions, after overcoming great difficulties in traversing the ice-floes, succeeded in landing on the east coast of Greenland in August 1888, and reached a height of 7000 feet on the glacier, in 64° 50′ N., on the 27th. Here there is an extensive flat plateau resembling a frozen ocean, rising to 8000 and 9000 feet. The cold was intense, and for more than two weeks they travelled over these regions, each man dragging a small sledge, while the two leaders, Nansen and Sverdrup, drew a somewhat larger sledge between them. As they approached the western side their progress was checked by dangerous crevasses, but on the 26th of September Nansen and his gallant little party arrived at the inner end of the Ameralik-fjord, in 64° 12′ N., having traversed 260 miles of glacier. He discovered that in this latitude the inland ice of Greenland has the shape of a shield, rising rather rapidly, but regularly, from the east coast to 9000 feet, flat and even in the middle, and falling again regularly towards the western side.

In 1892 Mr Peary, accompanied by Eivind Astrup, made his great journey across the inland ice to ascertain the northern limit of Greenland. The party consisted of four men and sixteen dogs. Starting in April from Whale Sound, on the west coast, in 77° N., they took a north-easterly course. The highest part of the glacier was 6000 feet above the sea, gradually sloping down on either side. At last they sighted land, indicating the termination of the glacier in 82° 12′ N., on the 26th of June. Soon afterwards they obtained a view of a bold line of cliffs, forming part of the east side of Greenland, in 81° 37′ N. It was discovered that land masses extended to the north where the great glacier terminated, thus establishing the northern limit of the inland ice-cap. Peary's subsequent journey in 1895 did not add much to the information gained in 1892.

The year 1893 saw the departure of Dr Nansen on his famous expedition to cross the polar ocean by trusting to the drift from east to west. This was in several respects the most remarkable northern voyage that ever was undertaken. Dr Nansen had studied the Arctic problem exhaustively and with great care; his conclusions were sound, and he planned the expedition with ability, and with a close attention to details which ensured success. He knew exactly what he intended to do, and he adapted his means to a well-defined end. His ship, the *Fram*, was designed to sustain and rise to great ice pressure, and, in its interior arrangements, to ensure the health and comfort of his people; while minute attention was given to provisions and equipment. In the autumn of 1893 the *Fram* was forced into the ice to the north-west of New Siberia Island, and its memorable drift was commenced, and continued during three winters. Eventually the *Fram* came out of the pack to the north of Spitsbergen. Nansen's chief discovery is that there is a very deep ocean to the north of the Franz Josef group, continuous with that to the north of Spitsbergen, and that this deep sea has a relatively warm temperature in its depths. This ice-bearing ocean extends at least as far as the pole, and the time occupied by the ice in drifting across it from the Siberian side to Spitsbergen is about three years. The existing evidence points to the conclusion that there is a continuous drift from the eastern to the western hemisphere, across an ice-covered ocean uninterrupted by land of any magnitude. The light thrown upon the polar question by Nansen has not only extended our knowledge positively, but has had the effect of piecing together what appeared before to be fragmentary, and of making the detached pieces fit into their proper place and form a consistent whole.

After the second winter Dr Nansen, with a single companion, Johansen, left the ship to examine the nature of the ice to the northward on 14th March 1895. On 8th April, after travelling over very heavy ice for several days, he reached his farthest north in 86° 13′ N. He then returned southwards, and eventually reached an island of the Franz Josef group, where he wintered in a stone hut. In the spring of 1896 the journey was recommenced, and on 17th June Nansen and Johansen met Mr Jackson, and their troubles were at an end.

Mr Jackson was in command of an expedition to explore Franz Josef Land, fitted out at the expense of Mr A. C. Harmsworth. It consisted of Mr Armitage as second in command, and six scientific civilians, who were landed at Cape Flora, where log houses were erected. The vessel which took them out, the *Windward*, had to winter in 1894–95. In the spring of 1895 Mr Jackson made a journey northwards as far as 81° 19′ 30″ N., and discovered a channel leading between groups of islands, to the west of the Austria Sound of Payer. Later in the season he made an exploring boat voyage to the westward along the coast of Franz Josef Land. In June 1896, after the second winter, Mr Jackson's party welcomed Dr Nansen and his companion to their house at Cape Flora. The explorers returned to Norway on board the *Windward*, the *Fram* arriving a few days afterwards. In 1897 Mr Jackson, accompanied by Mr Armitage, made a remarkable journey, during which he discovered the western portion of Franz Josef Land and explored the glaciers of the most western island. The Jackson-Harmsworth expedition returned to England in the autumn of 1897. Mr Jackson had discovered a wide channel opening on a sea to the north, and numerous islands forming the western portion of the Franz Josef group. Careful series of meteorological and magnetic observations were taken during these years, and the geological collections indicated that the Franz Josef group and Spitsbergen were portions or fragments of one extensive land existing in the late Tertiary period.

Since the return of Mr Jackson, a party led by Sir Martin Conway has explored the interior of Spitsbergen, and the Swedish savant, Nathorst, has examined its eastern coast and the off-lying islands on that side. The Danes have established a new colony on the east side of Greenland, and a party under Lieut. Ryder has done some good exploring work along the east coast. A small party of Americans and Norwegians, led by Mr Wellman, was landed on Franz Josef Land in 1898 and wintered there. They returned in the autumn of 1899, and one of the party, Mr Baldwin, completed the discovery of the easternmost islands of the group.

In 1899 Captain Sverdrup, on board the *Fram*, led an expedition up Smith Sound, with the object of discovering the northern coast of Greenland. Lieut. Peary, trusting to the help of the northern Eskimo, pressed northwards by the same route. H.R.H. the duke of Abruzzi, on board the Norwegian whaler *Jason*, which was renamed the *Stella Polare*, proceeded to Franz Josef Land in the summer of 1899. The ship was put into Teplitz Bay in Rudolf Land, where the expedition wintered. The side of the ship was crushed by the ice-pressure. Three sledge expeditions were sent north in the spring of 1900, and one of these, under Captain Cagni, reached 84° 33′ N. at about 56° E., being about 20 miles farther north than Nansen's farthest. It was found that the Petermann Land of Payer does not exist, and the same is believed to be the case with King Oscar Land. The *Stella Polare* was patched up, and in her the expedition reached Norway in the beginning of September. Three members of the expedition, returning from Captain Cagni's party, were never heard of. Lastly, Baron Toll in 1900 led an expedition to discover islands supposed to exist to the north of the New Siberia group.

(C. R. M.)

II. The Arctic Ocean.

According to its geographical position, the Arctic Ocean may be described as the sea situated north of the Arctic Circle; but, according to its natural configuration, we may more adequately say that it is the gulf-like northern termination of the long and relatively narrow Atlantic arm of the ocean which extends north between Europe on one side and America on the other; for by this situation as the northern bottom of such a long arm of the ocean its physical conditions are to a very great extent determined. This Arctic gulf is bounded by the northern coasts of Europe, Siberia, North America, the North American Arctic Archipelago, Greenland, and Iceland. The entrance to this typical gulf, the largest in the world, is the opening between Europe and Labrador divided by Iceland, Greenland, and the American Arctic islands; and its natural southern boundary would be the submarine ridge extending from Scotland and the Shetland Islands over the Faröe Islands and Iceland to Greenland, and continuing on the other side of Greenland across Davis Strait to Baffin Land. This ridge separates the depressions of the Arctic Ocean, filled with cold polar water at the bottom, from the deep depression of the North Atlantic. The Arctic Ocean communicates with the Pacific Ocean through Bering Strait, which is, however, only 49 miles broad and 27 fathoms deep. The area of the Arctic Ocean may be estimated to be about 3,600,000 square miles, of which nearly two-thirds (or 2,300,000 square miles) is continuously covered by floating ice.

The Arctic Ocean may be divided into the following parts:—(1) The *North Polar Basin* (including the Siberian Sea), bounded by the northern coasts of Siberia (from Bering Strait to the western Taimyr Peninsula), Franz Josef Land, Spitsbergen, Greenland, Grinnell Land, the Parry Islands, and Alaska; (2) the *Kara Sea*, between Novaya Zemlya and the Siberian coast, south of a line from the north point of the former to Lonely Island (Ensomheden) and Nordenskiöld Island; (3) the *Barents* and *Murman Sea*, bounded by Novaya Zemlya, Franz Josef Land, Spitsbergen, Bear Island, and the northern coasts of Norway and Russia; (4) the *Norwegian Sea*, between Norway, Spitsbergen, Jan Mayen, Iceland, and the Faröes; (5) the *Greenland Sea*, between Spitsbergen, Jan Mayen, Iceland, and Greenland; (6) *Baffin Bay* and *Davis Strait*, between Greenland, Ellesmere Land, North Devon, and Baffin Land.

Depths.—The Arctic Ocean forms an extended depression separating the two largest continental masses of the world—the European-Asiatic (Eurasia) and America. Along its centre this depression is deep, but along its whole margin, on both sides, it is unusually shallow—a shallow submarine plateau or drowned plain extending northward from both continents, forming the largest known continental shelf. North of Europe this shelf may be considered as reaching Spitsbergen and Franz Josef Land, extending over more than 10 degrees of latitude, although there is a somewhat deeper depression in between. North of Spitsbergen it reaches north of 81° N., and north of Franz Josef Land probably somewhat north of 82° N. North of Siberia the shelf is 350 miles broad, or more, with depths of 50 to 80 fathoms, or less. In longitude 135° E. it reaches nearly 79° N., where the bottom suddenly sinks to form a deep sea with depths of 2000 fathoms or more. Farther east it probably has a similar northward extension. North of America and Greenland the shelf extends into the unknown north. This shelf, or drowned plain, evidently marks an old extension of the continents, and its northern edge must be considered as the real margin of their masses, the coasts of which have probably been overflowed by the sea at some comparatively recent geological period. On this submarine plateau the Arctic lands are situated—Spitsbergen (with Seven Islands to the north, Bear Island and Hope Island to the south), Franz Josef Land, Novaya Zemlya, Lonely Island, the New Siberia Islands, Wrangel Island, the American Arctic Archipelago. The depth of the shelf is, especially north of Siberia, very uniform, and usually not more than 50 to 80 fathoms. North of Europe it is intersected by a submarine, fjord-like depression, or broad channel, extending eastward from the Norwegian Sea. Between Norway and Bear Island this depression is about 240 fathoms deep, and between Novaya Zemlya and Franz Josef Land 100 to 150 fathoms deep. It gives off several submerged fjords or channels towards the south-east into the shallow Murman Sea, *e.g.*, one channel, more than 100 fathoms deep, along the Murman coast towards the entrance of the White Sea; another narrow channel, partly 100 fathoms deep, along the south-west coast of Novaya Zemlya through the Kara Strait. It also extends into the Kara Sea, rounding the north point of Novaya Zemlya and forming a narrow channel along its eastern coast. Just east of Vaigatch Island there are sounded depths of nearly 400 fathoms. On the American side similar but much narrower submarine depressions, or we might here call them submarine fjords, extend from Baffin Bay into the continental shelf, northward through Smith Sound, Kane Basin, and Kennedy Channel, and westward through Lancaster Sound, &c.

The greatest depths in the Arctic Ocean have been found in the North Polar Basin, where depths of 2100 fathoms, in about 81° N. and 130° E., have been measured with certainty. It is deeper than 1650 fathoms along the whole route of the *Fram*, from about 79° N. and 138° E. to near Spitsbergen. In 84½° N. and about 75° E. the depth is 2020 fathoms, and in 83° N. and 13° E. it is 1860 fathoms. The northern and eastern extension of this deep basin is not known. It was formerly believed that still greater depths existed west of Spitsbergen, the so-called Swedish deep, where 2600 fathoms had been sounded, but the Nathorst Expedition in 1898 found no greater depths there than about 1700 fathoms. The Norwegian sea, farther south, is 2000 fathoms deep midway between Iceland and Norway, in about 68° N. This so-called Norwegian deep is, as before stated, separated from the North Atlantic basin by the shallow Wyville Thomson ridge and the Shetland-Faröe-Iceland ridge. Farther north there is a low transverse ridge extending eastward from Jan Mayen, in about 72° N., which is about 1300 fathoms deep. North of this the sea is again deeper—1985 fathoms in 75° N. From the north-west corner of Spitsbergen a submarine ridge extends in a north-westerly direction, with depths of about 430 fathoms in 81° N. and about 4° E. How far this ridge extends is unknown, and there is a possibility that it reaches Greenland, and thus separates the Swedish and the Norwegian deep from the deep depression of the North Polar Basin. Baffin Bay forms, probably, a relatively deep basin of about 1000 or 1200 fathoms, which is separated from the West Atlantic Basin by the shallow submarine ridge from Greenland to Baffin Land in about 65° or 66° N.

The *deposit* composing the bottom of the Arctic Ocean contains in its northern part, in the North Polar Basin, extremely little matter (shells) of organic origin. It is formed by mineral material, sandy clay of very fine grain, to an extent which is hardly found in any other part of the sea with similar depths. It contains only from 1 to 4 per cent. of carbonate of lime. Farther south, in the sea between Spitsbergen and Greenland, the amount of carbonate of lime gradually increases owing to the shells of foraminifera (especially biloculinæ); west of Spitsbergen we may already find the proportion above 20 or even 30 per cent., while more towards Greenland it is considerably lower.

The *circulation* of the Arctic Ocean may be explained firstly by the vertical and horizontal distribution of temperature and salinity (*i.e.*, density); secondly, by the influence of the winds, especially on the ice-covered surface. The currents in this sea may to a very great

Walker & Cockerell sc

extent be considered as convection currents. The water near the surface is cooled down by radiation of heat; it becomes heavier, sinks to the bottom, along which it creeps slowly southward, while it must be replaced on the surface by warmer water coming from the south. To replace the northward-flowing surface water, the cold, heavy bottom water must again rise towards the surface in more southern latitudes. On account of the rotation of the earth the northward-running water on the surface, as well as the sinking water, will be driven in a north-easterly or easterly direction, while the southward-flowing water along the bottom, as well as the rising water, is driven south-west or westward. This very simple circulation is, however, to a great extent complicated on one side by the irregular configuration of the sea-bottom, especially the transverse submarine ridges—*e.g.*, the Spitsbergen ridge, the Jan Mayen ridge, and the Shetland-Faröe-Iceland ridge; and on the other side by the circumstance that the upper water strata of the sea are comparatively light in spite of their low temperature. These strata, about 100 or 120 fathoms thick, are diluted by addition of fresh water from the North European, Siberian, Canadian, and Alaskan rivers, as well as by precipitation, while at the same time the evaporation from the surface of the mostly ice-covered sea is insignificant. The light surface strata will have a tendency to spread over the heavier water farther south, and thus the polar surface currents running southward along the east coasts of Greenland, Baffin Land, and Labrador are formed, owing their westerly course to the rotation of the earth. These currents are certainly to a great extent helped and increased by the prevailing winds of these regions. The winds have a firm hold in the rough surface of the floating ice, which, with its deep hummocks and ridges, acts as a good stirrer of the water, transferring the movement of the surface immediately down to at least 5 or 10 fathoms.

The chief currents running into the Arctic Ocean are the following :—

1. The *Gulf Stream*, or Atlantic drift, passing northeastward over the Shetland-Faröe-Iceland ridge, along the west coast of Norway, with one arm branching off eastward round North Cape into the Barents Sea, and another branch running northward along the margin of the shelf between Norway, Bear Island, and Spitsbergen, passing as a very narrow current along the west coast of the latter, over the Spitsbergen ridge (at its north-west corner), and into the North Polar Basin, where it flows gradually northward and eastward (on account of the rotation of the earth) below the cold but lighter layer, 100 fathoms thick, of polar water, and fills the whole basin below 100 or 120 fathoms to the bottom with Atlantic water.

2. The *Irminger current*, running north along the west coast of Iceland. One part branches off westward and southward again in Denmark Strait, following the Greenland polar current, whilst another part evidently dives under the polar current and runs as an under-current northward into the Greenland Sea, and partly also eastward and south-eastward to the north and east of Iceland.

3. An Atlantic current runs northward along the west coast of Greenland, passes the ridge across Davis Strait, and flows into Baffin Bay, forming its deeper strata below the polar water in a similar way to the Gulf Stream in the North Polar Basin. There is a possibility that some slight portion of this current even reaches the latter along the bottom of the deep channel through Smith Sound.

4. A small current running northward into the North Polar Basin through Bering Strait.

The Arctic Ocean receives also a contribution of fresh water from the rivers of northern Europe, Siberia, and America, as well as from the glaciers of Greenland and the precipitation over the whole area of the sea itself.

The chief currents running out of the Arctic Ocean are these :—1. The Greenland polar current, running southward along the east coast of Greenland, and dividing into two branches north of Iceland—(*a*) the east Greenland branch, passing south through Denmark Strait and rounding Cape Farewell; (*b*) the east Icelandic branch, running south-eastward between Iceland and Jan Mayen, towards the Faröes. It seems as if only a small portion of this current actually passes the Faröe-Icelandic ridge and reaches the Atlantic Ocean. The greater part is partly mixed with the water of the Gulf Stream and is turned by the latter in a north-easterly direction, forming a kind of eddy in the Norwegian Sea. 2. The Labrador polar current, formed by the water running south through Smith Sound, Lancaster Sound, and Jones Sound, as well as water from Baffin Bay, and also from the east Greenland current rounding Cape Farewell and crossing Davis Strait. 3. Along the south-east coast of Spitsbergen a polar current is also passing in a southwesterly or westerly direction past South Cape, where it meets the Gulf Stream. 4. A very small current probably also runs out along the western side of Bering Strait.

Temperature and Salinity.—While the temperature is comparatively uniform, with small variations, the difference in salinity between the upper and lower strata is greater than in most other parts of the sea. In the North Polar Basin the vertical distribution of temperature as well as salinity is very much the same in all places examined. Near the surface, from 0 down to 100 fathoms, the water is below freezing-point—with a minimum of between 28·75° (−1·8° C.) and 28·57° (−1·9° C.) at a depth of about 30 fathoms—and is much diluted with fresh water (see above), the salinity gradually increasing downward from about 29 or 30 per mille near the surface to nearly 35 per mille in 100 fathoms. Below 100 fathoms the temperature as well as the salinity gradually increases until they approach their maximum in about 160 or 200 fathoms, where the temperature varies between 32·5° (0·3° C.), north of the New Siberia Islands, and about 33·8° (1° C.), north of Franz Josef Land; and the salinity is about 35·2 and 35·3 per mille. From this depth the temperature gradually sinks downward; 32° (0° C.) is found at about 490 fathoms in the western part of the basin—*e.g.*, between about 84° N. 15° E. and 85½° N. 58° E.—while it is found in about 400 fathoms farther east—*e.g.*, in 81½° N. and 123° E. In depths between 1400 and 1600 fathoms the temperature has a second minimum between 30·6° (−0·8° C.) and 30·4° (−0·9° C.), below which depth the temperature again rises slowly, a few tenths of a degree towards the bottom. In all depths below 200 fathoms the salinity of the water remains very much the same, between 35·2 and 35·3 per mille, with very slight variations. This comparatively warm and saline water evidently originates from the branch of the Gulf Stream passing north across the submarine ridge from north-west Spitsbergen (see above). The vertical distribution of temperature and salinity is very much the same, summer and winter, throughout the North Polar Basin, except near the surface, which in summer is covered by a layer of fresh water arising from the melting of the snow-covered surface of the floe-ice. This fresh-water layer may attain a thickness of 5 or 6 feet between the floes. North of the Siberian coast the sea is, during summer, covered with a layer of warm water from the Siberian rivers, and the temperature of the surface may rise to several degrees above freezing-point.

In the Norwegian and Greenland Sea there are greater variations of temperature. Below a certain limit, which in the northern part (on the eastern side) is about 550 fathoms deep, and in the southern part between 300 and 400 fathoms deep, the whole basin of this sea is filled with water which has an unusually uniform salinity of about 35·05 per mille, and the temperature of which is below zero centigrade, gradually sinking downward from the above-mentioned limit, where it is 32° (0° C.); and down to 29·85° (−1·2° C.) or 29·65° (−1·3° C.) near the bottom in 1400 or 1600 fathoms. In the northern part of this sea the bottom temperature seems even to be about 29·5° (−1·4° C.) or 29·3° (−1·5° C.). The origin of this cold underlying water of such a remarkably uniform and comparatively low salinity is not quite clear. On one side, the salinity of this water is considerably higher than that of the equally cold water of the east Greenland polar current (see later); but on the other side it seems to be distinctly different from the hitherto known water filling the deep of the North Polar Basin, as it has a lower salinity and lower temperature; the known bottom temperature of the North Polar Basin being between 30·7° (−0·7° C.) and 30·4° (−0·9° C.), and the salinity about 35·2 or 35·3 per mille. This fact seems to indicate that there can be no direct communication between the deep depression of the North Polar Basin and the Norwegian-Greenland Sea, which are probably separated by a submarine ridge from the north-west corner of

Spitsbergen to Greenland. The cold bottom water of the Norwegian-Greenland Sea may to some extent arise from the cooling down of the Atlantic water of the surface during the winter; to some extent also by mixing with the cold but less saline water of the polar current. There is, however, also another possibility: that the bottom water of the North Polar Basin is colder and less saline in its more northern and western parts, which are still unknown, and that this water has communication with the bottom water of the Norwegian-Greenland Sea through a deep channel along the western side of the sea between Spitsbergen and Greenland.

The above-mentioned underlying layer of uniform cold water of the Norwegian-Greenland Sea is, along its eastern side, covered by the warm and saline water of the Gulf Stream flowing northward along the west coast of Norway, Bear Island, and Spitsbergen, and forming the upper strata of the sea about 300 to 500 fathoms deep. The maximum temperature of this water is on the surface about 46° (8° C.) to 50° (10° C.) west of northern Norway, and about 37° (3° C.) to 39° (4° C.) west of Spitsbergen. The salinity is generally about 35·2 or 35·3 per mille, varying between 35·1 and 35·5 per mille.

Along the western side of this sea, towards the east coast of Greenland, the underlying cold water is covered by the less saline water of the polar current, which in the upper strata of the sea, from the surface down to about 100 fathoms, has very much the same temperature and salinity as in the upper cold and less saline strata of the North Polar Basin. Near the east coast of Greenland, as far north as 74° 45′ N., a layer of comparatively warm and saline water, with a temperature of 32·7° (0·4° C.) and a salinity of 35·2 per mille, has been found (by the Ryder Expedition in 1891) below the cold and lighter polar water in a depth of 70 to 90 fathoms. This warmer undercurrent probably runs northward, being a continuation of the warm Irminger current passing north along the west coast of Iceland.

In *Barents Sea* the temperature and salinity are highest in the western part near Norway or between Norway and Bear Island, where the eastern branch of the Gulf Stream enters and where in summer the salinity generally is about or a little above 35 per mille from the surface down to the bottom, and the surface temperature generally is about 41° or 43° (5° C. or 6° C.), and the bottom temperature is above zero centigrade. The eastern part of Barents Sea is filled with water of a little lower salinity, often below 35 per mille—the deeper strata of which are very cold, with temperature even as low as 28·9° (−1·7° C.). The bottom temperature is everywhere in the eastern part below zero centigrade and generally below −1° C.

The *Kara Sea* is, near the surface, covered with a layer of cold water much diluted by the fresh water from the Siberian rivers, especially the Obi and the Yenisei. The salinity varies between 29 and 34 per mille; near the mouth of the rivers it is naturally much lower. The deeper western parts of Kara Sea are filled with unusually cold and more saline water, with a temperature of about 28·4° (−2° C.) and a salinity of about 34·9 per mille. This water is colder and more saline than the water at similar depths in the North Polar Basin, which indicates that there is no direct communication between the deeps of the two basins.

The vertical distribution of temperature and salinity in *Baffin Bay* seems to be very similar to that of the North Polar Basin, with a cold but less saline upper stratum of water—with a minimum temperature of about 28·9° (−1·7° C.)—and a warmer and more saline deeper stratum from 100 or 200 fathoms downward, with a maximum temperature of 33·6° (0·9° C.) in about 200 fathoms, and the temperature slowly decreasing towards the bottom.

The Ice.—As before mentioned, at least two-thirds of the Arctic Ocean is constantly covered by drifting ice. This ice is mostly formed on the surface of the sea itself by freezing, the so-called floe-ice or sea-ice. A small part is also river-ice, formed on the rivers, especially the Siberian, and carried into the sea during the spring or summer. Another comparatively small part of the ice originates from the glaciers of the Arctic lands. These pieces of glacier-ice or icebergs are, as a rule, easily distinguished from the floe-ice by their size and structure. They occur almost exclusively in the seas round Greenland, where they originate from the glaciers descending into the sea from the inland ice of Greenland. Some small icebergs are also formed in Franz Josef Land, Spitsbergen, Novaya Zemlya, Grinnell Land, &c., but they are comparatively insignificant, and are not as a rule carried far from the coasts. Sea-ice or floe-ice is formed during the autumn, winter, and spring, especially in the North Polar Basin, but also in Kara Sea, a greater part of Barents Sea, the northernmost part of the Norwegian Sea (near Bear Island and towards Jan Mayen), Greenland Sea, and Baffin Bay. The floe-ice does not, as a rule, grow thicker than 7 or 8 feet in one year, but when it floats in the water for some years it may attain a thickness of 16 feet or more directly by freezing. By the constant upheaval from pressure much greater thicknesses are attained in the piled-up hummocks and rubble, which may be 20 to 30 feet high above the water when floating. During the summer the floe-ice decreases again by melting, partly on the surface owing to the direct radiation of heat from the sun, partly on the under side owing to the higher temperature of the water in which it floats. The first kind of melting is the prevailing one in the North Polar Basin, while the latter kind occurs in more southern latitudes. The floe-ice is constantly more or less in movement, carried by winds and currents. The changing wind, or also to a great extent the changing tide current, causes diverging movements in the ice by breaking it into larger or smaller floes. When these separate, lanes and channels are formed; when they meet, ice-pressures arise, and the floes are piled up to form hummocks or ridges, and thus the uneven polar ice arises. In the North Polar Basin the floe-ice is slowly carried by the prevailing winds and the currents in an average direction from Bering Strait and the New Siberia Islands, north of Franz Josef Land and Spitsbergen, more or less near the North Pole, towards the Greenland Sea and southward along the east coast of Greenland. Such a drift of an ice-floe from the sea north of Bering Strait to the east coast of Greenland probably takes, as a rule, four or five years, and the floes found in this part of the sea are not, therefore, generally older. How the drift of the ice is on the American side of the North Polar Basin is little known. But here it is probably more or less blocked up in its southward drift by the islands of the American Arctic Archipelago, and the ice-floes may thus grow very old and thick. The southward distribution of the drifting floe-ice (the pack ice) in Barents Sea, Norwegian-Greenland Sea, and Davis Strait, may differ much from one year to another, and these variations are evidently due to more or less periodical variations in the currents and also the directions of the prevailing winds. In most places the ice has its most southerly distribution during the late winter and spring, while the late summer and autumn (end of August and September) is the most open season.

Biological Conditions.—The development of organic life is comparatively poor in those parts of the Arctic Ocean which are continuously covered by ice. This is, amongst other things, proved by the bottom deposits, which contain exceptionally little carbonate of lime of organic origin. The reason is evidently that the thick ice prevents to a great extent the development of plant life on the surface of the sea by absorbing the light; and as the plant life forms the base for the development of animal life, this has also very unfavourable conditions. The result is that—*e.g.*, in the interior of the North Polar Basin—there is quite exceptionally little plant life in the sea under the ice-covering, and the animal life both near the surface and in deeper strata is very poor in individuals, whilst it is comparatively rich in species. Near the outskirts of the Arctic Ocean, where the sea is more or less open during a greater part of the year, the pelagic plant life as well as animal life is unusually rich, and, especially during the early summer, there is often here such a development of plankton (*i.e.*, pelagic life) in the sea-surface as is hardly found in any other parts of the ocean. It seems as if the polar water has specially favourable conditions for the development of the pelagic plant life, which makes the flora, and consequently also the fauna, flourish as soon as the ice-covering disappears and the water surface is exposed to full sunlight. At the same time the temperature of the water also rises, and thus the conditions for the chemical changes of matter and the nutritive assimilation are much improved. The Arctic Ocean, or more especially the North Polar Basin, might thus be considered as a lung or reservoir in the circulation of the ocean where the water produces very little life, and thus, as it were, gets time to rest and accumulate those substances necessary for organic life, which are everywhere present only in quite minimal quantities. It is also a remarkable fact of interest in this connexion, that the greatest fisheries of the world seem to be limited to places where water from the Arctic Ocean and from more southern seas meet—*e.g.*, Newfoundland, Iceland, Lofoten and Finmarken in Norway.

The mammal life is also exceptionally rich in individuals along the outskirts of the Arctic Ocean. We meet there, especially along the margin of the drifting ice, the enormous quantities of seals of various kinds, as well as whales, which live on the plankton and the fishes in the water. A similar development of mammal life is not met with anywhere else in the ocean, except perhaps in the Antarctic Ocean and Bering Sea, where, however, similar conditions are present. In the interior of the Arctic Sea or the North Polar Basin the mammal life is very poor, and consists mostly of some straggling polar bears, probably occasionally wandering everywhere over the whole expanse of ice; some seals, especially *Phoca fœtida*, which has been seen as far north as between 84° and 85° N.; and a few whales, especially the narwhal, which has been seen in about 85° N.

The bird life is also exceptionally rich in the outskirts of the Arctic Ocean, and the coasts of most Arctic lands are every summer inhabited by thousands and millions of sea-birds, forming great colonies almost on every rock. These birds are also dependent for their living on the rich plankton on the surface of the sea. In the interior of the Arctic Ocean the bird life is very poor, but straggling sea-birds may probably be met with occasionally everywhere during summer-time, even over the whole North Polar Basin.

III. ANTARCTIC REGIONS.

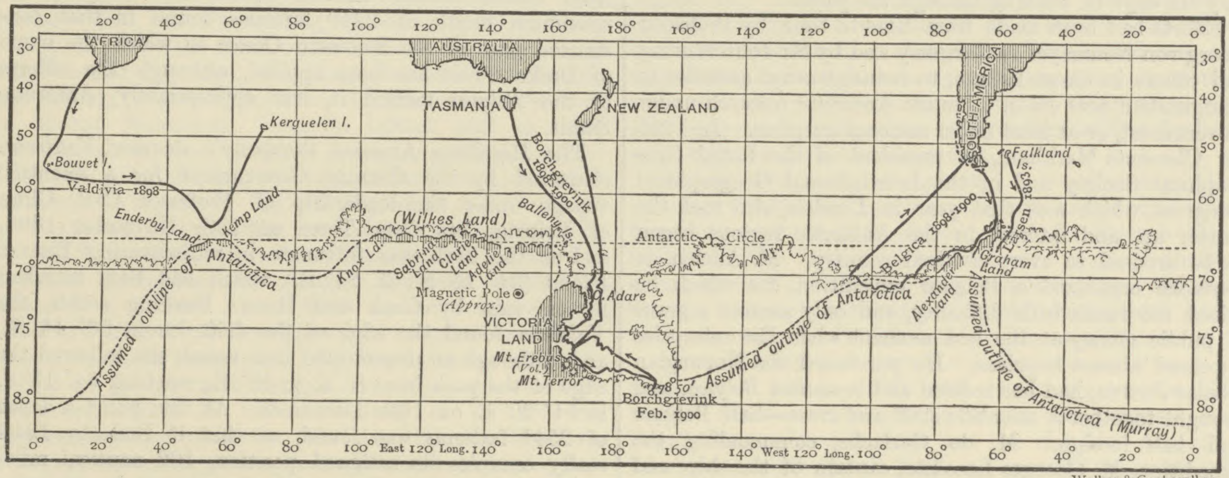
Strictly speaking, the Antarctic Regions are the portion of the Earth's surface lying south of the Antarctic circle, but it is usual to extend the term so as to include that part of the surrounding ocean which is influenced by Antarctic drift ice. The limits cannot be exactly defined. The long-cherished belief in a great Antarctic continent which extended into temperate and even tropical latitudes was disproved by Captain Cook in his second voyage of circumnavigation, and the fact was clearly established before 1839 that any southern land which may exist only extends appreciably beyond the Antarctic circle in one place—to the south of South America. The voyage of Weddell in 1824 to 74° 15′ in 34° 17′ W., and that of Ross in 1841–42 to

78° 10′ in 161° 27′ E., proved that navigable water extended into high latitudes on opposite sides of the polar circle.

Recent Exploration.—The first steamer to cross the Antarctic circle was H.M.S. *Challenger* on 16th February 1874: she only penetrated to 66° 40′ S., in 78° 30′ E., south of Kerguelen Island; but she continued her course to Australia for some distance in a high latitude, passing within 15 miles of the position assigned to Wilkes's Termination Land without seeing any sign of land. Her dredgings and soundings yielded indirect evidence as to the nature of the unknown region farther south. Sir John Murray believed that the soundings showed a general shoaling of the ocean towards the Antarctic ice, indicating the approach to a continent. By collecting and analysing all samples of deep-sea deposits which had been secured from the far south, he discovered a remarkable symmetry in the arrangement of the deposits. The globigerina ooze, or in deeper waters the red clay, carpeting the northern part of the Southern Ocean, merges on the southward into a great ring of diatom ooze, which gives place in turn, towards the ice, to a terrigenous blue mud. The fine rock particles of which the blue mud is composed are such as do not occur on oceanic islands, and the discovery of large blocks of sandstone dropped by icebergs proved the existence of sedimentary rocks within the Antarctic circle. The marine fauna discovered by the *Challenger* contained many species very similar to those common in the Arctic regions, if not identical with them. The suggestion of identical forms occurring in the two polar areas, and absent from the intervening seas, has given rise to a lively discussion amongst biologists.

During the southern summer in which the *Challenger* visited Antarctic waters, a German whale-ship, the *Grönland*, under Captain Dallmann, visited the western coast of the Antarctic land south of Tierra del Fuego, and rectified the chart in several particulars. The chief discovery was a channel, named Bismarck Strait, in 65° S., which seemed to run between Palmer Land and Graham Land.

When the International Circumpolar observations were set on foot in 1882, two scientific stations were maintained for a year in the southern hemisphere in order to obtain data for comparison with the observations at twelve stations round the North Pole. One of these was occupied by French observers in Tierra del Fuego in 55° S., the other by German observers at Royal Bay on South Georgia in 54° 30′ S. The magnetic and meteorological observations were of considerable importance.



Walker & Cockerell sc.

Sketch Map of the Antarctic Regions, showing Tracks of Recent Expeditions.

In 1892 four steamers of the Dundee whaling fleet—the *Balæna*, *Active*, *Diana*, and *Polar Star*—went out to test Ross's statement that the "right whale" inhabited Antarctic waters. The surgeons of two of the vessels—on the *Balæna* Mr W. S. Bruce, on the *Active* Dr C. W. Donald—were selected at the instance of Mr Leigh Smith and the Council of the Royal Geographical Society for their scientific tastes, and equipped with all requisite instruments for observations and collecting. The result of the experiment was disappointing. No whales were obtained, and all the ships devoted their attention to sealing on the east of Joinville Island and Louis Philippe Land, not going farther south than 65° S., although the floes were found fairly open, with numerous water channels. Some small changes were made on the chart, and the few opportunities which were permitted for scientific work were taken advantage of by the surgeons (*Geographical Journal*, vii., 1896, pp. 502–521, 625–643). The experiment has not been repeated by British ships.

During the summer of 1892–93 a Norwegian sealer, the *Jason*, Captain Larsen, also visited those seas, but did not go farther than about 65° S. The captain landed and collected fossils at several points. In 1893–94 the *Jason*, accompanied by two other Norwegian vessels, the *Hertha* and the *Castor*, returned to the Antarctic and entered the ice-laden waters in November at the very beginning of summer. Captain Larsen in the *Jason* made his way as far south as 68° 10′ in 60° W. on the eastern side of Graham Land, but several miles from the coast, which was bordered by a high ice-barrier. The most prominent headland, in 66° S., was named Cape Framnes. Returning northwards, two small islands, Lindenberg and Christensen, were discovered and found to be active volcanoes. Meanwhile the *Hertha*, Captain Evensen, had reached the South Shetlands on 1st November 1893, and worked her way southward along the west side of Palmer Land and past the Biscoe Islands, reaching the Antarctic circle on 9th November without meeting ice. This was the first time the Antarctic circle had been crossed since the *Challenger* did so twenty years before. Captain Evensen sighted Alexander Land, but did not follow the coast to find whether it is continuous with Graham Land; and without experiencing any trouble from ice-floes he reached his farthest south, 69° 10′ S. in 76° 12′ W. (*Mittheilungen der Geographischen Gesellschaft*, Hamburg, 1895, pp. 245–304). After visiting Tierra del Fuego, both the *Jason* and the *Hertha* returned to Antarctic waters towards the end of January, but went no farther than Joinville Island, and then sailed for Europe.

In 1894 the well-known Norwegian whaler, Svend Foyn, sent out one of his vessels, the *Antarctic*, Captain Christensen, to try his luck off the coast of Victoria Land. The *Antarctic* sailed from Melbourne in September, having on board C. E. Borchgrevink, a young Norwegian resident in Australia, who, being determined to take part in a voyage he could join in no other way, shipped as an ordinary seaman. He made notes of the voyage, and published an account of it on his return to Europe (*Report of Sixth International Geographical Congress*, London, 1895, pp. 169–175). The *Antarctic*, after being compelled to put back for repairs, left Stewart Island, New Zealand, on 28th November 1894, and entered the pack in 62° 45′ S., 171° 30′ E., on 8th December. The Balleny Islands were sighted on 14th December, and Cape Adare on Victoria Land two days later. On 22nd January 1895 the farthest point was reached at Coulman Island in 74° S.; the sea was then easily navigable to the south. On 23rd January a small party, including the captain and Mr Borchgrevink, landed on the mainland near Cape Adare, the first people to set foot on what is probably the Antarctic continent. On the return voyage the ship was only six days in working through the pack.

Efforts had been made from time to time, by Professor Georg von Neumayer in Germany and by Sir John Murray and others in Great Britain, to induce learned societies to inaugurate a new era of scientific Antarctic research under Government, or at least under national auspices. In 1895 Sir Clements Markham, as president of the Royal Geographical Society and of the International Geographical Congress, which met that year in London, also took the matter up, and interest in the Antarctic regions began to be aroused in every civilized country. M. Adrien de Gerlache organized a Belgian expedition, for which he raised the funds with difficulty, and only secured a grant of public money at the last moment when the enterprise appeared almost hopeless. He purchased the Norwegian whaler *Patria*, had her refitted and re-named *Belgica*, and brought together a scientific staff and crew—half Belgian and half foreign. M. de Gerlache, commanding the expedition, M. Georges Lecointe, captain of the ship, and Lieutenant Danco, magnetic observer, were Belgians; Mr Amundsen, the mate, a Norwegian; M. Arçtowski, the geologist and physicist, a Pole; M. Racovitza, the biologist, a Rumanian; and Dr F. A. Cook, the surgeon, an American. The *Belgica* sailed from Antwerp on 16th August 1897, but it was 14th January 1898, already long past midsummer, before she left Staten Island for Antarctic waters. She sighted the South Shetlands on the 21st, and proceeded to Hughes Gulf, from which a channel was explored leading south-westward between continuous land, named Danco Land, on the east (possibly the northern extension of Graham Land), and Palmer Land on the west. Palmer Land was found to be a group of large islands. Both coasts of Belgica Strait, as the new channel was named, were surveyed and twenty landings made, so much time being occupied that it was 12th February when the *Belgica* re-entered the open sea to the west at Cape Tuxen in 65° 15′ S. A large bay opening eastward was so encumbered with ice that it was impossible to find whether or not it led to Bismarck Strait. Much fog was experienced, but on the 16th Alexander Land was sighted in the distance. Continuing on a westerly course, the *Belgica* made every effort to enter the pack, which was successfully accomplished after a heavy storm on the 28th. By taking advantage of the leads, the expedition advanced to 71° 30′ S. in 85° 15′ W. by 2nd March, but the ship was blocked next day by the growth of young ice soldering the pack into one continuous mass. For more than a year further independent movement was impossible; but the ship drifted with the ice between the limits of 80° 30′ W. and 102° 10′ W., and of 69° 40′ and 71° 35′ S., which was the highest latitude attained (31st May 1898). The sun did not rise for seventy days, and all on board suffered severely from depression of spirits and disorders of the circulation, which Dr Cook attributes to the darkness and to improper food. Lieutenant Danco died during the period of darkness. On 13th March 1899, when a second winter in the ice began to seem probable, the *Belgica* was released in 69° 50′ S. and 102° 10′ W. (*Bulletin de la Société Royale Belge de Géographie*, 1900, *passim*). The geographical results of this expedition were insignificant so far as the discovery of land or penetration to a high latitude is concerned. The ship passed several times to the south and west of Peter I. Island, proving that the land seen by Bellingshausen at that point is of very limited extent. During the drift in the ice the soundings were usually between 200 and 300 fathoms, which, compared with the great depths to the north, clearly indicated a continental shelf of considerable breadth, probably connected with land in the south (*Geographical Journal*, xiv., 1899, pp. 77–82). A line of soundings was carried from Staten Island to the South Shetlands, and a maximum depth of 2210 fathoms found in that constricted part of the Southern Ocean to which the name of Drake Strait has been applied, although the officers of the *Belgica* termed it, less appropriately, Antarctic Strait.

The Hamburg America Company's steamer *Valdivia*, chartered by the German Government for a scientific voyage under the leadership of Professor Carl Chun of Leipzig, left Cape Town on 13th November 1898, and on the 25th was fortunate in rediscovering Bouvet Island (54° 26′ S., 3° 24′ E.), which had been searched for in vain by Cook and Ross. Steering south, the *Valdivia* found the edge of the drift ice in 56° 45′ S., and, although an unprotected iron vessel, she followed the edge of the pack from 8° E. to 58° E., reaching 64° 15′ S. in 54° 20′ E. on 16th December. At this point a depth of 2541 fathoms was found, so that if Enderby Land really occupies its assigned position, 102 nautical miles farther south, the sub-oceanic slope must be of quite unusual steepness. The rocks dredged up contained specimens of gneiss, granite, and schist, and one great block of red sandstone weighing 5 cwt. was secured, confirming the theory of the continental nature of the land to the south. From her farthest point the *Valdivia* returned northward *viâ* Kerguelen Island. Although only an incident in a voyage from the Cape to Kerguelen, this trip allowed of twenty-nine deep-sea soundings being made south of 50° S., where only fifteen had been recorded before. The general depth of the Southern Ocean proved to be much greater than had been formerly supposed, the greatest depth being 3155 fathoms in 58° S. No conclusion as to the existence of an Antarctic continent could be drawn from the soundings south of 55° S. between 0° and 50° E. (For abstract of observations, see *Geographical Journal*, xv., 1900, pp. 518–528; and for fuller report *Zeitschrift der Gesellschaft für Erdkunde zu Berlin*, xxxiv., 1899, pp. 75–192.) The physical and biological conditions of the water and the nature of the ice were very carefully investigated.

On his return to England in 1895 Mr C. E. Borchgrevink made strenuous efforts to organize an Antarctic expedition under his own leadership, and in August 1898 he left the Thames on the *Southern Cross*, a Norwegian whaler formerly known as the *Pollux*, in charge of a private expedition equipped by Sir George Newnes. His scientific staff included Lieutenant Colbeck, R.N.R.; Mr Louis Bernacchi, a trained magnetic observer; Mr N. Hanson and Mr H. Evans, biologists; and Dr Klövstad. About fifty dogs were taken out, the intention being to land at Cape Adare and advance towards the magnetic, and perhaps also towards the geographical, pole by sledge. The *Southern Cross* reached the edge of the ice in 52° S. and 154° E. on 30th December 1898; one of the Balleny Islands was sighted on 14th January 1899, and after in vain attempting to get south about the meridian of 164° E., the ship forced her way eastward and emerged from the pack (after having been beset for forty-eight days) in 70° S., 174° E. She reached Cape Adare, and anchored in Robertson Bay on 17th February. The land party, consisting of ten men, was established in a house built on the strip of beach at the base of the steep ascent to the mountains, and the ship left on 2nd March. Mr Borchgrevink found it impossible to scale the slopes to the snow-fields, which he believed to occupy the surface of a great plateau in the interior, and the party, except for short trips along the shore or on the sea-ice, spent the year of their sojourn—the first year ever passed by man on Antarctic land—in making natural history collections and keeping up meteorological and magnetic observations. The *Southern Cross* returned to Cape Adare on 28th January 1900, and after taking the winter party on board —diminished by the death of Mr Hanson—set out for the south on 2nd February. Landings were made on Possession Island, Coulman Island, on the mainland at the base of Mount Melbourne, Franklin Island, and on 10th February at the base of Mount Terror, near Cape Crozier. From this point the ship steamed eastward along the great ice-barrier to a point in 164° 10′ W., where an inlet in the ice was found, and the ship reached her highest latitude, 78° 34′ S., on 17th February. The edge of the ice was found to be farther south than it had been when Ross visited it in 1842. About 5000 square miles of open water are shown on Borchgrevink's map, where Ross's showed the solid ice-barrier. Mr Borchgrevink was able to land on the ice with sledges and dogs, and advanced southward about 16 miles, reaching in 78° 50′ the farthest south yet attained. On the 19th the *Southern Cross* started on her return, and, without encountering any pack ice, reached Stewart Island, New Zealand, on 30th March (*Geographical Journal*, xvi., 1900, pp. 381–414).

In the autumn of 1901 three well-equipped expeditions left Europe for Antarctic exploration. The British National Antarctic expedition was organized by a joint committee of the Royal Society and the Royal Geographical Society, and equipped under the superintendence of Sir Clements Markham. One half of the cost was borne by the Government, the rest mainly by Mr Ll. W. Longstaff, who provided £30,000, the Royal Geographical Society, and Mr A. C. Harmsworth. A strong wooden ship of about 700 tons register (1700 tons displacement) was built at Dundee, and named the *Discovery*. She was barque-rigged, with auxiliary engines, and amidships entirely non-magnetic, so that magnetic observations might be carried on without interference from local attraction. The vessel was equipped with all necessary scientific apparatus, and the expedition sailed under the command of Commander R. F. Scott, R.N., with Lieutenant Armitage, R.N.R., as second in command, Lieutenants Royds and Barne, R.N., Lieutenant Shackleton, R.N.R., and Mr Skelton, R.N. The crew of forty men were almost entirely sailors of the Royal Navy. The scientific staff included Dr Koettlitz, who had shared with Mr Armitage in the Jackson-Harmsworth Arctic expedition; Mr Louis Bernacchi, who had sailed with Mr Borchgrevink in the *Southern Cross*; Dr Wilson, Mr Hodgson, and Mr Ferrar. The scientific director, Mr George Murray, accompanied the vessel to Cape Town, and Dr H. R. Mill also went part of the way as instructor in oceanography. The *Discovery* left Cowes on 6th August 1901 and Simon's Bay on 14th October, and on the voyage to New Zealand entered the ice-pack and reached 62° 50′ S., 139° 40′ E., where a sounding of 2300 fathoms was obtained. She reached Lyttelton on 28th November, and finally, having embarked a number of dogs, she sailed from Port Chalmers for Victoria Land on 24th December.

The German expedition sailed from Kiel on 11th August 1901 in the *Gauss*, a vessel similar in size to the *Discovery*, and similarly equipped for scientific work, though of a different model and sail plan. The commander of the expedition was Professor Erich von Drygalski, of the University of Berlin, and he was supported by an able scientific staff of four specialists. The sailing-master, Captain Ruser, and crew were of the merchant service, although the vessel, unlike the *Discovery*, carried the naval flag. The *Gauss* reached Cape Town on 23rd November, and sailed for Kerguelen a few days later, taking in stores at that island, and departing southwards at the end of January 1902, with the object of penetrating the absolutely unknown part of the Antarctic area in the neighbourhood of Enderby Land. Simultaneous meteorological and magnetic observations were arranged to be carried out on both vessels and at a land station which has been established at Kerguelen Island, and the two expeditions, although entirely distinct, acted in perfect harmony. Magnetic and meteorological observations were also arranged for comparison at Lyttelton in New Zealand, and at Staten Island in Argentina.

Dr Otto Nordenskjöld organized a Swedish expedition on board the whaler *Antarctic*, Captain Larsen, and sailed from Falmouth on 26th October 1901 for Buenos Aires; he left on 24th December, bound for the coast of Graham Land, where he was landed with a wintering party in order to carry out exploration and scientific observations simultaneously with the British and German expeditions.

Arrangements were completed for two additional expeditions to sail in 1902, each employing an old Norwegian whaling vessel purchased for the purpose. The Royal Geographical Society sent out the *Morning* under Lieutenant Colbeck, R.N.R., as a relief ship to the *Discovery*; she sailed from the Thames on 9th July. Mr W. S. Bruce, who had experience of both Antarctic and Arctic exploration, completed the plans of a Scottish expedition under his command in the *Hecla*, which was greatly strengthened and refitted at Troon and renamed the *Scotia*. Captain Thomas Robertson went as master of the ship. Mr Bruce proposed to turn his attention to Weddell Sea.

The full results of the work of the *Belgica*, *Valdivia*, and *Southern Cross* were not available at the time of writing; but the preliminary observations convey much new information, especially with regard to climate.

Land.—No new land has been discovered south of the Antarctic circle, if we except the southern prolongation of what is probably the east coast of Graham Land, reported by Larsen. The observations of the *Belgica* increase the probability that the land known to exist to the south of South America is an archipelago, the islands being perhaps locked together by ice in the south. The relatively shallow water in which the *Belgica* drifted when fast in the floe indicates an extensive land or numerous islands of a continental character to the south on that side, while the very deep water found by the *Valdivia* to the north of Enderby Land appears to justify the supposition that the sea penetrates far to the south in that region. Active volcanoes have been seen both in the Graham Land and Victoria Land areas, and there is some probability that violent earthquakes are occasionally experienced. It has been suggested that the great increase in the amount of drift-ice from the Antarctic, and in the size of the bergs, observed in the period 1891–96, was due to the disruption by earthquakes of vast masses from the seaward ends of the Antarctic ice-sheet. Borchgrevink's observation of the apparent retreat of the southern ice-barrier is in accordance with this view. The hypothesis of a great Antarctic continent or continental archipelago continuously covered by an ice-sheet is confirmed by the observations of recent expeditions, but the evidence is not yet direct or conclusive.

Land-Ice.—The ice-barriers which have been seen extending for hundreds of miles along the coast of Antarctic lands, and reaching the height of from 100 to 200 feet, have hitherto been viewed as the seaward face of a vast ice-sheet or confluent glacier, the only analogous phenomena in the north being the great glaciers of northern Alaska. Mr Bernacchi, however, suggests that they may be the sides of great spurs of ice projecting at right angles from the land. The ice wall at the place of its greatest extension in Victoria Land is evidently afloat, for deep soundings have been obtained near the edge, but it is probably in continuous contact with the land. Borchgrevink advanced about 16 miles on it, and found a rising gradient all the way; but he does not report a crevassed zone, which analogy with Greenland would lead us to expect. East of Mounts Erebus and Terror, Ross reported that the ice-barrier was from 180 to 200 feet high; but Borchgrevink assigns to it only a height of 60 or 70 feet, and at the place where he landed the ice was only 3 feet above the sea. The fact that flat-topped icebergs of enormous dimensions, such as could only be produced by ice faces similar to that of Victoria Land, are found in large numbers wherever the Antarctic region has been approached, makes it probable that an ice-barrier girdles the Earth some short distance within the Antarctic circle. M. Arçtowski points out, with regard to the land bordering Belgica or Gerlache Strait, that small icebergs are formed from the ice-foot produced by the regelation of ice which has fallen from the glaciers on the upper part of the steep slopes.

Sea-Ice.—The pack formed of sea-ice and fragments of bergs appears to surround the Antarctic circle as a floating breakwater, and open water sometimes occurs to the south of it. So far as already known, this is the case only off the east coasts of land projecting northward from the unknown region; at least, it is only in such positions that latitudes beyond 72° S. have been reached, and farther to the east sea-ice has prohibited the advance of ships both in Ross Sea and Weddell Sea. The Antarctic pack differs from that of the Arctic region chiefly in the large number of bergs and fragments of hard land-ice frozen up in it, this unequal structure increasing the dangers of ice navigation. The northern edge of the pack appears to lie nearly along the parallel of 60° S. in summer; its position in winter is unknown. Drift-ice, consisting mainly of large, flat-topped bergs, is usually met with in the Southern Ocean at all times of the year south of 50° S., but most abundantly in the months of November and December (the southern summer), and least frequently between April and July. The drift-ice comes farthest north on the Atlantic side; an occasional berg may be sighted off the Cape of Good Hope, and the extreme limit at which ice has been seen was 26° 30′ S. in the very centre of the Atlantic in April 1894.

Magnetism and Aurora.—Mr Borchgrevink was led by the magnetic observations taken by Lieutenant Colbeck and Mr Bernacchi to assign to the magnetic pole the position of 73° 20′ S. and 146° E. The observations at Cape Adare, however, were rendered unsatisfactory by the local attraction exercised by the masses of volcanic rocks in the neighbourhood, and by frequent magnetic storms, the difference between the maximum and minimum declination in a single day sometimes amounting to 3°. Magnetic observations were made from the *Belgica* on the ice-floe, but the want of stability of the ice made the work difficult. During the drift of the *Belgica* the aurora was observed with great attention during the period 11th March to 10th September, when there was no daylight or strong twilight, although the cloudiness of the sky only allowed it to be seen on sixty-two occasions. A diurnal period was observed, the maximum intensity occurring between 9 and 10 P.M. The brilliance and variety of the display were less marked in July than in the other months. The commonest form was a luminous arch, the culminating point of which almost always bore S.S.W.; the arch did not attain so great an altitude at the solstice as at the equinoxes, the auroral phenomena appearing to retire towards the magnetic pole in midwinter. (H. Arçtowski, *Geographical Journal*, xvi., 1900, pp. 92–94.) At Cape Adare the aurora was observed "nearly every night," the prevailing form being a luminous arch, the centre of which always lay to the north, never to the south. This would appear to indicate an unsymmetrical distribution of the aurora with regard to the pole. The period of diurnal maximum was between 8 and 9 P.M., and here also the annual minimum seemed to occur at midwinter.

Climate.—The summer climate of the Antarctic region has long been known to be extremely cold and ungenial. Bruce on the *Balæna* found the average temperature during the three summer months of 1892–93 to be rather under 31° F. for latitude 62° S. The actual figures were December 31·1°, January 31·1°, February 29·6°. The following table shows the monthly mean temperatures observed on the *Belgica* west of Graham Land in the pack about latitude 70° S. (H. Arçtowski, *Geographical Journal*, xiv., 1900, p. 417), and of Borchgrevink's expedition at Cape Adare in latitude 71° S. (C. E. Borchgrevink, *Geographical Journal*, xvi., 1900, p. 405):—

Average Temperature in the Antarctic Regions.

	W. of Graham Land, 1898–1899. March 1898 to February 1899. Means of hourly observations.			Cape Adare, 1899–1900. February 1899 to January 1900. Means of daily maximum and minimum.		
	Mean.	Max.	Min.	Mean.	Max.	Min.
January	29·8	...	17·4	33·0	48·9	22·5
February	30·2	...	14·7	(26·4)	...	...
March	15·6	...	− 4·5	17·7	31·1	− 2·5
April	10·8	...	−15·7	10·3	30·0	−10·0
May	20·3	...	−13·4	− 4·6	23·2	−31·1
June	4·1	...	−22·0	−11·8	14·1	−36·0
July	−10·3	...	−34·8	− 8·6	23·8	−39·9
August	11·7	...	−21·3	−13·4	18·9	−43·1
September	− 1·3	...	−45·6	−11·9	11·5	−36·1
October	17·8	...	−15·3	− 1·8	19·6	−35·5
November	19·6	...	− 6·5	17·8	45·7	− 4·0
December	28·0	...	5·9	31·8	42·2	20·4
Year	14·7	...	−45·6	7·0	48·9	−43·1

The temperatures in the pack were, as might be expected, less extreme than those on the land, and subject to great variations as the wind blew from the ice on the south or from the open ocean on the north. The temperature found by the *Belgica* for August is remarkably high, so high that it is advisable to say that it is +11·7° F., not a slip for −11·7°. The summers are remarkably cold, the winters by no means extraordinarily so. Indeed, the severity of the climate at Cape Adare seems to be due to the fact that the mean temperature remained below zero Fahrenheit for six consecutive months; the minima were not lower than occur every year in lower latitudes in central Canada and Siberia. At the southern ice-barrier a minimum of −12° was found by Borchgrevink in February, during the height of summer. A rise of temperature was found to be a sure indication of an approaching storm; at Cape Adare the thermometer was more sensitive than the barometer in prognosticating gales.

Pressure and Wind.—The barometric observations at Cape Adare are not available for discussion, but the maximum observed was 30·182 inches and the minimum 27·860 inches. On the *Belgica* the mean pressure for the year was 29·319 inches. The maximum pressure observed was 30·400 and the minimum 28·022. The isobaric charts compiled from all previously existing data show the isobar of 29·30 running slightly to the north of 60° S.; and as the same pressure occurs again in 70° S., it seems fair to infer that the belt of minimum mean pressure lies somewhere about 65° S., and that higher pressures will be found farther south. A belt of comparative calm appears to lie between the "roaring forties" and the tempestuous margin of the Antarctic continent. This was particularly noticed by the *Valdivia*. The record kept on the *Belgica* showed that the number of hours when the wind blew from southerly or easterly directions was slightly less than from northerly or westerly directions; in other words, the probability appeared to be slightly greater that the pressure was, on the whole, lower to the south than to the north. However, the vessel was drifting over a considerable area during the time of observation, and there was also a well-marked seasonal range. Westerly winds predominated in winter (June to August), and easterly winds in summer (December to February); the northerly and southerly components show no clear seasonal range, and are nearly equal in frequency. The weather as a whole was due to a succession of cyclones. At Cape Adare winds from southerly directions predominated, and especially heavy gales from E.S.E., affording some evidence of a permanent south polar anticyclone. As the latitude differs but slightly from that of the mean position of the *Belgica*, it would seem that the anticyclone lay towards the Victoria Land side; and this in turn suggests that the main body of the land lies in that direction, an inference supported by the temperature observations also. But the records of a single year do not allow of any definite conclusions being arrived at; they furnish at most a legitimate basis for tentative hypotheses. At both positions terrific storms of wind were very frequent, making the cold unbearable while they lasted. These are probably due to the proximity of the relatively warm sea to the cold ice or land, and it is probable that farther in the interior there will be a region of relative calm, although of lower temperature.

Precipitation.—Frequent mists and snow squalls have been reported by all voyagers in the Antarctic seas, even in the height of summer. The immense thickness of snow necessary to form the Antarctic icebergs presents a problem of great difficulty. If the prevailing winds were northerly, a heavy precipitation would be a natural consequence; but if there is an anticyclone over the land, giving rise to prevailing southerly winds, the source of moisture is a mystery. A ring of high pressure near the Antarctic circle, surrounding a low pressure area lying over an open polar sea, might account for observed facts; but there are no observational data for or against this fancy.

Flora and Fauna.—Terrestrial flora and fauna have been discovered on Victoria Land and in the Palmer Archipelago, but both are very limited. Borchgrevink reports five species of lichens, including the ordinary reindeer moss. Lichens were found as far south as 78° S. Insects of three species were discovered, all very minute, but capable of being detected by the naked eye as they moved about on the lichen. The *Belgica* found a more extensive flora on the shores of Belgica Strait, mosses and a single species of grass being observed as well as lichens. The insects found there included a species of diptera with rudimentary wings, poduridæ, and minute acarides. Marine life was very abundant even in the highest latitudes. It included a great number of species representing plankton, littoral forms, and fishes, as well as benthos. The seals and sea-birds have for the most part been described before. The right whale seems to be absent. There is no walrus nor narwhal, and no trace of land mammals has been found.

Pole, William (1814–1900), English engineer, was born at Birmingham on 22nd April 1814. He was a man of many accomplishments. Having spent his earlier years in various engineering occupations in England, he went out to India in 1844 as first professor of engineering at Elphinstone College, Bombay, where he had to organize the course of instruction for native students, but his health obliged him to return to England in 1848. For the next ten years he worked in London under James Simpson and J. M. Rendel, and the high reputation he achieved as a scientific engineer gained his appointment in 1859 to the chair of civil engineering in University College, London. He obtained a considerable amount of official work from the Government. He served on the committees which considered the application of armour to ships and fortifications (1861–64), and the comparative advantages of Whitworth and Armstrong guns (1863–65). He was secretary to the Royal Commission on Railways (1865–67), the duke of Richmond's Commission on London Water (1867–69), also taking part in the subsequent proceedings for establishing a constant supply, the Royal Commission on the Disposal of London Sewage (1882–84), and the Departmental Committee on the Science Museums at South Kensington in 1885. In 1871 he was employed by the War Office to report on the Martini-Henry rifle, and in the same year was appointed consulting engineer in London to the Japanese Government, a position through which he exercised considerable influence on the development of the Japanese railway system. He was elected a fellow of the Royal Society in 1861, in recognition of some investigations on colour-blindness. Music was also one of his chief interests. At the age of twenty-two he was appointed organist of St Mark's, North Audley Street, in open competition, the next selected candidate being Dr E. J. Hopkins (1818–1901), who subsequently was for fifty years organist of the Temple Church. He took the degree of Bachelor of Music at Oxford in 1860, proceeding to his doctor's degree in 1867, and in 1879 published his *Philosophy of Music.* He was largely concerned in the institution of musical degrees by the University of London in 1877, and for many years acted as one of the examiners. His mathematical tastes found congenial occupation in the study of whist, and as an exponent of the scientific principles of that game he was even earlier in the field than "Cavendish." His literary work included treatises on the steam engine and on iron construction, biographical studies of famous engineers, including Robert Stephenson and I. K. Brunel, Sir William Fairbairn and Sir C. W. Siemens, several books on musical subjects and on whist, and many papers for reviews and scientific periodicals. He died on 30th December 1900. His son, William Pole (b. 1852), is known, under the stage-name of William Poel, for his studies in Shakespearian drama and his work in connexion with the Elizabethan Stage Society.

Police.—The powers and duties of the police in England and Wales with respect to the detection and prevention of crime have not been materially altered since 1884, but in each session of Parliament new offences are created, and an enormous amount of subordinate legislation in the form of bye-laws has added to the duties of the force. The summary remedy given by the Prevention of Crimes Act, 1871, § 12, for assaults on the police in the execution of their duty was in 1885 extended to cases of resistance or wilful obstruction. The usefulness of constables in cases of serious accident has been much increased by systematic instruction in the modes of giving first aid to injured persons; and they are now authorized to destroy at once animals seriously injured in the streets (57 and 58 Vict. c. 22). It is now usual, in order to ensure the proper treatment of women on arrest, to employ police matrons at the police stations, and to arrange for the presence of female attendants or searchers when required. Under the Sheriffs Act, 1887, courts of quarter sessions may direct the attendance of constables at the assizes to keep order, and when such direction is given the sheriff is relieved of his common-law duty to provide javelin men for the purpose. Under the Police Act, 1890, § 25, provision is made for sending constables of one force to the assistance of those of another authority at the request of the latter, and at the expense of the police area to which they are sent.

In 1897 was established a uniform system for dealing with property coming into the hands of the police in connexion with a criminal charge or in execution of certain of their duties. Courts of summary jurisdiction are empowered to make orders for the restitution of the property to the owner. If not claimed, it is dealt with under regulations made by the Home Secretary on 14th February 1898, which include a power of sale at the end of a year after the police got possession of the property (see 60 and 61 Vict. c. 30). The constables of a borough police force may now be employed as firemen, and constables of any force who under general or special directions act as firemen, or assist in extinguishing fires, or in saving life or property, are entitled, in the event of injury, to pensions, &c., as for injury in the execution of their duty (56 and 57 Vict. c. 10). In 1887 policemen were allowed to vote at parliamentary elections, and in 1893 at municipal elections and the like.

Management.—On the establishment of county councils in 1888 the police of each administrative county (except London) were put under the control of a standing joint committee composed of an equal number of justices, appointed by the court of quarter sessions, and of members of the county council, appointed by the council, subject to the power of the Home Secretary to fix the number of each if the council and the quarter sessions cannot agree. The joint committee appoints the chief constable, divides the county into police districts, and generally controls the police of the county, subject to the rights of the justices as conservators of the peace, and to the rights of quarter sessions or of the county council to impose additional duties on the force under the Police Act, 1856. It is also the duty of the standing joint committee in a county, and of the watch committee in a borough, to transmit as soon as possible after the end of each calendar year an annual return of offences reported to the police, of persons arrested by the police, the charges against them, the result of the proceedings there, and such other particulars as to the state of crime in their district as they think material (55 and 56 Vict. c. 38). By the Act of 1888 the police forces of liberties or of boroughs with less than 10,000 inhabitants in 1881 and lying within an administrative county were merged in the county force.

The cost of the police in England and Wales for the year 1900,[1] including salaries and pay allowances, contributions of deficiency in the pension account, clothing and accoutrements, the cost of buildings, and the other expenses incidental to the maintenance of the force, was £4,822,886.

Separate Forces.	No. of each Force: average Daily Strength.	Population Policed; by Census of 1891.	Gross Cost.
Counties and boroughs (185) . . .	26,376	23,384,932	£2,802,212
Metropolitan police .	13,588	5,595,638	1,871,363
City of London . .	1001	37,705[2]	149,311

The cost of maintenance of the force is now defrayed in the following manner :—From the local taxation grant from the Imperial Exchequer to each county there is transferred to the police account of the county fund half the cost of the pay and clothing of the county police, and there is paid over to the council of each borough within the county which has a separate police force half the cost of the pay and clothing of the borough force, including the cost, &c., of any extra police temporarily added from another force and paid for under agreement under the Police Act, 1890. The balance of the expense of the force is defrayed from the county or borough fund. The Government inspection of local police is unaffected by the Act of 1888, but if the Home Secretary withholds his certificate of efficiency in point of numbers and discipline, the authority in default forfeits the amount applicable for police out of the local taxation grant, and must pay the whole cost of the force out of its own funds. The county council of any county within the Metropolitan Police District has to transfer to the receiver of police a sum bearing such proportion to the police rate levied in the parts of the county lying within that district as the Home Secretary certifies would have been proper under the arrangements in force from 1875 to 1899.

In 1890 a complete system of superannuation and pensions was established for every force in England except that of the City of London. The pensions are awarded in accordance with a prescribed scale, and under certain conditions: (*a*) On retirement after 25 years' service; (*b*) on retirement after 15 years' service or certificate of incapacity for duty; (*c*) at any time in the event of certified incapacity for duty in consequence of mental or bodily infirmity due to injuries in service as a constable or at a fire. Gratuities may be granted on retirement with less than 15 years' service on a medical certificate of incapacity for duty, and pensions and allowances may be given to the widows or children of deceased constables.

Elaborate machinery is created for settling the amount of pension and the mode of calculating service and to prevent fraud. The cost of the pensions is defrayed from the pension fund of each force, to the account of which are carried certain deductions from the pay of the force and certain classes of fines imposed by courts of summary jurisdiction. But the chief item is the Exchequer contribution of £300,000 a year made to the pension funds of authorities outside the Metropolitan Police District from the proceeds of the local taxation customs and excise duties (56 and 57 Vict. c. 45, § 17; 56 and 57 Vict. c. 60). The contribution is forfeited where a force is certified not to be efficient. Any deficiency in the pension fund is made good from the police fund.

United States.—The organization of police forces in the United States differs more or less in the different states of the Union. As a rule the force in cities is under municipal control, but to this rule there are numerous exceptions. In Boston, for instance, the three commissioners at the head of the force are appointed by the Governor of Massachusetts. The force in New York City, alike from the standpoint of numbers and of the size and character of the city, is the most important in the United States, and in its general composition may be taken as typical. It includes a commissioner appointed by the mayor for a term of years and exercising a wide range of authority; a chief of police, who has immediate charge of the force and through whom all orders are issued; he is assisted by four deputies; inspectors, who are in charge of different sections of the city, and who carry out the orders of the chief; captains, each of whom is in direct charge of a precinct; sergeants; roundsmen; and last of all, the ordinary policemen, or patrol men as they are often called from the character of their duties. There is a separate branch, the detective bureau, composed of picked men, charged with the investigation and, still more, the prevention of crime. The total number is about 4000. Appointments are for life, with pensions in case of disability and after a given number of years of service. The cost of the police department in New York in the year 1900 approximated $12,000,000, and in Chicago $3,800,000.

As regards the prevention of ordinary crime, the preservation of the peace, the protection of life and property, the American police is probably about as effective as that in English or Continental cities. But in certain cities there have been serious scandals. Under the Tammany government in New York City a system of almost organized blackmail came into existence, by which the keeper of the saloon and the house of ill-fame paid regularly and liberally to the police captains for impunity in breaking the law; and it was repeatedly shown that candidates for the position of captain paid large sums to their superiors for appointment to that post. The demoralizing effect of such a system needs no demonstration. (W. F. C.)

[1] See *Parl. Paper*, 1901 (200).

[2] Sleeping population. The day population is over 300,000.

Pollokshaws, a burgh of barony and police burgh of Renfrewshire, Scotland, now, by the extension of the city and itself, virtually a suburb of Glasgow, with which it is connected by rail and tram. A great many houses have been built in recent years for the accommodation of the working classes and Glasgow business people. A public hall has been presented to the town by Sir John Stirling-Maxwell, Bart., the feudal superior. The academy is a secondary school with an elementary department. Population (1891), 10,228; (1901), 11,169.

Polna, a town in the government district of Deutschbrod, in Bohemia, Austria, on the frontier of Moravia, north-east of Iglau, and just beyond the bounds of the German-speaking enclave. It has manufactures of starch and syrup, glass-cutting and brewing. On the 29th of March 1899 Polna was the scene of a sensational murder of a young girl (Agnes Hruza), which led to a revival of the accusation of "Ritual Murder" against the Jews, and was made the starting-point of an anti-Semitic agitation. The trial of the accused, a Jew named Hilsner, which took place at Kuttenberg on the 12th–16th September, ended in his conviction on purely circumstantial evidence. The sentence was subsequently commuted to a term of imprisonment. Population (1890), 4923; (1900), 5013.

Polo.—Since the article on polo was written for the earlier volumes of the *Encyclopædia Britannica* (ninth edition), the game has altered in character and increased in popularity. There were over sixty clubs in the United Kingdom in 1902, besides many others in British colonies and dependencies. In France and Russia, and in Spain, as well as all over America and the Argentine Republic, polo has taken root and flourishes greatly, games, matches, and tournaments being played throughout the season. As the game differs slightly in the United Kingdom and its colonies from that played in America and India, it will be convenient to consider its present conditions under these three heads.

The United Kingdom and Colonies.—The game of polo is ruled by the code of laws and by-laws laid down by the committee of the Hurlingham Club, which, with some few inconsiderable exceptions, are everywhere in force. The height of the ponies played is in England 14 hands 2 inches. Every pony is measured by an official measurer, and registered in a book kept for that purpose at Hurlingham. No ponies above that height are permitted in any circumstances to play in matches or tournaments. A polo ground should be a parallelogram 300 yards in length by 200 yards in breadth. The longer sides are boarded with planks from 9 to 11 inches in height. Full-sized grounds, however, are not entirely satisfactory in practice, and it is probable that 300 yards by 150 or 170 will become the standard size in England. So large a ground as 300 by 200 is found to keep the ball in play too long, and to be tiring to the players and hard on the ponies. It must be remembered that good polo is played at full gallop. At each end of the ground are two goal-posts, which are placed 8 clear yards apart in the centre of the back line, which is marked with lime-wash. At a distance of 30 yards from the back line a second line is marked parallel to the back one. Then, taking the point midway between the goal-posts, a half circle of 25 yards should be described in white lime-wash. A scoring board, a clock to mark the time, a bell to sound the close of the periods of play, and a pavilion or dressing tent, are also necessaries of a well-appointed polo ground.

The game is played by eight players, four a-side. Each of the four players has his appointed place in the game and his particular duties, which may consist either in forwarding the progress of the ball towards the adversaries' goal or impeding its course towards his own. Taking the players in order of importance, number 4 is the back; and his ultimate duty is to guard his own goal in defence, and in attack to prevent the ball from coming back, and, having stopped it, to pass it forward to the man in front of him, who should be number 3. This player, whose position is one of great responsibility, should either help the back in defence, or support his own forwards when they are attacking. Number 2, who should ride a fast pony and be a brilliant and hard hitter with control of the ball, generally leads the attack on the enemies' goal. Number 1 is supposed to hamper the movements of the opposing number 4, and by "riding him off" to clear the way for number 2 on his own side. It will thus be seen that the players are in pairs, whose duty in attack is to press the ball forward, and in defence to impede the corresponding man. Thus, let A and B be two sides: number 1A will impede number 4B; number 2A will try to carry the ball on, be impeded by number 3B; number 3A will endeavour to place the ball so that number 2A can obtain possession, or, if the game is against him, hinder number 2B, while number 4A will be impeded by number 1B doing the like. Both backs will use every endeavour to place the opposing number 1 off side, while both numbers 1 will endeavour to ride off the backs.

The rules as to off side and riding off are given here:—

Off side (Rule 18).—No player who is off side shall hit the ball, or shall in any way prevent the opposite side from reaching or hitting the ball.

Definition of off side.—A player is off side when at the time of the ball being hit he has no one of the opposite side nearer the adversaries' goal line, or that line produced, or behind that line, and he is neither in possession of the ball nor behind one of his own side who is in possession of the ball. The goal line means the 8 yards line between the goal-posts. A player, if off side, remains off side until the ball is hit or hit at again.

Riding out an antagonist.—A player may ride out an antagonist, or interpose his pony before his antagonist so as to prevent the latter reaching the ball, but he may not cross another player in possession of the ball, except at such distance that the said player shall not be compelled to check his pony to avoid a collision.

It is thus evident that polo is a game in which combination and tactics count for much. In order to prevent the game from becoming a mere rough-and-tumble, there are always on the ground, besides the players, two experienced and well-mounted men who have the rules of polo at their finger-ends, and whose duty it is to check all unfair play and enforce the penalties on the offending side. The position of umpires is one of great responsibility and importance, and the whole welfare of the game of polo depends on their duties being thoroughly and efficiently carried out. In addition to the umpires there should be a referee, to whom appeal may be made if the two umpires differ.

Penalties (Rule 22).—Any infringement of the rules constitutes a foul. In case of an infringement of Rules 16, 17, 19, 20, and 21, the umpire shall stop the game; and in case of an infringement of Rule 18, the umpire shall stop the game on an appeal by any one of the side which has been fouled. On the game being stopped as above, the side which has been fouled may claim either of the following penalties:—(*a*) A free hit from where the ball was when the foul took place, none of the opposing side to be within 10 yards of the ball. (*b*) That the side which caused the foul take the ball back and hit it off from behind their own goal line. The side injured by the foul may claim either penalty. There is also the extreme penalty of disqualification of the whole team for disregarding the umpire's decisions. There is also a minor penalty (New Rule, May 1898) inflicted on a side which, when being hard pressed, hits the ball behind their own goal line, thus putting the ball out of play and of course depriving the adversary of the chance of making a goal. Rule 14. If the ball be hit behind the back line by one of the opposite side, it shall be hit off by one of the side whose line it is, from a spot as near as possible to where it crossed the line. None of the attacking side shall be within 30 yards of the back line until the ball is hit off. If, however, the ball be hit behind the back line by one of the players whose line it is, they shall hit it off from behind the goal line between the posts, and all the defending side shall, until the ball is hit off, remain behind their back line, and between two lines which shall be drawn at right angles to the goal line produced, from points 10 yards distant from the centre of the goal on either side, the attacking side being free to place themselves where they choose, but not within 25 yards of the centre of the goal-posts. The penalty shall not be exacted should the ball glance off a player or pony.

The game is played with a ball made of willow root, about 3 inches in diameter and painted white. No ball should be over 5 ounces in weight. The sticks used are made of cane and wood, white Malacca cane being the best. There is no rule as to the length or weight of the stick; each player is left to suit himself. Whippy canes, however, are dangerous; those too stiff are apt to strain the wrists of the players. The stick is most important, and good players spare no pains to obtain suitable ones. The heads are usually square in England and cigar-shaped in India, these forms being found better for soft and hard ground respectively.

The full match time in England is one hour. This is divided into six periods of ten minutes each. As the players do not leave the ground until the ball is actually out of play by having been hit over the boundary boards or back line, a period of actual play may, and sometimes does, exceed ten minutes; but in this case the excess is deducted from the following period, so that if, for example, a period of play lasted twelve minutes, the next one would only last eight. At the close of each period of ten minutes two minutes are allowed for changing ponies, and after each twenty minutes there is an interval of five minutes. In the event of the scores being equal at the close of the hour of actual play, the rules provide that the period shall be prolonged till the ball goes out of play. Then, if it is still a tie, after an interval of five minutes the ball shall be started from where it went out of play, and the game continued as before, until one side obtain a goal which shall determine the match. In the earlier matches of tournaments the whole period of play is often reduced to forty minutes.

The polo pony is any small horse of 14·2. There are animals from America, Canada, Argentina, Africa, India, and Australia playing, as well as a considerable but diminishing number of Arabs. The polo pony must be fast, docile, and well-mannered, and thoroughly trained to the game. The best ponies are those obtained by crossing a thoroughbred sire with a mare having some Arab, or Welsh, or Exmoor pony blood. There are a few dwarf thoroughbred horses playing, but these are accidents, though it will be noted that the best-known are all descendants of Newminster. A considerable trade exists in polo ponies, and there is a stud book under the supervision of the Polo Pony Society. The qualities of a first-rate pony are so many and so rare, that high prices are often paid for really high-class specimens.

The principal tournaments of the year in England are the Inter-Regimental and Championship played at Hurlingham, the Hunt Cup and Subalterns' Cup played at Ranelagh, the Rugby Tournament and the County Cup; the All Ireland, Dublin Inter-Regimental and Phœnix Park are also important fixtures. The ties of the County Cup tournament are played off at different centres under the control of the County Polo Association, the final only being played on the grounds of the Hurlingham Club at Fulham.

America.—The game of polo, which is very popular in America, differs a good deal from that in England. Whereas in the latter country the whole conception of correct play is based on combination, in America individual brilliance counts for more. The American Association thus promotes games of two and three a-side, which are never attempted in England. Each player has his handicap, as at golf, which is based on the number of goals he is supposed to be worth to his side. When two sides meet for a match, the handicaps of the players on either side are added together and the less subtracted from the greater; thus, A side with a handicap of twelve meets B side with a handicap of ten. Then A would have to make two goals to start on even terms with B. Polo was introduced into America by Mr James Gordon Bennett in 1876, and has gradually grown in popularity. The American regulation ground is 250 by 166 yards. They have no off side, and it is not permitted to crook the stick of an adversary. America has produced some fine individual players, but no team, so far, equal to the English Rugby, Freebooter, or Hurlingham teams.

India.—Polo in India is under the control of the Indian Polo Association, which is responsible to the military authorities that the game is played in such a way as to make the danger as little as possible and to avoid needless expense to players. The Indian game is in the main the same as that in England, with the following exceptions:—The height of ponies is 14·1. The rules as to riding off are much stricter, or it would perhaps be true to say more strictly enforced by the umpires. The time allowed for a match is forty minutes. In order to avoid a tie, the subsidiary goal is scored. The following is a definition of a subsidiary goal: "A subsidiary goal is obtained in the same way as a true goal, except that to score a subsidiary goal—11 feet from outside of each goal post—the ball must pass between the subsidiary goal mark and the goal post which is nearest to it." (*Riding and Polo*, p. 377 (ed. 1899), Rule 37.) Left-handed players are forbidden altogether. The Indian grounds are usually 300 by 200, and there are no boards. In India polo is a much less expensive game than in England, and is almost universally played by officers of the British army stationed in that country, and to a less extent by civilians. There are 120 clubs in India affiliated to the Indian Polo Association. In addition to these there are many small associations for polo which are not registered. There are about 600 ponies holding the Indian Polo Association certificate of age and height, without which no pony can play in a tournament.

Poltava, a government of south-west Russia, to the north of Kherson, has an area of 19,265 square miles. The population was 2,418,870 in 1881 and 2,794,727 in 1897, of whom 1,406,736 were women, and 271,459 lived in towns. The government is thus the fourth in Russia in respect of density of population outside Poland, although considerable numbers of people have emigrated to Siberia. The land is chiefly owned by the peasants, who possess 52 per cent. of the cultivable land; 42 per cent. belongs to private persons, and the remainder to the Crown, the clergy, and the municipalities. In 1895, 283 private owners held over 2700 acres each, 380 held from 1350 to 2700 acres, 2092 from 270 to 1350 acres, 1966 from 135 to 270 acres, and 22,570 persons owned less than 135 acres each. Twenty per cent. of the peasants hold no field-land, and 26 per cent. hold less than 8 acres per family. Land is sold and rented at very high rates. The average yield per annum from 1895 to 1899 was of wheat 9,361,000 cwt., of rye 9,679,000 cwt., of oats

3,882,000 cwt.—of all cereal crops 29,664,000 cwt.; of potatoes 9,010,000 cwt. Nearly 670,000 cwt. of beetroot are grown annually, while tobacco plantations cover 2310 acres and yield some 302,500 cwt. annually. Gardening for commercial purposes (melons, sunflower, &c.) is extensively carried on, as also is bee-keeping. There were in the province in 1898, 289,400 horses, 793,500 horned cattle, 1,530,960 sheep, and 390,000 swine. Domestic industries are but slightly developed, and the factories (flour mills, tobacco and sugar works, and distilleries) afford employment to only 9200 persons, and have an output valued at only 23,000,000 roubles a year. The Dnieper is the chief artery for the exports—grain, live stock, hides—and imports—timber. The chief river ports are Kremenchug and Poltava. Steamers ply between Kieff and Ekaterinoslav.

Owing to the efforts of the *zemstvo* (provincial council), there were in 1896, 721 primary schools, attended by 52,242 boys and 7154 girls; the total number of schools of all kinds in the government in 1898 was 2142 (87,227 boys and 17,960 girls). Poltava is divided into fifteen districts, of which the chief towns are Poltava, Gadyach (7714 inhabitants), Khorol (8390), Kobelyaki (11,936), Konstantinograd (6456), Kremenchug (58,648), Lokhvitsa (8917), Lubny (10,108), Mirgorod (10,023), Pereyaslav (14,609), Piryatin (8545), Priluki (19,055), Romny (22,539), Zenkoff (10,542), and Zolotonosha (9900). Several villages have from 7000 to 9000 inhabitants each.

Poltava, capital of the above government, is situated on the Vorskla river, 88 miles by rail west-south-west of Kharkoff. Its population was 53,060 in 1897, as compared with 41,050 in 1881. The great fair is gradually losing its importance since Kharkoff has become the centre of the wool trade. The stock at the fair was valued at only £142,880 in 1895, as compared with £2,800,000 in 1865; and the sales amounted to £110,700. Industrial establishments (flour mills and tobacco works and tanneries) give employment to 1000 persons. The town is well built, and has beautiful public and private gardens.

Polynesia.—Under this general expression are comprised three great oceanic divisions: *Melanesia* (*q.v.*), *Micronesia* (*q.v.*), and *Eastern Polynesia*, but it is to the third that, according to present usage, the term Polynesia (Polynesia proper) is commonly restricted. Between this eastern section and the two western divisions the parting line runs from New Zealand somewhat obliquely between Fiji and Tonga north-eastwards to Hawaii, but north of Fiji is deflected considerably westwards, so as to bring the Ellice and Phœnix groups within the eastern area. Polynesia proper thus lies roughly between the two tropics, dipping southwards below 30° S. to include Kermadec, and extending from about 180° to a little beyond 110° W., so as to take in the outlying Easter Island, about 400 miles from South America. A certain ethnical unity is imparted to this fragmentary oceanic world by its inhabitants, who are all without exception members of the large brown Polynesian race, and speak closely related dialects of the Polynesian stock language. But of political unity there can be no question, since the whole region has been partitioned between France, Great Britain, Germany, the United States, and the Republic of Chile. The partition began in 1841, when the Marquesas were occupied by the French, and was completed in November 1899, when Samoa was divided between Germany and the United States.

Before 1893 Hawaii (the Sandwich Islands) had been recognized as an independent kingdom by Great Britain, France, the United States, and other governments. But in that year the reigning Queen, Liliuokalani, was deposed, and after the proclamation of a republic in 1894 the archipelago was formally annexed to the United States in August 1898, and constituted the *Territory of Hawaii*. All whites, people of colour, and Hawaiian natives who were free citizens prior to the annexation, became citizens of the United States; and all who could speak, read, or write either Hawaiian (a pure Polynesian dialect) or English have the right to vote. For details, see HAWAII.

Partition of Polynesia.

In the subjoined table is shown the distribution of all the Polynesian archipelagoes and islands amongst the five above-mentioned Powers:—

	Area in Square Miles.	Population.
Great Britain:		
Kermadec	15	10
Tonga	374	17,500
Cook (Hervey)	142	8,400
Savage (Niuë)	24	5,000
Tokelau (Union)	7	1,050
Ellice (Lagoon)	14	2,400
Phœnix	16	60
Gilbert	166	35,200
Ducie	...	...
Pitcairn	2	126
Manahiki (Humphry), Tongarewa (Penrhyn), Caroline (Voslok, Flint)	12	1,000
Suvarof	2	...
Dudoza	2	...
Malden	35	170
Christmas	234	100
Fanning	15	150
Total	1,060	71,166
France:		
Tahiti	410	10,300
Moorea	50	1,600
Tuamotu	600	6,000
Marquesas	500	6,500
Gambier	...	300
Tubuai	...	1,000
Rapa	20	200
Tetiaroa	...	...
Raiatea	110	2,300
Wallis	50	3,500
Total	1,740	31,700
Germany:		
Marshall Group	150	10,000
Savaii } Samoa	600	12,000
Upolu } Samoa	250	20,000
Total	1,000	42,000
United States:		
Hawaii	6,640	109,000
Tutuila (Samoa)	180	4,000
Total	6,820	113,000
Chile:		
Easter Island	110	100
Total Polynesia	10,730	257,966

Subjoined are particulars of those Polynesian islands belonging to Great Britain which are not described in separate articles:—

Kermadec, a small group of hilly islands 500 miles north of New Zealand, named from D'Entrecasteaux's able captain, Huon Kermadec, in 1791. The largest is 12 miles round, 1600 feet high, and thickly wooded. The flora and fauna belong for the most part to those of New Zealand, on which colony the islands are also politically dependent.

Niuë, or *Savage*, a raised mass of coral rock 9 miles long, mid-way between the Tonga and Samoa groups, is very fertile, and inhabited by a mixed Polynesian and Melanesian people of Samoan speech; an intelligent Christian community, said to be increasing.

Tokelau, or *Union*, a group of three islets about 350 miles north-east of Samoa, produces little but copra; the natives are all Christians, akin to the Samoans in type and speech.

Manahiki, a scattered group, sometimes also called *Penrhyn*, lying north of Samoa about the equator, and comprising *Manahiki*, *Penrhyn*, or *Tongarewa*, *Caroline* or *Thornton*, *Suvarof*, *Flint*, *Vostok*, *Starbuck*, *Malden*, *Funafuti*, and a few other typical lagoon islets, sparsely peopled and producing a little copra and guano. There are pearl and pearl-shell fisheries at Suvarof and Penrhyn, and the natives, of Polynesian stock, are all nominal Christians.

Christmas is the largest lagoon island in the Pacific, a little north of the equator, 154° W.

Fanning and *Palmyra* are lagoon islets lying north-west of Christmas.

These last three are commonly known as the *America Islands*, because chiefly frequented by traders from the United States. There is a settlement at English Point on Fanning, where good drinking water is procurable.

Phœnix is a small scattered cluster a little south of the equator and north of Samoa, between 170° and 180° W. The rich guano deposits formerly worked by the Phœnix Guano Company have been exhausted, and all the buildings, wharves, &c., abandoned. The group appears to be now uninhabited.

Decay of the Polynesian race.

That the Polynesian race has been continuously, and in some places rapidly, decreasing since their first contact with Europeans, is the unanimous opinion of all observers. But doubts have been thrown on the current statements regarding the rate of decrease, which some good authorities believe to be not so great as is commonly represented. They hold that former estimates of the number of inhabitants in the various insular groups were mere guesswork, and often far in excess of the real facts. Thus it is pointed out that Cook's estimate of 240,000 for the Society Archipelago (Tahiti) was at the time reduced by his associate, Forster, to 150,000, so that the 300,000 credited by him to the Sandwich Islands should also be heavily discounted. That is probably true, and it may be admitted that, as a rule, the early calculations erred on the side of excess. But when full allowance is made for all such exaggerations, the following considerations will show that, except in a few small areas subject to special conditions—Lukunor in Mortlock (Carolines), Futuna in Wallis, Niuë or Savage—the falling off has been excessive both in Polynesia proper and in Micronesia. For the last-mentioned division some 50,000 must be added to the 257,966 given in the preceding table, besides 40,000 for the Maori of New Zealand, all true Polynesians, but excluded from the table as belonging to the Australian area. We should thus get a present total of 350,000, from which, however, have to be deducted some 80,000 of the inhabitants of Hawaii, where the Polynesian aborigines now number only about 30,000, all the rest being Chinese (22,000), Japanese (25,000), Portuguese (15,000), Europeans, Americans, and half-castes (20,000). Thus is reached an absolute total of 270,000 as the probable number of pure and mixed (Micronesian) Polynesians in 1900. But the careful observers George and J. R. Forster gave as a moderate estimate 650,000 at the time of Cook's last voyage (1774), showing an absolute decrease of 380,000, or about three-fourths. This conclusion is fully borne out by a detailed study of all the larger insular groups, where more accurate figures are available since the occupation of the islands by the European Powers. Thus in the Marianas the Chamorro aborigines had fallen from 50,000 or 60,000 in 1700 to less than 2000 in 1760, and the group had to be repeopled from the Philippines. Even now the whole population scarcely exceeds 10,000, mostly centred in Guam. The neighbouring Pelew Islanders, numbering 50,000 in 1800, had been reduced to 12,000 in 1880 and about 10,000 in 1900. The Tahitians, 150,000 in 1774, fell from 17,000 in 1880 to 10,300 in 1899; and in this group, while the pure stock appears to be dying out, there is a small increase amongst the half-breeds. When New Zealand was occupied (1840) the Maori were said to number 120,000, and were doubtfully stated to be still 56,000 in 1857; since then the returns of the 1881 and 1891 censuses gave 44,000 and 40,000 respectively. During the last two decades of the 19th century the decrease has been from 30,000 to 17,500 in Tonga; from 11,500 to 8400 in the Cook group; from 8000 to 3600 in Wallis; from 1600 to 1000 in Manahiki; from 1400 to 1000 in Tubuai; and from 600 to 100 in Easter Island. A general decline seems thus to be placed beyond doubt, though it may be questioned whether it is to be attributed to a decayed vitality, as some hold, or to external causes, as is the more general opinion. The prevalence of elephantiasis and the occurrence of leprosy, for instance, in Hawaii, would seem to point at least in some places to a racial taint, due perhaps to the unbridled licentiousness of past generations. On the other hand, the rapid disappearance of whole communities, as in the Marianas, and the reduction of others to one-half or even one-fourth of their former numbers, as in Tahiti and Tonga, can be accounted for only by an accumulation of outward causes, such as wars, massacres, and raidings for the Australian and South American labour markets before this traffic was suppressed or regulated. Other destructive agencies were epidemics, such especially as measles and small-pox, which swept away 30,000 Fijians in 1875; the introduction of strong drinks, including, besides vile spirits, a most pernicious concoction brewed in Tahiti from oranges; the too sudden adoption of European clothing, rendering the body supersensitive to changes of temperature; lastly, the action of over-zealous missionaries in suppressing the dances, merry-making, and free joyous life of pagan times, and the preaching of a sombre type of Christianity, with deadening effects on the buoyant temperament of these blithesome children of nature. Most of these abuses have been checked or removed, and the results may perhaps be detected in a less accelerated rate of decline, which no longer proceeds in geometric proportion, and seems even almost arrested in some places, as in Samoa and New Zealand. If such be indeed the case, perhaps the noblest of all primitive races may yet be saved from what at one time seemed inevitable extinction; and the Maori, the Samoans, and Tahitians may, like the Hawaiians, take their place beside the Europeans as free citizens of the various states of which they are now subjects. For the original home and dispersion of the Polynesian race over the Pacific Ocean, see SAMOA.

Polytechnics.—The word "Polytechnic" (πολύς many, and τέχνη an art) may be held to designate any institution formed with a view to encourage or to illustrate various arts and sciences. It has, however, been used with different applications in several European countries. In France the first *école polytechnique* was founded by the National Convention at the end of the 18th century, as a practical protest against the almost exclusive devotion to literary and abstract studies in the places of higher learning. The institution is described as one "où l'on instruit les jeunes gens, destinés à entrer dans les écoles spéciales d'artillerie, du génie, des mines, des ponts et chaussées, créé en 1794 sous le nom d'école centrale des travaux publiques, et en 1795 sous celui qu'elle porte aujourd'hui" (*Littré*). In

The term and its applications.

Germany there are nine technical colleges which, in like manner, have a special and industrial rather than a general educational purpose. In Switzerland, as will be found explained in the article EDUCATION, the principal educational institution, which is not maintained or administered by the communal authorities, but is non-local and provided by the Federal Government, is the Polytechnikum at Zurich. In all the important towns of the Federation there are trade and technical schools of a more or less special character, adapted to the local industries; *e.g.*, schools for silk-weaving, wood-carving, watchmaking, or agriculture. But the Zurich Polytechnikum has a wider and more comprehensive range of work. It is a college designed to give instruction and practical training in those sciences which stand in the closest relation to manufactures and commerce and to skilled industry in general.

The first polytechnics in England.

To the English public the word *polytechnic* has only recently become familiar, in connexion with some London institutions of an exceptional character. In the reign of William IV. there was an institution in London called after the name of his consort—"The Adelaide Gallery"—and devoted rather to the display of new scientific inventions and curiosities than to research or to the teaching of science. It enjoyed an ephemeral popularity, and was soon imitated by an institution called the Polytechnic in Regent Street, with a somewhat more pretentious programme, a diving-bell, electrical and mechanical apparatus, besides occasional illustrated lectures of a popular and more or less recreative character. Both of these institutions, after a few years of success, failed financially; and in 1880, Mr Quintin Hogg, an active and generous philanthropist, purchased the disused building in Regent Street, and reopened it on an altered basis, though still retaining the name of Polytechnic, to which, however, he gave a new significance. He had during sixteen years been singularly successful in gathering together young shopmen and artisans in London in the evenings and on Sunday for religious and social intercourse, and in acquiring their confidence. But by rapid degrees his enterprise, which began as an evangelistic effort, developed into an educational institution of a novel and comprehensive character, with classes for the serious study of science, art, and literature, a gymnasium, library, reading circles, laboratories for physics and chemistry, conversation and debating clubs, organized country excursions, swimming, rowing, and natural history societies, a savings bank, and choral singing, besides religious services, open to all the members, though not obligatory for any. The founder, who from the first took the closest personal interest in the students, well describes his own aims: "What we wanted to develop our institute into was a place which should recognize that God had given man more than one side to his character, and where we could gratify any reasonable taste, whether athletic, intellectual, spiritual, or social." The success of this effort was remarkable. In the first winter 6800 members joined, paying fees of 3s. per term, or 10s. 6d. per year; and the members steadily increased, until in 1900 they reached a total of 15,000. The average daily attendance is 4000; six hundred classes in different grades and subjects are held weekly; and upwards of forty clubs and societies have been formed in connexion with the recreative and social departments.

Later institutions of this class.

The precedent thus established by private initiative has since been followed in the formation of the public institutions which, under the name of "Polytechnics," have become so prominent and have exercised such beneficent influence among the working population of London. It has been shown in the article on EDUCATION that the principal resources for the foundation and maintenance of these institutions have been derived from two funds—that administered under the City Parochial Charities Act of 1883, and that furnished to the London County Council under the terms of the Local Taxation (Customs and Excise) Act of 1890. More detailed reference to these two Acts seems to be necessary in this place.

The City Parochial Charities Act.

The Royal Commission of Inquiry into the Parochial Charities of London was appointed in 1878, mainly at the instance of Mr James Bryce, and under the presidency of the Duke of Northumberland. Its report appeared in 1880, giving particulars of the income of the parishes, and revealing the fact that the funds had largely outgrown the original purposes of the endowments, and were ill adapted to the modern needs of the class for whose benefit they were intended. The Act of Parliament of 1883 was designed to give effect to the recommendations of the Commissioners. It provided that while five of the largest parishes were to retain the management of their own charitable funds, the endowments of the remaining 107 parishes in the City should be administered by a corporate body, to be entitled "the Trustees of the London Parochial Charities," this body to include five nominees of the Crown and four of the Corporation of London. The remaining members were to be chosen under a subsequent scheme of the Charity Commission, which added four nominees of the London County Council, two of the Ecclesiastical Commissioners, and one each by the University of London, University College, King's College, the City and Guilds Institute, and the governing body of the Bishopsgate and the Cripplegate foundations. For the purpose of framing the scheme, a special commissioner, Mr James Anstie, Q.C., was temporarily attached to the Charity Commission, and it thus became the duty of the Commission to prepare a statement of the income possessed by the 107 parishes, distinguishing between the secular and the ecclesiastical parts of the endowments. The value of the estates and stocks rendered available for the purposes of the scheme amounted to £1,590,442; the annual income derived from the ecclesiastical fund was £35,000, and that from the secular portion of the fund £50,000. The scheme assigned capital grants amounting to £155,000 to the provision of open spaces, and £149,500 to various institutions, including free libraries in Bishopsgate and Cripplegate, the People's Palace, the Regent Street and Northampton Institutes, and the Victoria Hall. A capital sum of £49,355 out of the ecclesiastical fund was devoted to the repair of City churches; and the balance of this fund, after allowances for certain vested interests, was directed to be paid annually to the Ecclesiastical Commissioners. This balance has varied by slight increases from year to year, and amounted in 1899 to £11,545. The remaining fund thus set free for secular purposes was by the scheme largely devoted to the erection and maintenance of polytechnic institutions, or "industrial institutes," as they were at first called. It was the opinion of Mr Anstie and his fellow-commissioners that in this way it would be possible to meet one of the most urgent of the intellectual needs of the metropolis, and to render service nearly akin to the original purposes of the obsolete charitable endowments.

A typical scheme under the Act.

The general scope and aims of the institutions thus contemplated by the Commissioners are defined in the scheme for the Borough Road (Southwark) Polytechnic, which may be taken as a fairly typical example of the rest:—

The object of this institution is the promotion of the industrial skill, general knowledge, health, and well-being of young men and women belonging to the poorer classes by the following means:

I. Instruction in—

(*a*) The general rules and principles of the arts and sciences applicable to any handicraft, trade, or business.

(*b*) The practical application of such general rules and principles in any handicraft, trade, or business.

(*c*) Branches or details of any handicraft, trade, or business, facilities for acquiring the knowledge of which cannot usually be obtained in the workshop or other place of business.

The classes and lectures shall not be designed or arranged so as to be in substitution for the practical experience of the workshop or place of business, but so as to be supplementary thereto.

II. Instruction suitable for persons intending to emigrate.

III. Instruction in such other branches and subjects of art, science, language, literature, and general knowlege as may be approved by the governing body.

IV. Public lectures or courses of lectures, musical and other entertainments, and exhibitions.

V. Instruction and practice in gymnastics, drill, swimming, and other bodily exercises.

VI. Facilities for the formation and meeting of clubs and societies.

VII. A library, museum, and reading room or rooms. Within the limits prescribed, the governing body may from time to time, out of the funds at their disposal, provide and maintain buildings and grounds, including workshops and laboratories suitable for all the purposes herein specified, and the necessary furniture, fittings, apparatus, models, and books, and may provide or receive by gift or on loan works of art or scientific construction, or objects of interest and curiosity, for the purpose of the institute, and for the purpose of temporary exhibition.

Other provisions in the scheme require: (1) that the educational benefits of the institute shall be available for both sexes equally, but that common rooms, refreshment rooms, gymnasia, and swimming-baths may be established separately, under such suitable arrangements as may be approved by the governing body; (2) that the fees and subscriptions shall be so fixed as to place the benefits of the institute within the reach of the poorer classes; (3) that no intoxicating liquors, smoking, or gambling shall be allowed in any part of the building; (4) that the buildings, ground, and premises shall not be used for any political, denominational, or sectarian purpose, although this rule shall not be deemed to prohibit the discussion of political subjects in any debating society approved by the governing body; (5) that no person under the age of sixteen or above twenty-five shall be admitted to membership except on special grounds, and that the number thus specially admitted shall not exceed 5 per cent. of the total number of members.

The Technical Board of the London County Council. These and the like provisions have formed the common basis for all the metropolitan polytechnics. When in 1890 a large sum was placed by the Local Taxation Act (Customs and Excise) at the disposal of the county and county borough councils for the general purposes of technical and secondary education, the London County Council determined to devote a considerable portion of this revenue to the further development and sustentation of polytechnics. While the funds granted by the City Parochial Trustees may be employed in aid of the social and recreative as well as the educational purposes of the various institutes, it was decided by the County Council that the sums contributed by its Technical Board should be applied to educational work only.

Dr Garnett, the secretary and educational adviser of the Technical Board of the London County Council, has, in a published lecture delivered before the International Congress on Technical Education in June 1897, thus described the conditions under which that Board offers financial help to the London polytechnics:—

The objects which the Technical Education Board has had in view in its dealings with the polytechnics have been:—

1. To allow to the several governing bodies the greatest possible freedom in the conduct of social, recreative, and even religious work within the provisions of the schemes of the Charity Commissioners.

2. To secure to each polytechnic the services of an educational principal, who should be responsible to his governing body for the organization and conduct of the whole of the work of the institution.

3. To provide in each polytechnic a permanent staff of teachers, who should be heads of their respective departments and give their whole time to the work of the institution, and thus to establish a corporate or collegiate life in the polytechnic.

4. To ensure that all branches of experimental science are taught experimentally, and that the students have the opportunity of carrying out practical laboratory work, at an inclusive fee not exceeding ten shillings for any one subject.

5. To provide efficient workshop instruction in all practical trade subjects.

6. To secure that the number of students under the charge of any one teacher in laboratory or workshop classes, or in other classes in which personal supervision is of paramount importance, shall not exceed a stated limit (fifteen in the workshop, or twenty in the laboratory).

7. To exclude from classes students who, for want of preliminary training, are incapable of profiting by the instruction provided; and to this end to restrict the attendance at workshop classes to those who are actually engaged in the trades concerned, and have thus opportunities of acquiring the necessary manual dexterity in the performance of their daily duties.

8. To furnish an adequate fixed stipend for all teachers, in place of a contingent interest in fees and grants.

9. To encourage private subscriptions and donations.

10. To establish an efficient system of inspection.

11. To facilitate the advertisement of polytechnic classes, and especially to invite the co-operation of trade societies in supporting their respective classes.

12. To encourage the higher development of some special branch of study in each polytechnic.

13. To utilize the polytechnic buildings as far as possible in the day time by the establishment of technical day schools, or otherwise.

14. To secure uniformity in the keeping of accounts.

In furtherance of these objects, the Technical Education Board has offered to each polytechnic—

(*a*) Such equipment grants as may from time to time be made by the Board for specific purposes on the application of the governing body.

(*b*) A fixed contribution of £1000 a year.

(*c*) Three-fourths (not exceeding £500 a year) of the stipend of the educational principal.

(*d*) Ten per cent. on the fixed salaries of the teachers.

(*e*) One penny for each hour's attendance of each student.

(*f*) Fifteen per cent. on all voluntary subscriptions and donations from private sources.

Provided that the total payment to any polytechnic in any one year under (*b*), (*c*), (*d*), and (*e*) does not exceed £3000, and under (*f*) does not exceed £2000.

London Polytechnic Council. With a view to a due division of labour, and also to the co-operation of the public bodies concerned, the "London Polytechnic Council" was created in 1894. It is composed of representatives of the City Parochial Trustees, the Technical Education Board of the London County Council, and the City and Guilds of London Institute, and its duty is to consult together as to the appropriation of funds, the organization of teaching, the holding of needful examinations, and the supervision of the work generally. The statement on the following page shows the number and names of the several institutions, and the extent to which they have been severally aided by the trustees of the two funds.

The People's Palace. The "People's Palace" owes its origin in part to the popularity of a novel by Sir Walter Besant, entitled *All Sorts and Conditions of Men*, in which the writer pointed out the sore need of the inhabitants of East London for social improvement and healthy recreation, and set forth an imaginary picture of a "Palace of Delight," wherein this need might be partly satisfied. Much public interest was awakened, large subscriptions were given, and the trustees of the Parochial Charities Fund aided the project; but the munificence of the Drapers' Company in setting aside £7000 a year for its permanent maintenance has released the London County Council from any obligation to make a grant out of its technical fund. Apart from the social and recreative side of this popular institution, the educational section, under the name of the East London Technical College, has steadily increased in numbers and influence since it has enjoyed the fostering care of the Drapers' Company.

The institutions marked thus * are fully equipped, and are the best examples of polytechnics in the stricter sense of the term.

The Birkbeck Institute and the City College are older institutions, which have been long very successful rather with educational than with social work. By the scheme of the Commissioners they have been federated with the Northampton Institute, a large and fully equipped establishment of the best modern type, with unusual provision for recreation and for workshop training. The three institutions together form the City Polytechnic.

The Goldsmiths' Institute in like manner owes its existence and its annual maintenance to the generous initiative of the ancient City Guild whose name it bears. It is therefore entirely independent of pecuniary subsidy from any other public body. In the year 1900 the number of class entries to the institute at New Cross was 7574. The Clothworkers' Company has also contributed £18,000 to the Northern Polytechnic at Holloway.

Aims and methods.

In all these institutions the general aims have been practically the same, although special features have been differentiated in order to meet the local needs and the wishes of the inhabitants. In all there are laboratories and lecture rooms, trade classes, art studios, gymnasia, provision for manual training and domestic economy, and applied science. In nearly all, at first, mechanical and manual instruction were the prominent objects in view, partly owing to the conditions under which grants were made by the Science and Art Department of the Board of Education. But of late increased attention has been paid year by year to literary and humaner studies, and to general mental cultivation, pursued *pari passu* with technical and scientific training. The aid of the London organization for University Extension has been especially serviceable in providing courses of lectures and classes in literary subjects at nearly all of the polytechnics. As subsidiary to their main work, each of them has established a junior continuation school, with a view to provide suitable instruction for scholars who have left the public elementary schools and are not yet prepared to enter the technical and trade classes. Although the workshops and the classes for artisans are used chiefly in the evenings, there is an increasing number of day students: *e.g.*, in the Birkbeck Institute, classes in natural science, mathematics, and languages; at Chelsea, a domestic economy school and an arts school; at the East London Technical College and at Regent Street, engineering departments; at the Goldsmiths' Institute, a "Commercial and Civil Service" department, largely attended by young women; at Battersea, regular day classes for mathematics, building and machine construction, wood work, and metal work. In short, the schemes of the several institutions are so elastic that the governing bodies are at liberty to open any classes or to try any educational or recreative experiment for which they can find a genuine local demand.

It is computed by Dr Garnett that the sites, buildings, and equipment of the London polytechnics represent a total capital outlay of £500,000, and that the annual revenue required for their sustentation is about £120,000. Of this sum about one-fourth is contributed by the City Parochial Charities, one-fourth by the Technical Education Board, one-fourth by the fees of students and members, and the remaining fourth by the subscriptions of the City Guilds and the grants received from the Science and Art Department of the Board of Education. The total number of scholars in the polytechnics and their branch institutions is variously estimated at from 40,000 to 50,000, and the total number of regular scholars in the evening schools of the London School Board does not exceed 100,000. These figures may be usefully compared with the census returns, which show that within the Metropolitan area there are 704,414 young persons between the ages of thirteen and twenty-one. It is a noteworthy fact, that whereas in the population statistics for the whole of England and Wales the number at each year of age is regularly diminished by death from eight years onwards, there is a steady increase in London, year by year, from fourteen up to the age of thirty. This fact is owing to the constant immigration of young men and women from the provinces to the metropolis. The Census Commissioners in their report for 1901 (p. 15) compute that more than one-third of the population of London are not natives. They show also that, if all England and Wales be taken together, the number of persons between twenty and twenty-one is less by 12·8 per cent. than the number between thirteen and fourteen; but that, taking London alone, the number of persons between twenty and twenty-one is greater by 14·4 per cent. than the number between thirteen and fourteen. Hence the proportion of the inhabitants who are of an age to benefit by polytechnics and continuation schools is in London exceptionally large. It would not be right for Londoners to complain that there is thus cast upon them the duty of providing suitable instruction for so many immigrants, for if the great city drains the rural districts of some of their best brain and muscle, she gains much from their industry and productive power.

But it follows from the particulars thus given that at present neither the supply of suitable provision for mental improvement and rational recreation for the wage-earning classes, nor the demand for such provision on the part of the workers themselves, is commensurate with the moral and intellectual needs of a community of nearly seven millions of people. The provision in evening schools, institutes, classes, and polytechnics is still far inferior to that which is to be found in most German and Swiss towns, and needs to be greatly increased. In matters relating to the higher life, demand does not always precede supply; it is supply which is needed not only to satisfy the public demand, but to create it. As new and well-devised opportunities for mental culture are placed within reach, they will be more and more appreciated, new and healthier appetites will be stimulated, the art of employing leisure wisely and happily will be more systematically studied, and the polytechnics will become still more important centres of civilizing and educating influence than they have already become.

In particular, the reconstituted University of London will probably be placed in new and most helpful relation to the best of the polytechnics. By the statutes which have recently come into force, the Senate of the University is empowered to include in the list of "schools of the University" all institutions which are duly equipped and able to furnish suitable instruction of an advanced and scholarly type; and also to recognize all thoroughly qualified professors in their several faculties and subjects as "teachers of the University," although some of their classes may meet in the evening only. There is thus a way open for the due admission of the best polytechnics to the University, and for the recognition of the best students as undergraduates, with all the rights of internal students. At present the great possibilities of the metropolitan University under its new conditions are hardly revealed or accurately foreseen. But it is probable that while the greater and older colleges of the University—such as University and King's—will devote their efforts largely to such post-graduate lectures and intellectual and scientific research as are the special province of the higher order of professors, most of the aid required by the ordinary undergraduate will be provided in institutions of minor rank, officered by experienced and well-accredited teachers, who are fully able to give the needful instruction and preparation for a degree in arts and science. The best of the polytechnics are already competent, both as regards their staff and their equipment, to perform this task adequately, and thus to become integral parts of the London University of the future. There is no reason to fear that the recreative, social, manual, and industrial training, to which at first the special attention of the founder was directed, will suffer from a fuller expansion of the academic and literary side of "polytechnic" life. Rather it may be hoped that the due co-ordination of the practical with the purely intellectual purposes of these institutions will serve to give to all the students, whatever their future destination may be, a truer and broader conception of the value of mental culture for its own sake.

See also a paper by Mr SIDNEY WEBB, *The London Polytechnic Institutes*, in the second volume of special reports on educational subjects (1898) issued by the Education Department; the *Report of the Central Governing Body* (1900) *of the London Parochial Charities*; the *Annual Reports* and the *Monthly Gazette of the Technical Board of the London County Council*; the *Polytechnic Magazine*, published from time to time at the institute in Regent Street; and various memoirs and papers contained in the *Proceedings of the International Congress on Technical Education* (1897), especially two—that by Mr QUINTIN HOGG, detailing his own early experience in founding the first polytechnic, and that of Dr WILLIAM GARNETT, the secretary of the Technical Education Board. (J. G. F.)

Polyzoa.—The researches of the last few years have gone far to show that the classification adopted in the earlier volumes (9th edition) of this *Encyclopædia* can no longer be accepted. *Cephalodiscus* and *Rhabdopleura*, then regarded as constituting the Section PTEROBRANCHIA, have been proved to possess unexpected resemblances to Balanoglossus. *Phoronis*, the solitary member of the Section Vermiformia, appears to have affinities in the same direction. By the removal of these two Sections to another group (see HEMICHORDA), the remaining Section, Eupolyzoa, acquires the same limits as the Class Polyzoa, and the term Eupolyzoa hence becomes unnecessary. The Class Polyzoa as thus restricted includes only the Subclasses *ENTOPROCTA* and *ECTOPROCTA*. The recent Ectoprocta are divided into A. GYMNOLAEMATA, with the Sub-orders CYCLOSTOMATA, CHEILOSTOMATA, and CTENOSTOMATA; and B. PHYLACTOLAEMATA.

The association of the Polyzoa with the Sipunculoidea and the Brachiopoda in a phylum Podaxonia rested mainly on the belief that *Phoronis* is an annectant form between the three groups. Delage and Hérouard introduce the term Vermidia as the name of a group including the Gephyrea in the widest sense, with the Polyzoa, Pterobranchia, Rotifera, Gastrotricha, Kinorhyncha, Chaetognatha, and Brachiopoda. The Polyzoa here occupy a central position, leading through *Phoronis* and the Sipunculoidea to the remaining Gephyrea, and in other directions to the Brachiopoda, the Pterobranchia, and the Rotifera respectively; the last being believed to lead to the Gastrotricha, Kinorhyncha, and Chaetognatha. Cori, basing his views principally on the excretory organs of fresh-water Polyzoa (Phylactolaemata), supports the association of *Phoronis* with the Polyzoa; but it may be noted that the Phylactolaemata are in certain respects highly specialized forms, whose peculiarities are not likely to have an ancestral significance. Hatschek separates the Entoprocta from the Ectoprocta as a division of his group Scolecida, characterized by the possession of a primary body-cavity and of protonephridia, the Ectoprocta being placed in a group Tentaculata, which nearly corresponds with the Molluscoidea after the removal of the Tunicata. Against this view may be urged the essential similarity between the processes of budding in Entoprocta and Ectoprocta (cf. Seeliger, *Zeitschr. wiss. Zool.* xlix. 168; l. 560), and the resemblances in the development of the two groups. These instances will show the wide discrepancies which exist between current views. Without disputing the possibility that the Polyzoa are distantly related to other animals, it will be best to regard them as an isolated Class which is not proved to have close affinities to any other group.

Adult Structure and Vital Phenomena.—The general account of the adult structure, habits, &c., of the Eupolyzoa given in the earlier volumes is still valid, though certain points, which were then imperfectly understood, have since been investigated more thoroughly. The problematical "intertentacular organ" (Fig. 1, *int.*) of Farre has been considerably elucidated by Prouho (*Arch. Zool. Exp.*(2) x. 557). In *Alcyonidium duplex* a male "polypide" (= alimentary canal, tentacles, &c.) occurs in a "zoœcium" (= body-wall) and produces spermatozoa, though it has no intertentacular organ. It then degenerates to the condition of a "brown body," its place being taken by a new polypide, produced as a bud, which develops ova. The female polypide is provided with an intertentacular organ, a tubular passage from the body-cavity to the exterior, situated between the bases of the tentacles on the anal side; and through this passage the eggs pass into the tentacle-sheath. The structure plays the part of an oviduct

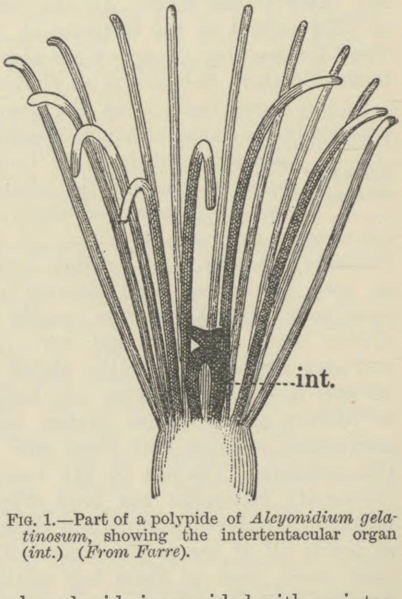

FIG. 1.—Part of a polypide of *Alcyonidium gelatinosum*, showing the intertentacular organ (*int.*) (*From Farre*).

in three species investigated by Prouho, although there is evidence that spermatozoa and fragments of brown bodies may also be evacuated by the same passage. The external opening of the excretory organs described in some Phylactolaemata may be a homologous structure. These organs (see Verworn, *Zeitschr. wiss. Zool.* xlvi. p. 114; Braem, *Bibl. Zool.* ii. Heft 6, p. 51; Cori, *Zeitschr. wiss. Zool.* lv. p. 626; Oka, *J. Coll. Japan*, iv. p. 108; viii. p. 339) are specially ciliated portions of the lophophore-cavity (a space which is incompletely separated from the principal body-cavity), at the regions where its two halves unite on the distal side of the cavity of the epistome, at the base of the anal tentacles. The "oral glands" of certain Cheilostomata, developed in connexion with the distal end of the tentacle-sheath, are believed by Waters to be excretory in their nature; but they cannot be regarded as corresponding in any way with the organs just mentioned. The body-cavity of Gymnolaemata is not lined by a ciliated epithelium; and it is, indeed, seldom possible to distinguish a cœlomic epithelium of any kind in the adult zoœcium. The structure of the Phylactolaemata has been further elucidated by the researches of Kraepelin (*Abh. Ver. Hamburg*, x. No. ix.; xii. No. ii.), Braem (*loc. cit.*), Cori (*loc. cit.*), and Davenport (*Bull. Mus. Harvard*, xx. p. 101). Wesenberg-Lund (*Vidensk. Meddel. Copenhagen*, 1896, p. 253) gives interesting information regarding their biology. The form of *Plumatella* known as *Alcyonella fungosa* is usually the result of the simultaneous germination of numerous sessile statoblasts, whereby a composite colony results and the crowded tubes take on their characteristic parallel arrangement. Colonies which persist through several years may show distinct annual rings of growth. The statoblasts are said to be derived partly from an ectodermic core of the funiculus, and partly from its external mesoderm (Braem, *loc. cit.*), the former giving rise to the chitinous envelope and to a nucleated layer (Fig. 2, *ect.*) immediately inside the chitin, which later invaginates to form the inner vesicle of the polypide-bud. The mesodermic portion becomes charged with a yolk-like material (*y*), and, on the germination of the statoblast, gives rise to the outer layer (*mes.*) of the bud. The production of a polypide by the statoblast thus differs in no essential respect from the formation of a polypide in an ordinary zoœcium. The statoblasts require a period of rest before germination, and Braem has shown that their property of floating at the surface may be beneficial to them, by exposing them to the action of frost, which in some cases improves the germinating power. The occurrence of Phylactolaemata in the tropics (see Meissner, *Zool. Anz.* xx. 173) would show, however, without further evidence, that frost is by no means a factor essential for germination. Important memoirs have been published on the structure of the Entoprocta, of which those by Foettinger (*Arch. Biol.* vii. 299), Ehlers (*Abh. Ges. Göttingen*, xxxvi.), Davenport (*Bull. Mus. Harvard*, xxiv. p. 1), and Prouho (*Arch. Zool. Exp.* (2) ix. p. 91) may be specially mentioned. There is no confirmation of the view that the lophophore of *Pedicellina* has the structure indicated in Fig. 15 c of the article in *Ency. Brit.* vol. xix. p. 438. The budding of Polyzoa has been studied by Seeliger (*loc. cit.*), who finds, with most others who have investigated this subject, that the polypide-bud is derived from ectoderm and mesoderm only (see, however, Calvet, *C. R.* cxxvii. pp. 79, 194). Ladewig (*Zeitschr. wiss. Zool.* lxvii. p. 323) controverts Calvet's statements. The ectoderm forms the inner layer of the two-layered vesicle, and gives rise to the lining of the tentacle-sheath ("kamptoderm," Kraepelin), the ganglion, and the whole of the epithelium of the alimentary canal. The mesoderm constitutes the outer layer, and forms the muscles, the reproductive organs, and other structures. The periodical histolysis of the polypide, leading to the formation of a "brown body," may partly be due to the accumulation of excretory substances in the cells of the alimentary canal (Harmer, *Quart. J. Micr. Sci.* xxxiii. p. 123); but the effects of artificially introduced pigments (indigo-carmine, &c.) suggest that the excretory function is in part performed by some of the mesodermic tissues.

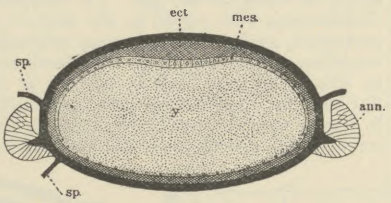

FIG. 2.—Section of a germinating statoblast of *Cristatella mucedo*:—*ann.*, chitinous annulus, containing air-cavities, which enable the statoblast to float; *ect.*, thickened part of the ectoderm, which will give rise to the inner layer of the polypide-bud; *mes.*, mesoderm, forming the outer layer of the bud; *sp.*, anchoring spines of the statoblast; *y*, the yolk-like mesodermic mass of the statoblast. (*After Braem.*)

Development.—The eggs are rarely laid (*Cyphonautes* type), but in the great majority of cases undergo their early development in some part of the parent. The vestibule of the adult may be employed as a brood-chamber (Entoprocta, *Alcyonidium duplex*); the eggs may pass into the tentacle-sheath of a degenerated polypide, or even develop in the body-cavity (Prouho, *Arch. Zool. Exp.* (2) x. p. 625); but in a large proportion of the marine forms they develop in ovicells. The ovicell of the Cheilostomata is a derivative of a zoœcium, and is usually situated just above the orifice, while that of the Cyclostomata is a modified zoœcium. The egg may be without yolk, but it commonly possesses a moderate quantity of yolk, which, however, does not interfere with the regularity of the segmentation. Two polar bodies have been observed in some cases. Some of the details of fertilization have been made out in Phylactolaemata (Kraepelin, *loc. cit.*). The segmentation of the egg of marine Ectoprocta is remarkably regular, and leads to the formation of a hollow blastula. The endoderm is formed by invagination; and in *Cyphonautes* (Prouho, *loc. cit.*) it gives rise to the mid-gut; the stomodaeum being represented by the large vestibule, and the anus being formed as a proctodaeum. The origin and complete history of the mesoderm have not been satisfactorily made out in Ectoprocta. There is hence no embryological evidence that the large body-cavity which characterizes these forms is to be regarded as a space which precisely corresponds with that of other "Coelomata"; and it is not impossible that it may have been evolved by the enlargement of the space between the alimentary canal and the skin in the Entoprocta, in order to permit of the complete retraction of the part of the body which bears the tentacles. The stages which succeed the completion of segmentation are much obscured in most Ectoprocta. This depends on the facts that no functional alimentary canal is developed by the larva, and that the larval organs are merely of a temporary nature, destined to be profoundly modified by the complicated metamorphosis which follows fixation. The larva of *Pedicellina* (the epistome of which must be regarded as ventral) fixes itself by its *oral* surface (Barrois, *Ann. Sci. Nat.* (7), i. No. 1; Harmer, *Quart. J. Micr. Sci.* xxvii. p. 239), and the mouth and anus are carried away from the plane of fixation by a rotation of the entire alimentary canal about an axis cutting the middle of the two sides through an angle of 180°. This movement is permitted by the histolysis of most of the larval vestibule; part of this passes to the side remote from the object on which fixation has taken place, and there forms the adult vestibule, by acquiring a new opening to the exterior. The "ciliated disc" and the cephalic ganglion atrophy during the metamorphosis. This is the only case in which the larval digestive apparatus is known to become that of the primary individual of the colony.

The *Cyphonautes* larva, distinguished by the possession of a functional alimentary canal, was formerly supposed to be peculiar to the Cheilostome genus *Membranipora*, but has been shown by Prouho (*loc. cit.*) to occur in *Alcyonidium* and *Hypophorella* among the Ctenostomata. The marked similarity between the *Cyphonautes* larvae of these three genera, which have no special connexion with one another, may indicate that the larva itself has a phylogenetic significance; it may, in fact, be regarded as a modification of the Entoproct larva. Fixation takes place, as in the Entoprocta, by the oral surface, and is effected by the eversion of a special organ ("sucker" or "internal sac") which opens to the exterior, between the mouth and the anus. The alimentary canal undergoes histolysis (Ostroumoff, *Arch. Slaves Biol.* ii. p. 333). In larvae of the type shown in *Ency. Brit.* vol. xix. p. 440, fig. 20, the alimentary canal may still be recognizable (Harmer, *Arch. Zool. Exp.* (2) v. p. 443), though it is no longer functional; *st* is the internal sac, and *m?* is a problematical larval structure known as the "pyriform organ" (*x* in fig. 21). The vestigial mouth is situated between *st* and *m?* The metamorphosed larva of the Ectoprocta becomes the primary zoœcium of the colony. Its definitive alimentary canal is developed in the same way as that of any of the secondary zoœcia formed by budding; that is to say, by the formation of a polypide-bud, which appears on the aboral surface, and therefore in the position finally acquired by part of the larval vestibule, with the alimentary canal, of the fixed larva of *Pedicellina*.

The spermatogenesis, oogenesis, and development of Phylactolaemata are described by Kraepelin (*loc. cit.*) and Braem (*Bibl. Zool.* Bd. x. Heft 23). The ovum is taken up by a special polypide-bud which grows into a protecting envelope for the embryo, the early development of which somewhat resembles that of the Cyclostomata. Larval organs are hardly represented, and the embryo, before birth, becomes a zoœcium, with one, two, three, or more polypides, produced as buds from its two-layered body-wall. After a short period, during which it swims by means of its uniformly ciliated ectoderm, it fixes and forms a new colony. This type of development may be regarded as a further modification of that found in Gymnolaemata. The Cyclostomata are characterized by the occurrence of a remarkable process of embryonic fission (Harmer, *Quart. J. Micr. Sci.* xxxiv. p. 199; xxxix. p. 71; xli. p. 73), which is most nearly paralleled in certain Hymenopterous insects (Marchal, 1898), and by the fact that eggs which actually develop are restricted to a few individuals of the colony. A zoœcium in which the egg develops becomes an ovicell; it differs to a conspicuous extent from the other individuals of the colony, and often acquires a complicated form. Its orifice ("oœciostome") is valuable for the discrimination of the species.

Classification. — The existing classifications of the Cheilostomata, the largest division of recent Polyzoa, will probably be much modified when the details of their anatomy are more fully worked out. It may be expected that the arrangements in connexion with the protrusion and retraction of the polypide will prove to give important indications of affinities. The view that the characters of the front wall (that on which the operculum is situated) of the Cheilostomata is of primary importance in the classification of this group, has already been maintained by Jullien. The retracted polypide of the Ectoprocta (Fig. 3) lies in a cavity which contains a considerable quantity of fluid and is bounded by the body-wall. The protrusion of the tentacles and other parts of the polypide implies the temporary removal of some of the organs in the body-cavity. It is possible to imagine two methods by which this movement can be permitted without producing a partial vacuum in the body-cavity. The body-wall must either be flexible, so that the volume of the zoœcium may diminish when the polypide is protruded; or, in cases in which the body-wall is rigid, there must be some arrangement by which the amount of fluid it contains can be altered from time to time, in order to permit of the free movements of the polypide. In the Phylactolaemata the body-wall is muscular, and can thus exert a pressure on the fluid of the body-cavity sufficient to cause protrusion. In the Gymnolaemata the body-wall is not muscular, and protrusion of the polypide is effected by the contraction of the parietal muscles (*p.m.*), which pass freely across the body-cavity from one part of the body-wall to another. In the more delicate branching Ctenostomes (Vesicularina) the entire body-wall is flexible, so that the contraction of a parietal muscle acts equally on the two points of the body-wall with which it is connected. In encrusting Ctenostomes (Alcyonellea) and in the *Membranipora*-like Cheilostomes (Figs. 3, 4, A) the zoœcia are attached by their basal wall and united to one another by their vertical walls, so that the free surface or front wall is the only one in which any considerable amount of movement can take place. The parietal muscles (*p.m.*), which pass from the vertical walls to the front wall, thus act by depressing the latter and so exerting a pressure on the fluid of the body-cavity, as shown to be the case by Nitsche in 1871. This explanation of the movement will obviously not apply to Cheilostomata in which the front wall is rigid; and in 1888 Jullien showed that the protrusion and retraction were rendered possible by the existence of a "compensation-sac," lying inside the body-cavity and in communication with the external water (*Bull. Soc. Zool. France*, xiii. p. 67).

A renewed investigation of this subject proves that this sac is present in a considerable number of the Cheilostomata. In its most fully developed condition (Figs. 3, 4, C, *c.s.*) it is a large cavity, with delicate walls of great tenuity, which lies beneath the calcified front wall of the zoœcium, and opens to the exterior at the proximal border of the chitinous operculum (Fig. 5, C). This structure is not hinged to the calcareous wall which is adjacent to its base-line, but it is continuous with the floor of the compensation-sac, a passage by which water can pass in and out of the sac existing between its base and the calcareous body-wall. The sac is joined to the rigid body-wall by numerous muscle-fibres, the contraction of which must therefore exert a pressure on the fluid of the body-cavity in which the sac lies. The comparison of various genera of Cheilostomes with regard to the method in which the polypide is protruded, leads to the following conclusions. The most primitive condition is that shown in the Membraniporidae, Flustridae, &c., in which the front wall is entirely or partially membranous or flexible, the membranous part constituting the "aperture" (Fig. 5, A, *ap.*), so called from the fact that its disappearance in fossil forms leaves a wide opening into the body-cavity. The parietal muscles

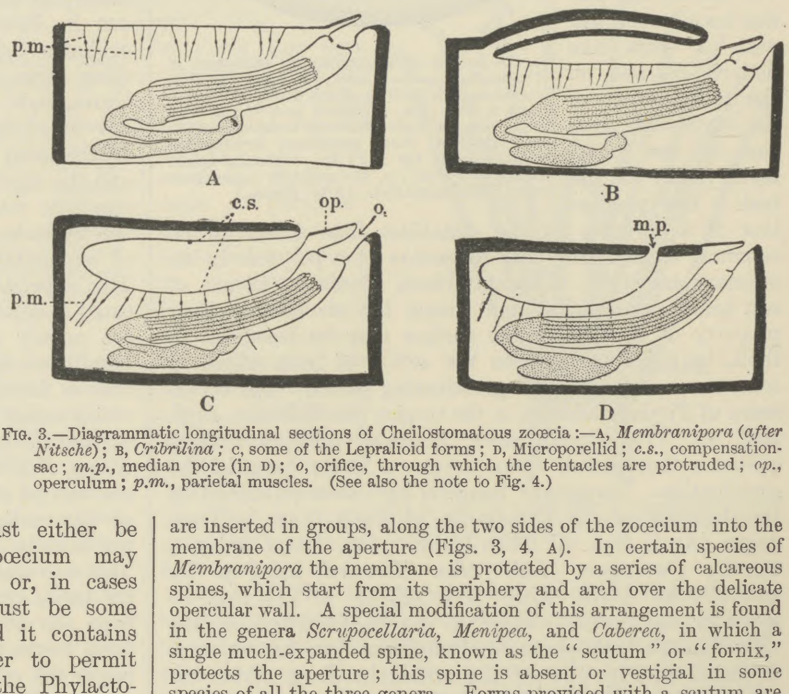

FIG. 3.—Diagrammatic longitudinal sections of Cheilostomatous zoœcia:—A, *Membranipora* (*after Nitsche*); B, *Cribrilina*; C, some of the Lepralioid forms; D, Microporellid; *c.s.*, compensation-sac; *m.p.*, median pore (in D); *o*, orifice, through which the tentacles are protruded; *op.*, operculum; *p.m.*, parietal muscles. (See also the note to Fig. 4.)

are inserted in groups, along the two sides of the zoœcium into the membrane of the aperture (Figs. 3, 4, A). In certain species of *Membranipora* the membrane is protected by a series of calcareous spines, which start from its periphery and arch over the delicate opercular wall. A special modification of this arrangement is found in the genera *Scrupocellaria*, *Menipea*, and *Caberea*, in which a single much-expanded spine, known as the "scutum" or "fornix," protects the aperture; this spine is absent or vestigial in some species of all the three genera. Forms provided with a scutum are probably related to one another, and they are usually characterized by the high development of avicularia or vibracula. Cheilostomata first become common in Cretaceous strata, in which a large propor-

tion of the genera belong either to the Membraniporidae or to a family known as the Cribrilinidae, which is represented at the present time by the genera *Membraniporella* and *Cribrilina.* In these a series of calcareous spines are formed, in the young zoœcium (Fig. 4, B), round the membranous aperture, as in the species of *Membranipora*

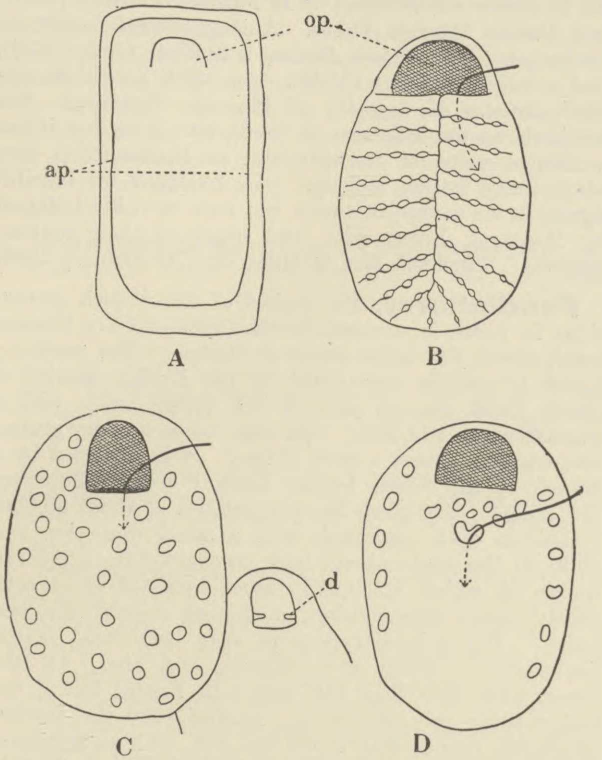

FIG. 5.—Zoœcia of A, *Membranipora;* B, *Cribrilina;* C, *Lepralia;* D, *Microporella.* The arrow shows the entrance to the compensation-sac in B, C, and D; in D passing through the "median pore"; *ap.*, "aperture," or membranous front wall (in A); *d.*, the "denticles," forming the hinge of C (seen after the removal of the operculum); *op.*, operculum.

referred to above. While in these latter the spines remain free from one another, they unite to a greater or less extent in the Cribrilinidae (Fig. 5, B), thereby forming a secondary front wall pierced by slits or rows of pores, corresponding with the intervals between the original spines. The operculum retains its connexion with the membranous aperture (Fig. 3, B), into which the parietal muscles are still inserted. The condition found in a certain proportion of existing Cheilostomes is probably a further development of the Cribrilinidan arrangement. The original spines are no longer distinct in ontogeny, but are represented by the calcareous wall, which is usually pierced by irregular pores (Fig. 5, C), now filled with living protoplasmic structures, instead of by the regularly arranged slits or pores of most Cribrilinidae. This conclusion is arrived at by the study of the compensation-sac (Figs. 3, 4), the floor of which is seen to correspond with the aperture of Membraniporidae by its relations to the parietal muscles and to the operculum. The compensation-sac may develop by the formation of a calcareous lamina which overarches the membranous aperture (*Umbonula* (Fig. 6, A)), differing from the condition found in Cribrilinidae only in the fact that the original spines are not distinct from one another; or the calcareous front wall is formed first and the sac is developed as an invagination (Fig. 6, C) from the region of the base of the operculum (*Lepralia, Schizoporella, Euthyris, Calwellia,* &c.). This may be regarded as a modification in ontogeny of the phylogenetic history of the organ.

In certain Lepralioid forms (*Microporella, Calwellia,* &c.) the operculum becomes separated from the floor of the compensation-sac by a portion of the calcareous front wall (Figs. 3, 5, 6, D). The sac now opens to the exterior by the so-called "median pore" (*m.p.*), which has probably been formed by the closure of the "sinus," which receives a small, median, tongue-like projection of the proximal side of the operculum in such genera as *Schizoporella* (Fig. 6, B). It remains to be seen whether all forms which possess this arrangement are really related, or whether the median pore has been evolved independently in several cases.

The development of the compensation-sac can be studied in the young zoœcia which are formed at the margins of a growing colony. The primary individual ("ancestrula," Jullien), formed by the metamorphosis of the larva, commonly shows characters different to those of the other zoœcia, and confirming the views above suggested.

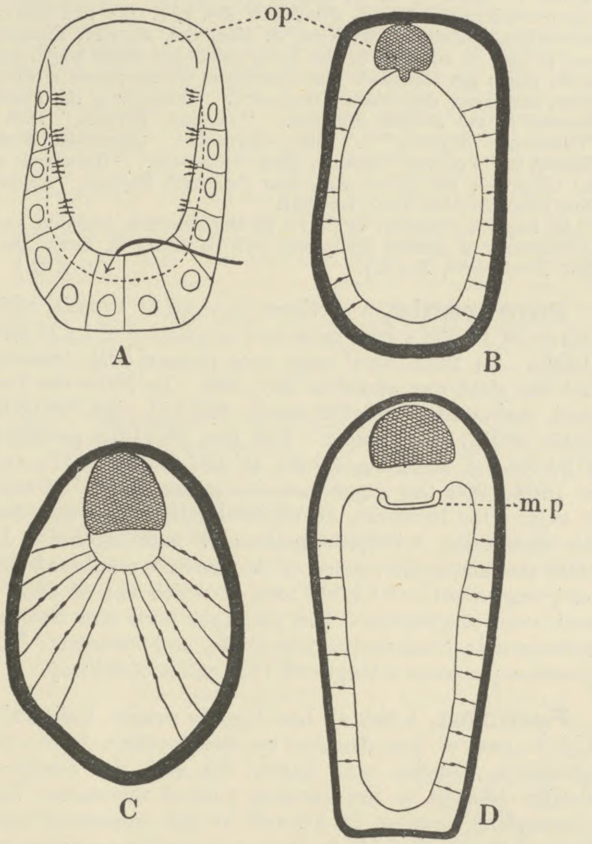

FIG. 6.—A, *Umbonula verrucosa,* at an early stage of its calcification; a calcareous wall is overarching a *Membranipora*-like aperture (cf. Fig. 5), into which the parietal muscles are inserted; B, *Schizoporella,* showing the "sinuate" operculum (*op.*); the compensation-sac opens at the sinus, and is attached to the wall of the zoœcium by parietal muscles; C, a young zoœcium of *Lepralia pallasiana;* the front wall (not shown) is completely calcified; the compensation-sac, from which the parietal muscles radiate, is still small; D, *Calwellia sinclairii,* showing the compensation-sac opening by the median pore (*m.p.*).

It results from an examination of the compensation-sac that many of the existing divisions of the Cheilostomata are unnatural. This applies particularly to the so-called Cellularina, an assemblage of erect and branching forms, of delicate habit. Some of these, such as the Bicellariidae, are quite *Membranipora*-like in the character of their front wall and in the arrangement of their parietal muscles. Others, such as the genera *Catenicella, Calwellia, Ichthyaria, Urceolipora,* &c., are Lepralioid forms with a completely calcareous front wall and a typical compensation-sac.

In the Microporidae and Steganoporellidae, and perhaps in many of the Lepralioid Cheilostomata, the body-cavity is partially subdivided by a calcareous lamina ("cryptocyst," Jullien) which grows from the proximal side, parallel

[1] It appears probable that in most Lepralioid forms the calcareous front wall (upper in figures) is not arranged as in Fig. 3 (C, D?) and in Fig. 4 (C); but that it may (in some cases) correspond with the *inner* layer of the *Cribrilina* spines (Figs. 3, 4, B), the outer layer of which is then represented by a membranous layer known as the "epitheca."

to the opercular wall, which remains membranous. The parietal muscles are here reduced to a single distal pair, which may pass through foramina ("opesiules," Jullien) to reach their insertion into the aperture.

The determination of the recent marine Polyzoa has been greatly facilitated by the publication of Miss Jelly's *Synonymic Catalogue*. Bibliographies of recent and fossil Polyzoa have been published by Vine (*Brit. Assoc. Reps.*, 1880–85, 1890, 1892), and by Nickles and Bassler (*Bull. U.S. Geol. Survey*, No. 173, 1900). Important work on recent marine Polyzoa has been done by Hincks, Waters, MacGillivray, Levinsen, and others. The most complete classification of recent marine forms is that given by MacGillivray (*Proc. Soc. Victoria*, xxiii. p. 187), but the works of Vine and of Delage and Hérouard (*Traité de Zoologie Concrète*, vol. v. Paris, 1897) will also be found specially helpful. The fossil forms have been studied by Gregory, Pergens, Waters, Neviani, and others. The English edition of Zittel's *Palaeontology* contains an elaborate account of them by E. O. Ulrich, who accepts the sub-orders TREPOSTOMATA (Ulrich, *J. Cincinnati Soc.* v. p. 151) and CRYPTOSTOMATA (Shrubsole and Vine, *J. Geol. Soc.* xxxviii., *Proceedings*, p. 245) in addition to the three sub-orders under which the recent forms are classified. In addition to the references already given, the reader may consult GREGORY. *Catalogue of the Fossil Bryozoa in the British Museum.* "Jurassic Bryozoa," 1896; "Cretaceous Bryozoa," i. 1899.—HARMER. *Cambridge Nat. History*, ii. "Polyzoa," London, 1896.—SIMPSON. "Handbook of the Genera of the North American Palaeozoic Bryozoa," *Report State Geologist New York*, for 1894.

[An important memoir by Calvet on the structure, budding, and development of marine Ectoprocta will be found in *Trav. Inst. Zool. Montpellier*, No. 8.] (S. F. H.)

Pomerania, a northern province of Prussia, with an area of 11,628 square miles and population of 1,634,832 (1900). In 1897, 3600 acres were planted with tobacco, and the yield was valued at £85,500. In 1900 the live stock embraced 1,296,832 sheep, 935,043 pigs, 685,509 cattle, and 213,637 horses. The iron foundries produced 9724 tons of materials, valued at £87,300 in 1897; and in 1899–1900 the sugar factories produced 89,192 tons of sugar; the breweries, 18,766,000 gallons of beer; and the distilleries, 9,123,400 gallons of pure alcohol. In 1899 the mercantile marine of the province numbered 356 sea-going vessels of 82,523 tons, of which 124 of 65,979 tons were steamboats. The principal ports are Stettin, Swinemünde, Stralsund, Stolpmünde, and Sassnitz. The province possesses a length of 1128 miles of railway.

Pomona, a city of Los Angeles county, California, U.S.A., east of Los Angeles, on the Southern California (Atchison, Topeka, and Santa Fé) and the Southern Pacific railways, in the southern part of the state. The surrounding country is devoted to the culture of subtropical fruits, for which Pomona serves as a shipping point. Population (1900), 5526.

Ponce, town on the south coast of Porto Rico, 50 miles south-west of San Juan. It is the largest commercial place in the island, and was founded in 1752, and is second to San Juan in population, having in 1899 27,952 inhabitants. It consists of two parts, Ponce and Ponce Playa. Ponce, the residence and business portion, is situated at the interior margin of a beautiful plain, where the latter meets the foot-hills. It has a handsome plaza, hospitals, municipal hall, barracks, and other public buildings. There are medicinal springs and baths. Ponce Playa is the seaport. It is two miles from Ponce, and lies on a spacious bay. The custom-house, shipping offices, and wholesale stores are situated at Playa. An electric railway connects the city and port. A short line of railway runs from Ponce to Yauco to the west, and good highways extend to San Juan, 80 miles, and to Guayama, about 44 miles.

Ponchielli, Amilcare (1834–1886), Italian musical composer, was born near Cremona on 1st September 1834. He studied at the Milan Conservatoire. His first dramatic work, written in collaboration with two other composers, was *Il Sindaco Babbeo* (1851). After completing his studies at Milan he returned to Cremona, where his opera *I Promessi Sposi* was produced in 1856. This was followed by *La Savojarda* (1861, produced in a revised version as *Lina* in 1877), *Roderigo, Rè dei Goti* (1864), and *La Stella del Monte* (1867). A revised version of *I Promessi Sposi*, which was produced at Milan in 1872, was his first genuine success. After this came a ballet, *Le due Gemelle* (1873), and an opera, *I Lituani* (1874, produced in a revised version as *Alduna* in 1884). Ponchielli reached the zenith of his fame with *La Gioconda* (1876), written to a libretto founded by Arrigo Boito upon Victor Hugo's tragedy, *Angelo, Tyran de Padoue*. *La Gioconda* was followed by *Il Figliuol Prodigo* (1880) and *Marion Delorme* (1885). Among his less important works are *Il Parlatore Eterno*, a musical farce (1873), and a ballet, *Clarina* (1873). In 1881 Ponchielli was made *maestro di cappella* of Piacenza Cathedral. His music shows the influence of Verdi, but at its best it has a distinct value of its own, and an inexhaustible flow of typically Italian melody. His fondness for fanciful figures in his accompaniments has been slavishly imitated by Mascagni, Leoncavallo, and many of their contemporaries. Ponchielli died at Milan on 17th January 1886.

Pondicherry, the capital of the French possessions in India, is situated on the Coromandel or western coast, about 100 miles south of Madras. The territory, which is entirely surrounded by the British district of South Arcot, has an area of 115 square miles, with a population of 182,000. The chief crops are dry grains, rice, earth-nuts, and a little indigo. It is traversed by a branch of the South Indian Railway from Villupuram (24 miles). The town has a population of about 50,000. It has an open roadstead, with a small iron pier. In 1900–01 the total seaborne trade was valued at 13,257,116 francs, of which 8,329,013 francs consisted of exports, chiefly cotton manufactures, earth-nuts, cleaned rice, and hides. The principal imports were betel-nuts, cotton manufactures, wines and liqueurs, and oils. Of the export trade more than half was with France, but of the import trade only one-fourth. During 1900 the number of British vessels that called was 204, with an aggregate tonnage of 312,488 tons. A cotton mill has recently been opened by a company with a capital of £200,000. In 1900 there were altogether 4 mills, with 1144 looms and 71,432 spindles, employing 2628 persons.

Pondoland. See CAPE COLONY.

Pont-à-Mousson, town, arrondissement of Nancy, department of Meurthe-et-Moselle, on the river Moselle, 17 miles north-north-west of Nancy by rail. It is of considerable antiquarian interest, and has a library, three hospitals, engineering workshops, blast furnaces, and manufactures of lacquered ware, paper, cardboard, cables, and electrical apparatus. Population (1901), 12,847.

Pontarlier, a fortified town and chief town of arrondissement, department of Doubs, France, 37 miles south-east of Besançon, on the railway from Dijon to Berne. It forms a very important strategic point at the mouth of the Cluse, one of the principal passes across the Jura. It was here that the French army of the east made its last stand against the Prussians in 1871, in order to cover the retreat of the main army into Switzerland. The distillation of herbs, extensively cultivated for absinthe, gentian, kirsch, and liqueurs, occupies several establishments. The town has considerable commerce with Switzerland in spirits and agricultural produce, &c. Population (1901), 8031.

Pont Audemer, chief town of arrondissement, department of Eure, France, 43 miles north-west of Evreux, on the Risle, a left-bank affluent of the Seine, and on the railway from Evreux to Honfleur. The churches of St Ouen and St Germain date in part respectively from the 11th and the 12th centuries. Local institutions are a hospital, chamber and tribunal of commerce, and small public library. Manufacturing industry is very active, and includes the founding of malleable metal, a large spur factory, and various important branches of leather manufacture. There is considerable trade in flax, wool, grain, cattle, cider, paper, iron, wood, and coal. The port has a length of about half a mile on the Risle, navigable to this point. It is bordered by quays for 450 yards, and vessels drawing 6½ to 9½ feet of water are towed up by horses from Roque, 17 miles below. Population (1901), 5908.

Pontefract, a municipal and parliamentary borough (since 1885 returning only one member) and market-town of Yorkshire, England, 13 miles south-east of Leeds by rail. An isolation hospital was erected in 1900, costing £9000. New waterworks have been constructed by the corporation at a distance of 8 miles from the town at a cost of £30,000. Population (1881), 8798; (1901), 13,422.

Pontevedra, an Atlantic province of Spain; area, 1739 square miles; population (1897), 447,612; death-rate 2·38 per cent.; birth-rate 2·66 per cent. It is divided into 11 districts and 65 parishes.

Much business is done at the great fairs held at several towns, where the country folk bring in live stock, poultry, and dairy produce. The foreign trade is considerable. The exports are cattle to England and Portugal, hams, salt meat and fish, eggs, bread-stuffs, leather, wine. Vigo, Carril, Marin, Villagarcia, Bayona are the principal ports. In 1898 wheat was grown on 5865 acres; rye, oats, barley, and maize on 249,527 acres; pod fruit and beans on 88,635; vines on 13,022; live stock included 3928 horses, 1282 mules, 623 asses, 73,531 cattle, 42,201 sheep, 14,840 goats, and 32,581 pigs. The mines are not important.

Pontevedra, capital of the above province, near the coast, on the river Lerez, here spanned by a bridge of twelve arches. The country around produces wheat, wine, and fruit. It is a station on the Monforte-Vigo Railway. The institute and primary schools are well attended. The town contains many convents, some of which have been turned into public buildings, refuges, hospitals, schools. Some of the modern provincial and municipal buildings are very handsome. Population (1897), 19,986.

Pontiac, a city of Michigan, U.S.A., capital of Oakland county, on the Clinton river, and the Grand Trunk and the Pontiac, Oxford, and Northern railways, in the south-eastern part of the state, at an altitude of 932 feet. It is surrounded by many small lakes and ponds, which have become well-known resorts for sportsmen. The city is the site of the Eastern Michigan insane asylum. Population (1880), 4509; (1890), 6200; (1900), 9769, of whom 2020 were foreign-born and 151 negroes.

Pontivy, formerly NAPOLEONVILLE, chief town of arrondissement, department of Morbihan, France, 32 miles north-north-west of Vannes, on the Blavet. The town comprises two distinct parts: that built by order of Napoleon I., who desired to make it the military head-quarters for Bretagne, and consisting chiefly of barracks, subsequently gave name to the whole town, but in 1871 the former name was resumed. The ancient castle of the dukes of Rohan, built in 1485, is now occupied by the Musée Le Brigant of art and archæology. A monument to commemorate the Breton-Angevin Union was erected in 1894, and there are statues of Dr Guépin, a Democrat, and General de Lourmel (d. 1854). Population (1881), 5720; (1901), 9359.

Pontoon.—The pontoon equipments of European armies have undergone few changes in recent years. In the British army Colonel Blood's equipment has been modified by the introduction of a bipartite pontoon designed in 1889 by Lieut. Clauson, R.E.

Each pontoon is carried on one waggon with a bay of superstructure, and consists of two sections, a bow-piece and a stern-piece, connected together by easily manipulated couplings of phosphor bronze. Decks and "coamings" are dispensed with, and the rowlock holes are sunk in a strong gunwale. The detachable saddle-beam, which receives the load on the centre of the thwarts, is made in sections, so as to form a continuous saddle of any length required. The baulks (or road-bearers) and chesses (or planks) remain unaltered, but chess-holders and chess-bearers are added for use in constructing light bridges for infantry in file. In this kind of bridge each pontoon section is used separately, with a roadway of chesses placed longitudinally four abreast. In the normal or medium bridge two sections, and in heavy bridge three sections, are joined together. The chief advantages of the equipment are (1) the buoyancy of the piers can be proportioned to the weight of traffic and to the roughness of the water; (2) owing to the special design of the bows, boats and rafts are easy to row, while the pontoons in bridge oppose little resistance to the current, and so require less anchor power; (3) transport rafts, pier-heads, and flying bridges can be constructed with great ease, owing to the flush gunwales on which baulks can rest if necessary; (4) the pontoon sections are convenient to handle, easy to ship or to transport by rail, and can readily be replaced singly if damaged in bridge. A canoe pontoon and superstructure adapted for pack transport has also been adopted from designs by Colonel Elliott Wood, C.B., R.E. The pontoon consists of four sections laced together, each section being a framework of wood covered with waterproof-sheeting. Three pontoons and eight composite planks form a "unit," from which can be constructed 48 feet of bridge for infantry in file, 84 feet for infantry in single file, or a raft to carry 15 men or an empty waggon. The Indian demi-pontoon is of the same length (22 feet) as the Blood pontoon, but is sheathed with copper. It has a square stern, to enable it to be used in pairs. The Chitral Relief Expedition, 1895, brought to light some defects in this pontoon. The shape of the bows proved unsuited to rapid currents, the balance was unsatisfactory, and cracks developed in the copper sheathing. Experiments have been made with bipartite pontoons.

The French pontoon is a somewhat cumbrous wooden boat. The German army is equipped with a galvanized iron pontoon in one piece, handy as a boat, but of insufficient buoyancy to form a satisfactory bridge support, as the spans have to be unduly diminished for heavy traffic, and the waterway is consequently obstructed. The Bavarian equipment has been improved; it approximates to the Austrian type. Aluminium pontoons have been tried in Germany, but have not been adopted. For the German cavalry the Berthon folding-boat equipment has been introduced. Each regiment has a waggon carrying sufficient equipment to form a road-bridge 26 feet long, a foot-bridge 65 feet long, or a raft capable of ferrying a field gun and limber, 45 sets of saddlery and kits, or 25 equipped infantrymen. In Austria, repeated but unsuccessful efforts have been made to reduce the weight of the Birago pontoon sections still in use, by the substitution of steel for iron. The Russian pontoon, of Birago type, with sheer sides, and the heavy wooden boat of the Italian equipment, have not been modified.

The methods of constructing pontoon bridges have been simplified of late years in most armies, and are usually restricted to (1) adding pontoons one by one to the head of the bridge; (2) connecting rafts of two or more pontoons into bridge by intermediate bays of superstructure; and (3) swinging across the river a bridge previously prepared alongside the shore. The formation of a bridge from rafts touching one another consumes an excessive amount of equipment, and opposes unnecessary resistance to the stream; it is therefore being discarded in most armies. "Booming out" the bridge bay by bay from the shore until the head reaches the opposite bank is unsuited for rapid currents, and is almost obsolete except for light infantry bridges.

The organization of bridging *personnel* in different armies shows as much divergence of opinion as the design of pontoon equipment. In the British army a pontoon troop, R.E., is included in the corps engineers of each army corps, with a war establishment of 5 officers, 81 dismounted men, 132 mounted men, and 186 horses.

In peace the pontoon troops constitute an administrative unit called the bridging battalion, with an establishment of 197 all ranks and 70 horses. A pontoon troop can make 185 yards of light bridge, 105 yards of normal, or 75 yards of heavy bridge. Each of the four field companies R.E. in an army corps can make 25 yards of light, 15 yards of normal, or 10 yards of heavy bridge, the equipment being of the same pattern as that of the pontoon troop. In France an important change was made in 1894, when the two pontoon regiments were transferred from the artillery to the engineers. In war these regiments furnish five army bridge trains, forming 280 yards of bridge each, besides supplying to each army corps a pontoon company with 140 yards of bridge. The requirements of divisions are met by an advanced guard bridge train (33 yards of bridge) carried on two waggons with each divisional company of sappers and miners. In the German army the pioneer company attached to each division can throw 47 yards of bridge. The corps pontoon train carries 133 yards of bridge, which is constructed by one of the pioneer companies of the army corps. The cavalry equipment has already been described. In Austria the pioneers are in charge of the pontoon equipment. Forty-five normal bridge trains, each carrying 58 yards of bridge, are at the disposal of army headquarters, and a light bridge train carrying the same length of bridge would usually be allotted to each army corps. In Russia half a pontoon battalion, carrying about 140 yards of bridge, is detailed to each army corps, and in addition the divisional sapper company has a light bridge train carrying 22 yards of bridge on six waggons. In Italy the pontoon companies provide eight army bridge trains (219 yards of bridge each), and the sapper company attached to each division carries 43 yards of bridge on six waggons.

See VON RIPPER, *Europäischen Kriegsbrücken-Systeme*, Vienna, 1896; and *Instruction in Military Engineering*, part iii., Bridging, 1894. (J. E. C.)

Pontremoli, a town and bishop's see of the province of Massa and Carrara, Tuscany, Italy, in the upper valley of the Magra, 20 miles north by east of Spezia. It has a 17th-century cathedral, a citadel, and an episcopal library. There are also mineral springs; and the people quarry marble and polish it, as well as make lime and bricks. The town was an independent republic in the 12th and 13th centuries, and in 1495 was sacked by the troops of Charles VIII. of France. Population (1899), 11,000.

Pontypool, a town in the northern parliamentary division of Monmouthshire, England, 8 miles north of Newport by rail. An electric lighting power company was formed in 1893 to supply the district with electric light. The market-house was opened in 1894, after a reconstruction which cost £22,280, and a new cattle market was formed in 1899. A new recreation ground was opened in 1893. Population (1901), 6126.

Pontypridd, market-town, urban district, and parish in the eastern parliamentary division of Glamorganshire, Wales, on the Taff river, 12 miles south of Merthyr Tydfil by rail. A new town hall has been built over the market, and a free library erected. New gas works have been established, and a water reservoir to store 200,000,000 gallons was completed in 1900. Population (1891), 24,763; (1901), 32,319.

Poole, a municipal borough, county in itself, seaport, and market-town in the Eastern parliamentary division of Dorsetshire, England, 20 miles east of Dorchester on the South-Western Railway. Modern erections are the free library and school of art; and the Cornelia Hospital. Poole Park, containing 40 acres of land and 62 acres of water, was acquired in 1887 and 1889, and Brankstone Park of 40 acres in 1895. Since 1885 the Poole corporation has had power to regulate the oyster fisheries in the harbour, and 200 acres in the Wareham Channel have been granted to a local company, under whose management the oyster beds are again productive. The harbour, which has a depth of only 8½ feet, is beset by shifting sand-banks, through which there are only narrow channels. In 1888 the registered shipping totalled 42 vessels of 2257 tons; in 1900, 45 vessels of 2834 tons. In 1888, 1002 vessels of 87,299 tons entered and 984 of 83,567 tons cleared; in 1900, 1353 vessels of 156,399 tons entered and 1366 of 158,414 tons cleared. The total trade is valued at £130,000 annually. Area, 5333 acres. Population (1881), 12,310; (1891), 15,438; (1901), 19,461.

Poole, Reginald Stuart (1832–1895), English archæologist and orientalist, was born in London, 27th January 1832. On his mother's side he was a nephew of E. W. Lane, the Arabic scholar, with whom he lived in Cairo from 1842 to 1849, thus imbibing an early taste for Egyptian antiquities. In 1852 he became an assistant in the British Museum, and was assigned to the department of coins and medals, of which in 1870 he became keeper. His work in that capacity was of the highest value, alike as a writer, teacher, and administrator. In 1882 he was largely responsible for founding the Egypt Exploration Fund, and in 1884 for starting the Society of English Medallists. He retired in 1893, and died on 8th February 1895. Some of Poole's best work may be found in his articles for the *Ency. Brit.* (ninth ed.) on EGYPT, HIEROGLYPHICS, and NUMISMATICS; he also wrote for Smith's *Dictionary of the Bible*, and published several volumes dealing with his special subjects. He was for some time professor of archæology at University College, London, and also lecturer at the Royal Academy.

Poona, or PUNA, a city and district of British India, in the Deccan division of Bombay. The city is on the right bank of the Muta river, 1850 feet above the sea; railway station, 119 miles from Bombay. Municipal area, about four square miles; population (1881), 129,751; (1891) 161,390; (1901) 111,385, showing an increase of 24 per cent. between 1881 and 1891, but a decrease of 31 per cent. between 1891 and 1901. From its healthy situation, Poona has been chosen not only as the headquarters of the Bombay army, but also as the residence of the Governor of Bombay during the rainy season, from July to November. The native town, along the river bank, is somewhat poorly built. The European quarter extends to the north-west as far as the cantonment of Kirkee. The modern waterworks have been constructed mainly by the munificence of the late Sir Jamsetjee Jeejeebhoy. Poona was never a great centre of trade or manufacture. Two cotton mills, with 1250 looms and 33,000 spindles, employing 1000 hands; a paper mill, employing 340 hands, with an out-turn valued at Rs.3,09,000; a brewery (at Dapuri) producing 800,000 gallons of beer; two flour mills, with an out-turn valued at Rs.42,000; factories of ice and mineral waters; four dairy farms, furnish the chief industries. Educational institutions are numerous, but their statistics since 1896 have been vitiated by the prevalence of the plague. They include the Government Deccan College, with a law class; the aided Fergusson College; the unaided Maharashtra College; the Government college of science, with agricultural and forest classes; seven high schools; training schools for masters and mistresses; medical school; municipal technical school; and several schools for European boys and girls. There are altogether forty-three printing-presses, including those belonging to Government departments, which issue two English and a large number of vernacular newspapers. Since 1896 the history of Poona has been painfully associated with the plague. Down to July 1898 the total number of cases of plague reported in Poona city was 9362, and the number of deaths was 6967. During 1897 the death-rate rose to 93 per thousand in Poona city, 71 per thousand in the cantonment, and 93 per thousand in Kirkee.

The district of POONA has an area of 5369 square miles; population (1881), 901,828; (1891), 1,067,800; (1901), 995,074, showing an increase of 18 per cent. after the disastrous famine of 1876–77, but a decrease of nearly 7 per cent. between 1891 and 1901; average density, 185 persons per square mile. Land revenue and rates, Rs.19,32,443, the incidence of assessment being R.0–10–3 per acre; cultivated area (1897–98), 1,860,195 acres, of which 142,948 were irrigated, including 54,492 from Government canals; number of police, 1210; children at school (1897–98), 20,699, being 2 per cent. of the total population. The principal crops are millet, pulse, oilseeds, and wheat. The two most important irrigation works in the Deccan are the Mutha canal, with which the Poona waterworks are connected, and the Nira canal. The total capital outlay on the former has been Rs.66,00,979; in 1897–98 the gross receipts were Rs.2,34,211 and the expenditure Rs.79,818, showing a profit of 2·34 per cent. The capital outlay on the latter has been Rs.56,71,000; in 1897–98 the gross receipts were Rs.1,35,705 and the expenditure Rs.61,694, showing a profit of 1·30 per cent. There are manufactures of cotton, silk, and blankets. The district is traversed for 106 miles by the Great Indian Peninsula Railway, and also by the Southern Mahratta line, which starts from Poona city towards Satara. It is liable to drought, from which it suffered severely in 1866–67, 1876–77, and again in 1896–97. (J. S. CO.)

Poor Laws.—The chief difficulty in understanding the English poor law arises from the fact that there are three authorities, each of them able to alter its administration fundamentally. Few statutes relating to the poor law have been repealed, and the need of consolidation is very generally admitted. The poor law, however, is not only the creation of statutes passed by Parliament; it is also controlled by the subordinate jurisdiction of the Local Government Board, which in virtue of various Acts has the power to issue Orders. The Board possesses great facility for consolidating its Orders, and probably all that is here possible has been done. A third source of authority is the local board of guardians, which, within the discretion allowed to it by Statutes and Orders, can so variously administer the law that it is difficult to understand how procedure so fundamentally different can be based on one and the same law. This elasticity, admirable or mischievous, as we choose to regard it, is the most characteristic feature of the English poor-law system, and a supplementary note in illustration of its working during the closing years of the 19th century will give a better idea of the public policy in this respect than an elaborate analysis of statutes.

I. *Legislation.*—The burden of pauperism was in 1834 so heavy that England hardened its heart to perform a very drastic act of social surgery. The Poor Law Amendment Act, 1834, checked the growth of pauperism. Relatively to the wealth and population of the country, pauperism has never since that date been an overwhelming burden. Apprehension was allayed, and a certain humanitarian reaction against the strict theory which underlies the Act of 1834 set in almost at once. Up to 1869 the local administrative bodies, with few exceptions, although in self-defence they applied the provisions of the Act, never embraced its principles with enthusiasm. About 1869, owing to a variety of causes (*e.g.*, the influence and example of men like Edward Denison, followed as a result by Mr Goschen's circular of 20th November 1869 and Mr Fawcett's book on Pauperism, published in 1871), a deeper theoretical interest was aroused, and several boards of guardians adopted (as recommended in these and other treatises) a stricter administration of outdoor relief. The burden, it was argued, might no longer be intolerable to the ratepayer, but the dependence of the pauper was a cruelty to himself, and a firm policy, tending to infuse a spirit of independence into the pauper population, was the truest philanthropy. Thoroughgoing support to this policy has been confined to a few unions, but some advance in this direction has been well-nigh universal. A reduction of pauperism from 47·1 per 1000 of population in 1871 to 21·9 in 1900 (see *Monthly Statement of Pauperism*, March 1900) is a solid achievement. The improvement, however (so at least advocates of the principles of 1834 argue), is much less marked than it might have been had the policy of 1834 been frankly adopted. This belief in the emancipating effect of a stricter policy has not had much weight with the legislature, and effort has chiefly been directed to secure the comfort rather than the emancipation of the pauper. Legislative changes, indeed, with regard to the actual administration of the law, have not during the period under review been numerous or important.

The first Act to be noticed in this connexion is the Medical Relief Disqualification Removal Act, 1885, passed by Lord Salisbury's Government. This Act relieves voters from disqualification which would otherwise attach in consequence of the receipt by them or their families of medical or surgical assistance, or of medicine, at the expense of the poor rate. This does not apply to guardian elections, and it does not include persons who, in addition to medical relief, receive nourishment or other relief from the poor rate. The provisions which require the removal of the names of paupers from the electoral roll are, it is understood, very perfunctorily carried out. The Outdoor Relief Friendly Societies Act, 1894, authorizes guardians, in calculating the proper allowance to be made, to disregard an income derived from a friendly society, and to give relief as if the applicant in receipt of such an allowance was wholly destitute. This Act is a curious illustration of the English poor-law system. In earlier years, notably in what is known as Paget's letter (22 Rep. Poor Law Board, p. 108), the Central Board had, in answer to inquiry, pointed out that such preferential treatment given to men receiving benefit, insufficient to maintain them, from a friendly society, could not in equity be withheld from persons in receipt of an adequate benefit, or from those whose savings took the form of a deposit in a bank, of a share in a co-operative society, or of cottage property; and further, that an engagement on the part of guardians to supplement insufficient allowance from a friendly society was a bounty on inadequate and insolvent friendly society finance. The Central Board went so far as to say that relief given in such disregard of the pauper's income was illegal. They had, however, issued no peremptory order on the subject, nor had guardians been surcharged for neglect of the rule. The local authorities followed their own discretion, and a very general practice was to reckon friendly society allowances at half their value. The above Act sets aside the Central Board's earlier interpretation of the law. It makes, however, no attempt to enforce its procedure on the numerous boards of guardians who regard the course thereby authorized as contrary to public policy.

The period under review has also seen the passage of several Acts designed to secure a more effective treatment of lunatics and children. The Lunacy Act of 1890 is a consolidation of the Acts affecting lunatics. It is further amended by the Lunacy Act, 1891. An explanatory letter issued by the Local Government Board will be found in the 20th Annual Report, p. 33. The tendency of this and of all recent legislation for an afflicted class is to increase the care and the safeguards for their proper treatment. The same desire to improve administrative methods for the rescue of the helpless is shown in the Poor Law Act, 1889, and in the Custody of Children Act, 1891, sect. 3. The evil of allowing children who have been reputably brought up in poor-law schools to relapse into vicious habits on return to the custody of unworthy parents, has been the subject of frequent remark. By the Act of 1889, guardians are authorized to detain children who are under their charge, as having been deserted by their parents, up to the age of 16 if boys and of 18 if girls. By the Poor Law Act, 1899, the principle is extended to orphans and the children of bad parents chargeable to the rates. The Act of 1891 goes farther, and enacts that where a parent has (*a*) abandoned or deserted his child, or (*b*) allowed his child to be brought up by another person at that person's expense, or by the guardians of a poor-law union for such a length of time and in such circumstances as to satisfy the Court that the parent was unmindful of his parental duties, the Court shall not make an order for the delivery of the child to the parent unless the parent has satisfied the Court that, having regard to the welfare of the child, he is a fit person to have the custody of the child.

Some important readjustments of the burden of local expenditure have next to be noticed. The system of making grants from the national taxes in aid of local rates has proceeded to considerable lengths. The article in the ninth edition of the *Ency. Brit.* notices the institution of the Metropolitan Common Poor Fund, a device for giving metropolitan grants assessed on the whole of London in aid of the London local poor-law authorities. The same principle, *mutatis mutandis*, is also followed in the relations which now obtain between the national and the local exchequers.

At the time of the repeal of the Corn Laws, Sir R. Peel expressed an opinion that this fiscal change necessitated some readjustment of local rates. In that year, 1846, a beginning of grants from the national exchequer in aid of local expenditure was made. The salaries of poor-law teachers, medical officers, and auditors were provided from the larger area of taxation, and in 1867 the salaries of public vaccinators were added to the list. In 1874 a grant of 4s. per head per week was made for each pauper lunatic passed by the guardians to the care of a lunatic asylum. By the Local Government Act, 1888, supplemented by the Local Taxation (Customs and Excise) Act, 1890, this principle was more widely extended. The various grants in aid were abolished, and in substitution the proceeds of certain specified taxes (*i.e.*, additional beer and spirit duties, (*a*) customs and (*b*) excise; excise licences, share of the probate, now termed the estate duty) were set aside for local purposes. From this source, the gross amount of which of course varies, there are now distributed to local poor-law authorities 4s. a week for lunatics in asylums, and allowances based on their average expenditure in previous years in salaries of officials and other specified charges. In London, in order not to conflict with the operation of the Common Poor Fund, which had already spread these charges over a wide area, the grant takes the form of a sum equivalent to 4d. per diem for each indoor pauper. The number on which this calculation is based is not, however, to be the actual number, but the average of the last five years previous to the passing of the Act. By this legislation something like one-quarter of the total expenditure on poor-law relief is obtained from national taxes as opposed to local rates. By the Agricultural Rates Act, 1896, enacted for a period of five years, the occupier of agricultural land is excused one-half of certain rates, including the poor rate. The deficiency is supplied by a contribution from the National Exchequer. Meanwhile, the spending authority continues to be elected by the local ratepayers. In this connexion two further anomalies deserve notice. By the Poor Rate Assessment and Collection Act, 1869, owners who compound to pay the rates in respect of tenement property are entitled to certain deductions by way of commission. Such payments by the owner are constructively payments by the occupier, who thereby is to be deemed duly rated for any qualification or franchise. Under these arrangements a large number of electors do not contribute directly to the rate. A converse process is also going on, whereby the ownership of an important and increasing body of property is practically unrepresented. This is due to the great growth of property in the hands of railway companies, docks, and limited liability companies generally. The railways alone are said to pay 13 per cent. of the local taxation of the country, and they have no local representation. There is, in fact, in local administration a divorce between representation and taxation to a greater extent than is generally supposed, and it is impossible not to connect the fact with the rapid growth of local expenditure and indebtedness.

The Local Government Act, 1894, did away with *ex officio* and nominated guardians. The plural vote (which gave to the votes of the larger ratepayers a higher value) was also abolished; and in place of the old property qualification for the office of guardian, a ratepaying or residential qualification was substituted. In urban districts the Act in other respects left the board of guardians untouched, but in rural districts it inaugurated a policy of consolidating local authorities which is capable of further extension. In the rural districts the district council is practically amalgamated with the guardians, for, though each body retains a separate corporate existence, the district councillors are the guardians, and guardians as such are no longer elected. These electoral changes, extremely democratic in their character, have not brought about any marked general change in poor-law administration. Here and there abrupt changes of policy have been made, but the difficulty of bringing general principles to bear on the administration of the law remains much as before. Two statutes important to the official staff of the guardians may be mentioned—the Poor Law Officers' Superannuation Act, 1896, and the Poor Law Officers' Superannuation Act Amendment Act, 1897. The Poor Law Act, 1897, is a consolidating and amending Act on the important question of the repayment of loans. This Act, together with the Poor Law Act, 1889, which it partially repeals, are the principal statutes governing the question. With the sanction of the Local Government Board, guardians may borrow, and repay in a period not to exceed sixty years; such loans are not to exceed one-fourth of the total annual rateable value of the union.

II. Passing to the *subordinate jurisdiction* of the Local Government Board, we may notice that in the year ending 31st March 1899 over eighteen hundred Orders were issued by the Board, over one thousand of them having special reference to the poor law. It is not possible, therefore, even to summarize this mass of subordinate legislation. The Orders and circulars (these last are hardly less important) quoted below are mentioned merely as illustrations.

Several circulars and Orders with reference to the detention of casual paupers have been issued since 1885. These are summed up in the General Order, 11th June 1892. Its general purpose is to mitigate the severity which might seem authorized by the provisions of the Pauper Inmate Discharge Act of 1871 and the Casual Poor Act, 1882. By this order the guardians are called on to use a reasonable latitude in allowing the departure of the casual pauper who professes to be in search of work. Against this we have to set a circular letter of 25th February 1896, calling attention to the increase of vagrancy, and stating that "there appeared to be reason for considering that this increase was to a considerable extent not unconnected with a failure on the part of boards of guardians to enforce the provisions of the Pauper Inmate Discharge and Regulation Act, 1871, as amended by the Casual Poor Act, 1882; and of the regulations of the Board." On inquiry, the Board found that "in a large proportion of unions" the deterrent regulations authorized by these Acts had been neglected.

The earlier years of the period were years of commercial depression, and the boards of guardians throughout England were much exercised as to the best means of dealing with the "unemployed." On the 15th March 1886 an important circular was issued from the Local Government Board. It states that while "the Board have no doubt that the powers which the guardians possess are fully sufficient to enable them to deal with ordinary pauperism, and to meet the demand for relief from the classes who usually seek it," yet "these provisions do not in all cases meet the emergency. What is required to relieve artisans and others who have hitherto avoided poor-law assistance, and who are temporarily deprived of employment, is—(1) Work which will not involve the stigma of pauperism; (2) work which all can perform, whatever may have been their previous occupations; (3) work which does not compete with that of other labourers at present in employment; and lastly, work which is not likely to interfere with the resumption of regular employment in their own trades by those who seek it."

The circular goes on to recommend that guardians should confer with the local authorities, "and endeavour to arrange with the latter for the execution of works on which unskilled labour may be immediately employed." The conditions of such work were (1) the men to be employed must be recommended by the guardians; (2) the wages must be less than the wages ordinarily paid for such work.

The circular was widely distributed. Many boards that were inclined in that direction regarded it as an encouragement to open or to promote the opening of relief works. Others, again, looked closely at the conditions, and declared roundly that it was impossible to fulfil them. A poor-law authority, they said, cannot give relief which will not subject the recipients to the legal (if any) and economic disabilities attaching to the receipt of poor-law relief. Work which all can perform can only be found in the shape of task-work under adequate supervision. If the work is of a useful and necessary character, it must compete with the labour of others belonging to the trades affected. If the relief works are opened by authorities other than the poor-law guardians, the conditions that the men were only to be employed when recommended by the guardians, and then paid less than the current rate of wages, were calculated, it was urged, to secure bad work, discontent, and all the "stigma of pauperism." The ambiguity of the circular indeed is such, that both action and inaction, as presently to be described, seem amply justified by it.

Two important Orders on the subject of the boarding out of poor-law children were issued in 1889. By the *Boarding of Children in Unions Order*, orphan and deserted children can be boarded out with suitable foster-parents in the union by all boards of guardians except those in the metropolis. This can be done either through a voluntary committee or directly. By the *Boarding Out Order*, orphan and deserted children may be boarded out by all boards of guardians without the limits of their own unions, but in all cases this must be done through the offices of properly constituted local Boarding-Out Committees. The sum payable to the foster-parents is not to exceed 4s. per week for each child. The local committee require to be approved by the Local Government Board.

The question of the education of poor-law children has been much discussed of late years. During the early years of the Central Authority, it was the object of the Commissioners to induce boards of guardians to unite in *Districts* for educational purposes. This was advocated on grounds of efficiency and economy. It was very unpopular with the local authorities, and the number of such districts has never exceeded a dozen. In London, where this aggregation was certainly less desirable than in rural unions, several districts were formed and large district schools were built. Adverse criticism, by Mrs Nassau Senior in 1874, and by a departmental committee appointed twenty years later, has been directed against these large, or, as they are invidiously called, barrack schools. The justice of this condemnation has been disputed, but it seems probable that some of these schools had grown too large. One of the districts was dissolved by order of the Local Government Board on the application of the unions concerned, and others were in 1900 in course of dissolution. This condemnation of some schools has in certain quarters been extended to all schools, and is construed by others as an unqualified recommendation of boarding out, a method of bringing up poor-law children obviously requiring even more careful supervision than is needed in the publicity of a school.

The classification of children apart from adult paupers is peremptory. Even in those unions where what is called a *Workhouse School* is maintained, the children are kept in detached parts of the building, and do not associate with the adult paupers. The *Separate School* is built on a separate and often distant site. Sometimes the separate school is one building, sometimes *Detached "Blocks,"* and sometimes a group of *Cottage Homes.* There still remain ten *District Schools.* In Sheffield and other places an experiment which is called the *Scattered Homes* system has been adopted. This consists in lodging-homes for the children placed in different parts of the town, from which the children attend the local public elementary schools. In the rural districts and in less populous unions the children generally attend the local public elementary school. To these expedients *Boarding-out* must be added. The above refers of course only to those children who as inmates are under the charge of the guardians. Outdoor paupers are responsible for the education of their children, but guardians cannot legally continue outdoor relief if the children are not sent regularly to school.

Summary, for year ending Lady Day 1898, of the number of unions in which the children attend the different classes of schools :—

Class of School.	Attended by the Children belonging to	Average daily Number of Children.
Poor-law schools—		
District schools . .	28 unions	6,811
Separate schools . .	38 ,,	10,230
Workhouse schools .	63 ,,	3,531
Schools of other unions .	26 ,,	...
	155 ,,	20,572
Public elementary schools .	493 ,,	...
TOTAL . .	648 ,,	...

A later return with regard to boarding out gives the number boarded out *within the Union* on 1st January 1899 as 5191, the number boarded out *beyond the Union* as 1896.

III. *Local Administration.*—The above recorded variations of the educational policy must to a certain extent be regarded as the result of differences of local administration, but as each system is supervised in considerable detail by the Local Government Board, they have been noticed in connexion with the Orders issued by the Central Authority. The administration of relief to the adult population affords a better instance of the strangely divergent methods in which the poor law is *normally* carried out in contiguous and similar areas. These differences of policy largely turn on the attitude taken by guardians towards outdoor relief. Both in town and country, since 1875, a few boards have practically discontinued to give outdoor relief—that is, relief to paupers at their own homes. Other boards have continued to give it lavishly. Between the two extremes almost every variety is to be found. The following table will illustrate the position. The figures are taken from the summer returns (a period less affected by weather conditions), at a date previous to the change of policy which arose from the above-mentioned discussions of 1869, and from returns for 1899.

For this comparison unions in proximity have been chosen. More striking contrast could be obtained by a wider selection (see *Guardians' Guide*, by an Official, p. 27). The motives which underlie these two entirely divergent methods of administration require careful consideration, if the current operation of the law is to be understood. The strict or indoor policy is based on the belief that the more eligible the endowment of pauperism, the easier will

be the descent into pauperism and the greater the reluctance to undergo the effort necessary for emancipation. The supporters of this policy also point with confidence to the expansive nature of the English industrial system, and they complain that the progress of the poorer population from the servile conditions of feudalism and pauperism (influences both historically and essentially closely related) is retarded and arrested by a lavish poor-law administration. The offer of indoor maintenance, if strict and repressive, is also, they contend, adequate and humane. If hard cases arise, they should not be strained to make bad law, but should be dealt with by private charity or by voluntary agencies, a method of relief which has a less disturbing effect on the calculation and conduct of the poor. The opponents of this stricter system have had the great advantage of being the party in possession. They appear to believe less firmly in the possibility of a complete emancipation of the poorer class. Their principal desire is to relieve the sufferer in the manner most agreeable to him. They persuade themselves that the general effect of this policy will not be detrimental to the general welfare. Or, if they admit a danger, they argue that progress is too dearly purchased by curtailment of a system of relief to which the poorer population has become habituated.

Two instances may be added to show how on *abnormal* occasions the widest variety of policy can be introduced, with the sanction apparently of one and the same set of statutes and orders. During the decade beginning in 1885 there was much complaint made on behalf of the unemployed. A large number of unions passed through the crisis without any relaxation of their procedure. Whitechapel, which may be again taken as typical, offered "the house" to the able-bodied, as directed by the law. They obtained, but we believe made no use of, a special Order from the Local Government Board authorizing them to receive the able-bodied male head of a family into their workhouse and to relieve the family at their home; after a short detention they were authorized to let the man go out to look for work during the day, and to continue for a limited period the outdoor relief to the family.

They opened no labour-yard, and the crisis passed without any apparent pressure on the relief authorities. No large additional class found it necessary to become dependent, and no exceptional hardship, it is alleged, was imposed on the class which undoubtedly would have availed itself of relief offered under more eligible conditions. Separated only by the Thames is the union of St Olave's, containing a population industrially superior rather than inferior to the Whitechapel population. London, it should be premissed, is administered under the Outdoor Relief Regulation Order, 1852, which permits the local board to open a labour-yard. Unions under the Prohibition Order, 1844, require the sanction of the Local Government Board. The St Olave's board availed itself of this privilege, and, accepting with more enthusiasm than discrimination the recommendations of the circular of 15th March 1886, opened a labour-yard, gave relief at trade union wages, and speedily attracted an enormous and unmanageable crowd. This policy reached a climax in the winter of 1894–95. The labour-yard was opened 7th January 1895, and remained open till the end of March. The guardians spent £18,000 in employing all applicants at stone-breaking, paying trade union wages. Each ton cost £7, as against 4s., which was said to be the market price. The labour-yard was largely monopolized by the worst characters, and the conditions of relief were thus rendered extremely distasteful to any respectable workman who was obliged to apply. Supervision was so lax, that the men absented themselves till the hour of payment arrived. On the day before the yard was closed, presumably because the guardians thought it was no longer necessary, there were over 1000 men in attendance. No evil consequences are said to have followed the closing of this source of relief. The facts as above stated are derived from the evidence of the chairman of the board, given to the Committee on Distress from Want of Employment.

One other instance of the large discretion placed in the hands of the local administrator may be cited. In April of the year 1898 a strike affecting some 100,000 colliers took place in South Wales. The union of Merthyr found its workhouse full, and opened a labour-yard. The representatives of the employers, who were the principal ratepayers, objected to relief being given to workmen on strike; being in a minority, they appear to have withdrawn from attendance at the board. The stone-yards were failures in two respects—they did not serve as tests of destitution, and each ton of stone broken involved a dead loss and seriously added to the cost of relief. The guardians accordingly closed the labour-yards, and gave relief on the plea of "sudden and urgent necessity," without calling on the able-bodied head of the family to enter the workhouse, and without subjecting him to the task of work. (See *L. G. B.*, 28*th Annual Report*, p. 174.) One of the leading colliery companies took the matter into court, asking for an injunction to stop further relief to the colliers, and for a declaration as to the legality of relief given in such circumstances. On appeal, it was affirmed by the Master of the Rolls "that the payment by the defendants out of the poor rates of any money for setting to work or for the relief of able-bodied men, who were at the time able to obtain and perform work at wages sufficient to support themselves and their wives and families (if any), was unlawful. . . . But this declaration does not include relief given to or for the wives and children of such men." This judgment may be of less importance than at first sight appears. It leaves an enormous discretion in the hands of the local authority. A board of guardians favourably disposed to the employers, or determined to be neutral, would, as has frequently been done in similar cases, have exerted themselves to provide temporary workhouse accommodation, a course of procedure which, all previous experience seems to show, would have enabled them to surmount the difficulty. Very few would have accepted the condition. On the other hand, even with the declaration of law as above quoted, a board of guardians determined to favour a strike can still do so by relieving the wives and families on terms which it is known will be readily accepted. Happily, such questions do not often arise, but the incident and the declaration of the law which it called forth are both very characteristic of the elastic, not to say arbitrary, nature of local administration.

Pope, John (1822–1892), American soldier, was born at Louisville, Ky., 16th March 1822, and graduated at the United States Military Academy in 1842. Brevetted for gallantry at Monterey and Buena Vista, he next made surveys over the Mexican frontier, and was commissioned a captain of engineers, 1st July 1856. In the political campaign of 1860 he earnestly espoused Lincoln's candidacy, and was nearly court-martialled for his remarks. As brigadier-general of volunteers, 17th May 1861, he was placed in command of the Missouri military districts. He co-operated in 1862 with Admiral Foote's flotilla in the capture of New Madrid and Island No. 10, taking over 6000 prisoners. Promoted major-general of volunteers, March 1862, he next united with General Halleck's combined armies in the capture of Corinth, 30th May. He was now summoned to the east and assigned to command of the army of Virginia, while McClellan was at the Peninsula. Upon the latter's want of success the army of the Potomac was recalled to aid Pope's operations close to Washington; but the new campaign was unfortunate, and culminated in the disastrous second battle of Bull Run, 29th and 30th August; and a few days later Pope resigned his command, and never again actively engaged at the seat of war. Controversy arose over the failure of these operations, which Pope himself imputed to the personal hostility of Generals McClellan and Fitz-John Porter, though not himself free from blame. He subsequently commanded departments at the North-West and the Pacific; was made major-general United States army, 26th October 1882; retired, 16th March 1886; and died at Sandusky, Ohio, 23rd September 1892.

Poperinghe, a town of Belgium, in the province of West Flanders, 40 miles south-west of Bruges, with a station on the line from Ypres to Hazebrouck (France). The district around is covered with hop-gardens. Among the industries are the manufacture of woollen goods, tobacco, and tanning. Population (communal) (1880), 11,007; (1900), 11,124.

Population.—The total population of the world continues to be very largely a matter of rough approximation, though every decade brings a certain diminution of the field of conjecture, as some form of civilized administration is extended over the more backward tracts. In the following table the results of the most recent census and estimates are compared with those given in 1882, the proportion of guesswork being indicated against both population and area.

TABLE I.

	Population, in Thousands.			Square Miles, in Thousands.			People per Square Mile in 1900.
	1882.	1900.	Percentage Unenumerated.	1882.	1900.	Percentage Unsurveyed.

[1] Excluding the Polar regions.

Next to Africa, China and its neighbourhood, with Turkey, Persia, the large islands of the south-eastern oceans and the wilder tracts of Central and South America, furnish the greater part of the field still open to inquiry (see CENSUS).

Sex.—Investigations into the subject of the normal distribution of the sexes have added comparatively little directly to our knowledge of the question, though much valuable information in this respect has been obtained from the wider study of factors which tend to disturb that proportion. Among the undeveloped communities brought under observation, the relatively low value set upon female life results possibly in a real, certainly in a recorded, paucity of that sex. Again, in a far more advanced stage of civilization, convention entails a similar inaccuracy of the record. In most Oriental and orientalized countries, for instance, the strict seclusion of the women of the household and consequent reticence regarding them, is habitual among the upper classes, and naturally tends to spread downwards throughout the community. Even in the higher and more progressive civilization of Western Europe and its offshoots in other continents, where neither of the above-mentioned disturbing considerations are operative, other causes, such as the greater dangers to which men are exposed in war and industry, together with the wider prevalence of migration among that sex, tend to counteract what appears to be the better vitality of women and a possibly growing proportion of female births. All that can be said on the subject with certainty, therefore, is that in long-settled and prospering communities, where accuracy of data may be fairly assumed, there will be found a greater or less excess of females, whilst in their colonies the influence of immigration throws the weight into the opposite scale. Elsewhere, on the other hand, the general preponderance in the returns of males may be attributed both to neglect of female life and to the concealment of those in existence, according to circumstances. In illustration of these general propositions, the following table, giving the number of females per 1000 males, is subdivided into groups showing Western European countries, Oriental countries, and European colonies respectively, with, in some cases, the variation in the proportion that has been returned at different periods.

TABLE II.

Country.	Year.	Females per 1000 Males.	Country.	Year.	Females per 1000 Males.

Age.—The general distribution of the population by age is ascertained in the first instance at the census, but the return, when based upon the untested statement of the individual, is apt to err, owing to the ignorance or deliberate intent of those furnishing the information. Of the latter class of error examples are given in the census reports for England and Wales. The possibilities of the former may be judged by the preference shown by the enumerated for the even multiples of ten in the following selected figures.

TABLE III.

Age.	Number at each Age per 10,000 of Population.			
	Germany, 1890.	United States, 1890.		India, 1891. Females.
		White.	Coloured.	
19	160	195	196	64
20	183	202	225	505
21	177	200	187	54
29	138	148	101	42
30	149	214	238	624
31	143	123	69	30
49	86	70	50	12
50	101	119	156	386
51	87	56	35	12
59	59	41	20	10
60	69	77	103	281
61	56	35	17	11

In order to neutralize such irregularity, the return is subdivided into aggregates of five to ten years, from which the annual detail can be obtained by graduation. Shown in some such form, it will be found that the distribution by age varies not only in the different countries, but also from decade to decade in the same country. To facilitate comparison in this respect, the table given below contains

TABLE IV.

Country.	Year.	Proportion in 1000 Persons.

United States (coloured)	1890	421	404	129	46
Canada	1891	365	411	153	71
Cape Colony	1891	432	390	130	48
Australia	1891	374	427	149	50
India	1891	392	399	157	52

the number per thousand of the population of each of the selected countries, returned at the different periods corresponding with early youth, prime, middle age, and decline of life. Most of the more recent figures are borrowed from the report on the German census of 1890, whilst the earlier are compiled from the original returns. At the head of the list stands the distribution of a standard West Eu opean population established by Dr Sundbärg, of Stockholm, from the unrivalled series of data available in Sweden, with which the figures for countries more subject to abnormal disturbance may be compared. Amongst the prominent features of the return may be mentioned the high proportion of those under forty in the British Colonies, England, and Germany; the low proportion of the young in France, Ireland, and Italy, with a corresponding weight of the aged; and the generally close approach of Austria to the standard.

General Rate of Increase.—The variation in the total population of a country and in its distribution by sex and age at different times, as reflected in the preceding table, is mainly due, apart from the effects of war, pestilence, or famine, to the ordinary relation between births and deaths on the one hand, and the interchange of population with other countries on the other. The former, or natural, variation usually manifests itself in a greater or less excess of births over deaths, while the tide of migration sets, on the whole, steadily from the old world to the new, and from the north of Europe to the north of Asia. The resultant of these two factors is shown in Table V. below, which gives the annual rate of increase per cent. during the 19th century of some of the principal countries of the civilized world. It should be noted, however, that the returns for the earlier years dealt with are by no means as accurate as those for the years since 1840 (see the *Bevölkerungslehre und Bevölkerungspolitik* of A. F. von Fircks, p. 197). The rate, again, is in geometrical, not arithmetical, progression; and is lower, accordingly, than that shown in some current publications. The total for Europe includes the figures for Ireland, the population of which has been decreasing since about 1845, as well as those for countries in the east of Europe, of which the population is at present, or was until recently, a matter of conjecture. Taking only the western countries, the returns for which are more trustworthy, the percentage for the century is something over ·68 instead of ·76. France, Spain, and Italy fall far below this average, while England and Scandinavia considerably surpass it. The rate in "new" countries is given by way of contrast.

Migration.—The want of full information as to emigration from the different countries precludes any accurate demarcation by statistics of the respective influence upon the rates of increase given above of migration and natural growth. It has been calculated by the author quoted just now, Dr Fircks, that during the period 1825–1900 over 23 millions of people left western Europe in excess of those received from abroad. To this sum Ireland contributed 8·7 millions; Germany, 5·5; Great Britain, 2·3; Italy, chiefly during recent years, 1·6; and Scandinavia, about a million. The loss to Germany during the twenty-four years ending with 1895 is stated to have amounted to about 18 per cent. of the natural increase. In the United States the census of 1890 gives nearly 15 per cent. of the population as foreign-born, as compared with 9·68 per cent. in 1850. The census of Canada, too, in 1891 gave a proportion of about 14 per cent. In Australia in 1891 the corresponding figure was nearly one-third, and the census of Argentina in 1895 showed over one-fourth to be of foreign birth.

Natural Increase.—The general rate of increase given above may be compared with the average annual excess per cent. of births over deaths shown in Table VI. The only general tendency to be noted in the figures is that while both birth- and death-rates appear to diminish, the former does so far more slowly than the latter. There are important exceptions, however, amongst which are France, England, and Ireland.

* Or later.

In comparing the conditions of different countries as judged by their vital statistics, the question arises: What standard should be applied? By some authorities civilization is judged by the death-rate. Others, however, regard as of equal importance the gradual extension of that rate over a wider field, and take the birth-rate also into account. In order to avoid giving the latter undue preponderance in the equation, Herr Rubin, Director of Statistics for Denmark, has suggested as the most representative measure of civilization the quotient of the birth-rate into the square of the death-rate (*Journal of Royal Statist. Soc., London, 1897*, p. 154). The serial order of the twelve principal countries of Europe for which figures are available is shown in Table VII. according to all three methods. In the two first sections the order is that of the death- and birth-rates respectively, beginning in each case with the lowest, that is, Norway as to the former and France in respect to births. The last section of the table combines in like order these two factors in the ratio proposed by Herr Rubin. In two of the three divisions Scandinavia and England occupy the first place, but the high birth-rate of England places it below France and Belgium. The decreasing natality of France takes that country far down the list in the combined figure; but Austria and Hungary, with high rates of both natality and mortality, occupy the lowest places. The position of Finland is obviously due to the abnormal death-rate in the decade 1861–70, otherwise its place would fall between Holland and Belgium.

TABLE VII.—*Countries in Serial Order according to the Birth and Death-Rate.*

Nuptiality and Fecundity.—In connexion with the subject of natural increase may be mentioned the tendency of a people towards marriage, and the average fertility of each union, so far as these facts can be tested statistically. In Table VIII., based on German authority of some years ago, the yearly rate of marriages per 1000 of population is shown for three periods, together with the average number of children per marriage and the births per thousand married women of between fifteen and forty-five years old.

TABLE VIII.—*Marriage Rates, &c.*

Country.	Annual Marriages per 1000 of Population.			Average Number of Children per Marriage.	Average Number of Births per 1000 Wives, aged 15–45.
	1841-50.	1861-70.	1891-95.	1871-80.	1871-80.

Norway . .	15·56	13·28	12·92	3·9	322
Denmark .	15·74	14·90	13·84	4·3	286
Finland . .	16·30	15·50	12·98	4·1	309
England and Wales . .	16·10	16 69	15·16	4·2	302
Ireland . .	...	10·50	9·48	5·5	...
France . .	15·88	15·62	14·90	2·9	201
Germany . .	16·10	17·04	15·88	4·2	332
Holland . .	14·82	16·44	14·48	4·3	367
Belgium . .	13·58	15·04	15·24	4·1	342
Italy . .	...	15·20	14·96	4·5	291
Austria . .	17·25	17·36	15·76	4·0	...
Hungary . .	...	18·60	17·92	4·4	...

The general tendency shown in this table is for the marriage rate to decline. It is apparently the same with the number of births compared with that of married women of the productive ages, for in England that rate, which was in 1871, 292 per thousand wives, fell in 1891 to 264. In Prussia the corresponding figures were 409 and 383. The Swedish returns, which go back to 1811, show considerable fluctuations, but seem to indicate a decline dating from the middle of the 19th century.

The average age at marriage is another factor not without its importance in connexion with this subject. Without entering into details, it may be said that in Switzerland and Austria the husband's age tends to a little above 31, and in Scandinavia and Belgium to a little below that figure. It is about a year less in France, Italy, and Holland. England, with 28·4, stands lowest. As to the average age of the wife at marriage, there seems a considerable tendency towards 27 years, Scandinavia, Holland, and Belgium exceeding, and England and France falling short of it. Italy returns the lowest figure, namely, 24¼. Most of Europe, excluding Russia and the east, shows a difference in age between husband and wife of from two to three years. In Italy the interval is nearly 5 years, in Ireland and Austria, about 4, in France, 3½, and in England and Holland, 2¼ years.

Mortality.—The influence on the constitution of a population of the distribution by age and sex of the annual death-rate can only be given in outline here. The most prominent feature in the returns of mortality is the heavy proportion borne to the total by the deaths of children of under five years old. This ratio varies according to the birth-rate, from a little over a quarter, in France, to over 40 per cent. in the greater part of central Europe, and even higher in Russia and the east. The predominant factor is the rate during the first year of life, which tends to be twice, thrice, and even four times that which prevails in the succeeding year. The two first columns of Table IX. give the rate of this infantile mortality at two decennial intervals computed by Dr Bodio. In the rest of the table the sexes are distinguished, as the rates of the two differ materially. Thus the predominating numerical superiority of women in most civilized countries is shown by the third column to be not attributable to the fact that more of them come into the world, since boys are born in far greater numbers than girls, though the disproportion seems, from the English returns, to tend to diminish. But, except between the ages of 10 and 20, the vitality of the female sex exceeds that of males throughout life, the advantage in the first year, according to the theoretical constitution of a life-table, being as great as is shown below:—

TABLE IX.—*Infantile Mortality, &c.*

Country.	From Returns.			From Life-Tables.					
	In 1000 Births, Deaths in First Year.		Boys born Alive per 1000 Girls.	Annual Deaths per 1000 at each Age.				Mean After-life-time, in Years.	
				Under 1 Year.		Under 5 Years.			
	1874-83.	1884-93.	1894.	Boys.	Girls.	Boys.	Girls.	M.	F.
Sweden .	128	107	1050	141	119	50	44	45·3	48·6
Norway .	104	96	1058	113	96	43	39	47·4	49·9
Denmark .	141	136	1048	147	124	47	42	45·6	47·4
England .	144	146	1039	161	131	55	48	43·7	47·2
Holland .	204	174	1055	197	165	64	56	42·5	45·0
France .	165	168	1046	198	167	64	57	40·8	43·4
Italy . .	208	190	1058	213	193	89	85	35·1	35·4
Prussia .	216	207	1052	221	189	73	65	39·0	42·2
Saxony .	284	282	1050	303	258	96	84	34·6	38·5

A considerable difference will be noted between Scandinavia and England and the rest of the countries mentioned. In the former not only is infantile mortality lower, but the difference between the sexes in this respect is less. It is true that Italy precedes them in regard to this last point; but there the conformity of the two rates is apparently the result of a high female rather than of a low male mortality. The general results tend to confirm the indications afforded in the last portion of Table VII.

Comparison between the countries is carried a little farther by the addition of the mean after-lifetime from birth, calculated from the life-tables. It must be understood that where, as in England, there is a large natural increase, the mean age at death is necessarily much lower than the figures here given, which are those derived solely from a stationary community.

The normal course of a generation in the different countries is as follows:—

Table X.—*Survivals at Various Ages of* 100,000 *Births of each Sex.* (*Herr Fircks.*)

Country.	Males.				Females.			
	5 Years.	15 Years.	45 Years.	70 Years.	5 Years.	15 Years.	45 Years.	70 Years.

(J. A. B.)

Porbandar, a native state of India, in the Gujarat division of Bombay, extending along the south-west coast of the peninsula of Kathiawar. Area, 636 square miles; population (1881), 71,072; (1891) 85,785; estimated gross revenue, Rs.6,50,000, of which Rs.2,62,560 was expended on public works in 1897–98; tribute, Rs.48,504. The chief, whose title is Rana, is a Jethwa Rajput. At present the state is under British administration. Limestone is largely exported to Bombay. The town of Porbandar is on the seacoast, and the maritime terminus of the Kathiawar railway system. Population (1881), 14,569; (1891), 18,805. A large trade is conducted in native boats as far as the west coast of Africa. There are an oil mill and a state printing-press, issuing a gazette.

Pordenone, a town of the province of Udine, Venetia, Italy, 30 miles west by south of Udine on the railway to Treviso. It was the birthplace of the painter Il Pordenone (1483–1539). Paintings from his brush adorn the Renaissance cathedral, and others are preserved in the gallery of the town hall. Cotton industries are active, and silk and pottery are manufactured. There is an industrial school (1872). Population (1881), 6996; (1899), 7500.

Portadown, an inland town and urban sanitary district in the county of Armagh, Ireland, on the river Bann and the Great Northern Railway, 25 miles west-south-west of Belfast. There are frequent markets for the sale of agricultural produce, and a large number of persons are engaged in the manufacture of linen and cotton goods. The town, which belongs to the Duke of Manchester, has been much improved. Population (1881), 7850; (1891), 8430; (1901), 10,046.

Portaels, Jean François (1818–1895), was born at Vilvorde (Brabant), in Belgium, 30th April 1818. His father, a rich brewer, sent him to study in the Brussels Academy, and the director, François Navez, ere long received him as a pupil in his own studio. About the year 1841, Portaels, wishing to make further progress, went to Paris, where he was kindly received by Paul Delaroche. Having returned to Belgium, he carried off the Grand Prix de Rome in 1842. He then travelled through Italy, Greece, Morocco, Algeria, Egypt, the Lebanon, Judæa, Spain, Hungary, and Norway. On his return to Belgium in 1847, Portaels succeeded H. Vanderhaert as director of the Academy at Ghent. In 1849 he married the daughter of his first master, Navez, and in 1850 settled at Brussels; but as he failed in obtaining the post of director of the Academy there, and wished, nevertheless, to carry on the educational work begun by his father-in-law, he opened a private studio-school, which became of great importance in the development of Belgian art. He again made several journeys, spending some time in Morocco; he came back to Brussels in 1874, and in 1878 at last obtained the directorship of the Academy which had so long been the object of his ambition. Portaels executed a vast number of works. Decorative paintings in the church of St Jacques-sur-Caudenberg; Biblical scenes, such as "The Daughter of Sion reviled" (in the Brussels Gallery, see Plate), "The Death of Judas," "The Magi travelling to Bethlehem," "Judith's Prayer," and "The Drought in Judæa"; genre pictures, amongst which are "A Box in the Theatre at Budapest" (Brussels Gallery), portraits of officials and of the fashionable world, Oriental scenes, and, above all, pictures of fancy female figures and of exotic life. "His works are in general full of a facile grace, of which he is perhaps too lavish," wrote Théophile Gautier. Yet his pleasing and abundant productions as a painter do not constitute Portaels's crowning merit. The high place his name will fill in the history of contemporary Belgian art is due to his influence as a learned and clear-sighted instructor, who formed, among many others, the painters E. Wauters and E. Agneesens, the sculptor Ch. van der Stappen, and the architect Licot. He died at Brussels on 8th February 1895.

See E. L. de Taeye, *Peintres Belges contemporains;* J. du Jardin, *L'Art Flamand.* (F. K*.)

Portage, a city of Wisconsin, U.S.A., capital of Columbia county, on the Wisconsin river and the Chicago, Milwaukee, and St Paul and the Wisconsin Central railways, south of the centre of the state, at an altitude of 813 feet. It is in a farming and lumber region, has considerable trade and important manufactures of lumber. Population (1880), 4346; (1890), 5143; (1900), 5459, of whom 1184 were foreign-born.

Portage la Prairie, a port of entry and the chief town of Macdonald county, Manitoba, Canada, situated 50 miles west of Winnipeg, on the Canadian Pacific and Canadian Northern railways, at an altitude of 854 feet above the sea. It is in the midst of a fine agricultural district, and a large export trade in grain and other farm produce is carried on. Population (1891), 3363; (1901), 3901. (J. W.)

Portalegre, a city and episcopal see of Portugal, capital of district of Portalegre, 103 miles north-east of Lisbon. Population (1890), 10,354. The district of Portalegre, with an area of 2482 square miles, and population (1890), 112,834, and (1900), 124,697, giving 50 inhabitants to the square mile, produces corn, olive oil (annual average, 325,400 gallons, valued at £40,000), and wine (246,578 gallons in 1892); but the chief occupation is the breeding of pigs. Woollens and corks are manufactured.

Port Arthur, or, as it is called by the Chinese, Lu-shun-kou, a fortress situated at the extreme south of the peninsula of Liaotung, which stretches down between the Gulf of Pechili and the Yellow Sea in the Chinese province of Manchuria. It was formerly a Chinese naval arsenal and fortress, but was captured by the Japanese in 1894, who destroyed most of the defensive works. In 1898 it

"THE DAUGHTER OF SION REVILED." BY F. PORTAELS.

(*In the Brussels Gallery.*)

was leased to Russia along with the neighbouring port of Talienwan, and was gradually converted into a Russian stronghold. The port or harbour is a natural one, entirely landlocked except to the south, where the entrance is very narrow, being less than a quarter of a mile wide. The basin inside is of limited extent, but is being improved by dredging. Barren and rocky hills rise from the water's edge all round. Extensive barracks have been constructed for the accommodation of troops. A railway connects the port with the Russian lines in Manchuria. The harbour is ice-free all the year round, a feature in which it contrasts favourably with Vladivostok.

The Liao-tung peninsula, separated from Korea by the Bay of Korea, from the Chinese mainland by the Gulf of Liao-tung, runs in a south-westerly direction from the mainland of Manchuria, and is continued by a group of small islands which reach another peninsula projecting from the mainland of China in a north-easterly direction, and having at its north-eastern extremity the port of Wei-hai-wei. The Liao-tung peninsula is indented by several bays, two of which nearly meet, making an isthmus less than 2 miles wide, beyond which the peninsula slightly widens again, this part of it having the name of Kan-tun (Regent's Sword). Two wide bays open on the eastern shore of the latter: Lu-shun-kou (now Port Arthur) and Talienwan. Both have been leased to Russia. The bay is nearly 4 miles long and 1¼ mile wide, the entrance being only 350 yards wide. The Chinese deepened the bay artificially and erected quays, and the population of the village at its extremity reached 6000, Chinese and Japanese. The roadstead is exposed to south-easterly winds, and in this respect the wider bay of Talienwan is better. Port Arthur is well connected by roads with Peking, Korea, and Manchuria, and lies 270 miles from Mukden, 500 miles from Kirin, and 800 miles from the Nikolsk station of the South Usuri railway. Coal is found near to the port. The climate is very mild, and similar to that of south Crimea, only with more moisture. The small peninsula above mentioned has received in Russia the official name of Kwang-tung province. Since its occupation by the Russians, Port Arthur has become Europeanized. The Russian military port, Dalny, is a few miles to the north.

Port Augusta, a town of South Australia, in the county of Frome, the northernmost port of the colony, on the east shore of Spencer Gulf, 259 miles by rail northwest of Adelaide. There is a fine natural harbour. The Government wharf has berthing for large vessels. The town is the starting-point of a railway, which joins the main line from Adelaide to the north. Valuable gold reefs were discovered in 1900 at Tarcoola. A water reservoir (200,000,000 gallons) has been formed at Nectar Brook, 22 miles distant. The town hall is the finest in the colony, that of Adelaide excepted. Population (including Port Augusta West, 369), 1370.

Port-au-Prince. See HAYTI.

Port Chester, a village of Westchester county, New York, U.S.A., on the shore of Long Island Sound, and the New York, New Haven, and Hartford Railroad, 26 miles north-east of New York. Its site is hilly and its plan irregular. It has varied manufactures, consisting in part of woollen goods, carriages, and iron and steel goods. Population (1880), 3254; (1890), 5274; (1900), 7440, of whom 2110 were foreign-born and 97 negroes.

Port Darwin, or PALMERSTON, the chief town of the Northern Territory of South Australia, on the eastern shore of Port Darwin inlet, in the county of Palmerston, about 2000 miles north-north-west of Adelaide. It possesses a magnificent harbour, and a jetty connecting it with the railway, which runs for a distance of 146 miles to Pine Creek. There are a Government House, town hall, and other public buildings, and a Government experimental nursery garden has been laid out in the vicinity. The mean yearly rainfall (13 years) is 63·21 inches. Population, about 2600.

Port Elizabeth, a town and seaport of Cape Colony. The population increased from 13,000 in 1875 to 23,266 in 1891, while the foreign exchanges have in some years exceeded £10,000,000. The imports, chiefly textile fabrics, machinery, and hardware of all kinds, apparel and haberdashery, spirits and provisions, rose from £2,800,000 in 1891 to £8,670,000 in 1896, £7,877,000 in 1897, and £6,246,000 in 1898; for the same years the exports (gold, diamonds, wool, ostrich feathers, hides) were £2,000,000, £1,921,000, £1,950,000, and £2,103,000. The commercial importance of Port Elizabeth is largely due to its position nearly midway between Cape Town and Durban, about 800 miles from both places, and a little over half that distance from Kimberley. The opening of several important railways, by which it communicates with Port Alfred, Graaff Reinet, the Orange River Colony, and Rhodesia, has also helped to make it the most convenient outlet for the whole of South Africa. Lying on the west side of Algoa Bay, under the sheltering headland of Cape Recife, it is protected from the west winds, but is still exposed to the more violent easterly gales pending the completion of extensive harbour works.

Porter, David Dixon (1813–1891), American admiral, was born in Chester, Pennsylvania, 8th June 1813. Three generations of his family before him had commanded vessels upon the high seas. It was under his father, Admiral David Porter of the war of 1812, that he took his first lessons in naval service, when at the age of eleven he accompanied an expedition to the West Indies. He studied for a time at Columbian College, Washington; but the sea soon claimed him, and at the age of fourteen he was a midshipman in the Mexican navy (of which his father was then commander-in-chief). In 1829 he entered the U.S. navy as midshipman, in 1841 was made lieutenant, and in the war with Mexico was in command of the naval rendezvous at New Orleans. At the outbreak of the Civil War he was given command of the steam-frigate *Powhatan*, and joined the expedition for the relief of Fort Pickens. On 22nd April 1861 he was appointed to the rank of commander. In the battle of New Orleans he was in charge of the auxiliary fleet of mortar-boats which made the preliminary five days' bombardment upon Forts Jackson and St Philip. It was he, also, to whom the forts surrendered after the capitulation of New Orleans to Farragut. In October 1862 he took command of the Mississippi Squadron, and the following January had an important part in the capture of Arkansas Post. He next formed the original and daring plan of cutting the levee of the Mississippi at the old Yazoo Pass, and sending a fleet of vessels through the gap into the Cold Water, and thus down the Tallahatchie and the Yazoo rivers to the rear of Yazoo city; but the almost insuperable physical difficulties involved gave the Confederates time to block the advance. In March 1863 another expedition no less daring, and, as it proved, still more perilous, attempted under Porter's personal command to penetrate through connecting streams and bayous to the Yazoo river, and thus reach the rear of Vicksburg; but even greater obstacles thwarted its success. These two expeditions illustrate how difficult and dangerous were the enterprises undertaken by Porter and other naval commanders in their river operations far inland, largely with miscellaneous and improvised vessels, often under conditions hitherto unknown in the history of naval warfare, and yet not infrequently with brilliant success. When Grant decided to approach the rear of Vicksburg from the south, Porter ran his fleet successfully down past the Vicksburg batteries and co-operated with him in the undertaking, and also with General Banks in an expedition up the Red river against Alexandria. On 4th July 1863 he was appointed rear-admiral. In September 1864 he was transferred to the command of the North Atlantic

Blockading Squadron, and in December, with the largest fleet that was assembled at one point during the war, bombarded Fort Fisher, N.C., and silenced the enemy's guns. After a second bombardment (15th January 1865) a land force stormed the fort, and with the aid of the guns of the fleet captured it. After the war he was superintendent of the U.S. Naval Academy (1865–69), and was then assigned to departmental duty at Washington. He was made vice-admiral 25th July 1866, and admiral 15th August 1870, being the only person except his predecessor, Admiral Farragut, who had ever reached that rank. He died at Washington, 13th February 1891. Among his writings are *The Life of Commodore David Porter*, *Incidents and Anecdotes of the Civil War*, and *The Naval History of the Civil War*. His reputation, although somewhat overshadowed by that of his foster-brother, Farragut, was deservedly great. Marked ability and skill as an officer, readiness to take hazardous risks when needed, and an order of originality and resourcefulness quite invaluable in the work that he had to do, were his characteristic qualities as a naval commander. (G. B. L.)

Porter, Fitz-John (1822–1901), American soldier, was born at Portsmouth, N.H., 31st August 1822, the son of Captain John Porter, U.S.N., and graduated at the United States Military Academy in 1845. He served with honour in the Mexican War, was instructor at West Point, 1849–55, and in 1856 became assistant adjutant-general, with the rank of captain, serving in the Utah expedition of 1857–60. In 1860 he was assistant inspector-general, with headquarters in New York City; and he superintended, in 1861, the protection of the railway between Baltimore and Harrisburg during the Baltimore riot, and also organized volunteers in Pennsylvania. He became colonel of a new regiment of regulars, 14th May 1861, and, 17th May, was made brigadier-general of volunteers. In 1862 he took part in the Virginia Peninsular campaign; he was at the siege of Yorktown; and upon the evacuation of that place took command of the 5th Corps, and fought splendidly in June in the battles of Mechanicsville and Gaines's Mill; taking a leading part, besides, at Malvern Hill, 1st July, when McClellan changed his base to the James river. Promoted major-general of volunteers 4th July 1862, and temporarily attached to the army of Virginia, he fought under Pope in the second battle of Bull Run, 29th and 30th August 1862; his corps was unable to move forward the first day, when ordered to advance, but in the afternoon of the second day fought well to save the army from utter rout. Porter, as a warm friend of McClellan, had shown dislike of Pope, and charges were preferred against him; he was tried by court-martial, November 1862, and sentenced to be cashiered, 21st January 1863, "and for ever disqualified from holding any office or trust under the Government of the United States." The justice of this sentence was much discussed after the Civil War, and upon a re-examination made in 1882 Porter was acquitted of the main charge, and President Hayes remitted the disqualifying penalty. General Grant had now taken Porter's part. Against much opposition, partly political, 1879–86, and a veto from President Arthur, a relief Bill finally passed Congress, and Porter was, 7th August 1886, restored to the United States army as colonel, and placed on the retired list. He was commissioner of public works, New York City, 1875–76; police commissioner, 1884–88; and fire commissioner, 1888–89. He died 21st May 1901, at Morristown, New Jersey. (J. SCH.)

Porter, Noah (1811–1892), American educationist and philosophical writer, was born in Farmington, Connecticut, 14th December 1811. He graduated at Yale College, 1831, and laboured as a Congregational minister in Connecticut and Massachusetts, 1836–46. He was elected professor of moral philosophy and metaphysics at Yale in 1846. From 1871 to 1886, when he resigned, he was president of the same college. He edited several editions of Noah Webster's English dictionary, and wrote on education, books and reading, moral science, and the ethics of Kant; but his best-known work is *The Human Intellect, with an Introduction upon Psychology and the Human Soul* (1868), comprehending a general history of philosophy, and following in part the "common-sense" philosophy of the Scottish school, while accepting the Kantian doctrine of intuition, and declaring the notion of design to be *a priori*. He died in New Haven, 4th March 1892.

Port-Glasgow, a seaport, burgh of barony, and parliamentary burgh (Kilmarnock group) of Renfrewshire, Scotland, on the Clyde about 20 miles below Glasgow by rail. The output from the shipbuilding yards, 71,325 tons in 1889, was only 48,123 tons in 1899. There are two graving docks, and a considerable amount of repair work is done. The manufacture of tents and trawling gear has been introduced. The port has an area of 16 acres and nearly 6000 feet of quayage. In 1900, 23 vessels of 15,494 tons were on the register of the port. Modern erections are a library, orphan homes, and public baths. The Birkmyre Park was opened in 1894. Population (1881), 13,294; (1891), 14,685; (1901), 16,840.

Port Hope, the chief town of Durham county, Ontario, Canada, situated 58 miles east-north-east of Toronto, on the north shore of Lake Ontario and on the Grand Trunk Railway. File and machine shops, tanneries, breweries, canneries, carpet and carriage factories, are the principal industries. Population (1901), 4188.

Port Huron, a city of Michigan, U.S.A., capital of St Clair county, on the St Clair river, at the foot of Lake Huron, and the Grand Trunk and the Pere Marquette railways, in the eastern part of the state, at an altitude of 586 feet. The site is level, the street plan regular, and it is divided into ten wards. It has the Holly system of waterworks, the supply being pumped from Lake Huron, and the city is well paved. It is an important railway centre, and has a large trade in grain and lumber. It has the works of the Grand Trunk Railway, many grain elevators, and manufactures of varied character. It is connected with Sarnia, Canada, on the opposite side of the river, by ferries and by a railway tunnel. Population (1890), 13,543; (1900), 19,158, of whom 7142 were foreign-born and 69 negroes.

Port Jervis, a village of Orange county, New York, U.S.A., on the Delaware river, at the mouth of the Neversink, near the junction of the three states of New York, New Jersey, and Pennsylvania. It is on the Erie Railway, and at an altitude of 442 feet. It contains works of the Erie Railway, and has varied manufactures. Population (1890), 9327; (1900), 9385, of whom 895 were foreign-born and 119 negroes.

Portland, a town of Middlesex county, Connecticut, U.S.A., on the east side of the Connecticut river, 40 miles from Long Island Sound and the New York, New Haven, and Hartford Railroad. It comprises an area of 26 square miles of hilly country, containing rural population, and a village of the same name as the town. It contains quarries of brown sandstone. Population of the town (1890), 4687; (1900), 3856, of whom 1316 were foreign-born.

Portland, a city and seaport of Maine, U.S.A., capital of Cumberland county, in the south-western part of the state, the largest and most important city in the state. It has an uneven, hilly site, broad, well-shaded streets, is divided into nine wards, and derives an excellent water-supply from Sebago Lake to the north by gravity, the works being owned privately. It is well sewered, and the business streets are paved. It is situated on a neck or promontory, rising, in Munjoy Hill, to an altitude of 161 feet, and lying between the harbour and Back Bay. The deep and capacious harbour has made Portland mainly a commercial city. Its exports for the year ending 30th June 1901 amounted to $12,416,793, and its imports to $633,114. The Grand Trunk, the Maine Central, and the Boston and Maine railways meet here. The manufactures are large and varied; in 1900 it contained 639 establishments, with a total capital of $6,991,251, employing 5699 hands, and with a product valued at $11,440,201. One of the largest industries was carpentering, the products of which were valued at $1,094,788. Other items of importance were foundry and machine-shop products, lumber, and clothing. The assessed valuation in 1900 was $45,128,305, the net debt was $1,287,533, and the rate of taxation was $21 per $1000. Population (1890), 36,425; (1900), 50,145, of whom 10,435 were foreign-born and 291 negroes. There were 12,645 persons of school age (5 to 20 years). Of 15,433 males 21 years of age and over, 597 were illiterate (unable to write). In 1899 the city of Deering was included within the charter limits of Portland.

Portland, a city of Oregon, U.S.A., capital of Multnomah county, on both banks of the Willamette river, 12 miles above its junction with the Columbia, in the north-western part of the state. The city is built mainly on the west side of the river, the portion on the east side consisting of recent inclusions within the charter limits, which were formerly known as East Portland and Albina, and which were annexed in 1891. The business portion lies mainly on low ground near the river on the west side, whence the residential quarter extends up the slope to the hills, now being dotted with villas. The water supply is drawn from streams and lakes in the Cascade range by gravity, the sewer system is excellent, and the city is divided into eleven wards. It derives its power for manufactures, for trolley cars, and for lighting, from the falls of the Willamette at Oregon city by electric cable. Portland is the chief city and seaport of the state. Although situated more than 100 miles from the mouth of the Columbia, the largest vessels can reach its wharves, and its foreign commerce is considerable. For the year ending 30th June 1901, its exports, consisting almost entirely of wheat and wheat flour, had a value of $10,381,884. It is the meeting-point of four railways, the Southern Pacific from California, the Northern Pacific from Seattle and the north, the Astoria and Columbia River from the west, and the Oregon Railroad and Navigation Company from east Washington and Oregon. The latter line brings to Portland for shipment the enormous wheat crop of southern Washington and north-eastern Oregon. It has regular steamship lines to San Francisco, to Puget Sound, Alaska, China, and Japan. The volume of business may be summarized by the statement that in 1898 the exchanges at its clearing-house aggregated $94,572,454. The number of manufacturing establishments in 1900 was 1064, with a total capital of $13,331,500. They employed 8572 hands, and the product was valued at $23,451,132. The chief industries, with the value of their products, were lumber and timber, $3,539,268; flouring and grist mill products, $1,759,262; and slaughtering and meat-packing (wholesale), $1,306,996. Among the many fine buildings may be mentioned the magnificent new Union depôt, the Portland Hotel, the Oregonian Building, the Chamber of Commerce, and the City Hall. Among the institutions of the city is the *Portland Oregonian*, one of the best-known newspapers of the West. The assessed valuation of real and personal property in 1900, on a basis of about one-fourth of the full value, was $29,554,209. The net debt was $5,631,548, and the rate of taxation $36 per $1000. Population (1890), including that of Albina and East Portland, since annexed, 62,046; (1900), 90,426, of whom 25,876 were foreign-born and 9812 coloured, including 775 negroes. There were 23,211 persons of school age (5 to 20 years). Of 38,353 males 21 years of age and over, 3251 were illiterate (could not write).

Portland Canal, a typical fjord on the north-west coast of America, leading from Dixon's Entrance in 54° 40′ N. north-eastwards and northwards for a distance of some 80 miles, with an average width of a mile and a half north of lat. 55°. The lower portion, commonly known as Portland Inlet, is divided by islands on the northern side, receives from the eastward the estuary of the Nasse river, and sends out an arm called Observatory Inlet, 40 miles long, to the north-east, which is divided from Portland Canal by a peninsula terminating at Point Ramsden. These inlets were discovered and named by Vancouver in 1793, and surveyed again by Staff Commander Pender in 1868. The water is deep, and the shores are for the most part precipitous and bordered by mountains from 3000 to 6000 feet in height. There are no settlements on the canal except those of the Nasse river Indians. The canal derives its interest from the fact that its mid-channel line, according to the treaty of 1825 between Great Britain and Russia, forms the boundary between Alaska and British Columbia.

Portland, Isle of, a peninsula and town of England, projects from the south coast of Dorsetshire, 4 miles south of Weymouth and 50 miles by rail south-west from Southampton. The harbour of refuge, and the gigantic moles by which it is enclosed, are described under Dockyards. Population (1891), 9443; (1901), 15,262.

Port Louis. See Mauritius.

Port Mahon, or Mahon, a seaport and the capital of the island of Minorca. Its population in 1897 was 17,790. Mahon is still the principal quarantine station of Spain, with a large lazaret. The bay and splendid roadstead cause it to be frequently visited by Spanish and foreign fleets. The modern buildings are a town hall, military and civil hospitals, the Coliseum Theatre, the institute and primary schools, the public library, the museum, a few parish churches that have been restored, and the Government House. The trade is important. The imports in 1898 amounted to £133,596, and were mainly cement, coal (chiefly from England), flour, iron, raw cotton, hides, and machinery. The exports, principally live stock, bread-stuffs, agricultural products, shoes, and cotton stuffs, were valued at £127,772. The shipping returns showed that 165 vessels entered and 136 cleared, mostly Spanish.

Porto Alegre, a city of Brazil and capital of the state of Rio Grande do Sul, at the head of the Bay of Patos and the mouth of the Pardo river. Owing to the shallowness of the bar at the mouth of the lagoon and the temporary closing of the custom-house (reopened in 1900), the trade of the port is not in a flourishing condition. The bar, too, is rapidly increasing in height, for whereas in 1898 the average depth of water was $16\frac{1}{2}$ feet, in 1900 it was only $15\frac{1}{6}$ feet. Important works are contemplated to improve the port. The exports, chiefly lard, jerked beef, salt pork, hides and leather, and manioc flour, vary between £560,000 and £630,000 annually. The greater part of the trade is with other Brazilian ports, and with Hamburg, New York, and Great Britain. Amongst its public institutions counts a school of engineering and an efficient fire brigade. A successful exhibition of industrial and other products was held here in 1901. Population (1890), 52,421; (1900, estimate, probably too high) 100,000, including 10,000 Germans.

Porto Empedocle, formerly MOLO DI GIRGENTI, a seaport town of the province of Girgenti, Sicily, Italy, 6 miles by rail south-west of Girgenti. It exports large quantities of sulphur, the total export increasing from £371,800 in 1888 to £792,400 in 1898. The other exports are chiefly almonds (£50,000 in 1897 and £42,000 in 1898). The total exports rose from £387,000 in 1888 to £774,600 in 1898. The imports increased in the aggregate from £10,350 in 1888 to £60,000 in 1898. The port is protected by two breakwaters, and affords a depth of 17½ to 22½ feet. Vessels load and unload from and into lighters. It was cleared by 1322 vessels of 323,120 tons in 1898. The inhabitants carry on fishing and fish-curing, especially of anchovies and sardines, and there are quarries of calcareous tufa. Population, about 7500.

Port of Spain. See TRINIDAD.

Porto Maurizio, capital of the province of the same name, Liguria, Italy, on the north shore of the Gulf of Genoa, 71 miles by rail south-west of Genoa. It is visited for sea-bathing, and possesses a school of navigation and a meteorological observatory. It has trade in olive oil. In 1897 the port was cleared by 198 vessels of 68,096 tons. Population (1881), 6591; (1901), 7207.

Porto Rico, or PUERTO RICO ("Rich Harbour"), the most easterly and fourth in size of the Antilles, situated between 17° 50′ and 18° 30′ N. and 65° 35′ and 67° 10′ W., roughly rectangular in shape, being 108 miles long and 37 broad, and with an area of 3550 square miles.

Population.—In 1900, the people, almost entirely natives, numbered 953,243. They are divided into a better class of whites of Spanish descent, which constitutes the commercial, professional, and planter element, and a lower class of peasants, known as *gibaros*, which includes whites, people of mixed blood (coloured), and blacks, and constitutes the labouring and agricultural element. Among the *gibaros* there were many traces of the aboriginal Borinquens or Boricuans, who were absorbed into the Spanish cult by the application of the Encomienda in 1512. Of the total population, 589,426 are white and 363,817 black and coloured. Nearly all the people are Roman Catholic in religion and Spanish in language, customs, and dress. The density of population is about 225 to the square mile, and the island presents a continuous series of farms and small villages. The lower classes generally are indolent and thriftless. The question of education was neglected under the Spanish dominion, and the proportion of persons unable to read or write (75 per cent. of these over 10 years of age) is unusually large. The scattered character of the population accounts to some extent for the absence in the past of any effective educational system for the lower classes. The clergy have from time to time attempted to cope with these difficulties, but without any marked degree of success. The United States Government since its occupation has initiated a comprehensive and thorough system of public schools directed by duly qualified teachers, and attendance is compulsory. The cost of these schools is defrayed by the State.

Industries.—One of the principal industries is the production of *coffee*. There are approximately some 110,000 acres under cultivation, and the area is increasing. It is of high quality, and the prices realized are much greater than for the Brazilian article. The coffee plantations are as a rule situated on the higher lands in the interior of the island, where the climate is temperate and healthy. The amount available for export in average years is 26,000 to 27,000 tons. Excessive rain or unusually dry weather seriously affects the yield. Little attention is paid to scientific methods of cultivation. The preparation of the bean for the market is also carried out in a slovenly manner. Labourers on the plantations earn an average wage of 50 cents a day in Porto Rican money, equal to a little less than two shillings. Some foreign capital is invested in the industry besides that belonging to Spaniards, who own, however, most of the larger estates not in the hands of natives. A few plantations are owned by British subjects.

The *sugar* industry showed fairly good prospects in 1902, chiefly owing to the small intrinsic value of the wage rate and the advantage the producer gains from the removal of the American duties. The majority of the plantations are on the lower lands near the seaboard, where the ground allows of easy ploughing. The great central factories common in Cuba are nowhere found. The sugar available for export amounts to some 60,000 tons annually, the greater part being sent to the United States. Rum of excellent quality is largely manufactured, and finds a ready sale in European markets. A considerable amount of foreign capital, some of it British, is invested in the sugar industry. Several properties changed hands after the island became a colony of the United States, the buyers being Americans.

Cacao is also cultivated to some extent. The bean is exported in its natural state, and also as manufactured chocolate. There is room for a great extension of this industry, lands suitable for plantation being abundant and reasonable in price, and the demand for the product showing a steady increase in the United States. The principal plantations are situated in the valleys, at no great height above sea-level, where the climate is moist and warm, and the trees are sheltered from the prevailing winds.

Tobacco is largely grown, both for local consumption and for export. The quality is, however, inferior, although seed is annually brought from Cuba. Cigar and cigarette manufactories are established in all the larger towns. It has been stated by experts that with more attention to the curing of the leaf the quality could be much improved.

Cattle-farming is an important source of wealth, the number of animals in the island being estimated to exceed 400,000. Cuba was a purchaser of the surplus stock, and a market was also found in Barbados and other West Indian islands. In 1896 the value of the live cattle exported was $139,000, and this has since increased considerably. Hides are shipped to the United States and Spain, and have constituted a regular article of trade with these countries for many years. Little attempt has been made to improve the breed of cattle.

Communications.—Porto Rico requires both railways and roads for the proper development of its resources. In all there were 137 miles of railway open to traffic in 1902, and other lines were under construction. San Juan is connected with Arecibo by rail, and Ponce with Mayaguez. The railway system was built by a French company under a concession from the Spanish Government, by which interest on the capital invested was guaranteed. An excellent road with easy gradients runs from San Juan across the island to Ponce, passing through the towns of Caguar, Cayey, Aybonito, and Coamo. The distance from San Juan to Ponce is 90 miles, the journey in a carriage usually occupying 12 hours. This road was built by the Spanish authorities for military purposes, and similar works in other sections of the island were in progress when the war broke out. In 1898 there were 470 miles of telegraph open to public service. A submarine cable connects San Juan with St Thomas and Jamaica, and thence with the outside world.

Finance and Commerce.—There is no public debt, the revenue obtained under Spanish administration having been sufficient to balance expenditure. In the year from 1st July 1894 to 30th June 1895 the receipts and expenses were returned as:—

Revenue.		Expenditure.	
Property taxed	$1,045,417	General expenses	$715,297
Customs duties	2,904,138	Justice and worship	368,953
Stamps	318,747	War	1,142,906
National properties	17,887	Marine	255,555
Miscellaneous	168,771	Finance	160,479
		Interior	702,014
		Public works	558,667
Total	$4,454,960	Total	$3,903,871

The currency was the silver dollar coined specially for use in Porto Rico, and exchange in 1898 averaged $11 to one sovereign. The United States authorities have brought the currency to a gold basis. The foreign trade in 1895 amounted to $33,245,000, the value of the imports being $17,446,000, and of the exports $15,799,000. In 1896 the amount was $37,953,000, distributed as follows:—

Countries.	Imports.	Exports.
Spain	$6,188,000	$5,480,000
Great Britain	2,350,000	144,000
France	299,000	2,701,000
Germany	1,344,000	1,954,000
United States	4,118,000	2,645,000
Cuba	718,000	4,014,000
British Colonies	2,734,000	298,000
Other countries	1,195,000	1,771,000
	$18,946,000	$19,007,000

The principal articles exported in 1896 were coffee to the value of $13,864,000, sugar to the amount of $4,242,000, and tobacco worth $423,000. The principal imports are textiles, rice, flour, provisions, oils, hardware, machinery, and wines. In 1896 the number of vessels calling at Porto Rico was 1142, with a tonnage of 1,407,240. The number sailing from the island was 1116. Oranges, bananas, pine-apples, and many other tropical fruits grow to perfection, and can be delivered in the United States in four days, the distance from San Juan to New York being only 1420 miles. The demand for fruit in that market, especially during the winter months, is practically unlimited.

Towns and Cities.—The Americans found seventy-one municipalities in Porto Rico, including many cities and villages. These were all either agricultural centres or shipping places, which had little commerce with one another, owing to the difficulties of inland communication. All were built upon the Spanish plan, with public edifices massively constructed of mamposteria, and had paved streets, central plazas, and gardens. Some of them dated back to 1511. San Juan (27,000), on the north side, was the political capital; Ponce (42,389), on the south side, the largest commercial city; and Mayaguez, on the west side, the abode of wealthy planters and an important seaport. Arecibo (26,000), Aguadilla, Guayama (the seaport of which is Arroyo), and Humacao (12,000) were capitals of departments which bear their names, and Naguabo and Fajardo, in Humacao, smaller maritime cities of the second class, of from 6000 to 15,000 population. Each transacted considerable foreign commerce by means of steamers and sailing ships. Sabana Grande, Yauco, Juana-Dias, and Salinas, on the south side, are small commercial towns of less than 10,000 people each, situated near the foot of the mountains a few miles from the south coast. Adjuntas, Aguas Buenas, Aybonito, Caguas, Cidra, Cayey, Juncos, Las Marias, Lares, Moca, San Sebastian, and Utuado are neat country towns of 5000 people each, more or less, situated in the coffee districts of the central mountains. They are essentially agricultural towns, Cayey and Caguas being chiefly dependent upon the surrounding tobacco farms. Many of the villages, like Lares, were handsome and well improved. Each had an imposing church and ayuntamiento. With the exception of Caguas, Aybonito, and Cayey, which are situated upon the macadamized highways, they were almost inaccessible except by pack trains.

History.—During the great Spanish-American uprising at the beginning of the 19th century, and the various Cuban insurrections, Porto Rico exhibited slight sympathetic signs of unrest; but Spain was always kinder to this island than to Cuba, and met these disturbances by enacting conciliatory legislation. Between 1815 and 1820 a Junta was formed of Republicans, who later declared independence. Governor de la Torre took prompt action, and restored tranquillity in 1823. Many of the leaders were executed. During the ten years' war in Cuba the Porto Rico Republicans again attempted an uprising. In 1868 there were insurrections at Ponce, Bayamon, and Arecibo, but these were quickly suppressed. A result of the last outbreak was the passage of a measure by the Spanish Cortes, in 1860, which took away the colonial character of the island and made it a political province and organic part of Spain. The province was divided into seven departments for convenience of central administration, while the old municipalities continued to constitute the units of local government. The island was given representation in the Spanish Cortes by five regular Deputies and two Senators, elected upon the same suffrage as those in Spain. With the outbreak of the last Cuban revolution in 1895 the insurrectionary spirit again became noticeable. The Spanish garrisons were increased and the island volunteers strengthened. Many arrests were made, and suspects fled to the United States and Mexico. An insurrectionary Junta was maintained in New York. In 1897 the Spanish Prime Minister, Canovas, instituted a system of reform called provincial autonomy, which was, however, merely a matter of form, the island being governed, as of old, by the representatives of the Crown at San Juan. When, in April 1898, war was declared between Spain and the United States, the Spanish naturally expected that Porto Rico would be assaulted, and the island was strongly garrisoned. In July 1898 the American army reached the island, and was received with a patriotic outburst of welcome by the Porto Ricans that surprised Americans and Spaniards alike. The people, it seems, like those of all other Spanish-American countries, looked upon the American flag as the symbol of democracy and Republican government, and expected that it would bring to them, as General Miles at the time told them it would, all the privileges of other citizens of the United States. When war broke out, General Macias was the Spanish captain-general. He was without adequate means of defending the colony in the event of any serious attack on the part of the United States. In the harbour of San Juan were a few antiquated cruisers and one first-class torpedo boat, the *Terror*. The latter properly belonged to the squadron under Admiral Cervera. The fortifications, especially at San Juan, were of old-fashioned massive stone construction, and most of the artillery was of an obsolete type. A few earthworks were thrown up for the defence of the capital, and orders were given to the troops in the various coast

The Spanish-American war.

towns to report immediately any indication of the appearance of the enemy. General Macias then waited quietly for developments. On 12th May an American squadron, under the command of Admiral Sampson, appeared off San Juan and bombarded the forts. Having satisfied himself that the squadron under Admiral Cervera was not in the harbour, the American commander withdrew. No great damage was effected by the shells from the American ships, but the fire of the Spanish guns was silenced and a panic was created in the city. On 22nd June the United States converted cruiser *St Paul* appeared off San Juan, having been detailed to watch the seas in that direction. The Spanish gunboat *Isabella II.* and the torpedo boat *Terror* were ordered by General Macias to put to sea and attack the American vessel. The *St Paul* was armed with ten 6-inch quick-firing guns, and a secondary battery of three- and six-pounder Hotchkiss and Gatling guns. The *Isabella II.* soon retired, but the *Terror* approached within 1500 yards of the *St Paul.* The American vessel had been holding her fire while the Spaniard was attempting to reach her, but suddenly opened with a broadside, and continued firing rapidly. The *Terror* was struck by a shell, which exploded on board; but she managed to steam back into the harbour, the *St Paul* not attempting to pursue. The residents of San Juan fled in large numbers from the town, and did not return until after the protocol of peace was signed in August. All communication was cut off between Porto Rico and the outer world; but the food supplies were fairly abundant, and little real distress prevailed. No change occurred in the situation until 25th July, when a United States fleet appeared off the southern coast, San Juan being also threatened by a small squadron. A bombardment of the Playa, the port of Ponce, then took place. While this was in progress, an expedition of United States troops was landed at Guanica, fifteen miles to the eastward, the small Spanish garrison of which surrendered. A movement of the American troops was then made towards Ponce, which capitulated without resistance on 28th July. General Miles, the commander-in-chief of the United States army, was in command of the forces, and was assisted by Generals Brooke, Ernst, Schwan, Henry, and Wilson. The first expedition disembarked consisted of 3415 officers and men, but reinforcements arrived immediately after the first landing and brought the number up to 10,000 in round figures.

The Spanish forces in the southern section of the country were ordered to fall back towards the ridge of mountains intersecting the island from east to west, and a little to the north of the town of Coamo. This was a strong position, and here General Macias determined to endeavour to check the American advance. Reinforcements were brought up from San Juan, and all preparations made to resist an attack. General Miles advanced towards the Spanish position, and occupied Coamo after a sharp skirmish. Other movements were in progress, when the peace protocol was signed on 12th August, and orders were at once issued to suspend hostilities. The section of the island occupied by the Americans remained under the jurisdiction of the United States military authorities, while to the north the Spaniards remained in possession. This condition of affairs continued during the arrangements for the evacuation of the island by Spain. The total loss on the American side in the campaign was three killed and forty wounded. The Spanish casualties were somewhat greater, but were not heavy.

The commissioners appointed to arrange the evacuation of the island were Admiral Schley, General Brooke, and General W. Gordon for the United States; and Admiral Villarino, General Ortega, and Señor Dellagiulia for Spain. The meetings of the Commission began early in September, and continued regularly for six weeks. It was arranged that the Spanish troops should be concentrated at San Juan for embarkation. As the Spaniards withdrew from the positions occupied, American troops were detailed to garrison the different towns. While the evacuation was taking place, disturbances occurred at various points, owing to certain natives having instigated their neighbours to revenge themselves on Spanish civilians. The United States military authorities were prompt in quelling these outbreaks; and when it was understood that the first person found implicated in these attacks would be shot or hanged, the trouble practically ceased. By the beginning of October the greater portion of the island had been evacuated by the Spaniards; and on 15th October 1898 Captain-General Macias embarked for Spain, leaving General Ortega to make the final delivery of the island to the American authorities. On 1st January 1899 the sovereignty of Spain, which had dominated the island for four hundred years, was formally transferred to the United States.

Porto Rico—an American dependency.

Pending the action of Congress, the island was temporarily placed under a military government, presided over by the commanding officer of the military department of Porto Rico, General Guy V. Henry, to whom any one treated unjustly had the right of appeal. The four Spanish insular bureaus of administration—State, Justice, Treasury, and Interior, each under a prominent citizen—were continued. The old municipal local governments and Spanish laws remained as before and were not interfered with, except in cases of notorious corruption or injustice. In August 1899 a tropical hurricane of unusual severity devastated the island. Towns, estates, and habitations were destroyed in a day, and thousands of people were reduced to dependence. In Arecibo alone 540 persons were killed by falling houses or masonry thrown down by the wind. The total loss of life was reported to be nearly 5000 persons. The administration of General George B. Davis, who succeeded General Henry shortly after this event, was largely devoted to alleviating the suffering. Over $5,000,000 was expended by the Government of the United States.

Reconstruction and civil government.

Meanwhile the people of Porto Rico awaited patiently the action of the American Congress, which alone had power under the Constitution to devise for them a territorial form of government. The old Spanish tariff laws were still in force, and the island suffered a heavy loss of trade, due to the fact that the customs laws of both Spain and the United States were operative against it. The commercial conditions during this interval were well described by the President in his annual Message of 1899, in which he said: "Since the cession, Porto Rico has been denied the principal markets she had long enjoyed, and our tariffs have been continued against her products, as when she was under Spanish sovereignty. The markets of Spain are closed to her products except upon terms to which the commerce of all nations is subjected. She has therefore lost her free intercourse with Spain and Cuba, without any compensating benefit in this market. The markets of the United States should be opened up to her products. Our plain duty is to abolish all customs tariffs between the United States and Porto Rico, and give her products free access to our markets." When the American Congress assembled in December 1899, the problem of a government for the Porto Ricans quickly came to the front, and unexpectedly resulted in legislation divergent from all traditions and precedents of the American people. A revenue Bill, reported to the House of Representatives by the Ways and Means Committee, provided for a continuance of a tariff between Porto Rico and the United States. This measure was considered unconstitutional by many, and was so directly in opposition to the President's recommendation, that "it was our plain duty" to give the island free trade, that it resulted in a violent storm of opposing public opinion, which bade fair to wreck the organization of the dominant political party. But in spite of the great sentiment against this proviso, the discipline of the party leaders was so perfect that the measure was forced through the House by a small majority. The Bill made no provision for the government of the island. In President McKinley's Message of 5th December 1899 to the fifty-sixth Congress, first session, he stated that it was desirable that the military government should be superseded by an administration entirely civil in its nature, and recommended that Congress pass a law for the organization of a temporary government, which should provide for the appointment by the President (subject to confirmation by the Senate) of a governor and such other officers as the general administration of the island might require; and that for legislative purposes upon subjects of a local nature a legislative council, composed partly of Porto Ricans and partly of citizens of the United States, should be nominated. In the municipalities and other local subdivisions he recommended that the principle of local self-government be applied at once, so as to enable "the intelligent citizens of the island to participate in their own government, and to learn by practical experience the duties and requirements of a self-contained and self-governing people." When the House Bill, providing revenues for Porto Rico, reached the Senate, an amendment providing for a government of Porto Rico was appended thereto. The Bill as amended then passed and became a law. Under this Act the government of Porto Rico is vested in the hands of a governor, to be appointed by the President of the United States. The governor has absolute power to veto all Acts of the legislature. A legislative assembly, also provided, consists of an Executive Council and a House of Delegates. The Executive Council comprises the Island Secretary, Attorney-General, Treasurer, Auditor, and Commissioners of the Interior and Education, none of whom need be citizens of the island, and five other persons to be appointed by the President, who shall be native inhabitants. The House of Delegates is to consist of five members from each of the seven districts of the island. This legislature is given no authority which the governor has not the power to veto; and all power whatsoever over the local questions of franchises, rights, provisions, or concessions is left solely in the hands of the non-resident Executive Council and governor. The ultimate judicial power is vested in the Supreme Court, to be composed of a Chief Justice, Associate Justices, and a Marshal, to be appointed by the President, who need not be residents of the island. Minor judicial matters remain vested in the courts and tribunals already established. The island is elevated into a judicial district, to be called the District of Porto Rico. The pleadings of the court must be conducted in the English language, and appeals may be taken to the Supreme Court of the United States. A Commission was also constituted to revise the laws of Porto Rico, to consist of three members, one of whom shall be a native citizen. Each commissioner is to receive $5000 per annum, to be paid out of the treasury of Porto Rico, together with an allowance for necessary clerks and other assistance. The Act did not give Porto Rico a territorial delegate to Congress, as has heretofore been provided in the case of new territorial organizations; but the island is allowed a resident commissioner at Washington, who is to receive $5000 per annum. The Act leaves no substantive authority whatever in the hands of the people of the island, and does not give them American citizenship. Under the law, furthermore, all administration officials may be Americans, with the exception of the five native members of the Council and the thirty-five members of the House of Delegates. The form of government greatly resembles that of the British Crown Colony of Jamaica.

On 1st May 1900, Mr Charles A. Allen, who had been appointed the first American civil governor of Porto Rico, was installed in office at San Juan. Under his administration the island became peaceful, and prosperity was attained through the removal of duties by executive proclamation of President McKinley.

Portovenere, a town and summer resort of the province of Genoa, Liguria, Italy, at the southern extremity of the peninsula which protects the Gulf of Spezia on the west, 7 miles south of Spezia. It still retains portions of the fortress and walls with which it was provided by the Genoese in 1113; also of the church of St Peter (1118, destroyed by the Aragonese in 1494), which is reputed to occupy the site of a temple of Venus (whence *Portus Veneris*). The parish church dates from 1139. Here is the cave in which Lord Byron was inspired to write *The Corsair.* To the north of the towns is the Varignano lazaretto, where Garibaldi was imprisoned in 1860 and 1867. Marble and building-stone are quarried, and oysters are caught. Population, about 4000.

Portraiture.—The earliest attempts at individual portraiture are found in the eidolon and mummy-cases of the ancient Egyptians; but their painting never went beyond conventional representation—mere outlines filled in with a flat tint of colour. In Greece portraiture probably had its origin in skiagraphy or shadow-painting. The story of the Greek maiden tracing the shadow of her departing lover on the wall points to this. The art developed rapidly. In 463 B.C., Polygnotus, one of the first Greek painters of distinction, introduced individual portraiture in the decoration of public buildings, and Apelles nearly a century later showed so much genius in rendering character and expression, that Alexander the Great appointed him "portrait painter in ordinary," and issued an edict forbidding any one else to produce pictorial representations of his majesty. Similar edicts were issued in favour of the sculptor Lysippus and Pyrgoteles the gem engraver. No works of the Greek painters survive, but the fate of two portraits by Apelles, which were in the possession of the Emperor Claudius (A.D. 41–54), is known, the heads having been painted out to make room for the features of the divine Augustus!

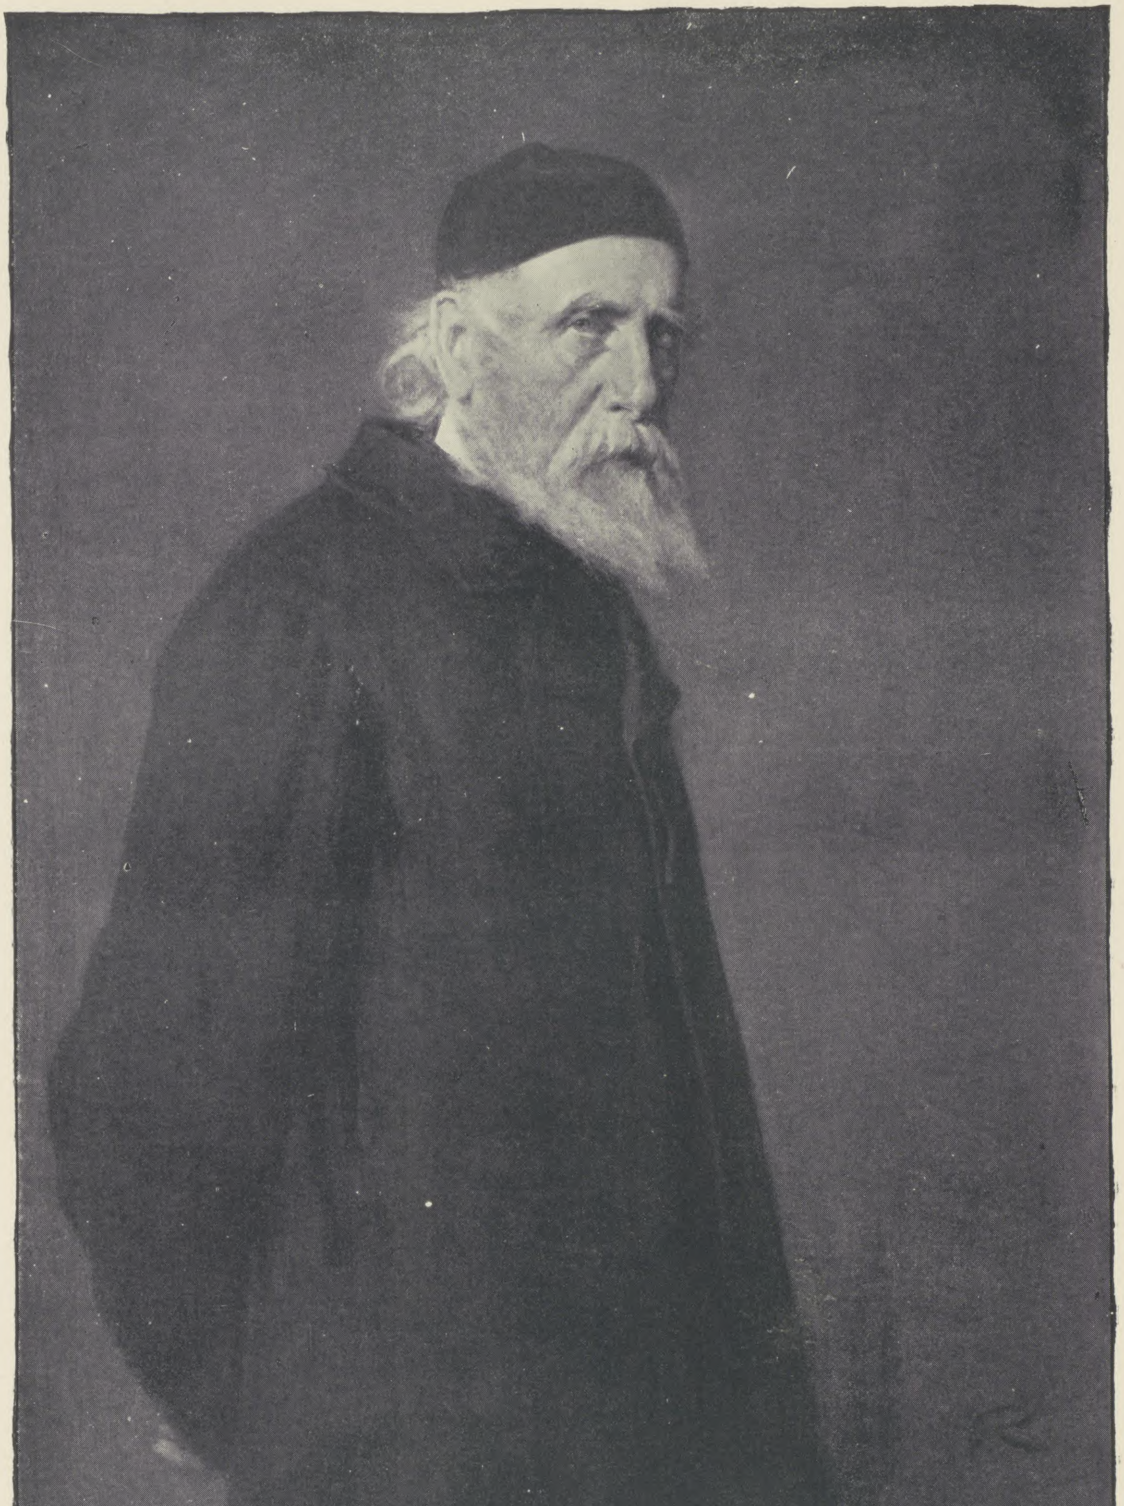
After the time of Alexander (300 B.C.) Greek art rapidly deteriorated. There is, perhaps, nothing in the history of human intelligence to compare with the dazzling swiftness of its development or the rapidity of its decline. War was followed by pillage and devastation, and victorious Roman generals, mere depredators and plunderers, crowded Rome with the stolen treasures of Greece, with the result that Greek art and Greek influence soon made themselves felt in the imperial city, and for generations its artists were almost exclusively Greeks, chiefly portrait-painters and decorators. The Romans possessed no innate aptitude for art, and rather despised it as a pursuit little becoming the dignity of a citizen. Although lacking in appreciation of the higher conditions of art, they had from early times decorated their atria with effigies—originally wax moulds—of the countenances of their ancestors. These primitive "wax-works" ultimately developed into portrait busts, often vivid and faithful, the only branch of art in which Rome achieved excellence.

With the invasion of the Northern barbarians and the fall of the empire Græco-Roman art ended. In the following centuries Christianity gradually became the dominant religion, but its ascetic temper could not find expression in the old artistic forms. Instead of joy in the ideals of bodily perfection, came a loathing of the body and its beauty, and artists were classed among "persons of iniquitous occupations." Before the 5th century these prejudices had relaxed, and images and pictures again came into general favour for religious uses. In the 8th and 9th centuries the iconoclasts commenced their systematic destruction, and it was not till the Renaissance in the 13th century that art began again to live. The great revival brought with it a closer observation of the facts of nature and a growing sense of beauty, and the works of Cimabue and Giotto prepared the way for those of Benozzo Gozzoli, Ghirlandaio, and the long line of masters who raised Italian art to such a height in the 15th and 16th centuries. Although the works of the early painters of the Renaissance were mostly devoted to the expression of the dogmas of the Church, the growing love and study of nature led them, as opportunity afforded, to introduce portraits of living contemporaries into their sacred pictures. Gozzoli (1420–1498) and Ghirlandaio (1449–1494) began the practice, followed by nearly all the old and great painters, of introducing portraiture into their works; Ghirlandaio especially filling some of his great fresco compositions with the forms and features of the living men and women of Florence, members of the Tornabuoni, Medici, and other great families. Acuteness of observation was innate in the race. By degrees it manifested itself in a marvellous subtlety in the rendering of individual character, in the portrayal of individual men and women, and a school of portraiture was developed of which Titian became the crowning glory. This great Venetian painter, by universal consent reckoned one of the masters of portraiture, has handed down to us the features of many of the greatest historical and literary personages of his time—Emperor, Pope, King, Doge—all sat by turn to him and loaded him with honours. The names of Bellini, Raffaelle, Tintoret, Veronese, and Moroni of Bergamo occur among those of the great Italian portrait painters of the 15th and 16th centuries. The last named, some of whose finest works are now in England, was highly praised by Titian.

A love of ugliness characterizes the artists of the early German and Flemish schools, and most of the portraits produced by them previous to Holbein's time suffer from this cause. Schöngauer, Dürer, and Lucas Cranach are never agreeable or pleasant, however interesting in other respects. Dürer, the typical German artist, the dreamer of dreams, the theorist, the thinker, the writer, was less fitted by nature for a portrait painter than Holbein, who, with a keen sense of nature's subtle beauty, was a far greater painter although a less powerful personality. He produced many fine works in other branches, but it is as a portrait painter that Holbein is chiefly known, and his highest claims to fame will rest on his marvellous achievements in that branch of art. He first came to England in 1526, bringing with him letters of introduction from Erasmus. Sir Thomas More received him as his guest, and during his stay he painted More's and Archbishop Warham's portraits. In 1532 he was again in London, where till his death in 1543 he spent much of his time. He was largely employed by the German merchants of the Steelyard and many Englishmen of note, and afterwards by Henry VIII., by whom he was taken into permanent service with a pension. As a portrait painter Holbein is remarkable not only for his keen insight into the character of his sitters, but for the beauty and delicacy of his drawing. As colourist he may be judged by an admirable example of his work, "The Ambassadors," in the National Gallery in London. Many of his drawings appear to have been made as preliminary studies for his portraits.

In Flanders, Jan van Eyck (1390–1440), his brother Hubert, Quintin Matsys, Memlinc, and other artists of the 15th century, occasionally practised portraiture. The picture of Jean Arnolfini and his wife, in the National Gallery, London, is a remarkable sample of the first-named artist, and the small half-length of young Martin van Nieumenhoven, in the Hospital of St John at Bruges, of the last-named. Nearly a century later the names of Antony Mor (or Moro), Rubens, and van Dyck appear. Rubens, although not primarily a painter of portraits, achieved no small distinction in that way, being much employed by royalty (Maria de Medici, Philip IV., and the English Charles I. among the number). His services were also in request as ambassador or diplomatist, and thrice at least he was sent on missions of that nature. His personal energy and industry were enormous, but a large proportion of the work attributed to him was painted by pupils, of whom van Dyck was one of the most celebrated. Van Dyck (1599–1641) early acquired a high reputation as a portrait painter. In 1632 he was invited to England by Charles I., and settled there for the remainder of his life. He was knighted by Charles, and granted a pension of £200 a year, with the title of painter to his majesty. Many of van Dyck's portraits, especially those of his early and middle periods, are unsurpassed in their freshness, force, and vigour of handling. He is a master among masters. England possesses many of his works, especially of his later period. To van Dyck we owe much of our knowledge of what Charles I. and those about him were like. A routine practice, luxurious living, failing health, and the employment of assistants, told upon his work, which latterly lost much of its early charm.

In Holland, in the 17th century, portraiture reached a high standard. A reaction had set in against Italian influence, and extreme faithfulness and literal resemblance became the prevailing fashion. The large portrait pictures of the members of guilds and corporations, so frequently met with in Holland, are characteristically Dutch. The earliest works of the kind are generally rows of portraits ranged in double or single lines, without much attempt at grouping or composition. Later, in the hands of painters like Rembrandt, Frans Hals, and van der Helst, these pictures of civic guards, hospital regents, and masters of guilds assumed a very different character, and



Professor Mitchell, D.D., St Andrews. By Sir George Reid, P.R.S.A.

are among the very finest works produced by the Dutch portrait painters of the 17th century. They may be termed "subscription portraits,"—each member of the guild who desired a place on the canvas agreeing, before the commission was given, to pay, according to a graduated scale, his share of the cost. Among the most famous examples of this class of portraits are "The Anatomy Lesson," "The March-out of Captain Banning Kock and his Company" (erroneously called "The Night Watch"), and "The Five Syndics of the Cloth-Workers' Guild," by Rembrandt. The magnificent portrait groups at Haarlem by Hals—the next greatest portrait painter of Holland after Rembrandt—and the "Schuttersmaaltyd" by van der Helst, in the Amsterdam Museum, which Reynolds considered "perhaps the first picture of portraits in the world," must also be mentioned.

Of the pictorial art of Spain previous to the 15th century, little, if any, survives. Flemish example was long paramount, and Flemish painters were patronized in high places. In the 16th century the names of native Spanish artists begin to appear—Morales, Ribera, Zurbaran, a great though not a professed portrait painter; and in the last year of the century Velazquez was born, the greatest of Spain's artists, and one of the great portrait painters of the world. None, perhaps, has ever equalled him in keen insight into character, or in the swift magic of his brush. Philip IV., Olivarez, and Innocent X. live for us on his canvases. His constantly varying, though generally extremely simple, methods, explain to some extent the interest and charm his works possess for artists. Depth of feeling and poetic imagination were, however, lacking, as may be seen in his prosaic treatment of such subjects as the "Coronation of the Virgin," the "Mars," and other kindred works in the Madrid Gallery. Velazquez must be classed with those whose career has been prematurely cut short. His works often show signs of haste and of the scanty leisure which the duties of his office of "Aposentador Mayor" left him—duties which ended in the fatal journey to the Isle of Rhé.

In France the most distinguished portrait painters of the 16th and 17th centuries were the Clouets, Cousin, Vouet, Philippe de Champaigne, Rigaud, and Vanloo. French portraiture, long inflated and artificial, reached the height of pomposity in the reigns of Louis XIV. and XV., the epoch of which the towering wig is the symbol. In the 18th and early part of the 19th centuries occur the names of Boucher, Greuze, David, Gérard, and Ingres; but somehow the portraits of the French masters seldom attract and captivate in the same way as those of the Dutch and Italian painters.

Foreign artists were engaged for almost every important work in painting in England down to the days of Sir Joshua Reynolds and Gainsborough. Henry VIII. employed Holbein; Queen Mary, Sir Antonio Moro; Elizabeth, Zucchero and Lucas de Heere; James I., van Somer, Cornelius Janssens, and Daniel Mytens; Charles I., Rubens, van Dyck, Mytens, Petitot, Honthorst, and others; and Charles II., Lely and Kneller, although there were native artists of merit, among them Dobson, Walker, and Jamesone, a Scottish painter. Puritan England and Presbyterian Scotland did little to encourage the portrait painter. The attitude of the latter towards it may be inferred from an entry in the diary of Sir Thomas Hope, the Scottish Lord Advocate in 1638. "This day, Friday, William Jamesone, painter (at the earnest desyr of my sone Mr Alexander) was sufferit to draw my pictur." He does not even give the painter's name correctly, although Jamesone at the time was a man of some note in Scotland. At the commencement of the reign of George I., art in England had sunk to about the lowest ebb. With the appearance of William Hogarth (1697–1764) the English school of painting may be said to have commenced, and in Reynolds and Gainsborough it produced two portrait painters whose works hold their own with those of the masters of the 16th and 17th centuries. Both Sir Joshua and Gainsborough are seen at their best in portraits of women and children.

George Romney (1734–1802) shared with Reynolds and Gainsborough the patronage of the wealthy and fashionable of his day. Many of his female portraits are of great beauty. For some unknown reason he never exhibited his works in the Royal Academy.

Sir Henry Raeburn (1756–1823) was a native of Edinburgh, and spent most of his life there. His portraits are broad and effective in treatment, masterly and swift in execution, and often fine in colour. He painted nearly all the distinguished Scotsmen of his time — Walter Scott, Adam Smith, Braxfield, Robertson the historian, Dugald Stewart, Boswell, Jeffrey, Professor Wilson, and many of the leading noblemen, lairds, clergy, and their wives and daughters. For a considerable period his portraits were little known out of Scotland, but they are now much sought after, and fine examples appearing in London salerooms bring remarkable prices. Raeburn's immediate successor in Scotland, J. Watson Gordon (1788–1864), also painted many excellent portraits, chiefly of men. A very characteristic example of his art at its best may be seen in his "Provost of Peterhead" in the Scottish National Gallery.

Sir Thomas Lawrence (1769–1830) was the favourite English portrait painter of his time, and had an almost unrivalled career. He had an immense practice, and between the years 1787 and 1830 exhibited upwards of three hundred portraits in the Royal Academy alone. The Waterloo Gallery at Windsor contains some of his best work, chiefly painted in 1818–19, including his portraits of the Emperor Francis, Pope Pius VII., and Cardinal Gonsalvi. He was loaded with honours, and died President of the Royal Academy.

Sir J. E. Millais (1829–1896), although most widely known as a painter of figure subjects, achieved some of his greatest successes in portraiture, and no artist in recent times has approached him as a painter of children. His portraits of Mr Gladstone, Sir James Paget, Sir Gilbert Greenall, Simon Fraser, J. C. Hook, and Mrs Bischoffsheim, to name only a few, are alone sufficient to give him a high place among British portrait painters.

Frank Holl (1845–1888) first came into note as a portrait painter in 1878, and during the subsequent nine years of his life he painted upwards of one hundred and ninety-eight portraits, an average of over twenty-two a year. The strain, however, proved too great for a naturally delicate constitution, and he died at the age of forty-three—another instance of a brilliant career prematurely cut short.

It is always a matter of considerable difficulty to estimate the work of contemporary artists, for, owing to its nearness, it is apt to assume an importance which with the lapse of time it loses, but the names of a few of the best portrait painters living in 1902 may be mentioned, including those of G. F. Watts (*b.* 1820), to whom we are indebted for admirable portraits of many of the leading men of the Victorian era in politics, science, literature, theology, and art; Orchardson (*b.* 1835), like Millais more widely known as a painter of figure subjects, but also admirable as a portrait painter; Sargent (*b.* 1856), whose brilliant and vigorous characterization of his sitters leaves him without a rival; as well as Ouless, Shannon, Fildes, Herkomer, and others, who have worthily carried on the best traditions of the art.

In France contemporary portraiture is ably represented in the works of Carolus-Duran, Bonnat, and Benjamin-Constant, and in Germany by Lenbach, who has handed down to posterity with uncompromising faithfulness the form and features of Prince Bismarck.

Of portraiture in its other developments little need be said. Miniature painting, which grew out of the work of the illuminator, appears to have been always successfully practised in England. The works of Hilliard, Isaac and Peter Oliver, Samuel Cooper, Hoskins, Engleheart, Plimer, and Cosway hold their own with the best of the kind; but this beautiful art, like that of the engraver, has been largely superseded by photography and the "processes" now in use. It is unnecessary to refer to the many uses of portraiture, but one of its chiefest has been to transmit to posterity the form and features of those who have played a part, worthy or otherwise, in the past history of our race. Of its value to the biographer and historian, Carlyle, in a letter written in 1854, says, "In all my poor historical investigations it is one of the most primary wants to procure a bodily likeness of the personage inquired after; a good *portrait*, if such exists; failing that, even an indifferent, if sincere one; in short, *any* representation, made by a faithful human creature, of that face and figure which *he* saw with his eyes and which I can never see with mine. Often I have found the portrait superior in real instruction to half-a-dozen written biographies, or rather, I have found the portrait was as a small lighted *candle*, by which the biographies could for the first time be *read*, and some human interpretation be made of them." (G. RE.)

Port Richmond, formerly a village of Richmond county, New York, U.S.A., and since 1st January 1898 a part of Richmond borough, one of the five boroughs constituting New York city. It is situated on the northern shore of Staten Island, in the south-east part of the state. Population (1890), 6290.

Portrush, a seaport town in the extreme north of Co. Antrim, Ireland. It is very picturesquely situated, and is on the Belfast and Northern Counties Railway. A fine new hotel and an excellent golf-course are the chief new features, and the place is much frequented both for golf and sea-bathing. It is also the centre for visitors to the Giant's Causeway, with which it is connected by an electric railway (see ELECTRICITY SUPPLY, III., vol. xxviii.). There is a thriving trade in salmon. Population, about 2500.

Port Said, a seaport town of Egypt, at the Mediterranean end of the Suez Canal. Its prosperity is bound up with the traffic going through the Canal; for statistics, &c., see EGYPT. In 1893 it was connected with Ismailia by railway. Population, 37,000.

Portsea. See PORTSMOUTH.

Portsmouth, a municipal, county (1888), and parliamentary borough, seaport, naval station, and arsenal of England, an aggregate of four towns, namely, Portsmouth, Portsea, Landport, and Southsea, in the south-west of the island of Portsea, Hampshire, opposite the Isle of Wight, from which it is separated by Spithead, 75 miles by rail south-west of London. It is a terminal station of the London and South-Western and of the London, Brighton, and South Coast railways. There are about 20 churches. The new church of St Mary's, or Kingston Church, with a tower 165 feet high, was erected in 1889, at a cost of nearly £50,000. Twenty-six board schools include 2 of higher grade, one of them (1896) equipped with chemical and physical laboratories. There are also schools for engineering students and dockyard apprentices. Public buildings of modern erection are the town hall (1890), costing £140,000, and the Royal Hospital (1899). Close to the town hall is Victoria Park (15 acres), with a monument to Admiral Napier; on the north side of it is the still unfinished Roman Catholic cathedral. Whale Island, in Portsmouth harbour, has, by the continuous accretion of excavated mud, grown to nearly 90 acres in area, and is now covered with naval and military buildings. It is proposed to connect the island by a causeway with the mainland. Between Portsmouth and Portsea is the gunwharf of 14 acres reclaimed from the harbour; the grand depôt for ordnance and ammunition, both for land and sea service, with an aggregate of about 40,000 stand of arms. A floating bridge (1892), 100 feet in length of hull by 62 feet wide, with capacity for 1400 passengers, connects Portsmouth with Gosport. There are now only seven barracks, including the Marine Artillery Infantry barracks at Eastney, beyond Southsea, the Anglesea barracks having been absorbed by the extending dockyard. On the Gosport side of the harbour (see GOSPORT) are two barracks—making in all nine barracks. An extension of 62 acres beyond the Royal Dockyard was determined on by the Admiralty in 1897 for the erection of naval barracks to accommodate about 3000 men. Portsmouth Dockyard covered an area of 294 acres—the total area planned out when the extension works were commenced in 1864—by 1890. Since then it has been further enlarged, and is now said to be the greatest dockyard in the world. Down to August 1900 the extension works cost about 2¼ millions sterling. Altogether the dockyard comprises 15 dry docks, 2 building slips, 60 acres of enclosed basins, 18,400 feet of wharfage, and about 10 miles of railway, with iron foundry, gun-mounting and boiler-making stores, joinery, mast-house, pump-house, block-making machines, naval college, observatory, Admiralty house, official residences; sheer, boat-house, south, and troopship jetties, &c. The men employed in the dockyard number about 9800. (See also DOCKYARDS.)

On the north defensive works stretch nearly 7 miles along Portsdown Hill, with a total barrack accommodation for 3000 men. On the south there are various forts. On the sea face of Gosport, again, the line of defence is continued for two miles westwards along Stokes Bay to Browndown. Thence a line of 5 forts stretches across the marshy ground between the Solent and Portsmouth harbour. On the east side of the harbour other forts take up the defence works of Portsdown Hill and continue the defence southwards to Hilsea lines, 2800 yards long. The south face of Portsea island is defended by 4 works. There are also forts on the Isle of Wight and a line of forts on shoals between St Helens (Isle of Wight) and Portsmouth. The shipping registered at the port in 1888 amounted to 262 vessels, of 15,520 tons; in 1900, to 253 vessels, of 13,539 tons. 14,601 vessels, of 1,524,939 tons, entered in 1888; in 1900, 16,743, of 1,851,593 tons. In 1888, 14,130 vessels, of 1,490,163 tons, cleared; in 1900, 16,552, of 1,800,507 tons. The total foreign and colonial imports in 1888 were valued at £221,797; in 1900, £222,174. The total exports amounted to £121,022 in 1900. Two daily newspapers are issued. Area of the municipal and parliamentary boroughs, which are coextensive, 4320 acres. Population (1881), 127,989; (1891), 159,251; (1901), 189,122.

Portsmouth, a city of New Hampshire, U.S.A., capital of Rockingham county, on a peninsula at the mouth of the Piscataqua river, in the south-eastern part of the state. The city is irregularly laid out, divided into five wards, and supplied with water from springs by gravity. Though a seaport and the only one in the state, Portsmouth has practically no foreign commerce. It has manufactures, largely of cotton goods and boots and shoes. In 1900 there were 176 manufacturing establishments, having a capital of $4,167,545, employing 1809 wage-earners, and turning out products valued at $4,813,138. Population (1890), 9827; (1900), 10,637, of whom 2033 were foreign-born and 101 negroes.

Portsmouth, a city of Ohio, U.S.A., capital of Scioto county, on the Ohio river, at the mouth of the Scioto, in the southern part of the state, at an altitude of 525 feet. It has a level site on the flood plain of the river, partly enclosed by terraces, is divided into seven wards, and derives its water supply from the river by pumping. It has three railways, the Norfolk and Western, the Cincinnati, Portsmouth, and Virginia, and the Baltimore and Ohio South-Western, which, with boats on the river, give the city a large trade. It has also extensive manufactures, consisting in great part of iron and steel goods, boots and shoes, lumber, and flour. In 1900 its 284 manufacturing establishments had a total capital of $4,113,700, and employed 4586 hands. Their products were valued at $7,532,976. Population (1890), 12,394; (1900), 17,870, of whom 1064 were foreign-born and 947 negroes.

Portsmouth, a city and seaport of Virginia, U.S.A. Though within the limits of Norfolk county, it is not subject to county government. It is situated at the mouth of the Elizabeth river, opposite Norfolk, in the south-eastern part of the state. It is irregularly laid out on a level site, and is divided into five wards. It shares Norfolk harbour with the city of Norfolk, and has some commerce by sea. It is traversed by five railways, the Atlantic and Danville, the Atlantic Coast Line, the Chesapeake and Ohio, the New York, Philadelphia, and Norfolk, and the Seaboard Air Line. It contains the works of the last-named line. In 1900 there were 103 manufacturing establishments, employing 1154 hands. Population (1890), 13,268; (1900), 17,427, of whom 710 were foreign-born and 5625 negroes.

Port Townsend, a city and seaport of Washington, U.S.A., capital of Jefferson county, at the north-eastern point of the Olympic peninsula, in the north-western part of the state. It is at the entrance to Puget Sound, and, as a commanding point, has been fortified by the United States, which has also established there a quarantine station and a marine hospital. The city is well laid out, with a water supply by gravity from Little Quilcene river. It has regular lines of steamers to Sound ports and to Victoria, and is the terminus of the Port Townsend Southern Railroad. It is in a lumber region, and its industries consist largely in the sawing and manufacture of lumber. Population (1880) 917; (1890), 4558; (1900), 3443, of whom 1042 were foreign-born and 218 coloured.

PORTUGAL

I. Geography and Statistics.

PORTUGAL, one of the two constituent kingdoms of the Iberian Peninsula, lies to the west of Spain, and is washed by the Atlantic for a distance of 473 miles out of a total frontier line of 1075 miles. It is the most westerly country of the continent of Europe.

Orography.—Portugal embraces three mountain systems: (1) the Transmontane, embracing the ranges which lie north of the Douro and stretch through the provinces of Minho, Traz-os-Montes, and a small part of Douro; (2) the Beirene, comprising the ranges of the two provinces Beira and the province of Douro, lying between the rivers Douro and Tagus; (3) the Trans-Tagine, or the ranges which lie south of the Tagus. To the Transmontane system belong the following ranges: Peneda (4728 feet), forming the watershed between the rivers Minho and Lima; Gerez (4817 feet), which rises like a gigantic wall between the Lima and the Homem, and sends off a spur known as the Amarella, Oural, and Nora, parting the Homem from the Cavado; and Cabreira (4196 feet), which gives birth to the Ave, and separates the basin of the Cavado from that of the Tamega. These three main ranges belong to the province of Minho. In the province of Traz-os-Montes these ranges occur: Larouco (5184 feet), which continues the Serra do Gerez, and gives birth to the river Cavado; Padrélla (3776 feet), Villarelho (3668 feet), and Marão (4666 feet), forming an enormous *massif* between the rivers Tamega, Tua, and Douro; and Nogueira (4331 feet) and Bornes (3944 feet), separating the basins of the Tua and the Sabor. To the Beirene system belong the following chains: Montemuro (4557 feet), between the Douro and its left-hand tributary the Paiva; Gralheira (3681 feet), separating the Paiva from the Vouga, and continued south by the Serra do Caramullo (3511 feet), parting the basins of the Vouga and Dão; and Lapa (3330 feet), lying to the north-east of the last-named, and giving rise to the Tavora and Paiva (tributaries of the Douro), the Vouga, and the Dão. All these lie north of the Mondego; south of this river come the loftiest ranges in the kingdom, still belonging to the same system, namely, the Serra da Estrella (6539 feet), and Louzã (3944 feet), between the Mondego and the Zezere; Mesas (3465 feet), the watershed between the Coa and the Zezere; and Guardunha (4016 feet) and Moradal (3547 feet), separating the Zezere from the Ponsul and Ocreza, right-hand tributaries of the Tagus. The constituent ranges of the Trans-Tagine system are the Serra da Arrabida (1637 feet), between Cape Espichel and Setubal; São Mamede (3363 feet), in Portalegre; Ossa (2129 feet), Monfurado (1378 feet), and Mendro (1332 feet), forming the high ground between the Sorraia, Sado, and Guadiana. Finally, in the province of Algarve, in the south, a series of low ranges—Alcaria do Cume (1716 feet), Malhão (1887 feet), Mesquita, Monchique (with the summit of Foya, 2963 feet), and Espinhaço de Cão—stretch from east to west, and terminate in Cape St Vincent. Plains and level expanses are comparatively few, the most notable being the *veigas* of Chaves and Valença, in the north, the *campos* of the valley of the Tagus, the *baixas* of the coast in Alemtejo, the *campos* of Beja, the *baixas* of the Sorraia, and the *campos* of Aviz. To these may be added the high plains known as the *cimas* of Mogadouro, in Traz-os-Montes, and the *cimas* of Ourem, east of the Tagus.

Geology.—Nearly every geological formation is represented in the structure of Portugal. The district of Minho, in the extreme north, is almost entirely built up of granites, amongst them being granite with white mica and granite with black mica in the valley of the Cavado, and porphyritic granite extending from the Minho to the Serra do Marão, and thence passing over into the district of Traz-os-Montes. Between the granites, on the north and south, lie embedded strata of crystalline and Silurian schists, in the middle. The Serra de Padrélla is formed of ramifications of the Transmontane granites. In Beira Baixa (province) granites, irregularly intermingled with schists, compose the great mass of the Serra da Estrella. Jurassic formations predominate in the province of Estremadura, constituting the bulk of the Serra do Bouro, the Serra de Penella, the Serra de Sicó, and the south face of the Serra de Cintra, as well as the peninsula of Peniche. South of Torres Vedras, between the Tagus and the coast, Cretaceous rocks prevail, and along a line drawn from Leiria to Aveiro they are overlain by a Tertiary deposit. In Alemtejo, although the granite reappears, the greater part of the province consists of schists accompanied by crystalline limestones. In the southernmost province of Algarve, Cretaceous, Jurassic, and Triassic rocks are all represented. Basalt is encountered near Lisbon, and between that city and Alhandra, Tertiary formations.

Climate.—Meteorological observations are taken at eleven stations. Those with the lowest mean temperature are on the Serra da Estrella (44·7° F.), at Montalegre (48·3°), and at Guarda (50·3°); those with the highest mean are Lagos (63·5°), Campo Maior (60·9°), Evora (61·9°), and Lisbon (60·5°). The greatest daily variations have been registered at Campo Maior (22·8°) and Evora (18·5°); and the least at Lisbon (12·5°) and on the Serra da Estrella (11·3°). The greatest humidity is at Guarda, the smallest at Campo Maior; and the heaviest rainfall occurs on the Serra da Estrella, and at Vizeu, Oporto, and Montalegre; and the smallest at Lagos, Campo Maior, and Moncorvo.

Area and Population.—Particulars of the area and population in 1890 and 1900, together with the density in the latter year, are given in the following table:—

District.	Area in Square Miles.	Population, 1890.	Population, 1900.			Density per Square Mile, 1900.
			Males.	Females.	Total.	
Aveiro	1213	287,437	137,257	164,924	302,181	249
Beja	4196	157,571	81,233	80,369	161,602	38
Braga	1057	338,308	161,727	195,092	356,819	338
Bragança	2574	179,678	91,924	93,662	185,586	73
Castello Branco	2556	205,211	105,752	110,877	216,629	85
Coimbra	1499	316,624	153,545	179,960	333,505	222
Evora	2736	118,408	64,779	62,453	127,232	45
Faro	1872	228,635	127,221	127,630	254,851	136
Guarda	2145	250,154	126,618	136,674	263,292	122
Leiria	1343	217,278	117,169	122,998	240,167	178
Lisbon	2718	611,168	360,806	347,944	708,750	260
Oporto	885	546,262	280,370	321,318	601,688	680
Portalegre	2482	112,834	63,052	61,645	124,697	50
Santarem	2649	254,844	139,661	144,015	283,676	107
Vianna do Castillo	866	207,366	93,766	120,833	214,599	248
Villa Real	1717	237,302	116,949	126,635	243,584	142
Vizeu	1920	391,015	186,149	216,650	402,799	209
Portugal	34,428	4,660,095	2,407,978	2,613,679	5,021,657	146
Angra do Heroismo	281	72,151	33,361	40,091	73,452	264
Horta	304	58,685	24,461	30,995	55,456	182
Ponta Delgada	337	124,758	59,208	68,358	127,566	378
Azores	922	255,594	117,030	139,444	256,474	278
Madeira (Funchal)	315	134,040	72,262	78,266	150,528	477
Grand Total	35,665	5,049,729	2,597,270	2,831,389	5,428,659	152

During the period 1878 to 1890 the increase per cent. was ·85, and between 1890 and 1900, 7·5 per cent. In 1890 there were 41,339 subjects of foreign countries in Portugal; and at the same date 3,067,408 of the population (1,507,269 males and 1,560,139 females) were unmarried and 1,669,874 were married, and there were 94,198 widowers and 218,249 widows. The following table shows the movement of the population in continental Portugal and the Azores and Madeira in 1890 and 1896:—

	1890.		1896.			
	Total.	Per Thousand.	Continent.	Islands.	Total.	Per Thousand.
Births	164,627	32·60	144,530	13,335	157,865	31·24
Deaths	127,237	25·19	110,970	8,761	119,731	23·71
Marriages	35,769	7·08	30,585	2,433	33,018	6·54

Thus the natural increase in 1896 was 38,134, or at the rate of 7·53 per thousand of the 1890 population. Emigration is still relatively heavy. In 1890 there were 29,421 emigrants; in 1895 (an exceptional year), 44,746; in 1898, 23,510. Of the last number, 21,422, or more than 91 per cent., went to America, Brazil being the destination of practically all; 1854, or nearly 8 per cent., were bound for Africa. From 15 to 20 per cent. of the emigrants are from the Azores and Madeira. Only about one-fifth are females.

Government.—Various modifications have been made in the constitution of the two Houses of Parliament since 1885. Until that year certain members sat in the House of Peers by hereditary right. It was then decided, however, that such rights should cease, except in the case of princes of the royal blood, with those of the members who then held them, and that when all the hereditary peerages had thus lapsed, the House should be composed of the princes of the royal blood, the twelve bishops of the continental dioceses, a hundred legislative peers appointed by the king for life, and fifty elected every new Parliament by the deputies of the Lower House. A further modification was decided on in 1895, when the number of life peers was reduced to ninety and the elective branch was abolished. The House of Deputies was reconstituted in 1899, when all citizens 21 years of age who could read and write, or who paid taxes to the value of 500 reis (except non-commissioned soldiers, Government workmen, domestic servants, &c.), were declared qualified electors. The House is composed of 145 deputies—six from Lisbon, three from Oporto, one from each of 129 other electoral districts into which the mainland, the Azores, and Madeira are divided, and seven from the colonies. Both life peers and deputies must possess certain qualifications. Besides the courts of appeal at Lisbon and Oporto, there is a third at Ponta Delgada (Azores). About 17,500 persons, of whom some 20 per cent. are women, are, on an average, annually convicted of crime, the proportion of convictions thus being about 1 in 300 inhabitants.

Religion.—Not only is Roman Catholicism the State religion of Portugal, but it is professed by nearly all the inhabitants; Protestants do not number more than 500. The total income of the upper hierarchy of the Church is estimated to be about £70,000.[1]

Education.—The law making primary education compulsory, provided there be a school within a mile, is not stringently enforced, and in 1890, nearly 50 years after the passing of the Act, 79·2 per cent. of the total population could not read. In the same year the children attending primary schools formed less than 1 in 20 of the population; there were 5339 primary schools (3864 public), with 237,783 scholars (152,707 boys and 85,076 girls). In 1357 communes there were no primary schools. By 1899, however, 619 additional public primary schools had been established. The system of secondary education was improved and set upon a sound basis in 1894. New state lyceums have been established since 1885 at Amarante, Guimarães, and Lamego, and these, with the district lyceums, were attended in 1898 by 3976 pupils. Private secondary schools affording a general education are numerous, and there are 18 theological seminaries, with (1897) 2262 pupils. Technical and commercial schools number about 30 and educate over 4000 scholars, while special mention may be made of a college for those who intend to go into the army. Under the head of secondary education, also, notice may be taken of the increase in the number of training colleges for primary school teachers, and of the pilot schools established at Lisbon, Oporto, Faro, and Ponta Delgada (Azores). In addition to the institutions for higher education mentioned in the ninth edition of this work, there are military and naval colleges, a high school of letters, a second school of fine arts (at Oporto), and a conservatorio at Lisbon for music and dramatic art. At the University of Coimbra there were 1429 students in 1900. According to the Budget of 1898–99, the total Government expenditure on education in that year was over £282,200, of which about £20,260 was expended through the War and Marine ministries.

Finance.

In 1891 the financial condition of the kingdom had become so serious that the public debt had to be reorganized. A marked improvement was subsequently observed. While the revenue increased very considerably, the expenditure had not up to 1901 grown to any appreciable extent, and though it always exceeded the revenue, the deficits were much smaller than was formerly the case. In 1891–92 the revenue was £8,587,380 and the expenditure £12,210,460. Between then and 1901 the worst financial year was 1896–97, when the revenue had increased to £11,287,955 and the expenditure stood at £12,946,820. The Budget estimates for 1900–01 were as follows:—

Revenue.		Expenditure.	
Direct taxes	£2,722,080	Consolidated debt	£4,434,243
Indirect taxes	5,398,680	Loss on exchange	111,111
Additional taxes	244,155	Sums voted for the several ministries	4,986,296
Registration and stamps	1,223,555	Civil list, Cortes and various	2,172,212
Receipts *d'ordre*	974,015	Deposit and Consignment Office	15,408
National property and sundries	779,320		
Total ordinary	£11,341,805	Total ordinary	£11,719,270
Extraordinary	255,555	Extraordinary	469,384
Total	£11,597,360	Total	£12,188,654

[1] Throughout this article $4\frac{1}{2}$ milreis (thousand reis) has been taken as the equivalent of one pound sterling.

Thus the deficit on the Budget of 1900–01 was only a little over half a million sterling, compared with more than 3½ millions in 1891–92 and more than 1½ million in 1896–97. The outstanding debt in 1899 was estimated to be—

Total external	£62,901,275
Internal, 3 per cent. (quoted in London) .	58,951,812
Total . .	£121,853,087
Also outstanding—	
Internal, at 4 and 4½ per cent. . .	£6,143,426

£2,318,819 of the external debt and £27,579,446 of the internal debt—total, £29,898,265—was stated to be in the hands of Government. The floating debt in 1899 amounted to £9,738,350.

Defence. The Portuguese army is maintained at its normal strength partly by conscription, the chief law regulating it being that of 1887 as variously modified in subsequent years. The Cortes fixes the number of conscripts to be enrolled in each year (in 1899, 16,500 for the army, 200 for the navy), and with certain exceptions all men over 21 years of age are liable for service —3 years in the regular army, 5 years in the first reserve, and 7 years in the second reserve. In time of peace the effective force of the regular army is 1723 officers, 29,703 men, 5404 horses and mules, and 144 guns; that of the reserve troops is 81 officers and 297 men, making the total number of officers 1804 and of men 30,000. In time of war the regular army has an effective force of 2029 officers, 82,843 men, 10,736 horses and mules, and 216 guns; while the reserve forces can muster 1447 officers, 62,796 men, 5113 horses and mules, and 96 guns, making a total effective force of 3476 officers, 145,639 men, 15,849 horses and mules, and 312 guns. In time of war, also, the municipal guards, numbering 80 officers and 2176 men, and the fiscal guards, numbering 136 officers and 5619 men, may be incorporated in the army. The Portuguese navy is being gradually increased, and in 1901 consisted of 1 armoured vessel, 5 protected cruisers, 3 third-class cruisers, 21 gunboats, 2 destroyers, 4 torpedo boats, 21 river gunboats, 5 steamers, and 4 training ships. The whole fleet was manned by about 5000 men.

Production and industry. *Minerals.*—Coal is scarce, and, owing to that fact and to the lack of cheap transport, the mines still remain to a large extent unworked. In 1899 the principal products were copper ore (366,680 tons, value £212,698); anthracite and lignite (10,942 tons, value £10,178); lead ore (1866 tons, value £8411); and iron ore (11,169 tons, value £7066). The market value of the total output was £285,887.

Agriculture.—In spite of the great improvement in roads and in agricultural training and agricultural machinery during the last quarter of the 19th century, it is estimated that from 5 millions to 10 millions of acres of land are still uncultivated, notably large tracts in Alemtejo and Traz-os-Montes, and in the higher parts of the mountains. Owing to this fact, the very large proportion of 45·8 per cent. of the country is classed as "waste" in the returns. Notwithstanding this, more than 65 per cent. of the population are agricultural, and agricultural products constitute more than 60 per cent. of the exports. But Portuguese agriculture is not in a flourishing condition. Wages have nominally increased, but the effects, so far as the workers are concerned, have been neutralized by the high protective duties. Other retarding influences are the lack of education, ignorance of modern methods of agriculture, and a slowness to adopt modern machinery; these are all in addition to the hampering conditions of heavy landed mortgages and scarce and dear capital. The branches of agriculture in which there is the greatest amount of energy and enterprise are wine-growing, the production of fruit and vegetables (especially in the south), and cattle-breeding. Olive trees abound, and large quantities of oil are manufactured, though in an unscientific way. The country may be divided into four agricultural divisions: (i.) the north, producing millet and other cereals and cattle; (ii.) the centre, producing millet, wheat, and rice; (iii.) the south, producing wheat and pigs; and (iv.) the mountainous regions, in which rye is the chief crop and the breeding of live stock the chief occupation. In divisions (i.) and (iii.) large estates are the rule; small estates in divisions (ii.) and (iv.). Of the whole area of the country, 26·7 per cent. is pasture and fallow; 12·5 per cent. under cereals; 7·2 per cent. under fruit trees; 2·9 per cent. under forests; 2·7 per cent. under pulse and other crops; and 2·2 per cent. under vineyards, all these areas forming the 54·2 per cent. of the country not returned as waste. The average annual yield of cereals is estimated as follows: wheat, 5,670,900 bushels; millet, 11,729,550 bushels; rye, 4,678,850 bushels; barley, 2,693,800 bushels; and oats, 797,500 bushels. The yield of potatoes averages 120,108 tons annually, and of beans, 18,103 tons. Wine, however, though vineyards cover a relatively small area, is still the most important product. Attempts have been made to find foreign markets for the great quantity of light cheap wine which has always been made in Portugal, for since 1886 greater care has been given to the manufacture, so as to produce good sound wine of the nature of claret and hock. In 1900, while 6,057,000 gallons of port wine and 576,450 gallons of Madeira were exported, the export of the lighter Portuguese wines amounted to 11,597,200 gallons. In 1892 the produce amounted to 79,336,360 gallons, valued at £3,495,150; by 1898 the figures had increased to 93,399,537 gallons and the value to £4,169,692. All live stock numbered 5,786,610 in 1898, and was valued at £9,456,100.

Fisheries.—In 1898 the fisheries yielded fish estimated to be worth £826,250, the most important being the sardine fishery, valued at £386,650; the tunny fishery, the next most important, was far below, being of the estimated value of £62,650. Both these fisheries have developed greatly along the south coast of Portugal. About 4000 vessels of all kinds are engaged in the fisheries.

Manufactures.—Since the institution of protective duties in 1892, Portuguese industries, stimulated also by the growing demands of the Portuguese colonies on the south-west coast of Africa, have made considerable progress. The most advanced are the manufactures of cottons and woollens, the chief centres of which are Lisbon, Oporto, and Covilhã. Other branches which have been thus artificially fostered are the manufacture of linen fabrics, china, earthenware, and metal goods.

Commerce. The following table shows the value of the imports and of the exports (including coin and bullion) in four several years since 1880:—

	1885.	1890.	1895.	1900.
Imports .	£8,261,177	£12,385,161	£9,107,555	£13,272,088
Exports .	6,017,639	7,255,317	6,504,245	10,451,333

These figures fairly illustrate the fluctuations in the respective values, but special reference should be made to the exports in 1891, when they reached the quite exceptional value of £11,373,944. The figures for 1900 show the highest point reached by the imports and exports in the years quoted. Of the imports in 1898 (£11,293,946) the most valuable were wheat, £812,925; cotton, £784,905; and cottons and yarn, £636,900; while sugar, cod-fish, coal, iron, cattle, leather and hides, wool, and woollens and yarn, ranged in value from £453,900 for the first to £227,900 for the last. The only exports higher in value than this last item of the imports were wine, £2,551,327, which it will thus be seen provided more than one-third of the total value of all exports (£7,379,370); cork, £734,000; cottons, £521,770; and sardines, £338,600. Of the imports, 32 per cent. came from Great Britain, 14 per cent. each from Germany and the United States, 10 per cent. from France, and 9 per cent. from Spain. Great Britain received 28 per cent. of the exports (with Brazil, Great Britain received most of the wine export, Portuguese vintages being valued at more than one-fifth of the total wine import of the United Kingdom), Brazil received 20 per cent., the Portuguese colonies 16 per cent., and Spain 13 per cent.

Shipping. In 1890, 6110 foreign vessels (including those merely calling at different ports), of 5,288,000 tons, entered, and 6381, of 5,276,000 tons, cleared; in 1900, 5744, of 9,464,386 tons, entered, and 5733, of 9,425,758 tons, cleared. In the coasting trade, 5438 vessels, of 1,006,000 tons, entered in 1890, and 5244, of 977,000 tons, cleared; in 1900, 4294 vessels, of 1,452,335 tons, entered, and 4219, of 1,416,017 tons, cleared.

Internal communications. There are 8700 miles of public roads. In 1898, 1464 miles of railway were open for traffic, the State owning 507 miles. There were 1304 post offices, and the total number of pieces of all kinds carried during the year was: internal, 55,201,810; international and colonial, 10,202,493. The number of telegraph offices was 425, controlling 4584 miles of line and 9475 miles of wire, and dealing with 1,272,042 internal and 1,065,309 international telegrams, including those in transit.

Banking and credit. In 1896 there were in all 35 banks (including savings banks). Only the Bank of Portugal can circulate notes in the country, though the Ultramarine Bank may issue them in the colonies. No gold has been coined since 1891, and in the present condition of the monetary system paper and silver are the chief media of circulation. The amount of the State Bank notes in circulation in February 1900 was £14,404,400. At the beginning of 1899 the deposits in savings banks amounted to £3,084,000, of which rather less than £700,000 was in the State Savings Bank.

Colonies. The table on next page shows the area and population of the several Portuguese colonies as nearly as possible; in the case of the African continental possessions and the Indian Archipelago, only estimates are possible. The figures in parentheses indicate the year of the last census.

Colonial Possessions.	Area in Sq. Mls.	Population.	Colonial Possessions.	Area in Sq. Mls.	Population.
In Africa:			*In Asia:*		
Cape Verde Islands (1896)	1,480	114,130	India: Goa (1887)	1,390	494,836
Guinea	4,440	820,000	India: Damâo Diu (1887)	168	77,454
Prince's and St Thomas's Islands	360	24,660	Indian Archipelago (Timor, &c.)	7,458	300,000
Angola	484,800	4,119,000	China: Macao, &c. (1896)	4	78,627
East Africa	301,000	3,120,000	Total Asia	9,020	950,917
Total Africa	792,080	8,197,790	Total Colonies	801,100	9,148,707

Few of the colonies are self-supporting, and between 1870 and 1899 Portugal expended about 15 millions sterling on them. Between 1897 and 1900 there was a noteworthy increase in the trade between Portugal and her colonies, especially her African colonies. During the six years ending 1897 the aggregate of this commerce was under 2 millions sterling; but only two years later it had jumped up to over 12½ millions sterling. The total inclusive commerce (imports and exports) of the several colonies in the year 1899 amounted to the following sums:—Cape Verde, £392,830; Guinea, £223,190; St Thomas, £1,188,220; Angola, £3,346,830; Mozambique, £1,890,510; India, £572,400; Macao, £4,992,100; and Timor, £86,600,—total, £12,692,680. The total trade between Portugal and her colonies in 1900 was £4,194,950, as follows:—Cape Verde, £224,040; Guinea, £51,650; St Thomas, £1,281,710; Angola, £2,223,500; Mozambique, £403,000; India, £7670; Macao and Timor, £3380.

II. HISTORY.

The closing years of the reign of King Luis of Portugal (b. 1838, succeeded 1861, died 1889) were comparatively uneventful. The policy of reform begun by his first Ministers was steadily continued, and in many cases received his active co-operation. Progress and material prosperity had advanced, the army and navy had been reorganized on a modern basis, the system of railway communications largely developed, new ports made at Lisbon and Oporto, the constitutional charters modified in a liberal sense, and compulsory education more stringently enforced. On the whole there had been a great increase in commerce and a marked improvement in the national credit. The de Mello Ministry, which came into office in October 1883 and resigned in February 1886, was succeeded by that of José de Castro, the leader of the Progressives. The marriage of the king's son and heir, Dom Carlos, to the daughter of the Comte de Paris in 1886, attracted considerable attention, and the attitude of the French Government raised it even to international importance. Then colonial affairs almost exclusively occupied public attention. The Congo Convention of 1885, by which a considerable portion of the Lower Congo territory was ceded to the king of the Belgians, had produced in Portugal a feeling akin to national humiliation, and, accordingly, the first care of the new Ministry was devoted to strengthening the ties between the mother country and its other colonies. In 1886, Germany and Portugal defined by treaty their respective spheres of influence in Africa. In the following year a native military force was organized in Angola, and the country opened up by a line of railway. Macao, hitherto leased to Portugal, was formally ceded by China on the 26th of March 1887, and steps were taken to revive the trade of this island, which had long languished. A resolution was unanimously adopted in 1889 by both Chambers, calling upon the Government to assert with all energy the legal claims of Portugal to the territories in East and Central Africa. This action was due to apprehension of attempts by Great Britain to extend her sphere of influence in those regions at the expense of Portugal.

Accession of King Charles.

On the 19th of October 1889 Luis died of typhoid fever, and was succeeded by his son Carlos (*q.v.*), who expressly declared his intention of walking in his father's footsteps. Shortly after his accession, colonial affairs took a threatening turn. Major Serpa Pinto having invaded British territory on the Shiré river, the British Government had demanded satisfaction of Barros Gomes, the Portuguese Minister for Foreign Affairs. The dilatory tactics of Portugal were met by the despatch of a British fleet to Portuguese waters, and an ultimatum of the 11th of January 1890, peremptorily requiring the withdrawal of all the Portuguese forces, civilians, and agents on the Shiré, under threat of breaking off diplomatic relations. Barros Gomes, declaring that Portugal yielded to superior force, gave way under protest on the following day. Disturbances at once broke out in Lisbon and Oporto.

Crisis with Great Britain.

In the face of the popular indignation, De Castro's Ministry resigned office, and made way on 14th January following for a Coalition (Liberal–Conservative) Government under Serpa Pimental, with Hintze-Ribeiro as Foreign Minister. The Republicans, stimulated by the success of the revolution in Brazil in the previous year, fomented the spirit of disaffection, and were so far successful that in many cities demonstrations, ostensibly directed against Great Britain, assumed an anti-dynastic character. The king, yielding to public opinion, openly espoused the patriotic attitude of the demonstrants, and in a letter to Queen Victoria declined for the time being the Order of the Garter which had just been offered him. On the 6th of February the Government addressed a circular to the Great Powers proposing to submit the Anglo-Portuguese differences to the arbitrament of a European Conference, and suspended its naval and military preparations. Meanwhile an attempted Republican pronunciamiento in Lisbon was suppressed, sixty-three arrests were made, and many officers who were under suspicion degraded. The elections resulted in an overwhelming majority for the Government, only three Republicans being returned. On the 20th of August an Anglo-Portuguese agreement respecting Africa was settled in London; but its terms were regarded in Portugal as greatly to that country's disadvantage, and their publication was a signal for a fresh outburst of disturbances in the larger cities, and even in the Cortes itself, which refused to ratify the treaty. The Ministry resigned, making way on the 14th of October for Abreu e Sousa, who formed an administration of a decidedly constitutional character. The new Cabinet approached the British Government with proposals for a revision of the agreement of 20th August; and, pending the result of the negotiations, a *modus vivendi* for six months was agreed to.

Great Britain showed herself conciliatory and ready to make concessions, with a view to relieving the tension in Portugal. Yet, in spite of the utmost vigilance, more than one collision took place between the Portuguese and the forces of the British South Africa Company in Manica, on territory which by the Convention of August was acknowledged to be under the influence of Portugal. The Portuguese forces were defeated, and the repetition of occurrences of this kind for a time threatened the very existence of the monarchy. But the Government proceeded warily, and was successful in suppressing a military revolt which broke out in Lisbon on 30th January 1891. It followed up this action by repressive measures against the Republican press. The enhanced prestige of the Cabinet prevailed with the Chambers, which forthwith by an increased majority approved the convention with Great

Britain in its original form; and the ratification of the treaty followed on 28th May following. The next step of the Government in colonial matters was the granting of a charter to a limited company to exploit and administer the African colony of Mozambique, saving the paramount sovereignty of the Crown and the surveillance of the State.

A new crisis was brought about by the unfortunate financial position of the country. The careless and extravagant management of the railways guaranteed by the State had entailed such heavy deficits that the payment of the coupon of the Railway State Loan, due on 2nd January 1892, had to be suspended. Consequently the Minister of Finance, Marianino de Carvalho, resigned; and his example was followed on the 15th of January by the other members of Abreu e Sousa's Cabinet, which a few days later was replaced by a Ministry with Diaz Ferreira as Premier and Oliveira Martins as Minister of Finance. The new financial Minister reported a great deficiency in the revenue and a heavy increase of debt, and as a remedy proposed largely to curtail the expenditure and to increase taxation. Unable, however, to obtain the sanction of the Minister to certain arrangements proposed by the Paris Syndicate of Foreign Bondholders with a view to rehabilitating the financial position, he resigned in the May following. Thereupon the Portuguese Government committed a formal act of bankruptcy by issuing a decree reducing the payments to foreign bondholders then due to one-third the amount. The committees of bondholders at once energetically protested against this illegal action, and were supported in their remonstrances by several of the official representatives of their countries. The elections to the Cortes, which took place at the end of October 1892, gave the Conservatives (Regeneradores) a substantial majority, and the Ministry was reconstructed by introducing conservative elements. But Ferreira was unable to cope with the situation; and on disagreement with the king as to the proposals for improving the financial situation, his Ministry resigned office in February 1893, and Senhor Hintze-Ribeiro undertook the formation of a Liberal Ministry. The new council promised only slightly better terms to the foreign bondholders, but on the whole it improved the position of the State finances, and by coming to an understanding with Germany in East and with Great Britain in South Africa as to the delimitation of frontiers, minimized the risks of a conflict with either country. The elections of the 15th of April 1894 resulted in a large majority for the Government, but the reform of taxation proposed by the Minister of Finance met with great opposition. Hintze-Ribeiro, however, held to his scheme and, the better to carry it, relinquished the office of Premier for that of Finance, Lobo d'Avila taking his place. But Ribeiro's proposals were nevertheless rejected by the Cortes, which were forthwith adjourned and then dissolved, the new elections again resulting in a majority for the Government. In the same year diplomatic relations with Brazil were suspended for a time, because Portugal had offered an asylum to insurgents who had fled from that country.

Financial difficulties.

Parliamentary reform had long been in the air, and the year 1895 saw the accomplishment of far-reaching reforms in the constitution of the Chambers and the qualifications of electors. By an electoral law of 28th March, the number of deputies to the Lower Chamber was reduced from 170 to 145. Every responsible male citizen of twenty-one years of age who can read and write, or pays at least 500 reis in taxes, has the right of suffrage, which is denied to domestic servants, Government servants, and soldiers. By a subsequent law of 25th September of the same year, the reform of the Upper Chamber was also effected. The elective members were abolished, and the house now consists of 90 members chosen by the king, 12 bishops, and the princes of the blood royal. Thus professional politicians, who had been the source of much mischief in Portugal, were restricted both in numbers and influence, whilst greater political influence was assured to the commercial, industrial, and agricultural classes.

Parliamentary reform.

In the autumn of 1895, the king, after undertaking a journey through France and Germany, paid a long-deferred visit to England, where he was warmly received. The Order of the Garter was now conferred upon him, and his visit did much to remove the last traces of the misunderstanding between the ancient allies.

The Hintze-Ribeiro Ministry resigned in February 1897. The chief reproach against it was its inability to remove the economic difficulties under which Portugal had suffered in consequence of bad harvests and colonial troubles. The State was forced in March of the year 1898 to come to an arrangement with its external creditors. In view of the British attitude, all attempts—notably that of the Governor of Mozambique, Major d'Albuquerque — to improve the frontier of the Portuguese colonies failed (see AFRICA, and EAST AFRICA), and this and the ensuing year closed gloomily, with a deficit in the public revenue.

Portugal observed neutrality on the outbreak of the South African war, but the permission it conceded to the British Consul at Lourenço Marques to search for contraband of war among goods imported there, and the free passage accorded to an armed force under General Carrington from Beira through Portuguese territory to Rhodesia, were vehemently attacked in the press and at public meetings. The Ministry resigned, and gave place to a Conservative Government under Hintze-Ribeiro. The award of the Swiss arbitrators in the matter of the Delagoa Bay Railway was given in 1900; it was in favour of Portugal in regard to the seizure of the railway, but the country was condemned to pay 15,314,000 francs compensation; and this sum (less than was expected) was immediately raised by loan from the Portuguese Tobacco Company. The new elections resulted in a majority for Government; and the century closed in the midst of signs that the period of gloom which had oppressed the country was passing away, and that its relations with Great Britain rested on a more friendly basis.

Boer War; Delagoa Bay award.

Posen, an eastern province of Prussia, with an area of 11,184 square miles, and population of 1,887,275 (1900). In 1900 the live stock embraced 867,795 cattle, 609,816 sheep, 772,402 pigs, and 263,284 horses. The iron foundries produced 6288 tons of iron, valued at £56,930, in 1897; and in 1899–1900 the sugar factories produced 193,243 tons of sugar; the breweries, 13,530,000 gallons of beer; and the distilleries, 13,582,360 gallons of pure alcohol. For further particulars, see under PRUSSIA.

Posen, in Polish *Poznan*, a fortified town and archiepiscopal see of Prussia, capital of the province of Posen, 103 miles by rail north from Breslau, on the river Warthe, a first-class fortress and the headquarters of the 5th German Army Corps. In 1902 the Prussian Government voted a first instalment of £200,000 for the demolition of the old fortifications, which greatly cramped the town. The modern fortifications embrace a dozen inner forts and nearly twenty outer forts. The cathedral was restored in 1898. Of the public institutions and newer buildings may be mentioned several churches, the provincial archæological museum and library (1894), the (Renaissance) town-house (1895), the Mielzynski Museum, the royal palace with state archives, the archbishop's palace, the Emperor William library, a couple of handsome fountains, zoological gardens, art and other collections of the Society (Polish) of Friends of Science, a monument to the Polish poet Mickiewicz, a monument (1870) to the soldiers who fell at Nachod in 1866, a monument of the war of 1870–71, three theatres, a theological college, a building and trades school (1892), with over 1000 pupils, a trade and domestic economy school for girls, a Jewish teachers' seminary, and a (female) normal school. The industries are of a miscellaneous character—machinery, furniture, vehicles, cigars, beer, chemicals, &c. Population (1885), 68,315; (1895), 73,239; (1900), 117,014, of whom about one-half are Germans and one-tenth Jews. The rural communes of Jersitz, Wilda, and St Lazarus were incorporated in 1900.

Pössneck, a town of Germany, duchy of Saxe-Meiningen, 21 miles by rail south of Jena, with a Gothic church (1390) and a Gothic town hall (1443), an agricultural school, and manufactures of porcelain and flannel, besides tanning, dyeing, brewing, and gardening. The town dates from the 11th century or earlier. Population (1885), 7653; (1900), 12,268.

Posters (see also ADVERTISEMENT).—The earliest examples of pictorial posters were adorned with rough woodcuts. When lithography became a common commercial process, wood-blocks ceased to be employed. The modern artistic poster made a definite beginning in France about 1836, with a design by Lalance to advertise a book entitled *Comment Meurent les Femmes.* His example was followed by C. Nanteuil, Raffet, Gavarni, Bertrand, Grandville, Tony Johannot, É. de Beaumont, T. H. Frère, Édouard Manet, and other artists of high repute. Most of these early designs were printed in black on white or tinted paper. Between 1860 and 1866 crude attempts at printing posters in colours were made in both France and England. In 1866, Jules Chéret began what was destined to be the most noticeable series of pictorial placards in existence, a series containing over a thousand items. Chéret was the first artist rightly to appreciate the possibilities of the poster and to raise it to high consideration in the opinion of the art world. Brilliant colour in acute contrast characterized his work, which rapidly achieved, and still retains, immense popularity. He may be fairly described as the father of the modern pictorial placard. Chéret was originally employed in a lithographic establishment in England before he began to work for himself, and he used his knowledge there acquired to adapt all three primary colours, economically used, to astonishingly brilliant ends. For a considerable time he remained without a rival, though he had hosts of imitators. Eugène Grasset, a decorative designer of great versatility, produced the first of a small number of placards which, though inferior as advertisements to those of Chéret, were learned and beautiful decorations. Somewhat later a sensation was caused in Paris by the mordantly grotesque posters of Henri de Toulouse-Lautrec, in which the artist reduced detail to a minimum and obtained bold effects by the employment of large masses of flat colour. Important work, similar in character to Lautrec's, was produced by Ibels, Bonnard, Steinlen, and others. A new and contrary direction was given to poster design by Mucha, a Hungarian resident in Paris, whose placards are marked by delicate colour and richness of detail. The following are amongst French artists who have designed posters of conspicuous merit: Forain, Willette, Paléologue, Sinet, Jossot, Rœdel, Mayet, Cazals, Biais, De Feure, Guillaume, Ranft, Réalier-Dumas, Valloton, and Metivet. Occasionally eminent French painters, such as Carrière, Boutet de Monvel, Aman-Jean, Schwabe, have made essays in poster-designing.

In England the first artists of repute to attempt the pictorial placard were Godfroy Durand and Walter Crane; but the first bill to attract widespread attention was one by Fred Walker to advertise a dramatized version of *The Woman in White* (1871). This was engraved on wood by W. H. Hooper. Shortly after this time pictures by Royal Academicians and others began to be reproduced as advertisements (the best known case being that of Sir John Millais's "Bubbles"), but these have nothing directly to do with poster-designing. Mr Stacy Marks, Hubert von Herkomer (the great poster for the *Magazine of Art*), Sir Edward Poynter, and Sir James Linton are among popular painters who have made special drawings for reproduction as posters.

About 1894 the English poster began to improve. Designs by Aubrey Beardsley for the Avenue Theatre, by Dudley Hardy for various plays, and by Maurice Greiffenhagen for *The Pall Mall Budget*, were widely noticed by reason of their originality, simplicity, and effectiveness. Simplicity was carried even farther by "the Beggarstaff Brothers" (James Pryde and William Nicholson), whose posters are perhaps the most original yet produced by Englishmen. Among other British designers the following have executed artistic and interesting placards: Frank Brangwyn, R. Anning Bell, John Hassall, Cecil Aldin, Phil May, Raven-Hill, Henry Harland, Robert Fowler, Wilson Steer, Charles R. Mackintosh, MacNair and MacDonald, Edgar Wilson, Charles I. Foulkes, Mabel Dearmer, Albert Morrow, and C. Wilhelm.

Poster design on the continent of Europe has been largely influenced by French work, but designs of much originality have been made in Germany, Belgium, Italy, and Spain. In Germany, among the most typical posters are those of Sattler, Otto Fischer, Gysis, T. T. Heine, Speyer, Max Klinger, Dasio, Hofmann, and L. Zumbrusch. The principal Belgian designers include Privat Livemont, Rassenfosse, Berchmans, Meunier, Duyck and Crespin, V. Mignot, Donnay, Evenepoel, Cassiers, and Toussaint. Of Italian designers those whose work is most characteristic are Mataloni and Hohenstein; while the best Spanish posters—those to advertise bull-fights and fairs—are mostly anonymous. The Spanish artists Utrillo and Casas have signed posters of more than ordinary merit. Curious if not very artistic bills are being produced in Russia; and in Austria good work is being done by Orlik, Schliessmann, Oliva, and Hynais.

In the United States of America, however, with the exception of some designs by Matt Morgan, few posters of artistic interest were produced before 1889, in which year Louis J. Rhead commenced a notable series of decorative placards. Will H. Bradley began to produce his curious decorative grotesque posters a little later. If American artists are behind Europeans in the artistic designing of large posters, they have no rivals in the production of small illustrated placards for publishers of books and magazines. Chief among those who have devoted themselves to this branch of poster design is Edward Penfield. Others who have achieved success in it include Maxfield Parrish, Ethel Reed, Will Carqueville, J. J. Gould, J. C. Leydendecker, Frank Hazenplug, Charles Dana Gibson, Will Denslore, Florence Lundbourg, and Henry Mayer.

Exhibitions of artistic posters have been held in the chief cities of Europe and America, and the illustrated placard has already a literature of its own. In England a monthly magazine (*The Poster*) was for a time specially devoted to its interests, and collectors are numerous and enthusiastic.

The following are the most important books of reference on the subject:—ERNEST MAINDRON. *Les Affiches Illustrées.* Paris, 1895. *Les Maîtres de l'Affiche.* Paris. *Les Affiches Étrangères Illustrées* (Belgium, Austria, Great Britain, United States, Germany, and Japan). Paris, 1897.—CHARLES HIATT. *Picture Posters.* London, 1895.—J. L. SPOUSEL. *Das Moderne Plakat.* Dresden, 1897.—ARSÈNE ALEXANDRE, M. H. SPIELMANN, H. C. BUNNER, and A. JACCACCI. *The Modern Poster.* Scribners, New York 1895.

(C. HI.)

POST OFFICE.

I. United Kingdom.

Since 1884 the business of the British Post Office has continued to grow at a more rapid rate than the population of the United Kingdom. Some of the causes of this development must be sought within the Post Office department, *e.g.*, improved facilities, lower charges, and the assumption of new functions; but others are to be found in the higher level of popular education, the increase of wealth, industry, and commerce, and the rapid expansion of Greater Britain.

On the death of Mr Fawcett (7th November 1884), the Right Hon. G. J. Shaw Lefevre was appointed Postmaster-General. His successors have been Lord John Manners, afterwards Duke of Rutland, who had already been Postmaster-General from 1874 to 1880, and again held the office from 1885 to 1886; Lord Wolverton, 1886; the Right Hon. H. C. Raikes, 1886 to 1891; Sir J. Fergusson, 1891 to 1892; the Right Hon. Arnold Morley, 1892 to 1895; the Duke of Norfolk, 1895 to 1900; and the Marquess of Londonderry, 1900. The Secretary to the Post Office, Sir A. Blackwood, died in 1893, and was succeeded by Mr (afterwards Sir) S. Walpole, on whose retirement in 1899 Sir G. H. Murray was appointed permanent head of the Post Office.

The following table shows the increase in the number of letters delivered:—

Letters Delivered.

Estimated number of letters delivered in the United Kingdom, and the increase per cent. per annum. Also the average number to each person. 00,000's omitted.

[1] It was discovered in the course of this year that the estimated figures for previous years had been swollen by an imperfect method of reckoning the London letters, &c. In 1883 as many as 2,770,000 valentines were sent through the post. The numbers gradually decreased until in 1890 only 320,000 were observed. Christmas cards have, however, considerably increased.

[2] Since 22nd June 1897, all packets over 2 oz., formerly counted as book packets, are reckoned as letters.

Inland Letter Rates.—The rates of inland letter postage have been altered as follows:—

From 5th October 1871 to 1st July 1885 the charges were:—

	s.	d.
Not exceeding 1 oz.	0	1
Over 1 oz. and not exceeding 2 oz. . . .	0	1½
,, 2 ,, ,, ,, 4 ,, . . .	0	2
,, 4 ,, ,, ,, 6 ,, . . .	0	2½
,, 6 ,, ,, ,, 8 , . . .	0	3
,, 8 ,, ,, ,, 10 ,, . . .	0	3½
,, 10 ,, ,, ,, 12 ,, . . .	0	4
,, 12 ,, ,, ,, 13 ,, . . .	1	1
,, 13 ,, ,, ,, 14 ,, . . .	1	2

and 1d. for each succeeding ounce.

On 1st July 1885 the postage on letters over 12 oz. was reduced, and the gradation of charge beyond 2 oz. was made uniform, at the rate of ½d. for each additional ounce. Thus a letter weighing over 12 and not exceeding 14 oz. was charged 4½d., 14 to 16 oz. 5d., and so on. Notwithstanding this change, it was found as late as 1895 that 95 per cent. of the letters sent through the post weighed not more than 1 oz. each.

In his Budget speech of 29th April 1897, the Chancellor of the Exchequer, Sir M. Hicks-Beach, announced that a number of postal and telegraphic concessions would be made to the public on Jubilee Day, the 22nd June 1897, the sixtieth anniversary of Queen Victoria's accession to the throne. The new rates for letters were:—

	d.
Not exceeding 4 oz.	1
Over 4 oz. and not exceeding 6 oz. . . .	1½
,, 6 ,, ,, ,, 8 ,, . . .	2

with ½d. for each succeeding 2 oz.

This change, while it saves both the Post Office and the public the trouble of testing the weight of a large number of letters, has also the advantage of simplicity of calculation—one halfpenny is charged for each 2 oz., with a minimum charge of 1d.

Arrangements were at the same time made to ensure a delivery of letters by postmen at every house in the United Kingdom. It was estimated that 16 millions of letters, whose owners had previously to fetch them from the post office or from some point on a postman's walk, would thus be added to the official delivery. The estimate proved, however, to be much under the mark. Fifty-five millions of letters are already brought annually into the official delivery under this arrangement, which still awaits completion in a few remote districts of Scotland and Ireland. In May 1892 the House of Commons, on the motion of Sir E. Birkbeck, had passed a resolution in favour of a more liberal extension of the free delivery in rural districts. Under the relaxed Treasury regulations, 155,000 letters a week were brought into the delivery in 1892, but a large number still remained outside. Financial considerations have now been entirely disregarded for the benefit of these letters, and the cost of their delivery alone, excluding sorting, carriage, cost of post office buildings, &c., greatly exceeds the whole revenue derived from them.

In studying the statistics of letters delivered, it should be remembered that the figures for any particular year are affected by circumstances like a general election or a boom in trade, as well as by changes in the rates or condition of the Post Office services. The letters from foreign countries have been stimulated by lower charges, and those from the colonies by the Imperial Penny Post, to which reference is made below.

Letter Cards.—On the 12th February 1892 letter cards bearing an imprinted penny stamp, and made to be fastened against inspection, were issued to the public at a charge of 1s. for 10 cards. The charge was reduced almost at once to 9d. for 8 cards. Similar cards have long been in use on the Continent, but they do not enjoy much popularity in Great Britain either with the Post Office, which finds them inconvenient to handle in sorting and stamping, or with the public. The number issued annually is about 10 millions, not counting those of private manufacturers.

Post Cards.—The following table gives the number of post cards:—

Estimated Number of Post Cards delivered in the United Kingdom, and the Increase per Cent. per Annum.

Year.	England and Wales.		Scotland.		Ireland.		United Kingdom.	
	Number.	Inc. per Cent. per Annum.	Number.	Inc. per Cent. per Annum.	Number.	Inc. per Cent. per Annum.	Number.	Inc. per Cent. per Annum.
1884–85 .	134,100,000	4·3	18,400,000	5·5	7,900,000	3·1	160,400,000	4·4
1889–90 .	184,400,000	8·4	22,900,000	5·0	9,800,000	5·4	217,100,000	7·8
1893–94 .	209,100,000	1·4	27,400,000	2·2	12,000,000	6·2	248,500,000	1·6
1894–95[1]	271,600,000	29·9	28,700,000	4·7	12,500,000	4·2	312,800,000	25·9
1895–96 .	268,300,000	dec. 1·2	32,200,000	12·2	14,000,000	12·0	314,500,000	0·6
1900–01 .	359,400,000	inc. 4·9	41,600,000	2·0	18,000,000	6·5	419,000,000	4·7

[1] Private cards with adhesive stamps first allowed in this year.

Post cards were first introduced in Austria on the 1st October 1869, and were first issued in Great Britain on 1st October 1870. Only one kind of card was employed, and this was sold for one halfpenny; but on the complaints of the stationers, a charge of ½d. a dozen for the material of the card was made in 1872, and permission was given for private persons to have their own cards stamped at Somerset House. In 1875 a stouter card was put on sale, and the charges were raised to 7d. per dozen for thin cards and 8d. per dozen for stout cards. In 1889 the charges were reduced to 5½d. for 10 and 6d. for 10 respectively. On 1st September 1894 private post cards with an adhesive halfpenny stamp were allowed to pass by post, and the result has been greatly to diminish the number of cards purchased through the Post Office. It is estimated that 232 out of the 400 millions of cards delivered in 1899–1900 were private cards. The sizes of the official cards were again altered in January 1895 and November 1899. Reply post cards were issued on 1st October 1883. The regulations forbidding anything but the address to be written on the address side of a post card were made less stringent on 1st February 1897; and in 1898 unpaid post cards, which were previously charged as unpaid letters, were allowed to be delivered on payment of double the post card rate. These various changes, especially the use of the private card and the popularity of illustrated post cards, have contributed to the rapid increase in the number of post cards sent by post. Reply post cards were first issued on 1st October 1893. Their use has not been very extensive. Only about 1½ million are issued yearly.

Book Packets and Samples.—The following table shows the estimated number of book packets, circulars, and samples delivered in the United Kingdom, and the increase per cent. per annum:—

Year.	England and Wales.		Scotland.		Ireland.		United Kingdom.	
	Number.	Inc. per Cent. per Annum.	Number.	Inc. per Cent. per Annum.	Number.	Inc. per Cent. per Annum.	Number.	Inc. per Cent. per Annum.
1884–85 .	269,400,000	8·1	34,500,000	10·0	16,500,000	18·9	320,400,000	8·8
1889–90 .	378,200,000	7·5	42,100,000	3·7	21,600,000	9·6	441,900,000	7·3

[1] Book packets over 2 oz. transferred to the letter post as a result of the Jubilee changes.

The rate of ½d. for 2 oz. for the book post has remained unaltered since 1st October 1870. Changes have from time to time been made in the regulations defining the articles which may be sent by book post, and prescribing the mode of packing them so as to admit of easy examination for the purpose of detecting letters, &c., sent by the halfpenny post. The book post received a great impetus in 1892 (28th May) by the permission to enclose book packets in unsealed envelopes. Complaint is, however, made that such envelopes form a dangerous trap for small letters, which are liable to slip inside the flaps of open envelopes, and so suffer delay and loss. On the other hand, as the rate of postage for articles weighing over 2 oz. is now the same for letters and for book packets, articles over that weight derive no advantage from being sent in open covers.

Sample Post.—The sample or pattern post, which was confined to *bonâ fide* trade patterns and samples on 1st October 1870, was then assimilated to the book post (½d. for 2 oz.); but the restriction was found to be both difficult to enforce and irritating to the public, and the sample post was abolished on 5th October 1871, when the rates of letter postage were lowered. It was re-established on 1st October 1887 (1d. for 4 oz. or under, and ½d. for each succeeding 2 oz.); but when the Jubilee letter rates were introduced (22nd June 1897) it lost its *raison d'être*, and ceased to exist for inland purposes.

Newspapers.—The first table on next page shows the estimated number of newspapers delivered in the United Kingdom, and the increase per cent. per annum.

The carriage of newspapers by the Post Office does not show the same elasticity as other post-office business. The Postmaster-General's Report of 1896 states that this is "due to increased energy and improved system on the part of the great newsagents." It is also, no doubt, in part due to improvements in provincial journalism, and especially to the extension of the halfpenny press. The practice of posting a newspaper after reading it, under a co-operative arrangement, has practically ceased to exist. The carriage of newspapers by post is conducted at a loss by the Post Office, which can thus regard with satisfaction the comparatively slow increase in the numbers sent.

[1] See note to table of *Letters Delivered*.

Halfpenny Post Finance.—It has been frequently stated on behalf of the Post Office that the halfpenny post is unremunerative. Representations are, however, made from time to time in favour of lower postage for literature of all kinds. It may therefore be of interest to mention that the Postmaster-General of the United States has, in successive annual reports, deplored the effect on the Post Office service of the cheap rates for "second-class matter." The cost of carriage over so large a territory is heavier than in the United Kingdom; but the Postmaster-General states that the low rates of postage "involve a sheer wanton waste of $20,000,000 or upwards a year." Facilities like the extension of free delivery are stifled, and the efficiency of the whole service is cramped, by the loss thus sustained.

Inland Parcels.—The following table shows the number of parcels delivered in the United Kingdom:—

Year ending 31st March.	Number of Parcels.	Year ending 31st March.	Number of Parcels.
1884 . .	14,000,000	1893 . .	52,370,326
1885 . .	22,910,040	1894 . .	54,034,000
1886 . .	26,417,397	1895 . .	57,136,000
1887 . .	32,860,154	1896 . .	60,527,000
1888 . .	36,731,786	1897 . .	63,715,000
1889 . .	39,589,313	1898 . .	67,823,000
1890 . .	42,852,600	1899 . .	71,913,000
1891 . .	46,287,956	1900 . .	75,448,000
1892 . .	49,378,365	1901 . .	81,017,000

The inland parcel post commenced on 1st August 1883. No parcel might exceed 7 lb in weight, $3\frac{1}{2}$ feet in length, or 6 feet in length and girth combined. The rates were:—

	s.	d.
Not exceeding 1 lb	0	3
Exceeding 1 lb, but not exceeding 3 lb .	0	6
,, 3 ,, ,, ,, 5 ,, .	0	9
,, 5 ,, ,, ,, 7 ,, .	1	0

Arrangements were made with the railway companies, under which they receive 55 per cent. of the postage on each parcel sent by train. This arrangement, which was to hold good for 21 years, proved, however, an onerous one, and on 1st June 1887 the Post Office started a parcel coach between London and Brighton. The coach, which travels by night, arrives at Brighton in time for the first delivery, and there is thus no loss of time to the public. The experiment proving successful, other coach services were started at different dates between London and Chelmsford, Colchester and Ipswich, London to Oxford *viâ* Reading, London to Chatham, Tunbridge Wells, Bedford, Guildford, Brighton, Watford, and Windsor respectively, Birmingham and Coventry, Liverpool and Manchester, with branch coach services to Cambridge, Hitchin, &c. Motor-cars have also been employed. Nearly $11\frac{1}{2}$ millions of parcels were conveyed by the Post Office in 1900–01 without passing over a railway.

On 1st May 1896 the maximum weight was increased to 11 lb, and the postage rates were reduced:—

	s.	d.
Not exceeding 1 lb	0	3
For each succeeding pound	0	$1\frac{1}{2}$
The charge for a parcel of 11 lb was thus .	1	6

On 22nd June 1897 the present (Jubilee) rates were introduced:—

	s.	d.
Not exceeding 1 lb	0	3
For each succeeding pound up to 10 lb .	0	1
The charge for a parcel of 10 lb is thus .	1	0,

and this is also the charge for a parcel of the maximum weight (11 lb).

Registered Letters.—The number of letters registered by the public in the United Kingdom in 1884–85 amounted to 11,365,151. In the next ten years the numbers oscillated between 10,779,555 (1886–87) and 12,132,144 (1892–93); but since 1894–95, when 11,958,264 letters were registered, the number has steadily increased, until it stood at 17,729,869 for 1900–01. It has been surmised[1] that the introduction of postal orders checked the growth of registered letters for some years after 1880. In 1886 a system of insurance for registered letters was adopted. The ordinary registration fee entitled the owner, in case of loss, to recover compensation from the Post Office up to a limit of £2. For an additional insurance fee of 1d. the limit was raised to £5, and for 2d. to £10. Various changes have since been made, and the separate insurance system has been abolished. At present a registration fee of 2d. entitles to compensation up to £5, 3d. £10, and each additional penny to a further £10, up to a maximum of £120. The system of registration has also been extended to parcels.

Railway Letters.—On 1st February 1891 the railway letter service came into operation. At passenger stations on the principal railways a letter not exceeding 4 oz. in weight may be handed in at the booking office for conveyance by the next train. A fee of 2d. is payable to the railway company as well as the ordinary postage of 1d. The letter may be addressed to a railway station to be called for. If it bears any other address it is posted on arrival at its proper station. The number of packets so sent is about 200,000 a year.

Express Letters.—The express delivery service dates from 25th March 1891. A private company formed for the purpose of supplying the public on demand with an express messenger to execute errands, was found to be infringing the Postmaster-General's monopoly both as regards the conveyance of letters and the transmission of communications by electricity. The services of the company were, however, so much appreciated by the public, that the suppression of the company would have seemed both harsh to its shareholders and inconvenient to its customers, who could not obtain similar facilities from the Post Office itself. The Government accordingly authorized the Post Office to license the existing company to continue its business, on the payment of royalties, till 1903,[2] and to start an express service of its own. Messengers can be

[1] Thirty-second Report of Postmaster-General.
[2] Afterwards extended to 31st March 1922.

summoned from the post office by telephone, and arrangements can be made with the Post Office for the special delivery of all packets arriving by particular mails in advance of the ordinary postman. The sender of a packet may have it conveyed by express messenger all the way, or may direct that, after conveyance by ordinary post to the terminal post office, it shall then be delivered by special messenger. The fees, in addition to ordinary postage, were originally fixed at 2d. for the first mile, 3d. for the second mile, and 1s. a mile additional when the distance exceeded 2 miles and there was no public conveyance. Further changes of rates were made in 1892, 1893, 1895, 1897 (Jubilee revision), and 1900. Under the present regulations the fee is 3d. for each mile covered by special messenger before delivery. No charge is made for postage in respect of the special service, but if the packet is very weighty or the distance considerable, and no public conveyance is available, the sender must pay for a cab or other special conveyance.

Letters and parcels to or from a number of foreign countries and colonies may also be marked for express delivery after transmission by post; and residents in London, not having a delivery of ordinary letters on Sunday, may receive on that day express letters from home or abroad which have come to hand too late for express delivery on Saturday nights. The total number of express services in 1900–01 was 804,447. In many cases one of these services included the delivery of batches of letters, so that in London alone 819,959 articles were delivered by express messenger—307,051 being letters sent out for delivery in advance of the postman.

Returned Letters.—There are 16 depôts for dealing with "dead" or returned letters. The principal office is in London. Others are at Manchester, Liverpool, Birmingham, Leeds, Bristol, Newcastle-on-Tyne, Nottingham, Plymouth, Edinburgh, Glasgow, Aberdeen, Inverness, Dublin, Belfast, and Cork. In the year 1900–01, 7,470,288 letters were received at the various returned letter offices, of which 6,226,805 were returned to the senders, while 377,261 were returned unopened to foreign countries to be dealt with by the post offices of the country of origin, leaving only 832,421 undisposed of. Such of these as contain nothing of value are at once destroyed, and no record of them is kept. The others are recorded, and (if not previously claimed by the owners) their contents are sold by auction at intervals. If the owner applies after the sale, the proceeds are handed over to him. In addition to these 7½ millions of letters, there were 2,316,582 disposed of at head post offices, whence they were returned direct and unopened to the senders, whose names and addresses appeared on the outside of the letters. The total number of post cards received in the various offices as undelivered was 1,619,391; book packets, 11,911,614; newspapers, 627,642; and parcels, 227,252. 174,193 of these last were re-issued. Articles sent by the halfpenny post are destroyed at the head offices if they cannot be delivered; but the sender may have such articles returned if he writes a request to that effect on the outside of the packet, together with his name and address, and pays a second postage on the return of the packet.

No fewer than 85,640 articles were found loose in the post (*i.e.*, without envelopes or wrappers) in 1901–2. In 1900–1, 345,690 packets were posted unaddressed, containing £251 in cash and bank notes, and £7203 in bills, cheques, postal orders, stamps, &c. The coin found loose in the post amounted to £902. The total value of property found in undelivered letters opened in the returned letter office was £681,335.

Foreign Mails.—The following table shows the estimated weight of the mails (excluding parcels) exchanged with the British colonies and foreign countries in 1900–01. The number of letters and post cards may be roughly taken at 40 to the ℔:—

During the same year 2,005,506 parcels were despatched out of the United Kingdom, and 1,118,788 were received from the British colonies and other countries. Excluding Cape Colony, where the statistics are inflated by the parcels for the British army, Germany, with 281,145, received the largest number of any one country, and easily heads the list of countries from which parcels were imported into the United Kingdom, with 392,426, France coming next with 212,032.

It will be noticed that while the totals of letters and post cards sent abroad exceed those received by only one-ninth, the printed matter exported was nearly three times as great as that received. This is due in great measure to the large numbers of books and newspapers sent to the British colonies, and especially to the army in Egypt, India, and South Africa.

Foreign and Colonial Letter Rates.—On 1st January 1889 a weekly all-sea service to the Australasian colonies was opened. The rates were 4d. per ½ oz. for letters, and 2d. for post cards, as compared with 6d. and 3d. by the quicker route. In his Budget of April 1890, Mr Goschen provided for a lower and uniform rate of postage from the United Kingdom to India and the British colonies generally. The rates, which had hitherto varied from 2½d. to 4d., 5d., or 6d. per ½ oz., were fixed at 2½d. per ½ oz. The change took effect on 1st January 1891, and resulted at the outset in a loss of £100,000 a year. The fourth Postal Union Congress, which met at Vienna in May and June 1891 (third congress at Lisbon, February and March 1885), took a further step in the direction of uniformity, and on 1st October 1891 the 2½d. rate was extended to foreign as well as colonial letters from the United Kingdom. The Australasian colonies gave their adhesion to the Union at this congress, leaving the Cape Colony, British Bechuanaland, and St Helena the only important parts of the British Empire still outside. St Helena and Ascension joined the Union in 1896, and the Cape signified its adhesion at the next congress (Washington, May and June 1897), while British Bechuanaland and Rhodesia entered in 1900, and practically the whole of the British Empire is now included in the International Union. Abyssinia, Afghanistan, Arabia, China, and Morocco are the chief countries which remain outside.

Imperial Penny Post.—Advantage was taken of the presence in England of special representatives of India and the principal British colonies, to hold an Imperial Postal Conference in London in June and July 1897, under the presidency of the Duke of Norfolk, Postmaster-General. The duke was authorized by the Government to announce that on and from Christmas Day, 1898, an imperial penny post would be established with such of the British colonies as were prepared to reciprocate. The new rates (1d. per ½ oz.), which had long been advocated by Mr Henniker Heaton, came into effect in most cases on the appointed day, and with the other colonies and protectorates shortly afterwards, with the exceptions of Australasia and the Cape, where the 2½d. rate remained unaltered. The Cape came afterwards into the scheme, which has also been extended to Rhodesia, British Bechuanaland, Orange River Colony, Transvaal, and New Zealand. The Australian colonies are now the only important exception. At the same conference it was proposed that the parcel rates with British possessions should be lowered and simplified by the adoption of a triple scale for parcels exchanged by sea, namely, 1s. up to 3 lb, 2s. from 3 to 7 lb, and 3s. from 7 to 11 lb. This scale has been adopted by many of the British colonies. The parcel post has been gradually extended to nearly the whole civilized world, with the exception of the United States, while the rates have in many cases been considerably reduced.

On 1st January 1885 the post office at Malta was transferred from the control of H.M. Postmaster-General to that of the local administration, and a similar change was made as regards Gibraltar on 1st June 1896.

Foreign Mail Service.—Remarkable improvements have been effected in the speed and frequency of the mails sent abroad, and contracts are entered into from time to time with the mail steamship companies, of which the Peninsular and Oriental, the Orient, the Cunard, the Oceanic or White Star, the Pacific, and the Royal Mail are the principal lines. The approximate time occupied in course of post between London and the following places is: Cairo, 6 days; New York, 8 days; Bombay, 14 days 16 hours; Cape Town, 19 days; Hong Kong, 29 days; Adelaide, 30 days 16 hours. The transit charges for special trains conveying mails through France and Italy for Egypt, India, Australia, and the Far East have been successively reduced until they now stand at the ordinary Postal Union transit rates.

Army Post Office Corps.—Mention should be made of the Army Post Office, which is now an essential accompaniment of military operations. On the outbreak of hostilities in South Africa in 1899, the British Post Office supplied a force of 10 officers and 392 men for the purpose of sorting and delivering the mails of the forces, despatching their replies, selling postage stamps, dealing in postal orders, &c. Contingents were also sent by the Canadian, Australian, and Indian Post Offices. During the first eight months of the campaign the letters despatched to the seat of war numbered over 5½ millions, while about half that number were sent home. Including telegraphists, and men of the army reserve, 3400 post office servants were sent to the front.

Money Order Rates.—The decrease in the number of inland money orders till 1890–91 was due to the competition of postal orders (introduced on 1st January 1881), and to the reduction (on 1st January 1878) of the charge for registering a letter from 4d. to 2d.[1] Between 1878 and 1886 the commission on money orders under 10s. was 2d., but on the 1st September in the latter year the rates were altered as follows:—

Orders not exceeding £1	2d.
,, ,, ,, 2	3d.
,, ,, ,, 4	4d.
,, ,, ,, 7	5d.
,, ,, ,, 10	6d.

On 1st February 1897 new rates were introduced: on orders not exceeding £3—3d.; over £3 and not exceeding

[1] The total sums remitted did not fall off to the same extent, showing that the small orders alone were affected. The average amount for ordinary inland orders is now £2, 19s. 5d.

£10—4d. The cost of a money order transaction (at least 3d.) is very little affected by the amount of the remittance, and it was thought undesirable to continue the unremunerative business of sending small sums by money order at less than cost price at the expense of the senders of larger orders. The needs of smaller remitters appeared to be sufficiently met by postal orders and the registered letter post. It appeared, however, that the new charges fell with great severity upon mutual benefit societies, like the Hearts of Oak, which send large numbers of small money orders every week, and on 1st May 1897 the 2d. rate was restored for orders not exceeding £1.

Money Orders.—The following table shows the movement of money-order business since 1883:—

Year.	Inland Orders. Number.	Inland Orders. Amount.	Inland Orders. Increase per Cent. on Number.	Inland Orders. Increase per Cent. on Amount.	Colonial Orders. Number.	Colonial Orders. Amount. Foreign and Colonial Money Orders.—The rates brought into force on 1st January 1883 were as follows:—

	s.	d.
Not exceeding £2	0	6
,, ,, 5	1	0
,, ,, 7	1	6
,, ,, 10	2	0

On 1st February 1897 these rates were reduced to the present scale:—

	s.	d.
Not exceeding £2	0	6
,, ,, 6	1	0
,, ,, 10	1	6

Money orders may be sent to almost any country in the world. Russia, Spain, Greece, and some of the states of Central and Southern America are the principal exceptions.

The money order system is largely used by the British Government departments for the payment of pensions, separation allowances, remittance of bankruptcy dividends, &c.; and free orders may be obtained by the public, under certain conditions, for the purpose of remitting their taxes. The cost of management of the Money Order Office was reduced by the substitution, since 1898, of a number of women clerks for men and boys.

Telegraph Money Orders.—On 2nd September 1889 the issue of telegraphic money orders between London and seventeen large towns was commenced as an experiment, and on 1st March 1890 the system was extended to all head post offices and branch offices in the United Kingdom. Two years later it was extended to every office which transacts both money order and telegraph business. The rates were:—

	s.	d.
Not exceeding £1	0	4
,, ,, 2	0	6
,, ,, 4	0	8
,, ,, 7	0	10
,, ,, 10	1	0

in addition to a minimum charge of 9d. for the official telegram of advice. The rate was lowered on 1st February 1897 to 4d. for sums not exceeding £3, and 6d. for sums from £3 to £10, and the minimum charge for the telegram was reduced to 6d. The sender of a telegraph money order may give instructions that, instead of being left at the post office to be called for, it should be delivered at

Table showing the Number and Value of Postal Orders issued to the Public from the commencement on the 1st January 1881 to the 31st March 1900, with those of typical years.

Postal orders for the sums of 12s. 6d. and 17s. 6d. were abolished on the 31st May 1884.
Postal orders for the sums of 2s., 3s., 3s. 6d., 4s., 4s. 6d., and 10s. 6d. were established on the 1st June 1884.

the payee's residence, and that it should be crossed for payment through a bank. He may also, on paying for the extra words, send a short private message to his correspondent in the telegram of advice.

Telegraph money orders may also be sent to Austria, Belgium, Egypt, France, Germany, Holland, Hungary, Italy, Luxemburg, Norway, Rumania, Sweden, and Switzerland. A fee of 2d. is required in addition to the usual money order commission and the cost of the telegram. The system is being rapidly extended to other countries.

The telegraph inland money orders in 1899–1900 amounted to 311,943, and the sums so remitted to £999,086, an average of £3 4s. 1591 were sent abroad for a total of £7213, while 2183 for £12,576 were received from foreign countries.

Postal Orders.—The table at foot of preceding page relates to postal orders.

It will be observed that in 1884 six new denominations of postal orders were introduced, while those for 12s. 6d. and 17s. 6d., which were comparatively little used, were discontinued. At the same time permission was given to make up broken amounts by affixing postage stamps for sums not exceeding 5d. to the order. The stamps so affixed now amount to £100,000 a year. The postal orders for 1s. have recently greatly increased, owing to the number of sporting competitions, for which a fee of 1s. is required. British postal orders may also be obtained at Constantinople, Malta, Gibraltar, India, Straits Settlements, Hong Kong, and Newfoundland, and by sailors on H.M. ships.

Savings Banks.

A succinct account of the history of the Post Office Savings Bank, "so far as depositors and the general public are concerned," will be found in an Appendix to the Forty-third Report of the Postmaster-General (1897). The growth of business is shown in the following table:—

Year ending 31st December.	Average Number of Accounts.	Average Amount of Deposits.	Average Balance in each Account.	Average Number of Offices.
			£ s. d.	
1863-68 .	663,000	7,000,000	11 3 5	3,390
1869-74 .	1,373,000	18,000,000	13 5 3	4,498
1875-80 .	1,889,000	29,000,000	15 12 5	5,742
1881-85 .	3,088,000	42,000,000	13 11 3	7,348
1886-90 .	4,248,000	59,000,000	13 16 10	9,025
1891-95 .	5,776,000	83,000,000	14 7 0	10,888
1896-99 .	7,444,744	119,000,000	16 0 4	12,404

"It is no slight testimony," says the report referred to, "to the skill of the able men who drew the original regulations of 1861, that these regulations remained unchanged, in spite of the vast expansion of the Bank, until a new code was prepared under the Act of 1887" (50 & 51 Vict. c. 40). The code of 1st November 1888, issued under this Act, did not enlarge the limits of deposits or make any great and conspicuous change in the general system, but the Postmaster-General obtained power to offer certain facilities for the transfer of money from one account to another, for the easier disposal of the funds of deceased depositors by means of nominations, and in various ways for the convenience of the customers of the bank. Arrangements were made for reducing to 1s. the cost of certificates of births, deaths, and marriages required for savings bank purposes. In July 1889 Local Loans 3 per cent. stock was made available for purchase through the Post Office Savings Bank.

"In July 1891," continues the report, "another Act of Parliament was passed by which the maximum amount which might be deposited was raised from £150 to £200, inclusive of interest. The annual limit remained at £30, but it was provided that, irrespective of that limit, depositors might replace in the bank the amount of any one withdrawal made in the same year. The object of this provision was to avoid curtailing the saving power of a person who might be driven by emergency to make an inroad upon his store, but who might nevertheless, when the emergency had passed, find himself none the poorer and able to replace the money withdrawn.

"The Act provided also that where on any account the principal and interest together exceeded £200, interest should cease only on the amount in excess of £200, whereas previously interest ceased altogether when it had brought the balance of an account up to £200.

"The next striking development of the Savings Bank arose out of the Free Education Act, passed in September 1891. The Government of the day desired that advantage should be taken of the opportunity to inculcate upon parents and children alike a lesson of thrift—that they should save the school pence which they were no longer bound to pay. The Education Department and the Postmaster-General worked in concert to realize this end. School managers were urged to press the matter upon all concerned, special stamp slips were prepared and issued, managers were supplied on credit with stocks of stamps to be sold to the children, and clerks from the nearest post offices attended at schools to open accounts and receive deposits. The arrangement began in January 1892; about 1400 schools adopted the scheme at once, and three years later this number had risen to 3000. A sum of nearly £14,000 was estimated to have been deposited in schools in 5 months, and about £40,000 in the first year.

"Concurrently with the spread of the stamp-slip system in the schools, the extension of School Penny Banks, connected intimately with the Savings Bank, was a conspicuous result of the effort to turn into profitable channels the pence which no longer paid school fees.

"In December 1893 another Act of Parliament extended the annual limits of deposits from £30 to £50. The maximum of £200 remained unchanged, but it was provided that any accumulations accruing after that amount had been reached should be invested in Government stock unless the depositor gave instructions to the contrary.

"In December 1893 arrangements were made for the use of the telegraph for the withdrawal of money from the Savings Bank. Postmasters-General had hesitated long before sanctioning this new departure. It was known that the system was in force abroad, and it was recognized that there might be, and doubtless were, cases in the United Kingdom where the possibility of withdrawing money without delay might be all-important, and might save a depositor from debt and distress. But, on the other hand, it was strongly held that the cause of thrift was sometimes served by interposing a delay between a sudden desire to spend and its realization; and it was also held to be essential to maintain a marked distinction between a bank of deposit for savings and a bank for keeping current accounts."

On the whole, the balance of opinion was in favour of the change, and two new methods of withdrawal were provided. A depositor might telegraph for his money and have his warrant sent to him by return of post, or he might telegraph for his money and have it paid to him in an hour or two on the authority of a telegram from the Savings Bank to the Postmaster. The first method cost the depositor about 9d., the second cost him about 1s. 3d. for the transaction. In 1899, 161,190 applications were received for withdrawal by telegraph, and 11,405 telegrams were received requesting payment by return of post.

By an Act which came into force on 1st January 1895, building societies, duly incorporated, were enabled to deposit at any one time a sum not exceeding £300, and to buy Government stock up to £500 through the Savings Bank.

Savings Bank Finance.—The increase in the deposits lodged in the Post Office Savings Bank must be ascribed to a variety of causes. Numbers of trustee banks have been closed, and have transferred their accounts to the Post Office Bank; greater facilities have been offered by the bank; the limits of deposit in one year, and of total deposit, have been raised; and, since October 1892, deposits may be made by cheque; while the long-continued fall in the rate of interest made the assured 2½ per cent. of the Post Office Savings Bank an increasing temptation to a class of investors previously accustomed to look elsewhere. The high price of Consols, due in part to the magnitude of purchases on Savings Bank account, proved a serious embarrassment to the profitable working of the bank, which had shown a balance of earnings on each year's working until 1896, after paying its expenses and 2½ per cent. interest to its depositors. Economical working minimized, but did not remove, the difficulty. The average cost of each transaction, originally nearly 7d., has been brought down to 5⅜d. Down to the year 1896, £1,598,767 was paid into the Exchequer under sec. 14 of the Act 40 Vict. c. 13, being the excess of interest which had accrued year by year. But since 1895 there have been deficits amounting to £6162 in 1896, £9232 in 1897, £7018 in 1898, and £11,711 in 1899—in all, £34,123.

The Central Savings Bank having outgrown its accommodation in Queen Victoria Street, London, a new site was purchased in 1898 for £45,000 at West Kensington, and the foundation-stone of a new building, to cost £300,000, was laid by the Prince of Wales on behalf of Queen Victoria on 24th June 1899.

Under the Workmen's Compensation Act of 1897, sums awarded as compensation may be invested in the Post Office Savings Bank. This arrangement proved so convenient, that an Act of 1900 authorized a similar investment of money paid into an English county court in ordinary actions at common law, and ordered to be invested for the benefit of an infant or lunatic.

Inducements to Thrift.—By arrangement with the War Office in July 1893, the deferred pay of soldiers leaving the army was invested on their behalf in the Post Office Savings Bank, but it was found that the majority of the soldiers draw out practically the whole amount at once, and the experiment was discontinued in 1901. At the request of large employers of labour, an officer of the Savings Bank attends at industrial establishments on days when wages are paid, and large numbers of workmen have thus been induced to become depositors. The advantages of the Savings Bank are brought prominently before the public by notices and leaflets, and appear to be now thoroughly appreciated throughout the United Kingdom, as shown by the following table:—

	On 31st December 1900.			
	Number of Depositors.	Total Amount to Credit of Depositors.	Average Amount to Credit of each Depositor.	Proportion of Depositors to Population.
		£	£ s. d.	
England and Wales	7,685,317	122,365,193	15 18 5	1 in 4
Scotland . .	372,801	5,126,299	13 15 0	1 in 12
Ireland . . .	381,865	8,058,153	21 2 1	1 in 12
Totals .	8,439,983	135,549,645	16 1 3	1 in 5

Between the foundation of the bank and the end of 1899, upwards of £648,000,000, inclusive of interest, was credited to depositors, of which £474,000,000 was withdrawn. There were 232,634,596 deposits, 81,804,509 withdrawals, 27,071,556 accounts opened, and 18,631,573 accounts closed. The cross-entries, or instances where the account is operated upon at a different office from that at which it was opened, amounted to 33 per cent. It is chiefly in respect of this facility that the Post Office Savings Bank enjoys its advantage over the trustee savings bank. In 1900, 14,969,849 deposits were made, amounting to £40,516,436. In the same year the withdrawals numbered 5,406,347, the total sum withdrawn being £38,231,372. The interest credited to depositors was £3,145,978, and the total sum standing to their credit on 31st December 1900 was £135,549,645.

A classification of accounts opened for 3 months in 1896, and assumed to be fairly typical, showed the following results:—

Occupation as stated by Depositors in opening Account.	Percentage to Total.
Professional	1·55
Official	2·81
Educational	1·01
Commercial	3·88
Agricultural and fishing	1·83
Industrial	18·43
Railway, shipping, and transport	2·96
Tradesmen and their assistants	8·14
Domestic service	8·61
Miscellaneous	0·37
Married women, spinsters, and children . .	50·41
	100·00

Women and children of all ranks are believed to be 60·59 of the total number of depositors.

The accounts open at the end of 1895 showed the following division of deposits:—

		Per Cent.
Balances not exceeding . .	£50	36·1
Exceeding £50 and not exceeding	100	24·5
,, 100 ,, ,, ,,	150	17·3
,, 150 ,, ,, ,,	200	14·8
,, 200		7·3
		100·0

The division according to number of accounts, in the same groups, was 90·8, 5·3, 2·2, 1·3, and 0·4 respectively.

Investments in Government Stock.—In September 1888 the minimum amount of Government stock which might be purchased or sold through the Post Office Savings Bank was reduced from £10 to 1s., and it was also provided that any person who had purchased stock through the Savings Bank could, if he so desired, have it transferred to his own name in the books of the Bank of England. The Act of 1893 raised the limit of stock to £200 in one year, and £500 in all; but any depositor might purchase stock, to replace stock previously sold, in one entire sum during that year. If a depositor exceeds the authorized limits of deposit in the Post Office Savings Bank, the excess is invested in stock by the Post Office on his behalf.

During the year 1900 the investments of depositors in Government stock were 41,030, amounting to £2,830,513. The sales were 12,028, amounting to £678,510. On the 31st December there were 93,965 depositors, whose total holding of stock amounted to £10,468,290.

Annuities and Life Insurances.—The Act of 1882, which came into operation on the 3rd June 1884, utilized the machinery of the Post Office Savings Bank for annuities and life insurances, which had been effected through the Post Office at selected towns in England and Wales since 17th April 1865. Under the Act of 1882 all payments were to be made by means of money deposited in the Savings Bank, and an order could be given by a depositor that any sum—even to 1d. a week—should be devoted to the purchase of an annuity or insurance so long as he retained a balance in the Savings Bank. In February 1896 new life insurance tables came into operation, with reduced annual rates, and with provision for payment of sums insured at various ages as desired. In 1900 contracts were entered into for 2258 immediate annuities for £49,893, 137 deferred for £2722, and 677 life insurances for £32,512. The receipts for the year were £728,142 immediate and £19,852 deferred annuities, and £22,185 for life insurances. The payments amounted to £503,297 in respect of immediate annuities, to 31,409 persons; £12,921 deferred annuities, to 1020 persons; and 364 persons had claims amounting to £15,422 on account of life insurances, on death and surrender.

Telegraphs and Telephones.

On the 5th of February 1870 the monopoly conferred upon the Postmaster-General by the Telegraph Act of the previous year took effect. The Post Office assumed control of telegraphic communication within the United Kingdom, and it became possible to send telegrams throughout the country at a uniform charge irrespective of locality or distance. The purchase-money paid to the telegraph companies, the compensation to railway companies for their interest in telegraph business, and the expense of new lines, amounted to upwards of ten millions sterling. On the day of the transfer a thousand

Telegraphs.

post offices and 1900 railway stations were opened as telegraph offices. The public at once showed their appreciation of the change. In 1869 but seven millions of telegrams passed on the companies' wires. In 1870 the Postmaster-General transmitted ten millions.

In 1885 sixpenny telegrams were introduced. The charge for a written telegram which came into force in 1870 was one shilling for the first twenty words, and threepence for every additional five words, the addresses of sender and receiver being sent free. In 1885 the charge was reduced to a halfpenny a word throughout, including addresses (a system of abbreviated addresses, which could be registered on payment of a guinea a year, being introduced), with a minimum charge of sixpence. The effect of this reduction was to raise the number of telegrams in two years from 33,000,000 to 50,000,000. During the first six months the number of telegrams increased by 48 per cent., while the gross telegraph revenue fell off to the extent of £40,233, though £18,124 had been received in respect of abbreviated addresses. In April 1886 the telegrams exceeded those for April 1885 by 40 per cent.; the revenue was £11,800 less. In May the increase in telegrams was 51 per cent., and the revenue £4100 less than in the previous May. In June the increase was 61 per cent.; the revenue £2800 less. The working expenses were thus increased, while the receipts were diminished. In London alone the receipts from local messages fell off by as much as 74 per cent.

The following table shows the total number of telegrams forwarded from telegraph offices in England and Wales, Scotland, and Ireland, in each year since 1883:—

Year.	Number of Telegrams. 000's omitted.					
	England and Wales.			Scotland.	Ireland.	Total.
	Provinces.	London.	Total.			
1884–85	15,195	12,930	28,125	3,257	1,894	33,278
1885–86	18,029	15,081	33,110	3,812	2,223	39,146

1895–96	39,411	27,025	66,436	8,095	4,307	78,839
1896–97	40,305	26,645	66,950	8,094	4,378	79,423
1897–98	42,542	27,419	69,961	8,463	4,605	83,029
1898–99	44,781	28,468	73,249	9,064	4,729	87,043
1899–1900	46,144	29,971	76,115	9,387	4,910	90,415
1900–01	46,029	29,355	75,384	9,289	4,903	89,576

In 1891 the terms under which a new telegraph office was opened, on the request of a person or persons who undertook to guarantee the Post Office against loss, were reduced. In 1892 rural sanitary authorities were empowered to give such guarantees out of the rates. In 1897, as part of the Jubilee concessions, the Government undertook to pay one-half of any deficiency under guarantees. During the six years ended in 1891 the average number of telegraph offices guaranteed each year was 77. From 1892 to 1897 the average rose to 167. In 1898 and 1899 it amounted to 290. The number of telegraph offices opened without guarantee has increased apace, and there are now 11,512 telegraph offices in all. As part of the Jubilee scheme the charges for porterage—formerly 6d. per mile beyond the free postal delivery of a town, or beyond one mile from an office, and 1s. per mile from the office door when the distance exceeded 3 miles and a mounted messenger was sent—were reduced as follows: Up to 3 miles, free; beyond 3 miles, 3d. per mile, reckoned from the post office; and arrangements were made for the free delivery at all hours of the day or night of any telegram within the metropolitan postal district. The cost of free delivery up to 3 miles was estimated at £52,000 a year.

On the 26th April 1892 the House of Commons passed a resolution, moved by Sir E. Birkbeck, in favour of providing telegraphic or telephonic communication between coastguard stations, for the better prevention of loss of life and property by shipwreck. £20,000 a year was voted for 1892–93 and for each year in succession till 1900–01 (£30,000; 1901–02, £15,000), and a Royal Commission was appointed to consider the best means of connecting lightships and lighthouses with the telegraph system of the country. The *Post Office Guide* contains a list of 48 points at sea from which casualties can be reported by telegraph or telephone. A new line from London to Nevin, on the coast of Wales, and thence to Ireland, was laid in 1887, at a cost of £40,700. In June 1899 an additional cable was laid from Nevin to Newcastle, Co. Wicklow.

In order to obviate the damage and interruption resulting from storms, large numbers of wires have been laid underground; and a system of underground wires between London and Birmingham has been completed, to secure the storm-swept centre from the Wash to the Bristol Channel.

Foreign Telegrams.—The Sixth International Telegraph Conference, held at Berlin in 1884, effected a reduction in the charges to many countries. *E.g.*, the rate per word was reduced for Russia from 9d. to 6½d., Spain 6d. to 4½d., Italy 5d. to 4½d., and India 4s. 7d. to 4s. The cost of repeating a message was reduced from one-half to one-fourth of the original charge for transmission. The next Conference (1890) was held at Paris. Further considerable reductions were effected. The rates to Austria-Hungary and Italy were reduced from 4½d. to 3d., Russia 6½d. to 5½d., Portugal 5½d. to 4½d., Sweden 5d. to 4d., Spain 4½d. to 4d., Canary Islands 1s. 7½d. to 1s., &c. The minimum charge for any foreign (European) telegram was fixed at 10d. The Eighth Conference (Budapest, 1896) succeeded in making the following reductions, among others, from the United Kingdom: China 7s. to 5s. 6d., Java 6s. to 5s., Japan 8s. to 6s. 2d., Mauritius 8s. 9d. to 5s., Persia 2s. 5d. to 1s. 9d. At this Conference it was made incumbent upon every State adhering to the Union to fix in its currency an equivalent approaching as nearly as possible the standard rate in gold, and to correct and declare the equivalent in case of any important fluctuation. The limit of letters in one word of plain language was raised from 10 to 15, and the number of figures from 3 to 5. The International Telegraph Bureau was also ordered to compile an enlarged official vocabulary of code words, which it is proposed to recognize as the sole authority for words which may be used in cypher telegrams sent by the public. (See Appendix to Postmaster-General's Report, 1897.)

In the meantime progress had been made in the transfer of international cables from private companies to the State. The concession held by the Submarine Telegraph Company, for cables between the United Kingdom and the continent of Europe, expired in January 1889, but was extended to the 31st of March in that year. From that date the undertaking was purchased by the Governments concerned. France and Great Britain jointly acquired the cables between Calais and Dover, Boulogne and Folkestone, Dieppe and Beachy Head, Havre and Beachy Head, Piron, near Coutances, and Vieux Chateaux (St Heliers, Jersey). Belgium and Great Britain became joint-proprietors of the cables between Ramsgate and Ostend and Dover and De la Panne (near Furnes). The two cables to Holland and one of the cables to Germany were already the property of Great Britain, and the German Union Company's cable to Germany was purchased by the German Government. The offices of the Submarine Company in London, Dover, Ramsgate, East Dean, and Jersey were purchased by the Post Office, as well as the cable ship; and the staff, 370 in number, was taken over by the Government. The capital amount laid out by Great Britain was £67,163, and on 1st April the new business was commenced with a uniform rate to France, Germany, Holland, and Belgium of 2d. a word, with a minimum of 10d.

In 1890 Liverpool was placed in direct telegraphic communication with Hamburg and Havre, and London with Rome. The following year an additional cable was laid from Baeton, in Norfolk, to Borkum, in Germany, at the joint expense of the British and German Governments. Direct telegraphic communication was thus afforded between London and Vienna. In 1893 a contract was made with the Eastern and South Africa Telegraph Company for the construction, laying, and maintenance of a cable from Zanzibar to the Seychelles and Mauritius, a distance of 2210 miles, for a subsidy of £28,000 a year for twenty years, to be made up as follows: Great Britain 10 millions, India 10 millions, Seychelles 1 million, Mauritius 7 millions. The cable has been worked since November 1893. In 1894 the Eastern Extension Telegraph Company laid a cable from Singapore to Labuan and Hong Kong, thus duplicating the route and making it an all-British line. The following year the rates to and from East and South Africa were reduced, by negotiation, from charges varying from 7s. 9d. to 8s. 11d. a word to 5s. 2d. or 5s. Government messages were accorded a rate of 2s. 6d. and press telegrams from 1s. 6d. to 1s. 7½d. a word. In 1896 it was arranged to lay two new cables to France and one (for duplex working) to Germany. On 1st February 1898 a new cable was laid between Bermuda and Jamaica (*viâ* Turks Islands), giving an all-British line to the West Indies, with reduced charges. In 1900 direct telegraph working was established between London and Genoa, and a third cable was laid to South Africa *viâ* St Helena and Ascension.

Experiments by Sir W. Preece in electrical communication without wires have been reported from time to time by the Postmaster-General, and the method has been employed by the Post Office in practical working across the Severn Channel, and in instances where an inland telegraph has been interrupted.

Telephones. Ten years of State administration of the telegraphs had not passed before the Postmaster-General was threatened with a formidable rival in the form of the telephone, which assumed a practical shape about the year 1878, the first exchange in the United Kingdom being established in the City of London in that year. It was claimed by those in possession of the telephone patents that they could supply the means of telephonic communication to the public without the licence of the Postmaster-General, and could thus, in effect, compete with the State in the transmission of messages by means of electricity. The Postmaster-General resisted this view, and in 1880 it was judicially determined (Attorney-General *v.* The Edison Telephone Company, 6 Q. B. D. 244) that the telephone was a telegraph, and that telephone exchange business could not legally be carried on except by the Postmaster-General or with his sanction. Licences were then granted to the United Telephone Company, the owners of the master-patents, and to a number of subsidiary companies, to establish exchanges in specified places, on condition that a royalty of 10 per cent. on the gross receipts of each enterprise was paid to the Post Office. The business grew rapidly, and in 1884 the local licences (which were found to hamper business) were superseded by licences applicable to the whole country. At the same time a few Post Office exchanges were established, and the Postmaster-General undertook the business of supplying private telephone wires.

Between 1884 and 1889 the three principal telephone companies (the United, the National, and the Lancashire and Cheshire) greatly extended their business, and on 1st May 1889 they became merged in the National Telephone Company Limited. On 1st May 1890 the company reduced its rates in the North of England from £20 to £15 per annum, and on 1st January 1891 a general reduction of rates outside the metropolis took place from £15 and £12 per annum to £10 per annum. The remaining companies were shortly afterwards amalgamated with the National Telephone Company. In July 1891 the last of the patents expired, and in March 1892 Sir C. Cameron moved a resolution in the House of Commons in favour of nationalizing the telephone service. The Government therefore announced its intention of purchasing the trunk lines (*i.e.*, lines connecting town and town), leaving to the companies the local exchange business. A Treasury Minute of 23rd May 1892, printed in full in the Postmaster-General's Thirtieth Report (1892), sets out the objects of the Government's policy. It points out that the telegraph revenue was being checked by the telephones, and that at the same time the public was dissatisfied with the practical monopoly of the company, which by buying up its rivals had destroyed competition, while the system still lacked its necessary development. The charges for trunk conversations were to be fixed at 3d. for 3 minutes for any distance not exceeding 20 miles, 6d. for over 20 and not exceeding 40 miles, and 6d. for every additional 40 miles.

A Select Committee of the House of Commons in 1892, under Mr Goschen, recommended that the companies' licences should not be extended, but that the Government should on its own responsibility settle the details of an agreement to be laid before Parliament. The New Telephone Company had arisen in Manchester after the patents had expired, but by arrangement with its more powerful rival it went into liquidation, leaving the National Telephone Company alone in the field. The Telegraph Act, 1892 (55 & 56 Vict. c. 59), authorized the Treasury to borrow one million sterling for the purchase of the trunk telephone lines of the company, and for the connexion of business centres by new trunk lines; and also conferred upon the Postmaster-General additional powers in regard to wayleaves, upon which the efficiency of a telephone service largely depends. New trunk lines were at once laid down by the Post Office, and were opened to the public on 16th July 1895. The trunk fees were fixed as follows:—

	s.	d.	
25 miles or under	0	3	for 3 minutes.
Over 25 miles and not exceeding 50 .	0	6	,,
,, 50 ,, ,, 75 .	0	9	,,
,, 75 ,, ,, 100 .	1	0	,,
For each 40 miles beyond . .	0	6	,,

The heads of the agreement with the company were initialled on the 11th August 1892; but the complication and magnitude of the details to be arranged for the transfer of the lines occupied a period of nearly four years, and the final agreement was not signed until 25th March 1896. Nearly 30,000 miles of wires were taken over, at a cost of £459,114, and new areas were allotted to the company for the prosecution of its exchange business. All communication between one exchange area and another now involves the use of the trunk wires. A large number of the operatives employed by the company on the trunk wires passed into the service of the Post Office at the time of the transfer.

Meanwhile the draft agreement with the National Telephone Company, laid on the table of the House of Commons on 7th August 1894, had been followed by much public discussion. The principle of competition in exchange business again found favour with a section of the public, and the corporation of Glasgow, in particular, pressed its application for the grant of a licence to carry on telephone business. Local authorities objected in some instances (notably in London and Glasgow) to permit the company to take up the streets for the purpose of laying underground wires; while overhead wires, apart from æsthetic objections, were liable to interruptions from fire, storms, and accidents. Accordingly in 1895, a Select Committee of the House of Commons was appointed, with Mr Arnold Morley, Postmaster-General, as chairman, "to consider and report whether the provision now made for the telephone service in local areas is adequate, and whether it is expedient to supplement or improve this provision, either by the granting of licences to local authorities or otherwise." As the dissolution of Parliament was imminent and the Committee was not unanimous, it failed to do more than report the evidence to the House.

The corporation of Glasgow persevered in its efforts to obtain a licence, and in 1897 the Treasury appointed Sheriff Andrew Jameson a Special Commissioner to hold a local inquiry in Glasgow whether the telephone service in that city was adequate and efficient; whether the price charged was reasonable; whether any inefficiency or inadequacy was due to the refusal of facilities on the part of the municipal authorities and others, and how far such refusal was reasonable or justifiable; and finally, whether it was expedient to grant the corporation a licence to carry on a telephone service. After taking evidence for a fortnight, the Commissioner reported that the service was inefficient, but adequate—*i.e.*, no undue conditions were imposed upon applicants. The price was reported to be reasonable. The corporation was held responsible for unreasonably withholding facilities, and so rendering the service inefficient; while it was held inexpedient to give the corporation a licence, on the grounds that (i.) the funds of a city ought not to be applied for the benefit of a limited class of citizens only, (ii.) that delay and waste result from two systems in one area, (iii.) that the acquisition of all telephones by the Government in 1911 would become more difficult and expensive, and that (iv.) the corporation had not proved that they could work the licence without throwing a new and serious burden on the rates.

On 1st April 1898 a further debate was opened in the House of Commons by Mr Caldwell, in the course of which Mr Hanbury, Financial Secretary to the Treasury and representative of the Post Office in the House, stated on behalf of the Government the objections to purchasing a company whose capital stock had been largely watered, whose plant was in many cases old-fashioned, consisting of single overhead wires, and whose term of existence was approaching its end. A Select Committee was appointed, with Mr Hanbury as chairman, to consider "whether the telephone service is, or is calculated to become, of such general benefit as to justify its being undertaken by municipal and other local authorities, regard being had to local finance"; and if so, under what conditions. The Committee reported (9th August) to the effect that the telephone service of the country was not likely to become of general benefit "so long as the present practical monopoly in the hands of a private company shall continue." The trunk service in the hands of the Government and worked on the toll system (*i.e.*, a separate payment for each service) was the most expensive in Europe. The exchange service, chiefly confined to annual subscribers to the National Telephone Company, was much behind what it should be as judged by Continental standards. The company's capital of £3,105,000 at the time of amalgamation included £1,292,000 of "water." £300,000 had been spent on patents which expired in 1891. And the service, practically limited to the wealthy classes or large users who could afford to become annual subscribers, was rendered precarious by the difficulty of obtaining way-leaves, which, even when secured, were held upon short notice. Out of 143,000 miles of wire, 120,000 were liable to be removed at 6 or 12 months' notice. The company's rates were unregulated, and it claimed the right to give preferences, or even to refuse its services altogether. The Committee found that the Post Office was "not prevented, either by legal agreement or by good faith, from limiting or ending the monopoly of the company"; and that "competition appears to be both expedient and necessary, in order, first, to extend and popularize the service, and, next, to avoid a danger, which is by no means remote if no alternative service is in operation, that a purchase of the company's undertaking at an inflated price may be forced upon the Government of the day." They therefore recommend that "general immediate and effective competition" should be at once undertaken either by the Post Office or by local authorities, while considering that "a really efficient Post Office service affords the best means for securing such competition." The Post Office should either start services of its own, or grant licences to local authorities, subject to proper regulations. Equal terms should be aimed at where the local authorities came into competition with the company; and proposals were made with a view to the purchase by the Post Office in 1911, at the then value, without any compensation for goodwill or future profits, of any suitable plant or buildings held by a competing and expiring licensee.

In addition to the £1,000,000 raised for trunk line purposes by the Act of 1892, further sums of £300,000 and £1,000,000 had been authorized by the Telegraph Acts of 1896 (59 & 60 Vict. c. 40) and 1898 (61 & 62 Vict. c. 33). Following upon the report of the Select Committee of 1898, the Telegraph Act, 1899 (62 & 63 Vict. c. 38), was passed for the purpose of enabling the Post Office to develop its exchange business, for which a loan of two millions was authorized, and to empower local authorities under certain conditions to carry on telephone exchange business under licence from the Postmaster-General. The position of the National Telephone Company was also defined in case of competition by local authorities, and its licence was extended to be coextensive with that of a new licensee in any locality on condition of its affording intercommunication and coming under the control of the Post Office as regards rates.

The Post Office opened its exchange telephone service in London in 1902. It has granted licences to the States of Guernsey (1898), Glasgow, Huddersfield, Tunbridge Wells, Brighton, and other centres.

Financial results of State telegraphy.

The principal reasons alleged for the unfavourable financial results of the working of the telegraphs are: (i.) The large price (£10,130,000) expended as purchase-money—an argument of little weight so long as working expenses are not paid. (ii.) The right accorded to railway companies at the time of the transfer, of sending postal telegrams free of charge. The number of these telegrams, at first insignificant, reached a total of 1,600,000 in 1891, with an average length of 25 words, representing a value of over £80,000 a year. Arrangements were afterwards made under which the companies surrender this privilege in return for permission to send a fixed number of free telegrams in the course of each year. (iii.) The loss on press telegrams. To quote the Forty-first Report of the Postmaster-General: "A still more serious burden is caused by the loss on press telegrams. The charge specified in the Telegraph Act of 1868 for press telegrams is 1s. for 75 words during the day, or for 100 words at night. But a proviso was added that for copies the charge was to be only 2d. per 75 or 100 words, and no condition was laid down as to the copy being for the same town as the original. The newspapers accordingly combined to receive from the News Associations messages in identical terms, and by dividing the cost they are enabled to get the benefit of a rate which comes nearer 2d. than 1s., the average charge being in fact about 4½d. per 100 words. Notwithstanding the economical arrangements which have been made for the transmission of the telegrams (5,400,000 in number, containing 650,000,000 words), the loss incurred by the Post Office in dealing with them is estimated to amount to £300,000 per annum." (iv.) The reductions in the tariff (especially in 1885 and 1897). (v.) The competition of the telephone (upwards of 450,000,000 messages a year transmitted by the National Telephone Company alone), though it must be remembered that the royalties of the company, exceeding £100,000 per annum, figure among the receipts of the Post Office telegraph service. (vi.) The increased wages paid to telegraphists: in 1880–81 the wages and salaries represented 44 per cent. of the total revenue; they now exceed 66 per cent.

The real success of the State administration of the telegraph lies not in any contribution to the revenue, but in cheap telegrams and a large use of the service. The average price paid for the ordinary inland telegram is 7¾d.; and there are far more telegrams sent in the United Kingdom, both positively and relatively to population, than in any other country, with the possible exception of the United States. For every 100 persons there are sent, in the United Kingdom, 184 telegrams, while in France there are but 108, and in Germany but 66. The accompanying table shows the revenue and expenditure of the telegraph service:—

Year.	Revenue.				Expenditure.									Net Revenue.	Interest on Stock created for Purchase of Telegraphs.
	Telegraph Receipts.	Extra Receipts.	Estimated Value of Services to other Departments.	Total.	Sites and Buildings.		Telegraph Extension.	Superannuations and other Non-effective Charges.	Salaries, Wages, &c.	Maintenance of the Telegraph System.	Other Expenditure.		Total.

[1] Deficits.

Post Office Staff.

The staff of the Post Office on 31st March 1901 amounted to 173,184, or 1 in 236 of the whole population of the United Kingdom. Of these, 35,377 were women, a proportion of over one-fifth of the staff. The postmasters numbered 909 (including 11 employed abroad), and the sub-postmasters 21,027. The total number of offices (including branch offices) was 22,189. The unestablished staff, not entitled to pension, made up chiefly of telegraph boys, and of persons who are employed for only part of the day on Post Office business, included 79,052 out of the grand total, and almost the whole of the sub-postmasters. The pay and prospects of almost all classes have been greatly improved since 1884, when the number stood at 91,184. The principal schemes of general revision of pay have been:—1881, Mr Fawcett's scheme for sorting-clerks, sorters, and telegraphists (additional cost £210,000 a year), and for postmen, 1882, £110,000: Mr Raikes's various revisions, 1888, chief clerks and supervising officers, £6230; 1890, sorting-clerks, sorters, and telegraphists, £179,600; 1890, supervising force, £65,000; 1890, London sorters, £20,700; 1891, London overseers, £9400; 1891, postmen, £125,650: Mr Arnold Morley, 1884, London overseers, £1400, and rural auxiliaries, £20,000.

On June 10th 1895 a committee was appointed, with Lord Tweedmouth as chairman, to consider the pay and position of the whole Post Office staff, excluding the clerical force and those employed at headquarters. After exhaustive inquiry, the committee reported its recommendations on 15th December 1896, and these were adopted in their entirety by the Government at an immediate increased expense of £139,000 a year, which has since risen to £500,000. In 1897 a conference of members of the House of Commons, under the presidency of the Duke of Norfolk and Mr Hanbury, considered further representations of grievances on the part of the staff, and in the result additional concessions were made at a cost of £100,000 a year.

In July 1890 a number of postmen in London went out on strike. Over 450 were dismissed in one morning, and the work of the Post Office was carried on without interruption. The men received no sympathy from the public, and most of them were ultimately successful in their plea to be reinstated. A quasi-political agitation was carried on during the general election of 1892 by some of the London sorters, who, under the plea of civil rights, claimed the right to influence candidates for Parliament by exacting pledges for the promise of parliamentary support. The leaders were dismissed, and the Post Office has upheld the principle that its officers are to hold themselves free to serve either party in the State without putting themselves prominently forward as political partisans. Parliament has been repeatedly asked to sanction a parliamentary inquiry to reopen the settlement of the Tweedmouth Committee, and the telegraphists have been especially active in pressing for a further committee. The rates of pay now, and at various dates since 1881, are set out with great fulness in two Parliamentary papers (*Postmen*, No. 237 of 1897, and *Sorters, Telegraphists, &c.*, No. 230 of 1898).

The pay of a sorter or telegraphist in London rises to £160 a year, with prospects of promotion to higher classes. The maximum pay of a postman in London is 34s. a week, but he may receive as much as 6s. a week extra for good-conduct stripes. The Parliamentary returns above referred to show the perquisites in the form of overtime, allowances, double increments, uniform, free medical attendance, holidays, and pensions, &c., enjoyed in addition to the bare wages. "The mere scales of pay given to the staff only imperfectly represent the full advantages arising from their position; and the growing disinclination of the staff to leave the service, and the increasing desire of outsiders to enter it, afford a fair presumption that the position and prospects of the employés in the Post Office are at least equal, if not superior, to those of persons employed on similar duties outside the service."[1]

The estimated expenditure of the Post Office on account of salaries and wages in 1900–01 amounted to £8,620,171, representing 49·38 of the total revenue and 62·11 of the total expenditure. These percentages were respectively 36·72 and 50·32 in 1884–85, and have been steadily increasing, notwithstanding the considerable extension of Mr Fawcett's successful experiment of employing women and girls in the clerical work of certain branches of the service.

[1] Forty-first Report of the Postmaster-General, 1895, p. 11.

In November 1891 an important change was made in the method of recruiting the staff of postmen, with the object of encouraging military service, and of providing situations for those who after serving their country in the army or navy are sometimes left without employment at a comparatively early age. In making appointments to the situation of postman, preference was given to army, navy, and royal marine pensioners, and men of the army reserve. Due regard was paid to the legitimate claims of telegraph messengers or other persons who had prospects of succeeding to these situations, but on March 31st, 1892, no fewer than 1379 old soldiers and sailors were serving as postmen. Since that time the number has considerably increased. In August 1897 the Government decided to reserve one-half of all suitable vacancies for ex-soldiers and sailors, as postmen, porters, and labourers, and preference has been shown to them for employment as lift-attendants, caretakers, &c.

Finance.—The following table shows the financial working of the Post Office :—

Postage Stamps.

The pamphlet of Mr (afterwards Sir) Rowland Hill, *Post Office Reform: Its Importance and Practicability*, 1837, led to the appointment of a committee of the House of Commons on 22nd November 1837, "to inquire into the rates and modes of charging postage, with a view to such a reduction thereof as may be made without injury to the revenue." This committee reported in favour of Hill's proposals; and an Act, 2 & 3 Vict. c. 52, was passed in 1839, authorizing the Treasury to fix the rates of postage, and regulate the mode of their collection, whether by prepayment or otherwise. By Treasury Minute of 23rd August 1839, published in the press, it was announced that "My Lords . . . feel it will be useful that artists, men of science, and the public in general may have an opportunity of offering any suggestions or proposals as to the manner in which the stamp may be best brought into use." A premium of £200 was offered for the best, and £100 for the next best, proposal. The points to be considered were: "(1) the convenience as regards the public use; (2) the security against forgery; (3) the facility of being checked and distinguished at the post office, which must of necessity be rapid; and (4) the expense of the production and circulation of the stamps." To this invitation 2600 replies were received, but no improvement was made upon Rowland Hill's suggestions. A further Minute, of 26th December 1839, announced that the Treasury had decided to require that, as far as practicable, the postage of letters should be prepaid, and such prepayment effected by means of stamps. Stamped covers or wrappers, stamped envelopes, and adhesive stamps were to be issued by Government. The stamps were engraved by Messrs Perkins, Bacon, & Petch, of Fleet Street, from Hill's designs, and the Mulready envelopes and covers by Messrs Clowes & Son, of Blackfriars. The stamps were appointed to be brought into use on 6th May 1840, but they appear to have been issued to the public as early as 1st May. The penny stamp bearing a profile of Queen Victoria was coloured black, and the twopenny stamp blue, with check-letters in the lower angles (in all four angles from April 1858). Up to 28th January 1854 the stamps were not officially perforated, except in the session of 1851, when stamps, perforated by a Mr Archer, were issued at the House of Commons post office. In 1853 the Government purchased Archer's patent for £4000. The stamps were first water-marked in April 1840.

(i.) *Line-engraved Stamps.*

Halfpenny Stamp.—First issue, 1st October 1870 : size 18 mm. by 14 mm.; lake red varying to rose-red.

One Penny Stamp.—First issue, 1st (for 6th) May 1840 : the head executed by Mr Frederick Heath, from a drawing by Mr Henry Corbould of Mr Wm. Wyon's medal struck to commemorate her Majesty's visit to the City of London on 9th November 1837 : size $22\frac{1}{2}$ mm. by $18\frac{3}{4}$ mm.; black, watermarked with a small crown; a few sheets in 1841 struck in red, two essays were made in April and October 1840 in blue and blue-back. Imperforate. The *second issue*, 20th January 1841, differed only from the first issue as to colour—red instead of black. It is stated[1] that the colour, "though always officially referred to as 'red,' was really a red-brown, and this may be regarded as the normal colour; but considerable variations in tone and shade (brick-red, orange-red, lake-red) occurred from time to time, often accentuated by the blueing of the paper, though primarily due to a want of uniformity in the method employed for preparing the ink." The change of colour from black was made in order to render the obliteration (now in black instead of red ink) more distinct. Imperforate. *Third issue*, February 1854 : small crown watermark, perforated 16 (*i.e.*, 16 holes to 2 centimetres). The *fourth issue*, January 1855, differed only from the third issue in being perforated 14. *Fifth issue*, February 1855 : from a new die, with minute variations of engraving. In the second die the eyelid is more distinctly shaded, the nostril more curved, and the band round the hair has a thick dark line forming its lower edge. Small crown watermark. Perforated 16 and 14. *Sixth issue*, July 1855 : large crown watermark. Perforated 14; a certain number 16. *Seventh issue*, January 1858 : carmine-rose varying from pale to very deep. Large crown watermark. Perforated, chiefly 14. *Eighth issue*, 1st April 1864 : check-letters in all four corners instead of two only; large crown watermark. Perforated 14.

In 1880 the line-engraved one penny stamps were superseded by the surface-printed one of similar value in Venetian red, designed and printed by Messrs De la Rue & Co.

Three-halfpenny Stamp.—1st October 1870 : large crown watermark; lake-red; perforated 14. Superseded in October 1880 by De la Rue's surface-printed stamp.

Twopenny Stamp.—First issue, 1st (for 6th) May 1840 : small crown watermark; light blue, dark blue; imperforate. *Second issue*, March 1841 : small crown watermark; white line below "Postage" and above "Twopence"; dull to dark blue; imperforate. *Third issue*, February (?) 1854 : small crown watermark; blue, dark blue; perforated 16. *Fourth issue*, March 1855 : small crown watermark; blue, dark blue; perforated 14. *Fifth issue*, July 1855 : large crown watermark; blue; perforated 16; blue, dark blue; perforated 14. *Sixth issue*, May (?) 1857 : large crown

[1] Wright and Creeke, *History of the Adhesive Stamp of the British Isles available for Postal and Telegraph Purposes.* London, 1899.

watermark; white lines thinner, blue, dark blue; perforated 14; dark blue; perforated 16. *Seventh issue*, July 1858: large crown watermark; white lines as in fifth issue; deep to very deep blue; perforated 16. *Eighth issue*, April (?) 1869: large crown watermark; white lines thinner; dull blue, deep to very deep blue, violet blue; perforated 14. Superseded in December 1880 by De la Rue's surface-printed stamp.

(ii.) *Embossed Stamps.*

Produced by Dryden Brothers, of Lambeth, from designs submitted by Mr Ormond Hill of Somerset House, engraved after Wyon's medal.

Sixpence.—1st March 1854: violet, reddish lilac, dark violet; imperforate. Superseded in October 1856 by De la Rue's surface-printed stamp.

Tenpence.—6th November 1848: pale to very deep chestnut-brown; imperforate. Superseded by De la Rue's surface-printed stamp in 1867.

One Shilling.—11th September 1847: emerald green, pure deep green, yellow green; imperforate. Superseded in November 1856 by De la Rue's surface-printed stamp.

(iii.) *Surface-printed Stamps before 1880.*

Twopence Halfpenny.—First issue, 1st July 1875: small anchor watermark; lilac-rose; perforated 14. *Second issue*, May 1876: orb watermark; lilac-rose; perforated 14. *Third issue*, 5th February 1880: orb watermark; cobalt, and some ultramarine; perforated 14. *Fourth issue*, 23rd March 1881; large crown watermark; bright blue; perforated 14.

Threepence.—All perforated 14. *First issue*, 1st May 1862: heraldic emblems watermark; carmine (pale to deep). *Second issue*, 1st March 1865: same watermark as above; carmine-pink. *Third issue*, July 1867: watermarked with a spray of rose; carmine-pink, carmine-rose. *Fourth issue*, July 1873: watermark as third issue; carmine-rose. *Fifth issue*, 1st January 1881: watermark large crown; carmine-rose. *Sixth issue*, 1st January 1883; watermark as fifth issue; purple shades overprinted with value in deep pink.

Fourpence.—All perforated 14. *First issue*, 31st July 1855; watermark small garter; deep and dull carmine. *Second issue*, February 1856: watermark medium garter; pale carmine. *Third issue*, 1st November 1856: watermark medium garter; dull rose. *Fourth issue*, January 1857; watermark large garter; dull and pale to deep rose, pink. *Fifth issue*, 15th January 1862: watermark large garter; carmine-vermilion, vermilion-red. *Sixth issue*, July 1865; watermark large garter; pale to dark vermilion. *Seventh issue*, 1st March 1876: watermark large garter; pale vermilion. *Eighth issue*, 27th February 1877: watermark large garter; pale sage-green. *Ninth issue*, July 1880: watermark large garter; mouse-brown. *Tenth issue*, 1st January 1881: watermark large crown; mouse-brown.

Sixpence.—All perforated 14. *First issue*, 21st October 1856: no letters in angles; watermark heraldic emblems; dull lilac. *Second issue*, 1st December 1862: small white letters in angles; otherwise as first issue. *Third issue*, 1st April 1865: large white letters in angles; otherwise as first issue. *Fourth issue*, June 1867: watermark spray of rose; otherwise as third issue; some in bright lilac. *Fifth issue*, March 1869: as fourth issue; lilac, deep lilac, purple-lilac. *Sixth issue*, 1st April 1872: as fourth issue; bright chestnut-brown. *Seventh issue*, October 1872: as fourth issue; buff. *Eighth issue*, April 1873: as fourth issue; greenish grey. *Ninth issue*, 1st April 1874: watermarked as fourth issue; large coloured letters in angles; greenish-grey. *Tenth issue*, 1st January 1881: large crown watermark; otherwise as ninth issue. *Eleventh issue*, 1st January 1883: as tenth issue; purple, overprinted with value in deep pink.

Eightpence.—11th September 1876: watermark large garter; chrome-yellow, pale yellow; perforated 14.

Ninepence.—All perforated 14. *First issue*, 15th January 1862: watermark heraldic emblems; ochre-brown, bright bistre. *Second issue*, 1st December 1865: watermark as above; bistre-brown, straw. *Third issue*, October 1867: watermark spray of rose; straw.

Tenpence.—1st July 1867: watermark spray of rose; red-brown; perforated 14.

One Shilling.—All perforated 14. *First issue*, 1st November 1856: watermark heraldic emblems; no letters in angles; dull green, pale to dark green. *Second issue*, 1st December 1862: as above; small white letters in angles; pale to dark green. *Third issue*, February 1865; as above; large white letters in angles; pale to dark green, bluish green. *Fourth issue*, August 1867: watermark spray of rose; otherwise as third issue; pale to dark green, bluish green. *Fifth issue*, September 1873: large coloured letters in angles; otherwise as fourth issue; light to dark green, bluish green. *Sixth issue*, 14th October 1880: as fifth issue; pale red-brown. *Seventh issue*, 15th June 1881: watermark large crown; otherwise as sixth issue; pale red-brown.

Two Shillings.—Watermark spray of rose; perforated 14. *First issue*, 1st July 1867; pale to full blue, very deep blue. *Second issue*, February 1880: light brown.

Five Shillings.—First issue, 1st July 1867: watermarked with a cross *paté*; pink, pale rose; perforated $15\frac{1}{2}$ by 15. *Second issue*, November 1882: watermark large anchor; carmine-pink; perforated 14.

Ten Shillings.—First issue, 26th September 1878: watermark cross *paté*; green-grey; perforated $15\frac{1}{2}$ by 15. *Second issue*, February 1883: watermark large anchor; green-grey; perforated 14.

One Pound.—First issue, 26th September 1878: watermark cross *paté*; brown-violet; perforated $15\frac{1}{2}$ by 15. *Second issue*, December 1882: watermark large anchor; brown-violet; perforated 14.

(iv.) *After* 1880.

In 1880–81 the halfpenny, penny, three halfpenny, and twopenny surface-printed stamps superseded the line-engraved stamps of the same value, and a new surface-printed stamp of fivepence was introduced. These stamps are distinguished from the stamps already described by the absence of plate-numbers and (except in the penny stamp) of check-letters in the corners; also by the coarser style of engraving necessary for printing by machines driven by steam-power.

One Halfpenny.—First issue, 14th October 1880: large crown watermark; pale green, bluish green, dark green; perforated 14. *Second issue*, 1st April 1884: slate-blue.

One Penny.—1st January 1880: large crown watermark; venetian red; perforated 14.

Three Halfpence.—14th October 1880: large crown watermark; venetian red; perforated 14.

Twopence.—8th December 1880: large crown watermark; pale to very deep carmine red; perforated 14.

Fivepence.—15th March 1881: large crown watermark; dark dull indigo, indigo-black; perforated 14.

The Customs and Inland Revenue Act which came into force on 1st June 1881 made it unnecessary to provide separate penny stamps for postal and fiscal purposes. By an Act of 1882 (45 & 46 Vict. c. 72) it became unnecessary to provide separate stamps for postal and fiscal purposes up to and including stamps of the value of 2s. 6d. A new series was therefore issued:—

One Penny.—All perforated 14. *First issue*, 12th July 1881: large crown watermark; 14 pearls in each angle; purple-lilac, purple. *Second issue*, 12th December 1881: as first issue; 16 pearls in each angle; purple.

Three Halfpence.—1st April 1884: large crown watermark; purple; perforated 14.

Twopence.—Ditto.

Twopence Halfpenny.—Ditto.

Threepence.—Ditto.

Fourpence.—Ditto, except in colour (sea-green).

Fivepence.—As fourpence.

Sixpence.—Ditto.

Ninepence.—Ditto.

One Shilling.—Ditto.

Two Shillings and Sixpence.—22nd July 1883: watermark large anchor; purple, dull lilac, dark purple; perforated 14.

Five Shillings.—1st April 1884: ditto; pale to very deep carmine.

Ten Shillings.—Ditto; pale blue, cobalt, light to dull blue.

One Pound.—First issue, 1st April 1884: large crown watermark, 3 appearing in each stamp; brown-violet; perforated 14. *Second issue*, 27th January 1891: same watermark; bright green; perforated 14.

Five Pounds. — 21st March 1882: large anchor watermark; orange-vermilion, vermilion, bright vermilion; perforated 14.

Following upon the Report of a Committee of Officials of the General Post Office and Somerset House, a series of new stamps, commonly known as the "Jubilee" issue, was introduced on 1st January 1887, all of which between one halfpenny and one shilling exclusive were printed either in two colours or on a coloured paper, so that each stamp was printed in part in one or other of the doubly-fugitive inks—green and purple.

One Halfpenny.—1st January 1887: large crown watermark; orange vermilion to bright vermilion; perforated 14.

Three Halfpence.—1st January 1887: as the halfpenny; green and purple.

Twopence.—Ditto: green and scarlet to carmine.

Twopence Halfpenny.—1st January 1887: blue paper; watermark large crown; dark purple; perforated 14.

Threepence.—1st January 1887: yellow paper; watermarked with a large crown; purple; perforated 14.

Fourpence.—1st January 1887: watermark and perforation as in threepence; green and brown.

Fourpence Halfpenny.—15th September 1892: as the fourpence; green and carmine.

Fivepence.—1st January 1887: as the fourpence; purple and blue.

Sixpence.—1st January 1887: pale red paper; watermarked with a large crown; purple; perforated 14.

Ninepence.—1st January 1887: large crown watermark; purple and blue; perforated 14.

Tenpence.—24th February 1890: as the ninepence; purple and carmine-red.

One Shilling.—1st January 1887: as the ninepence; green.

The various fiscal stamps admitted to postage uses, the overprinted official stamps for use by Government departments, and the stamps specially surcharged for use in the Ottoman Empire, do not call for detailed notice in this article.

The distinctive *telegraph stamps* are as follows:—

One Halfpenny.—1st April 1880: shamrock watermark; orange-vermilion; perforated 14.

One Penny.—1st February 1876: as the halfpenny; reddish brown.

Threepence.—Perforated 14. *First issue,* 1st February 1876: watermark spray of rose; carmine. *Second issue,* August 1881: watermark large crown; carmine.

Fourpence.—1st March 1877: watermark large garter; pale sage-green; perforated 14.

Sixpence.—Perforated 14. *First issue,* 1st March 1877: watermark spray of rose; greenish grey. *Second issue,* July 1881: as first issue; watermark large crown.

One Shilling.—Perforated 14. *First issue,* 1st February 1876: watermark spray of rose; green. *Second issue,* October 1880: watermark spray of rose; pale red-brown. *Third issue,* February 1881: watermark large crown; pale red brown.

Three Shillings.—Perforated 14. Slate blue. *First issue,* 1st March 1877: watermark spray of rose. *Second issue,* August 1881: watermark large crown.

Five Shillings.—*First issue,* 1st February 1876: watermark cross *paté;* dark to light rose; perforated 15 by 15½. *Second issue,* August 1881: watermark large anchor; carmine-rose; perforated 14.

Ten Shillings.—1st March 1877: watermark cross *paté;* green-grey; perforated 15 by 15½.

One Pound.—1st March 1877: watermark shamrock; brown-purple; perforated 14.

Five Pounds.—1st March 1877: watermark shamrock; orange-vermilion; perforated 15½ by 15.

In addition to these, there were stamps specially prepared for the army telegraphs.

II. Foreign Countries.

Postal statistics for different countries will be found under the separate headings for each. But the following tables show comparatively the business done in the principal countries:—

Postal Statistics, 1900.

Country.	1 Sent by Inland Letter Post (Millions).	2 Inland Parcel Post (Millions).	3 Total of Articles posted per Head of Population.	4 No. of Post Offices (Thousands).	5 No. of Persons employed (Thousands).	6 No. of Inland Money Orders (Millions).	7 Receipts in Millions of Francs.	8 Expenses in Millions of Francs.	9 Surplus + or Deficit − in Millions of Francs.	10 Remarks.
Austria . .	741	22	37·4	7	22	24	112	102	+10

United Kingdom .	93	12	556	

These figures in some cases include, and in others exclude, the telegraph lines of railway companies, &c.

(H. H*.)

III. United States.

The financial statements of the United States Post Office for a series of years show the following figures:—

Year ended 30th June.	Revenue.	Expenditure.	Deficit.
1893 . . .	$75,896,933	$81,074,104	$5,177,171
1894 . . .	75,080,479	84,324,414	9,243,935
1895 . . .	76,983,128	86,790,172	9,807,044
1896 . . .	82,499,208	90,626,296	8,127,088
1897 . . .	82,665,462	94,077,242	11,411,780
1898 . . .	89,012,618	98,033,523	9,020,905
1899 . . .	95,021,384	101,632,160	6,610,776
1900 . . .	102,354,579	107,740,267	5,385,688
1901 . . .	111,631,193	115,554,920	3,923,727

The revenue quoted does not include any allowance for the large quantity of official matter carried for other public departments, &c.; nor does the expenditure include the amounts certified to the Treasury for the transportation of mails over aided Pacific railways, or any allowance for the use of such buildings as are provided by the Government. Contrary to expectations repeatedly expressed, each year since 1883 has shown a deficit. This is partly explained by reductions in charges. The rate of postage on first-class matter was reduced from three cents to two cents on 1st October 1883, and the unit of weight was increased from half an ounce to one ounce on 1st July 1885. On the latter date, also, the postage on second-class matter was reduced from two cents to one cent per pound. This low rate has led to wholesale violation of the purpose of the law. In his report for 1899 Mr Emory Smith, Post-master-General, estimated that "fully one-half of all the matter mailed as second-class, and paid for at the pound rate, is not properly second-class within the intent of the law"; and that the cost of mere transportation of this wrongly-classed matter exceeded the revenue derived from it by more than $12,000,000 for the year.

Recent Developments.—The free delivery service has grown rapidly during recent years. On 1st July 1901, 866 cities and towns were included in the scheme, and 16,389 letter-carriers were serving a population of 32,000,000. An extension to rural districts was started in 1896, and by December 1901, 4,000,000 of the rural population were within the scope of free delivery. Since 1st October 1885 a system has been in force for the immediate delivery by special messengers of letters, parcels, &c., for addresses within certain areas. A special ten-cent stamp is required in addition to the ordinary postage. Under this arrangement, 7,133,263 articles were transmitted during the year ended 30th June 1901, resulting in a net profit of $167,727. A step towards the popularization of the registry system was authorized in December

1899: letter-carriers in many city districts now accept and register letters at the door of the householder. Sea post offices for sorting mails during the Atlantic transit were established in December 1890 on the steamers of the North German Lloyd and Hamburg-American lines, and later on the vessels of the International Navigation Company. This plan effects a saving of from two to fourteen hours in the delivery of mails from Europe. The issue of "postal notes," commenced in 1883, was abandoned in 1894. The introduction of "postal checks" for small fixed amounts is now being advocated. A new postal convention with Canada, removing the former restriction against sending merchandise, came into force on 1st March 1888. Uniformity of postage rates having been previously established, the United States and Canada became virtually one postal territory.

The limit of weight for domestic parcels in the United States is four pounds. A convention for an exchange of parcels with Jamaica, admitting articles not exceeding eleven pounds, was, however, agreed to in 1887; and since then conventions on similar lines have been concluded with a number of other colonies and countries in America. The first arrangement of the kind with any European country was made with Germany, and came into operation on 1st October 1899. During the year to 30th June 1901, 76,148 parcels of a total weight of 252,791 pounds were despatched to foreign countries, &c., and 42,522 foreign parcels of a total weight of 281,813 pounds were received.

Considerable progress has been made in the organization of the postal service in the newly-acquired possessions and Cuba. The postal laws, regulations, and domestic conditions of the United States have been extended, by Act of Congress, to Porto Rico and Hawaii. The "island possessions" (Guam, the Philippine Archipelago, and Tutuila) have also been brought within the scope of the domestic conditions, including the rates of postage. The service introduced into Cuba, though modelled on the American plan, is practically autonomous.

The following statistics are taken from the report of the Post Office Department for the fiscal year ended 30th June 1901. On that date the number of post offices was 76,945. The sales of stamps for the year amounted to $102,023,473, and the collections from publishers and newsagents for second-class postage to $4,294,445. The total estimated number of letters was 3,604,322,767, of post cards 659,614,800, of pieces of second-class matter (newspapers and periodicals) 2,206,791,539, of pieces of third-class and fourth-class matter (books, circulars, parcels of merchandise, &c.) 953,661,223. The registered letters and parcels numbered 20,814,501, and the irrecoverable losses are given as 466, or one in every 44,666 articles registered. It is estimated that there were sent to foreign countries 76,536,229 letters, 4,324,709 post cards, and 90,153,343 packets containing printed matter, commercial papers, or samples of merchandise; and that there were received from foreign countries 62,698,084 letters, 3,584,208 post cards, and 58,123,993 packets of printed matter, &c. A total of 8,507,257 articles of undelivered mail was received at the dead-letter office; 23,362 magazines, illustrated papers, &c., which could not be returned, were distributed among the inmates of various charitable institutions. The total number of domestic mail routes of all classes was 35,316, their aggregate length 511,808 miles, and the annual transportation 466,146,059 miles. Of these, the "star" routes had a total length of 267,357 miles and an annual transportation of 134,404,541 miles, the railway routes a total length of 183,358 miles and an annual transportation of 302,613,325 miles, and the steamboat routes a total length of 33,970 miles and an annual transportation of 4,652,257 miles. The "railway mail service" maintained 1306 lines of travelling post offices (on railway trains, steamboats, and electric and cable cars), covering a total length of 182,154 miles. It employed 9182 clerks, who during the year travelled "in crews" a total distance of 210,221,576 miles. Their manipulations of pieces of ordinary mail matter numbered 14,181,224,420, and of packages and pouches of registered matter 21,284,833. The number of domestic money orders issued was 35,586,379, representing $274,546,067. The international orders issued numbered 1,247,888 and amounted to $20,072,613, while those paid numbered 492,408 and amounted to $7,972,453.

Telegraphs.—The formation of a postal telegraph system has continued to be a subject of discussion by the Postmasters-General. In his report for the year 1888, Mr Dickinson proposed the appointment of an expert commission authorized to erect short experimental lines. His successor, Mr Wanamaker, for four years vigorously advocated a limited postal telegraph service. Under this proposal, contracting telegraph companies were to furnish lines, instruments, and operators, and to transmit messages at rates fixed by the Government; the department was to receive a small sum per message, to cover its expenses in collection and delivery. In 1894 Mr Bissell expressed the opinion that a Government system would be unprofitable and inexpedient.

Savings Banks.—The establishment of postal savings banks was also recommended by Mr Wanamaker in his reports for the years 1889 to 1892, and by Mr Gary in 1897. What is regarded as a step in this direction was taken in 1898, when the postal regulations were modified to allow money orders to be made payable at the office of issue. This change is described by Mr Emory Smith as "establishing a mild and very convenient adaptation of the European savings bank system, without the payment of interest." (E. J. H*.)

The various postal and telegraph rates and regulations are set out in the quarterly *Post Office Guide* (price 6d.) and the *Post Office Handbook* (price 1d.), which may be purchased at any post office. The penny handbook was first issued in 1886, and has a circulation of over half a million.

Pöstyén (*Pistyan*), a market town of Hungary, in the county of Nyitra, situated near the Vág, with 5661 inhabitants in 1901. It is famous for its sulphur and mud baths, which in 1900 attracted 6600 patients. There are separate bathing-houses for poor people.

Potenza, a town, bishop's see, and capital of the province of the same name, Basilicata, Italy, 93 miles by rail west by north of Taranto. It stands 2712 feet above sea-level, its mean temperature being 53° Fahr.; Jan., 37·8°; July, 70·9°. It has a school of the industrial arts and sciences, grows good wine, and makes bricks. Population (1881), 17,978; (1901), 16,520.

Potgieter, Everhardes Johannes (1808–1875), Dutch prose writer and poet, was born at Zwolle, in Overyssel, 17th June 1808. As a young man Potgieter went to Antwerp, where he started a commercial career at the office of a local merchant. In 1831 he made a journey to Sweden, subsequently described in two volumes, which appeared at Amsterdam in 1836–40. Soon after his return from the North, he settled in Amsterdam, still engaged in commercial pursuits, on his own account, but with more and more inclination towards literature. With Heije, the popular poet of Holland in those days, and Bakhuizen van den Brink, the rising historian (see also GROEN VAN PRINSTERER), Potgieter founded *De Muzen* ("The Muses," 1834–36), a literary review, which was, however, soon superseded by *De Gids* ("The Guide"), a monthly which became the leading magazine of Holland. In it he wrote, mostly under the initials of "W. D——g," a great number of articles and poems, collected and published both before and after his death. The first collected edition of his poems (1832–1868) appeared in 2 vols. (Haarlem, 1868–75), preceded by some of his contributions to *De Gids*, in 2 vols. also (Haarlem, 1864), and followed by 3 vols. of his *Studien en Schetsen* ("Studies and Sketches," Haarlem, 1879). Soon after his death (3rd February 1875) a more comprehensive edition of Potgieter's *Verspreide en Nagelaten Werken* ("Miscellaneous and Posthumous Works") was published in 8 vols. by his friend and literary executor, Johan C. Zimmerman (Haarlem, 1875–77), who likewise supervised a yet more complete edition of Potgieter's writings which appeared at Haarlem in 1885–90 in 19 vols. Of Potgieter's *Het Noorden in Omtrekken en Tafreelen* ("The North in Outlines and Pictures") the third edition was issued in 1882, and an *édition de luxe* of his poems followed at Haarlem in 1893. Under the title of *Personen en Onderwerpen* ("Persons and Subjects") many of Potgieter's criticisms had collectively appeared in 3 vols. at Haarlem in 1885, with an introduction by his lifelong friend and collaborator, Busken-Huet, the famous critic, to whom we owe the best biographical notice and the truest appreciation of Potgieter. The latter's great influence upon Dutch language and literature in the second half of the 19th century is undisputed. It was largely enhanced by his *Gids* circle in Amsterdam, all the more prominent *littérateurs*, poets, and artists of his day frequenting it at his house in Amsterdam. Potgieter, with all his learning and accomplishments, was a very modest man. His favourite master among the Dutch classics was Hooft, whose peculiarities in style and language he admired and imitated. The same vein of altruistic, if often exaggerated and biassed, abhorrence of the wonted conventionalities of literary life runs through all his writings, even through his private correspondence with Huet, parts of which have been published. Potgieter remained to his death the irreconcilable enemy of the Dutch "Jan Salie," as the Dutchman is nicknamed who does not believe in the regeneration of the Dutch people. Potgieter held up the Netherlanders of the golden age of the 16th and 17th centuries as models to be emulated. In these views he essentially differed from Huet. Yet the two friends worked harmoniously together; and when Potgieter reluctantly gave up *De Gids* in 1865, it was Huet whom he chose as his successor. Both then proceeded to Italy, and were present at the Dante festivities at Florence, which in Potgieter's case resulted in a poem in twenty stanzas, *Florence* (Haarlem, 1868), which certainly proved, if nothing else, that he could appreciate and glorify greatness in a Southern people, as well as in a Northern. In Holland Potgieter's influence has been very marked and beneficial; but his own style, that of an ultra-purist, was at times somewhat forced, stilted, and not always easily understood. (H. TI.)

Potosi, a department of Bolivia, bounded on the N. by the departments of Oruro and Cochabamba, on the S. by Chile and the Argentine Republic, on the E. by Chuquisaca and Tarija, and on the W. by Tarapacá and Chile. Area, 52,100 square miles. Population (1893), 360,400. The capital, Potosi, situated 13,350 feet above sea-level, has 40,000 inhabitants. The department is divided into 9 provinces, and in 1898 had 63 schools and 2900 pupils.

Potsdam, a town of Prussia, 16 miles by rail southwest of Berlin, beautifully situated at the centre of the network of Havel lakes. The town has been greatly embellished, and the gardens and parks with which it is surrounded have been laid out with care. There is an excellent railway service with Berlin, with which it is connected by a third suburban line of railway running by way of Wannsee. Among modern buildings must be mentioned the new stone bridge, ornamented by statues, which connects the Altstädt with the suburb of Teltow. To the Friedenskirche is attached a mausoleum built after the model of a chapel at Innchen in Tirol, in which lie the Emperor Frederick, his consort, Princess Royal of Great Britain, and two of their children who died in infancy. The Marble Palace on the "Leiliger See" was the residence of Kaiser Wilhelm II. until his accession. To Potsdam has been removed the Geodetic Institute, which occupies extensive premises. Population (1880), 48,447; (1900), 59,814.

Pott, August Friedrich (1802–1887), German philologist, was born at Nettelrede, Hanover, 14th November 1802. He studied in Göttingen, and in 1825 became schoolmaster at Celle, Hanover; but after two years removed to Berlin, where he became *privat docent* at the university. He applied himself to the study of comparative philology, and in 1883 was made professor at Halle, where he lived till his death on 5th July 1887. His *magnum opus* was his *Etymologische Forschung* (1834–36), which entitled him to rank as Bopp's foremost disciple in the Indo-Germanic science of language. See the article PHILOLOGY (vol. xviii.). Pott also devoted much attention to the origins of the gipsies (*q.v.*).

Potter, Henry Codman (1835-——), American bishop of the Protestant Episcopal Church, born in Schenectady, New York, 25th May 1835, is a son of Bishop Alonzo Potter of Pennsylvania. He was a graduate of the Theological Seminary of Virginia in 1857, and was ordained in 1858. After serving churches at Greensburgh, Pa., Troy, N.Y., and Boston, Mass., he became rector of Grace Church, New York City, from 1868 to 1884. In 1883 he was chosen assistant bishop of New York; and on the death in 1887 of the bishop, his uncle, he became bishop of the diocese. He published *Sisterhoods and Deaconesses* (1872), *The Gates of the East* (1876), and other ecclesiastical and religious works; and he received the degrees of D.D. and LL.D. from Union College (New York), and D.D. from Trinity College (Connecticut), Harvard, Oxford, and Cambridge Universities.

Pottery and Porcelain.—Recent advances in the potter's art, as practised in Europe, have sprung fundamentally from the growth of real scientific knowledge of the potter's materials and methods. Until well within the 19th century the potter's knowledge was purely empirical, built up on traditional methods of working with the materials of a particular district, and failing when the conditions changed. Since 1850, however, the foundations at least of sounder knowledge have been laid by the labours of men of an eminently scientific turn of mind, of whom Brongniart, Salvétat, and Seger must be regarded as the chief. These men and their disciples have examined not only all modern materials and methods, but those of the past as well; and as their researches have been published, they have had the most direct influence on the work of the practical potters of every country. The bodies (clay mixtures), glazes, and colours of the older forms of pottery, Persian and Rhodian faience, Italian majolica, Hispano-Moresque ware, Chinese porcelain, are no longer forgotten secrets or "lost arts"; they are, or may be, as well known as the bodies, colours, and glazes of the most everyday pottery produced in Staffordshire or Delft. Neither is the potter any longer dependent on the materials or the technical methods found in his own particular district: he has the materials and the knowledge of a continent at his disposal; and the science of his craft has been so far reduced to system, that he can readily produce a hundred varieties of ware, running through all the range of earthenware, stoneware, and porcelain, with a higher degree of technical accomplishment in each than his fellow of a previous century would have attained in one kind alone.

This remarkable growth and concentration of accurate knowledge regarding the chemical laws underlying the composition of the different materials used by potters, as well as their behaviour, singly and in combination, when exposed to varying temperatures and conditions of the kiln, have been accompanied by changes almost as important in the mechanical methods of mixing and purifying the materials, forming the clay articles into shape, and supporting them during the firing, so that even the commonest wares are now produced with a degree of certainty, accuracy, and finish formerly undreamt of. The extended modern use of articles made from clay for the construction and decoration of buildings, for lavatories and other sanitary appliances, and for the technical work of the chemist, the distiller, and the electrician, has only become possible because of this advance in precise knowledge. Admirable and entirely useful as this development of the technical side of pottery has been, the fear has often been expressed by persons qualified to judge, that progress in this direction would inevitably destroy the artistic qualities which have in the past been such a precious possession of the potter's productions. The first results of the changed conditions were undoubtedly depressing from the artistic point of view. Certainty of result, precision and finish of manufacture, together with mechanical imitation of well-known effects, seemed to result in the production only of wares the merits of which were in the sharpest contrast with all that made the old pottery artistically admirable.

The development of scientific and mechanical knowledge and skill has brought with it a much juster appreciation of the familiar qualities and possibilities of different substances and processes. The success achieved by Deck and De Morgan in adapting the principles of the Persian, Cantigalli those of the Italian Cinque-cento, and Copenhagen those of the Japanese pot painter, compared with Wedgwood's reproduction of classic pottery or Dresden imitation of Chinese porcelain, proves that vital progress has been made. The present position is one of development and change, even more so than at any previous period in the history of the art. Pottery is now being made in all the leading European states, and in some states of the American Union, possessing a high degree of technical excellence, and in such a variety of forms as all the previous centuries combined have not produced. The great bulk of this production is frankly utilitarian, either making no pretence of art, or manifesting such debased and mechanical ideas of it as to be infinitely more objectionable. In every country, however, there is a general endeavour to infuse a spirit of art into modern production, manifesting itself in two distinct ways—first, in the efforts of the large commercial firms to make some portion of their productions as artistic as may be under their methods of working; and, secondly, by the labours of a number of individual artist potters, caring for the artistic side of their work above everything, and by their example influencing the large manufacturers. As an actual result, the potter's art is full of vitality; more alive and more energetic, indeed, than at any time since the rise of the china factories of the 18th century, while the variety of uses to which pottery is being put shows that, through all the changes of fashion and of taste, pottery holds its own in popular favour and appreciation.

Among modern wares of considerable technical interest, mention must be made of the fine semi-porcelains produced in Staffordshire, in which the ordinary English earthenware body has been pushed to its utmost limits. The ware is thin, light, beautifully potted, and of the utmost durability. Sanitary appliances, electric fittings, door furniture, and wall tiles are also produced with almost the same high degree of technical excellence. The tendency to use some finer form of pottery than ordinary brickwork for the construction or embellishment of buildings, has brought about a great extension of the manufacture of architectural terra-cotta, faience, and stonewares. For all such purposes the hard-fired varieties are undoubtedly best fitted; and while the colours obtainable in terra-cotta or in faience are the more brilliant, the once-fired stonewares have greater durability. In Germany and France this use of pottery has made even greater advances than in the United Kingdom. On the Continent the material has been considered more sympathetically; in England it is too often apparent that a design originally intended for stone construction has been executed unaltered in the plastic material.

Turning to the decorative side of pottery work, we have in *slip-painting* a method as old as primitive pottery itself, the practice of which persists in a variety of forms and on wares of every class. The work produced in Germany under the influence of Professor Laüger merits notice. It is simple and direct, almost brutal, in method; splashes of red, blue, or green clay, touched into shape by a brush or a modelling tool, on a ground of white, buff, or red; making no pretence but of directness and simplicity, and interesting only from the frankness of the work and the brightness and richness of the colour. At the opposite extreme in this method is the *pâte-sur-pâte*, first produced at Sèvres, but best known in connexion with M. L. Solon of Mintons'. Here material and method have been refined to their utmost. The clays used are of translucent china, white or delicately tinted for the raised ornament, and strongly tinted in brown, dark green, or celadon for the grounds. The ornament, largely figure work, is got by laying on successive layers of slip with a brush, with modelling when required to soften or define, as the case may be, much as an artist would work in gesso. When the work is finished and glazed with a rich glaze, the effect is like cameo work of the finest kind, but with a breadth and softness peculiarly its own. M. Taxil Doat, of Sèvres, has also done much excellent work by this method; and by superposing clays of different colours on the ground, he has obtained richly broken colour in an effective manner.

Apart from the production of stonewares for architectural and technical purposes, there has been a notable development of stonewares for jars, vases, and ornamental objects generally. Doultons undoubtedly led the way in this revival, and, under the direction of Mr John C. Sparkes, produced the Lambeth stonewares, which in their low key of greys and blues were admirably decorative, and formed a distinct advance on the stonewares of Germany and Flanders. It is on the Continent, and particularly in France, however, that one finds *grès* turned to the best account. A number of men, like Delaherche, Lachenal, Dalpayrat, as well as Taxil Doat and Chaplet, inspired obviously by the hard-fired unglazed wares of the Japanese, but showing an intimate knowledge and appreciation of their material, which stamps them at once as potters and as artists, are now working on stonewares. In the hands of one of these men the material is neither hidden out of sight nor exalted to vulgarity, but shows its qualities of texture, surface, colour, and plasticity perfectly yet quietly. Fine work has also been produced by such firms as Émile Muller, Bigot & Co., but in their case the results are often disfigured by unnecessary coarseness of execution.

Among the new departures that are being turned to artistic account, one of the most interesting is that of *crystalline glazes.* The first of these in point of time was the so-called "cat's-eye" or "tiger-eye" glazes produced by the Rookwood pottery in America. In this case the glaze is full of small metallic-looking spangles, which give it an appearance like the mineral known as "aventurine." The glazes produced at Rookwood are all very deep in colour, and are only obtained on a red body. In England, Pilkingtons have produced a series of glazes, yellow, brown, and green, all possessing the same appearance of gold-coloured spangles in the glaze; but, unlike Rookwood, they can produce the effect on any earthenware or china body. Totally different are the crystalline glazes produced by the Royal Copenhagen Works, and now also made at Sèvres, Berlin, Meissen, Rörstrand, and elsewhere. Here the crystallization generally occurs in radiating or star-like masses, apparently on the surface of the glaze, sometimes beautifully coloured blue, grey, yellow, or brown, but otherwise resembling the patterns formed by frost on a window-pane. These effects are always quasi-accidental, and only partially under the control of the potter. Occasionally they take the form of blobs and patches on the glaze which are positively unpleasant; but when the star-like forms are well developed and fairly disposed over the surface of the piece, the effect is magical.

About 1870, William De Morgan in England, and Cantigalli of Florence, rediscovered the method of producing iridescent lustres from copper and silver fired on the glaze in a reducing atmosphere, which had been so largely practised during the Middle Ages by the Persian potters, the Moors in Spain, and the Italian majolica potters. Since that time the production of this *reflet métallique* has been greatly extended. In the hands of Clément Massier in France most vivid effects of iridescence have been produced, apparently in many cases by acting on the glaze itself with reducing gases at high temperature. Zsolnay, of Fünfkirchen in Hungary, has produced a pottery decoration in which minute patterning of silver lustre is produced on a ground of dark copper or other metallic lustre. The patterns, which are often of the most intricate character, are evidently inspired by every phase of Oriental design, from ancient Assyrian downwards; but the effect is novel, rich, and in the best pieces subdued. The best lustre work, however, has been done, and already the vulgarization of the process has set in by the development of the cruder shades of colour from which the earlier work was free.

From time to time European potters receive fresh inspiration from the East. Reference has already been made to the influence of the Japanese potters on the production of *grès* in France. This influence is equally felt in the modern painted porcelains of the Royal Copenhagen Works, and in the somewhat similar effects obtained at Rörstrand and by the Rookwood Company. In the last case a Japanese artist was brought to the works for that specific purpose. Though the delicate underglaze painting on hard-fired porcelain of Copenhagen and Rörstrand owes its inception to this foreign influence, it proceeds on its own lines, and is far from being a slavish imitation. The temperature of firing having fixed a palette in which blue and some greyish or drabbish tones predominate, the artists have wisely adapted their painting to this, and have made the utmost of their available colour scheme. The rich glazes of the Oriental potter have also formed a point of departure for another set of potters. Deck in France, and afterwards Minton, Maw, De Morgan, and Moore in England, produced brilliant turquoise blue and violet glazes rivalling the Persian and Chinese. Even the long-sought secret of the Chinese *sang de bœuf* and *rouge flambé* glazes has been worked out in Europe. Salvétat in France and Seger in Germany analysed specimens of Chinese glazes, and synthesized the glaze from its elements. Chaplet in France and Bernard Moore in England produced pieces independently; and *flambé* glazes are now being produced by many potters in Europe on every kind of pottery ware, and with every variety of surface, from the driest and most opaque to the brightest and most transparent.

Within the last ten years of the 19th century, a certain reaction set in against the brilliant glazes in ordinary use, and potters began to produce glazes with a dull or egg-shell surface. In some cases this effect was apparently obtained by dulling the surface of an ordinary glaze by vapours of hydrofluoric acid or by the sand-blast, but in the best of them the effect was actually due to the nature of the glaze, which fired only to a dull vitreous surface. (For Japanese Keramics, see JAPAN.)

(W. B*.)

Pottstown, a borough of Montgomery county, Pennsylvania, U.S.A., on the Schuylkill river, at the intersection of branches of the Pennsylvania and the Philadelphia and Reading railways, in the south-eastern part of the state, at an altitude of 138 feet. Its industries consist chiefly in iron and steel manufacture, for which there are blast furnaces, rolling mills, bridge works, nail mills, and boiler works. Population (1890), 13,285; (1900), 13,696, of whom 802 were foreign-born and 292 negroes.

Pottsville, a borough of Pennsylvania, U.S.A., capital of Schuylkill county, on the Schuylkill river, in the eastern part of the state, at an altitude of 611 feet. The street plan is irregular, it is divided into seven wards, has a steam heating plant, and its water supply, obtained by gravity, is owned by private parties. It is on four railways, the Lehigh Valley, the Pennsylvania, the People's, and the Philadelphia and Reading. It is situated within the anthracite coal region, and is one of the principal coal-shipping points. Population (1890), 14,117; (1900), 15,710, of whom 1652 were foreign-born and 168 negroes.

Poughkeepsie, a city of New York, U.S.A., capital of Dutchess county, on the eastern bank of the Hudson river, 73 miles north of New York, in the south-eastern part of the state, at an altitude of 42 feet. Its street plan is irregular, it is divided into seven wards, and its water supply, derived from the Hudson, is pumped and filtered. It has four railways, the New York Central and Hudson River, the Poughkeepsie and Eastern, the West Shore (by ferry), and the Central New England. The latter road crosses the Hudson here by a fine cantilever bridge. The city is of importance in manufactures. In 1900 it contained 377 manufacturing establishments, with a total capital of $5,688,058; the hands numbered 3432, and the products were valued at $6,826,769. Among the principal articles of manufacture were clothing and iron and steel goods. Vassar College for women, situated 2 miles east of the city, had in 1900 a faculty of 64, and was attended by 700 students. In 1899 its property was valued at nearly $2,268,805, and its income was $319,957. Population (1890), 22,206; (1900), 24,029, of whom 3998 were foreign-born and 623 negroes.

Poulton-le-Sands. See MORECAMBE.

Poultry and Poultry-farming.—The later years of the 19th century witnessed a very great development in poultry-breeding, which could scarcely have been foreseen, and which in some of its aspects has contradicted opinions that had been more or less generally expressed during a period of less experience and knowledge. The broad result is that poultry-culture in one form or another has become a really important industry both in Europe and America, one in which much capital is invested, and the returns from which form a considerable item in national food and wealth.

Poultry Shows and Prize Poultry.—During the last ten years of the 19th century especially, the number of poultry exhibitions multiplied to such an extent that as many as twenty shows have been criticized in print in one week in Great Britain during the height of the season. Such a ceaseless round of competition has increased the money value of prize fowls, and created a large class—almost a profession—who have considerable pecuniary interests embarked in breeding and exhibiting such birds. This professionalism, and the interests at stake, have in turn naturally given rise to many proceedings of doubtful character, which it has been found needful to keep in check by an organization known as the Poultry Club. An enormous multiplication of varieties is another phase of this development, nearly all breeds having had their older subdivisions supplemented by new colours, produced through crossing and skilful selection, amidst which buff or orange, now bred in nearly all fowls, has had a curious popularity. There may also be mentioned the fact that whilst formerly the diminutive Bantams were confined to a few well-marked varieties, all the large breeds of poultry have now been dwarfed into Bantam size by the skill of breeders. To enter farther into this branch of the subject is beyond the scope of the present article, but it may be interesting to state that at a public auction in 1901 one prize fowl was knocked down to a *bonâ-fide* purchaser at the sum of £150.

Breeds.—Not only have many additions been made, either by discovery or manufacture, to the breeds known in 1880, but considerable changes have taken place in their relative importance, in some of which a principle of substitution can be traced. The unfortunate exaggeration of fluff and leg-feather has removed all Cochins—it is to be feared permanently—from amongst popular and useful breeds, and in only less degree the Brahma, once the most popular breed of the day. On the other hand, new sub-breeds, based upon a cross from one or the other of the Asiatic races, have been multiplied and largely bred, these being all of smooth-legged type, and somewhat less in size. To the original cuckoo-coloured Plymouth Rock have been added buff and white varieties; and by crossing Cochins and Brahmas with other fowls, American breeders produced another useful race of compact form with smooth yellow legs, and white feathers laced with black round the edges, called the silver-laced Wyandotte, to which were speedily added other colours and patterns of plumage. The feathered Langshan has given rise to the Black Orpington with smooth legs; and a local cross of Cochin and Dorking prevalent in Lincolnshire, to a buff breed with smooth white legs, now called the Buff Orpington, though quite unrelated to the former. All these are useful for table, and good layers. Among non-sitting breeds the white-faced Black Spanish, once the most widely kept, has almost disappeared; but the allied red-faced Minorca and the blue Andalusian have achieved great popularity as free layers of large white eggs; and the yellow-legged Leghorns of similar type, though rather smaller, have spread on all sides with much multiplication of varieties, the latest of which, with mottled black and white plumage, is termed the Ancona. Hamburghs have been depressed by the complicated system of breeding separate strains for each sex; but there has been introduced from the Continent the hardy Campine or Braekel, resembling the pencilled Hamburgh in plumage, but larger and with a single comb, and laying a large egg in great numbers. The older French breeds are less kept than formerly; but a race originated in France by crossing Houdans with Dorkings and Light Brahmas, and known as the Faverolles, is taking a strong position as a tender and quick-growing table fowl, and even in the Houdan district itself is displacing the Houdan, one of its ancestors. The Faverolles have single upright combs, beards and whiskers, slightly feathered legs, and five toes on each foot; and the general colour of the hen is salmon or fawn, with an almost white breast. This list might be extended, but must close with the supersession of the stilty exhibition Game fowl by the old and genuine type of English Game.

Most of these changes, broadly speaking, have been in the direction of replacing poultry with chiefly fancy points by really *useful* fowls, yet it is noteworthy that they have been carried out by fanciers, or breeders for exhibition, proving that there has not been that practical antagonism between the aims of these breeders and the production of food which some have alleged. But there has further been, since 1890 especially, a remarkable development of what has been termed "utility" poultry-breeding. It had always been taught by a few, but was only grasped later by the many, that a fowl could be bred with as much certainty for tender and juicy flesh, or great number of eggs laid in a year, as for some colour of feather, and without losing any real features of its race. Many varieties are now bred, and advertised and sold as being bred, for these objects; and thus the stock kept up by the fancy breeders is gradually becoming spread amongst farmers, to their marked advantage where properly used.

Feeding and Egg-production.—These aspects of poultry-culture are closely connected, and in both such advances have been made as almost amount to a revolution. As will appear natural if the enormous poultry interest in America is considered, in these matters the breeders of the United States have led the way, and, though it had first been taught in England, were the first to practise generally the systematic breeding, year after year, from the best layers only. It had always been known that some hens would lay from 150 to 200 eggs in a year, whilst many did not exceed 100, and some laid much less. This was tested (on a better stock than the average) at the Maine Experimental Station in 1898–99, 260 pullets being selected, of which 5 died and 19 were stolen. Of the remainder, 39 laid 160 eggs each or more, and 22 less than 100, the rest coming between these figures; the five best laid 200, 201, 204, 206, and 208 eggs in twelve months, and the three worst only 36, 37, and 38 in the same time. From such figures the money value of selective breeding is apparent. In England, those who practise it usually secure the better layers by selecting those which lay early in the season, or early in the day, or are first down from the perch in the morning; in America trap-nests have been used, which automatically confine the laying hen till she is released and her number or mark registered. As a proof of what may be done by systematic breeding, one American breeder obtained an average of 196 eggs per annum from as many as 600 White Leghorns, and another 194 eggs from 140 Plymouth Rocks: greater numbers have been obtained from single birds or small pens of fowls, but these are results from considerable flocks.

It has been proved, however, that such averages as these cannot be obtained unless they are fed for as well as bred for. Such an enormous production of albuminoids can only come from adequate supplies; while, on the other hand, such supplies as would be profitably turned into eggs by a prolific layer would only produce fat, or hypertrophy, or disease in a poor layer. The most successful egg-farmers now feed their poultry on definite "rations," compounded so as to give what is termed a proper "nutritive ratio," or proportion of albuminoids to carbonaceous material. The basis of such feeding is analysis of food-stuffs, in some form which shows simply their percentages of albuminoids, fats or hydro-carbons, carbohydrates (starch, sugar, &c.), salts, crude husk or fibre, and water. Fats being relatively much richer in carbon than the starch compounds, are generally multiplied by 2·25, and this product added instead to the carbohydrates; then the ratio of albuminoids or nitrogenous matter to this total of carbonaceous compounds is the "nutritive ratio." The following is a useful table of analyses made out in this way, taken from *The Book of Poultry* :—

Analyses of Poultry Foods.

Articles of Food.	Albuminoids or Flesh-formers.	Fats or Oils.	Fats × 2¼ = Value in Carbohydrates.	Carbohydrates.	Salts and Minerals.	Husk or Fibre.	Water.
Grains and Meals.							
Linseed Meal . .	32·9	7·9	=17·8	35·4	5·7	8·9	9·2

,, (white only) .	12·0	2·0	= 4·5	0·0	1·2	0·0	84·8

A glance will show how greatly various foods differ in their nutritive ratio, what variety of composition is therefore possible, and that if we wish for cheapness to use some food of low ratio, it must be "balanced" by some other whose ratio is high.

Many writers have introduced unnecessary complication into a very simple matter. Some elaborately compute the amount of "dry matter," which is needless if our analyses show the proportion of water, as above. Others have calculated "digestibility," on the theory that food not rejected as excrement is "retained in the body." This theory has a basis in the case of animals which consume a large amount of hard indigestible fibre, excreted in such a form as horse manure; but fowls macerate all they eat in the crop, and grind it in the gizzard, and in their case the excreta represent very little undigested food, but mainly the final result of the vital processes, and of food usefully employed in carrying these on. We may be sure that we more than allow for any factor of indigestibility if we merely leave out any crude husk or fibre, giving that to the fowl for whatever it is worth, and calculate our ratio direct from the figures of the table.

Two extremely simple cases will suffice as examples of the modern method. Potatoes are often cheap, but on account of their starchy composition require a "balance," and the same may be said of maize: one method of balancing each will show what is meant, and the simplicity of the calculation. We will take potatoes and bran first :—

Ratio of Potatoes and Bran.

	Albuminoids.	Fat × 2¼.	Carbohydrates.	Salts.
1 lb Potatoes . .	6·5	0·0	41·0	2·0
1 lb Bran . . .	15·5	9·0	44·0	6·0
	22·0	9·0	85·0 +9·0	8·0
			94·0	

Adding here the fats × 2¼ to the carbohydrates, we get the ratio of the mixture as 22 : 94, or about 1 : 4¼, which is very good. Coming next to the maize, let us suppose that it is desired to feed this as grain in the evening, and to "balance" it by an equal weight of "mash" or soft mixture in the morning. One way would be as follows :—

A Diet containing Maize.

	Albuminoids.	Fat × 2¼.	Carbohydrates.	Salts.
3 lb Maize (× 3) .	31·5	54·0	199·5	4·5
1 lb Horse-flesh . .	21·7	5·8	0·0	1·0
2 lb Ground Oats (× 2)	30·0	24·8	96·0	5·0
	83·2	84·6	295·5 +84·6	10·5
			380·1	

This ration explains how in such a case we must multiply the figures for maize by 3, and those for oats by 2, being the proportions we are taking to one portion of horse-flesh. The ratio of this dietary comes out slightly lower than 1 : 4½.

The proper ratio for feeding fowls has received much discussion. Dietetic authorities mostly agree that about 1 : 5 is the best for maintenance of animal life generally, and more specifically that there should be of albuminoids about 18 parts in 100, of fats 7, and carbohydrates 75. That should suffice for growing chickens; but it is fairly obvious that fowls fattening may require more fat, while the constant production of eggs, whose high ratio is shown in the analyses, must require a larger amount of albuminoids. This fact is indicated by the hen herself, which when laying devours large earthworms, usually rejected with disgust at other times. She shows by this appetite how specially she needs albumen; and fowls on a wide range, though only fed with corn, may thus in summer "balance" a dietary for themselves by the worms and insects which they procure. When they cannot do this, more albumen must be supplied, and the general opinion of practical egg-farmers has tended towards a ratio of 1 : 4 or 1 : $4\frac{1}{4}$ for hens in full lay. One successful American breeder feeds as high as 1 : 3, and states that his results have been best at that figure.

Passing from theory, the greatest practical advance in poultry-feeding has probably been the discovery of the benefit to be derived from dividing the extra supply of albumen between fresh bones cut up small in a mill (known amongst breeders as "cut bone") and such green food as clover or cabbage. The bones, it will be seen, contain a good proportion of fat, and of mineral salts also, which careful experiments have shown to be of great importance both in egg-production and for growing stock. Green food had until recently been looked upon chiefly as a corrective, or necessity for health, though it was known that fowls on a pasture grazed largely. But the nutritive ratio of clover is as high as 1 : 3, and American poultry-farmers now use it largely as really albuminous food, to promote laying. Its use in this way also allows more animal food to be used without ill effect; and to this free use of clover and cut bone in conjunction the improved results upon American egg-farms are largely due. So beneficial is this combination found, that for winter use clover-hay is cut up small, or ground into "clover-meal," to be used in the same way, being generally mixed with boiling water in the other soft food at night, and kept covered to cook or soak until the morning. The following is the "mash" ration on a successful American egg-farm, and represents a high forcing diet: middlings or sharps 100 ℔, maize-meal 75 ℔, gluten-meal (a highly nitrogenous bye-product of American flour-milling) 25 ℔, clover-meal 80 ℔, meat meal 35 ℔; all weighed dry, mixed with boiling water in the evening, and kept covered all night.

This introduces another practical question. The majority of poultry-farmers give their stock each day one feed of grain, and one of soft meal-food or "mash," but by no means agree as to the times for these meals. In England, morning mash and evening grain are almost universal, the latter giving more support during the long fast at night, and the former more rapid recuperation on cold mornings. But in America and Canada, where the climate compels confinement of the fowls for months together in enclosed sheds, health and eggs can only be secured by constant "scratching," to promote which the grain is scattered amongst loose litter spread several inches deep. Many, therefore, prefer to scatter the grain in the morning and feed the mash at night, alleging that a good breakfast of mash makes the fowls lazy, with bad results. Others state that this is avoided by a rather scantier morning feed of mash, with a slight sprinkle of grain in the litter afterwards. In 1890 a careful experiment was made by the Massachusetts Agricultural College, two similar lots of pullets being fed upon similar food, on the two plans, for two periods of several months each, in summer and winter seasons, and each lot receiving, besides the morning and evening feeds, a slight sprinkle of millet in the litter, to promote exercise. In egg-production there was scarcely any difference, what little there was being in favour of the morning mash; and the birds thus fed became also somewhat the heaviest. The most remarkable result was that the weight of manure voided in the night was nearly double in the case of the evening-mash birds, showing the rapid digestion of mash food. This might have been expected; and in some cases the transference of so much weight of manure from day to night deposit might be found convenient.

Artificial Incubation and Rearing.—In this department immense progress has been made, which has created practically new industries. None of the incubators in use about 1875 has survived; but it is known now that while some of them failed from insufficient regulation of temperature, and others from want of a proper balance between ventilation and moisture, the cause of failure in most cases was lack of practical knowledge, and that some of them would give very good results in the hands of present operators. The incubators now used are of two distinct types, and it is noteworthy that British practice so far has mainly adopted one, while the best recent American practice prefers the other.

In what may be called the "tank" system, the heat from a lamp is led through flues traversing a tank of water which forms the upper side of the egg-chamber. Most usually the lamp has a vertical chimney, closed at the top by a valve rising or falling at one end of a lever, while the tank flue issues from one side of this chimney: then if the valve be raised, more heat passes directly into the outer air, and less through the tank, and so the temperature is lowered; while conversely, if the valve sinks, more heat is diverted through the tank, and its temperature is raised. The valve-lever is in Europe generally actuated by a thermostat invented by Mr C. Hearson, and known as the "capsule" regulator, which consists of two flat plates of thin brass soldered together round their edges. Between them is introduced a drop or two of ether, so diluted as to boil at a suitable temperature, after which the capsule is sealed. When the given temperature is exceeded, the ether vaporizes, and the bulging of the plates is easily made to work the valve-lever. Boiling-point being affected by pressure, it is only necessary to apply an adjustable weight to the rod resting on the capsule to alter the point at which the valve shall open, and thus all is easily controlled. This form of regulator, and all others which depend upon vaporization of a liquid, have, however, the serious defect that the boiling-point differs also with atmospheric pressure, to the extent in this case of about 2° F. for every inch of barometer; hence in England, where the barometer often varies as much as $1\frac{1}{2}$ inch and sometimes 2 inches, this kind of thermostat may vary the heat as much as 3° or 4° F., quite independently of the real necessities of temperature in the egg-chamber. Machines of this kind, therefore, require constant adjustment for rise or fall in the barometer.

In most British machines of this class, the eggs are laid in a drawer with perforated bottom, and the air enters below this, passing on the way either over an open tray of cold water or through cloths dipping in such a tray; it then passes through the perforated bottom of the drawer and between the eggs, escaping through holes round the upper part of the chamber, which is thus ventilated and supplied with fresh moist air. The chief point in regard to success, next to a proper uniform temperature and regular turning of the eggs, is a proper balance of ventilation and moisture. The chick ought at the end of the period to occupy about four-fifths of the shell, the other fifth being vacant. If too much moisture be supplied, the egg is too full and the chick perishes; while, on the other hand, if the egg is too much dried out by too great air-current without enough moisture, the fatal result equally follows in another way. Eggs are always tested at the end of five or six days, and unfertile ones withdrawn; as are any which perish later.

The other class of incubators, more general in America, is known as the hot-air or atmospheric type. In such machines there is no water-tank, but air heated by the lamp passes more or less directly into the egg-chamber, in different ways which cannot be described in detail here. This mode of heating is found more economical in oil, which in large establishments becomes of importance; and it is also more sensitive to outer changes of temperature, and responds more quickly to any regulation; but for that very reason it requires more efficient thermostats, and especially such as are not affected by the state of the barometer. The hot-air incubators of America are almost universally regulated by compound thermostatic bars of metal, which operate subject to temperature alone, and the best of which will keep the heat uniform within about half a degree.

Even in England the eggs hatched in incubators now probably equal, or nearly equal, those hatched under hens: in America the wide practice of artificial incubation is difficult to realize. Of small-sized machines one Illinois maker sold 14,800 in the year 1899; and in regard to large sizes, in 1900 at least seven names and addresses were known of operators who each used from 55 to as many as 85 machines, every machine holding 300 or more eggs: somewhat smaller plants were of course far more numerous. Experience on such a vast scale has led to a practical advance of considerable importance. While in England it is still usual to effect empirical adjustment of ventilation and moisture as above indicated, the better American incubators now dispense with direct moisture altogether. It was remembered that the hen hatches without moisture, and equally so the egg-ovens of Egypt; the absence of direct air-current, and consequently of any rapid evaporation, being the obvious explanation. The manufacturers therefore set themselves to slow the movement of the air; and when this object was effectually accomplished, it was found that there was no need for moisture, and that the chicks also hatched out stronger and in higher proportion. The general opinion in the United States, where many farmers tested both hens and machines on a large scale, whilst still undecided between them, is that the proceeds of artificial incubation are superior by about 10 per cent., and this is based upon hatches of thousands annually.

Artificial hatching necessitates artificial brooding, and in this also great changes have taken place, any real success in rearing having been for some years far behind that in hatching. The method universally attempted at first might be called the "coverlet" system, nestling material such as strips of flannel or wool, warmed from above, being provided for the chicks to nestle under, as they do under the feathers of the hen. Many were reared in this way, but failures were also terribly general, and these were ultimately traced to confinement and pollution and heating and rebreathing of the air, caused by the nestling material. That system is now abandoned, warmed but open chambers being provided, which the chicks use at pleasure, but which have no coverlet to rest upon their bodies. In some, heated pipes traverse the upper part of the chamber, some inches above the chicks; in others a warm iron plate radiates heat in the same way; in others warmed air is brought in by flues or openings; in some small ones the lamp itself burns in the chamber of the brooder: but the principle is common to all of a warmed shelter, open above, and generally with an outer chamber also, sheltered but not heated, which breaks the transition to the open air outside. In America a very large proportion of the chickens reared are brought up till hardy in the large brooder-houses mentioned below.

Poultry-farming.—The advances here described have brought poultry into greater prominence as an industry, and poultry-farming in a practical sense is now carried on somewhat extensively in various ways, understanding that term to include any case where poultry-culture is carried on for substantial profit, or as an important interest of the holding, beyond the mere breeding of prize birds for exhibition. The difficulty never had been, as some have stated, in ground getting tainted or rent costing too much. It is now well understood that in the English climate 100 birds per acre must not be exceeded, though it is far better to confine them to one-half or one-third of the space, while some crop is got off the remainder when they go yearly to absolutely fresh ground. The mere rent of an acre is not much for 100 fowls, but the real difficulty was and is that a fowl is such a *small* unit, entailing constant liability to small losses and wastes, and necessity for labour and oversight out of proportion. Hence at a time when 100 eggs per annum was thought a fair return for each bird, and there was but a poor and uncertain market for them, this difficulty was insuperable. A very different average production would now be worked for; while, on the other hand, the greater crowding into cities, and growing appreciation of eggs as an article of diet, have caused a market for "new-laid" eggs at good prices, which previously did not exist. It is these changes which have altered the conditions.

The chief development in England at the beginning of the 20th century was a very large increase in the poultry kept upon farms. Formerly very few were kept, looked after casually by the mistress or a boy, and only expected to provide for the household and occasionally a few shillings in cash, while any food expressly fed to them was grudged. It has now been taught all over the country, by lecturers under the County Council Technical Instruction Committees, that poultry pay best of any branch upon a farm. It has become generally known that, provided they can be run over the farm by using detached houses, and not huddled together, a dozen hens per acre can be kept upon a holding without interfering with any other stock; indeed, the curious fact is observed that horses and cattle prefer to graze over grass that might be thought soiled by the fowls. Where the statement was once derided, it is now a commonplace of County Council lecturers, that the additional manure thus made is really worth to the farm from sixpence per bird per annum for small breeds to as much as one shilling for very large ones. Out of a large number of similar instances collected in 1900, two specimens may be given. In Worcestershire 210 fowls had the run of 100 acres, lots of 20 to 30 being kept in detached houses. From 20,000 to 25,000 eggs per annum were marketed, and 150 to 200 chickens, the food averaging about £40, and the cash return £90 to £100. In Leicestershire, on part of a holding of 500 acres, 372 hens had in 1898 produced a profit of £100; the following year, owing to illness and consequent lack of oversight, 440 only paid a profit of £92. The almost universal opinion is that the manure pays for the labour, and that the annual profit averages from 4s. to 5s. 6d. per head. It has been estimated by many different observers that the number of poultry kept in Great Britain on farms is now probably five times as large as it was in 1875: in some districts "ten times as many" have been reported, but such are exceptional.

Poultry-farming on a larger scale than this is also carried on in connexion with the Sussex fattening industry, presently described. That was until recently a separate business, chickens being bought from neighbouring small rearers, or imported from Ireland, to go directly into fattening cages; and it has often been stated that rearing and fattening together were incompatible. This was so far true that the manure made by numbers of fattening poultry was very considerable, and had to be used upon a small holding kept in order to use it; such a holding, therefore, received as much as it could possibly bear, and was thereby "sickened" for live poultry running at large. But with an extra holding or larger holding this is not the case, and increasing competition and the desire for the two profits have led to a large amount of rearing and fattening combined. In 1894 one of the officers of the Agricultural Commission found 8000 chickens being reared and fattened annually on one farm of 200 acres, and this proved only a pioneer: in 1900 he found (amongst many such instances) 4000 reared upon 80 acres, 1500 upon 22 acres, and 5000 upon an extra holding (taken for the purpose) of 40 acres. In most cases the main cereal crop was oats, to be fed to the fowls; and some cows were kept, the skim milk from which was used in the same way; but the poultry was the controlling interest of the whole.

On any such scale as this the manure becomes of great importance, and the manner in which the compulsory use of large quantities has taught Sussex farmers its value is interesting. Of course there is no uncertainty about the value of manures, and about 1880 the late Dr Augustus Voelcker, chemist to the Royal Agricultural Society, made the following analysis of two samples, one moist or fresh dropped, the other freed from much moisture by storing under cover for four weeks:—

	Fresh Manure.	Partially Dried Manure.
Moisture	61·63	41·06
Organic matter and ammonia salts	20·19	38·19
Tribasic phosphate of lime	2·97	5·13
Magnesia, alkaline salts, &c.	2·63	3·13
Insoluble silicious matter (sand)	12·58	12·49
	100·00	100·00
Containing nitrogen	1·71	3·78
Equal to ammonia	2·09	4·59

Valued in the usual way, Dr Voelcker found that the moist manure was worth £2 per ton, and the drier stored manure £4 4s. per ton; but though the figures were indisputable, for many years such manure was practically unsaleable. Gradually in Sussex it became saleable at 6d. per bushel, and in 1900 some of the smaller fatters were selling it at prices varying from 4s. to 15s. per load; the larger men either used it themselves or obtained higher prices. In one district this manure was to be found in railway trucks, purchased for the growing of grapes and tomatoes under glass; and one fatter in a fairly large way, who once sold his at £2 10s. per ton for this purpose, having lost his market to some competitor, had put up a number of glass-houses and was using it himself for tomato culture. Others utilize it mainly for hay, the effect upon scrubby land being remarkable. Off one holding of 123 acres, some portion of which was wood and coppice, and the whole worn out when entered upon, the owner had sold nothing for several years but poultry products and hay: of the former, 8700 chickens had been marketed in one season, and of hay 90 tons had been cut, worth about £3 5s. per ton.

Really large poultry-farms are few in England, and it is difficult to state any recent facts without some risk that they may prove ephemeral; but a few existed at the end of 1900 which had by no means failed after two years, as some allege to be invariably the case. Two in Berkshire were selling eggs from over 2000 and 3000 laying hens; and there was one farm in the West of England, occupying 300 acres with the poultry (besides a shorthorn herd and some other branches), which had a stock of 5000 pullets for laying, and had been in existence four years, a large capital amounting to thousands of pounds having been sunk in it. The owner explained that two years was the critical period, simply because for about that time there were practically no returns, and that in his case he had only "turned the corner" after three years. Though a practical man already, he had begun in a small way with one incubator and training one man; gradually extending, building up his own market, organizing his own selling agency, and building a mill to grind his own grain. Only such gradual extension by practical men can ever lead to success: what people term "embarking" in poultry-farming can only end in ruinous failure. One reason is the error of supposing that buyers are waiting at a certain price for any new supply: the new-comer has to creep in, and find out for himself how to bring his supply and a profitable demand together. Unless this is done gradually, there is heavy loss, and while it is being done there is little return. The egg-farmer, again, has to breed up his own laying stock, as above indicated. And, finally, the business is terribly exacting: there is no rest, no holiday, no relief; intermission of labour and care for a few hours means loss or disaster, and paid oversight that will avoid this is both expensive and difficult to find.

Besides the breeding of prize poultry, which need not be discussed here, but which is remunerative enough to a certain number of persons who possess the necessary peculiar qualifications, the changes mentioned in the early portion of this article have led to another class of breeding directed to the supply of pure races from good stock, but bred mainly for purposes of utility. The demand for such stock, at fair prices, though far below those for prize stock, is a good index of the development of the poultry industry. The establishments which supply it furnish eggs for hatching, or stock birds, or newly-hatched chickens, which are now hatched in incubators and sold by thousands when only one day old, at which age they travel without needing food. Some of such establishments are quite large. One in Yorkshire occupies 43 acres solely devoted to this business. In 1900 there were on the farm about 100 breeding-pens of poultry, confined by 6½ miles of wire-fencing. The few waste eggs sold for market realized about £100; over 4000 sittings of eggs for hatching were sold, and about 1500 stock birds. This farm had then been carried on for ten years, and was purchased out of the proceeds of another held previously; but the business qualifications which could build up such an establishment must always be rare.

Poultry-farming has reached its fullest development in the United States, owing no doubt to the apparently inexhaustible market; butcher's meat being far less eaten than in England, and poultry and eggs to a large extent replacing it as national food. More especially is there an enormous demand for small chickens, known as "broilers," weighing from 1½ lb to 2 lb only, destined to be split in half and broiled on a gridiron. These birds being unfattened, and ready at ten or twelve weeks, give a quick turnover with less expense and risk than older fatted birds; and this peculiar demand has largely dominated American poultry-farming, a great deal of which runs in the direction of great "broiler-plants" solely devoted to the hatching and rearing of these broilers, while large "brooder-houses," similar to those used in that business, are prevalent on more miscellaneous farms. The broiler business started at Hammonton in New Jersey about 1880–85, when plant after plant was rapidly erected, some of which have since shut down; but many others have taken their place, and some of the originals are still running. The chicks are all hatched in incubators (many plants running from 20 to 40 machines), and then transferred to long "brooder-houses," built with a corridor all along one side, the rest being divided into successive pens for the chickens. These latter are moved along every few days to the next of the pens, which are arranged so as to give rather more space as the birds grow larger. Each pen has next the corridor a "hover" or brooding-shelter. These have no nestling material, but only a roof or cover somewhat to retain the heat, closed by a curtain cut into strips in front; and are warmed by hot-water pipes running along the building. Generally these pipes run some inches above the chicks reposing on the floor, and are set rather on a slant, so as to be higher for the bigger chicks in the larger pens; but in some cases they run under the floor, and warm the air which enters under the hovers. Every hover, with its inmates, can be reached from the corridor at the back of all. In many cases the chickens are confined in these small pens until large enough, the floors being littered and regularly cleaned; but some raisers have also small outside yards which they use in fine weather. The mortality in nearly all plants is great, as might be supposed. There are said to be some at Hammonton which only market 30 per cent. of the eggs incubated, yet pay a modest profit at that, which is allowed for. On the one hand, a broiler realizes about four times the cost of its own hatching and food; on the other hand, the labour is very heavy and the loss considerable: these factors obviously give a very wide margin of possibilities as regards success or failure.

The most remarkable establishment of this kind, embodying some novel features, was erected in Ohio at the end of 1896 by Mr J. Loughlin, and was still running in 1901, though many believe its permanent success doubtful. The plant cost over 60,000 dollars, and was designed to market 250 to 300 broilers per day regularly, weighing $1\frac{1}{2}$ lb each, which are sold alive to one large dealer at three dollars per dozen. Each day an average of 450 eggs are started, the chicks from which go into one pen. For the chicks, while small, there are thirty small pens, each with 5 by 10 feet of floor space, or at the rate of six chickens per square foot; and there are sixty larger pens each 8 by 12 feet, with outer runs to each of 8 by 20 feet. Every day the chickens are marketed from the ninetieth pen, and all the rest moved one pen forward, leaving the first small pen vacant for the day's hatch: thus fully 22,000 birds are in the plant at one time. The crowding appears very great—we should say far too great—yet the plant had run four years, and was stated to make a profit of 14,000 dollars annually.

In more general American poultry-farms the same system of brooder-houses largely prevails, and from many great numbers of broilers are sent to market; but as both heart and liver are perceptibly affected by such rearing, birds intended for stock are either taken out of doors early, or reared in detached brooders, as in England. Some establishments are mainly egg-farms, high averages being obtained by the system before described. Many breeders have a high reputation for their stock as layers, and derive large profit from selling stock or eggs to other farms. There are many immense duck-farms or "ranches," as mentioned below, which sell nothing except stock ducks or market ducklings. A great many combine the breeding and sale of exhibition poultry with some or all of these objects, fancy points being on the whole less distinct from useful qualities than in England, and the farmer and exhibitor far more commonly combined.

As a rule, American poultry-farmers employ long ranges of buildings divided into pens or houses, with enclosed yards in front; and the most remarkable fact is that interest can be paid upon the capital sunk in such buildings. The explanation in some cases is that much is put up by personal labour and energy of which British farmers have no idea, while the cheapness of land and feed are also favourable. But the climatic conditions also differ. During the winter months the birds have to be confined in what are called "scratching-sheds," and American farmers have successfully reduced to a system the keeping of them healthy and in profit by scratching amongst litter in a small space. During this period the outer runs sweeten and recuperate; smaller runs therefore suffice, and the stock is kept closer and more compact. Another system is pursued, more especially about Rhode Island, called the "colony" plan; detached rough houses, holding forty or fifty hens each, being scattered over the farm: there may be a hundred houses, but there is no fencing. This is very economical in buildings, but expensive in the labour of feeding and collecting eggs, and the system is only possible near the sea or where there is little snow. In several cases it has been abandoned for the system of houses and scratching-sheds.

There are a few very large establishments indeed in the United States, combining almost every branch; but some which did well on a rather smaller scale, when enlarged by companies have been less successful, and had either to contract again or shut down. The largest single establishment at the end of 1901 was probably the Meadow Brook Farm, in Pennsylvania, occupying 80 acres, the buildings of which totalled 112,000 square feet under cover. There were half a dozen brooder-houses; one hen-house is 1000 feet long; and the farm sent to market in one year 25,000 chickens and 20,000 ducklings, besides selling many stock birds, and an enormous number of eggs for hatching at an average price of $40 per thousand. But an even larger business has been built up in Ohio by the former minister of a church, whose health had broken down. The chief and centre establishment, known as Crescent Farm, is itself pretty large, and carries many buildings; but, by a system of contracts, there is also secured the absolute control of a number of other establishments, some of considerable size. A special business has been developed here of "stocking-up" new egg-farms and broiler-plants with laying stock in September, birds "bred to lay" being supplied in lots of one hundred at a dollar each. Ten thousand such birds are raised: there is also a reputation for exhibition stock; and the demand for eggs for incubation sometimes reaches nearly 3000 per day: one order for 20,000 eggs was received on 18th March 1901. Chickens and ducklings are also marketed, about 50,000 ducklings being the expected product of the year just named. Of course businesses like these are very exceptional; but farms on a more moderate scale are numerous, and intelligent American farmers reckon to make a profit of a dollar per annum for each head of their laying or breeding stock.

Table Poultry.—National taste governs the market for table poultry to a large extent. In England white meat, skin, and legs are preferred, and at one time black legs or yellow skin were heavily discounted. More knowledge has largely removed that prejudice, but white has a market value still. In France exceedingly white and smooth skin is preferred, but buyers are indifferent to black legs. In America yellow skin and legs are actually preferred, such fowls being thought more juicy; but there has been some tendency towards white meat of late. Belgian feeders think the best result follows from crossing a yellow-skinned race upon a white-fleshed one. It is some confirmation of this idea that one of the best English table fowls is the produce of a cross between Dorkings and the yellow-skinned Indian Game, while other similar instances might be cited. For some years past the quality of British table poultry has been shown by displays of plucked birds in connexion with the Christmas Smithfield Cattle Show. For many years France had a reputation for greatly surpassing British production; and as the best French fowls readily sell for £1 each and more in the Paris market, it would not be surprising if they were superior to such as have to be sold for 15s. per couple. French fatters appear to seek and obtain a smooth whiteness of fat under the skin, almost like that of a bladder of lard, which does not find favour in the British market; but the best judges have considered that the finest English specimens staged were equal to all comers, and some realized high prices. Foreign experts, equally with English, admitted in 1899 and 1900 that England had now little to learn from any foreign feeders.

The chief supply of the best fowls for the London market has long come from the Sussex district whose centre is Heathfield: these are termed "Surrey" fowls, though Surrey now sends few in comparison. This local industry has been founded in a curious way upon the "ground oats" of the district, the whole grain being ground up, husk and all, nearly as fine as flour. This is done by a peculiar local dressing of the stones, which are "stitched" into little pits by a pointed pick, instead of being dressed into narrow grooves, as for flour-milling; and this meal is found specially suitable for feeding and fattening poultry. In early times cottagers crammed a few fowls with pellets of meal dipped in milk, but this method is now quite superseded by machine-cramming, a rubber tube from the machine being introduced into the crop of each fowl, and a stroke of the foot on a pedal squeezing out a ration of thin, almost creamy, paste, composed of the ground oats, fat, and sour skim-milk, a food which puts on flesh fast and makes it white and delicate. Great experience is required in this business. When killed and plucked, the fowls are placed in a trough whilst still warm, close side by side, and their backs and breasts pressed closer together by a board loaded with heavy weights. This combination of fattening and subsequent shaping constitutes the Sussex system.

The trade in these fatted and shaped fowls is still increasing, so that in 1900 more than 2500 tons of poultry went up from Heathfield station alone to London. There are a few very large establishments; many small men fatten a few; and a fair number send up about four to six dozen fowls three times a week. This growth is in spite of the fact that increased competition and that of cheap foreign poultry have somewhat reduced profits, so that a large portion of the trade now consists of a lower class of birds, at a narrow margin. They are all carried up and the packages brought back empty at the inclusive charge of one penny per bird. The Sussex system is extending in some other parts of England, and many excellent fowls, well fed, but unfattened, are also supplied from Lincolnshire (known as "Bostons") and other districts. The largest provincial towns have similar supplies in less degree.

In America larger fowls are called "roasters," to distinguish them from the broilers above described; and quite recently there has grown up in the Eastern states a system of rearing these also in confinement. Hatching them begins in September, and the birds are at first reared in brooder-houses; but when large enough are placed about fifty together in small houses, with 6 by 8 feet of floor, in small yards about 20 feet square. One very successful raiser puts 200 birds into one pen 10 by 17 feet, in a warmed house, where they remain till killed at 7 lb or 8 lb weight. One firm had raised in this way, for seven years in succession, 2000 birds per annum upon half an acre of ground; but occasionally there is serious mortality in this kind of business, and as a rule only 60 per cent. are reared of those hatched, the loss of the rest being averaged and allowed for.

In western Europe there has grown up some demand for chickens fattened quite young, weighing only 8 oz. to 12 oz. each, and known as *petits poussins*, or "milk chickens." In Belgium somewhat older ones, weighing up to 1½ lb, are sold as *poulets de grains*. The demand for such birds in England is small, and confined to the West End of London, the flesh being too excessively tender for average English palates. Birds of similar sizes have lately been finding a market in the United States as "squab broilers," but are split and broiled, and not fattened, the difference being that a whole bird is served for one portion.

Ducks, Geese, and Turkeys.—Little need be added under these heads. During the last fifteen years of the 19th century the Indian Runner Duck, formerly known as the Penguin Duck, became very popular as a hardy forager and good layer, many birds laying 150 to 180 eggs in a year. It is small in body but good in flavour, and is a great favourite in many districts. Formerly the greater number of ducklings came to the London market from the Vale of Aylesbury, the birds being carried and empties returned for one penny per head, as in Sussex. This trade still continues, but the adherence of the Aylesbury duckers to old-fashioned methods, and the increasing demand, has led to great competition in other districts, such as Norfolk, Lancashire, Kent, &c. Some of the new duck-farmers market 10,000 to 15,000 annually, mostly hatched in incubators, and never allowed in the water or out of the small rearing-pens. In America, however, this kind of rearing has found its fullest development, the number who raise 10,000 ducklings or more being considerable, and a few sending to market, as above indicated, very large numbers indeed, requiring 40 to 80 incubators to keep up the supply. It is remarkable that while in England the Aylesbury is generally preferred, in America the Peking duck is universally used, and has been made by selection both larger and a better layer. Some duck-farmers in England have, however, also adopted the Peking.

Geese in England are declining in relative popularity. In Germany they are consumed to an enormous extent, and the British Consul-General at Berlin reports that even the large domestic supplies have to be supplemented by considerable imports from Russia, a special "goose-train" of fifteen to forty cars arriving daily from the Russian frontier at that city. In America there has been increased interest in goose-breeding, and in the Chinese Goose especially, which has been largely bred (with some trifling peculiarities) under the name of the African Goose, and crossed with the Embden and Toulouse. The produce of this African cross is considered very fertile and profitable to rear.

Turkey-breeding has been largely dominated by the magnificent American Bronze breed, derived from wild blood, and distinguished for size and weight. There is some question whether it does not require more space and fresher ground than the older English strains, and may not be more delicate on small holdings. French birds come largely to the Christmas market in London, but, as compared with English, are small.

National Interests and Commerce.—The foreign importations of eggs into Great Britain have increased rapidly, and are now very considerable. Taking only alternate years for brevity's sake, the following table shows the amount, value, and average price per 120 since the year 1870:—

Number, Value, and Price of Imported Eggs.

Year.	Number of Eggs.	Value.	Average Price.
		£	
1870 . .	430,842,240	1,102,080	6/1½
1872 . .	531,591,720	1,762,000	7/11¼
1874 . .	680,552,280	2,433,134	8/7
1876 . .	753,026,040	2,620,396	8/4
1878 . .	783,714,720	2,511,096	7/8¼
1880 . .	747,408,600	2,235,451	7/2
1882 . .	811,922,400	2,385,263	7/1
1884 . .	993,608,760	2,910,493	7/0
1886 . .	1,035,171,000	2,884,063	6/8
1888 . .	1,126,793,000	3,083,167	6/6
1890 . .	1,234,950,000	3,428,806	6/8
1892 . .	1,336,730,000	3,794,718	6/10
1894 . .	1,425,236,000	3,786,329	6/5
1896 . .	1,589,401,000	4,184,656	6/4
1898 . .	1,730,952,000	4,457,117	6/2
1900 . .	2,025,820,560	5,406,141	6/5½

From such figures the conclusion has been drawn, and at first sight is natural, that foreign eggs have been "ousting" British to a formidable extent; but such a conclusion is dispelled when we take into consideration questions of price and nationality. The following are the values imported from the chief foreign sources during the last ten years of the 19th century, taken every alternate year until the last:—

Value of Imports of Foreign Eggs.

Year.	France.	Russia.	Denmark.	Germany.	Belgium.
	£	£	£	£	£
1889	1,181,335	165,740	286,917	893,902	565,057
1891	1,259,099	383,791	395,963	781,903	539,666
1893	1,611,495	426,106	376,793	618,631	682,636
1895	1,069;580	601,460	447,709	916,821	713,458
1897	1,022,869	812,297	546,282	813,022	768,077
1899	867,865	1,183,031	808,543	966,641	759,250
1900	868,133	1,109,553	923,551	1,106,719	733,453

These eggs are of very different qualities and prices, France averaging for the year 1900, 7s. 7½d. per 120, Denmark 7s. 6¾d., Belgium 6s. 2d., Germany 5s. 9½d., and Russia 5s. 6d., many of the latter being almost putrid when sold in England, and chiefly used in manufactures, for which, at a low price, they answer perfectly. Many eggs are sent from Russia to Germany, Belgium, and even Denmark, so that some of these also come from her, at an original price with which no British producer could compete. The steady decline in imports of the higher-priced French eggs, and enormous increase of low-priced eggs, explain the drop in average price from 8s. 7d. per 120 in 1874 to 6s. 5½d. in 1900; and were this all, the inference would be simply that the selling price of eggs had fallen. But this is not so. While the higher-priced *foreign* eggs have thus been largely displaced from the market, there has grown up a very large demand for British "new-laid" eggs, at prices much higher than any of the above. Every observer must have noticed the many packages of such eggs now exposed for sale in all towns; and what is still more significant, there is now a wholesale market for such eggs in London, the lowest price (in May) for 1900 being 7s. 6d. to 8s. 6d., and the highest (in December) 19s. to 20s. per 120. This market is steadily increasing, the greatest difficulty being to ensure really genuine freshness from producers. The quantity of reputed "new-laid" British eggs now sold is simply enormous, and has grown up in the face of foreign imports, the native producer selling in spite of them, and at far better prices, many times more than he did, say, in 1875.

The following are the British imports of dead poultry and game for the last three years of the 19th century:—

Value of British Imports of Poultry and Game.

Year.	France.	Russia.	Belgium.	Other Countries.
	£	£	£	£
1898	217,703	164,498	127,923	127,368
1899	296,555	139,834	165,803	183,102
1900	333,148	199,282	213,603	264,327

The total for 1900 thus amounted to £1,010,360. The imports from France and Belgium are largely for the Christmas market. Those from Russia are chiefly very small fowls, wrapped in paper and packed in cases of a hundred each, which come over frozen, to be sold at 1s. 2d. or 1s. 3d. each. Other sources include America, Canada, and Australia, which have been sending smaller but increasing quantities of larger birds, packed in smaller numbers, and which realize 2s. 6d. to 3s. 6d. each, a few of the largest as much as 4s. each. Such supplies have somewhat affected the Sussex fattening industry, necessitating (as already hinted) the production of a lower class of bird at a lower price and narrower margin; but they look rough and inferior in colour, and chiefly supply restaurant and hotel demand. The foreign birds being cold-storage goods, which must be consumed quickly when taken out, a fresh Sussex fowl of the same weight will always sell for considerably more.

There are no statistics of British poultry; in Ireland they are collected. The year 1851 closed a decade in which the number of holdings under ten acres had decreased enormously, and the number of poultry in Ireland was then returned as 7,470,694. In 1889 this number had doubled to 14,856,517, and in 1899 there were 18,233,520, an increase in ten years of almost 25 per cent. The Irish Agricultural Organization Society is doing much to improve breeds and management, and the packing of eggs, of which Ireland is a considerable exporter to Great Britain. There is also now a considerable export of lean chickens for fattening to Sussex and other parts of England, and a smaller number have also been fattened in Ireland. Really great progress is manifest in the size and quality of the poultry in many districts, and in the freshness and packing of eggs for the English market.

The poultry industry is developing in Australia, and some export to England has arisen, but too recently for much definite information. Most of the federated States have a Produce Export Department, which receives eggs and dead poultry into cold storage and ships to London, managing, if desired, the whole business. That of South Australia shipped a good many eggs to England in 1895, but the temperature was found too low for eggs, and this trade has so far not developed. Dead poultry come in a similar way from West Australia and Victoria to London. In New South Wales such arrangements have inaugurated a small export business which seems the most active of any, and more seems known about the poultry industry in this state than in others. The Government statistician estimates the number kept in 1900 at 3,180,000 fowls, 320,000 ducks, 234,000 turkeys, and 97,000 geese, the annual consumption being about three-fourths of this, and of eggs about 97,000,000. Around Sydney there are many poultry and duck farms of one to a dozen acres, and one large duck-farm produces ten to twelve thousand ducklings annually. These farms supply the best export fowls for London, the Government depôt having to refuse many others sent in, as too small and poor to pay for export. From Tasmania there is no export as yet, but the colonial Government has started a poultry farm, in order to improve the stock kept and afford instruction in poultry-breeding.

In Canada the Government makes considerable effort to encourage poultry. It has established several stations where systematic fattening of chickens in the English manner is taught, and official experiments are also made on the results of various feeding-rations and other matters. From these stations shipments of fatted chickens were first made to Liverpool and London, commencing an export trade which shows signs of growth. In 1900 the eggs exported to England were valued at £288,945 in London; and the dead poultry shipped realized in Canada for 1898, 100,739 dollars; for 1899, 140,142 dollars; and in 1900, 211,181 dollars. These have improved in quality, and the largest have realized 3s. 6d. and 4s. each. There are no statistics of home production.

The poultry industry in the United States is the most gigantic in the world, and probably the greatest pecuniary interest the country possesses. By the census of 1900, which tabulates returns from 5,096,252 out of the 5,739,657 farms in the States, the number of fowls over three months old on 1st June 1900 was returned as 233,598,085, with 6,599,367 turkeys, 5,676,863 geese, and 4,807,358 ducks, or 250,681,673 birds in all, valued at 85,794,996 dollars. This, however, would include very few of the chickens raised that year, which would not have reached the age stated, and mainly represents breeding and laying stock, which thus averages about 49 birds to every holding; it also of necessity omits many of the smaller city-lot raisers. The value of the poultry raised during the whole year 1899 is given as 136,891,877 dollars, and of the eggs produced (1,293,819,186 dozen) at 144,286,186 dollars; a total year's product of over £56,000,000. Adding only a very moderate amount for city-lot and other small producers not making return, it will be seen that the poultry industry in America exceeds in value either the wheat crop, or swine crop, or cotton crop, which probably comes next in value. Reasons for this enormous production have been indicated, and much is done to foster it by the state governments, which carry out numerous experiments that are reported all over the country. The last development here also, dating only from 1899, is a commencement of export to England of some of the larger fowls produced in the establishments above described. The best are selected, the greater portion so far being sent by one firm in Chicago; and the birds vary in price from 1s. 6d. for the smallest to 3s. 6d. and 4s. for the largest, being sold chiefly to London hotels.

The importance of poultry in France has long been recognized, being due mainly to the prevalence of moderately small holdings and the national disposition to small rural industries. There are no very recent statistics available, but whereas in 1862 the poultry in France were reported as 43,000,000 head, these had increased in 1892 to 54,000,000 head, besides 9,000,000 ducks, geese, and turkeys. The eggs exported are collected from the farmers by such a well-organized system that eggs collected on Wednesday are in the London market the following Tuesday. The home consumption of eggs is also enormous, so that when prices for foreign eggs decreased in England, the Paris market paid better. In 1899 the Paris Municipal Council reported the consumption of eggs in that city alone in the previous year as 212 per head, and the taste for omelettes must make the number used in France very great. Eggs are imported from Italy to some extent.

The conditions in Belgium are somewhat similar to those in France. No domestic statistics are available. Some eggs are imported from Italy, and much of the home production is from imported Italian hens, kept laying for a year and then killed: eggs are exported chiefly to France, Great Britain, and Germany. There is a fattening industry somewhat similar to that in Sussex, lean chickens being bought for fattening in certain markets. The chief export of these is to Germany, but there is some to the London market, especially in December.

The Netherlands statistics for 1898 show that the number of poultry had increased considerably during the previous ten years, excepting turkeys, which had diminished. There were in that year 4,083,312 fowls, 430,022 ducks, 36,307 geese, and 13,130 turkeys; and there were about 70 special establishments for poultry-rearing, which were rather on the increase, chiefly for local requirements. Of eggs there were exported to Belgium 656,898, England 370,418, and Germany 3,212,845 kilos; but the imports were in excess of this by 2,916,269 kilos, and came chiefly from Russia. Dead fowls and ducks also go to the countries above named.

In Denmark there were in 1900 about 9,000,000 fowls, mostly local and Italian. The eggs exported numbered 332,000,000, practically all to England; there were imported 35,600,000, practically all Russian, re-exported to England. The flourishing export trade is due to a good co-operative system, to which the Government contributes £555 annually towards poultry-breeding and the holding of exhibitions.

The customs returns of Germany must truly represent her imports, but obviously give little idea of her exports, since eggs are only given as exported in 1899 to the value of £23,900 (reckoning 1 mark = 1 shilling), whilst English imports from her are above given as amounting to £1,106,719. Her enormous imports of geese have already been alluded to: these come alive from Russia, and in 1899 numbered 6,875,810, of the value of £978,350, all for home consumption. Other poultry and eggs are tabulated in quantities of 100 kilos, and were valued as follows: live fowls £508,350, other live poultry (than geese) £171,650, dead poultry £290,150, eggs £4,815,450, not far from the imports in England. It is clear, as was incidentally apparent before, that Germany is a large consumer rather than a producer of poultry products, and chiefly a carrier of her nominal exports. She imports eggs from Italy and Austria-Hungary as well as from Russia. These large imports may probably be profoundly affected by the new tariff legislation.

There are no domestic statistics for Austria-Hungary, but her trade in poultry and eggs is considerable. In 1900 the dual monarchy imported poultry to the value of £268,240 and eggs to the value of £1,230,655. But the exports of poultry amounted to £977,051, and of eggs to no less than £3,750,078. This country is therefore a very large producer, most of the eggs going to Germany, and some of them through her on to England.

Italy sends live fowls, for laying, to northern Europe, and some eggs to Belgium and France; but no definite figures are accessible.

In Russia the growth of the poultry industry has been very great since 1890. In that year her British trade was small: in 1900 we have seen that she bulked largest of all countries in eggs sent to England direct, and that some nominally from others really came from her. Her exports of eggs (reckoned as £1 = 10 roubles) were valued in 1898 at £3,113,386, and of live poultry (chiefly geese) at £637,000; but this latter sum is now exceeded by geese alone sent to Germany, as above noticed. Her vast southern provinces are, of course, the origin of this produce, which is collected by dealers from the farmers, the price realized by the latter for eggs being in summer sometimes less than a rouble per hundred. The Government has shown considerable interest in this growing industry in several ways, and produce is carried at almost incredibly low rates on the State railways; but the vast distances involved must always confine Russian produce to the supply of the cheaper class of demand in western Europe.

For these details we are mainly indebted to the consuls-general of Germany and the Netherlands in London, to the British consuls in Copenhagen, Antwerp, Vienna, and Berlin, and to various miscellaneous tables and returns, including those obtainable from the agents-general of the principal British colonies.

(L. Wr.)

Povoa de Varzim, a seaport and bathing resort of Portugal, district of Oporto, 17 miles north of Oporto, on a small and ill-sheltered bay. The people, who are good seamen, are mostly engaged in fishing, 2644 persons and 649 boats being so employed in 1898, the value of the fish caught being £22,000. Population (1890), 12,057; (1900), 12,623.

POWER TRANSMISSION.

I. Electric.

The electric transmission of power may be briefly defined as the art of delivering electric energy at any desired point and there transforming it into mechanical energy. It therefore involves not only the design and construction of the delivery circuits and the generators which feed them, but the properties and the use of the electric motors which accomplish the transformation. As the former considerations are somewhat contingent upon the latter, it will be convenient first to discuss the properties of the electric motor in its various forms, and later the transmission systems as such.

Motors.

Fundamentally, electric motors are electric generators reversed in function: they convert into mechanical energy the continued stresses between two electromagnetic fields relatively movable, just as generators convert into electromagnetic stresses the mechanical energy applied to them. Since no transformation of energy is ever absolutely quantitative, the conversions just considered are not accomplished without loss of energy to about the same extent in both cases. The sources of this loss are ohmic loss in the conductors, hysteresis, friction of bearings and brushes, air friction, and eddy currents; the sum of these losses in large modern machines does not exceed 5 or 6 per cent. The torque of the motor is the dynamical result of the electromagnetic stresses between the magnetic field of the motor and that due to the armature currents, the latter field being proportional to the strength of the current sheet due to the numerical strength of the current and the number of its effective convolutions. This applies to all types of motors, if one remembers that whenever either of these two factors is a periodic variable, as in the case of alternating motors, the torque is proportional to their geometrical co-directed product and not merely to their numerical product. At this point it will be convenient to distinguish between the various types of motors. The first broad distinction is between continuous-current and alternating-current motors, a distinction rather of convenience than of necessity, for in point of fact the two depend upon the same broad principles and can be considered on precisely the same lines. Each class is composed of numerous possible types, of which comparatively few are in considerable use for the purpose of power transmission, and of these few two or three go to make up the vast majority of those generally employed. Motors may be conveniently divided as follows:—

(A) *Continuous Current.*
1. Separately excited.
2. Series-wound constant current.
3. Series-wound constant potential.
4. Series-wound interdependent current and potential.
5. Shunt-wound constant potential.

(B) *Alternating Current.*
1. Synchronous constant potential.
2. Induction-polyphase constant potential.
3. Induction-monophase constant potential.

Of these, the series-wound constant potential, shunt-wound constant potential, and polyphase induction motors do a very large proportion of the active work of power transmission: the first-mentioned furnish power for electric railways; the second, power distribution from public electric supply stations; while the third are mainly relied upon in long-distance transmission systems.

In class (A) in general, for a certain value of the torque current must be forced through the armature against the motor electromotive force which results from the rotation of the armature in a given field. This demands a certain greater applied electromotive force to produce the current required, which is determined by the effective electromotive force, equal to the geometrical difference between the applied and motor electromotive forces, and by the impedance of the armature. For steady currents this is of course the same as the ohmic resistance, just as for steady electromotive force the geometrical and the numerical difference of the applied and motor electromotive forces are coincident. The torque depends, as heretofore noted, on the field strength and the strength of the current sheet due to the current thus determined. For small values of the torque the speed practically depends upon the applied electromotive force and the field, so that if the former and the latter be constant the speed is also sensibly constant. This is likewise the case if the armature resistance be very small, and in general the variations of speed at constant potential are determined by the product of this resistance and the torque, while the absolute speed depends essentially upon the field strength. Motors for low speed or high electromotive force must have both a strong field and many turns upon the armature, so that both the fundamental stresses may be large. As the field is generally strong—to secure economy of iron—low-voltage and high-voltage machines differ principally in the number of armature turns. For variable speed, this latter factor being fixed, field strength and applied electromotive force are the factors easily altered, and most of the speed variation is accomplished by changing one or both of them. Torque is at a maximum when the current is the greatest possible at the given voltage—that is, when the motor is at rest. With a small armature resistance, this current is generally far too great for convenience; hence the motors are usually started with a rheostat in series with the winding if the current is not limited by the generator itself. The torque then depends on the sum of the resistances in circuit, and can be made just sufficient to start the motor under the required load. By the same device, the motor can run at reduced speed, although with a considerable loss of energy in the rheostat; it is indeed, as a rule, difficult to get effective speed variation in motors of any kind without serious loss of energy. The field can be changed within wide limits only by a considerable increase of the iron in the magnetic circuit, the applied electromotive force cannot usually be varied except by increasing the resistances in circuit, and the number of armature turns cannot be varied without complication, although the effective number can be modified by shifting the brushes, probably at the expense of sparking. Altogether, if the speed variation demanded be more than 15 or 20 per cent., it causes, in one way or another, considerable expense and trouble, particularly if each speed must be closely held irrespective of load. No large change in absolute speed can readily be made without considerable change in the percentage variation of speeds at various loads. Practically the best results are obtained from motors of very low armature resistance, in which the field or the applied electromotive force, or both, are varied. The whole problem is nearly identical with the production of constant potential or constant current from generators driven at constant speed, and is solved by similar means. For any one absolute speed a generator can be made to give constant potential, nearly irrespective of load, by compound winding. Similarly, a motor may give a very nearly constant speed at constant potential by a differential winding in series with the armature, weakening the field as the armature current rises. This device, however, obviously increases the energy required for magnetization, and decreases the effective torque at starting. Practically the best continuous-current motors can be made to hold their speed to within 1 or 2 per cent. from no load to full load. Commercial machines, however, generally vary from 5 to 10 per cent. in speed. With respect to the direction of rotation of a motor, the torque changes sign with a change of sign in either field or armature current, but not with a change of sign in both. The input of the motor is numerically equal to the product of the current and the applied electromotive force, while the output is determined by the product of the current and motor electromotive force; hence the efficiency of the motor, as a transformer of energy, is the ratio between these two quantities. The output is a maximum when the applied electromotive force is double the motor electromotive force, and the efficiency is a maximum when the motor and applied electromotive forces are substantially equal. At the point of maximum output, the speed is that sufficient to reduce the current to one-half its static value. No motor is worked at or near this point, except momentarily, on account of the low efficiency and severe heating in the armature. These theoretical values are slightly modified in practical machines by the small miscellaneous losses subject to independent variations.

(A) 1. *Separately excited Motors* are seldom used in power-transmission work, but they are interesting principally on account of the very efficient method of speed regulation possible by their use. In this method the field of the motor is excited from the supply mains, and the armature current is furnished by a motor-generator running at constant speed. A rheostat in the shunt field of the latter element enables the applied electromotive force to be varied to any desired extent, and hence the working motor can be given full torque at any speed up to that assigned by the maximum value of the electromotive force which can be applied to the armature. Moreover, if the armature resistance be small, the motor is fairly self-regulating at all speeds. The effect is rather startling, since the motor may be giving a very great torque when it is merely turning over at a few revolutions per minute; and although the process is complicated, it leads to excellent results.

(A) 2. *Series-wound Constant-current Motors* were early worked to a considerable extent on arc-light circuits, but have now passed out of use save in a small number of constant-current power-transmission systems on the continent of Europe. In these motors the motor electromotive force is directly proportional to the output, the torque being constant. They will not start with more than a certain definite load, but once started, the speed will increase until added work (internal or external) balances the torque. The type is intrinsically bad in speed regulation, and must be treated by the same methods as are adopted to secure constant current in arc machines. The most successful device in most cases is to vary the field strength by shunting the field coils, or to vary the number of effective armature conductors by shifting the brushes. Both methods are carried out mechanically rather than by purely electrical means—in the first case by an automatic rheostat, and in the second by an automatic brush shifter—but neither is wholly satisfactory.

(A) 3. *Series-wound Constant-potential Motors* comprise nearly all motors used for electric traction—aggregating not less, probably, than one million horse-power; hence they are of great practical importance. These traction motors are usually highly specialized machines with very powerful armatures, and fields strongly saturated at all working values of the current. The brushes have an invariable position. Such motors behave much like separately excited motors having a rather large armature resistance. Speed regulation has to be obtained by varying the applied electromotive force. In early traction motors this variation depended upon inserting a rheostat; in modern practice it is customary to employ two or even four identical motors on each car, operated in series for low speeds and in parallel for full speed. In practice, however, resistances are inserted when necessary to prevent too sudden changes of speed, and to secure intermediate steps between those obtained by the series-parallel connexions. In rare instances a still further variation is secured by the use of a field only partially saturated at ordinary loads.

(A) 4. *Series-wound Motors with Interdependent Current and Potential* are used only in connexion with generators of similar design, motor and generator forming a dynamical unit. This system is occasionally used with good results in power transmission. Assuming the motor field to be saturated, if the speed is to be constant the applied electromotive force must rise with the load to an amount depending on the resistances in circuit. If the corresponding generator has a field less fully saturated, the increase in current demanded by the increment of torque in the motor can be made not only to raise the applied electromotive force enough to compensate for armature resistance, but for the total resistances in circuit, including the line. With this difference in saturation, the motor will automatically maintain constant speed. The fields of the machines need not be designed for a given saturation, since shunting them with a suitable resistance will give the same result.

(A) 5. *Shunt-wound Motors at Constant Potential* are the mainstay of continuous-current distributions for industrial purposes. At constant potential the field remains sensibly constant, and the torque is directly proportional to the current. The motor then behaves much like a separately excited motor, and the armature resistance being generally very small, the speed is very nearly constant, varying less than 5 per cent. from no load to full load in the best commercial machines. Operating on a compound-wound generator, a single motor of this type can be made to regulate with great precision, as in the previous case. If the motor field be only moderately saturated, its strength, and hence the motor electromotive force, rises and falls with the applied electromotive force; and therefore at constant load these motors run at very nearly constant speed, in spite of small variations of voltage. If speed variation be required, it can be obtained to a moderate extent by a rheostat in the field circuit. At starting, a rheostat is necessary in the armature circuit. The differentially wound modification is now seldom used.

(B) 1. *Synchronous Alternating-current Motors.*—The simplest starting-point in the consideration of this class is the continuous-current generator. This machine actually generates within the armature alternating currents; and if the commutator be replaced by two or more slip-rings connected symmetrically to two or more points on the armature winding, alternating currents, monophase or polyphase, according to the number of connexions and the points touched, can be withdrawn therefrom. The simplest case involves only two slip-rings, joined to the winding at diametrically opposite points. Consider two such modified machines as motor and generator. The condition of complete reversibility is that the instantaneous values of the currents, and the instantaneous values of the angular displacements between poles and armature coils, shall be equal throughout. This evidently requires that the rotation of the motor should be synchronous, pole for pole, with that of the generator. Here, as before, the torque depends on the two fundamental stresses, but the torque has no determinate sign in the absence of an initial rotation. The instantaneous value of the torque depends on the instantaneous value of the current and on its angular displacement. The speed of the motor being invariable, its motor electromotive force depends only on the effective excitation, including the armature reactions, and it may or may not, according to the conditions of load, be in phase with the impressed electromotive force. In the case of the continuous-current motor, the motor output is numerically equal to the product of current and motor electromotive force; and since, in the alternating circuit, these quantities are usually not in phase, in alternating motors the activity is determined by the co-directed part of their product. The current in the alternating motor depends, not on the ohmic resistance, but upon the impedance, and upon the geometrical difference between the applied and motor electromotive forces. At a given applied electromotive force and an armature impedance assumed constant, the fundamental variables in the motor are the output, motor electromotive force, and motor current. The two last factors are interdependent, so that the current may have a wide range of values, according to the excitation, while the output remains constant, or itself remaining constant, may cover a variety of values of the power corresponding to different excitations. These changes involve changes in the phase angle between the motor electromotive force and the current, so that, at given output, the power-factor of the motor — that is, the ratio between the numerical and geometrical products of current and electromotive force—may be given various values at will by changing the field excitation of the motor, a most unique and valuable property. If the motor electromotive force be fixed and the output varied, the phase angle between current and motor electromotive force varies by reason of the armature taking up a new angular position with respect to the field, backward for increasing load, forward for decreasing load. The minimum value of the current for a given load is reached when the excitation is such that the applied electromotive force and current are in phase, at which point the real and the apparent energy in the circuit coincide. The input can then be accurately measured by voltmeter and ammeter readings, and the motor is working at its best efficiency for the given load. For greater values of the motor electromotive force, the current leads in phase with respect to the applied electromotive force; for less values it lags. The former condition is accompanied by the rising of the electromotive force at the motor terminals, the latter by its fall. It therefore becomes possible to use a synchronous motor, if the necessary current due to the load be not too great, as a voltage and phase regulator upon an alternating circuit, a function very valuable in power-transmission work. If the excitation be set to produce leading phase at small loads, the phase angle will gradually diminish as the load rises, and then, passing through zero, increase again with the lagging current, thus holding the power-factor near to unity at all working loads. In a well-designed synchronous motor, by proper initial adjustment of the field, the power-factor can easily be kept between 0·95 and 1 from quarter load to full load, and very close to unity within the ordinary working range. Save for its inability to start, the synchronous motor is a highly desirable addition to a transmission system. Starting is generally accomplished by the help of an induction motor or other auxiliary power, and the motor is treated exactly like an alternator to be thrown in parallel with the supply circuit. A synchronous motor will pull itself up to synchronism if brought near to its synchronous speed, but this requires a very large amount of current. Operating from a generator of its own, it can be brought to speed by giving it a small initial rotation and raising the generator speed very carefully and gradually, when the two machines will accelerate in synchronism. Polyphase synchronous motors obey these same general laws; they can, however, be started as quasi-induction motors with an open field circuit, the pole faces serving as secondary conductors, but require so large currents in thus starting themselves that it is better practice to bring them to speed by extraneous means.

Synchronous moters sometimes cause serious trouble by "pumping," a phenomenon closely allied to the surging of current between alternators in parallel, and due to similar causes. If not due to defective governing of the prime mover, it usually starts with a change of load or of phase, producing fluctuations in the electromotive force in the system great enough to interfere seriously with incandescent lighting, and continuing with uniform amplitude and frequency for hours if unchecked. The amplitude varies with the conditions, but in the same machine the frequency is nearly constant. The fluctuation affects both the armature and the field circuits, but it can as a rule be controlled by varying the excitation until a neutral point is found, usually when the phase angle is near to zero. Motors with solid pole pieces give little trouble of this sort, the oscillations being rapidly counteracted by the eddy currents. In motors with laminated fields, the most effective remedy is chamfering away the edges of the pole pieces so as to admit heavy copper shoes running along and under the edges, and even bridging the spaces between the pole pieces. The eddy currents in these shoes completely check the "pumping."

Rotary Converters.—These are, in effect, synchronous motors, and have the same general properties so far as their motor functions are concerned. When practicable, it is desirable to start them from the continuous-current side; otherwise, through auxiliary motors. They often show an inclination towards "pumping," and, as in all parallel working of alternators and in synchronous motor practice, they work best when all the machines involved have similar characteristics, and, as nearly as may be, the same form of electromotive wave.

(B) 2. *Polyphase Induction Motors.*—Speaking broadly, an induction motor is one in which the armature current is introduced into the armature windings by electromagnetic induction instead of by brushes. It is at once an alternating current transformer and an alternating current motor, operating in the latter function by virtue of the current received from the former. In the commonest form the alternating currents are of two or more phases interacting in carrying on these duplicate functions. Induction motors consist of two concentric masses of laminated iron taking the form of short hollow cylinders, of which the outer is fixed and the inner fitted to revolve. The outer surface of the inner drum and the inner surface of the outer drum are slotted or perforated, to receive the primary and secondary windings of the apparatus. The outer winding is usually the primary, and the inner (or armature) winding the secondary. The primary winding is almost universally a multipolar drum in character; the secondary is, in the most highly developed motors, of the same character, but very often consists merely of numerous insulated armature bars united at each end of the drum by a common end-plate or end-ring, forming the structure usually known as a "squirrel-cage" winding. In polyphase motors of the usual type the primary drum winding is in duplicate or triplicate, resembling very closely the armature winding in a two- or three-phase generator. The actions which go on in these motors have been the subject of much debate; most of the theoretical discussions of the matter have been based upon the concept of a rotary magnetization produced by two simple sinusoidal magnetisms superimposed in quadrature upon the same core, or in the case of a three-phase motor, three superimposed in a similar symmetrical manner. This hypothesis is often most convenient, being merely an application of the general physical thesis that two equal simple harmonic motions in quadrature produce circular motion, as in the case of the conical pendulum. All the results of this hypothesis follow, however, from the introduction of two alternating magnetizations, acting in quadrature in time but independently; and one or the other view of the matter is convenient according as, in the structure considered, the effective magnetizations do or do not produce a definite physical resultant. There is no discrepancy between the two hypotheses; they are merely two points of view of the same phenomena. In the general case, one need make no supposition as to the existence or non-existence of the physical resultant rotary magnetization; it is merely necessary to note that if one phase-winding predominately produce a magnetic field, and the other a current in the rotary member fitted to react with that field, torque will result, whether the two phase-windings act upon the same magnetic structure, or upon two entirely separate magnetic structures merely connected by the leads which deliver current from one to the other.

Induction motors having both these forms of structure are in successful use. If one considers the latter case, the two phase-windings have exchanged functions every 90 degrees in the two-phase structure, each phase-winding serving to produce a magnetic field and to deliver, almost as if it were merely a pair of brushes, current to react with this field alternately, and the two halves of the motor structure exchange functions every 90 degrees. Considering the motor in which the two phase-windings are superimposed on the same core, there is a virtual magnetic resultant rotating at a speed determined by the frequency of the current and the number of poles, and setting up induced currents in the secondary member, which currents are so disposed as to react with the field to produce rotary motion. At rest, the secondary electromotive force produced by the machine as a transformer is a maximum; when the motor is running at speed, unloaded, it is a minimum, and an increment of load causes the secondary member merely to slip behind synchronous speed far enough to receive an increment of transformed energy sufficient to carry the new load. If the secondary member is of very low resistance, the slip behind synchronism is very small even at full load, less than 2 per cent. in motors developed for this particular property. An increase of secondary resistance produces increased falling behind from synchronous speed; and if resistance be added to the secondary member by interpolating rheostats in its circuits, the motor can be made to produce uniform torque over a very wide range of speed, as is the case with continuous current motors. The percentage of slip is the percentage of energy lost in the secondary member, as likewise in continuous-current motors if one regards their synchronous speed as that at which the motor electromotive force would equal that impressed. Polyphase induction motors start, when properly designed, with a very powerful torque, even up to three or four times the full load running torque of the same motor. With a very low-resistance secondary member, this torque demands an immensely large current, the structure acting almost like a short-circuited transformer, and the lag in the secondary circuit is considerable. In motors in which this large starting current is objectionable, it may be reduced very greatly by interpolating resistances in the secondary circuits at starting, the effect of these being to diminish the lag in the secondary circuit and to decrease the demand for primary current. A certain critical value of this resistance gives a maximum torque per ampere in the primary circuit. Where a small primary current in starting is of considerable importance, this extra resistance is frequently introduced at starting and cut out afterwards, particularly in cases where large torque is necessary. If great starting torque is not necessary, the primary electromotive force is often diminished by inductive resistances, or a change in the connexions of the transformer from which the motor is fed. Both methods of starting are in commercial use on a very large scale.

In efficiency and closeness of speed regulation and good general running properties, polyphase induction motors approximate very closely to the best continuous-current practice. They produce, however, a certain amount of lag between primary electromotive force and current, which causes the apparent input to be larger than the real input, as often happens in alternating current work. The ratio between the real and the apparent watts input is the power-factor of the motor. In well-designed modern machines this is usually from 85 to 90 per cent. at rated load; it should seldom fall below the former figure, and rarely rises more than 1 or 2 per cent. above the latter, though in rare instances power-factors as high as 94 or 95 per cent. have been obtained. Condensers have sometimes been employed in connexion with such motors to increase the power-factor, and with considerable success, particularly in maintaining the power-factor at low and moderate loads, but their use is generally unnecessary. The weakest point in these polyphase induction motors is the importance of employing a very small clearance between armature and field, in order to increase the power-factor by making the structure more efficient, considered merely as a transformer. The clearances in ordinary use are seldom greater than one-sixteenth of an inch even in motors as large as one hundred horse-power, and in smaller machines are frequently not more than one thirty-second of an inch. Induction motors, however, possess many valuable properties, and are the mainstay of long-distance power-transmission work at the present time.

(B) 3. *Monophase Induction Motors* closely resemble the polyphase motor in construction, but have only a single-phase winding in the primary. The theories of their action are very similar to those of polyphase motors. The essential point of difference is that the stable angular displacement between the field magnetization and the armature currents which co-act with it is obtained in the polyphase motor by the time-displacements in the several phase windings, while in the single-phase motor it is obtained by the angular space-displacement of the armature, which has to be set up by an initial rotation. Single-phase motors therefore are not inherently self-starting, and run in either direction equally well when once started. The torque is always in the direction of the initial rotation. This rotation is sometimes given by hand and sometimes by auxiliary phase-windings supplied by derived current from the main circuit, or merely short-circuited on themselves and receiving induced currents from the main winding. Both these devices give a small initial torque in a definite direction. Once up to speed, the single-phase motors act much like the polyphase. They are conspicuously weak in the matter of power-factor, however, as well as in that of starting-torque, and have as yet not come into very extensive commercial use, although under special conditions they have been and are successfully employed. A theoretically interesting form of induction motor is a modification which runs at absolutely synchronous speed, receiving the necessary energy in the secondary not in virtue of slip behind synchronous speed, but from great difference in wave form between the primary and secondary circuits, so that energy is periodically received by the armature in spite of synchronism in speed. Such motors are not employed commercially, but sometimes find a field for usefulness in the laboratory.

General Methods of Power Transmission.

The largest single department of power transmission—that is, transmission for traction purposes—is at present almost wholly carried on, as has already been indicated, by continuous currents. The usual voltage is 500 to 600, and the motors are almost universally series-wound constant-potential machines. The total amount of such transmission in daily use reaches almost to a million horse-power. In power transmission proper continuous currents are not used to any considerable extent, owing mainly to the difficulty of generating continuous currents at sufficient pressure to be available for long-distance work, and the difficulty of reducing such pressure, even if it could be conveniently obtained, far enough to render it available for convenient distribution at the receiving end of the line. Single continuous-current machines have seldom been built successfully for more than about 2000 volts, if at the same time they were required to deliver any considerable amount of current. About 200 kilowatts per machine at this voltage appears to be the present limit. For distances at which more than this very moderate voltage is desirable, one must either depend on alternating currents or use machines in series. In American practice the former alternative is universally taken. On the continent of Europe a very creditable degree of success has been achieved by adopting the latter, and plants upon this system, aggregating something like 20,000 horse-power, are in use, mostly in Switzerland. In these, generators are worked at constant current, a sufficient number in series being employed to give the necessary electromotive force. They have usually had a total voltage of less than 10,000, although in one instance the plans call for about double this figure. These systems are, however, characterized by the fact that the full working pressure is only carried at extreme load, and under ordinary conditions of working this is greatly reduced. They are subject, however, to a very grave inconvenience in the utilization of the power transmitted; and in the present state of the art of insulation, both in machines and lines, the advantages of the system are not generally conspicuous, although in particular cases it may be of material service.

The great bulk of power transmission all over the world is at the present time carried on by the use of polyphase alternating currents. The alternating current, as such, possesses for this purpose conspicuous advantages. In the first place, whatever the voltage of transmission, the voltage of generation and that of distribution can be brought within moderate limits at a very high degree of efficiency by the use of transformers; and, in the second place, it is possible to build alternating-current generators of any required capacity, and for voltages high enough to permit the abolition of raising transformers except in unusual circumstances. At present such generators, giving 10,000 to 12,000 volts directly from the armature windings, are in common and highly successful use in America and elsewhere; and while the use of raising transformers is preferred by some engineers, experience shows that they cannot be considered essential, and are probably not desirable for the voltages in question, which are as great as at the present time seem necessary for the vast majority of transmission plants. But for very large transmission work to considerable distances where still higher voltages are requisite, such transformers cannot be dispensed with. Alternating currents are practically employed in the polyphase form, on account both of increased generator output in this type of apparatus, and of the extremely valuable properties of the polyphase induction motors, which furnish a ready means for the distribution of power at the receiving end of the line. As between two- and three-phase apparatus, the present practice is about equally divided; the transmission lines themselves, however, are, with rare exceptions, worked three-phase, on account of the saving of 25 per cent. in copper secured by the use of this system. Inasmuch as transformers can be freely combined vectorially to give resultant electromotive forces having any desired magnitudes and phase relations, the passage from two-phase to three-phase, and back again, is made with the utmost ease, and the character of the generating and receiving apparatus thus becomes almost a matter of indifference. As regards such apparatus, it is safe to say that honours are about even: sometimes one system proves more convenient, sometimes the other. The difficulty of obtaining proper single-phase motors for the purpose of general distribution has so far prevented any material use of single-phase transmission systems.

Generators for Power Transmission.

The generators are usually large two- or three-phase machines, and in the majority of instances they are driven by water-wheels. Power transmission on a large scale from steam plant has, up to the present, made no substantial progress. The size of these generators varies from 100 to 200 kilowatts in small plant up to several thousand in the larger ones. The voltage of the generators varies greatly. When raising transformers are used, it is usually from 500 to 2000 volts; without them, the generators are usually wound for 10,000 or 12,000 volts. Intermediate voltages have sometimes been employed, but are rather passing out of use, as they seem to fulfil no particularly useful purpose. The tendency at the present time, whatever the voltage, is towards the use of machines with stationary armatures and revolving field magnets, or towards a pure inductor type having all its windings stationary. At moderate voltages such an arrangement is merely a matter of convenience, but in high-voltage generators it is practically a necessity. Low-voltage machines are usually provided with polyodontal windings, these windings having several separate armature teeth per pole per phase, while the high-voltage machines are generally monodontal; in both classes the edges of the pole pieces are usually chamfered away in such form as to produce at least a close approximation to the sinusoidal form for the electromotive force. For this purpose, and to obtain a better inherent regulation under variations of load, the field magnets are, or should be, particularly powerful. In the best modern generators the variation of electromotive force from no load to full load, non-inductive, is less than 10 per cent. at constant field excitation. Closeness of inherent regulation is an important matter in generators for transmission work, inasmuch as there is as yet no entirely successful method of automatic voltage regulation on very large units; and the less hand regulation the better. Moreover, the design which secures this result also tends to secure stability of wave form in the electromotive force, a matter of even greater importance. There has been much discussion as to the best wave form for use on alternating circuits, it having been conclusively shown that the sinusoidal wave does not give the most economical use of iron in the transformers. For transmission work, however, particularly over long lines, this is a matter of inconceivably small importance compared with the stability and the freedom from troubles from higher harmonics that result from the use of a wave as nearly sinusoidal as can possibly be obtained. In every alternating circuit the odd harmonics are considerably in evidence in the electromotive force, either produced by the structure of the generator or introduced by the transformers and other apparatus. These are of no particular moment in work upon a small scale, but in transmission on a large scale to long distances they are, as will be seen in the consideration of the transmission line itself, a serious menace, the gravity of which is just coming to be fully realized. Inasmuch as the periodicity of an alternating circuit must be maintained sensibly constant for successful operation, great care is usually exercised to secure such governing of the prime movers as will give constant speed at the generators. This can now be obtained, in all ordinary circumstances, by several forms of sensitive hydraulic governors which are now in use. The matter of absolute periodicity has not yet settled itself into any final form. American practice is based largely upon 60 cycles per second, which is probably as high a frequency as can be advantageously employed. Indeed, even this leads to some embarrassment in securing good motors of moderate rotative speed, and the tendency of the frequency is rather downward than upward. An inferior limit is set by the general desirability of operating incandescent lamps off the transmission circuits. For this purpose the frequency should be held above 30 cycles per second; below this point, flickering of the lamps becomes very serious —so serious, indeed, as practically to prohibit their successful use—and plant installed for such low frequencies is generally confined to motor practice, or to the use of rotary converters, which are somewhat easier to build in large units at low than at high periodicities. Nearly all the work of power transmission, however, is carried on between 30 and 60 cycles per second. The inferior limit at which it is possible to operate alternating arc lamps is about 40 cycles; and if these are to be and to remain an important feature in transmission systems, the indications are that practice will tend towards a periodicity of between 40 and 50 cycles per second, at which all the accessory apparatus can be successfully operated.

Transmission Lines.

Power transmission lines differ from those used for general electric distribution principally in the use of higher voltage and in the precautions entailed thereby. The economic principles of design are precisely the same here as elsewhere, save that the conductors vary less in diameter and far more in length. Inasmuch as transmission systems are frequently installed prior to the existence of a well-developed distribution system, the conditions of load and the market for the power transmitted can seldom be predicted accurately; consequently, the cases are very rare in which Kelvin's law can be applied with any advantage; and as it is at best confined to determining the most economical conditions at a particular epoch, this law is probably of less use in power transmission than in any other branch of electric distribution. A superior limit is set to the permissible loss of energy in the line by the difficulty attending regulation for constant potential in case the line loss is considerable. The inferior limit is usually set by the undesirability of too large an investment in copper, and lines are usually laid out from the standpoint of regulation rather than from any other. In ordinary practice, it seldom proves advantageous to allow more than 15 per cent. loss in the line even under extreme conditions, and the cases are few in which less than 5 per cent. loss is advisable. These few cases comprise those in which the demand for power notably overruns the supply as limited by the maximum power available at the generating station, and also the few cases in which a loss greater than 5 per cent. would indicate the use of a line wire too small from a mechanical standpoint. It is not advisable to attempt to construct long lines of wire smaller than No. 4 American wire-gauge (·204 inch diameter), although occasionally wire as small as No. 6 (·162 inch diameter) may safely be employed. The vast majority of transmission lines are composed of overhead conductors. In rare instances underground cables are used. In single-phase work these are preferably of concentric form, which, however, gets too complicated in the three-phase lines, generally employed to secure economy in copper; for the latter, triplicate cables lead sheathed, laid in glazed earthenware ducts, seem to give the best results. On account of the cost and the difficulty of repair of such lines, they are not extensively used, and cables have not yet been produced for the extremely high voltages desirable in some very long circuits. As to the material of the conductors, copper is almost universally used. For very long spans, however, bronze wire of high tensile strength is occasionally employed as a substitute for copper wire, and more rarely steel wire; aluminium too is beginning to come into use for general line work. Bronze of high tensile strength (say 80,000 to 100,000 ℔ per square inch) has unfortunately less than half the conductivity of copper; and unless spans of several hundred feet are to be attempted, it is better to use hard-drawn copper, which gives a tensile strength of from 60,000 to 65,000 ℔ to the square inch, with a reduction in conductivity of only from 3 to 4 per cent. As to aluminium, this metal has a tensile strength slightly less than that of annealed copper, a conductivity about 60 per cent. that of copper, and for equal conductivity is almost exactly one-half the weight. Mechanically, aluminium is somewhat inferior to copper, as its coefficient of expansion with temperature is 50 per cent. greater; and its elastic limit is very low, the metal tending to take a permanent set under comparatively light tension, and being seriously affected at about half its ultimate tensile strength. Joints in aluminium wire are difficult to make, since the methods of soldering amount to little more than cementing the metal with the flux; in practice the joints are purely mechanical, being usually made by means of tight-fitting sleeves forced into contact with the wire. With great caution in stringing, aluminium lines can be successfully used, and are likely to serve as a useful defence against increase in the price of copper. Overhead lines are most commonly strung upon wooden poles, set generally fifty to the mile; a pole forty feet long set seven feet in the earth is a favourite size in American practice. The conductors are systematically transposed, to suppress inductive disturbances; or if, as usually, they are worked three-phase, the three-wire system is often disposed at the vertices of an equilateral triangle, and the transposition is effected by spiraling the lines in cyclic order. The distance between wire and wire is usually from 18 to 24 inches—at extreme voltages, more. The insulators are of a rather large triple-petticoat design, of porcelain or glass: the former material, when thoroughly vitrified, has the greater mechanical strength, and is less likely to weather on the surface from protracted use, but glass insulators are more uniform in quality, less subject to inherent electric and mechanical defects, and moreover are materially cheaper.

Voltage.—The most important factor in the economy of the conducting system is the actual voltage used for the transmission. This varies within very wide limits. For transmissions only a few miles in length, the pressures employed are generally from 2000 to 5000 volts, but for the serious work of power transmission less than 10,000 volts are now seldom used. This pressure, under all ordinary conditions and in all ordinary climates, can be and is used with complete success, and apparently without any greater difficulty than would be encountered at much lower voltage. It is regarded as the standard transmission voltage in American practice for distances up to 20 or 25 miles. Beyond this, and sometimes even on shorter lines, it is greatly increased; up to 20,000 volts there seems to be no material difficulty whatever in effecting and maintaining a sufficient insulation of the line. Forty thousand volts is in successful use on two or three American transmission systems without any serious difficulty having been encountered. The longest transmission yet attempted commercially —that of 1000 kilowatts from Colgate, California, to Stockton, California, 218 miles (viâ Mission San Jose)—is at 40,000 volts, the line being three-phase at 60 cycles per second; and on this system there has been no more trouble in maintaining the insulation of the line than would be met in ordinary working at one-tenth the voltage in question. Above 40,000 volts the situation is complicated by a tendency towards breaking down of the air as a dielectric, and the establishment of serious leakage or even actual arcs between wire and wire. With a wave form very closely sinusoidal, transmission at 60,000 volts may be successfully accomplished; but small variations from a sinusoidal wave make themselves felt seriously, in an increase of the tendency to leaking and arcing. The lines become self-luminous at a little above 20,000 volts, and at 40,000 or 50,000 volts the phenomenon, which is often closely connected with *resonance*, becomes of a striking, not to say startling, character.

Resonance, in substance, is due to synchronism of the periodic electromotive force, or a harmonic thereof, with the electromagnetic time-constant of the system. The frequency of the currents actually employed in transmission work is so low that resonance with the fundamental frequency must be extremely rare; resonance with the harmonics is, however, common—much commoner than is generally supposed. In every electromotive force wave the odd harmonics are more or less in evidence, particularly the third, fifth, and seventh. If the electromotive force wave departs notably from a sinusoidal form, traces of harmonics up to at least the 15th may generally be found; the third, seventh, and the alternate higher harmonics are manifest in flattening the crest of the wave. Supposing, what is seldom quite true, that the harmonics are symmetrically disposed in phase with the fundamental, all the harmonics tend somewhat to elevate the shoulders of the wave; a wave, therefore, with peaked shoulders and a depression in the centre is certain to be affected by harmonics, while if it has a high central crest, there is evidence of great predominance of the fifth and higher harmonics. Generally the harmonics are slightly out of phase with the fundamental, so that the wave is both deformed and unsymmetrical. As to the amplitude of these harmonics, the third is usually the largest, and may sometimes in commercial machines amount to as much as 20 per cent. of the amplitude of the fundamental, and frequently 10 per cent. In machines giving nearly sinusoidal waves, it is of course much less, but it is not difficult to find even the seventh and higher harmonics producing variations as great as 5 per cent. Since, other things being equal, the rise in electromotive force due to resonance is directly proportional to the magnitude of the harmonics, and the chance of getting it increases rapidly with the presence of those of the higher orders, the desirability of using the closest possible approximation to a sinusoidal wave is self-evident. The greater the inductance and capacity of the system and the less its ohmic resistance, the greater the chance of getting serious resonance. As regards the distributed capacity and inductance due to the line alone, the ordinary conditions are not at all formidable; the general effect of such distributed capacity and inductance is to produce in the system a series of static waves, their length varying inversely with the frequency. At commercial frequencies the wave length is very great, so great that even in the longest lines at present employed only a small fraction of a single wave length appears; the total length of the line is generally less than one quarter the complete wave length, and the only notable effect is a rise of potential along the line. The time-constant of the alternating circuit is

$$T = \cdot 00629\sqrt{LC}$$

where L is the inductance in henrys and C the capacity in microfarads; and if the frequency, or a marked harmonic thereof, coincide with this time-period, resonance may safely be looked for, and resonance of the harmonics may appear conspicuously in lines of ordinary lengths. The following table gives the values, both L and C, per mile of line, of the sizes (American wire-gauge) ordinarily employed for transmission circuits, the wires being assumed to be strung 18 inches apart and about the height already indicated:—

Size No.	Diameter (inch).	L.	C.
0000	·460	1·48	·0102
000	·410	1·52	·0099
00	·365	1·56	·0097
0	·325	1·59	·0095
1	·289	1·63	·0093
2	·258	1·67	·0090
3	·229	1·71	·0088
4	·204	1·74	·0086
5	·182	1·78	·0084
6	·162	1·82	·0083

In cases where underground cables form a part of the system, the above values are likely to be very largely increased, and the probability of resonance is in proportion enhanced. A still further complication is introduced by the capacity and inductance of the apparatus used upon the system, which may often be far greater than that due to the entire line, even if the latter be of considerable length. In point of fact, it is altogether probable that resonance due to the distributed capacity and inductance of the overhead line alone is of rare occurrence and generally of trivial amount, while it is equally probable that resonance due to capacity and inductance other than that of the line conductors may, and often does, cause very serious disturbances upon the system. The subject has never been adequately investigated, but the tendency towards formidable sparking and arcing at various points on long-distance transmission systems is generally far greater than can be accounted for by consideration of the nominal voltages alone. The conditions may be still further complicated by the effect of earths or open circuits, which sometimes may produce, temporarily, appalling resonance phenomena, through bringing into action the capacity and inductance of the apparatus. In ordinary working the resonance of the harmonics is not very conspicuous, and the fact that it occurs not systematically, but only in special ways and under special conditions, indicates more strongly than anything else that the vital point is not the time-constant of the line alone, but those of the apparatus connected thereto. A definite and persistent tendency towards resonance may sometimes be effectively checked by the introduction of suitable inductance in the parts of the system most seriously affected, but the best general policy is to avoid as far as possible the presence of the higher harmonics which are the chief sources of danger.

Maintenance.—Generally speaking, a transmission line is rather less than more difficult to maintain than an equal amount of distribution system, for it generally encounters fewer sources of trouble. Transmission lines are, when practicable, laid out through open country, and along roads which furnish easy access for inspection and repairs. The chief sources of danger in temperate climates are mechanical injury from the falling of branches of trees across the circuits, sleet and wind storms, and lightning. The first-mentioned difficulty may be avoided by keeping clear, so far as possible, of wooded country, and it should be remembered that, at the voltages customarily used for transmission, a twig the size of a lead-pencil, falling across the wires, may set up arcing, and it will end by burning the wires completely off—not directly by fusion, but by persistent arcing. A properly constructed overhead line is practically safe against all storms, save those of most extraordinary violence, and with care may be made secure even against these. As a matter of practice, interruptions of service upon transmission systems are very rarely due to trouble upon the main line itself, but are far more likely to occur in some part of the distributing system. The most dangerous combination of circumstances is a sleet storm sufficient to coat the wires with ice, followed by heavy winds; if the line, however, is constructed with proper factors of safety, bearing this particular danger in mind, there need be very little fear of serious results. Lightning is a much more formidable enemy. The lightning discharges observed upon electric circuits are of two general descriptions:—first, a direct discharge of lightning upon the line, more or less severe, and always to be dreaded; and secondly, induced discharges due to lightning flashes which do not hit the line, or to static disturbances which may or may not produce actual lightning. Discharges of the former class are vastly more severe than those of the latter, and, fortunately, are somewhat rare. They may actually shatter the line, or may distribute themselves along it for a considerable distance, leaping from wire to pole, and thence to earth, without actually damaging the line to any marked degree. The induced discharges are felt principally in the apparatus, causing many of the burn-outs observed in transformers and generators. There is no complete protection against the effects of lightning upon the apparatus. The best lightning arresters are palliatives rather than preventives. If, however, a number of arresters are put in parallel, with reactance coils between them on the way towards the apparatus, the vast majority of lightning discharges, to whatever cause they may be due, will be deflected harmlessly to earth. Moreover, the apparatus itself has a considerable power of resistance, due to its high insulation. The ends of the line should be very thoroughly protected by such lightning arresters, and other points, such as prominent elevations along the line, should receive similar additional protection. In some cases a strand of barbed wire, stretched along the tops of the poles, and well grounded at frequent intervals, has been found very advantageous. With the best protection at present available, lightning is not a serious menace to continuity of service, and the apparatus of the distributing system is far more difficult to protect than the main line and its apparatus.

Sub-stations.—In most long-distance transmission work, the transmission line itself terminates in a sub-station, which bears to the general distribution system precisely the same relations which are borne by a central electric supply station to its distributing lines. Such a sub-station should be treated, in fact, as a central station, receiving its electric energy from a distance instead of employing local generators driven by prime movers. The design of the sub-station, however, is somewhat different from that of the ordinary central station. The transmission lines terminate generally in a bank of reducing transformers, bringing the voltage from the 10,000 or 20,000 employed upon the line to the 1000 or 2000 used in the distribution. These transformers are usually large, and their magnitude should be determined by the same considerations which apply to determining the size of the units to be employed in a generating station. The general rule to be followed is that the separate units shall be of such size that one of them may be dispensed with without serious inconvenience. In the case of transformers, the unit in two- or three-phase working is the bank of transformers which must be used together. In Continental practice three-phase reducing transformers are frequently made to include all three phases in a single structure; this practice is not followed in American plant, separate transformers being used in each phase. In this case, two or three transformers, according as the two- or three-phase system is used, constitute a single transformer unit in the sense just mentioned. If a change is to be made from three-phase line to two-phase distribution, the change is made by the appropriate vector connexion of the transformers. In any case, the sub-station is furnished with voltage regulating appliances, to enable the voltage upon the distribution lines to be held constant and uniform, just as in the case of central-station distribution. These regulators are, in practice, transformers with a variable transformation ratio. This is obtained in divers ways—sometimes by changing the inductive relations of the primary and secondary coils, sometimes by changing the relative number of effective turns in primary and secondary. Sets of these inductive regulators enable the voltage to be controlled over a sufficiently wide range to secure uniform potential on the system, and with a degree of delicacy that obviates any undesirable changes in voltage. The regulation is usually manual, no automatic regulator yet having proved entirely satisfactory. In very large systems, it is worth noting that the so-called "skin effect" in alternating current conductors may become conspicuous. In the transmission circuits themselves the wires are, in practice, never large enough to produce any sensible difference in conductivity for continuous and for alternating currents. In the heavy omnibus-bars of a large sub-station this immunity may not be continued, but in such cases flat strips are frequently employed. If these are not more than, say, a centimetre in thickness, the "skin effect" is practically insignificant for all frequencies used commercially. Not infrequently the sub-station also contains devices for the changing of alternating to continuous current, usually rotary converters feeding either traction systems or electric lighting mains. Beyond these rotary converters the system becomes an ordinary continuous-current system, and is treated as such. When very close regulation is necessary, motor-generators are often preferred to rotary converters. Arc lighting from transmission circuits is a much more serious problem. At the present time two methods are in vogue:—first, the operation of continuous-current series-arc machines by synchronous or induction motors driven from the transmission system; and, secondly, series alternating apparatus for feeding alternating arcs. This apparatus consists either of constant-current transformers with automatically moving secondaries, or of inductive regulators, also automatic in their action, supplemented by transformers to supply them with the necessarily rather high voltage employed for arc distribution. As between these two systems practice is at present divided; electrically, the alternating apparatus gives a rather higher real efficiency, but involves the use of alternating arcs, which are somewhat less efficient, watt for watt, as light producers than the continuous-current arcs. The apparatus, however, requires practically no care, while the arc machines, driven by motors, require the same amount of care as if they were driven by other power. Arc light transformers, however, are likely to have low power factors, hardly above ·8 at full load, and rapidly falling off at lower loads. Rectifiers changing the alternating current into a unidirectional current, suitable for use with arc lights, have been employed with some measure of success, but not to any considerable extent. They are, of course, satisfactory in avoiding the use of alternating currents in the arc, and consume but little energy in the transformation from one form of current to the other, but involve the use of static transformers automatically giving constant current, which are somewhat objectionable on the score of low power-factor.

Distances of Transmission.—Obviously the ultimate determining factor in the distance to which power can be commercially transmitted is the economic side of the transmission, the maximum distance being the maximum distance at which the transmission will pay. As a mere engineering feat, the transmission of power to a distance of several hundred miles is perfectly feasible, and, judging from the somewhat extensive data now available, the phenomena encountered in increasing the length of lines have not been of such character as to cause any hesitation in going still farther, provided the increase is commercially feasible. In American practice, it is within the truth to say that nearly all transmissions of reasonable size (say a few hundred kilowatts) to distances of twenty miles, or less, are pretty certain to pay. At distances up to fifty miles, in a large proportion of cases power can be delivered at prices which will enable it to compete with power locally generated by steam. From fifty to one hundred miles (on a large scale—several thousand kilowatts) the chances for commercial success are reasonably good. The larger the amount of power transmitted, the better on the whole is the commercial outlook. In rare instances transmissions of still greater length will prove feasible. The longest one yet operated (218 miles) has already been noted, and may be regarded as a commercial success. In attempting transmissions over far greater distances, one fact (sometimes forgotten) must be borne in mind—that the conditions which indicate profit may not persist. In certain localities where the cost of fuel is extremely high, transmissions of several hundred miles may prove successful from a commercial as well as an engineering standpoint, but the growth of industry, which indicates the necessity for such a transmission, may go on until, through improved facilities of transport, the cost of fuel may be greatly lowered and the economic conditions entirely changed. Such a modification of the conditions sometimes takes place much more quickly than would be anticipated at first sight, so that when very long distance transmissions, involving the locking up of large amounts of capital in apparatus and lines, are under consideration, the permanence of the conditions which will render them profitable should be a very serious subject of consideration. Cases may arise of transmissions over very long distances on an enormous scale to regions in which the fuel conditions may have already reached stability, and in these there may be assurance of a continued profitable market for power, but it is necessary to say that at the present time such instances seem to be extremely rare. As the world's coal supply is diminished, and industrial growth goes on, colossal transmissions of power from fuel beds and natural or artificial hydraulic sources, including the tides, may become an important factor in the world's work; but this state of things belongs to the future rather than to the present. (L. BL.)

II. HYDRAULIC.

The first proposal for a general transmission of hydraulic power was made by Bramah in 1802. In 1846, Lord Armstrong's hydraulic crane was erected at Newcastle, and was worked from the town water mains, but the pressure in such mains was too low and uncertain to secure satisfactory results. The invention of the accumulator in 1850 enabled much higher pressures to be used; since then 700 ℔ per square inch has been adopted in most private hydraulic power transmission plant. An attempt to give a public supply of hydraulic power was made in 1859, when a company was formed for laying mains in London along the river Thames between the Tower and Blackfriars, the engineer being Sir George Bruce; but though an Act of Parliament was obtained, the works were not carried out. The first public hydraulic supply station was established at Hull in 1877. In 1883 the General Hydraulic Power Works, Messrs Ellington and Woodall being the engineers, were started in London, and they now form the largest system of hydraulic power transmission in existence. Works of a similar character have since been established in several other towns. The general features of hydraulic power transmission are:—(1) a central station where the hydraulic pressure is created, usually by means of steam pumping engines; (2) a system of distribution mains; (3) machines for utilizing the pressure. In cases of public supplies there is the further important matter of registration. The theoretical principles involved belong to the subject of Hydromechanics, and this article has reference only to their practical application.

Central station.

When dealing with any practical problem of hydraulic power transmission, it is of the first importance to determine the maximum demand for power, its duration and frequency. If the duration of the maximum demand is limited and the frequency restricted—for instance, when a swing bridge has to be opened and closed only a few times in the course of a day—a small pumping plant and a large accumulator (see *Ency. Brit.*, 9th ed., vol. xii. p. 522) will be desirable. If the maximum demand is more or less continuous, as when hydraulic pressure is used for working a pump in a mine or a hydraulic engine in a workshop, the central station pumping engine must be capable of supplying the maximum demand without the aid of an accumulator, which may or may not, according to circumstances, be provided to serve as a regulator. The aim should be to employ a pumping engine of such capacity that it can be worked as nearly as possible continuously at its maximum output; the same consideration should, in the main, determine the size of the pumping units in a station where more than a single unit is employed. In most hydraulic power transmission plants the demand is of a very intermittent character, the periods of approximate maxima rarely exceeding in the aggregate two or three hours a day (cp. Fig. 2). With a number of units, each can be worked, when in use, at or near the most economical speed. Moreover, reserve plant is necessary if the supply of power is to be constant, and where the units are many the actual reserve required is less than where the units are few.

An effect of the multiplication of power units is to increase the capital outlay; indeed, it may be stated quite generally that economy in working and maintenance cannot be obtained without a larger capital outlay than would be required for a simpler and less economical plant. A high degree of economy estimated on financial data—the ultimate base on which these practical questions rest—can only be obtained in large installations where the averaging effect of the combination of a large number of comparatively small intermittent demands for power is greatest. The term *load-factor*, since it was first coined by Mr R. E. Crompton in 1891, has come into common use as an expression of the relation between the average and the maximum output from any central source of supply. No argument is required to show that a given central station plant working continuously at its maximum speed day and night all the year round, say for 8760 hours in a year, should produce the power more cheaply per unit, not only as to the actual running cost, but also as to the capital or interest charges, than the same plant running on the average at the same speed for, say, one-third the time, or 2920 hours. In this case the load-factor 2920/8760 = ·333, or 33·370 per cent. The saving on the whole expenditure per unit is not in direct proportion to an increase in the load-factor, and its effect on the various items of expenditure is extremely variable. The influence is greatest on the capital charges, and it has no influence at all, or may even have a detrimental effect, on some items; for instance, the cost of repairs per unit of output may be increased by a high load-factor. Its effect on the coal consumption depends very much on the kind and capacity of the boilers in use; on whether the engines are condensing or non-condensing; on the hours of work of the engine staff, &c. The economic value of the load-factor is of great importance in every installation, but its influence on the cost of supply varies at each central station, and must be separately determined. There is a load-factor peculiar to each use for which the power is supplied, and the whole load-factor can only be improved by the combination of different classes of demands, which differ in regard to the time of day or season at which they attaint heir maximum. It is in this respect that the great economy of a public distribution of power is most apparent, though there is also, of course, a direct economy due simply to the presumably large size of the central stations of a public supply. Demands for power of every kind have unfortunately a tendency to arise at the same time, so that in the absence of storage of power there seems no prospect of the load-factors for general supply of power in towns exceeding, in the most favourable conditions, 40 per cent. The load-factor of most public hydraulic power supplies is considerably under 30 per cent. It is questionable, however, whether a very high load-factor conduces to economy of working expenses as a whole in any general supply of energy. The more continuous the supply during the twenty-four hours of the day, the greater is the difficulty of executing repairs, and the greater the amount of the reserve plant required.

In all central station work where fluctuating loads have to be dealt with, it is most important that there should be ample boiler power. In a comprehensive system of power supply, demand arises in a very sudden and erratic manner, and to meet this by forcing the boilers involves greater waste of coal than keeping steam up in sufficient reserve boilers. For this purpose, boilers with large water capacity, such as the Lancashire, are preferable to the tubular type, if sufficient space is available. Feed water heaters or economizers should always be used, all steam and feed pipes should be carefully protected from radiation, and the pipe flanges should be covered; in short, to secure good results in coal consumption, every care must be taken to minimize the stand-by losses which are such serious items in central station economy when the load-factor is low. Though hydraulic power has the peculiar advantage, as regards coal consumption, that it is the speed of the engines which varies with an intermittent demand, nevertheless at the London stations it has been found that during a year's working only from 60 to 75 per cent. of the coal efficiency of trial runs of the engines can be obtained—*i.e.*, at least 25 per cent. of the coal is wasted through the stand-by losses and

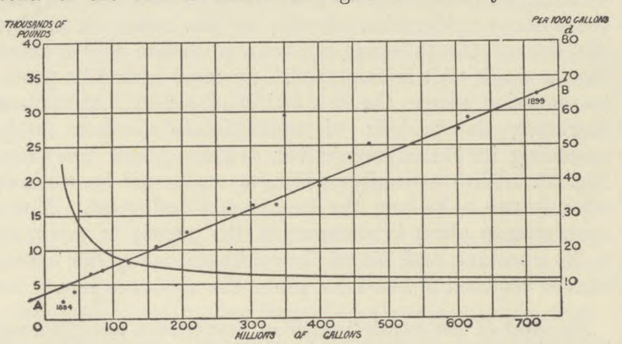

Fig. 1.

through the pumping engines having to run at less than full power. The use of superheated steam, which is now being introduced, will certainly lead to further economy.

To determine the scale on which a central station plant should be designed is frequently a difficult matter. The rate of growth of the expected demand for the power is an important factor, but it has been clearly established that the reduction of working expenses resulting from the increase of size of an undertaking proceeds in a diminishing ratio. The diagram (Fig. 1) of the costs of the London undertaking and the amount of power supplied shows this very clearly. The curve on the diagram gives the cost per 1000 gallons. The straight line A B has been drawn approximately as a mean through the points marking the total expenses of each year in relation to the output of power. This line cuts the boundary above the origin O at A, and indicates by the amount of the running expenses the initial size of the central station adopted in this case. Whether it is more economical to have several smaller stations, in any particular system of power transmission, or a single centre of supply, is mainly governed by the cost of the mains and the facilities for laying them in the area served. No general rule can, however, be formulated, for, as in many engineering problems, it is a question of balance of advantages, and the solution must be obtained by consideration of the special circumstances of each case as it arises.

There were in 1900 four central stations at work in connexion with the public supply of hydraulic power in London, having an aggregate of 4600 i.h.p.; a fifth station which had been begun at Rotherhithe would raise the horse-power to 6200. All the stations and mains are connected together and worked as one system. There are nine accumulators with a total capacity of 2600 gallons, most of them having rams 20 inches diameter by 23 feet stroke. The pumping engines are able together to deliver 7000 gallons

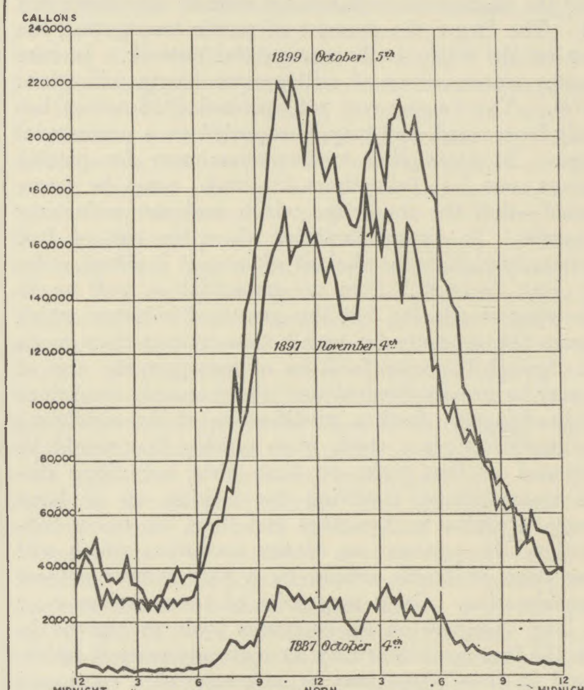

Fig. 2.

per minute, and the accumulators are principally of use in regulating the pressure and facilitating the control of the work of the stations. Details of the London supply are given in Fig. 2 and in the following table:—

Year.	Gallons pumped.	Annual Load-Factors.	Max. 24 hours Load-Factors.	Cost of Fuel per 1000 gallons.	Price of Fuel per ton in bunkers.	No. of Machines at work.	Miles of Mains.
				d.	s. d.		
1889	163,883,000	0·328	0·524	3·11	10 9	1022	38
1891	267,671,000	0·339	0·462	3·21	12 9	1503	53
1894	400,316,000	0·338	0·553	1·96	10 0	2204	73
1896	472,507,000	0·347	0·481	1·91	10 0	2796	89
1897	600,974,000	0·379	0·518	1·88	10 5	3141	98
1898	620,662,000	0·340	0·483	1·98	11 3	3515	109
1899	718,028,000	0·332	0·466	2·11	12 9	3964	118

The load-factors are calculated on the actual recorded maximum output, and not on the estimated capacity of the plant running or installed. The daily periods of maximum output are shown in Fig. 1. The very high load-factor in 1897 was due to special circumstances. The table shows that the load-factors have not been affected either by the increase of the area of supply or by the increased consumption of power. The coal used has been principally Durham small. The capital cost of the London undertaking has been about £650,000. In the central station at Wapping, erected in 1891, there are six sets of triple-expansion, surface-condensing vertical pumping engines of 200 i.h.p. each; six boilers with a working pressure of 150 ℔ per square inch, and two accumulators with rams 20 inches diameter by 23 feet stroke loaded up to 800 ℔ per square inch. The engines run at a maximum piston speed of 250 feet per minute, and the pumps are single-acting, driven directly from the piston rods. The supply given from this station in 1899 was approximately 6,000,000 gallons per week, and the cost for fuel, wages, superintendence, lighting, repairs, and sundry station expenses, 3½d. per 1000 gallons, the value of the coal used being 12s. 6d. per ton in bunkers. The capital cost of the station, including the land, was £70,000. The load-factor at this station for 1899 was ·39, and the supply was maintained for 163 hours per week. The conditions are exceptionally favourable, and the figures represent the best result that has hitherto been obtained in hydraulic power central station work.

The installation in Hull differs little from the numerous private plants at work on the docks and railways of the United Kingdom. The value of the experiment was chiefly commercial, and the large public hydraulic power works established since are to be directly attributed to the Hull undertaking. In Birmingham gas engines are employed to drive the pumps, but though the plant has recently been extended, the whole power available is only 250 h.p. In Liverpool the central station has five engines of 200 i.h.p. each, and a second station which is being erected is laid out for a further 1600 i.h.p. The working pressure in Liverpool is 850 ℔ per square inch. There are 23 miles of mains, and between 700 and 800 machines at work. In Manchester and Glasgow the pressure adopted is 1100 ℔ per square inch. In Manchester this pressure was selected principally in view of the large number of hydraulic packing presses used in the city, and the result has been altogether satisfactory. The works were established by the corporation in 1894, the central station being designed for 1200 i.h.p. Another station has since been built of equal capacity, and 3 to 4 million gallons per week are being supplied to work about 1400 machines. About 17 miles of mains are laid. In Geneva there is a distribution of hydraulic power at the moderate pressure of 200 ℔ per square inch, the pumps being driven by turbines which are worked by the water of the Rhône. 3000 h.p. is supplied to work 268 machines, principally turbines, at a cost of £3 per brake h.p. per annum for 3000 hours' work, and about half the total is used for creating electric current for lighting and traction. Public supplies of hydraulic power exist also in Melbourne and Sydney.

In Antwerp a regular system of high-pressure hydraulic power transmission was established in 1894, specially to provide electric light for the city. The scheme was due to the late Professor von Rysslеburgh, an electrical engineer of Ghent, who came to the conclusion that the most economical way of installing the electric light was to have a central hydraulic station, and from it transmit the power through pipes to various sub-stations in the town, where it could be converted by means of turbines and dynamos into electric energy. The coal cost of the electricity supplied —0·88d. per kw. hour—compares favourably with most central electric supply stations, although the efficiency of the turbines and dynamos used for the conversion does not exceed 40 per cent. Von Rysslеburgh argued that hydraulic pumping engines would be more economical than steam engines and dynamos, and that the loss in transmission from the central station to the consumer would be less with hydraulic converters than if the current were distributed directly. The loss in conversion, however, proved to be twice as great as had been anticipated, owing largely to defective apparatus and to under-estimation of the expense of maintaining the converting stations; and the net result was commercially unsatisfactory. The system, therefore, is not likely to be extended, but the facts regarding the coal consumption are a striking testimony to the great economy of hydraulic power transmission.

At Buenos Aires hydraulic mains are laid in the streets, not for a general power supply, but solely for drainage purposes. Each of the sumps, which are provided at intervals, contains two hydraulic pumps which automatically pump the sewage from a small section of the town into an outfall sewer at a higher level. The districts where this system is at work lie below the general drainage level of Buenos Aires. The average efficiency (pump h.p. to i.h.p.) is 41 per cent., which is high, having regard to the low heads against which the pumps work. In this application all the conditions are favourable to hydraulic power transmission. The work is intermittent, there is direct action of the hydraulic pressure in the machines, and the load at each stroke of the pumps is constant. The same system has been adopted for the drainage of Woking and district, and a somewhat similar installation is in use at Margate.

The minimum cost at which hydraulic power is supplied from the hydraulic mains in London at present is 1s. 6d. per 1000 gallons, made up approximately as follows:—

	s.	d.
Coal, wages, repairs, &c., at central station .	0	3½
Distribution and general charges . . .	0	2½
Rates and interest on capital at 6 per cent. .	1	0
	1	6

The average cost is much higher (cp. Fig. 2). In 1000 gallons at 750 ℔ per square inch there is an energy of $\frac{10,000 \times 1730}{33,000 \times 60}$ $= 8{\cdot}74$ horse power hours; thus 1s. 6d. per 1000 gallons $= 2$d. per h.p. hour nearly. It is evident that the capital charge is the dominating factor, and that the influence of the load-factor on this charge is far more important than it is on the station cost. The capital employed in building and equipping the central stations bears a nearly fixed ratio to the supply, but the relative cost of mains may be expected to decrease as the supply is augmented. It does not, however, appear probable that hydraulic power at 750 ℔ per square inch can be supplied from central stations in towns on a commercial basis over any considerable areas at less than 1s. per 1000 gallons. Allowing 75 per cent. as the efficiency of the motor through which the power is utilized, this rate would give 1·83d. per brake or effective h.p. hour. This cost seems high, and it is difficult to believe that it is the best hydraulic power transmission can accomplish, having regard to the well-established fact that the mechanical efficiency of a steam pumping engine is greater than any other application of a steam engine, and that the power can be conveyed through mains without any material loss for considerable distances. Still no other system of power transmission except gas seems to be better off, and there is no method of transmission by which power could, at the present time, be supplied in towns with commercial success at such an average rate when steam is employed as the prime mover. The average rate (2s. 6d. to 3s. per 1000 gallons) charged for hydraulic power in London and other towns agrees, in fact, very closely with the average rate charged for the supply of electrical energy. Gas is undoubtedly cheaper, but in a large number of cases is mechanically inconvenient in its application. Hydraulic pressure, electrical energy, and compressed air (with reheating) can all be transmitted throughout towns with approximately the same losses and at the same cost, because the power is obtained in each system from coal, boilers, and steam engines, and the actual loss in transmission can be kept down to a small percentage. The use of any particular system of power does not, however, primarily depend upon the cost of running the central station and distributing the power, but mainly upon the mechanical convenience of the system for the purpose to which it is applied. One form of energy is, in practice, found most useful for one purpose, another form for another, and no one can command the whole field.

Cost of power.

When water is employed as the fluid in hydraulic transmission, the effects of frost must usually be provided against. In London and other towns, the water, before being pumped into the mains, is passed through the surface condensers of the engines, so as to raise its temperature. The mains are laid 3 feet below the surface of the ground. Exposed pipes and cylinders are clothed, and means provided for draining them when out of use. When these simple precautions are adopted, damage from frost is very rare. In special cases oil having a low freezing point is used, and in small plants good results have been obtained by mixing glycerine and methylated spirit with the water.

Precautions against frost.

A few gas jets judiciously distributed are of value where there is a difficulty in properly protecting the machinery by clothing.

From the central station the hydraulic power must be transmitted through a system of mains to the various points at which it is to be used. In laying out a network of mains, it is first necessary to determine what velocity of flow can be allowed.

Distribution.

Owing to the weight of water, the medium usually employed for hydraulic transmission, a low velocity is necessary in order to avoid shocks. The loss of pressure due to the velocity is independent of the actual pressure employed, and at moderate velocities of 3 to 4 feet per second the loss per 1000 yards is almost a negligible quantity at a pressure of 700 ℔ per square inch. For practical purposes Box's formula is sufficiently accurate—

$$\text{Loss of head} = \frac{\text{gallons}^2 \times \text{length in yards}}{(\text{diameter of pipes in inches} \times 3)^5}.$$

There is a further loss due to obstruction caused by valves and bends, but it has been found in London that a pressure of 750 ℔ at the central accumulators is sufficient to ensure a pressure of 700 ℔ throughout the system. The greatest distance the power is conveyed from the central stations in London is about 4 miles. The higher the initial velocity, the more variable the pressure; and in order to avoid this variation in any large system of mains, it is usual to place additional accumulators at a distance from the central station. These have an important effect in maintaining regularity of pressure, as local demands are, in the first instance, supplied from them; and they act in the same way as air-vessels, giving the whole system an elasticity which would hardly be expected with such an inelastic substance as water. The largest pipes used in London are 7 inches internal diameter. In one or two places elsewhere 8-inch pipes have been used, and in Antwerp the pipes are nearly 12-inch bore. In the last case they are of steel, but as a rule the large pipes are of cast-iron, flanged, and provided with spigots and faucets. The joint (Fig. 3) is

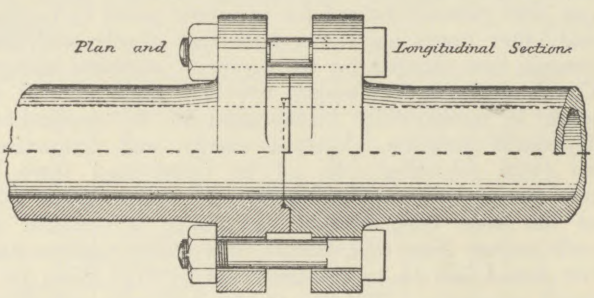

Fig. 3.

made with a gutta-percha ring, though sometimes asbestos and leather packing rings are used. The mains should be laid in circuit, and valves placed at intervals, so that any section can be isolated for repairs or for making connexions without affecting the supply at other points. The main valves adopted in London are shown in Fig. 4. Valves are also fixed to control all branch pipes, while relief valves, washouts, and air valves are fixed as required.

In public supplies the power used is in all cases registered by meters, and since 1887 automatic instruments have been used at the central stations to record the amount supplied at each instant during the day and night. The ratio between the power registered at the consumers' machines and the power sent into the mains is the commercial efficiency of the whole system. The loss may be due to leakage from the mains or to defects in the meters; or if, as is often the case, the exhaust from the machines is registered, to waste on the consumers' premises. The automatic recorders give the maximum and minimum supplies during 24 hours every day, the maximum record showing the power required for a given

Registration.

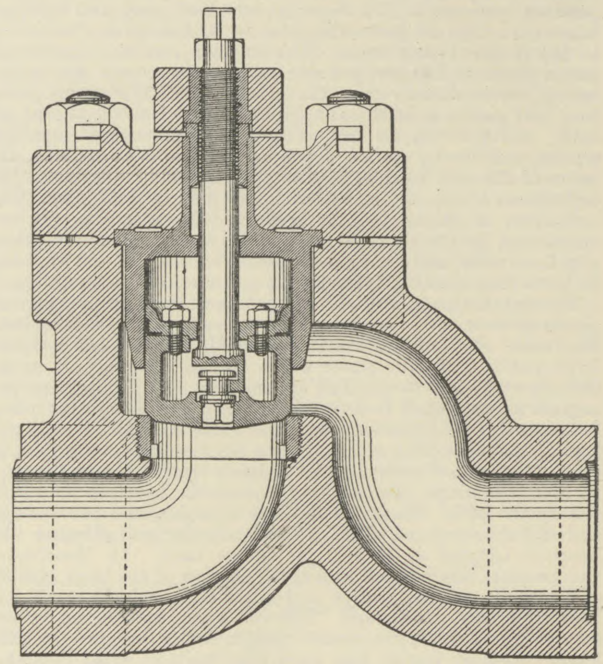

Fig. 4.

number and capacity of machines, and the minimum giving an indication of the leakage. It has been found practicable to obtain an efficiency of 95 per cent. in most public power transmission plants over a series of years, but great care and watchfulness are required to produce so good a result. In some years 98 per cent. has been registered. Up to a few years ago no meter was available for registering so high a pressure as 700 ℔ per square inch, and hence all that could be done was to register the water after it had passed through the machines and lost its pressure. This method is still largely adopted; but seeing that high-pressure meters have lately been perfected to give excellent results, it will doubtless be superseded to a considerable extent by the more satisfactory arrangement of registering the power on its entry into the consumers' premises, as is done with gas, water, and electricity. In Manchester Kent's high-pressure meters are now used exclusively. The water, after the pressure has been eliminated by passage through the machines, may run to a drain or be led back to the central station in return mains; the method adopted is a question of relative cost and convenience.

The subject of the transmission of hydraulic power cannot be regarded as in any way complete without reference to the machines which are actuated by it, for it is only by a comparison of the useful work done by them with the work done by the engines and boilers at the central station that the mechanical efficiency of the system as a whole can be gauged. At the central station and in the distribution there is no great difficulty in determining the efficiency within narrow limits; it should be 80 per cent. at the point of entry to the machine in which the pressure is used. But there a great uncertainty arises; the character of the machines and the nature of the conditions are so variable, that a really accurate general statement is impossible. In most cases the losses in the machine are constant for a given size and speed of working; consequently, the efficiency of a given machine may vary within very wide limits, according to the work it has to do. For instance, a hydraulic pump of a given

Machinery.

capacity, delivering the water to an elevation of 100 feet, will have an efficiency of 80 per cent.; but if the elevation of discharge is reduced to 15 feet, even though the hydraulic-pressure rams may be proportioned to the reduced head, the efficiency falls below 50 per cent. The ultimate efficiency of the system, or $\frac{\text{pump h.p.}}{\text{i.h.p.}}$, in the one case is 64 per cent., and in the other under 40 per cent. In crane or lift work the efficiency varies with the size of the apparatus, with the load, and with the speed. Efficiency in this sense is a most uncertain guide. Some of the most useful and successful applications of hydraulic power—as, for instance, hydraulic capstans for hauling waggons in railway goods yards—have a very low efficiency expressed on the ratio of work done to power expended. Hydraulic cranes for coal or grain hoisting have a high efficiency when well designed, but it is now very usual to employ grabs to save the labour of filling the buckets, and their use lowers the efficiency, expressed in tons of coal or grain raised, by 33 per cent. or even 50 per cent. When hydraulic machines are fully loaded, 50 per cent. to 60 per cent. of the indicated power of the central station engine is often utilized in useful work done within a radius of two or three miles from the station. In very favourable circumstances the efficiency may rise to over 70 per cent., and in a great many cases in practice it no doubt falls below 25 per cent. If, however, energy in any form can be obtained ready for use at a moderate rate, the actual efficiency of the machines (*i.e.*, the ratio of the useful work done to the energy absorbed in the process) is not of very great importance where the use is intermittent.

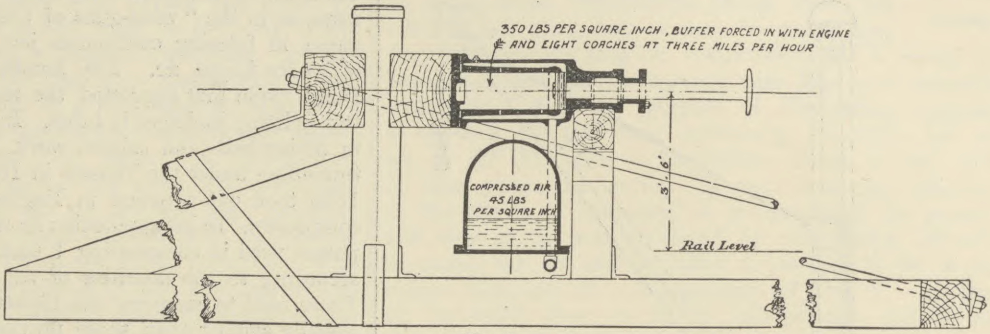

Fig. 5.

Hydraulic pressure is more particularly advantageous in cases where the incompressibility of the fluid employed can be utilized, as in hydraulic lifts, cranes, and presses. Hydraulic machines for these purposes have the peculiar and distinct advantage of direct action of the pressure on the moving rams, resulting in simplicity of construction, slow and steady movement of the working parts, absence of mechanical brakes, and greatest safety in action. When the valve regulating the admission of the pressure to the hydraulic cylinder is closed, the water is shut in, and, as it is incompressible, the machine is locked. Thus all hydraulic machines possess an inherent brake; indeed, many of them are used solely as brakes, so important is this property of fluids. The buffer-stop to be seen in terminal railway stations, and the hydraulic brakes of quick-firing guns, are examples. Mr F. W. Webb's buffer-stop is shown in Fig. 5.

Sometimes a much higher pressure than 700 ℔ or 1000 ℔ per square inch is desirable, more particularly for heavy presses and for machine tools such as are used for riveting and for punching, shearing, bending, drawing, and stamping metal. The development of these applications of hydraulic pressure has been largely due to the very complete machinery invented and perfected by the late Mr R. H. Tweddell. One of the principal installations of this kind was erected in 1876 at Toulon dockyard, where the machines are all connected with a system of mains of 2½-inch bore and about 1700 yards long, laid throughout the yard, and kept charged at a pressure of 1500 ℔ per square inch by engines of 100 h.p. with two large accumulators. M. Marc Berrier-Fontaine, the superintending engineer of the dockyard, has stated that the economy of the system over the separately-driven geared machines formerly used is very great. But while pressures so high as 3 tons per square inch (as in the 12,000-ton Armstrong-Whitworth press) have been used for forging and other presses, it is not desirable, in the distribution of hydraulic power for general purposes, that 1000 ℔ per square inch should be much exceeded; otherwise the rams, which form the principal feature in nearly all hydraulic machines, if proportioned to the work required, will often become inconveniently small, and other mechanical difficulties will arise. The cost of the machinery also tends to become greater. In particular cases the working pressure can be increased to any desired extent by means of an intensifier (Fig. 6).

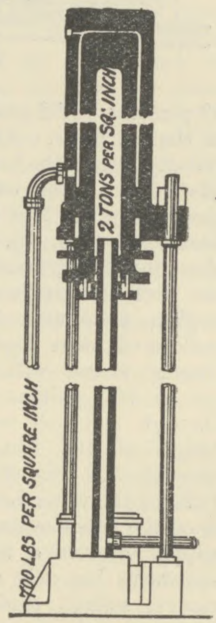

Fig. 6.

An important application of hydraulic power transmission is for ship work, the system being largely adopted both in H.M. navy and for merchant vessels. Hydraulic coal-discharging machinery was fitted by Armstrong as early as 1854 on board a small steamer, and in 1868 some hopper barges on the Tyne were supplied with hydraulic cranes. Mr A. Betts Brown of Edinburgh applied hydraulic power to ship work in 1873, and in the same year the first use of this power for gunnery work was effected by Mr G. M. Rendel on H.M.S. *Thunderer*. In 1883 the P. and O. steamer *Massilia* was fitted with hydraulic cranes, and since then all the large P. and O. boats have been supplied with hydraulic power (Fig. 7). The pressure usually employed in H.M. navy is 1000 ℔ per square inch. Accumulators are not used, and the engines have to be fully equal to supply directly the whole demand. The distance through which the power has to be transmitted is of course very short, and the high velocity of 20 feet per second is allowed in the main pipes. The maximum engine-power required under these conditions on the larger ships is very considerable. In the case of H.M.S. *Royal Sovereign* the pumping engines are capable of delivering 1340 gallons per minute.

In hydraulic transmission of power it is usually the pressure which is employed, but there are one or two important cases in which the velocity of flow due to the pressure is utilized in the machine. Reference has already been made to the use of turbines working at 750 ℔ per square inch at Antwerp. The Pelton wheel has also been found to be admirably adapted for use with such high pressures; in converting hydraulic power into electric by means of this device and a dynamo, the losses vary from

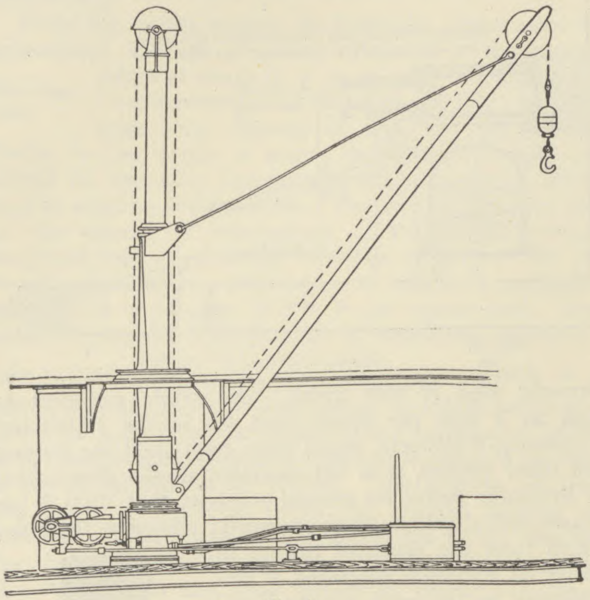

Fig. 7.

33 per cent. to 50 per cent., depending mainly on the sizes of the machines. Another very useful application of the velocity due to the head in hydraulic transmission is in an adaptation of the well-known jet pump to fire hydrants devised by the late Mr J. H. Greathead (Fig. 8). One of these injector hydrants will do the work of a single steam fire engine, and, with 30 to 40 gallons of water from the hydraulic mains, will deliver a jet of 150 gallons of water through a 1-inch nozzle to a height of 100 feet or more through 200 feet of hose, the bulk of the water being drawn from the low-pressure domestic supply or from a tank. The apparatus has only a low efficiency, seldom exceeding 25 per cent. At the present time there are about 120 of these hydrants at work from the mains in London.

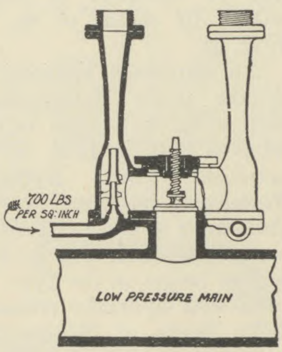

Fig. 8.

Improvements in hydraulic machinery since 1875 have been mainly in the direction of the perfecting of details, and in the adaptation of older and well-known apparatus to new requirements; but though many of these improvements have been of a highly interesting and important character, it would be outside the scope of this article to make further reference to them.

III. PNEUMATIC.

Probably the earliest recorded air-compressor is that found on the walls of a tomb in Egypt, in which two men standing on leather bags of air alternately press them down with their feet, to produce a blast for a furnace. The ancients employed compressed air in various ways, as in the "wind-guns of Ctesibus" (blow-guns), in forming continuous jets for their fountains, in blasts for forges, &c. Two hundred years ago, in France, Denis Papin first suggested the use of compressed air for transmitting packages in tubes. In later times it was used in diving-bells and caisson work, Brunel employing it in tunnelling under the Thames in 1825. William Mann in 1829 took out a patent in England for a compound air-compressor. In his application he states: "The condensing-pumps used in compressing I make of different capacities, according to the densities of the fluid to be compressed. Those used to compress the higher densities being proportionally smaller than those previously used to compress it at the first or lower densities," &c. This is a very exact description of the best methods of compressing air to-day, omitting the important intercooling. Baron Van Rathen in 1849 proposed compressing air in stages, and using intercoolers between each stage to get 750 lb pressure, for use in locomotives. For the next forty years inventors and engineers tried without success all manner of devices and complicated mechanism for cooling air during compression by the use of water, either injected into the cylinder or circulated around it, and finally, with few exceptions, settled down to direct compression with no cooling worthy of mention. Only in the last ten years of the 19th century were the fundamental principles of economical air-compression put into general practice, though all of them are contained in the patent of William Mann and the suggestion of Van Rathen.

History.

The first successful application of compressed air to the transmission of power as we know it, was at the Mont Cenis Tunnel in 1861. The form of compressor used was a system of water-rams—several of them in succession—in which the water was the piston, compressing the air upwards in the cylinder and forcing it out. Although the air came in contact with the water, it was not cooled, except slightly at the surface of the water and around the walls of the cylinders. Rotary drills for penetrating the rock were tried first, but were soon replaced by a percussion drill adapted from drawings in the United States Patent Office, copied by a French and Italian Commission from the patent of Fowle of Philadelphia. Drinker states positively that the first percussion drill ever made to work successfully was patented by J. J. Couch of Philadelphia in 1849. Shortly afterwards Fowle patented his drill, in which the direct-acting and self-rotating principle was used as we use it now. The first successful drill in the Hoosac Tunnel was patented 6th March 1866, by Brooks, Gates, and Burleigh, but after a few months was replaced by one made by Burleigh, who had bought Fowle's patent and improved it. The successful work in the Mont Cenis and Hoosac Tunnels with the percussion drilling machine caused the use of compressed air to spread rapidly, and it was soon found that there were many other purposes for which it could be employed with advantage, especially after economical compression was adopted. About 1870 there was started in Paris a pneumatic clock system, by which public and private clocks were run by compressed air from a central station. This soon developed into an immense system of distributing compressed air for power purposes, until Paris now has two great compressor plants and more than fifty miles of distributing pipes, furnishing air at 75 lb pressure to thousands of customers, who use it for every imaginable purpose, from cooling beer or dusting furniture to running electric light dynamos. The smaller motors are often of the rotary type and are not very efficient, though each has its little stove in which is a common kerosene lamp to heat the air before use. Compressed air is being largely and successfully introduced on tramways, in competition with electric and wire-rope traction systems. It was first tried in 1875 by Scott-Moncrieff, but failed owing to financial difficulties. Hardie, who was an assistant under him, made a success of it, and his system is now working on a very large scale in New York. The reheating is done with a tank of hot water. Mekarski uses hot water and steam. In his system, which was tried on tramways in the north of London, and is largely used in France, the air, under a high pressure, is passed over water at a temperature of 330° F., forming a combination of air and steam for use in the motor. For underground traction compressed air has been introduced in the coal mines of the Eastern states of America, and also to some extent in the metal mines of the West, but the difficulty of heating underground has not been overcome, though it might be, partially, by using compound engines and warming the air between the cylinders by the mine water, as in compound pumps.

Dr Pohle of Arizona, U.S.A., has patented and introduced extensively since 1890 the use of compressed air for lifting water directly, by admitting it into the water column. His plan is principally adopted in artesian wells, and is so arranged that the air-supply has a back pressure of water equal to half the lift. In the case of the artesian well, if it is desired to lift the water 30 feet, the air is admitted to the water column at least 30 feet below the water surface. The air admitted being so much lighter than the water it displaces, the column 60 feet high becomes lighter than that 30 feet high, and is constantly raised and flows out at the top. The efficiency of this method is only from 20 to 60 per cent., according to the height, but its adaptation to artesian wells renders it very valuable in some localities.

A remarkable compressed-air system was installed in 1890 by Priestly in the Snake River Desert, Idaho, U.S.A. On the north side of the river is a cliff, nearly perpendicular, about 300 feet high. One hundred and ninety feet above the river, for a considerable distance along the cliff, streams of water gush out from between the bottom of the great lava bed and the hardened clay of the old lake bottom. Priestly, without knowledge of Pohle's system, built a pipe line down the cliff, and trained the water into it in such a way that it carried a very considerable quantity of air in the form of bubbles along with it down the pipe, and compressed it on the way. The air was collected at the bottom in a covered reservoir, and taken up the cliff again to the lower part of an inverted siphon pipe, one side of which reached down from the water-supply about 60 feet, and the other side reached up and over the cliff. Allowing the water to fill both sides of the pipe to the level of the water-supply, he admitted his compressed air at about 75 ℔ pressure into the long side of the pipe near the bottom, and soon had the water flowing upwards over the cliff and irrigating a large tract of rich lava land. Here, then, was a power transmission and motor plant, without a moving part. A similar compressor was installed near Montreal, Canada, in 1896 (and patented), and another larger one at Ainsworth, British Columbia, Canada, in 1898, by the Taylor Hydraulic Air Compressing Co. of Montreal. Tests on the first compressor showed an efficiency of from 50 to 62 per cent., and it is thought that a few obvious improvements would bring the second one up to 75 per cent.

Saunders defines compressed air as "air under pressure." "It is usual," he continues, "to define compressed air as air increased in density by pressure, but we may produce compressed air by heat alone, as illustrated by the discharge of the cork from a bottle of air when heated." The laws of compression and expansion of gases may be found under PNEUMATICS (*Ency. Brit.*, 9th edition, vol. xix.), but it may be stated here that air develops heat on compression and is cooled on expansion, and that it expands with heat and contracts with cold. For the purpose of illustration, suppose a cylinder 10 feet long containing 10 cubic feet of air at 60° F., with a frictionless piston at one end. If this piston be moved $7\frac{1}{2}$ feet into the cylinder, so that the air is compressed to one-quarter of its volume, and none of the heat developed by compression allowed to escape, the air will be under a pressure of 90 ℔ per square inch and at a temperature of 460° F. If this air be cooled down to 60° F., the pressure will be reduced to 45 ℔ per square inch, showing that the heat produced in the air itself during compression gives it an additional expansive force of 45 ℔ per square inch. The average force or pressure in compressing this air without loss of heat is 21 ℔ per square inch, whereas if all the heat developed during compression had been removed as rapidly as developed, the average pressure on the piston would have been only 11 ℔ per square inch, showing that the heat developed in the air during compression, when not removed as fast as developed, caused in this case an extra force of 10 ℔ per square inch to be used on the piston. If this heated air could be transmitted and used without any loss of heat, the extra force used in compressing it could be utilized; but in practice this is impossible, as the heat is lost in transmission. If the piston holding the $2\frac{1}{2}$ cubic feet of air at 45 ℔ pressure per square inch and at 60° F. be released, the air expanding without receiving any heat would move it back to within $3\frac{1}{3}$ feet of the end only, and the temperature of the air would be lowered 170° F., or 110° F. below zero. If the air were then warmed to 60° F. again, it would move the piston back the remaining $3\frac{1}{3}$ feet to its starting-point, thus showing that air in expansion becomes cooled in the same manner as in compression it develops heat.

Theory.

From the foregoing it may be seen that the ideal air-compressing machine is one which will take all heat from the air as rapidly as it is developed during compression. This is called *Isothermal Compression*, and is never reached in practice, the best work yet done lacking 10 per cent. of it. It follows that the most inefficient compressing machine is one which takes away no heat during compression. This is called *Adiabatic Compression*, and in practice has been much more nearly approached than the ideal. It also follows that the ideal motor for using compressed air is one which will supply heat to the air as it is required in expanding. This is called *Isothermal Expansion*, and is often attained, and sometimes exceeded, in practice by supplying heat artificially. Finally, the most inefficient motor for using compressed air is one which supplies no heat to the air during its expansion. This is called *Adiabatic Expansion*, and has been very closely approached by most air motors until recent years. In practice isothermal compression is approached by compressing the air slightly, then cooling it, compressing it slightly again and again cooling it, until the desired compression is completed. This is called compression in stages, or compound compression. Isothermal expansion is approximately accomplished by allowing the air to do a part of its work (as expanding slightly in a cylinder) and then warming it, then allowing it to do a little more and then warming it again, and so continuing until expansion is complete.

A description of the actual performance may make the matter clearer. At the North Star Mines, in California, air is compressed by an ordinary pressure blower to about 5 lb pressure per square inch, its temperature rising from 60° to 100° F. It is then cooled again to 60° F. by a system of cooling-pipes placed in the tail-race of the water-wheel that runs the blower; then it is taken to the first cylinders of the compressor and compressed to 25 lb, its temperature being thus raised to nearly 200° F.; then it is passed through a system of cooling-pipes placed in the tail-race of the water-wheel that runs the compressor, and its temperature again reduced to 60° F.; thence it is passed to the second cylinders and compressed to 90 lb, and delivered to the transmission pipes conveying it to the mines. On reaching the motors at the mines, in some cases nearly 2 miles distant, the temperature, which had been raised by the last compression to over 200° F., has been reduced to about 70° F. Here, for the principal motors, the air, by being passed through a system of pipes heated by burning crude oil, has its temperature raised to 350° F., and is then taken by the first cylinder of the motor, where it is expanded down to 25 lb pressure per square inch and reduced to 75° temperature. It is then taken to the heater again, and after its temperature has been raised to 250° F., it is used in the second cylinders and exhausted at a temperature somewhat above that of the surrounding air.

Practice.

It will be seen that the air is carefully cooled during compression to prevent the heat it develops from working against compression, and even more carefully heated during expansion to prevent loss from the cold developed during expansion. More stages of compression, of course, give a higher efficiency, but the cost of machinery and friction losses have to be considered in practice. The reheating of the air is often considered a serious disadvantage, especially in mining, where there are great objections to having any kind of combustion underground. In the foregoing instance only one gallon of crude oil per hour is required to heat to 350° F. the air for a 300 horse-power hoisting engine. As Professor Unwin says: "For the amount of heat supplied the economy realized in the weight of air used is surprising. The reason for this is, the heat supplied to the air is used nearly five times as efficiently as an equal amount of heat employed in generating steam." Practically there is a hot-air engine, using a medium much more effective than common air, in addition to a compressed-air engine, making the efficiency of the whole system extremely high, probably over 90 per cent.

For underground work Rix has employed compound or triple expansion motors on pumps, using the pump-water in the tank as a reheater. The air enters the first cylinder at the normal temperature of the mine, the exhaust passes from that cylinder into a system of circulating pipes placed in the pump-tank, which warms the chilled air up to the temperature of the water; thence the air passes to the second cylinder, does its work there, and is again sent into a second system of circulating pipes in the tank, where it is again warmed to the temperature of the water; then it is used in the third cylinder, and exhausted. In this manner the heat that is lost in compressing the air is recovered without expense. This method has proved very successful, and as the heat costs absolutely nothing, it makes the system very economical. On account of the very considerable amount of heat taken from the water, the efficiency is high. A similar arrangement might be employed wherever there is cheap circulating water on the surface, to avoid any difficulty or complications arising from the use of fuel.

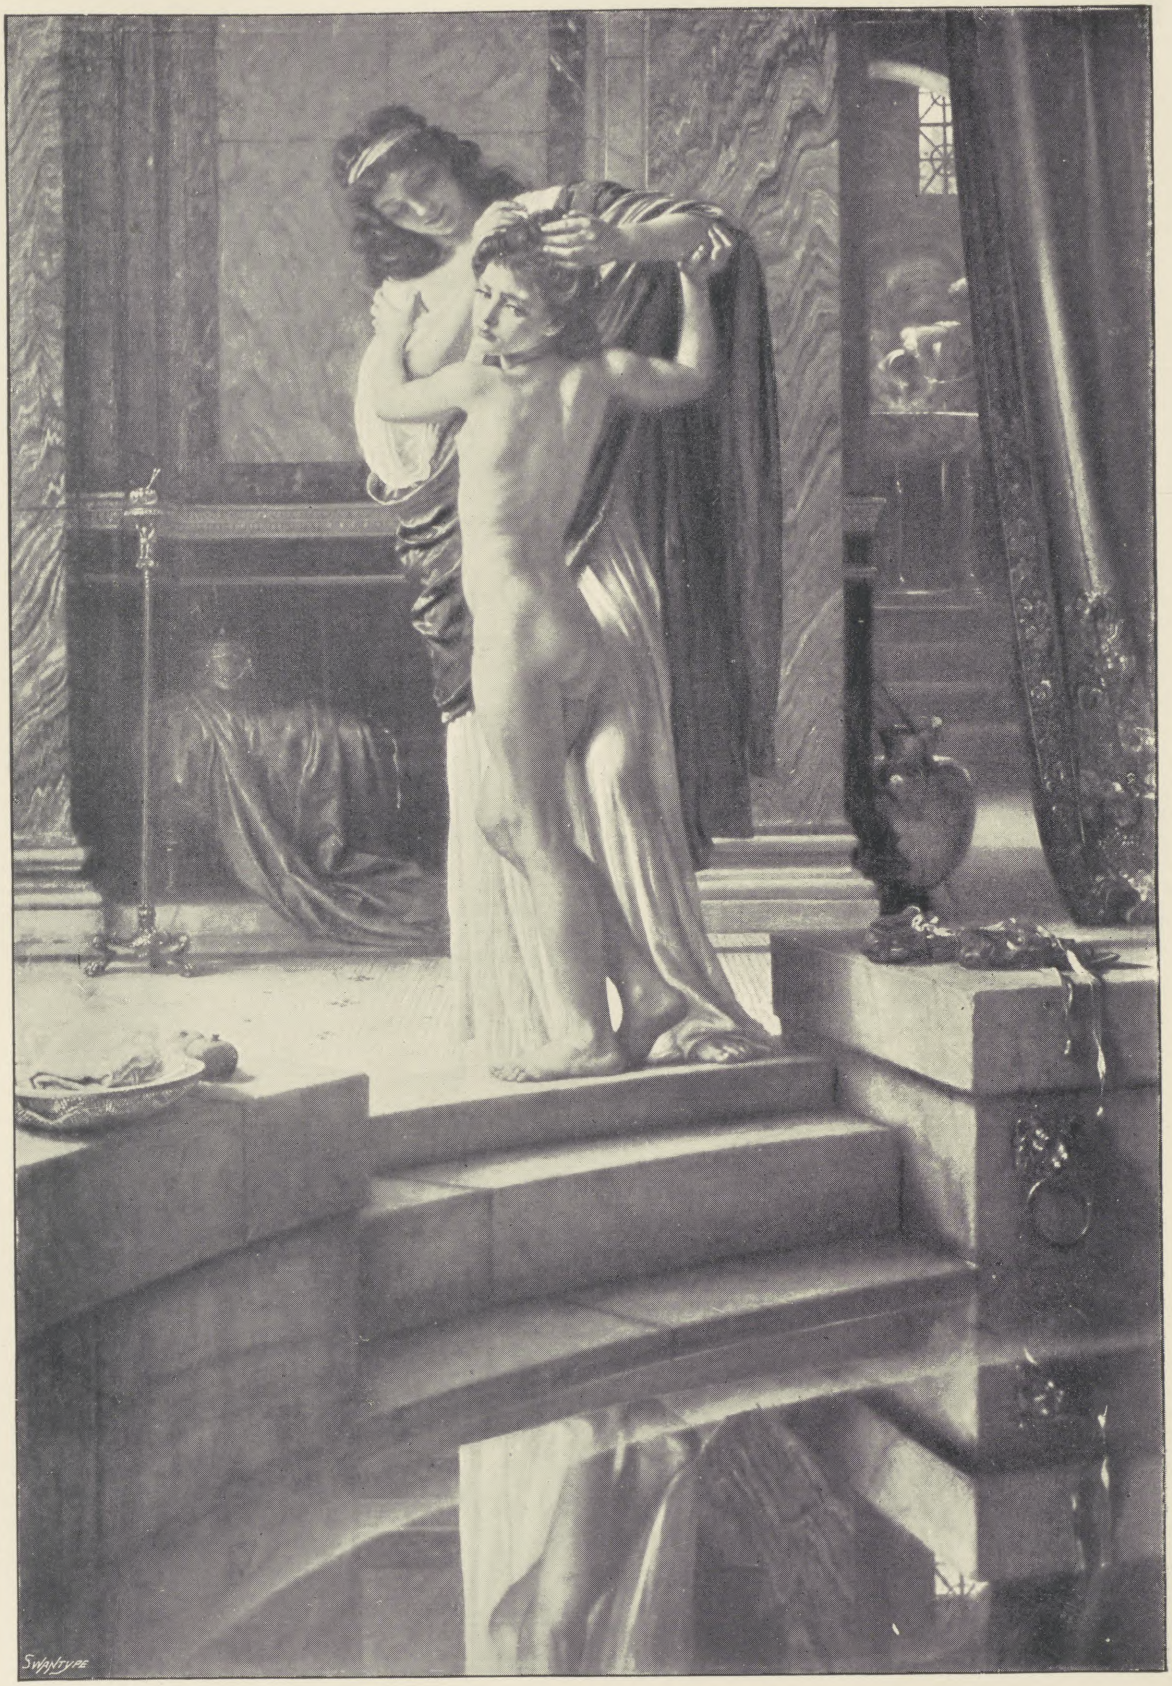
The use of compressed air without reheating should never be considered practical except in temporary emergencies, or where the cold exhausted air is of value, as is sometimes the case in sinking pumps or rock drills. An efficiency of less than 25 per cent. may be expected in such cases, where the motors are what might be called piston-displacement machines; that is, the compressed air is admitted at one end of the cylinder and moves the piston the length of the stroke at full pressure, and discharges without getting anything of the expansive force of the air. There are a great many of this class of motors in use.

The transmission of air from the compressor to the motor is much more simple and effective than is usually supposed. The air admits of a velocity of 15 to 20 feet per second through pipes, with very slight loss of friction, and therefore there is no necessity for an expensive pipe system in proportion to the power transmitted. It is found in practice that, allowing a velocity as given above, there is no noticeable difference in pressure between the compressor and the motor several miles away. Common oil well-tubing is largely used for the pipes, and if it is properly put in there is very slight loss from leakage, which, moreover, can be easily detected and stopped. In practice, a sponge with soap-suds, passed around a joint, furnishes a detective agency, the escaping air blowing soap-bubbles. In good practice there need not be more than 1 per cent. loss through leakage, and 1 per cent. possibly through friction, in the transmission of air. (See also PNEUMATIC TOOLS.) (A. DE W. F.)

Poynter, Sir Edward John, BART. (1836–——), President of the Royal Academy and Director of the National Gallery, son of Ambrose Poynter, architect, was born in Paris on 20th March 1836. He pursued his art studies in England and in Paris (under Gleyre, 1856–59), and exhibited his first picture at the Royal Academy in 1861. In 1869, after the exhibition of "Israel in Egypt" and "The Catapult," he was elected an Associate of the Royal Academy, and in 1876, the year of "Atalanta's Race," full Academician. From the beginning of his career Sir Edward Poynter was academical in his art—that is to say, he sought to base it on a profound and reverent study of the old masters, more particularly those of Italy. It has been objected, with much truth, that with all their learning and evidence of power, the greater number of his more important pictures display violent action which is not real so much as arrested movement. The true answer is not, as some have held, that this is the price paid for conscientious and deeply-studied drawing and complex composition laboriously overcome. It is that the artist's aim has been essentially decorative, and that by concession to the laws of decoration some sacrifice of realism and spontaneity is required. On the death of Sir John Millais in 1896, Sir Edward was elected to the Presidency of the Royal Academy—and to all the semi-official posts and duties, professional and social, it carries with it—and on that occasion he received his knighthood. He was made a baronet in 1902.

When the art teaching centre of South Kensington was assuming the importance it has since attained, Mr Poynter was appointed Director for Art in the Science and Art Department, and Principal of the National Art Training Schools (now the Royal College of Art), and by virtue of his vigorous and successful administration he invested his office with a distinction which, after his resignation in 1881, it soon notoriously lacked.

In the decorative arts Sir Edward practised freely as a designer in fresco, mosaic, stained glass, pottery, tile-work, and the like. While still quite a young man, he was encouraged by the architect William Burges, A.R.A., to design panels for his quaint Gothic cabinets; Messrs Powell obtained from him cartoons of designs for stained glass; for the decoration of Waltham Abbey church he was employed on a series of thirty important designs. Attracted by these, Dalziel Brothers commissioned a number of full-page drawings on wood for the illustration of their celebrated "Bible



"IDLE FEARS." By Sir E. J. POYNTER, P.R.A.

(By permission of Lord Hillingdon.)

Gallery." The cartoons for "St George" and "St David," the mosaic panels now embellishing the Outer Lobby of the Palace of Westminster, were produced in 1870, and they were followed by the "Apelles" and "Phidias," in the same method of reproduction, in the Victoria and Albert Museum; by the important series of frescoes in St Stephen's, Dulwich—scenes from the life of the saint; by the decoration of the Grill Room at the Museum at South Kensington, with the tiles *en camaïeu*—an achievement strikingly successful and pregnant with results. Sir Edward Poynter, always a lover of water-colour drawing and of the art of landscape painting, was elected to the Royal Society of Painters in Water Colours in 1883. In 1874 Sir Edward designed the Ashantee medal; and in 1892, for the coinage of that year, the reverse of the shilling and florin, to the obverse of Mr Thomas Brock, R.A.

The Directorship of the National Gallery became vacant in 1894, and Sir Edward, profoundly versed in the works of the Old Masters, especially of the Italian schools, was appointed to the post. From that date to the end of 1901 the collection largely increased in numbers, while in general arrangements, in hanging, &c., great improvements were introduced. Under Sir Edward's rule the National Gallery of British Art, at Millbank, presented by the late Sir Henry Tate, became a department of the National Gallery, and thither were removed many pictures formerly in the British rooms at Trafalgar Square, as well as the Chantrey Collection from South Kensington, &c. One of the most important services by the Director was the editing of the great *Illustrated Catalogue of the National Gallery* (1889–1900), in which every picture in the collection is reproduced—an unprecedented achievement in the annals of art-publishing.

PAINTINGS.—Sir Edward Poynter's most notable pictures have been the following: "Israel in Egypt" (1867); "The Catapult" (1868); "Perseus and Andromeda" (1872); "Atalanta's Race" (1876); "The Fortune-Teller" (1877); "Nausicaa and Her Maidens" (1879); "Visit to Æsculapius" (1880), now in the Chantrey Collection, in the Tate Gallery; "The Ides of March" (1883); "Diadumenè" (1885), now destroyed; "On the Terrace" (1889); "The Meeting of Solomon and the Queen of Sheba (1891); "Horæ Serenæ" and "Idle Fears" (1894; see Plate), and numerous portraits and water-colour drawings.

LECTURES.—The presidential discourses of Sir Edward Poynter have been of a purely academic character, dwelling on the necessity of conscientious labour and the study of tradition, in opposition to the modern tendency to avoid such study and to trust to genius. In his series of Slade Lectures, delivered from 1875 to 1879, and first published in 1879 (republished, with additions, in 1897), Sir Edward Poynter deals more fully with the whole subject of art education, considering in turn Decorative Art, Old and New Art, Systems of Art Education, Hints on the Formation of a Style, Training of Art Students, The Study of Nature, The Value of Things, Objects of Study, Professor Ruskin on Michelangelo (hotly controversial in tone), Influence of Art in Social Life, and Ancient Decorative Art.

Požarevatz, a town in Servia, situated in the Morava valley, 4 miles to the east of the Morava river and 8 miles south of the Danube. The station for steamers, Dubravitza, with its custom-house, standing on the banks of the latter river, forms practically the harbour of Požarevatz. The town has no special industry, but is the principal market of a very extensive and fruitful plain between the rivers Morava, Mlava, and Danube. It is the seat of the district prefecture, a tribunal of justice, a college, and several national or normal schools. It has a large modern penitentiary, with a department for political offenders and a prison for women. Two miles to the west, towards Morava, is situated Lubichevo, a model farm and stud belonging to the Government. The shady park and flower gardens are a popular resort of the people of Požarevatz. It is known in the history of international treaties as the place at which the famous "Požarevatz Peace" between Austria and Turkey was concluded in 1718. Population (1900), 12,957.

Pozoblanco, a town of Spain, province of Cordoba, to the south-west of Pedroche, with a little stream, De los Alamos, running through it. Its population was 11,522 in 1887, and 11,682 in 1897. It has clean, regular streets and some fine public buildings—the parish church, the town hall, the hospital, and numerous schools. The fairs are famed for their exhibit of live stock and agricultural products. There are argentiferous lead mines in the neighbourhood, and manufactures of cloth and leather in the town itself.

Pozsony (German, *Pressburg*), a municipal town, Hungary, the capital of the county of the same name, on the left bank of the Danube, 35 miles east of Vienna. Its dynamite factory produces yearly above one million kilograms of explosive material, and there is, besides, a well-known industry of fine brushes. The Danube here is spanned by a beautiful iron bridge, serving both for the railway and as a public road. In 1897 an equestrian statue in white marble of Queen Maria Theresa was erected, the work of the Hungarian sculptor Fadrusz. Population (1891), 56,048; (1901), 65,867.

Pozzuoli, a town and bishop's see of the province of Naples, Campania, Italy, on the north shore of the Bay of Naples, 6 miles west of Naples. A branch of the firm of Armstrong & Co. of Newcastle-upon-Tyne has been established here for, amongst other things, the making of guns for the Italian navy. A cement made from the volcanic earth of the neighbourhood (*pozzuolana*) is extensively used in building. The mineral baths attract numerous visitors in the summer. The Serapeum is by some authorities considered to have been a market, and —contrary to the common theory—they explain the holes made in the pillars by molluscs as due to the fact that the pillars formed part of a large tank for marine animals. In 1899 the Italian Government voted £32,000 for building a breakwater and improving the harbour. Population (1881), 14,703; (1899), 16,000.

Prachatitz, a town in Bohemia, Austria, at the foot of the Libin, on a tributary of the Blanitz river. It has a Gothic church of the 14th century, and remains of its old fortifications, together with a town hall and numerous castellated houses with mural decorations in colour. The manufactures produce hosiery, starch, matches, and electrical plant, beer and spirits. It is a favourite summer resort. Population (1890), 4141; (1900), 4338, mostly German.

Prague (German, *Prag*; Czech, *Praha*), the capital of Bohemia. The adjoining suburbs of Weinberge, Zizkoff, Karolinenthal, and Smichoff now practically form part of the town. Population (1880) 162,323, or including suburbs, about 250,000; (1890) with the garrison, 182,530 (of whom 27,125 were German), or with suburbs, 323,563; all Roman Catholic, with the exception of 17,635 Jews and 3288 Protestants, both religions showing a slight decline. In 1900 the population was 204,478, including the garrison of 7120 men, or with suburbs, 385,238 (estimated at 87 per cent. Czech, 13 per cent. German, 91 per cent. Roman Catholic, 7 per cent. Jews, and 2 per cent. Protestants). The relative diminution of the German element continues at an accelerated pace, mainly owing to the attraction of higher wages to the Czech rural population, but fostered by political causes. A token of the change that has converted Prague from a town in which German influence was paramount into a Czech stronghold, is the reduction in the decade 1880–90 of 3150 in the number of the German-speaking inhabitants, and an increase of the Czechs by 24,400. This progressive change is not exclusively due to the Czech immigration, however. In Prague, as elsewhere in the Czech provinces, the adoption of one or the other language is frequently a political confession of faith, so that a part of the Czech increase must be attributed to the conversion of former Germans. Another visible sign of the change is the removal of the German street names in the Hapsburg black and yellow, which have been replaced by the Bohemian language and colours. There are now two universities, one German and the other Czech (the latter a recent concession to Bohemian national sentiment), two polytechnics, a theological seminary, three upper and ten ordinary gymnasia, two commercial academies, an academy of arts, and a conservatory of music, together with five other special high schools, twelve intermediate and thirty-four elementary schools. Education is in an advanced state, being promoted not merely by the industrial progress and prosperity of the town and province, but by the rivalry of the two races. The boast of the Germans that they represent not merely the capital but also the culture of the city, is being steadily deprived of its justification, not through German decline but through Czech progress. In 1894 the German university was attended by 1287 and the Czech university by 2410; in 1901 the figures were 1314 and 3188 respectively. In 1894 the German polytechnic was attended by 244 students and the Czech by 417, the corresponding totals for 1901 being 585 and 1262. Twelve of the intermediate schools are Czech and six German, and of the elementary schools 39 are Czech and 18 German. Of the other educational institutions, the Czechs maintain 16 and the Germans 12. The same rivalry and separation are maintained in all grades and forms of instruction, even down to cookery, for which there are special German and Czech schools. In this struggle the Czechs have a decided advantage in their control of the municipal and provincial funds. The creation and the recognition by the State of a Czech Academy of Science are regarded as an important achievement by the dominant nationality. The addition (1878) of a new bridge, named after Palacky, the Bohemian historian, raised the number crossing the Moldau within the city to eight, and since then a ninth has been built. The Karls bridge, partially destroyed by floods in 1890, was restored in 1892. Prague now possesses fifty-seven Roman Catholic and four Protestant churches and one Russian church, together with ten synagogues. Among the public collections should be mentioned the Nostitz Picture Gallery, the Rudolphinum, and the Bohemian National Museum, in a building erected in 1889–93. In April 1901 the Emperor Francis Joseph founded, and endowed out of his privy purse, a gallery of modern painting, sculpture, and architecture, intended to contain representative works of Bohemian artists of both nationalities. There is a large and increasing number of scientific, literary, artistic, social, and benevolent institutions. The new towers of the cathedral, and the campanile, the Straha Ritter Academy, the new central market, and the Nostitz Palace constitute fresh architectural features. A second Czech national theatre was begun in 1900.

Prague has more than maintained its position as the leading centre of Bohemian industry and trade, and indeed as one of the most important places in the monarchy. Its progress has been greatly promoted by the development of communications. It is now the junction of seven railway lines, as well as of the extensive roads of the crown-land. It has also benefited by the growth of the sugar industry, of which it is the chief Austrian market, and by the efforts that have been made to promote inland navigation. In 1895 the shipping service on the Moldau numbered 56 steamers and 163 barges. The principal industries are milling, brewing, the production of cast iron, the manufacture of all kinds of metal wares and chemicals, cotton-spinning, calico-printing, tanning, and glove-making. Among the new industries is the construction of railway waggons and carriages. In Prague the struggle between the two races has of late years been marked by many vicissitudes, by ostentatious disaffection, rioting, plunder, incendiarism, bloodshed, revolutionary plots, and even murder, followed by the suspension of constitutional rights and severe measures of military repression. The upshot, thus far, has been the practical triumph of Czech aspirations in the Bohemian capital. (See BOHEMIA.)

(Æ. O'N.)

Prato, a town and episcopal see of the province of Florence, Tuscany, Italy, 11 miles by rail north-west of Florence, dominated by a mediæval castle and surrounded by walls. It has a picture gallery (in the town hall), a scientific, and a musical academy. Its varied industries embrace the manufacture of woollens (the most important), straw-plaiting, biscuits, hats, macaroni, candles, silk, olive oil, clothing, and furniture, also copper and iron works, and printing. Population (1881), 26,156; (1899), 27,000.

Prayers for the Dead.—Wherever there is a belief in the continued existence of man's personality through and after death, religion naturally concerns itself with the relations between the living and the dead; indeed, some philosophers have attributed the origin of all religion to the *cultus* of ghosts. Be that as it may, the existing conceptions of our relations to the dead vary widely. Sometimes they are worshipped, as in China. Sometimes they are consulted, as by necromancers. Sometimes the living think to furnish them with the means of enjoyment in the other world by slaying horses, &c., at their graves. Sometimes the dead are dreaded and propitiated. And, lastly, where the idea of a future judgment obtains, prayers are often offered on their behalf to the Higher Powers. Prayers for the dead are mentioned in 2 Maccabees xii. 43–45, where the writer is uncertain whether to regard the sacrifice offered by Judas as a propitiatory sin-offering or as a memorial thank-offering, a distinction of great importance in the later history of the practice. Prayers for the dead form part of the authorized Jewish services. The form in use in England contains the following passage: "Have mercy upon him; pardon all his transgressions . . . Shelter his soul in the shadow of Thy wings. Make known to him the path of life." The only passage in the New Testament which is held to bear directly on the subject is 2 Tim. i. 18, where, however, it is not certain that Onesiphorus, for whom St Paul prayed, was dead. Outside the Bible the proof of the early use of prayers for the dead has been carried a step further by Professor Ramsay's discoveries, for it is now impossible to doubt the genuineness of the copy (contained in the spurious acts of the saint) of the inscription on the tomb of Abercius of Hieropolis in Phrygia (see Lightfoot, *Apostolic Fathers*, part ii. vol. i. p. 492 ff.). The 19th line of the inscription runs thus: "Let every friend who observeth this pray for me," *i.e.*, Abercius, who throughout speaks in the first person: he died in the latter part of the 2nd century. The inscriptions in the Roman catacombs bear similar witness to the practice, by the occurrence of such phrases as "Mayst thou live among the saints" (3rd century); "May God refresh the soul of . . . "; "Peace be with them." Among Church writers Tertullian is the first to mention prayers for the dead, and that not as a concession to natural sentiment, but as a duty: "The widow who does not pray for her dead husband has as good as divorced him." This passage occurs in one of his later Montanistic writings, dating from the beginning of the 3rd century. Subsequent writers similarly make incidental mention of the practice as prevalent, but not as unlawful or even disputed (until Aerius challenged it towards the end of the 4th century). The most famous instance is St Augustine's prayer for his mother, Monica, at the end of the 9th book of his *Confessions.*

An important element in the liturgies of the various Churches consisted of the diptychs or lists of names of living and dead who were to be commemorated at the Eucharist. To be inserted in these lists was an honour, and out of the practice grew the canonization of saints; on the other hand, to be excluded was a condemnation. In the middle of the 3rd century we find Cyprian enjoining that there should be no oblation or public prayer made for a deceased layman who had broken a Church rule by appointing a cleric trustee under his will: "He ought not to be named in the priests' prayer who has done his best to detain the clergy from the altar." Although it is not possible, as a rule, to name dates for the exact words used in the ancient liturgies, yet the universal occurrence of these diptychs and of definite prayers for the dead in all parts of the Church in the 4th and 5th centuries tends to show how primitive such prayers were. The underlying principles of these recitations of names seem to have been, first, that the Eucharistic offering was the act of the whole Church, of those absent as much as of those present: "We offer on behalf of A and B"; and, secondly, that those who are asleep in Christ are as truly members of the Church as those who are alive. Hence there is in the earliest forms no sharp distinction, such as grew up later, between those who are commemorated with thanksgiving and those for whom prayers are made. The offering and the petitions embrace all alike, from the Blessed Virgin and the Twelve Apostles down to the sick and sorrowful on earth. God is further asked to hear the intercessions of the holy dead on behalf of the living. The language used in the prayers for the departed is very reserved, and contains no suggestion of a place or state of pain. We may cite the following from the so-called liturgy of St James:—

"Remember, O Lord, the God of Spirits and of all Flesh, those whom we have remembered and those whom we have not remembered, men of the true faith, from righteous Abel unto to-day; do Thou Thyself give them rest there in the land of the living, in Thy kingdom, in the delight of Paradise, in the bosom of Abraham, Isaac, and Jacob, our holy fathers, from whence pain and sorrow and sighing have fled away, where the light of Thy countenance visiteth them and always shineth upon them."

Public prayers were only offered for those who were believed to have died as faithful members of Christ. But Perpetua, who was martyred in 202, believed herself to have been encouraged by a vision to pray for her brother, who had died in his eighth year, almost certainly unbaptized; and a later vision assured her that her prayer had been answered and he translated from punishment. St Augustine thought it needful to point out that the narrative was not canonical Scripture, and contended that the child had perhaps been baptized. Similarly, a mediæval legend relates that Gregory the Great was so struck with the justice of the Emperor Trajan, that he prayed for him, and in consequence he was admitted to Paradise (cf. Dante, *Purg.* x., *Parad.* xx.).

As time went on, further developments took place. Petitions to God that He would hear the intercessions of the departed became direct requests to them to pray (*Ora pro nobis*); and finally, the saints were asked themselves to grant grace and help. Again, men felt difficulty in supposing that one who repented at the close of a wicked life could at once enjoy the fellowship of the saints in Paradise (St Luke xxiii. 43), and it seemed unfair that they should be made equal with those who had borne the burden and heat of the day (St Matt. xx. 12). And so the simple severance between good and bad indicated in St Luke xvi. 26, became the threefold division made familiar by Dante. First there were the saints in Paradise, awaiting their final glory, but already above the need of human prayers, and able to help men. Next came the forgiven sinners, who would ultimately pass on to Paradise, and were being prepared for it in Purgatory, and might be helped forward by the prayers of their friends on earth. And lastly, the impenitent wicked, whose destiny was Hell. These speculations were further fixed by the growth of the theory of satisfaction and of Indulgences: each forgiven soul was supposed to have to endure an amount of suffering in proportion to the guilt of its sins, and the prayers and pious acts of the living availed to shorten this penance time in Purgatory (see *Ency. Brit.*, 9th ed., art. INDULGENCES). It thus came about that prayers for the dead were regarded only as aiming at the deliverance of souls from purgatorial fires; and that application of the Eucharist seems to have overshadowed all others. The Council of Trent attempted certain reforms in the matter, with more or less success; but, broadly speaking, the system still remains in the Roman Church, and masses for the dead are a very important part of its acts of worship.

The Reformation took its rise in a righteous protest against the sale of Indulgences; and by a natural reaction the Protestants, in rejecting the Romish doctrine of Purgatory, were inclined to disuse all prayers for the dead. They tended to divide men sharply into two classes, the good and the bad; to speak as if judgment followed immediately on death, and as if the soul passed at once to Heaven. Prayers for the dead therefore seemed useless, if not presumptuous; though if the fact that a man's fate is already decided makes it vain to pray for him, it is difficult to see how a strict Calvinist could permit intercession even for the living. The formularies of the English Church speak plainly of an intermediate state, where disembodied spirits await their "perfect consummation and bliss," resting in Christ until "the general resurrection at the last day" (Burial Service); but they as clearly condemn the Romish doctrine of Purgatory. Important changes have been made, in the successive revisions of the Prayer-Book, in the commemorations of the dead at the Eucharist and in the Burial Service.

In the Communion Service of 1549, after praise and thanks were offered for all the saints, chiefly the Blessed Virgin, came the following: "We commend unto Thy mercy all other Thy servants, which are departed hence from us with the sign of faith and now do rest in the sleep of peace: grant unto them, we beseech Thee, Thy mercy and everlasting peace." The Burial Service of the same date contained explicit prayers for the deceased, and Introit, Collect, Epistle, and Gospel were provided for "the Celebration of the Holy Communion when there is a Burial of the Dead." In 1552, under the influence of Bucer, all mention of the dead, whether commemorative or intercessory, was cut out of the Eucharist; the prayers in the Burial Service were brought into their present form; and the provision for Holy Communion at a Burial was omitted. The thankful commemoration of the dead in the Eucharist was restored in 1661, but prayers for them remained, if they remained at all, veiled in ambiguous phrases.

The Church of England has never forbidden prayers for the dead, however little she has used them in her public services. It was proposed in 1552 to condemn the scholastic doctrine *de precatione pro defunctis* in what is now the 22nd of the Thirty-nine Articles, but the proposal was rejected. And these intercessions have been used in private by a long list of English divines, among whom Andrewes, Cosin, Ken, Wesley, and Keble form an almost complete chain down to the present day. On the tomb of Bishop Barrow (1680) stands a request to passers-by to pray for their fellow-servant. And in a suit (1838) as to the lawfulness of an inscription, "Pray for the soul of . . .," the Court decided that "no authority or canon has been pointed out by which the practice of praying for the dead has been expressly prohibited." As Jeremy Taylor put it (*Dissuasive from Popery*, I. I. iv.), "General prayers for the dead the Church of England never did condemn by any express articles, but left it in the middle."

In conclusion, we may quote the views of a writer who represents Eastern Christendom: "We pray . . . for the dead that they may become worthy of the vision of God's face. We know nothing of an intermediate state of souls which have neither been received into the kingdom of God, nor condemned to torture; for of such a state we have received no teaching, either from the apostles or from Christ. We do not acknowledge Purgatory—that is, the purification of souls by sufferings from which they may be redeemed by their own works or those of others; for the Church knows nothing of salvation by outward means, nor any sufferings, whatever they may be, except those of Christ; nor of bargaining with God, as in the case of a man buying himself off by good works" (Khomiakoff's "Essay on the Church," in W. J. Birkbeck, *Russia and the English Church*, p. 217. London, 1895).

Luckock. *After Death.* London, 1879, &c.—Plumptre. *The Spirits in Prison.* (W. O. B.)

Prenzlau, a town of Prussia, on the Ücker river and at the north end of the Lower Ücker lake, 30 miles west-south-west of Stettin by rail. There are 4 Evangelical churches, a Reformed church, a Catholic church, a synagogue, a gymnasium, a boys' and 2 higher grade girls' schools, a seminary for teachers, and a dairy school. Population (1880), 16,933; (1900), 20,228.

Prerau (Czech, *Přerov*), an important railway junction and commercial centre in Moravia, Austria, 13 miles south-east of Olmütz. Population (1890), 12,955; (1900) 16,738, chiefly Czech and Catholic (estimated to have 9 per cent. German, 5 per cent. Jewish). It has an important cloth industry, in addition to the staple manufactures of sugar, ropes, machinery, agricultural implements, &c. It was at one time the chief seat of the Moravian Brethren.

Presbyterianism.—The extent to which the Presbyterian form of Church polity prevails throughout the world has been made manifest in recent years by the formation of a Pan-Presbyterian Alliance. At a representative conference in London in 1875, the constitution of the Alliance was agreed upon, and arrangements were made for holding, every three or four years, a Presbyterian Œcumenical Council. This "General Council of the Alliance of Reformed Churches holding the Presbyterian System" met in Edinburgh in 1877, in Philadelphia in 1880, in Belfast in 1884, in London in 1888, in Toronto in 1892, in Glasgow in 1896, and in Washington in 1899. Churches which are organized on Presbyterian principles, and hold doctrines in harmony with the Reformed Confessions, are eligible for admission to the Alliance. Its object is not to form one great Presbyterian organization, but to promote unity and fellowship among the numerous branches of Presbyterianism throughout the world. On the roll of the General Council held at Washington there were 64 Churches. The statistics of these and of 16 others not formally in the Alliance were as follows: Congregations 29,476, ministers 26,521, elders 126,607, communicants 4,852,096. The approximate amount raised during the previous year (1898) for home and foreign work was £6,999,021. Of these 80 Churches, 12 were in the United Kingdom, 20 on the continent of Europe, 16 in North America, 3 in South America, 10 in Asia, 9 in Africa, 6 in Australia, 2 in New Zealand, 1 in Jamaica, and 1 in Melanesia. The desire for union which led to the formation of the Alliance has since 1875 borne remarkable fruit. In England in 1876 two Churches united to form the Presbyterian Church of England; in the Netherlands two Churches became one in 1892; in South Africa a union of the different branches of the Presbyterian Church took place in 1897; in Scotland the "Free Church" and the "United Presbyterian" became one in 1900, under the designation of the United Free Church; in Australia and Tasmania six Churches united in 1901 to form the "Presbyterian Church of Australia"; and a few months later the two Churches in New Zealand which represented respectively the North and South Islands united to form the "Presbyterian Church of New Zealand." "In no portion of the Empire," it has been said, "does the British flag now fly over a divided Presbyterianism except in the British Isles themselves."

The United Kingdom.

The development of Presbyterianism in the United Kingdom has been marked since 1875 by some features common to all the Churches. The first of these has been a restatement of doctrinal belief. No Church has proposed to set aside the Westminster Confession of Faith, but the United Presbyterian Church (which led the way in this matter), the Free Church of Scotland, and the Presbyterian Church of England, have taken steps to define more accurately their relation to the Confession. This has been done by a Declaratory Statement, or by an alteration of the formula by which ministers and other office-bearers express their adherence to the standards, or, as in the case of the Presbyterian Church of England, by the adoption of more briefly expressed "Articles of the Faith." No change, it is alleged, has been made in regard to the substance of the Westminster doctrine, but there has been a desirable alteration of emphasis and proportion. The Church of Scotland, in consequence of her relation to the State, has not found it so easy to move in this direction; and the Presbyterian Church of Ireland, in consequence of her conservatism in matters of doctrine, has not felt the need of change.

Doctrinal belief.

Another feature of development common to Presbyterianism in the United Kingdom is the great attention devoted to the improvement of public worship. The *service* as distinguished from the *sermon* has been the subject of much thought and care. Instead of one or two long prayers, there is a tendency to have a greater number of brief prayers, definitely apportioned into acts of confession, thanksgiving, supplication, and intercession. The repetition of a creed is also provided for. All the larger churches in Great Britain have produced books of the nature of a Directory of Worship, in which the right order of service and suitable topics for prayer are indicated. This help has in most cases been rendered by a Church Service Society not directly connected with the Courts of the Church. The Synod of the Presbyterian Church of England took the matter into its own hands and prepared a "Directory for the Public Worship of God on the Basis of that agreed upon by the Assembly of Divines at Westminster, A.D. 1644." The Service of Praise, too, has received special attention in all the Churches. The adoption of the new "Church Hymnary" by the Churches in Scotland and Ireland will do much to unify Presbyterian worship, as did the exclusive use of "Psalms and Paraphrases" before hymn-books were introduced. The "Church Hymnary" was the work of a joint committee representing the three Churches in Scotland and the Church in Ireland. Since 1875 the use of instrumental music has become much more general.

Public worship.

A third feature characteristic of British Presbyterianism during the period under review is a strenuous endeavour to provide for the higher instruction of youth, not only in the Sunday-school, but also in the Bible-class and in the home. Conspicuous service in this respect has been rendered by the production of handbooks covering the whole field of biblical and doctrinal education. Written examinations are held yearly, and honours and prizes are awarded. In this way much has been done to prolong the religious instruction of young people after they have ceased to be children, and it is hoped that a fruit of the movement will be a larger supply of well-equipped teachers for Sunday-schools.

Instruction of youth.

One other feature common to the development of Presbyterianism in several of the Churches in Great Britain concerns the tenure of the pastorate. In all Presbyterian Churches of the United Kingdom it has been the invariable rule and practice that a minister holds office *ad vitam aut culpam*, *i.e.*, for life or until found guilty of an offence which merits suspension or deposition. In the United Free Church of Scotland and the Presbyterian Church of England efforts have been made to formulate a quasi-judicial method of removing a minister from his charge on the ground of apparent inefficiency or want of success. This marks a new departure in British Presbyterian polity. The following deliverance of one of the Churches indicates the line along which the new movement tends to advance :—

Tenure of the pastorate.

If the Presbytery, after exhausting all ordinary means, shall find that the ends of the ministry are still not being served ; that there is *primâ facie* ground to believe that the responsibility for this state of things rests mainly with the minister ; and that there is no reasonable hope that these ends will be served by a continuance of his ministry in that congregation ; they shall prepare a full and explicit statement of the facts and grounds upon which they have come to this conclusion, and shall hear the minister and other parties thereupon. If, after due hearing of parties, the judgment of the Presbytery shall be that there is no hope of the ends of the Christian ministry being served in that particular congregation under the existing pastorate, they may, on such pecuniary provision being made for the minister as in the circumstances of each case the Presbytery shall deem equitable, dissolve the pastoral tie ; but without prejudice to his ministerial standing, and subject to complaint and appeal in the ordinary form.

There has been little time and less practical experience to test the effect of this departure from the immemorial law and practice of the Presbyterian Church, which went far to secure, even in unendowed churches, the independence of her ministers. But it seems likely to affect unfavourably the supply of high-class candidates for a sacred office, the independence of which, even when hedged about by constitutional safeguards, is often menaced by the unscrupulous exercise of money power.

Other features in the development of Presbyterianism in the United Kingdom are more specifically associated with individual Churches.

SCOTLAND.

In the CHURCH OF SCOTLAND by far the most important change was the abolition of patronage in 1874. It exercised a powerful influence upon the Scottish people, for it was the uprooting of the main cause of all the alienations and secessions from the National Church. The Act of 1874 gave back to the people the right to elect and call the minister to a vacant parish. Whatever effect it may have had in other respects, there is no doubt that it restored the affections of many of the people to the mother Church and caused them to return to her fold. From that time the increase in her membership has been rapid and continuous. The number of her communicants in 1874 was 460,464; in 1890 they had increased to 593,393; in 1901 the number was 661,629, and in 1902 it was reported as 668,335. The increase from 1874 to 1902 was 207,871, a yearly average of 7424. Contemporaneous with this movement of the people back to the Church, there has been within the Church a growing earnestness in promoting deeper spiritual life and in fostering organized Christian effort. Much work has been done among the young by the formation of guilds. The work of women has been recognized and encouraged. The ancient order of deaconess has been revived, and institutions founded in which women are trained for missionary work at home and abroad. The liberality of the Church has shown decided improvement, home and foreign missions have been better supported, large sums have been raised for the endowment of new parishes and for the better endowment of poor ones, the care of the toiling masses has come close to the Church's heart, and successful efforts have been made to minister to the large migratory population which follows the fishing every season round the coasts of the British Isles. The voluntary offerings of the people for 1901, as reported to the General Assembly of 1902, amounted to £545,785. This included a munificent gift of £62,000 from Lord Mount Stephen for increasing the stipends of certain parishes in his native district. Since 1875 the Church of Scotland has had on several occasions to meet the crusade of the Dissenting churches for Disestablishment by organization for Church defence. Coupled with this, a fine spirit was manifested towards the Churches outside the Establishment, and suggestions emanated from the Church of Scotland for the inclusion of them all within the Establishment, even at the expense of sharing with them her own privileges and endowments. The statistical return to the General Assembly of 1902 gave the number of parishes as 1391, of non-parochial churches as 217, of preaching stations and missions as 207, a total of 1815. Since 1875 the church accommodation has been increased by 184,870 sittings. Since the Disruption 420 new parishes have been endowed, at a cost to the Church of £1,547,000.

The outstanding feature in the history of the FREE CHURCH and the UNITED PRESBYTERIAN CHURCH after 1875 was the desire, expressed in repeated efforts, to accomplish the incorporating union which was at length effected in October 1900. The Free Church left the Establishment in 1843 strongly holding and frequently asserting what was called the Establishment principle. In the minds of her younger ministers this principle was gradually obscured by the splendid success of her practical voluntaryism, until at last, most of the "Disruption fathers" having passed away, it became possible to subordinate it to the expediency of uniting with a Church which was voluntary not only in practice but also in principle. Under the influence of a brilliant leader, successive General Assemblies by increasing majorities declared in favour of regarding the "Establishment principle" as a non-essential doctrine of the Free Church. Eventually the union of the Free Church and the United Presbyterian Church was "brought about on the understanding that the question as to the lawfulness of State endowments should be an open one." It is impossible to predict the effect of this union upon the Churches themselves, or upon the general ecclesiastical history of Scotland. The two Churches, differing widely in historical origin, traditions, and administrative methods, may for a time have to expend their energy on consolidation, internal adjustment, and assimilation. Agitation in favour of Disestablishment may henceforward be less emphatic, hampered as it will be by the presence of many in the united Church who conscientiously hold the "Establishment principle" and long for a reconstruction of Scottish Presbyterianism within the National Church. The heroic self-sacrifice of the Free Church ministers in 1843, the splendid liberality of her people, her marvellous power of organization, and the fervour of her evangelical teaching, won the admiration of all the Churches and gave a powerful impulse to the religious life of the country. The conspicuous missionary achievements of the United Presbyterian Church and her fearless advocacy of religious equality and freedom gained for her also a place of honour among sister Churches. The union of 1900 was therefore regarded with special interest, and took place amid almost universal congratulations and benedictions. Great things are expected from it, and its spiritual fruits will be hailed with joy.

The following statistics of the United Free Church were presented to the General Assembly of 1902: Congregations 1630, preaching stations 72, communicants 495,259; raised for home missions £20,051, for foreign missions £123,055, for all purposes £1,056,347.

Two small bodies of Presbyterians in Scotland continue to maintain a separate existence. One is the remnant of the Reformed Presbyterian Church, which united with the Free Church in 1876. It consisted in 1899 of 9 congregations, 8 ministers, and 1040 communicants. The other claims to represent the United Original Secession Church, and consists of 29 congregations, 24 ministers, and 3769 communicants.

England.

The union of the Presbyterian Church in England with the English congregations of the United Presbyterian Church of Scotland, which took place in 1876, gathered all English Presbyterians (with a few exceptions) into one Church, the Presbyterian Church of England. "What kept these bodies apart was their separate historic origin and development, but especially the alienation caused by the 'Voluntary controversy,' which had its roots in the difficult problems of State law in its relation to religion, and the stumbling-block of the civil magistrate's authority in relation to the Christian conscience."[1] Since the union the growth of the Church is indicated by the following figures:—

	1876.	1901.
Congregations	259	326
Communicants	51,013	78,024
Sittings provided	134,146	167,945
Value of church buildings	£973,485	£1,378,525

Presbyterianism is comparatively strong in three districts of England, namely, Northumberland, Lancashire, and London. Elsewhere it is either weak or non-existent. As yet it is largely an exotic. The membership is mainly Scottish, and the ministers have been imported principally from Scotland. Hence a distinctly Scottish accent and a Scottish type of theological thought in the pulpit; Scottish methods in church arrangements, and Scottish manners in religious worship. To the English people, therefore, the Presbyterian Church is "the Scottish Church," and they are slow to connect themselves with it. Though they see much in it to admire and approve, they look upon it as meant for the Scots rather than for themselves. Here and there a different state of things prevails, but this is the attitude of the English people as a whole. Earnest efforts have been made to counteract this feeling by making the Church more distinctively English. Hymns and organs were introduced earlier than elsewhere. The technical nomenclature of Presbyterian procedure is being modernized so as to be better understood in England. For a similar reason, Presbyterian procedure itself is sometimes modified. This readiness to make changes in her polity is regarded by some as a dangerous symptom; by others it is hailed as the indication of an open mind and a desire to make progress by adaptation to environment. Following the lead of the Independents, who set up Mansfield College at Oxford, the Presbyterian Church has founded Westminster College at Cambridge. It was opened in 1899. It is hoped that it will do much to ensure a home-bred and home-trained ministry more conversant with English academic life and thought.

The most notable feature of the Church's work is her foreign missions. The field is mainly China, and the results attained are remarkable, as the following statistics will show:—

	1876.	1901.
Ordained European missionaries	12	21
Medical missionaries	3	13
Lady missionaries (including two medical)	...	27
Native pastors supported by their own congregations	...	34
Native Evangelists	49	260
Organized congregations	14	87
Preaching stations	52	123
Communicants	1974	7560

There are also in England 14 congregations in connexion with the Church of Scotland, namely, 5 in Berwick and Northumberland, 1 in Carlisle, 2 in Liverpool, and 6 in London. The number of communicants in 1900 was 3799.

Many Unitarians in England call themselves Presbyterians. This is a misnomer, for though descended from the old English Presbyterians, they retain nothing of their distinctive doctrine or polity—nothing of Presbyterianism, indeed, but the name. This is retained on account of ancient Presbyterian endowments which they continue to hold.

Ireland.

The Presbyterian Church in Ireland, most conservative of the great Presbyterian Churches in the United Kingdom, has during recent years passed through some phases of development which the others reached considerably earlier. After heated discussions in her General Assembly for many years, she has come abreast of the sister Churches in regard to the use of hymns and organs in public worship. Her attitude is one of sturdy adherence to the old paths of Evangelical doctrine and Presbyterian polity. She zealously supports the Irish system of national education, which may be briefly defined as "united secular and separate religious instruction," and she declines to be bribed by the offer of a Presbyterian university in Belfast to consent to the formation of a Roman Catholic university in Dublin. The Church Act of Mr Gladstone which disestablished the Episcopal Church took away the Presbyterian *Regium Donum*. Her ministers, with all but entire unanimity, decided "to commute in the interests of the Church." The Commutation Fund thus formed is a permanent memorial of a generous and disinterested act on the part of her ministry. It amounted in 1902 to £588,028. The interest accruing from it is added to the yearly Sustentation Fund contributions to form a strong central fund for ministerial support. Since the State endowment ceased, the average income of her ministers has increased by about £30 a year.

Statistics show that whilst Ireland lost about a quarter of a million of its people during the decade 1890–1900, the Presbyterian Church is numerically almost the same as in 1891. Returns presented to the General Assembly in 1902 give the following particulars: Congregations 574, ministers and missionaries 655, communicants 106,121, amount raised in congregations and Sunday schools £229,307, collections for missions £18,892. Outside Ulster the number of strong, self-supporting congregations is small, but hearty support is given to weak congregations and mission stations in the south and west of Ireland. The Presbyterian Orphan Society was founded for the purpose of undertaking the support of every poor orphan child throughout the Church. No Presbyterian orphan now needs to seek workhouse relief. The orphans are boarded in the homes of respectable poor people, who thus also benefit by the Society. A training home for girls forms part of the scheme.

Three small bodies of Presbyterians maintain a separate existence, namely, the Reformed Presbyterian Church, with 36 congregations and 4040 communicants; the Eastern Reformed, with 6 congregations and 700 communicants; and the Secession Church, with 10 congregations and 1230 communicants.

Wales.

The Presbyterian Church of Wales, formerly better known as "The Calvinistic Methodists," had its origin in the great Evangelical revival of the 18th century. Its polity has been of gradual growth. In 1811 its preachers were first Presbyterially ordained and authorized to administer the sacraments. In 1823 a "Confession of Faith" was adopted. In 1864 the two Associations (or Synods) of North and South Wales were united in a "General Assembly." The progress and present strength of the Church are indicated by the following figures:—

	1850.	1882.	1901.
Ministers	172	616	834
Communicants	58,678	122,167	160,333
Churches and preaching stations	848	1372	1579

[1] Drysdale's *History of the Presbyterians in England*, p. 625.

In 1901 the Church raised for all purposes £305,745. Of this sum, £14,407 went to missions, £9041 to Sunday schools, £2899 to the poor, and £67,494 to reduce the debt on church buildings. (W. Y.)

UNITED STATES.

Although Presbyterians are closely united in America, twelve distinct organizations exist. The total number of Presbyterians at the beginning of the 20th century was 1,945,106. The Sunday-school teachers and scholars numbered 1,829,336. The largest body, known as *The Presbyterian Church in the United States of America*, had a membership in 1900 of 1,007,689. In 1880 the whole number of members reported was 578,671. *The Presbyterian Church in the United States*, commonly called the Church South, which separated from the main body during the Civil War in 1861, reported in 1900, 225,890 members. These two bodies differ only regarding civil relations, and the separation is simply an expression of disagreement concerning relations to the Government. When the happy reunion of the Old School and New School Churches was accomplished in 1869, it was the hope of many that the spirit of union would bring together again those who had been separated by the bitterness of war. Conferences have been proposed by the Northern Church frequently since the division, but up to 1902 these had not led to union. There is, however, a growing desire for fraternal federation, and it is the conviction of very many that the near future will bring to Presbyterianism the power of such federation. This federation, it is believed, will include all the organizations known as Presbyterian. *The United Presbyterian Church*, the result of the union of the Associate and Associate Reformed Churches, accomplished in 1858, numbered 128,836.. This Church represents a fine type of Presbyterians, the descendants of the Scottish and Irish loyalists who did not count their lives dear when truth was to be defended. The United Presbyterians are much closer to other bodies bearing the Presbyterian name than they were in 1875. New versions of the Psalms, instrumental music, and less vigorous protest against secret societies, together with a frequent exchange of ministers and members, are all significant signs of closer fellowship in work, if not actually signs of organic union. *The Cumberland Presbyterian Church* reported a membership in 1900 of 180,192. This organization flourishes chiefly in the South. It is not strictly Calvinistic in doctrine, but is Presbyterian in polity. Whether the revision movement in the Presbyterian Church may win the Cumberland Presbyterians into closer union, remains to be seen. But it is not likely that there will be any such modification of the Calvinistic faith as could satisfy the more liberal belief of this body of Presbyterians. There were thirteen thousand *Welsh Presbyterians*, and nearly thirty thousand other Presbyterians divided into half a dozen smaller organizations. There were also more than three hundred and sixty thousand Church members belonging to the Reformed Churches, which are closely associated with Presbyterians in faith and in government. They stand together in the defence of a common system of doctrine, and the government of the Churches is very similar. These organizations, Presbyterian and Reformed, comprise the Alliance of the Reformed Churches, which was formed in 1875, and has since held several general councils. Two of these councils have been held in the United States, four in Great Britain, and one in Canada. Ninety separate Churches or denominations comprised this great Reformed Presbyterian Alliance. These Churches represented five continents and twenty-five millions of adherents.

The Presbyterian Church in the United States of America has since 1880 enjoyed signal prosperity. In 1880 it included 177 presbyteries; in 1900, 232. There were 600 candidates for the ministry in 1880; in 1900, 973. There were 5044 ministers in 1880; in 1900, 7467. In 1880 there were 5489 churches; in 1900, 7750. Over 57,000 members were added to the Church in 1900 by examination and 40,000 by church letters. The whole membership in 1900 was 1,007,689, whereas in 1880 the number was 578,671. The Sunday-school membership in 1880 was 631,952; in 1900, 1,058,051. $429,769 was given for home missions in 1880, and $1,088,367 in 1900; $420,427 for foreign missions in 1880, and in 1900, $822,811. $6,098,150 was contributed for congregational purposes in 1880, and in 1900, $11,372,383. The total contributions of the Church in 1880 were $8,361,028, as compared with $15,054,301 in 1900. These contributions do not include the personal gifts of members of the Church to charitable and educational institutions. 1371 missionaries were employed in the home field during 1900, and 728 missionaries, with over 2000 native helpers, in foreign countries. The Board of Church Erection has secured church property valued at $14,500,000. The Board of Relief has under its care 363 ministers and 483 widows of ministers. The Board of Missions for Freedmen, which was organized in 1865, is represented by 340 churches and 20,000 members. 10,000 scholars are instructed in 80 day schools. This Board has also under its care 18 boarding schools, and supports 231 teachers. The Biddle University in Charlotte, North Carolina, is intended for coloured students, and eleven of its twelve professors are coloured men. Lincoln University, near Oxford, Pa., which is independent of the Board but connected with the Presbyterian Church, has an able faculty, is liberally endowed, and is concerned specially with the education and elevation of the coloured race. Through the Board of Aid for Colleges and Academies, old colleges have been strengthened, and new colleges and academies have been planted, particularly in the newer parts of the country, and the work of higher education has been fostered. Nearly $200,000 was so distributed in 1900 by this Board. There are 14 theological seminaries in connexion with the Presbyterian Church. Three large and prosperous hospitals have been established by the Church—one in New York, one in Philadelphia, and one in Chicago. There is a disposition in other cities to provide Church hospitals for the benefit of the poor. The charity of the Church is expressed also by homes and asylums of various kinds, and by many forms of mission work. The Presbyterian Church resolved to mark the advent of the 20th century by a great forward movement. While the synods are giving special attention to the increased endowment of colleges and theological seminaries, the Presbyteries are encouraging the churches to pay off their debts and to contribute money for the organization of new churches. Already gifts amounting to several millions of dollars have been received. This forward movement is both the cause and the result of a spirit of unity in the Church. Twenty years of discussion have ended in a harmonious and hopeful determination to find a satisfactory solution of the question that has so long disturbed the Church. Three-fourths of the Presbyteries having indicated a desire that there should be some revision, the General Assembly of 1901, by a vote of three to one—and finally by a unanimous vote—determined to have prepared (1) a Short Statement of doctrine for popular use and information, and (2) a Declaratory Statement, which might remove misapprehension regarding a few confessional statements; or, if necessary, revision by a change of text. These statements, however, could not be adopted without the prior approval of the General Assembly, and, this being given, the adhesion afterwards of two-thirds of the Presbyteries—that is, by more than 150 Presbyteries. (C. A. D.)

Prescot, a market-town in the Ormskirk parliamentary division of Lancashire, England, 8 miles east of Liverpool by rail. The streets are lighted both by electric light and gas, and the town has been connected by tramway with St Helens. A large factory has been built for the complete making of watches. There is also a manufacture of electric cables. Population (1891), 6745: (1901), 7855.

Preserved Fruits. See CANNING.

Pressburg. See POZSONY.

Preston, a municipal, county, and parliamentary borough, seaport and market-town of Lancashire, England, on the Ribble, 209 miles north-west of London by rail. Since 1880 the municipal borough has been successively extended. In 1894 the townships and parts of townships within the limits of the county borough were consolidated into one civil parish. The parliamentary borough returns two members. St Stephen's church was erected in 1888, and St Jude's in 1893. A new Harris Free Public Library and Museum was opened in 1893, and to this building was transferred in 1894 the free library of 1879. £40,000 has been given by the Harris trustees towards establishing a technical school, and part of this sum has been spent on a Victoria Jubilee Technical School (1897). A school for the education of the deaf and dumb was opened in 1894. There is one daily newspaper. The construction of spacious docks, in conjunction with the deepening of the river from the quays of Preston to its outfall in the Irish Sea, a distance of 16 miles, begun in 1884, has been carried out at a cost of over one million sterling. The main wet dock, opened in 1892, is 3240 feet long and 600 feet wide. The total quayage is over 8500 lineal feet. The channel of the river has been made straighter, and from docks to sea deepened, so that the dock is now accessible for vessels of 17 feet draught on ordinary spring tides. The waterworks are now the town property. Vessels entering port in 1888 numbered 198 of 15,362 tons; clearances, 198 of 15,462 tons. In 1900 entrances numbered 1223 vessels of 153,903 tons; clearances, 1183 of 151,298 tons. Imports of foreign and colonial produce in 1888 were valued at £7211; in 1900, £446,934; exports in 1888 at £207; in 1900, £14,812. Area, 4089 acres. Population (1881), 96,537; (1891), 107,573; (1901), 112,982.

Prestonpans, a police burgh and coast village of Haddington, Scotland, on the shore of the Firth of Forth, nine miles east of Edinburgh, with a station on the North British Railway. It was formerly the principal seat of the salt trade in Scotland, but has now only one salt work. There are a fire-brick and tile work, a brewery, a soap work, and a pottery. There is also an extensive coalfield in the vicinity. An oyster bed, once famous for its Pandore oysters (an esteemed variety), is now scarcely as productive. The cross of the Barony of Preston dates from 1617. The churches are Established and United Free. The public school had an average attendance of 540 in 1898–99. Prince Charles inflicted a severe defeat here upon the Hanoverian forces, under Sir John Cope, on the 21st of September 1745. An obelisk was erected to the memory of Colonel Gardiner, who fell in the battle. Population (1881), 2265; (1891), 2224; (1901), 1721.

Prestwich, Sir Joseph (1812–1896), English geologist, was born at Clapham on 12th March 1812, and was educated at Reading and at University College, London, where, under Dr Lardner, he paid special attention to scientific studies, particularly mineralogy and geology. Up to the age of 60 he was actively engaged in his business, which was that of a wine merchant, and therefore was only able to devote his leisure time to his favourite scientific pursuits. But the journeys he was obliged to make to various parts of Great Britain and the Continent afforded him opportunities of becoming acquainted with the geological conditions of many localities, and he was thus able to combine business and science so effectively that he won for himself a high place among the geologists of the 19th century. He began original work early in his career, publishing in 1836 a remarkable memoir on the structure of the Coalbrookdale coalfield, which embodied the results of observations made during visits there in 1831 and 1832. His name is especially known in connexion with his studies on the Tertiary deposits of the London Basin, which he systematically classified and correlated with similar deposits in other parts of the world. He was further led to investigate their water-bearing characteristics, and his extensive knowledge in that respect procured him a seat on the Metropolitan Water Commission in 1867. From about 1858 the question of the antiquity of man specially engaged his attention. On various occasions statements had been made as to the association of flint implements formed by man with the bones of extinct mammals which belonged to more remote periods than those generally assigned for the appearance of the human race on this earth, but the evidence adduced had usually been disregarded by geologists as not affording sufficient proof of the point. Prestwich, however, saw the desirability of a closer examination of the facts, particularly in regard to the implements discovered by Boucher de Perthes in the gravels of the Somme valley, and his investigation yielded evidence which was generally regarded as proving that man existed contemporaneously with the Pleistocene mammoth. In 1866 Prestwich became a member of the Coal Commission, the report of which in 1871 contained a paper by him suggesting the probability that a range of coalfields extended from Somerset to south-eastern England. He was inclined, however, to consider that the coal-trough would be found to lie in Essex and Hertfordshire, rather than on the more southerly line favoured by Godwin-Austen and actually verified by subsequent borings. After retiring from business in 1872, he was elected to the chair of geology at Oxford, and retained it till 1888. His two volumes on *Geology: Chemical, Physical, and Stratigraphical*, were the product of this period. He was knighted in 1896, and died on 23rd June of the same year at Shoreham, Kent.

Pretoria, city of the Transvaal Colony, British South Africa. It was the capital of the South African Republic since 1855, the seat of government being transferred from Potchefstroom after the death of Pretorius, in whose memory Pretoria was founded and named. It is pleasantly situated about 4500 feet above sea-level, near the southern slope of the Magaliesberg Range, which is here pierced by the Aapies headstream of the Limpopo. Like most of the Boer settlements, it was laid out on a regular and somewhat ambitious plan, with broad streets and boulevards disposed at right angles to each other, and ample enough to accommodate some 100,000 inhabitants. But Pretoria, which suffers from the rivalry of the neighbouring Johannesburg, has remained a small place, with a population estimated in 1899 at not more than 10,000 whites and perhaps half that number of natives. As a railway centre it is the converging point of the main lines from Delagoa Bay, Natal, and Orange River Colony, with extensions running north to Pietersburg and south-west to Potchefstroom and the Klerksdorp goldfields. In Church Street, the chief thoroughfare, stand several fine blocks, notably the former Raadzaal (Parliament House), an imposing structure, the "architectural glory" of Pretoria, crowned by the statue of Liberty, rising 120 feet above the pavement. In the northern outskirts is the perennial spring, where still flourishes the *Wonderboom* ("Wonder Tree") which first attracted the voortrekkers to the spot; and a little farther north is the Waterval station on the Pietersburg Railway, where were laagered the British prisoners captured during the war. All were released soon after 31st May 1900, when the capital surrendered to General Roberts without resistance, despite the formidable-looking encircling forts, now dismantled,—Wonderboom, Daspoort, Schanzkop, and Klapperkop—which, however, were so elaborately designed that they were never effectively armed.

Prevesa, the capital of a sanjak, in the vilayet of Janina, European Turkey, at the entrance to the Gulf of Arta. The houses are for the most part embosomed in gardens, and magnificent olive plantations surround the town. The chief exports are wool, butter, cheese (to the yearly value of about £14,000), olive oil and olives, valonea, skins, and coal. The total value of the exports in 1900 was £35,243, as compared with £31,100 in 1898; the value of the imports in the same years being £45,567 and £46,600 respectively. A hindrance to the commercial prosperity of the port is the impossibility of large steamers entering the harbour owing to a bar of sand, which reduces the depth of the gulf to 10 feet. The number of vessels that entered the port in 1900 was 1374 of 100,296 tons, as compared with 1785 of 98,761 tons in 1898. The population is estimated at 11,000, of whom about one-fifth are Moslems, the remainder being Greeks and Christian Albanians.

END OF SEVENTH VOLUME.

A PARTIAL LIST OF THE CONTRIBUTORS

TO

THE NEW VOLUMES

OF

THE ENCYCLOPÆDIA BRITANNICA

WITH THE INITIALS WHICH HAVE BEEN AFFIXED TO THEIR RESPECTIVE ARTICLES.

THE LIST OF CONTRIBUTORS here given is necessarily incomplete, as must be the case until the last of the New Volumes has been finished. On the other hand, the present List may contain a few names which ultimately will not appear in the final List of Contributors. Death or other cause may prevent certain writers who have undertaken the preparation of Articles from completing the contributions which they were to furnish. A full List, compiled when the final Volume goes to press, will be given later. The present List includes the names of all who have written signed Articles for the Volumes which have so far appeared.

After the few words of description which accompany the names are given the initials of the different authors as they have been affixed to the Articles contributed by them.

The Publishers congratulate themselves that in this List of a thousand names are to be found not only the most famous scholars and writers of Great Britain, but of the whole world.

A

ABBE, Prof. Cleveland, A.M., Ph.D., LL.D.; Meteorologist, U.S. Weather Bureau; author of 'Atmospheric Radiation,' etc.; editor of 'Monthly Weather Review'; Lecturer on Meteorology, Johns Hopkins University. (C. A.)

ABBOTT, Rev. Lyman, D.D.; editor of 'The Outlook' (New York); associate editor of 'The Christian Union' (New York) with Henry Ward Beecher, whom he succeeded as pastor of Plymouth Church, Brooklyn; author of 'Christianity and Social Problems,' 'Life of Christ,' 'Theology of an Evolutionist,' 'Life and Epistles of St Paul.' (L. A.)

ABNEY, Sir William de Wiveleslie, K.C.B., D.Sc., D.C.L., F.R.S.; Principal Assist. Sec., Board of Education, South Kensington, since 1899; President, Royal Astronomical Society, 1893-95; President, Physical Society, 1895-97; author of 'Photography' in Ninth Edition of the 'Ency. Brit.,' 'Instruction in Photography,' 'Treatise on Photography,' 'Colour Vision,' 'Colour-Measurement and Mixture,' 'Thebes and its Five Great Temples,' in part of 'The Pioneers of the Alps.' (W. de W. A.)

ADAMS, B. B.; associate-editor of the 'Railroad Gazette' (New York). (B. B. A.)

AIRY, Wilfred, B.A., M.I.C.E.; Examiner of Inspectors of Weights and Measures, Board of Trade; author of 'Levelling and Geodesy,' 'Weighing Machines,' etc. (W. Ay.)

AKERS, C. E.; author of 'Argentine, Patagonian, and Chilian Sketches,' etc. (C. E. A.)

ALCOCK, Charles William; Secretary Surrey County Cricket Club since 1872; Hon. Sec. Football Association, 1867-90; author of 'Football our Winter Game,' 1867; editor of 'Cricket Newspaper,' 1882-1900, 'Football Annual,' 'Cricketer's Annual' (Lillywhite's), etc. (C. W. A.)

ALEXANDER, Gen. Edward Porter; General of Ordnance; and later Brigadier-General of Artillery and Chief of Artillery in Gen. Longstreet's Corps, Confederate Army. (E. P. A.)

ALEXANDER, W. D., Honolulu; author of 'A Brief History of the Hawaiian People.' (W. D. A.)

ALLBUTT, Thomas Clifford, M.A., M.D., LL.D., D.Sc., F.R.S.; Regius Professor of Physic, Camb., since 1892; Commissioner in Lunacy, 1889-92; author of 'The Ophthalmoscope in Medicine,' 'Goulstonian Lectures (On Visceral Neuroses),' 'On Scrofula,' 'Science and Medical Thought'; editor of 'System of Medicine and Gynæcology,' etc.; inventor of short clinical thermometer. (T. C. A.)

ALLDRIDGE, T. J., F.R.G.S., F.Z.S.; for many years Travelling Commissioner of Sierra Leone; District Commissioner of Sherbro District, Sierra Leone; author of 'Sherbro and its Hinterland.' (T. J. A.)

ANDERSON, Miss A. M.; Principal Lady Inspector of Factories, Home Office. (A. M. An.)

ANDERSON, W., F.R.C.S., the late; Comp. of the Order of the Rising Sun (Japan); Professor at Royal Academy; Chairman of Council of the Japan Society; Medical Director, Imperial Naval Medical College, Tokio; author of 'The Pictorial Arts of Japan,' 'Japanese Wood Engravings,' 'Cat. of Chinese and Japanese Pictures in British Museum.' (W. An.)

ANDERSON, Lt.-Col. W. P.; Chief Engineer and Superintendent of Lights, Department of Marine and Fisheries, Ottawa, Canada. (W. P. A.)

ANDREWS, Hon. Elisha Benjamin, LL.D.; Chancellor of the University of Nebraska; late Superintendent of Schools of the City of Chicago; formerly President of Brown University; author of 'Institutes of General History,' 'Institutes of Economics,' 'History of the United States,' etc. (E. B. A.)

ANSTRUTHER-THOMSON, Major W., F.G.S., F.S.A.; Inspector of Concentration Camps, S.A. (W. A.-T.)

ARCHER, William; dramatic critic of 'World' (London), 1884 onwards; edited and translated Ibsen's 'Prose Dramas'; author of 'Life of Macready,' 'Masks or Faces,' 'The Theatrical World,' 'Study and Stage,' 'America To-day, 1900,' 'Poets of the Younger Generation,' etc. (W. A.)

ARMSTRONG, Edmund Archibald, Barrister-at-Law, Inner Temple. (E. A. Ar.)

ARMSTRONG, Henry Edward, Ph.D., LL.D., F.R.S.; Professor of Chemistry at the City and Guilds of London Central Institute, South Kensington; author of 'Carbon,' etc., in Ninth Edition of 'Ency. Brit.,' 'Introduction to the Study of Organic Chemistry.' (H. E. A.)

ARMSTRONG, Sir Walter; Director of the National Gallery of Ireland; author of 'Sir Joshua Reynolds,' 'Thomas Gainsborough,' 'Sir Henry Raeburn,' 'Alfred Stevens,' 'Peter de Wint,' 'Velasquez,' 'Scottish Painters,' 'J. M. W. Turner,' etc., and co-editor of 'Bryan's Dictionary of Painters.' (W. Ar.)

ASHWORTH, Philip A., Dr. Juris, of the Inner Temple, Barrister-at-Law; associate-editor of the new volumes of the 'Encyclopædia Britannica'; editor of Taswell-Langmead's 'Constitutional History of England,' translator of Gneist's 'History of the English Constitution,' etc. (P. A. A.)

ASKWITH, Rev. Edward Harrison, M.A., D.D.; Chaplain of Trinity College, Cambridge; author of 'Christian Conception of Holiness,' 'Epistle to the Galatians,' etc. (E. H. A.)

ASTON, Lt.-Col. George Grey, R.M.A., C.B.; late Professor of Fortification, Royal Naval College, Greenwich. (G. G. A.)

ASTON, William George, M.A., Hon. D.Lit., C.M.G.; student interpreter in Japan, 1864; interpreter and translator to British Legation at Yedo, 1870; assistant Japanese Secretary, Yedo, 1875-82; acting Consul, Hiogo, 1880-83; Consul-General for Corea, 1884; Japanese Secretary, Tokio, 1886; author of 'A Grammar of the Japanese Spoken Language,' 'A Grammar of the Japanese Written Language,' 'A Translation of the Nihongi, or Annals of Ancient Japan,' 'History of Japanese Literature,' etc. (W. G. As.)

ATWATER, Wilbur Olin, Ph.D.; Professor of Chemistry, Wesleyan University, U.S.A.; Special Agent of the U.S. Department of Agriculture in charge of Nutrition investigations. (W. O. A.)

AVES, Ernest, M.A.; formerly Sub-Warden of Toynbee Hall; author of papers on sociology and economics. (E. A*.)

AXON, William Edward Armitage, LL.D.; late Dep. Librarian Manchester Free Libraries; author of 'Manchester' in Ninth Edition of 'Ency. Brit.,' 'The Annals of Manchester,' 'Manchester a Hundred Years Ago,' 'Lancashire Gleanings,' 'Stray Chapters in Literature,' 'Folk-lore and Archæology,' etc. (W. E. A. A.)

B

BACON, Edwin Monroe, M.A.; editor of 'Time and the Hour' (Boston, U.S.A.); sometime editor-in-chief of the 'Boston Globe,' the 'Boston Advertiser,' and the 'Boston Post'; author of 'Boston Illustrated,' 'Bacon's Dictionary of Boston,' 'Boston of To-day,' etc. (E. M. B.)

BADEN-POWELL, Maj. Baden F. S.; inventor of man-lifting kites; late President Aëronautical Society; author of 'In Savage Isles and Settled Lands,' many articles on ballooning, etc. (B. F. S. B.-P.)

BAGWELL, Richard, M.A., D.L., J.P.; author of 'Ireland' in the Ninth Edition of the 'Ency. Brit.,' 'Ireland under the Tudors,' and of numerous Irish biographical articles in the 'Dictionary of National Biography.' (R. Ba.)

BAIN, Robert Nisbet; Assistant Librarian, British Museum; author of 'Peter III., Emperor of Russ[illegible],' 'Gustavus III. and his Contempo[illegible]aries[illegible]' (R. N. B.)

BA[illegible]NE[illegible], Jervoise Athelstane, C.S.I.; Hon. S[illegible] (gold medallist) and Vice-President Royal S[illegible]tistical Society; Census Commissioner u[illegible]er Government of India, 1889-93; employed at India Office and as secretary to Royal Commission on Opium, 1894-95; author of Official Reports on Provincial Administration, on Indian Census Operations, 1881-91, on Indian Progress, 1894, many papers, ethnographic and statistical, for London societies. (J. A. B.)

BAKER, Henry Frederick, M.A., F.R.S.; Fellow and Lecturer of St John's College, Cambridge; University Lecturer in Mathematics. (H. F. BA.)

BALCARRES, Lord, M.P., F.S.A., F.S.A.S.; Trustee of National Portrait Gallery, London; Hon. Sec. Society for Protection of Ancient Buildings; Vice-Chairman of National Trust. (B.)

BALDRY, Alfred Lys, artist; author of 'Albert Moore: his Life and Works,' 'The Life and Works of Marcus Stone, R.A.,' 'Sir John Everett Millais,' 'Hubert von Herkomer,' etc. (A. L. B.)

BALDWIN, Hon. Simeon Eben, A.M., LL.D.; Judge of the Supreme Court of Errors of Connecticut; Professor of Constitutional and Mercantile Law, Corporations, and Wills, Yale University; sometime President of the American Bar Association and American Social Science Association; author of 'Baldwin's Connecticut Digest,' 'Cases on R.R. Law,' 'Modern Political Institutions,' etc. (S. E. B.)

BALDWIN, W. H., Jr.; President of the Loug Island R.R. Co., U.S.A.; Chairman of 'The General Education Board' (an organization for promoting education in the Southern states of the U.S.A.) (W. H. B.)

BALE, Edwin, R.I.; Art Director, Cassell and Company; Hon. Sec. Artists' Committee for Promoting Art Copyright Bill, etc. (E. BA.)

BALFOUR, Isaac Bayley, M.D., D.Sc., M.A., F.R.S., F.L.S.; Regius Keeper of Royal Botanic Garden, Edinburgh; Professor of Botany, University of Edinburgh; Transit of Venus Expedition to Rodriguez, 1874; Regius Professor of Botany, University of Glasgow, 1879-84; explored island of Socotra, 1880; Sherardian Professor of Botany, University of Oxford, and Fellow of Magdalen College, 1884-88; author of 'Botany of Rodriguez,' 'Botany of Socotra,' editor of 'Annals of Botany.' (I. B. B.)

BANCROFT, Frederic, Ph.D.; Chief of Bureau of Rolls and Library, U.S. Department of State; author of 'Life of William H. Seward,' etc. (F. BA.)

BANISTER, G. H., M.I.C.E., M.I.M.E.; late Assistant to Superintendent of the Royal Carriage Department, Woolwich; Whitworth Scholar. (G. H. BA.)

BARCLAY, Thomas, LL.B., Ph.D.; member of the Institute of International Law; Vice-President of the International Law Association; Examiner in Jurisprudence and International Public and Private Law to the University of Oxford, 1900; member of the Supreme Council of the Congo Free State; Vice-President of the Franco-Scottish Society; President of the British Chamber of Commerce in Paris, 1899-1900; Knight of the Legion of Honour and of the Order of Leopold; author of 'Companies in France,' and other law books, all the articles on International Law in the 'Encyclopædia of the Law of England,' etc. (T. BA.)

BARING, The Hon. Maurice; Attaché to the British Embassy, Paris, 1899; Third Secretary to the British Embassy, Rome, 1902. (M. BA.)

BARLOW, Major H. W., R.A.; Secretary to Chief Superintendent, Royal Ordnance Factories, Woolwich. (H. W. B.)

BARNES, William Emery, D.D.; Fellow of Peterhouse, Cambridge; Hulsean Professor of Divinity, Cambridge; assist. editor of 'Journal of Theological Studies'; Lecturer in Hebrew at Clare Coll. Camb., 1885-94; in Hebrew and Divinity at Peterhouse, 1889-1901; author of 'The Genuineness of Isaiah xxiv.-xxvii.,' 'Canonical and Uncanonical Gospels, 'The Peshitta Text of Chronicles,' I. II. Chronicles, with Introduction and Notes (Cambridge Bible). Isaiah (Churchman's Bible). (W. E. B.)

BARNETT, Rev. Samuel Augustus, M.A.; Canon of Bristol; Founder and Warden of Toynbee Hall, Whitechapel; President of the Sunday Society; Chairman Whitechapel Board of Guardians, 1894; Chairman of Children's Country Holiday Fund; Chairman Pupil Teachers' Scholarship Fund; author of 'Practicable Socialism' with Mrs Barnett, 'Service of God.' (S. A. B.)

BARRETT, F. N., editor of the 'American Grocer' (New York). (F. N. B.)

BARTLET, Rev. J. Vernon, M.A.; Professor of Church History, Mansfield College, Oxford; author of 'Early Church History,' 'The Apostolic Age,' etc. (J. V. B.)

BARTLEY, George Christopher Trout, M.P.; Assistant-Director of Science Division of Science and Art Department, London, till 1880; established National Penny Bank, 1875; author of 'A Square Mile in the East of London,' 'Schools for the People,' 'Provident Knowledge Papers,' 'The Seven Ages of a Village Pauper,' 'The Parish Net.' (G. C. T. B.)

BARWICK, G. F., B.A.; Assistant Keeper of Printed Books and Superintendent of Reading-room, British Museum; author of 'International Exhibitions,' 'The Laws Regulating Printing and Publishing in Spain,' and translator of various works of travel, etc. (G. F. B.)

BASSETT, John Spencer, Ph.D.; Professor of History, Trinity College, N.C.; author of 'Constitutional Beginnings of North Carolina,' 'Slavery and Servitude of the Colony of North Carolina,' 'Anti-Slavery Leaders of North Carolina,' 'Slavery in the State of North Carolina.' (J. S. BA.)

BASTABLE, C. F., M.A., LL.D.; Professor of Political Economy, Dublin University, 1882; author of 'Money' in Ninth Edition of 'Ency. Brit.,' 'Theory of International Trade,' 'Commerce of Nations,' 'Public Finance,' 'Dictionary of Political Economy,' and 'Economic Journal. (C. F. B.)

BATHER, Francis Arthur, M.A., D.Sc., F.G.S.; Asst. Keeper of the Geological Department of the British Museum (South Kensington); Hon. Member Soc. Linnéenne de Normandie; author of 'Concise Knowledge of Natural History,' 'The Genera and Species of Blastoidea,' 'Echinoderma' (in Lankester's 'Zoology'), 'The Crinoidea of Gothland,' etc. (F. A. B.)

BAUERMAN, H., F.G.S.; Lecturer on Metallurgy, Ordnance College, Woolwich; author of 'Bismuth,' 'Coal,' 'Fuel,' 'Furnace,' etc., in Ninth Edition of 'Ency. Brit.,' 'A Treatise on the Metallurgy of Iron,' 'Text-book of Systematic Mineralogy,' etc. (H. B.)

BEALBY, J. T., B.A.; sometime acting editor of 'Scottish Geographical Magazine'; author of 'A Daughter of the Fen,' and numerous geographical magazine articles; joint author of 'Stanford's Compendium: Europe'; translator of Sven Hedin's 'Through Asia.' (J. T. BE.)

BEDDARD, Frank Evers, M.A., F.R.S.; Prosector of Zoological Soc. of England since 1884, and Vice-Sec. since 1898; formerly Lecturer on Biology at Guy's Hospital; has been Examiner in Zoology and Comparative Anatomy, University of London, and of Morphology at Oxford; now Examiner in the University of New Zealand; naturalist to 'Challenger' Expedition Commission, 1882-84; author of 'Worm' in Ninth Edition of 'Ency. Brit.,' 'Animal Coloration,' 'Text-book of Zoogeography,' 'A Monograph of the Oligochæta,' 'Structure and Classification of Birds'; and 'Mammalia' ('Cambridge Natural History'). (F. E. B.)

BELL, Charles Frederic Moberly; asst. manager of 'The Times'; formerly correspondent of 'The Times' in Egypt; author of 'Khedives and Pashas,' 'Egyptian Finance,' 'From Pharaoh to Fellah,' etc. (C. F. M. B.)

BELL, Dr Louis, Boston, U.S.A.; author of 'The Elements of Practical Electricity,' 'Power Distribution for Electric Railroads,' 'Electric Power Transmission,' etc. (L. BL.)

BELL, Malcolm; author of 'Rembrandt,' 'Sir E. Burne-Jones,' etc. (M. BE.)

BELLAIRS, Carlyon W.; Lieut. R.N., retired; writer of articles on naval subjects; Lecturer to the War Course of Captains and Commanders at the R. N. College, Greenwich; Medallist of the Society of Arts (for paper on the Coal Problem, 1901). (C. W. BE.)

BELLINGER, Hon. Charles Byron; Judge of the U.S. District Court, District of Oregon. (C. B. B*.)

BELTRAMI, Luca; architect; author of 'Storia della facciata di St Maria del Fiore in Firenza,' 'La Basilica Ambrosiana primitiva e la ricostruzione compiuta nel secolo IX,' etc. (L. BI.)

BÉNÉDITE, Léonce; Conservator, Musée du Luxembourg, Paris; author of 'Alphonse Legros'; editor of 'Bulletin des Musées,' etc. (L. BE.)

BENSON, Arthur Christopher, M.A., F.R.Hist. Soc.; Master at Eton College since 1885; author of 'Memoirs of Arthur Hamilton,' 'Archbishop Laud: a Study,' 'Poems,' 'Lyrics,' 'Essays,' 'Lord Vyet and other Poems,' 'Fasti Etonenses,' 'Life of Archbishop Benson,' 'The Professor, and other Poems.' (A. C. BE.)

BERG, Sigvard Johnson, A.M.I.C.E., Switzerland. (S. J. B.)

BERNARD, Rev. John Henry, D.D.; Fellow of Trin. Coll., Dublin; Archbishop King's Lecturer in Divinity, University of Dublin; member of University Council, 1892; Vice-Warden, Alexandra Coll., Dublin, for higher education of women, 1894; Secretary of Royal Irish Academy, 1899; Commissioner of National Education, Ireland, 1897; part-editor of 'Kant's Critical Philosophy for English Readers,' translator of 'Kant's Kritik of Judgment, joint-author of 'The Literature of the Second Century,' editor of 'The Pilgrimage of St Silvia of Aquitania,' 'The Pastoral Epistles of St Paul,' 'The Works of Bishop Butler,' etc. (J. H. BE.)

BERNSTEIN, Eduard; German Socialistic politician and writer; late editor of the 'Social Democrat'; author of 'On the History and Theory of Socialism,' 'The Communistic and Democratic-Socialistic Movements in England during the 17th Century,' etc. (E. BN.)

BERRY, George Andreas, M.B., F.R.C.S., F.R.S. Edin.; Vice-Pres. Ophthalmological Soc.; author of 'Diseases of the Eye,' 'The Elements of Ophthalmoscopic Diagnosis,' 'Subjective Symptoms in Eye Diseases,' etc. (G. A. BE.)

BESANT, Sir Walter, M.A., F.S.A., the late; Secretary Palestine Exploration Fund, 1868-85; Hon. Sec. Palestine Exp. Fund; First Chairman Society of Authors, 1884-85; Chairman Society of Authors, 1887-1892; author of 'Froissart' in Ninth Edition of 'Ency. Brit.,' 'Studies in Early French Poetry,' 'Rabelais,' Lives of 'Coligny,' 'Whittington,' 'Edward Palmer,' and 'Richard Jefferies,' 'London,' 'Westminster,' 'South London,' many Novels with the late James Rice. Novels alone: 'The Revolt of Man,' 'All Sorts and Conditions of Men,' 'Beyond the Dreams of Avarice,' 'The Orange Girl,' etc. (W. BE.)

BHOWNAGREE, Sir Mancherjee Merwanjee, K.C.I.E., M.P.; State Agent, Bombay, for the territory of Bhavnagar, 1873; author of 'History of the Constitution of the East India Company,' Gujerati translation of 'Her Majesty's Life in the Highlands,' etc. (M. M. BH.)

'BICKERDYKE, John' (Charles Henry Cook), M.A.; writer on angling and sporting subjects; President of Thames Re-stocking Association, and the Fly-Fishers' Club, 1899-1900; editor of the angling department of the 'Field'; author of 'Angling in Salt Water,' 'The Book of the All Round Angler,' 'Thames Rights and Thames Wrongs,' 'Days in Thule with Rod, Gun, and Camera,' 'Sea-Fishing,' 'Days of My Life in Water, Fresh and Salt,' 'Wild Sports in Ireland,' 'Letters to Young Sea-Fishers,' etc. ('J. B.')

BIDWELL, Shelford, M.A., Sc.D., F.R.S.; barrister; President of Physical Society, England, 1897-99; author of 'Curiosities of Light and Sight,' and numerous memoirs on physical subjects. (S. BI.)

BINDLOSS, Harold; Secretary Royal Mersey Yacht Club. (H. BS.)

BINYON, Laurence; assistant in the British Museum, Department of Printed Books, 1893; transferred to Department of Prints and Drawings, 1895; author of 'Lyric Poems,' 'Poems,' 'London Visions,' 'The Praise of Life, 'Porphyrion and other Poems,' 'Western Flanders,' 'Odes,' 'Catalogue of English Drawings in the British Museum.' (L. B.)

BIRD, Christopher John, C.M.G.; Principal Under Secretary of the Colony of Natal, and a Member of the Civil Service Board. (C. J. BI.)

BIRDWOOD, Sir George Christopher Molesworth, M.D., K.C.I.E., C.S.I., LL.D.; special assistant in Revenue and Statistics Department India Office, 1871-99; author of 'Incense' in Ninth Edition of 'Ency. Brit.,' 'Economic Vegetable Products of the Bombay Presidency,' 'The Industrial Arts of India,' 'Report on Old Records of the India Office,' 'First Letter Book of East India Company,' Appendix on the Aryan Fauna and Flora to Max-Müller's 'Biography of Words,' etc. (G. B.)

BIRKBECK, William John, M.A., F.S.A.; author of 'Russia and the English Church.' (W. J. BI.)

BIRKINBINE, John, M.E.; President of the Franklin Institute and the Pennsylvania Forestry Association; sometime President American Institute of Mining Engineers, and editor 'Journal of Iron Workers.' (J. BI*.)

BIRRELL, Augustine, K.C.; Hon. Fellow, Trinity Hall, Cambridge; LL.D. St Andrews (Honorary); Quain Professor of Law, University Coll. London, 1896; M.P. (L.) Fifeshire W., 1889-1900; author of Obiter Dicta, 1884, 1887; Life of Charlotte Brontë, 1885; Res Judicatae, 1892; Men, Women, and Books, 1894; Lectures on the Duties and Liabilities of Trustees, 1896; editor of Boswell's Life of Johnson, 1897; Sir Frank Lockwood, 1898; Collected Essays, 1900. (A. BI.)

BISHOP, Mrs Isabella L. (Miss Isabella Bird), F.R.G.S., Hon. F.R.S.G.S.; Hon. Member of Oriental Society, Pekin; first lady Fellow of the Royal Geographical Society; author of 'The Englishwoman in America,' 'Six Months in the Sandwich Islands,' 'A Lady's Life in the Rocky Mountains,' 'Unbeaten Tracks in Japan,' 'The Golden Chersonese,' 'Journeys in Persia and Kurdistan,' 'Among the Tibetans,' 'Korea and her Neighbours,' 'The Yangtze

Valley and Beyond,' 'Pictures from China,' etc. (I. L. B.)

BLACK, John A.; press reader of the New Volumes of the 'Ency. Brit.' (J. A. Bl.)

BLAIN, W.; of the Treasury, Whitehall. (W. Bl.)

BLAIR, Andrew A.; chief chemist of the U.S. Geological Survey, Division of Mining and Geology, Tenth Census of the United States; author of 'The Chemical Analysis of Iron,' etc. (A. A. B.)

CREAK, Capt. Ettrick William, R.N., C.B., F.R.S.; late Superintendent of Compasses, Hydrographic Department, Admiralty, London. (E. W. C.)

CREIGHTON, Charles, M.A., M.D. Aberdeen; author of 'A History of Epidemics in Britain,' 'Jenner and Vaccination,' etc. (C. C.)

CREWE, Earl of, P.C., M.A., F.S.A.; President of the Literary Fund; assist. priv. sec. to Sec. for Foreign Affairs, 1883-84; Lord-Lieut. of Ireland, 1892-95; author of 'Stray Verses,' articles on Ireland, etc. (C.)

CRIMP, Santo, M.I.C.E.; the late; author of 'Sewage Disposal Works'; joint author of 'Tables and Diagrams for use in designing sewers and water mains,' etc. (S. Cr.)

CRITCHELL, James Troubridge; London Correspondent of the 'Brisbane Courier,' 'North Queensland Herald,' etc.; author of 'Preliminary Enquiry into the Markets of the European Continent,' 'Guide to Queensland,' etc. (J.T.Cr.)

CROOKES, Sir William, F.R.S.; Past President of the Chemical Society, Great Britain; Past President of the Institution of Electrical Engineers; editor of 'Chemical News,' President of the British Association for the Advancement of Science, 1898; editor of 'Quarterly Journal of Science'; Professor of Chemistry, Training Coll., Chester, 1855; author of 'Assaying' in Ninth Edition of 'Ency. Brit.'; 'Select Methods in Chemical Analysis,' 'Manufacture of Beetroot-Sugar in England,' 'Handbook of Dyeing and Calico-Printing,' 'Dyeing and Tissue Printing,' 'Kerl's Treatise on Metallurgy,' with Ernst Rohrig, 'Wagner's Chemical Technology,' 'Auerbach's Anthracen and its Derivatives,' 'Ville's Artificial Manures,' 'A Solution of the Sewage Question,' 'The Profitable Disposal of Sewage,' 'The Wheat Problem,' etc. (W. C.)

CROSS, Charles Robert, B.Sc.; Professor of Physics and Director of Rogers Laboratory, Massachusetts Institute of Technology; Director of Rumford Committee, American Academy of Arts and Sciences. (C. R. Cr.)

CROZIER, Capt. T. H., R.A.; Professor of Artillery, Ordnance College, Woolwich. (T. H. C.)

CRUMP, Charles George, B.A.; of H.M. Record Office; editor 'The History of the Life of Thomas Ellwood,' 'The Works of Walter Savage Landor,' etc. (C. G. Cr.)

CUNDALL, F.; Sec. and Librarian, Institute of Jamaica; author of 'Studies in Jamaica History,' 'The Story of the Life of Columbus and Discovery of America'; edited 'Bibliotheca Jamaicensis,' etc. (F. Cu.)

CUNNINGHAM, J. T., M.A.; late Fellow of University Coll., Oxford; lecturer for Fisheries, Tech. Instruction Com. of Cornwall; late Asst. Professor of Natural History, Edinburgh; also Naturalist to Marine Biological Assoc. of the U.K.; author of 'Treatise on Common Sole,' 'Marketable Marine Fishes of the British Isles,' 'Sexual Dimorphism,' etc. (J. T. C.)

CURRAN, Rev. J. Milne; author of 'Geology of Sydney and the Blue Mountains,' 'A Contribution to the Geology and Petrography of Bathurst,' etc. (J. M. Cu.)

D

DABNEY, Charles William, Ph.D.; Pres. Univ. of Tennessee; assistant U.S. Secretary Agriculture, 1893-97, etc. (C. W. D.)

DABNEY, Richard Heath, A.M., Ph.D.; Professor of Historical and Economical Science, University of Virginia; author of 'The Causes of the French Revolution,' 'John Randolph: a Character Sketch.' (R. H. D.)

DALBY, W. Ernest, M.A., B.Sc., M.I.C.E., M.I.M.E., Assoc. M.I. Nav. Architects; Professor of Mechanical Engineering and Applied Mathematics, City and Guilds Technical College, Finsbury. (W. E. D.)

DALE, T. F.; author of 'The Game of Polo,' part-editor of 'Riding and Polo.' (T. F. D.)

DALL, Hon. William Healey, A.M.; naturalist, U.S. National Museum; author of 'Alaska and its Resources,' 'Tribes of the Extreme North-west,' etc. (W. H. D.)

DALLAS, J. M. M.; late Secretary of the Edinburgh Draughts Club. (J. M. M. D.)

DANNREUTHER, Edward, Professor Royal Coll. Mus.; author of 'Musical Ornamentation,' 'Liszt's Études,' 'Richard Wagner.' (E. Da.)

DARWIN, George Howard, M.A., LL.D., D.Sc., F.R.S.; Plumian Professor of Astronomy and Experimental Philosophy, Cambridge; Fellow of Trin. Coll. Camb.; author of 'Tides,' in Ninth Edition of 'Ency. Brit.' 'Reports to B.A. on Harmonic Analysis of Tidal Observations,' 'Memoirs on the Effects of Tidal Friction on the Earth and on the Moon,' Phil. Trans. Roy. Soc., 'The Tides and Kindred Phenomena in the Solar System,' etc. (G. H. D.)

DARWIN, Leonard, Major, late R.E.; Intelligence Dept. War Office, 1885-90; served on several scientific expeditions, including Transit of Venus of 1874 and 1882; author of 'Bi-metallism.' (L. D.)

DAVENPORT, Cyril James H., F.S.A.; British Museum; silver medal Society of Arts, 1900; binding editor to the Anglo-Saxon Review; author of 'The English Regalia,' 'Royal English Bookbindings,' 'Cantor Lectures on Decorative Bookbindings,' 'English Embroidered Bookbindings,' 'Life of T. Berthelet.' (C. D.)

DAVEY of Fernhurst, Lord, D.C.L., F.R.S.; Lord of Appeal in Ordinary; Solicitor-General, 1886; Lord Justice of Appeal, 1893. (D.)

DAVIDS, T. W. Rhys, LL.D., Ph.D.; Secretary and Librarian Royal Asiatic Society; Professor of Pali and Buddhist Literature, Univ. Coll. London; author of 'Buddhism,' 'Jains,' 'Lamaism,' in Ninth Edition of 'Ency. Brit.,' 'Buddhism,' 'Buddhist Birth Stories,' 'Buddhist Suttas from the Pali,' 'Hibbert Lectures,' 1881, etc. (T. W. R. D.)

DAVIDSON, William Leslie, M.A., LL.D.; Professor of Logic and Metaphysics, Aberdeen University; author of 'English Words Explained,' 'Theism as grounded in Human Nature,' 'A Philosophical Centenary: Reid and Campbell,' 'Christian Ethics.' (W. L. D.)

DAVIES, A. Llewelyn, B.A.; Barrister, Inner Temple; Assistant Reader in Common Law under the Council of Legal Education. (A. Ll. D.)

DAVIES, Henry Walford, Mus. Doc. (Camb.), A.R.C.M. (Lond.); organist and director of the choir, Temple Church, London; formerly organist and choirmaster, St Anne's, Soho; teacher of counterpoint, R.C.M., 1895. (H. W. D.)

DAVIS, John Patterson, Ph.D., A.M.; assistant in History and Economics, University of Michigan, 1894-1895; now Attorney-at-Law, Nampa, Idaho; author of 'The Union Pacific Railway,' etc. (J. P. D.)

DAVIS, William Morris, Professor Physical Geography, Harvard University; author of 'Physical Geography' and numerous scientific publications. (W. M. D.)

DAWKINS, William Boyd, M.A., D.Sc., F.R.S., F.S.A., F.G.S., A.M.I.C.E.; Professor of Geol. and Palæontology in Owens College, Manchester; geologist on Geological Survey of

Great Britain, 1861-69; author of 'Cave' in Ninth Edition of 'Ency. Brit.,' 'Cave Hunting,' 'Early Man in Britain,' 'British Pleistocene Mammalia.' (W. B. D.)

DAWSON, George Mercer, LL.D., F.R.S., the late; Director Geological Survey of Canada; Geologist and Naturalist to H.M. North American Boundary Commission, 1873-75; one of H.M. Bering Sea Commissioners, 1891, and under the Behring Sea Joint Commission Agreement, 1892; author of numerous scientific and technical reports printed by the Canadian Government, and scientific and other papers. (G. M. D.)

DAY, Lewis F.; English Designer and Art Lecturer; Med. Paris Exhibition (1900); Examiner for Art, Board of Education; author of 'Windows—Stained and Painted Glass,' 'The Anatomy of Pattern,' 'The Distribution of Ornamental Design,' 'Art in Needlework: A Book about Embroidery,' etc. (L. F. D.)

DEACON, George Frederick, M.I.M.E.; Member of Council of Institution of Civil Engineers, London; investigated schemes for water-supply of Liverpool; projected the Vyrnwy scheme, and subsequently carried it out (the first half in conjunction with the late Thomas Hawksley); President Association of Municipal and County Engineers, 1878; President Engineering Section Sanitary Institute, 1894; President Mechanical Science Section, British Association, Toronto, 1897. (G. F. D.)

DEANS, Richard Storry, LL.B.; Barrister-at-Law, Gray's Inn. (R. S. D.)

DENNING, W. F., F.R.A.S.; Gold Medal, R.A.S.; President Liverpool Ast. Society, 1877-78; author of 'Telescopic Work for Starlight Evenings,' 'The Great Meteoric Shower,' etc. (W. F. D.)

DE VILLIERS, John Abraham J.; British Museum. (J. A. J. DE V.)

DE VINNE, Theodore Low, printer and typographist, New York; head of the firm of Theodore L. de Vinne and Co.; author of 'Printers' Price List,' 'Invention of Printing,' 'Historic Types,' etc. (T. L. DE V.)

DEWAR, James, M.A., Hon. LL.D. (Glasgow, St Andrews, Edin.), D.Sc. (Victoria), F.R.S., F.R.S.Ed., F.I.C., F.C.S.; Professorial Fellow of Peterhouse, Camb.; Jacksonian Professor of Experimental Philosophy, Cambridge; Fullerian Professor of Chemistry, Royal Institution, London; Vice-President of the Royal Society; a Director of the Davy-Faraday Research Laboratory; President British Association for 1902; co-inventor with Sir Frederick Abel of cordite; late member of the Government Explosives Committee; author of 'Alum,' etc. in Ninth Edition of 'Ency. Brit.,' numerous papers contributed to the proceedings of the Royal Societies of London and Edinburgh, the Royal Institution, the British Association, the Chemical Society, etc. (J. DR.)

DIBDIN, Charles, F.R.G.S., A.V.I.; Knight of St John of Jerusalem in England; Hon. Corresponding Member of Institutions de Prévoyance, France; Secy. of the Royal National Lifeboat Institution, England; Hon. Secy. of the Civil Service Lifeboat Fund. (C. Di.)

DIBDIN, Lewis Tonna, K.C., D.C.L. (Durham), F.S.A.; author of 'Church Courts,' 'City Livery Companies,' 'Brewer's Endowment and Establishment,' 'Monasticism in England,' 'Hanson's Death Duties.' (L. T. D.)

DICEY, Edward, C.B., B.A.; editor of 'The Observer' (London), 1870-89; author of 'Rome in 1860,' 'Cavour,' 'The Morning Land,' 'England and Egypt,' 'Victor Emmanuel,' 'Bulgaria, the Peasant State,' 'The Story of the Khedivate,' etc. (E. D.)

DICKEY, Rev. Charles A., D.D.; President of the Presbyterian Hospital in Philadelphia; Moderator of the General Assembly of the Presbyterian Church in the U.S., 1900. (C. A. D.)

DICKSON, Henry Newton, B.Sc., F.R.S.E., F.R.G.S.; late Vice-President Royal Meteorological Society; Lecturer in Physical Geography, Oxford; author of 'Meteorology: the Elements of Weather and Climate,' etc. (H. N. D.)

DIXON, Capt. J. Whitly, R.N.; conservator of the river Humber; late Staff Commander of the Medway Fleet Reserve; author of 'Mariner's Compass in an Iron Ship,' etc. (J. W. D.)

DOBSON, George; Petersburg; author of 'Russia's Railway Advance and Central Asia,' etc. (G. D.)

DOBSON, Henry Austin, Principal, H.M. Board of Trade, to 1901; author of 'Hogarth' in Ninth Edition of 'Ency. Brit.'; 'Proverbs in Porcelain,' 'Old-World Idylls,' 'At the Sign of the Lyre,' 'Collected Poems,' 'Thomas Bewick and his Pupils,' Lives of Fielding, Steele, Goldsmith, Horace Walpole, William Hogarth, 'Four Frenchwomen,' 'Eighteenth Century Vignettes,' 'A Paladin of Philanthropy,' etc. (A. D.)

DODD, Lieut.-Col. John Richard, M.B., F.R.C.S., R.A.M.C.; Medical Officer, Royal Arsenal, Woolwich. (J. R. D.)

DOUGLAS, James, LL.D.; member and Vice-President Am. Inst. of Mining Engineers; member Am. Philosoph. Soc., Am. Geolog. Soc., Society of Arts, London, etc.; formerly Professor of Chemistry, Morrin College, Quebec; author of 'Canadian Independence,' 'Imperial Federation and Annexation,' numerous technical articles and reports, etc. (J. Ds.)

DOUGLAS, Robert Kennaway, Keeper of Oriental Printed Books and MSS. at the British Museum; Professor of Chinese, King's Coll. London; appointed China Consular Service, 1858; retired, and appointed assistant in charge of Chinese Library, British Museum, 1865; author of 'Canton,' 'China,' 'Jenghiz Khan,' 'Manchuria,' etc., in Ninth Edition of 'Ency. Brit.,' 'The Language and Literature of China,' 'Confucianism and Taoism,' 'China,' 'A Chinese Manual,' 'The Life of Li Hung-Chang,' 'China.' (R. K. D.)

DOUGLASS, William Tregarthen, M.I.C.E., M.I.M.E., M.I.E.E.; late Consulting Engineer to the Trinity House; Con. Eng. to Govts. of W. Australia, N. S. Wales, Victoria, Cape of Good Hope, etc.; erected the Eddystone, Bishop Rock Lighthouses, etc.; author of 'The New Eddystone Lighthouse,' 'On the More Efficient Lighting of Estuaries and Rivers,' etc. (W. T. D.)

DOWSON, J. Emerson, M.I.C.E., M.I.M.E.; Inventor of the Dowson Gas Plant; part author of 'Tramways,' 'Decimal Coinage,' etc., etc. (J. E. Do.)

DREYER, John Louis Emil, Director Armagh Observatory; assist. Astronomer at Dublin University Observatory, 1878-82; author of 'Observatory,' 'Sextant,' 'Time,' 'Transit Circle,' in Ninth Edition 'Ency. Brit.,' 'Second Armagh Catalogue of 3300 Stars,' 1886, 'New General Catalogue of Nebulæ and Clusters of Stars,' 'Tycho Brahe'; co-editor 'Copernicus: an International Journal of Astronomy,' 1881-84. (J. L. E. D.)

DRIESCH, Hans A. E., Ph.D. Jena; Stazione Zoologica, Naples; author of 'Analytical Theory of Organic Development,' 'Biology,' etc. (H. A. E. D.)

DRIVER, Rev. Samuel Rolles, D.D., D.Litt.; Regius Professor of Hebrew, and Canon of Christ Church, Oxford; member of Old Testament Revision Company; author of 'Isaiah,' 'Notes on the Hebrew Text of the Books of Samuel,' 'An Introduction to the Literature of the Old Testament,' various commentaries; joint-editor of the 'Holy Bible, with various renderings and readings from the best authorities,' 'A Hebrew and English Lexicon of the Old Testament.' (S. R. D.)

DUFF, Rt. Hon. Sir Mountstuart Elphinstone Grant, P.C., M.A., D.L., G.C.S.I., F.R.S.; Under-Secretary of State for India, 1868-74; Under-Secretary for the Colonies, 1880-81; Governor of Madras, 1881-86; Member of Senate University of London, 1891; President Royal Geographical Society, 1889-93; President Royal Historical Society, 1892-99; author of 'Miscellanies, Political and Literary,' 'Memoir of Sir H. S. Maine,' 'Ernest Renan,' 'Memoir of Lord de Tabley,' 'Notes from a Diary.' (M. G. D.)

ECCLES, Dorset; assistant, British Museum. (D. E.)

EDGINGTON, Charles, M.A.; President Oxford University Speed Skating Club; holder since 1898 of the world's speed record for the hour (19 m. 348 yds.). (C. E.)

EDGEWORTH, Francis Ysidro, M.A.; D.C.L.; Professor of Political Economy, Oxford, Fellow of All Souls' Coll. Oxford; Fellow of King's Coll. London; editor of the 'Economic Journal'; author of 'Mathematical Psychics,' etc. (F. Y. E.)

EDWARDS, William Seymour, Attorney and Counsellor-at-law, U.S.A.; author of 'Coals and Cokes in West Virginia.' (W. S. E.)

EGERTON, H. E., M.A.; author of 'A Short History of British Colonial Policy,' 'Sir Stamford Raffles,' 'Essays on Christ's Hospital,' etc. (H. E. EG.)

ELIOT, Charles William, LL.D., D.C.L.; President of Harvard University; author of 'American Contributions to Civilization,' 'Educational Reform,' etc. (C. W. E.)

ELIOT, Whately, M.I.C.E.; conducted survey of the coast of New Zealand; late Engineer to Peterhead Harbour Board; Resident Engineer Eastham section of the Manchester Ship Canal; Superintendent Civil Engineer, Keyham Dockyard Extension, etc. (W. E.)

ELLINGTON, E. B., M.I.C.E.; Member of the Council M.E.; Member of the Société des Ingénieurs Civils de France; Chief Engineer London and Liverpool Hydraulic Power Companies, etc.; inventor of numerous improvements in hydraulic machinery. (E. B. E.)

ERNST, Gen. Oswald Herbert; Brigadier-General U.S.A.; member of the U.S. Isthmian Canal Commission; Engineer in charge of Western River Improvements, 1878-86, and of Harbour Improvements on Texas Coast, 1886-89; Superintendent U.S. Military Academy, 1893-98; author of 'Manual of Practical Military Engineering,' etc. (O. H. E.)

EVANS, Hon. Henry Clay; U.S. Commissioner of Pensions, Washington. (H. C. E.)

EVERETT, Commander Allan F., R.N.; Signal School, H.M.S. 'Victory,' Portsmouth. (A. F. E.)

EVERETT, Joseph David, M.A., D.C.L., D.Sc., F.R.S.; late Professor of Natural Philosophy, Queen's Coll. Belfast; Assist. to Professor of Mathematics, Glasgow, 1864-67; author of 'Centimètre-Gramme-Second System of Units,' English edition of 'Deschanel's Physics,' 'Elementary Text-Book of Physics,' 'Outlines of Natural Philosophy.' (J. D. E.)

EWART, James Cossar, M.D., F.R.S.; Regius Professor of Natural History, Edinburgh; Professor Natural History, Aberdeen, 1878-82; member Fishery Board for Scotland; author of 'The Locomotor System of the Echinoderms' (with the late G. J. Romanes), 'On the Progress of Fish Culture in America,' 'On Whitebait,' 'On the Preservation of Fish,' 'The Development of the Limbs of the Horse.' (J. C. E.)

EWING, James Alfred, M.A., B.Sc., F.R.S., M.I.C.E.; Professor of Mechanism and Applied Mechanics, Cambridge; Fellow of King's College, Cambridge; Professor of Mechanical Engineering at the Imperial University, Tokyo, Japan, 1878-83; author of 'Pneumatic Despatch,' 'Seismometer,' 'Sewerage,' 'Siemens,' 'Steam Engine,' 'Strength of Materials' in Ninth Edition of 'Ency. Brit.,' 'Treatise on Earthquake Measurement,' 'Magnetic Induction in Iron and other Metals,' 'The Steam Engine and other Heat Engines,' etc. (J. A. E.)

EXETER, Bishop of, Right Rev. Herbert Edward Ryle, D.D., B.A.; Warburton Lecturer 1899-1903; Fellow King's

College, Cambridge, 1881; Divinity Lecturer at Emmanuel College, Cambridge, 1881-84; at King's College, 1882-86; Principal of St David's College, Lampeter, 1886-88; Professorial Fellow of King's College, Cambridge, 1888; examining chaplain to late Bishop of St Asaph, 1887-89, and to Bishop of Ripon, 1889; Hon. Canon of Ripon, 1895; Chaplain to the Queen, 1898-1901; Hulsean Professor of Divinity, Cambridge University, 1887-1901, and President of Queens' College, Cambridge, 1896-1901; author of 'The Canon of the Old Testament,' 'The Early Narratives of Genesis,' 'Commentary on Ezra and Nehemiah,' 'Philo and Holy Scripture,' etc. (H. E. E.)

F

FAIRBAIRN, Andrew Martin, M.A., D.D., LL.D.; Principal Mansfield Coll. Oxford; Principal of Airedale Coll. 1877-1886; Chairman of Congregational Union of England and Wales, 1883; Member of Royal Commission on Secondary Education, 1894-95; author of 'Arminius,' 'Independents,' in Ninth Edition of 'Ency. Brit.,' 'Studies in the Life of Christ,' 'The City of God,' 'Religion in History and in Modern Life,' 'Catholicism, Roman and Anglican,' 'The Philosophy of the Christian Religion,' etc. (A. M. F.)

FAIRBROTHER, William Henry, M.A., Lecturer in Philosophy, Lincoln College, Oxford; author of 'Philosophy of Thomas Hill Green.' (W. H. F*.)

FAIRLIE, John A., Ph.D.; Asst. Prof. of Administrative Law, Univ. of Michigan; author of 'Municipal Government.' (J. A. Fa.)

FARRAR, Very Rev. Frederic William, D.D., F.R.S.; Dean of Canterbury; Hulsean Lecturer at Cambridge; Bampton Lecturer at Oxford; Chaplain to the Speaker of the House of Commons, 1890-95; author of 'Jesus Christ' in Ninth Edition of 'Ency. Brit.,' 'The Life of Christ,' 'The Life of St Paul,' 'The Early Days of Christianity,' 'Darkness and Dawn,' 'The Bible, its Meaning and Supremacy,' etc. (F. W. F.)

FAUNCE, W. H. P., A.M., D.D.; President of Brown University, Providence, R.I. (W. H. P. F.)

FAUR, G., of the Egyptian Hall, London. (G. Fa.)

FERGUSON, J.; editor of the 'Ceylon Observer,' 'Tropical Agriculturist,' etc.; author of 'Handbook to Ceylon,' manuals on Coffee, Tea, Gold, Gems, etc. (J. F.)

FERRERO, Baron Augusto; editor of 'La Tribuna,' Rome; author of 'Nostalgie d'Amore'; edited 'From Florence to Rome: A Political Diary of 1870-71,' etc. (A. Fe.)

FFOULKES, Miss C. Jocelyn; translator of Morelli's 'Italian Painters,' etc. (C. J. F*.)
