Considerable exploring for oil was done in 1919 in the Ensenada consular district, Mexico. Concessions have been granted and some geological surveys made, but no drilling operations were conducted. More active prospecting is expected in 1920, and Canadian interests are reported as planning to drill near Rosario.

Oil Shales and Petroleum Prospects in Brazil

Suitable Processes of Extraction Will Make Available Large Petroleum Resources That Are Abundantly Distributed Throughout That Country

By Horace E. Williams*

BRAZIL has extensive petroleum resources in oil shales, which are found in different parts of the country. Although many of the shales are rich, suitable processes for the extraction of the oil are lacking, and at present only a few small experimental plants are producing oil by distillation from shales. The regions including the Upper Amazon, the Acre, the Rio Negro and the Peruvian frontier have received little investigation, although they appear to be the most promising fields for explorations in the country.

Information as to the detailed structure and distribution of the rock formations in the State of Maranhão is very meager. The Permian beds are exposed along the Rio Parnahyba for over 1,000 km., and, generally, over the southern and eastern half of the state. These beds are covered largely by thinner Triassic and Cretaceous formations. Although the Permian rocks have undergone considerable folding in a minor way, the material in hand seems to indicate a general synclinal structure across the state, with the main axis bearing northeast-southwest. On the middle reaches of the Itapicurú and Mearim rivers, bituminous shales are found together with calcareous sandy and marly beds associated with limestones.

Shales Overlain by Boghead Coal

At the occurrence on Rio do Inferno, the beds strike east and west with a dip of 30 deg. south. The lowermost bed consists of a boghead coal, somewhat similar to the Marahú beds of Bahia, overlying a thick bed of well-laminated bituminous shales. In the bed of the Rio Mearim, the bituminous shales are covered by a limestone with siliceous and gypsiferous intercalations. These beds have a southerly dip and are covered by over 50 m. of flaggy sandstones. At Grajahú, farther southwest, the same gypsiferous limestone occurs, but without the bituminous shales, which, if present, are below the water level of the river. The limestone dips northeast with the strike N. 60 deg. W. and it is covered by a red conglomeratic sandstone. Similar beds are found in the extreme southwest of the state and in northern Goyaz, on the Rio Tocantins.

The plains and lowlands of central Maranhão are covered by the lateritic formation, and observations on the underlying rocks are difficult, especially as regards character and structure. Samples of the oil shale from this region gave the following results on analysis: Bitumen, 36.5 per cent; clays, 22.6 per cent; soluble carbonates, 40.8 per cent; and on slow distillation 450 l. of oil (about 100 gal.) per ton.

Shales rich in oil are found at several places along the coast of Alagôas. The series of rocks to which the oil shales belong are found along the coast about Cape S. Agostinho, Rio Formosa, Tamandaré, Abreu da Una, and in some other localities, but at these places the unweathered shale does not appear. Farther along the beach, in latitude 9 deg. 3 min., at Maragogy, the oil-bearing shales appear at and a little above tide level. At this place they show a wrinkled synclinal structure and outcrop frequently from this point south, as at São Bento, Camaxó, Japaratubá, and in front of Pitinguy, in latitude 9 deg. 7 min., where they are exposed at low tide.

At Barreira do Boqueirão, north of the Porto das Pedras, the shale exposed has a thickness of 2 m., with a probable thickness of 3 or 4 m. in all. At Camaragibe, the shales form a wave-cut terrace about 150 m. wide, the dips observed were from 5 to 10 deg.

Shales are exposed at Barra do Santo Antonio and at Riacho Doce, in latitude 9 deg. 36 min. The exposure at Riacho Doce is quite similar to those already mentioned. Several pits were sunk, and the shales were found to be richer than those at Camaragibe.

Bituminous Beds in Bahia Have Appearance of Asphalt

The better-known occurrences of bituminous rocks in the state of Bahia are those found in the vicinity of Marahú and southward along the coast. These rocks occur along the coast in the flat region for considerable distances and widths. The Marahú deposits are about 30 km. long by about 15 km. wide. The beds contain both fresh-water and marine fossils. Resting up against the old crystalline rocks is a fresh-water series of rocks containing plant remains, which is largely impregnated with bituminous matter. This is characteristic of the western inland part of the basin. Farther east, resting on these beds, are found limestones containing marine fossils and also with impregnations and masses of asphalt. The beds are of Cretaceous age. The appearance of the bituminous and carbonaceous material everywhere is notable. These materials occur in the most varied forms. In the beds are found large solid impregnations having the appearance of asphalt; and at some points the bitumen is viscous like pitch. At Taipúmirim, cavities a meter or more in diameter and quite deep are filled with black bituminous matter. An analysis of this material gave the following: Volatile matter, 30 per cent; non-volatile combustible matter, 14 per cent; ash, 56 per cent. The material contains much pyrites. Alcohol dissolves little of it. On evaporation, it gives a brown rosin. Ether dissolves most of the material and benzol dissolves it almost completely.

Composition and Products of "Turfa de Marahú" Similar to Bituminous Coal

Resting on the Cretaceous beds, a clayey lignite is found in the lower beds of the Tertiary bluff formation of this coast. In the lowermost beds, almost at tide level, the boghead coal known as the "Turfa de Marahú" is found. This is different from other known bitumens, and is light yellow in color, with brown and gray veins, which appear as stratification planes. An analysis gave the following: Water (at 110 deg.) 2.75 per cent; volatile matter, 71.65 per cent; non-volatile combustible matter, 9.75 per cent; mineral residue, 15.85 per cent. The residue consists principally of silica, much alumina, lime, and grains of quartz. Horizontal beds of this material are exposed for a depth of 3 to 4 m. at the mouth of the Rio Arimembeca, and are said to continue in depth for over 15 m. On slow distillation, this coal yielded 430 l. of crude oil to the ton. The density of this oil varies between 0.870 and 0.880. Neither in

*Abstract of a paper presented at the St. Louis Meeting of the A.I.M.E., September, 1920.

color nor aspect does the rock have any resemblance to coal, but the composition and the products are those of the bituminous coals. It is not a bituminous schist, because the organic material greatly predominates over the mineral. The great mass of the rock is composed of yellowish-brownish humic material.

Farther south from Marahú, in the vicinity of Ilhéos, oil shales similar to those of Alagôas are found in several places. These are small exposures of beds that appear along the coast between the granite points, which hereabouts frequently extend down to the ocean. The area of these seems to be relatively small; and, although they are rich in oil content, their value remains to be determined.

Shales in São Paulo

The Tertiary basin in eastern São Paulo, on the upper reaches of the Rio Parahyba, is perhaps 150 km. long by 15 to 20 km. wide. Over a considerable part of this basin, oil shales have been found. They outcrop 10 to 15 m. above the Parahyba near Tremembé and Pindamonhangaba, where they are being mined. Quantities of these shales have been used at the gas works in Rio and in São Paulo at various times, especially during the war, on account of the shortage of coal. There exists at Taubaté a small plant for the distillation of oil from these rocks. An analysis of the shales gave the following composition: Crude oil, 13.08 per cent; water, 23.36 per cent; gas and loss, 4.02 per cent; mineral residue, 58.64 per cent. On slow distillation these shales yielded 27 gal. of crude oil per ton.

Extending through São Paulo, Paraná, Santa Catharina, Rio Grande do Sul, and into Uruguay is a persistent bed of black petroliferous shale in the upper Permian series of rocks, which is known as the "Iraty Black Shale." At places, the petroleum of these shales has been oxidized into albertite or other substance resembling coal, as about Piracicaba and Rio Claro, in the State of São Paulo. Material rich in oil is found between São Pedro and Piracicaba in beds of considerable thickness. A company has been formed recently in the city of São Paulo for explorations in this region. Near Rio Claro, several miles farther north, some drilling has been done during the last few years in an effort to find oil.

At about the same geological horizon as the above outcrops, but at a much lower level deposits of asphalt occur along the Rio Tieté near Porto Martins. Farther south, in the foothills of the Serra de Luiz Maximo, between Tatuhy and Botucatú, a heavy bed of bituminous sandstone is found some distance above the black shale. Recently a plant has been installed near São Gabriel, in Rio Grande do Sul, for the distillation of oil from these shales.

Though extensive faulting and fissuring of the strata of this region may have allowed the escape of contained petroleum in the vicinity of faults and fissures, but these are neither so numerous nor so extensive in area as to preclude its existence in other places. If one may judge by many examples known today, important deposits may still be present in the strata even in the vicinity of the eruptive dikes. Be this as it may, with regard to petroleum the fact is abundantly demonstrated that, in these shales, Brazil has an inexhaustible supply which only requires suitable processing to become available.

Oil Possibilities in Cuba

By E. R. Suarez Murias

Written for *Engineering and Mining Journal*

Petroleum indications are numerous in the Island of Cuba and consist of asphalt deposits, oil seepages, gas exudations, veins of native bitumen, pitch pools, bituminous limestones and inclusions of petroleum in igneous intrusions in the rock formations of the country.

On several occasions during the latter part of the last century attempts have been made to locate oil deposits, but without success. In the last four or five years oil has been struck at two points, one in the province of Havana, at Bacuranao, the other one in the province of Matanzas, at Cantel. At the latter place oil was found recently, whereas at the former they have been pumping it for the last two or three years. Close to the boundary of Santa Clara, at a place called Motembo, where several shallow wells were sunk years ago, two wells were sunk last year to a depth of approximately one thousand feet which produce naphtha. The owners assert that they will place this product on the market as soon as they can erect containers. Gas flows from the above mentioned relatively shallow wells at the estimated rate of one hundred thousand cubic feet per day.

Some forty wells have been drilled in Cuba during the last four or five years, although the work done has been conducted in a haphazard way. Little is known about the structural conditions of the subsoil, for geology has rarely been taken into account. In selecting sites for drilling more attention, perhaps, has been given to easy access for prospective purchasers of stock than to other more important factors governing the success of the enterprise. No conclusions should be drawn, therefore, from results thus far obtained in the attempts to locate oil. It is not surprising that the work done should have practically extinguished local interest in oil.

The oil showings above enumerated extend over miles of territory, appearing more or less conspicuously parallel to the strike of the long axis of the island over a distance of six hundred miles, covering an area of at least six thousand square miles.

Petroleum Never Considered a Metal

In reply to an inquiry as to whether petroleum ever has been classed as a metal or a semi-metal, the Director of the United States Geological Survey has made a reply which negatives any such assumption. Besides being unaware of any classification of that nature the Director does not know of it ever having been used. His reply follows:

"Neither any of my associates in the U. S. Geological Survey nor myself knows of any scientific or other classification of minerals and mineral substances published since 1867 in which petroleum is placed with the metals or semi-metals.

"As you probably are aware, oil, asphalt, and other bitumens of similar nature and origin were associated with coal even by the early mineralogists and metallurgists of the sixteenth and seventeenth centuries, and in many works were therefore placed in the stone and earthy groups, rather than with the metals. I doubt if extended research of early literature will reveal a mineral classification of any date in which these substances are put with the metals."

NEWS FROM THE OIL FIELDS

Oil Men Meet at Denver

From Our Special Correspondent

The Independent Oil Men's Association will hold its twelfth annual convention and exhibition in Denver beginning Sept. 28. The exhibition will be held in the Auditorium, and the different types of oil-producing and drilling machinery and equipment will be shown. A four-day session for papers and discussions is planned. A special train left New York on Sept. 24 for Denver, going by way of Chicago and Kansas City.

Frantz Pool, in Cat Creek, Wyo., Field Shows Enlargement

From Our Special Correspondent

Measurement of the flow of the well of the "56" Co., in the Cat Creek field, so-called because there are 56 units in the corporation, shows an output of 1,400 bbl. daily, with the sand drilled into only several feet, and it was believed that this production might be further increased. The significance of the bringing in of this well is the suggestion of the proving of the large Frantz pool for a distance at least of 3,000 ft. The Frantz No. 2 well continues production at a rate of 2,000 bbl. daily with the neighboring well, 440 ft. distant, owned jointly by the Frantz and the Midwest, showing an output of 3,500 bbl.

Walker Brothers' well, being drilled for interests idenified with the Anaconda, situated in the Cat Creek field, has an oil showing in a shale bedding above the sands, more than six barrels of oil being baled daily. This well is in what is known as the West Mosby structure, where are found the Frantz wells. Another Walker Brothers well is situated in the Kootenai dome, also in the Cat Creek field, 30 miles distant from the Frantz wells, and this well also is reported in, but the report lacks confirmation.

The Department of Oil and Gas of the California State Mining Bureau reports for the week ending Sept. 4, 1920, 16 new wells (587), 26 tests for water shut-off (859), 26 deepening or redrilling jobs (606), and 5 wells abandoned (146). The numbers in parantheses are the totals for the year to date.

More than 150,000 acres of public lands in California and Wyoming were classified during August by the U. S. Geological Survey as being within known oil and gas structures. This brings the total acreage thus classified under the Mineral Leasing Act to 340,000 acres.

Increase in August Kentucky Production

From Our Special Correspondent

Production showed up better during August than the preceding month. Wells that were completed number 255, an increase of 66. New production was 9,479 bbl., an increase of 1,950 bbl. Work under way totals 1,075 bbl. Runs of the Cumberland Pipe Line Co. for the week just closed, in eastern Kentucky, show a total of 76,808 bbl., or a daily average of 12,801 bbl. Activity in new business is again in the western part of the state. No. 3 on the C. E. Wilson lease in Warren County, rated at 50 bbl. when it was brought in a month ago, has been shot and is now good for 200 bbl. daily production. Whittle No. 1 on the Bailey farm, Warren County, was shot Thursday at 440 ft. The well started flowing at once, and production is rated at 300 bbl. Whittle No. 4 also has been brought in, rated at 125 bbl. Two others are going down on this lease.

Butler No. 1 was drilled in four miles south of Franklin in Simpson County, rated at 19 bbl. an hour. The well is only 150 ft. deep. It is the first shallow well in the county and has boosted the value of leases.

Phillips & Stewart recently brought in No. 3 on the Willoughby lease, Allen County, estimated at 200 bbl. a day. No. 1 and 2 are small wells. No. 4 is going down.

New Wyoming Pipe Line in Operation

Other News from Wyoming Fields

From Our Special Correspondent

The thirty-nine-mile pipe line of the Illinois Pipe Line Co. from Rock Creek oil field to the Midwest Refining Co.'s plant at Laramie is in successful operation. About 160 bbl. per hour are being transported.

The Bolton Creek Oil Syndicate recently brought in a 1,200-bbl. well in the Bolton Creek field, 20 miles southwest of Casper, Wyo. This is the largest producing well in the district.

The Riverton-Wyoming Refining Co. plans to raise capital for improvements and enlargements on its Riverton refining plant. The plant in treating Dallas field (Lander County) crude oil must now market the heavy residue which could be converted into lubricating oils at a considerable profit.

Part of the Graybull plant of the Midwest Refining Co. will be altered to treat oil from the Hamilton field. This oil is heavier than that treated heretofore and a different handling is required. About 40 per cent of the plant's capacity will be employed on the work of obtaining the new supply.

Texas Oil Transportation Agreement Ended

Empire Pipe Line Co. To Transport Oil in Cars

From Our Special Correspondent

The oil transportation agreement between the Texas Co. and the Empire Pipe Line Co., a Cities Service subsidiary, regarding crude petroleum transportation between Burkburnett and Healdton, has been cancelled by mutual agreement, to take effect Oct. 1. Hereafter all oil gathered at Burkburnett by the Empire Pipe Line Co. will be transported in tank cars.

The Empire Gas & Fuel Co. filed suit in the federal district court at Dallas on Sept. 7 against the Lone Star Gas Co. for $450,000 for alleged breach of contract. The suit arises from failure of the defendant to comp'y with the terms of a contract to buy 17,000 acres of land near Mineral Wells.

The Manhattan-Texas Petroleum Co., of Dallas, has acquired the property of the United Petroleum Trust Co. for a consideration said to be about $1,000,000. The Manhattan-Texas Co. will also purchase, if possible, producing areas in the Breckenridge field in accordance with its policy of expansion. The fourteenth consecutive monthly dividend of 2 per cent was paid recently by this company.

Breckenridge, Stephens County, is probably the most active and most interesting oil field in Texas today. The discovery of oil within the city limits has caused the formation of many small companies and partnerships, and drilling on many of the city blocks is now under way. Few, if any, dry holes have been drilled in Breckenridge, it is reported, and a big increase in production is expected in a few months.

Hull, Liberty County, was the field of chief interest on the Gulf coast during the second week of September. Five wells were completed with a total initial production of about 9,000 bbl. The largest well was the Morris-Phillips No. 11 of the Gulf Production Co. flowing 7,000 bbl. from 3,100 ft.

At West Columbia, Brazoria County, the No. 1 Abrams well of the Texas Co. is flowing about 8,000 bbl. through the drill stem after having sanded up due to a cave in the open part of the hold. Several wells in the immediate vicinity of this big well are being rushed to completion, including those of the Gulf Production Co., Humble Oil & Refining Co., Monarch Oil Co., Crown Oil & Refining Co., and Texas Company's offset wells. The deep well of the Gulf Production Co., which was completed recently at 3,700 ft., making about 700 bbl. has increased its flow so that nearly 2,000 bbl. are now being obtained.

ECHOES FROM THE FRATERNITY

The Federated American Engineering Societies

The Organizing Conference held in Washington on June 3 and 4, 1920, was attended by 140 delegates representing over 71 organizations, having an aggregate membership of over 110,000, or over 80 per cent of the aggregate membership of all of the organizations that were invited. The questions have been asked: "Who are these men?" "Who were invited?" and "Who should be interested in this movement?"

The Federated American Engineering Societies is constituted of engineering and allied technical organizations, whose chief purpose is the advancement of the knowledge and practice of engineering and allied technical arts which are not organized for commercial purposes. It includes the individual engineer and the allied technologist, who is represented through the society or societies of which he is a member which have membership in the organization. It includes civil, mining, metallurgical, mechanical, electrical, testing, railway, highway, municipal hydraulic, sanitary, water works, bridge, agricultural, illuminating, heating, ventilating, refrigerating, safety, radio, fire protection, automotive, industrial, military, marine, naval and chemical engineers, and architects, naval architects, chemists and geologists. These branches of engineering and allied sciences cover the whole range of activity in this country upon which is dependent its economic success. It has been said that

"Everywhere you look you see the work that the engineer has done."

FORMATION OF THE FEDERATED AMERICAN ENGINEERING SOCIETIES

Engineers and allied technologists have been content to perform their work without notoriety. Dating from a period considerably before the war, the engineer was gradually developing class consciousness, and a desire to be of public service. This desire was intensified as a result of the World War and led to the formation of Engineering Council by the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers. In the effort of these societies to determine in what way their activities could be improved and rendered of greater value, committees were appointed by each, and these committees in turn appointed conferees, who met and organized the Joint Conference Committee. As a result of this intensive desire for service, it was the unanimous opinion of the Joint Conference Committee that a comprehensive organization was desirable that could speak for the engineering and allied technical professions wherever engineering experience and technical training are involved, as well as in matters of common concern to these professions. This recommendation was accepted by the constituent societies who authorized the Committee to call, without delay, a conference of representatives of national, local, state, and regional engineering organizations and affiliations for the purpose of bringing into existence the comprehensive organization recommended. The Committee issued a call to 110 engineering and allied technical organizations for the thoroughly representative Organizing Conference of June 3-4, 1920, which has been characterized as the greatest event in the engineering history of this country.

This Organizing Conference, without a dissenting vote, created The Federated American Engineering Societies and authorized the Joint Conference Committee to act as the Ad Interim Committee between its adjournment and the first meeting of its governing body, American Engineering Council.

PROGRAM

First Meeting
of American Engineering Council
of
The Federated American Engineering Societies

Washington, D. C.

November 18-19, 1920.

All Sessions in Small Ball Room
New Willard Hotel

THURSDAY, NOV. 18, 1920.

MORNING SESSION

8:30 A.M. *Registration.*

10 A.M. *Opening Session of American Engineering Council of Federated American Engineering Societies.*

1. *Call to Order by Richard L. Humphrey, Chairman, Joint Conference Committee.*
2. *Election of Temporary Chairman.*
3. *Election of Temporary Secretary.*
4. *Appointment of Temporary Committees:*
   (a) *Program.*
   (b) *Credentials.*
   (c) *Constitution and By-Laws.*
   (d) *Nominations.*
   (e) *Plan and Scope*
   (f) *Budget.*
   (g) *Resolutions.*

AFTERNOON SESSION

2 P.M. Address, *"Engineering Council," J. Parke Channing, Chairman.*

2:30 P.M. *Discussion of the field of activity for The Federated American Engineering Societies.*

FRIDAY, NOV. 19, 1920.

MORNING SESSION

9 A.M. 1. *Report of Committee on Nominations.*
2. *Election of Permanent Officers.*
3. *Report of Committee on Constitution and By-Laws.*
4. *Formal Ratification of Constitution and By-Laws.*
5. *Report of Committee on Plan and Scope.*

AFTERNOON SESSION

2 P.M. 1. *Report of Committee on Budget.*
2. *Report of Committee on Resolutions*

EVENING SESSION

8:30 P.M. 1. *Introductory remarks by the President of American Engineering Council.*
2. *Address by Herbert C. Hoover, President, A. I. M. E.*

9:30 P.M. *Informal Reception and Smoker.*

SATURDAY, NOV. 20, 1920.

9 A.M. *Organization Meeting of the Executive Board of American Engineering Council.*

PUBLICATIONS OF THE JOINT CONFERENCE COMMITTEE

Immediately following the Conference, the Joint Conference Committee prepared an abstract of the proceedings of the Organizing Conference in Washington, copies of which were mailed to each of the organizations originally invited to participate and to the technical papers. The Committee was instrumental in securing the co-operation of the technical press and through the courtesy of McGraw-Hill Company, Inc., published and distributed a sixty-four page booklet entitled "Engineers Unite," setting forth "The High Spots in the Washington Organizing Conference, June 3-4, 1920, as Reported and Interpreted by the Editors of the Technical Press," in the issues immediately following the Conference. The Committee issued a formal invitation to each organization, originally invited to the Organizing Conference, to become a Charter-Member of The Federated American Engineering Societies, and to appoint delegates to the first meeting of American Engineering Council to be held in November of this year.

The Joint Conference Committee also edited and published in pamphlet form, the Constitution and By-Laws of The Federated American Engineering Societies which have not only been distributed to the organizations invited to participate, but also to the technical press, and to others, and copies are available for general distribution

The Joint Conference Committee received communications from the participating organizations and others asking for interpretations of the constitution and by-laws, or for explanation of matters pertaining to the movement, and as it was of the opinion that

there were doubtless many others to whom the same information would be helpful therefore decided to issue bulletins contining the information requested, which would be available to the organizations invited to participate, as well as to the technical press. Nine bulletins have so far been issued. These bulletins first make announcement of Society action in the matter of membership in, and then answer mooted points in connection with, The Federated American Engineering Societies. Copies may be obtained by any engineering organization not already supplied, on request to The F. A. E. S., Engineering Societies Bldg., 29 W. 39th., New York.

Joint Conference Committee Organized by A. I. M. E. and Mining Congress

A conference called by Herbert Hoover, president of American Institute of Mining and Metallurgical Engineers, and comprising representatives appointed by the governing bodies of American Mining Congress and American Institute of Mining and Metallurgical Engineers, was held at the Engineers' Club, New York City, Monday evening, Sept. 13, 1920. Those present were Herbert Hoover, Bulkeley Wells, Edwin Ludlow, Walter Douglas, J. R. Finlay, B. B. Thayer, A. C. Morrison, E. P. Mathewson, Walter R. Ingalls, J. F. Callbreath and Bradley Stoughton.

The purpose of the conference was to formulate plans and establish a committee to co-ordinate the activities of the Mining Congress and the institute in respect of legislative work relating to the mining industry. As examples of work needing to be done were mentioned: The co-ordination of government work at Washington so as to place the appropriate work within the field of the United States Bureau of Mines the Geological Survey, and other bureaus relating to mining; the formulation of a revenue-producing tax which shall supply the deficiency resulting from the expected reduction in excess profit taxes; the maintenance of adequate statistical service to the mining industry; assistance to gold mining; making possible an appeal to the Court of Claims by claimants who fail to secure relief from the commission established by the Minerals Relief Bill.

By unanimous vote Herbert Hoover, James F. Callbreath, Bulkeley Wells and Bradley Stoughton were added to the conference committee.

The committee then organized by the unanimous election of Walter Douglas, chairman, and Bradley Stoughton, secretary, and on motion adopted the title "Joint Conference Committee of Mining Congress and Institute."

The joint conference committee is made up as follows: Walter Douglas, chairman, 99 John St., New York; Bradley Stoughton, secretary, 29 West 39th St., New York; James F. Callbreath, secretary American Mining Congress, Washington, D. C.; J. R. Finlay, 170 Broadway, New York; Herbert Hoover, 115 Broadway, New York; Walter Renton Ingalls, 115 Broadway, New York; Edwin Ludlow, 149 Broadway, New York; E. P. Mathewson, 42 Broadway, New York; A. C. Morrison, 30 East 42nd St., New York; Henry M. Payne, 50 Church St.; W. L. Saunders, 11 Broadway; J. E. Spurr, Tenth Ave. and Thirty-sixth St., New York; B. B. Thayer, 42 Broadway, New York; Bulkeley Wells, 201 14th St., Denver, Col., and care of H. Payne Whitney, 120 Broadway, New York; Daniel B. Wentz, Land Title Building, Philadelphia, Pa.

Labor Conditions in Central and South America Resemble Our Own

Analysis of Mental and Physical Conditions of Peoples by V. L. Havens—Cures Suggested Emphasize Engineers' Chance for Service

The Editor of *Ingeniería Internacional*, Verne L. Havens, has returned from a seven-months' trip through Panama, Peru, Chile, Argentina, Brazil, and the Windward Islands. Nearly everywhere he has found that, though each people believe their problems are peculiar to themselves and their locality, the reported troubles were always of the same nature.

The inhabitants throughout the Americas are in a highly nervous state, he finds. They are groping for new ideals and standards on which to base their lives. No doubt this is due to the excitement and emotions released by the war, and the remedy lies in the hands of the leaders, who should and must teach peace, co-operation, and calmness.

The second great fact is the actual shortage of labor, and specially of skilled men. The millions who have died by land and by sea, the more millions that today will not or can not work, are the cause of a world-wide deficit. For example, men are scarce in São Paulo, because those who in Europe formerly made cloth and pottery and leather for the Paulistas no longer do so. The Paulistas must and do make it for themselves; but those who make cloth cannot also build the railways, or plant coffee, or load ships. The resulting establishment of the small new industries at home has drawn men from other home labor, and they have not been replaced. Buenos Aires has now to furnish farm and ranch hands to the Argentine to replace Spanish and Italian "golondrinas" whose flying trips are at an end. They stay at home, or visit France, at harvest time.

The shortage of men and lack of production have forced up wages and prices. In general wages have risen 50 per cent throughout South America; but the number of working hours has decreased 20 per cent, and productivity has fallen to about 75 per cent of the standard of a few years ago. No doubt the latter is due, in part at least, to the general nervous tension. In the worst cases these conditions have combined to make the cost of production today 250 per cent of that of 1913.

Two Ways to Improve Conditions

Mr. Havens finds there are only two ways to improve this existing state of affairs. His first cure, which will require years for completion, is to train the boys of today to take the places of the skilled labor of yesterday. Much quicker help is promised by the second solution, the introduction of machinery wherever possible to reduce the labor of the men still working. This would include the greater development of waterpower, and stopping the unnecessary mining, transportation and burning of fuels.

Peru is perhaps the first South American country to recognize and act on the immediate necessity of sanitation as essential to the preservation of the children and the future manpower of the nation. At Paita the government has ordered the incineration of all but six houses to destroy the centers of infection there. Sanitation is no longer only a humane issue but has become a crucial national economic problem, and its neglect involves definite monetary loss to family, nation, and the world at large.

It is evident, that, as Mr. Havens remarks, "The work of the engineers of this generation will decide whether we are to progress or retrograde; and perhaps at no time in all the centuries to come will the engineers and industrial executives of all the Americas have the opportunity to build for the future, that lies before them today."

The Story of Petroleum

Bureau of Mines Offers a Very Complete Film Survey of the Oil Industry

A new four-reel motion picture film telling the story of petroleum has just been completed by the United States Bureau of Mines in co-operation with the Sinclair Consolidated Oil Corporation, and will be loaned for educational purposes to those desiring the same. Applications should be addressed to the Director, U. S. Bureau of Mines, Washington, D. C. In this film the entire story of the petroleum industry, including prospecting, production, refining, distribution and its ultimate uses, is shown in such a way as to be readily understood by the layman as well as the engineer student.

The Bureau of Mines has recently completed films showing various phases of the mining and metallurgical industry, and it is hoped that the borrowers of these films will treat them with the same care that has been taken in preparing them. Those requesting the loan of any films belonging to the Bureau of Mines are expected to pay the cost of postage both from the Washington office and return.

Technical Papers

Petroleum in Alabama—The most that can be said of Alabama as an oil-producing state is that prospects are promising. The "structures," so dear to the heart of the true oil man, are favorable in several parts of the commonwealth. The discoveries in Texas and Louisiana have caused many to wonder if the neighboring state of Alabama did not also have some petroleum possibilities, and the State Geological Survey (University, Ala.), has prepared Bulletin No. 22 (p. 230, free), which is a compilation of all existing information on the subject. The first forty pages form a very readable account of the manner in which oil occurs and how to go about finding it, information which is of general application.

Educating Miners—The number of mining employees in this country considerably exceeds a million, about 74 per cent of whom are engaged in coal mining. Mississippi is the only state in the Union in which the work of extracting minerals from the earth is not a recognized industry. The problem of educating mine employees is a branch of vocational education which is extremely important, and a thorough discussion of the subject is contained in "General Mining," Bulletin No. 38 (p. 168), issued by the Federal Board for Vocational Education, Washington, D. C., from which it may be obtained free of charge. All executives who seek increased efficiency of mine, mill, and smelter employees, and freedom from accidents will find much of interest in this book.

Electro-deposition — *The Mining Magazine* (London, price 1s. 6d.) published in its July and August issues a discussion of the late Prof. S. B. Christy's work on the electro-precipitation of gold and silver from cyanide solutions. The article is by J. E. Clennell, and occupies, in all, twelve pages.

Petroleum Research—A seven-page article in the Sept. 8 issue of *Chemical & Metallurgical Engineering*, by Martin J. Gavin, tells the story of the technical development of oil-shale retorting in Scotland and indicates the necessity of research work on domestic shales.

Talc—A new use for talc has been found as an ingredient in fire-resistant paint. A three-page mimeographed report on the subject is contained in the U. S. Bureau of Mines *Reports of Investigations* for August, Serial No. 2,150. (Free from the Bureau on request.)

Compressed Air Blasting—Rock which is easily split and in which joint planes are absent may be "blasted" with 100 lb. compressed air, inserted through a drill hole, after starting the fracture with a spoonful of black blasting powder. The method is explained in *Reports of Investigations*, Serial No. 2,154, issued by the U. S. Bureau of Mines, Washington, D. C. (Free.)

Petroleum—The A. I. M. E. (29 W. 39th St., New York, N. Y.) has published three papers to be presented at the September petroleum meeting of the Institute in St. Louis: "Petroleum Industry of Trinidad," by G. A. Maccready; "Application of Taxation Regulations to Oil and Gas Properties," by Thomas Cox; and "Oil Shales and Petroleum Prospects in Brazil," by H. E. Williams. Brazil has enormous undeveloped oil resources in her areas of rich shales.

Gold and Silver.—"Gold and Silver in 1918" (pp. 60), a separate chapter of "Mineral Resources," has been issued by the U. S. Geological Survey.

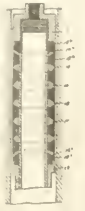
Iron in Europe—A discussion of the condition of the iron industry, a short description of the principal iron districts, and a tabulation of the iron-ore reserves in the new states of Europe are contained in a four-page article in the Sept. 9 *Iron Trade Review*. (Cleveland, Ohio; 25c.) Austria and Hungary have been shorn of their coal and iron resources, to the profit of Czecho-Slovakia.

Petroleum Bibliography—The U. S. Bureau of Mines is publishing periodically a list of recent important articles on petroleum and allied substances. It forms part of the *Reports of Investigations* series and may be obtained as issued upon request to the Bureau.

Recent Patents

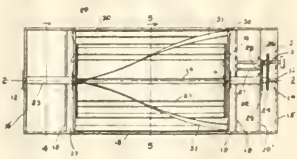
1,350,553. Oil-Well Packer. Patrick H. Mack, Bradford, Pa., assignor to Oil Well Supply Co., Pittsburgh, Pa. Filed Nov. 23, 1915.

In packing structures for wells, a tubular body member, opposing recessed end members carried thereon, an upper expansible member entered in one end member, a lower expansible member entered in the opposite end member, a series of expansible members intermediate the upper and lower expansible members, and a series of rigid members alternating with the intermediate expansible members.



1,350,509. Sand and Slime Separator. James D. McDonald, Hayden, Ariz. Filed Aug. 5, 1918.

In a slime and sand separator, the combination with a casing having an inlet at one end, a slime outlet at the other end, and a sand outlet at one side; of an outer reel rotatably mounted within the casing and having blade moving past said sand outlet, and an inner reel mounted within the outer reel



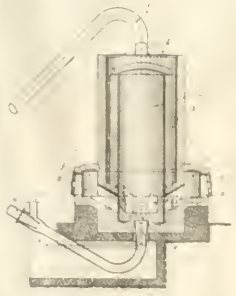
and rotating in the opposite direction, both reels having skeleton heads.

1,351,003. Well-Drilling Bit for Oil, Water, or Gas. Jefferson D. Pace, Shreveport, La., assignor to Acme Oil & Drill Co., Inc., Shreveport, La. Filed July 19, 1919.

In a well-drilling tool, a hollow drill rod, a coupling sleeve screwed upon the lower end of the drill rod, a block received within and screwed to the sleeve but spaced from the end of the drill rod, said block having a flared extension at its lower end, said extension having a circumferential series of slots, bits held upon the tool, said bits having beveled edges conforming to the flare of the extension, lateral extensions on each bit and adapted to fit said slots for holding the bits against longitudinal movement, said coupling sleeve being internally beveled to co-operate with the beveled edges of the bits to hold the bits in clamped position with their lateral extensions received within the slots.

1,315,551. Smelting of Ores in Suspension. F. H. F. Hampton, Sewell Chile, assignor of one-half to W. W. Stenning, London, England. Filed March 30, 1916.

A smelting process which comprehends projecting a finely divided self-fluxing material upwardly into a zone sufficiently heated to cause the formation of melted slag; permitting the



melted globules to coalesce to form a bath of slag and valuable products, and causing all the gases to escape at the base only of said zone.

MEN YOU SHOULD KNOW ABOUT

Edwin Higgins has returned to San Francisco from Virginia City, Nev.

D. M. Liddell has returned to New York City from Joplin, Mo.

O. C. Davidson was on the Gogebic range the week of Sept. 13.

Messrs. Condit and Howell are working in northwestern India, and not in Idaho.

A. W. Newberry of New York City, is in Canada. He expects to return early in October.

A. E. Holmberg has joined the mechanical engineering staff of the McKinney Steel Co.

J. B. Umpleby, who is now doing oil geologic work in Oklahoma, is in the East on a business trip.

David G. Kerr and a party of friends and associates are on a vacation in the woods of northern Michigan.

E. C. Dyason, of Victoria, Australia, was recently re-elected president of the Chamber of Mines of Victoria.

C. M. Weld, mining engineer, has returned to New York City after an absence of two weeks in West Virginia.

Arnold Jere Noerager, chief electrical engineer of the Braden Copper Co., Rancagua, Chile, is in San Francisco, Cal.

Prof. Robert M. Raymond, of the Columbia University School of Mines is in Santa Fe, N. M., this week on private business.

C. W. Purington, mining engineer, left Hakodate, Japan, about Aug. 7, for an examination of the coal fields of northern Sakhalin.

B. C. Yates, superintendent for the Homestake Mining Co., at Lead, S. D., is in Denver attending the First Aid and Mine Rescue contests.

H. A. Jenison of the U. S. Geological Survey is in San Francisco. He is completing a trip through the copper producing sections of the West.

O. U. Bradley, oil and gas inspector on the lands of the Five Civilized Tribes, Oklahoma, was in Washington, D. C., at the end of August on official business.

J. C. Kinnear, smelter superintendent of Nevada Consolidated Copper Co., McGill, Nev., stopped in San Francisco recently on his return from Bully Hill, Cal.

W. P. Woodring has sailed for Haiti in charge of a U. S. Geological Survey party to continue geologic examination of the mountainous area of that republic.

Professor Henry Leighton, of the University of Pittsburgh, has been examining pyrite and iron ore deposits in northern Ontario for Pittsburgh interests.

C. J. Diebel, of Spokane, Wash., president of the United States Silver Lead Mines Co., has returned from inspecting the company's property in the Coeur d'Alenes.

Ira B. Joralemon, assistant general manager of the Calumet & Arizona Mining Co., Bisbee, Ariz., has been elected commander of the Bisbee American Legion post.

M. Poncet, mining engineer and a graduate of Saint-Etienne in 1902, was recently appointed chief engineer of the mining company of the Loire (la Société des Mines de la Loire).

Fred H. Moffit and **Herbert Insley** have completed the geologic work which they were doing on the west coast of Cook Inlet, Alaska, and are now working in the Copper River region.

L. C. Graton, geologist to the Calumet & Hecla Mining Co., of Calumet, Mich., is in Cambridge, Mass., temporarily. His address at present is: Foxcroft House, Oxford St., Cambridge. 38, Mass.

Julien Raick, recent graduate of Liege, Belgium, is studying the electrometallurgy of copper, zinc, and lead, at Leland Stanford, Jr. University. Mr. Raick is an exchange scholar of the Commission for Relief in Belgium.

H. C. Wang, vice-president of Chinese-American Industrial Corporation, Ltd., left New York on Sept. 16, and is returning to China by way of Montreal and Vancouver. He expects to sail from Vancouver on Sept. 24.

Wilbur A. Nelson, state geologist of Tennessee, has been conferring with War Department officials in connection with the survey which is to be made by the War Department of the resources of the upper Tennessee River basin.

Jacques Heuhgen, who recently graduated in geology from the School of Mines at Mons, Belgium, is spending a year in graduate study at Yale University under the exchange scholarship arrangements organized by the Commission for Relief in Belgium.

Dr. Francis B. Laney, of the United States Geological Survey has been appointed professor of geology in the University of Idaho School of Mines. Dr. Laney has done considerable work for the Geological Survey in co-operation with the Idaho Bureau of Mines and Geology.

G. F. Loughlin, head of the division of mineral resources of the U. S. Geological Survey has returned to Washington after having done some geologic work on the stratigraphy of the Narragansett basin. He also made some study of the igneous geology of the surrounding islands.

Lewis A. Parsons has severed his connection with the *Mining and Scientific Press* and is recuperating at El Paso, Texas. Mr. Parsons was formerly engineer of mines for the International Nickel Co. and also did some valuable work estimating the ore reserves of the Dome mines.

Alfred H. Brooks, who has been studying the general mineral situation in Alaska with the idea of advising the Secretary of the Interior as to the adoption of measures to stimulate the mining industry there, reached Ketchihan on Sept. 17 and will spend the remainder of the month examining the copper deposits near there.

Lapsley W. Hope, mining engineer, who has been superintendent for the Eureka-Holly Mining Co., Eureka, Nev., for the past three years, has resigned from that position. Mr. Hope took charge of the Eureka-Holly after four years spent operating mines in British Columbia, but first went to Eureka in 1912 when he was connected with the Credo-Eureka Mines Co. and later with the Adam Hill Corporation. His present address is Eureka, Nev.

OBITUARY

J. J. Welch, general manager of the Majuba Silver, Tin & Copper Co., Reno, Nev., died in San Francisco, Cal., on Sept. 10, following a major operation. Mr. Welch, who was in his sixtieth year, was long associated with the Gunn-Thompson interests.

Henry Berry, vice president and general manager of the Canadian Asbestos Co., died at Montreal Sept. 13 after a long illness at the age of 54 years. He had been engaged in the asbestos industry for many years, was a member of the Montreal Board of Trade and belonged to the Masonic Order. He leaves a widow and three sons.

SOCIETY MEETINGS ANNOUNCED

The American Electro Chemical Society meets at Cleveland, Ohio, Sept. 30 to Oct. 2.

Institute of Metals Division of A. I. M. E. will hold its customary joint sessions with the **American Foundrymen's Association** at Columbus, Ohio, during the week of Oct. 4. The technical sessions will probably be held on Tuesday, Wednesday and Thursday of that week.

Independent Oilmen's Association holds its 12th annual national convention, and a petroleum exposition at Denver, Col., Sept. 28 to Oct. 1. Headquarters will be at the New Albany Hotel and the sessions will be held in the Denver Auditorium Building.

California Metal & Mineral Producers Association will hold its regular annual meeting at its offices in the Merchants National Bank Building, San Francisco, Cal., on Oct. 27, 1920, at 10 o'clock a. m. The annual reports of the president, secretary-treasurer and engineer of the association will be submitted, three directors elected, and a special delegate elected to attend the annual convention of the American Mining Congress at Denver, Col., Nov. 15.

THE MINING NEWS

LEADING EVENTS

WEEKLY RÉSUMÉ

The hearing in the Minerals Separation-Miami Copper Co. flotation case that was to have been resumed on Sept. 15 before the master in Philadelphia has been postponed two weeks. Likewise the Federal Trade Commission has put off until Sept. 30 the inquiry into the conduct of Minerals Separation that was scheduled for Sept. 20 in Washington. In Colorado metal mine operators have conferred with the traffic agents of the various railroads in an effort to secure the re-establishment of the old freight rates on low-grade ores and concentrates. In the Coeur d'Alenes the Federal Mining & Smelting Co. has been denied a rehearing of the Star apex case. The Consolidated Virginia and other mines under Alex Wise on the Comstock lode in Nevada have given their men the $6 wage recently demanded.

At Butte the Anaconda and Davis Daly companies are reported each to claim a body of rich silver-zinc ore recently opened in the Nettie workings. The new tramway of the Walker Mining Co. at Portola, Cal., has been placed in commission. In Arizona the tax commission has cut the valuation of forty-three producing properties. The Swansea property is running again, this time under lease to Consolidated Arizona. During the week the petroleum section of the A.I.M.E. met in St. Louis.

Hearing in Miami Flotation Case Postponed

The hearing before the master in the Minerals Separation-Miami Copper Co. suit, which was to have been resumed on Sept. 15, has been deferred for two weeks. This was done in order that counsel may have opportunity to prepare the papers in an appeal which Minerals Separation, Ltd., has made, seeking to have the U. S. Circuit Court of Appeals, at Philadelphia, review Judge Morris' recent orders dismissing Minerals Separation's contempt proceedings. Minerals Separation sought by these proceedings to have the Miami company punished for contempt of court for continuing to use its present flotation process. Miami claims this is not the process described in any one of the patents of Minerals Separation.

Federal Appeal for Rehearing of Star Case Denied

The application of the Federal Mining & Smelting Co., of Wallace, Idaho, for a rehearing in the case of the Star Mining Co. against the Federal has been denied by the U. S. Court of Appeals at San Francisco. This was a case involving the apex of the Star-Morning (Federal) vein. The Federal won the case in the United States District Court for Idaho, from which the Star appealed to the appellate court and secured a reversal of the lower court. It is expected that the Federal company will now appeal for a writ of *certiorari*.

Ninety-Eight Teams Compete at Denver First Aid and Mine Rescue Meet

Homestake Mining Co.'s Team Takes Third Place in Mine Rescue Contest, All Other Prizes Going to Coal Teams—Several Mid-Year Conventions Held During Meeting

The International First Aid and Mine Rescue Meet, which convened in Denver, Col., September, 9, 10 and 11, was participated in by seventy-three first aid teams and twenty-five mine rescue teams, representing twenty different states of the Union.

The meeting was held under the auspices of the U. S. Bureau of Mines, co-operating with the American Red Cross, the Rocky Mountain Coal Mining Institute, the Colorado Metal Mining Association, the Colorado Chapter of the American Mining Congress, the Colorado, New Mexico and Utah Mine Operators Association and the Colorado Society of Engineers.

During the meet the Rocky Mountain Coal Mining Institute, the Colorado Society of Engineers, the Colorado Metal Mining Association and the Colorado Chapter of the American Mining Congress held their mid-year meetings, their sessions convening during the morning hours and the first aid and rescue contests taking place in the afternoon. Joint meetings of the various organizations were held on the evenings of Sept. 9 and 10.

The mine-rescue contest was conducted on the afternoon of Sept. 9, and was participated in by teams from Illinois, Indiana, New Mexico, Pennsylvania, South Dakota, Utah, Washington, West Virginia, Wyoming and Colorado. J. F. Bailey, assistant director of the U. S. Bureau of Mines, and J. D. Parker, chief of the division of safety cars and stations, were in charge.

In the mine rescue work a wooden gallery 50 ft. long, with straight runways, rock obstructions, falls and two pitches of 45 deg. was filled with formaldehyde and sulphur gas. Each rescue team consisting of four men and a captain, equipped with oxygen-breathing apparatus, worked out "problems" in this chamber.

In connection with the mine rescue program was a new feature, an airplane rescue stunt. Lieut. Kenneth L. Walker with his mechanic, Staff Sergeant Moore, flew from the U. S. Aviation Station at Ft. Sill, Okla., to take part in the event. An imitation mine entrance had been erected and at a signal Lieut. Kenneth L. Walker, in a De Haviland army plane, came swooping over the field with a member of the mine rescue squad. With the gallery filled with smoke, a mine rescue team penetrated the chamber and rescued the supposed victim of the explosion.

Assistant Director Bailey of the U. S. Bureau of Mines in speaking of the airplane as a factor in mine rescue work said:

"The wonderful development of the airplane within the last five years has been so rapid that though it has serious limitations, it is bound to become an important factor in rescue work. The time element is often the deciding factor in this work and airplanes are the fastest mode of travel known to-day. The greatest drawback to their use is the lack of suitable landing fields.

"A preliminary survey has indicated that airplane service might be effectively used in the flat-lying coal fields of Illinois and Indiana and a co-operative agreement has been made whereby McCook field, Dayton, Ohio, will maintain in readiness planes for assisting the bureau of mines safety station at Vincennes, Ind., in its rescue work."

Another feature of the meet was an explosion of coal dust which wrecked an artificial gallery from which the teams were supposed to rescue an entombed miner.

In addition to miners, mine inspectors and operators from practically every state in the country, there was in attendance from Pachuca, Mex., three underground safety inspectors from the Cia. de Real del Monte y Pachuca, and three others from the Cia. de Santa Gertrudis. These men were desirous of obtaining information as to methods in first-aid, mine rescue and general mine safety work and were furnished guides and interpreters by the Bureau of Mines during their stay in Denver.

There were entered a total of seventy-three first aid teams from twenty states, of which sixty-eight teams from eighteen states actually participated; in the mine rescue contests twenty-one teams from ten states entered, and seventeen teams from ten states actually competed.

First place in the first-aid contest went to the New River Company, Scarbro, W. Va., with Louis Roncaglione as captain, thus winning the silver cup donated by the National Safety Council, the silver cup donated by *Coal Age*, and still a third silver cup donated by the Coal Mining Institute of America, as well as numerous other prizes.

Second place in first aid work went to Team No. 1 (Captain James L. Bisch), St. Louis Rocky Mountain & Pacific Coal Co., Raton, N. Mex.; and third place to the DeBardeleben Coal Co., Sipsey, Ala., (Captain L. Shores).

First place in mine rescue work was won by the H. C. Frick Coal Co.'s team from its rescue station at Leisenring, Pa., (Captain S. Cominsky), taking a silver cup donated by *Coal Age*, a silver cup donated by the *Rocky Mountain News and Denver Times*, of Denver, a gold cup donated by *Coal Industry* of Pittsburgh, Pa., and several other prizes.

Second place in the mine rescue contests was won by the Wadge team of the Victor-American Fuel Co., Routt County, Col., (Robert Halbert, captain); and third place by the Homestake Mining Co., Lead, S. Dak., (L. B. Wright, captain).

Copyright by Underwood & Underwood

FRONT OF U. S. ASSAY OFFICE, WALL ST., NEW YORK, DAMAGED BY BOMB EXPLOSION OF SEPT. 16

The best combination standing of any team performing both first aid and mine rescue was made by the team from the Wadge mine (Robert Halbert, captain), of the Victor-American Fuel Co., Routt County, Col.

The silver cup donated by the Ironton Engine Co. for the best rating in first aid for teams from Rocky Mountain states (Colorado, New Mexico, Arizona, Utah, Wyoming, Montana, Idaho, North and South Dakota), was won by the St. Louis Rocky Mountain and Pacific Team No. 1 of Raton, N. Mex., (J. L. Bisch, captain).

Mining Association Discusses Ousting of Golden Station

More Space Needed for Students, Says Skinner, in Addressing Members—Committee Named To Assist Trustees

The action of the trustees of the Colorado School of Mines in refusing to extend the lease of the U. S. Bureau of Mines on the Engineering building at Golden, Col., which resulted in the removal of the Federal station from Colorado, came up for discussion at the meeting of the Colorado Metal Mining Association which concluded its session in Denver, Sept. 13.

Louis F. Skinner, president of the board of trustees of the School of Mines, addressed the meeting and stated that the action of the trustees in refusing to renew the lease was based upon the pressing requirements of the school for more room for the students. He stated that the attendance was increasing from year to year and that already they were crowded for suitable class rooms, and that with the increased attendance this year it was imperative that additional accommodations be provided. Other phases of the administration of the school were discussed at considerable length.

A committee was appointed consisting of Bulkeley Wells, of Telluride, George M. Taylor, of Colorado Springs, and three other members, to be appointed by the president of the Metal Mining Association, which was instructed to consult with the governor and trustees of the School of Mines and to tender to them the good offices of the Association in the upbuilding of the institution. The committee was instructed to make its investigations and report at the annual meeting of the Association which will be held early in January.

It is reported that samples of iron ore from a field near Onundar Fjordr, in the west of Iceland, which have been sent to Sweden for analysis, have been found to contain 70 per cent of iron of unusually good quality. A company is to be formed to carry on mining operations.

U. S. Assay Office Exterior Damaged in Wall Street Explosion

Powerful Bomb Kills Thirty-five at Noon Hour in Heart of Financial District

On Sept. 16, at three minutes after noon, when the financial district of New York was at its worst period of congestion, a bomb of great power exploded at Wall and Broad Streets, in front of the new building of the United States Assay Office and directly opposite the J. P. Morgan Building. Thirty-five people were killed and 200 to 300 injured. The remains of a horse and fragments of a truck point to the fact that the explosive was conveyed to the district by these means. Nothing has thus far been learned as to the perpetrators of the crime but that it is a Red outrage seems unquestionably accepted.

The Assay Office and the Morgan Building were badly damaged and many other buildings in the vicinity suffered heavily through broken windows. No one in the employ of the Assay Office was killed. The stone façade of the building is badly pitted from the force of the explosion and the windows damaged as seen in the accompanying photograph.

It was likewise at noon, on July 1, a little over a year ago, when the district was similarly congested, that the cornerstone of the new Assay Office was laid with fitting ceremony, William G. McAdoo and Carter Glass, Secretary of the Treasury, taking part. Five of the building's eight stories are below the street level and three of them above.

Chemists Discuss Potash Problems

At the recent meetings of the American Chemical Society at Chicago several important reports were presented by the division of fertilizer chemistry. Potash problems were discussed by two speakers. S. W. Parr, of the University of Illinois, described several potash shales of Illinois which were recommended as suitable for cement manufacture with potash by-product recovery. These shales having more than 5 per cent of K_2O would yield, if properly handled, over 5 lb. of potash per barrel of cement, equivalent to 70 or 80c. per barrel of by-product income.

H. A. Huston who has investigated the potash situation in Germany personally gave a full report on the situation. He says a complicated organization has resulted from the socialization of the industry. Labor is available in sufficient quantity but is very high. Transportation is difficult and very expensive. The fuel supply is short and costs are very high. This fuel situation has been particularly aggravated by the interruption of Silesian coal supplies by the fighting between the Poles and Reds. Incidentally the shortage of fuel has also resulted in the shortage of ammonium sulphate for fertilizer use.

The claim that discrimination had been made against the United States

purchasers of potash is believed contrary to the fact by Mr. Huston. He states that contrary to general belief there were no large stocks of potash available either at the end of 1918 nor at any time since then. There were certain portions of production reserved for the United States purchasers through the arrangement of the inter-allied agents who controlled these matters. However these agents were notified by someone that the United States did not need these supplies. They were, therefore, quickly disposed of elsewhere. As a consequence when purchasers from this country attempted to secure potash there was none available except at excessive prices. This has naturally led to the conclusion that the American purchaser was being discriminated against. Mr. Huston states, however, that the American purchaser has at all times been able to purchase as favorably as others who are in the market at the same time.

Special London Letter

By W. A. Doman

London, Sept. 7—Embracing as it does world wide interests in mining, it is rather surprising that the department of the London Stock Exchange in which dealings in mining shares take place has remained so long neglected. In the main, of course, this is due to the fact that finance houses and speculative jobbers of the old-fashioned school are afraid to give a lead. The public would come along with support if it were convinced that any movement would continue, but after the experience of so many false starts, it has naturally become shy. Of course, partaking of a speculative character mining shares do not appeal to investors as a whole, despite the handsome dividends paid by many companies and the substantial profits that are made on dealing. Labor troubles have created a good deal of nervousness, and mining securities naturally feel the influence at once; they are the first to fall, and not always the earliest to recover. Whether we look at gold, silver, diamond, lead or tin descriptions conditions are to a certain extent the same, though causes are not in each case of an identical nature. Just at the moment there seems to be a rift in the labor clouds, and as the gold producing companies continue to realize a substantial premium upon their output the public is turning its attention to Kaffir shares again. Unfortunately, while the position of these companies has improved to a very remarkable extent in consequence of the gold premium, some mines being enabled to convert a loss into a surplus, it is not possible to make an effective comparison of outputs to-day with those of previous years.

Formerly the Rand production was given in fine ounces; now results look better in pounds sterling. It is regrettable from a statistical and comparative point of view, seeing that the Rand is the world's greatest goldfield. Output and profits are calculated upon gold at a certain price, though it is not clear that this price is the one at which the metal will be actually sold. It may be mentioned that this year the estimated price per oz. has been: January, £5. 7s. 6d.; February, £5. 10s.; March, £5. 5s.; April, £5. 2s. 6d.; May, £5. 5s.; June, £5. 2s. 6d.; July, £5. 5s.; August, £5. 12s. 6d. The New Modderfontein is still the world's premier producer and for August had an estimated working profit of £152,000 as compared with £135,000 in July. Similarly Government Areas report £140,000, or £6,000 more, and City Deep £73,000 for last month, an increase of £20,000. Prices of Kaffirs generally seem to be on the up grade again without much sign of activity. The influence of the gold premium can be seen in another way. The Globe and Phoenix, formerly the premier mine of Rhodesia, but now approaching its end unless additional orebodies can be discovered, has just declared a dividend of 1s. per share out of gold premium.

Diamond shares are affected by erratic movements in exchanges in the same way as certain Kaffirs shares in which free dealings take place on the Continent. De Beers Deferred are down to £19, purely on exchanges. The diamond trade has ruled quiet for some weeks, partly owing to over-speculation and partly owing to exchange vagaries. The intrinsic position, however, is perfectly sound. The Diamond Syndicate has outlined a policy from which they will not deviate; consequently, whether people buy diamonds now or later there will be no cheapening per carat. The tin world is still smarting from what is regarded as bad treatment on the part of the British government when dealing with the United States during the war, and fears are entertained that at present prices many Cornish mines cannot be profitably worked. Efforts are being made between Nigerian, Cornish, Far Eastern and Dutch interests to stabilize the price of tin.

National Mining Corporation shares were quoted during the week at *nil* to 1s. owing to a further call of 5s., making the shares 10s. paid. The Corporation is sound enough and exceptionally well managed, but has to develop its interests, the latest of which is a participation of 25,000 shares in British Equatorial Oil Corporation with a capital of £200,000 in £1 shares.

Although Utah is not a zinc producer of importance, its position as one of the far-western states producing this metal makes the recent rise in freight rates of importance particularly to small producers here, who for the most part ship to Kansas and Oklahoma. The Judge Mining & Smelting Co., of Park City is the largest producer of zinc in Utah treating its zinc ores, which are sulphide in its own electrolytic plant, but taking no custom ores.

Salt Lake Convention Discusses Mine Taxation

Committee's Report Presented by R. C. Allen—Paper Read by Paul Armitage

The National Tax Association, which began its annual convention in Salt Lake City on Sept. 6, held its closing meeting, consisting of a short business session at which officers were elected, on the evening of Sept. 10. Zenas W. Bliss, formerly governor of Rhode Island, and now chairman of the state board of tax commissioners of Rhode Island, was chosen president of the association, being succeeded as vice-president by Samuel Lord, of Minnesota. A. E. Holcomb was re-elected secretary and treasurer. William Bailey, secretary of the Utah board of equalization, was appointed a member of the committee on a model tax system, of which Prof. Chas. J. Bullock of Harvard is chairman.

The closing day was occupied with the subject of mine taxation, and the speeches were of especial interest in this community where mining is the chief industry. R. C. Allen, vice-president of the Lake Superior Iron Ore Association and chairman of the especial committee on mine taxation, presented the report of the committee, which was unanimous, being in favor of an *ad valorem* system of valuation of mines, it being held that such a method of valuation, although not easy to arrive at, was entirely practicable. Mines, it was stated, should be taxed according to the same system as other property, and not according to some system of multiple taxation, the actual value of a mine to be arrived at by taking into consideration all of the data available, including income.

A paper by Paul Armitage, attorney, and director of the United Verde Extension and a former chairman of the mine tax committee of the American Mining Congress, was read entitled "Income as a Factor in Mine Taxation," which discussed the various problems in determining what a mine's income really is. Stock prices were held to be deceptive, and the ability of an expert to fix valuation was strongly called into question, it being laid down that "the final and determinative factor in all mine taxation is the income received, and in using this for mine taxation, the principle that the base of all systems must be broad, not narrow, requires that the entire income, past, present, and future, be taken into consideration."

The Guyana Gold Placer Co., on whose estates in Suriname, Dutch Guiana, extensive iron-ore deposits are said to have been discovered at the Donderbariberg, now announces that manganese ore has been found in two places in the same field, accompanying ore in quartz veins. The ore occurs in the veins as a thin layer or as an irregular string between the quartz.

Gold Dredging Started at Dayton, Nev.

Operations of Gold Canyon Dredging Co. Begun With 9-Cu.Ft. Bucket Dredge on Alluvial Deposit — Governor's Wife Throws Switch in Presence of Two Thousand Onlookers

By George J. Young

About seventy years ago, prospectors and miners traveled on foot and packed their meager equipment upon horses. They scratched the surface and made their important discoveries but there were definite limits beyond which they could not go. On Sunday, Sept. 5, over three hundred "machines" brought over 2,000 people to a flat area just south of Silver City, Nev., near where the early miners had washed all the gold they could from the alluvial material filling the canyons and then had gone to other fields. The speed and promptness with which this assemblage was brought together reminds one of the way that Mark Twain brought his celestial audience together in describing Captain Eli Stormfield's adventures in heaven.

William Prouse is said to have been washing a milk can in the creek near Dayton when he discovered glistening particles of gold in 1850. He must have worn the conventional miner's costume of the period, which was very unconventional. If 2,000 miners of Prouse's time could have been assembled alongside of the 2,000 or more who patiently waited for the switch to be thrown that started the newly constructed dredge of the Gold Canyon Dredging Co., there would have been perhaps some mutual embarrassment, but on the whole there would have been two greatly astonished and amused groups of people. The group there on Sunday were dressed in their best. There were ladies present and silk gowns and smart hats. Only the legerdemain of modern times could have assembled such an audience in such a place. There was the same blue, cloudless sky, the bright sunshine, the brown hills thinly covered with silver-gray sagebrush that William Prouse looked upon in moments free from milk-can washing and gravel sluicing. The dredge occupied the center of the picture. It floated in a small pond at the head of an alluvial plain which sloped towards the distant Carson River. People swarmed all over it and walked around the pond. Throughout the excitement the 900-ton dredge maintained its equilibrium and waved its American flag.

After the public inspection the gangplank of the dredge was drawn up and used as a speaker's platform. R. H. Elliott, assistant general manager, represented Bulkeley Wells and was master of ceremonies, being assisted by Gerald H. Hutton, engineer in charge of the dredge construction and operation. Edwin Higgins, staff engineer of the Metals Exploration Co., was the first speaker. He gave a brief sketch of the historical development of gold dredging and explained the operation of the dredge, also giving a brief summary of the features of the dredge which will be found in the last paragraph of this article. In concluding Mr. Higgins said:

"The men behind this organization are good sports. Their policy is human treatment of their men. The latest safety devices will protect the workers. This is a record job, completed in about four months of actual work. The conditions remind me of a stiff grade of a certain railroad in Arizona where to an old-timer listening to the laboring engines trying to make the grade the pistons seemed to say, 'It can't be done—it can't be done,' but when the moguls came along puffing upgrade the pistons sang, 'It's got to be done—it's got to be done,' and in a little while they would go over the top snorting, 'I knew I could do it—I knew I could do it.'"

President Clark of the Nevada State University, the next speaker, spoke of the mining industry of Nevada and of the advance made in mining engineering in relation to the University. Dr. Aurelia Rhinehart, president of Mills College, captivated the audience by a witty address in which, among other things, she pointed out that women had a considerable interest in an enterprise like gold dredging because the greater part of the gold of the country is spent by women. Governor Emmet D. Boyle concluded the addresses by describing the part played by the engineer in developing natural resources and making the production of metals a profitable business. He pointed out the relation of both capital and labor in initiating enterprise.

Dredge Started by Mrs. Emmet D. Boyle

The dredge crew, as soon as the speakers were out of the way, went to their stations and Mrs. Emmet D. Boyle started the dredge in operation. The people swarmed around and took even greater interest in watching the wheels go around than they did in getting acquainted with the motionless machine before. The dredge crew had a hard task to keep the enthusiastic spectators out of the machinery, but everything went well and afterwards all departed homewards in clouds of dust and the roar of many machines, happy in the thought that they had participated in the historic event.

The dredge was constructed by the Bethlehem Shipbuilding Corporation, the dredging department of which corporation is managed by George L. Hurst. The hull is 108 ft. long, 52 ft. wide and 8 ft. deep. It is built of steel, the main deck being of welded steel plates $\frac{5}{16}$ in. thick. The well-hole plates are $\frac{1}{2}$ in. thick, and extend through the length of the dredge, giving great stiffness to the hull. All of the framing of the superstructure is steel. The digging ladder weighs 55 tons and is equipped with 9 cu.ft. manganese steel buckets, each weighing 2,500 lb. The speed is 20 buckets per min. The steel spuds are 55 ft. long, are built of steel I beams and weigh 20 tons each. The buckets discharge into a receiving hopper and this in turn to the revolving screen 6 ft. in diameter by 38 ft. long, revolving at 15 r.p.m. and provided with $\frac{3}{4}$-in. round holes. The stacker is equipped with a 34-in. conveyor belt, 120 ft. long. The stacking height is 30 ft., the digging depth 40 ft. and the arc of swing 175 ft. approximately. The sluice and riffle area is 3,000 sq.ft. The principal water supply is provided by a 10-in. centrifugal pump, the pressure water being under an 80-ft. head. The electric motors aggregate 500 hp. and work at 440 volts. The power line receives current at 22,000 v. from the line of the Truckee River General Electric Co. This voltage is stepped down to 4,400 and then to 440 volts. The total weight of the dredge is 900 tons. The material for it was transported to the building site by motor trucks from Dayton and erected in about four months working time. Its capacity is 5,000 cu.ft. per day. The proved dredging area is 200 acres with the possibility of further extension. It is expected that five years operation is assured. The investment is reported to be approximately $350,000.

Colorado Operators Want Old Rate on Low-Grade Ores and Concentrates

Meet Traffic Agents of Ore-Carrying Roads—Industry in State in Critical Condition, It is Claimed

At the request of the Colorado Metal Mining Association, a joint meeting of the traffic agents of railroads serving Colorado metal mining districts convened with mine operators in Denver, Sept. 13, to consider conditions brought about by the recent increase in freight rates, as authorized by the Interstate Commerce Commission.

Colorado operators assert that this increase, if maintained, will result in the closing down of at least 50 per cent of the mines now operating. The increase means an average boost in production costs of smelting grades of ore of more than $1 per ton, in addition to the 50c. advance in smelting charges announced by the smelters. On concentrates the advance in many instances absorbs the small margin of profit in milling the lower grades of ore, and several of the largest milling plants in the state, according to the management, will close down unless relief is afforded.

Operators assert that the metal mining industry in Colorado is in a critical condition and that the old freight rates were, in many instances, more than the industry could bear and that the present increase means absolute disaster. They contend that the increase in rates

will not only fail to increase the revenue of the railroads but will actually reduce receipts, as there will be much less ore to handle and a corresponding decrease in incoming freight to mining camps. They ask that the old rate be restored on low-grade ores and concentrates.

They point to the fact that during the first half of 1919 the smelters treated 194,031 tons of ore and concentrates as against 152,496 tons for the first half of 1920, and assert that any further increase in operating costs will result in a much larger falling off of production for the last half of 1920.

At the meeting, the foundation was laid for an appeal to the Interstate Commerce Commission for a readjustment of rates on interstate shipments. The 35 per cent increase in these rates has stopped all shipments of manganese ores from Colorado as well as absorbed practically all profit in producing zinc bearing ores or concentrates. The advance in bullion rates also seriously affects the industry and a determined effort will be made, in co-operation with the shippers in other mining states, to secure a readjustment of bullion rates.

At the conclusion of the hearing, the carriers announced that the appeal of the shippers would be taken under advisement and that a decision would be announced within a very short time. It is believed that very substantial relief will be granted.

Recent Production Reports

Cie. du Boleo, Santa Rosalia, Baja California, produced 618,390 lb. copper in August against 781,613 in July.

Government Smelter for Alaska Not Favored

Present Situation Being Studied by Survey and Bureau of Mines—Anyox Plant a Factor

There is an insistent demand in Alaska for a Government smelter. Although officials in Washington are lending no encouragement to the idea of the Government entering the smelting business they are receiving the plea sympathetically as they recognize it as the outgrowth of a very unsatisfactory situation in the territory. Since they do not favor a Government smelter they they hope to be able to offer some constructive alternative suggestion.

The most thorough study that ever has been made of the smelter situation in Alaska is now in progress. The work is being done by A. H. Brooks, of the U. S. Geological Survey, and O. C. Ralston, of the U. S. Bureau of Mines. Among other things they will report as to whether or not the policies of larger interests in Alaska handicap in any way the smelting of ores of the smaller producers. There is a custom smelter at Anyox, B. C., just below the Alaskan boundary. It is on tidewater and apparently is well adapted to the handling of Alaska ores. The smelter is not being operated to capacity. That situation also is to be reported on.

Anaconda To Start Making Fertilizer Soon

The Anaconda Copper Mining Co., the Bureau of Mines is informed, expects to begin quantitative production of a super-phosphate fertilizer in the near future. The company intends to enter actively into competition for a fertilizer market in the middle west. By manufacturing a fertilizer containing 48 per cent of the available phosphoric acid, the company's engineers are of the opinion that the high transportation charge can be absorbed and still be able to compete with the eastern-made fertilizers, most of which contain 16 per cent of available phosphoric acid.

Complex Ores of Nevada Studied by Bureau of Mines

Experimenting on Yellow Pine Ores Since February—Also on Ruby Hill Ores

In view of statements to the effect that research on the complex and oxidized ores of Nevada is being neglected the U. S. Bureau of Mines calls attention to the work which is now in progress on these ores. Experiments are being conducted on two kinds of ores which are being obtained from Goodsprings and Eureka, Nev., respectively. The work on the Goodsprings ore has been in progress for a year. Several months will elapse before a final report can be made on that work. It can be said, however, that the work is being conducted under a co-operative agreement with the Yellow Pine Mining Co. The ores contain approximately 5 per cent lead, 5 oz. of silver and 38 per cent zinc. The lead and silver content of the 1,500 to 1,800 tons that is shipped monthly is being lost. The object of the experiments has been to volatilize the lead and silver from the zinc and to raise the grade of zinc. Thus far in the experiments it has been possible to recover in excess of 90 per cent of the silver and lead with a small zinc loss.

The work has been in progress almost continually since February. Tests are being conducted in a fifty-foot kiln. The experiments have been sufficiently encouraging to the company so that it is anxious to put in a commercial plant to carry on the method of treatment.

Work on the ores containing gold, silver, lead and copper, mostly of the oxidized variety, has been in progress for six months. This work has been in co-operation with the Ruby Hill Development Co. High extractions have been obtained from the methods employed in these experiments. Some of the work has been done on a large scale. One of the more recent tests was run on a 3,000 lb. lot. The results obtained from such tests are more to be relied upon.

Arizona Smoke Farmers Appeal to Bureau of Mines

Latter Willing To Co-operate Where Both Parties to Dispute Request It

Vigorous claims are being made by farmers in the Verde Valley in Arizona that their crops are being damaged by smelter smoke. The U. S. Bureau of Mines has been requested to advise how relief can be obtained. In reply, Dr. F. G. Cottrell, the director of the Bureau, has explained that his Bureau has no authority to take the initiative in smelter smoke cases, but that it has co-operated in technical investigations on smelter smoke difficulties where each party to the controversy requests the Bureau's co-operation. Attention was called to the fact that since crop damage is caused largely by sulphur dioxide (compared wih other gases), which is not recoverable by electrical precipitation or baghouse installations, the only effective solution is the use of the sulphur dioxide in the manufacture of sulphur acid, as is being done at Copper Hill, Tenn., by the Tennessee Copper Co. It was pointed out that this is not feasible unless the sulphuric acid can be utilized. It cannot be discharged on the ground or in the streams, even if the companies would stand the expense of its manufacture without having a market for the product. Very high stacks also may decrease the smoke nuisance.

Products of mines to the extent of 143,323,954 tons were carried on the Class 1 railroads for the three months ended March 31, 1920. Class 1 roads are those having annual operating revenues above $1,000,000. Bituminous coal occupied first place with 90,600,000 tons, in round figures. Anthracite coal ranked next with 17,300,000 tons. Clay, gravels, sand and stone, which are classed together, came next with a total of 15,700,000 tons. Iron ore furnished 3,200,000 tons of revenue producing freight while all other ores and concentrates produced practically the same tonnage. Base bullion and matte provided 195,000 tons of freight.

NEWS BY MINING DISTRICTS

MEXICO

Big Increase in Mine Taxes Collected Expected This Year

Mexico City—The secretary of the department of commerce and labor of Mexico has recently issued some interesting figures on the mining and metal industry of the Republic. According to his statement, there are 60,569 mining claims now under title of which less than half, or 30,990, are in arrears with their taxes and subject to default. Of these properties 3,868 are actually being worked at this time.

The government collected from direct taxes on mines last year only 1,891,467.66 pesos due to the fact that conditions throughout the country kept most of the mine owners either out of the country or away from their properties. A big increase will be shown for this year. Aside from the direct *pertenencia* (claim) tax, the government got 11,988,329.22 pesos out of the miners as a metal tax, which income will likewise be greatly swelled for the year 1920.

Of the sixty odd thousand mining properties now on the books only 2,017 date further back than 1892.

The Alvarado Mining & Milling Co., operating in the Parral district, Chihuahua, has asked for *amparo* in the suit which has been pending for sometime over the Elvira claim, which was denounced sometime ago and patent issued by the secretary of commerce and Industry. The Alvarado people claim the Elvira as one of their properties of long standing. In a previous denouncement, the Alvarado people won their suit but a second time the matter has come up and the parties contesting the title of the Alvarado company have begun to drive a tunnel into the Elvira, backed by a specific permit from the mining authorities at Mexico City. A suspension has been granted by the local courts and work on the disputed property must be held up until the ownership is definitely decided.

CANADA

British Columbia

Litigation Over Molybdenum Properties at Alice Arm Before Victoria Court

Victoria—There is now before the Supreme Court, Victoria, B. C., an action involving title to molybdenum properties of Alice Arm, B. C. The suit is brought by Robert M. Stewart, manager of the Stewart Land Co., of Victoria, and the defendants are the Molybdenum Mining Co. H. A. McLean, counsel for the latter, in his summing up of the situation, explained that the purpose practically was to obtain judgment as to the ownership of the property.

Stewart—It is reported that the present bondholders of the Big Missouri Group, Salmon River, Portland Canal district, do not intend to continue development work. Operations have been under way for some time by a syndicate known as the Pacific Coast Exploration Co. prominently identified with which is Sir Donald Mann, of Toronto, Ont. Both diamond drills with which exploration work has been in progress have been withdrawn. The only information made public, and it is unofficial, is that the Big Missouri presents an unusual problem, that the small amount of drilling done has not given satisfactory results, and that the complete exploration of the entire mineralized zone is a work of such magnitude that the company does not feel disposed at present to continue.

Alice Arm—There now are 230 men employed at the Dolly Varden mine, on the Kitsault River, and the output of ore for July totalled 5,600 tons, all of which was sent to Anyox. In addition a quantity of high-grade ore was forwarded direct to the Tacoma smelter. The force indicated has been divided during the summer equally between the mine and the railroad and if the snow of the coming winter makes the continued operation of the railway impossible, only about 65 men will be kept on, and that on development work. At present power for the air compressors is secured from oil engines but a hydro-electric plant is being installed on the Wolf claims which will be used for all purposes. It will be capable of providing 500-hp. for operating a 12-drill compressor. The Wolf, which is situated three miles up the river from the Dolly Varden, is reported to have given gratifying indications in diamond drilling, and tunnelling is to be started without delay.

Trail—Ore shipments received at the Consolidated smelter during the week ended Sept. 7 totaled 7,718 tons, from the following shippers:

Mine	Location	Gross Tons
Emerald, Salmo		45
Josie, Rossland		170
Mandy, The Pas		371
North Star, Kimberley		125
Nettie L., Gerrard		18
Payne, Sandon		9
Taltapin, Taltapin		4
Velvet, Velvet		27
Company mines		6,949

Yukon Territory

Dawson—The placer camps of the Yukon Valley, it is estimated, will yield $4,485,000 for the season of 1920. Practically every camp in the North suffered a heavy decline for the reason that it has been a very dry season. Hydraulic operations consequently have been much curtailed. Yields by camps of the interior of Alaska and the Yukon for the season drawing to a close are estimated by competent authorities as follows: Dawson, $1,500,000; Fairbanks, $750,000; Tolovana, $750,000; Iditarod, $500,000; Tacotna and Ophir, $500,000; Hot Springs, $100,000; Ruby, $100,000; Koyukuk, $75,000; Circle, $70,000; Marshall, $50,000; Forty Mile, $50,000; Rampart, $20,000; Chandler, $20,000. Total, $4,485,000. In commenting on the situation thus disclosed, the Dawson *Daily News* observes that if the decline in gold production is to be arrested, it will be necessary to restore the purchasing power of gold by bonus or otherwise as low grade alluvial gravel cannot be worked under present conditions.

Ontario

Labor More Abundant—Excavation for Ontario-Kirkland Mill Started

Labor conditions in the Northern Ontario mining camps are beginning to improve. During the summer many laborers were attracted by the high wages paid by the automobile manufacturers in Detroit and Windsor, and later on the call of the West for harvesters was answered by many employed in the mines. The latter are returning in considerable numbers and the dullness in the automobile industry has resulted in a movement back to the mines, which is likely to increase very shortly. Many Italians, who left as soon as the war was over, are said to have written asking for jobs and a large influx from that country is anticipated.

Kirkland Lake—Excavating for the new 100-ton mill of the Ontario Kirkland has been started. The heavy equipment will be brought in over the winter roads for installation early in the spring.

The Lake Shore main shaft is being sunk to 800 ft. and conditions on the property are very satisfactory.

The final payment on the Murray Mogridge property has been met, and title to the property is now vested in the company. It is expected that extensive development work will be done.

The Thackery Mines have recently acquired two new properties, a gold prospect in the township of Lebel, and a silver prospect in Elk Lake.

Cobalt—The McDonald Syndicate, which has a lease on the Ruby Silver Mines, is making regular shipments of high-grade mill rock to the mining corporation.

Porcupine—The 84 vein of the Hollinger has been caught on the McIntyre by diamond drills below the 1,000-ft. level. This vein system is one of the most important on the Hollinger and will mean a great deal to the McIntyre. The values as shown by the drills are higher than the average of McIntyre ore.

ALASKA

Water Shortage in Interior Curtails Placer Output

Seattle—The production of placer gold in the interior camps of Alaska has been curtailed by the shortage of water with which to carry on sluicing operations, according to Volney Richmond, general manager of the Northern Commercial Co., who has just completed an inspection tour of the interior. This condition has been brought about by the unusually light precipitation. Dredges operated this season in the Iditarod, Ophir-Tacotna and Fairbanks districts but the Berry dredges in the Circle district have been shut down all season. In the Kantishna two big hydraulic plants have been installed, one by the Mount McKinley Gold Placers Co. and another by Fairbanks capital. Mr. Richmond estimated the total gold production for interior Alaska this year at $2,985,000, and the total for Dawson district at $1,500,000.

Considerable activity in lode mining is anticipated for the winter months. The Alaska Endicott Mining Co. will carry on active development work at their Windham Bay property according to Charles W. Mason, president, who has just returned to Seattle from a tour of inspection. Mr. Mason states that 3,000 ft. of development work has been completed to date and a five-stamp mill is now running on the tailings. The company expect to finish 4,500 ft. of pipe line and also a tram line to connect the mine and mill. Machinery for a 30-stamp mill is now on the ground and will be erected in the spring.

The Crystal Group at Snettisham are operating a five-stamp mill. The Chichagof Mining Co. is preparing to install a stamp mill on the Lisianski Group next spring. A considerable amount of underground development work has been completed on this property. The Admiralty Gold Mining Co. in the Funter Bay section has also been carrying on development work during the summer months.

CALIFORNIA

New Walker Tramway in Commission —New Level Opened by Plymouth Con

Portola—The Walker Copper Co., a subsidiary of Anaconda, has completed the aerial tramway to Spring Garden and is using it to ship its concentrates to the railroad station. The tramway eliminates the motor trucks formerly used.

The Gruss copper mine has developed several new and important orebodies and the management reports that in the next few months the mine will be firmly placed on a dividend paying basis. The mill continues to work on ore formerly blocked out. Assays of concentrates two weeks ago assayed as high as $250, with none lower than $232 per ton.

Sutter Creek—The South Eureka has installed additional pumping equipment and other improvements have been made by the Central Eureka company. Under an agreement made several months ago the Central Eureka is keeping both its own mine and the South Eureka free from water. Lack of electric power is hampering operation of the pumps and the mill is limited to half its capacity every sixteen hours of each day.

Plymouth—Profitable operations continue at the Plymouth Consolidated, near Plymouth, and at the Carson Hill, at Melones, according to the report recently made by the Loring Syndicate. A new level has just been opened in the Plymouth and the extension of the orebody uncovered. The Carson Hill group is now yielding excellent ore.

Oroville—The Cherokee hydraulic mine, in the Table Mountain district, plans to resume operations. The Cherokee formerly ranked among the largest hydraulic gold producers in California and under the new management a series of crosscuts will be driven to reach the channel believed to run under Table Mountain.

MILL AND TAILINGS POND AT ANACONDA COPPER MINING CO.'S WALKER MINE, PORTOLA, CAL. TRAMWAY TO UPPER MINE IS SEEN IN CENTER. SNOW SHED ON RIGHT BEYOND MILL LEADS TO LOWER TUNNEL.

NEVADA

Comstock Miners Get Wage Advance— Machinery Company Sues Gold Pen Mines Co.

Rand—The Western Machinery & Engineering Co., of Reno, has started suit against the Gold Pen Mines Co., alleging that machinery bought is not paid for.

Virginia City—The 250-hp. electric hoist which the Goldfield Consolidated had at its Clermont shaft has been bought by the Con. Virginia to replace its steam hoist. The Con. Virginia and the other Comstock mines under Alex Wise have met the demands of the miners for a $6 per day wage.

Tonopah—The latest bullion shipments from the Tonopah district, representing about fifteen days operations in the Tonopah Belmont and West End mines were $86,000 and $60,000 respectively. Regular development and production at the principal mines are reported with no important changes. Construction work at the Belmont milling plant in Millers is progressing, the plant being remodeled to treat the accumulated tailings at that point. In the North Star mine a discovery of promise has been made on the 1,050 level which may be the downward continuation of the rich orebody discovered on the 950 level in 1912. The ore was worked both below and above the 950 level but became low grade on the 1,050 where worked. The vein at present shows a width of 5 ft., all of which i ore of excellent grade.

Divide—In the Tonopah Divide mine good progress is being made in cutting the station on the 1,000 level preparatory to crosscutting. Values and widths are holding out well in develop ment faces on the upper levels and the future appears bright. The Gold Zone and Brougher Divide both report continued development in ore of milling grade. The management of the East Divide and Alto Divide have announced that operations will be resumed at once.

Broken Hills—Official announcement from the Broken Hills mine states that the shaft at 225 ft. depth shows the vein to be 8 ft. wide and to contain ore of good grade. The vein in the south drift on the 150 level is 4 ft. wide and the ore of good grade, two feet averaging over $100 per ton. On the 80-ft level the east drift on the Belmont veir shows two feet of high-grade ore.

Pioche—All ore shipments from the Pioche district are billed on the increased freight rate schedule which went into effect on Aug. 26. The shipments for the week ended Sept. 9 were as follows: Prince Consolidated, 1,950 tons; Virginia Louis, 350 tons; Bristol Silver Mines, 150 tons; Black Metals, 150 tons; Combined Metals, 100 tons; Ida May, 40 tons; total, 2,740 tons.

The Bristol Silver Mines Co. operating the Tempest, Hillside, Gypsy, May Day, Great Eastern and National Territory, are producing a large tonnage of silver-lead-copper ore, this ore being carried over Bristol Mountain by aerial tramway to the terminal bins at the Jackrabbit, whence it passes over the Pioche Pacific Ry., a distance of fourteen miles, to connect with the Salt Lake Route at Pioche.

Last month over 1,000 tons of ore was shipped to the Salt Lake smelters. The average analysis of this tonnage was 0.02 oz. gold; 23.2 oz. silver; 12.5 per cent lead; 3.3 per cent copper; 6.7 per cent zinc; 10.5 per cent iron; 23.5 per cent insoluble; 1.7 per cent manganese; 10.2 per cent lime, and 1 per cent sulphur, making a most desirable smelting product and bringing a handsome profit to the company.

This ore is being mined principally from the Lloyd Bent winze, which is situated about 200 ft. in a southerly direction from the Gypsy shaft, and about 800 ft. from the surface. The Lloyd-Bent winze was originally sunk to develop the Gypsy ore shoot, the famous orebody from which W. M. Christian, John R. Cook and the late William Lloyd took out a small fortune during their short lease in 1905.

At a later period the Uvada Copper Co. followed the ore down and made a satisfactory production from this section of the mine. At the time when the Bristol company started operations, examination disclosed the presence of good ore in the bottom of this winze, and since then the winze has been sunk to a point 800 ft. from the surface. At this depth a station has been cut and laterals will be run to prove up the extent of the orebody. The ore is soft and easily mined.

The management plans, in the near future, to improve the accommodations at the mine, and the boarding house will be enlarged and renovated. Twenty-five men are at present employed and it now seems certain that the former wonderful production by the Bristol mines will be materially added to in the future.

ARIZONA

Tax Commission Cuts Valuation of Forty-three Producers—Swansea Again Running

Phoenix—Mining circles are stirred at present by the situation resulting from the suspension of assessment work requirements during the war. It is expected that many claims will lapse and that there will be much trouble over re-locations. During the last three years many claims have been located by prospectors and miners who have done practically no work, hoping to sell before the usual Governmental demands again might be enforced. Individuals are known to hold over 100 claims in a single name. Naturally, there can be no fulfillment of the assessment requirements in such cases. Another class, including men of means who really want to comply with the law, are now finding it almost impossible to get miners, or even laborers, to do the necessary work, even at wages higher than ordinarily paid.

The State Tax Commission has cut down by $25,000,000 the valuation of forty-three Arizona producing mines, not including reduction works. The gross assessment on producing mines has been dropped from $414,236,000 in 1919 to $329,030,000. This has been done in consideration of the fact that the mines are working at only 35 to 60 per cent of normal and upon the relatively low price of the output, much of it unsold at this time. United Verde's valuation has been dropped about $3,000,000, Extension about $2,000,000, Miami over $4,000,000, Inspiration, $8,000,000, New Cornelia, $4,000,000. Copper Queen was raised about $2,000,000, to $65,394,000, thus taking place as the mine of highest assessment, somewhat overtopping Inspiration, which has been leader in the last few years. Calumet & Arizona also was raised the same amount to $42,163,000.

Bouse—Swansea is again in operation, shipping fluxing ores to the Humboldt smelter at the rate of 70 tons a day. The property is under lease to the Consolidated Arizona Smelting Co. of Humboldt and is being operated largely by Mexican labor. The Clark lease latterly found little or no profit in operating the new mill.

NEW MEXICO

Lordsburg—Ore shipments from this district for August amounted to 79 cars or 4,369 tons, of an approximate value of $87,000. The bulk of this ore went to the C. & A. smelter at Douglas, Ariz.

UTAH

Park City—Shipments of ore and concentrates for the week ended Sept. 11 amounted to 1,722 tons: Silver King Coalition shipped 636 tons; Judge M. & S., 429; Ontario, 333; Daly West, 115; Daly, 111; Naildriver, 50; and J. B. Ireland, leasing on Scott Hill, 38. In general, operations at the camp are hampered by lack of labor.

Eureka—Tintic shipments for the week ended Sept. 10 amounted to 142 cars.

MONTANA

Anaconda and Davis-Daly in Dispute Over Promising Ore in Nettie Workings

Butte—A large body of silver-zinc ore has been opened in what are known as the Nettie workings, but under the surface of the Horseshoe claim, adjoining the Hibernia mine of the Davis-Daly. Anaconda is laying claim to the orebody. Davis-Daly is endeavoring to prove an apex. This orebody shows for a width of ten posts, all of milling grade with the exception of 30 ft. which is sulphide ore without any waste.

Several days time were lost recently at the Black Rock mine in consequence of an air explosion in the engine room.

WASHINGTON

Zinc Ore Discovered Near Northport Proves Interesting

Northport—During April, 1920, a deposit of smithsonite was uncovered on land owned by Gust Maki, a rancher, six miles east of Northport, Stevens County, Wash. It was purchased by John Gorien, of Minneapolis. By August, 1920, six cars of ore averaging 40 per cent zinc had been shipped to Wisconsin for treatment. The deposit, which occurs along a shear zone through limestone, has been explored for 90 ft. along the strike and 100 ft. vertically. The ore is crystallized zinc carbonates with only minor amounts of the sulphides so far present. The orebody will no doubt prove of limited size but it can be expected to develop a reasonably good tonnage of shipping ore. The property is situated in an active mining district but 100 ft. from a well travelled road. Its earlier discovery was prevented by the fact that the outcrop was masked by considerable hillside wash.

MICHIGAN

Gogebic Range

Ironton Mine's New Hoisting Plant in Operation

Bessemer—The new hoisting plant at the Winona shaft of the Ironton mine has been put into operation, but has not as yet been tested with full loads. The two Nordberg hoists each have two drums 10 ft. in dia. by 72 in. face clutched to the shaft, and have rope capacities of 4,500 ft. of 1⅛-in. rope wound in three layers. The cage hoist is driven by a 400-hp. induction motor with herringbone gears, and the ore hoist is direct-connected to a 1,650-hp. 525-volt d.c. motor with a rated speed of 80 r.p.m., which gives a rope speed of about 2,500 ft. per min. The flywheel-motor-generator set which carries the peak of the ore hoisting load runs at 514 to 505 r.p.m. So far the installation is giving satisfaction, but until the regular ropes come and the hoists are operated under full load and speed their real performance can not be determined.

Ironwood—Erection of towers on the Pabst-Davis-Puritan transmission line has been started. There will be over thirty steel towers in the line varying in height from 40 to 80 ft.

The Copper District

Calumet—The Seneca shaft has now reached a depth of 2,223 ft. and laterals have been driven 2,722 ft. from the 1st to the 4th levels. It is estimated that 361,000 tons of shipping rock is ready for mining. When the present development campaign is completed (about April 1, 1921) the shaft will have reached the 8th level at 2,640 ft. with a total of 7,961 ft. of lateral stope drifts from the 1st to the 6th level. The tonnage of rock that will be ready for stoping then is estimated at something over 1,100,000.

THE MARKET REPORT

Daily Prices of Metals in New York

Sept.	Copper Electrolytic	Tin 99 Per Cent	Tin Straits	Lead N Y	Lead St L	Zinc St L
16	18.10@18.35	42.25	44.75@45.00	8.30	8.00@8.40	7.65@7.70
17	17.95@18.35	42.25	44.50@44.75	8.15	8.00@8.25	7.65
18	17.95@18.35	42.25	44.75@45.00	8.00	7.75@8.25	7.65
20	17.95@18.35	42.50	44.75@45.00	7.90	7.75@8.25	7.65
21	17.95@18.35	42.00	44.00@44.50	7.85	7.50@8.25	7.65
22	17.95@18.35	41.75	44.00@44.25	7.75	7.50@8.10	7.65

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point. All prices are in cents per pound.

Copper is commonly sold on terms "delivered," which means that the seller pays the freight from refinery to buyer's destination. The delivery cost varies, and it would be confusing to figure net prices on individual transactions. Consequently, an average deduction of 0.15c. is made from the "delivered" price, to arrive at the New York price. When copper is sold f.o.b. or f.a.s. New York, of course no deduction is made.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Sept.	Copper Standard Spot	Copper Standard 3 M	Copper Electrolytic	Tin Spot	Tin 3 M	Lead Spot	Lead 3 M	Zinc Spot	Zinc 3 M
16	99½	99½	112	274⅜	279½	35	35	39½	40½
17	99⅛	98⅞	112	277	281½	35¾	35¾	39⅝	40⅜
18	....	....	....	....	....	....	....	....	....
20	98	98	112	275	279½	35½	35½	40	41½
21	97	97	112	272¾	278	35⅜	35½	40⅜	41⅜
22	97	97½	112	269¾	275½	34⅞	34⅞	40⅜	41⅜

The above table gives the closing quotations on the London Metal Exchange. All prices are in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Sept.	Sterling Exchange	Silver New York, Domestic Origin	Silver New York, Foreign Origin	Silver London	Sept	Sterling Exchange	Silver New York, Domestic Origin	Silver New York, Foreign Origin	Silver London
16	348	99½	94¾	60½	20	353	99½	94⅛	59⅞
17	350	99½	94	60	21	351	99½	94⅛	59⅞
18	352½	99½	93⅞	59½	22	347¾	99½	94	60

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. Loeden quotations are in pence per troy ounce of sterling silver, 925 fine.

On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States. This quotation is retroactive to May 13.

Metal Markets

New York, Sept. 22, 1920

No encouraging factors are yet evident in the major metal market. London prices continue depressed and with exchange in the neighborhood of $3.50 any effort to raise prices here is fruitless. It is doubtful that the current year will see any material advances in metal prices, even though the present figures are, in many cases, at or below the cost of production.

Copper

Prices continue to trend farther away from those at which the larger producing interests are willing to sell. At least one large lot of metal has been sold during the last few days under 18c. f.o.b. refinery. Demand is spotty and sporadic and no evidences of any general buying movement can be detected. Inquiries for even small quantities have been few.

The foreign demand shows no appreciable change. France and Germany seem to be waiting for the settling of the indemnity question, before making any definite commercial programs. England is upset by the imminence of labor troubles which holds business in check.

Demand for forward delivery is absent but copper could doubtless be secured at little or no advance over the figures which we quote, which represent September and October delivery.

Lead

Lead is definitely weaker; the foreign importations have had a decided effect. It is not generally understood to what extent English metal has been coming into this country. In the first twenty days of this month, 5,700 tons of pig lead came into this port alone, from London. Adding to this 1,550 tons from Mexico and 350 tons from other countries makes 7,600 tons, a not inconsiderable amount, especially under the present market conditions. Brokers are offering this imported lead at 7¾@8c. New York without finding any great number of takers.

Large lots of lead have been sold at bargain prices, a considerable tonnage being marketed at 7½c., New York, for delivery during the next three months. Demand for prompt metal has been largely satisfied, but a premium over later deliveries is still asked by most sellers; 7⅞@8c., New York, for prompt and 7½c. for forward delivery about represent what lead can be obtained for in the open market at present. Chemical lead is scarcer and a premium of ¼@½c. would be asked in most cases.

Zinc

Conditions are unchanged. Business is very dull indeed and the price seems fairly constant at current levels for all deliveries though the little demand that exists is for September or October. About 1,000 tons of European zinc is reported in the harbor here, the importers expecting to enter it duty free. There is little doubt, however, that they will have considerable difficulty in doing so. Domestic producers do not feel at all kindly about this imported metal, news of which came at a time when market conditions had just begun to improve.

Tin

Tin is very quiet and the market is irregular, with price changes of ⅛@¼c. for the same grade of metal on the same day. Indications are that certain dealers are under considerable pressure to sell. Electrolytic has been in fair demand for small lots at prices equal to, or ⅛@¼c. under, those for spot Straits.

Straits tin for future delivery: Sept 16th, 45.50@45.75c.; 17th, 45.75@46.00c.; 18th, 46.00@46.25c.; 20th, 45.25@45.50c.; 21st, 44.75@45.00c.; 22d, 44.75@45.00c.

Arrivals of tin in long tons: Sept. 13th, Penang, 225; 15th, Liverpool, 50; London, 25; 16th, Rotterdam, 25; London, 25; 18th, China, 20; Straits, 15; 20th, Singapore, 50; China, 175; London, 50; Liverpool, 50.

Silver

The silver market for the last week has been fairly steady, with business on a moderate scale only, owing to continued scarcity of offerings, and a not very keen demand for China account.

In the early part of the year, the Indian government prohibition against dealing with silver coin otherwise than as currency was cancelled, and the Indian traders are therefore again able to melt and use rupees in other form than coin. Exports of silver from San Francisco to the East, for the period Sept. 1 to 10 were 2,695,000 oz. Exports of silver from New York to London, for the period Aug. 21 to Sept. 1 were 243,170 oz.

Mexican Dollars—Sept. 16th, 71⅞; 17th, 71⅞; 18th, 71; 20th, 71⅞; 21st, 71⅞; and Sept. 22d, 71⅞.

Gold

Gold in London on Sept. 16th, 118s. 6d.; 17th to 22d incl., 117s. 6d.

Foreign Exchange

Sterling was firmer toward the end of last week but has reacted so that today's price is not far different from that obtaining a week ago. On Tuesday, Sept. 21st, francs were 6.63c.; lire, 4.32c.; and marks, 1.55c. New York funds in Montreal, 11 per cent premium.

Other Metals

Aluminum—For 50-ton lots: ingot, 99 per cent and purer, 35c.; 98@99 per cent, 34.8c. Virgin metal still obtainable in open market at about 32.5c. for 98@99 grade.

Antimony—Spot metal, 7¼c. per lb. Cookson's "C" grade, 12½@13c. Chinese and Japanese brands, 7@7½c. W. C. C. brand, 9@9½c. Chinese needle antimony, lump, firm at 7½@9c. per lb. Standard powdered needle antimony (200 mesh), 11½c. per lb. Market dull.

Bismuth—$2.55 per lb., 500-lb. lots, and $2.57 per lb., 100-lb. lots. Market quiet.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady.

Cobalt—Metal, $6 per lb.; black oxide, $4 per lb.; sulphate, $1.60. Market probably firm for some time.

Iridium—Nominal, $350@$400 per oz. Heavy demand, but small supplies.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb. for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]**Molybdenum** Metal in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.

Monel Metal—Shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$100@$110 per oz.

Platinum—Firm at $115 per oz.; $105 per oz. in 100 oz. lots.

Quicksilver—Market quiet; $75 per 75-lb. flask. San Francisco wires $75. Weak.

Ruthenium—$200@$220 per troy oz.

[1]**Selenium**—Black powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]**Thallium Metal**—Ingot, 99 per cent pure, $20 per lb.

[1]**Tungsten Metal**—$35@$60 per kilogram, according to purity and gage.

Metallic Ores

Bauxite—About 52 per cent alumina content, less than 2 per cent iron oxide, up to 20 per cent silica and artificially dried to contain not more than 4 per cent free moisture, $10 per gross ton at mine; 54 per cent alumina and about 15 per cent silica, $11; averaging 57 per cent alumina, 8 to 12 per cent silica, less than 3 per cent iron oxide, $13 on basis of 8 per cent free moisture. Ores of very low silica content suitable for the manufacture of aluminum oxide and hydrate of alumina command a fancy price.

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a maximum of 6 per cent silica, 70@80c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 70@75c. California production has fallen off, even since May, owing to the low price, which does not permit operation of mines that were worked in 1918 when prices were $1.50 a unit for 50 per cent. The market is strengthening, and should prices rise some abandoned properties will be reopened. There are considerable tonnages of 40 per cent ore at different points in California, which are being held for prices of 50@60c. a unit, f.o.b. cars, California.

Iron Ores—Lake Superior ores, per ton, delivered at Lower Lake ports: Old Range bessemer, $7.45; Old Range non-bessemer, $6.70; Mesabi bessemer, $7.20; Mesabi non-bessemer, $6.55.

Manganese Ore—65@75c. per unit, seaport; chemical ore (MnO_2) $70@$90 per gross ton, lump; $80@$100 per net ton, powdered.

Molybdenum Ore—85 per cent MoS_2, 70@75c. per lb. of contained sulphide, New York.

[1]**Tantalum Ore**—Guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots, against recent price of 65@70c.

[1]**Titanium Ores**—Ilmenite, 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $6 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $5, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

[1]**Zircon**—Washed, iron free, 5c. per lb.

[1]**Zirkite**—$90@$100 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

Zinc and Lead Ore Markets

Joplin, Mo., Sept. 18—Zinc blende, per ton, high $49.90; basis 60 per cent zinc, premium $46; Prime Western, $45; fines and slimes, $42.50@$40; calamine, basis 40 per cent zinc, $36. Average settling prices: Blende, $45.60; calamine, $38.72; all zinc ores, $45.57.

Lead, high $109.05; basis 80 per cent lead, $100@$90; average settling prices, $105.10 per ton. Considerable lead tonnage shipped this week was purchased on $110 basis.

Shipments for the week: Blende, 12,995; calamine, 71; lead, 2,459 tons. Value, all ores the week, $853,830.

The zinc market was lifeless until today, with offerings of only $42.50 basis Prime Western. Today over 10,000 tons sold on a $45 basis. Offerings of lead dropped today to $90 basis, but the bulk of ore shipped was contracted on $100@$110 basis.

Platteville, Wis., Sept. 18—Blende, basis 60 per cent zinc, $49.75, contract, to $51, open market, base for high-grade. Lead ore, basis 80 per cent lead, $100 per ton. Shipments for the week: Blende, 969; calamine, 39; lead, 93 tons. Shipments for the year: Blende, 50,015; calamine, 2,399; lead, 4,208; sulphur ore, 1,241 tons. Shipped during week to separating plants: 2,569 tons blende.

Non-Metallic Minerals

Asbestos—Crude, No. 1, $2,400@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax.

Barytes—Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $24@$30 in bags, carload lots; (off-color) $22@$26 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $12 per gross ton; ground (white) $23@$25; ground (off color) $16@$19 per net ton, f.o.b. Cartersville, Ga. Crude, 88 to 94 per cent, $23; ground (white) $45; ground (off color) $30@$32 per net ton, less than carload lots, f.o.b. New York. Crude, not less than 98 per cent, $11@$11.25 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—Domestic, extra light, 5@6c. per lb.; light, 4½@5½c.; heavy, 4@5c; English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin)—Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground.

$15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$18 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $30@$35 car lots, f.o.b. Baltimore; ground, $17@$21, f.o.b. North Carolina points; $17@$21 per ton, No. 1 ground, f.o.b. New York State; $21@$23 per ton, ground, f.o.b. Maine.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Gypsum—Raw crushed rock, $3.50@$4 per ton; raw ground fine, $4@$4.50; calcined stucco, $9, all f.o.b. works. Containers extra. The last price quoted for plaster of paris in carload lots was $4.25 per 250-lb. bbl., f.o.b. mill, alongside dock, New York.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $75@$85 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—India block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20@$1.40; No. 4, $2@$3; No. 3, $4.25@$5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $4; No. 3, $5.75; No. 2, $7; No. 1, $9; A1, $14; extra large, $25, all f.o.b. New York; ground, $100@$150 per ton, Philadelphia. Domestic, uncut f.o.b. Franklin, N. C., as follows: Scrap, $45@$50 per ton; punch, 4@5c. per lb.; circle, 15@25c.; 1½ x 2 in., 75c.; 2 x 2 in., $1.15; 2 x 3 in., $1.65; 3 x 3 in., $2.10; 3 x 4 in., $2.50; 3 x 5 in., $2.75; 3 x 6 in., $3.75; ground 165 mesh, $240 per ton; ground roofing mica, $60; mica washers, 75c.@$2 per lb.; 1¼-in. disks, No. 1, $1.60 per lb.; No. 2, $1.30.

[1]**Monazite** — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses.

Pumice Stone—Imported, lump, 4@50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish fines, per unit, 12c., c.i.f. Atlantic seaport; furnace size, 17c.; Spanish lump, 14@16c.; domestic fines, f.o.b. mines, Georgia, 12@14c. Market improving.

Quartz—(Acid tower) fist to head, $10; 1¼ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines. F.o.b. Wausau, Wis., the price is $16 per ton in car lots, and $22 less quantities, including bags.

Sand (Glass)—Dry glass sand, $4 per net ton, f.o.b. cars Mapleton, Pa. Sand, f.o.b. Ottawa, Ill., is $3 per ton; $2.50 on annual contracts. Sand at Klondike, Gray Summit and Pacific, all in Missouri, is $2.50 on contract; some outside sales have been made at $4.

Sulphur—$18 per ton for domestic; $20 for export, f.o.b. Texas and Louisiana mines.

Talc — Paper making, $12@$22 per ton; roofing grades, $9.50@$15; rubber grades, $12@$18, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $12@$15 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60@$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $2.25@$2.50 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15 to 18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 17@18c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c. f.o.b. works.

Ferromanganese—For 76 to 80 per cent, prompt delivery, $200, freight allowed; last half, $170; English, $170@$175, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $80@$85, f.o.b. furnace.

Ferromolybdenum—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2.50@$3 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $82.50@$85; 75 per cent, $150@$160.

Ferrotungsten—70 to 80 per cent W, 90c.@$1.05 per lb. of contained tungsten, f.o.b. works.

Ferro-uranium—35 to 50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium—Basis 30 to 40 per cent, $6.50@$9.50 per lb. of V contained, f.o.b. works.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Metal Products

Copper Sheets — Current New York price, 29¾c. per lb.; wire, 22¼@23c.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver—Unchanged at 39½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 26⅜c.; sheathing, 25⅜c.; rods, ⅜ to 3 in., 23⅜c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $160 per 1,000, f.o.b. Pittsburgh.

Chrome Brick—$100@$110 per net ton, carload lots, eastern points; 9-in. straights, f.o.b. Baltimore, $100@$105.

Clay Brick — First-quality fire clay f.o.b. New Jersey, $75 per 1,000; second quality, 9-in. straights, f.o.b. Pennsylvania, Ohio and Kentucky works, $50@$55.

Magnesite Brick — 9-in. straights, f.o.b. Baltimore, $110@$120 per net ton.

Silica Brick—9-in., per 1,000, $65@$70, Chicago district; $65 Mount Union, Pa.

Iron Trade Review

Pittsburgh, Sept. 21, 1920

The pig iron and steel markets continue practically stagnant, but producers are well supplied with orders and production tends to increase rather than decrease. The industry is operating on its momentum and the outlook is that it will be able to continue for several months.

Cancellations of orders and instructions to defer shipment continue to be received, and attract considerable attention, but the volume is so small a percentage of the total business on books that producers are not incommoded. For instance, deliveries of sheets to the automobile industry are reduced by fully one-half from the high point, but the capacity released finds ready employment on orders already on books from other classes of consumers, and indeed the production of sheets is larger than for weeks, about 85 per cent of the mills being in operation, all that can secure steel supplies.

Pig Iron—The local market is stagnant, with practically no inquiry at all. Birmingham iron could be had for Pittsburgh delivery at more than $2 under the cost of Valley iron, but is not bought even at that. We quote: Bessemer and basic, $48.50; foundry and malleable, $50, f.o.b. Valley furnaces, with $1.96 freight to Pittsburgh.

Steel—Several sales of sheet bars have been made at $65, or $2.50 under previous sales, and further concessions could probably be secured. Billets are altogether inactive. We quote: Billets, $60; small billets, $65@$70; sheet bars, $65@$67.50.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $16@$16.50; foundry, $17@$18.

Four Months of Dollar Silver

Treasury Department Has Purchased About One-fifteenth of 207,000,000 Oz. Required Under Pittman Act—Government's Purchases Are Serving to Stabilize Silver Prices and Can Prevent a Runaway Market—Oriental Demand for Silver Slackening

FOR FOUR MONTHS the country has been able to watch the effect of the repurchase clause of the Pittman Act upon the silver market. Over 14,000,000 ounces of silver produced in the United States were purchased during that period by the Treasury Department at $1 per ounce, of a total of 207,000,000 ounces to be bought. Difficulties in the way of the silver producer have been gradually eliminated to the satisfaction of both producer and the Government. Those smelters which treated both domestic and foreign silver-bearing ores have been able to take adequate and necessary precautions to guarantee the unquestionable domestic origin of all the silver sold by them at the official government quotation. The system is working smoothly and efficiently, and the difficulties encountered when repurchases first went into effect no longer have much importance.

Foreign and Domestic Markets Close Together

The great stabilizing influence of the Pittman Act in the silver market of the world is emphasized by the small differtial in price existing between the unvarying official domestic dollar quotation and the quotations in the foreign market which singularly enough have fluctuated but little. Except for two days, Aug. 20 and 21, when a quotation of $1.01⅜ was recorded, the price of silver in the foreign market has remained below the dollar level. On those dates the immediate and quantitative offerings of domestic silver acted as a safety valve, relieving the pressure upon the market that had raised the price. Thereafter and to date the price of silver has consistently stayed below the dollar price.

The silver bullion purchases of the Treasury Department are being stored by the Mints preparatory to being coined into silver dollars to replace those melted under authority of the Pittman Act and shipped to India. Although the act specifies that the silver dollars melted be recoined, no time limit has been designated and in view of the pressure upon the Mints of the country to meet the pressing demand for subsidiary silver coinage and gold coins (to replace those exported) there is little disposition to recoin silver dollars at this moment. At best the silver dollars would lie idle in the vaults of the Treasury, silver certificates circulating in their place. The Philadelphia Mint is storing the bulk of all the silver purchased. Until the demand for subsidiary coinage abates there will be no call for the coinage of silver dollars.

There is another angle of the Pittman Act which is worth considering in the event of a runaway silver market — some persons insist this may occur again. The act authorizes the sale of silver bullion for the purpose of providing silver for subsidiary coinage and commercial use as well as facilitating the settlement of adverse trade balances in silver. According to Director Baker of the Mint, in the event that the price of silver should rise over the parity point of subsidiary silver ($1.38) the Treasury Department could conceivably prevent the breaking up of the silver currency and its export or sale for bullion content, by selling part of the large accumulated stocks of silver. Last November, it will be recalled, the price of silver reached a record price of $1.37½ per oz. which was close to the danger mark, but it did not stay there long enough to cause any discomfort to the subsidiary currency system of the country. However, in December standard silver dollars, which were not held against outstanding silver certificates, were made available to certain American banks operating in China on presentation of any form of United States currency (not necessarily silver certificates). By this action, the government showed a method of preventing the exportation of subsidiary silver coins to other countries. The great stock of silver accumulated by the United States between 1878 and 1893, idle though it may have been and idle though it may become, was of great service to the United States during the war. Other countries that did not possess a surplus stock of silver coin or metal were unfortunately placed and could not prevent the widely prevalent melting of their coins except through decrees forbidding exportation of silver, or by debasing the silver currency.

In some quarters the impression has been gained that the chief function of the Pittman Act is to make the Government purchase silver at a higher figure than the metal can be obtained in the general world market. Attacks upon the measure usually ignore the history of the legislation and the behavior of the silver market during the past six years. The seemingly distressing feature of the situation whereby the Government is paying more for its silver than anyone else—although absolutely justified—is emphasized, but the possibility of using this same legislation to prevent a runaway silver market and protecting our currency for one thing is minimized.

The fact that other countries have had such a difficult time trying to keep silver currency in circulation is due not only to the avidity for hoard ng exhibited by the people of European lands, but also to the fact that foreign silver currency because of its bullion value is worth so much more than depreciated paper currency using the same unit of value. A silver mark for its metallic content alone is many times more valuable than a paper mark worth say 2 cents. It is little wonder then that melted silver coins have been exported from Germany.

Less Dependence Upon Silver Coinage

Although the world is placing less dependence on metallic currency than ever before in modern times and the demand for silver for coinage purposes at the present time in European countries is negligible, sooner or later there must come a demand to replace the broken up and exhausted silver stocks of a country such as Germany. Nations are demonstrating ability to transact their business affairs without the aid of subsidiary silver coinage and are transferring former dependence upon this medium to such makeshifts as postage stamps and porcelain coins, to their own detriment, but as soon as financial order is established from the chaotic currency conditions abroad there should be a call for coinage silver once more.

Mexico is reported to be purchasing between one and two million ounces of silver per month at a premium of about 4 cents above the New York official price, which seems to be a rather stiff premium, in an attempt to meet currency requirements not fully met by local production. This action on the part of Mexico will aid the foreign market in maintaining the present level of prices as Oriental support is weaker. With quieter conditions in Mexico and a new regime that is functioning much better than the old, Mexico should once more become a steadily increasing silver producer.

India has become a seller of silver but whether this has been due to an unfavorable outlook for the Monsoon or an action made in anticipation of a possible decline in the market is conjectural. China is still counted upon to support the market but reports of poor harvest conditions in that country are disquieting. Furthermore, exports of Chinese goods are expected to decrease because of an oversupply of Chinese goods abroad, hence Oriental pressure on the market is expected to become lighter rather than heavier.

COMPANY REPORTS

St. Joseph Lead Co. Shows Profit for Six Months

Lead; Missouri

For the six months ending June 30, 1920, the St. Joseph Lead Co. reports net profits, after charges, but before Federal taxes, of $2,488,691, equivalent to $1.76 a share earned on the $14,094,660 capital stock (par value $10). Consolidated income and profit and loss account for the six months ended June 30, 1920, shows as follows:

Operating revenue	$3,266,841
Other income	116,787
Total income	$3,383,628
Charges	79,857
Net income	$3,303,771
Adjustments (credit)	6,392
Deductions	*821,472
Surplus	$2,488,691
Dividends	1,409,466
Balance	$1,079,225
Previous surplus	15,925,780
Total surplus	$17,005,005

*Includes $600,771 for depletion of ore reserves and mineral rights, and $120,265 adjustment of inventory value of matte, January 31, 1920

New York & Honduras Rosario Mining Co. Has a Prosperous Year

Gold, Silver; Honduras

The annual report of the New York & Honduras Rosario Mining Co. for the year 1919 indicates a financially successful year. There was produced from 133,900 tons of ore 1,584,579 oz. of silver, and 10,200 oz. of gold in 1919, compared with 1,587,468 oz. of silver and 9,748 oz. of gold in 1918 from 129,900 tons of ore. The total value of the output increased from $1,782,428 in 1918 to $1,788,579 in 1919.

Dividends paid during the year amounted to $200,000 on a capitalization of 200,000 shares of $10 par value each, or 10 per cent. An amortization distribution of $200,000 was also made to stockholders.

The following statement shows the income and profit and loss for the year:

Production of gold and silver	$2,115,158 25	
Less: Freight and expense on bullion	62,065 30	
Operating income		$2,053,092 95
Operating expense		1,132,805 61
Operating profit		$920,287 34
New York administrative expense		76,368 28
Net income from operating		$843,919 06
Other income		147,996 53
Total income		$991,915 59
Deductions from income		58,828 99
Net profit for period		$933,086 60
Appropriated for reserves		
Depreciation	$64,315 44	
Taxes	106,610 63	
Fire insurance	4,020 70	
		174,946 77
Profit and loss balance—carried to surplus		758,139 83
Add surplus balance—January 1, 1919		2,434,065 59
Total		$3,192,205 42
Deduct—Reserve for depletion of mines in 1919	$334,750 00	
Dividends paid in year 1919	200,000 00	
		534,750 00
Surplus balance—December 31, 1919		$2,657,455 42

The ore reserves reported Dec. 31, 1919, were 283,422 tons valued at $4,279,649 (silver at $1 per oz.), compared with 282,559 tons valued at $3,812,419 in 1918. The development driven was 15,900 feet, compared with 11,266 feet in 1918.

Wolverine Copper Mining Co. Shows a Deficit for the Year

Copper; Michigan

The Wolverine Copper Mining Co. in its report for the year ending June 30, 1920, indicates that 3,932,255 lb. of copper were produced from ore averaging 0.764 per cent copper to the ton. Total operating cost per pound of refined copper was 15.283c.; cost of smelting, freight and marketing product, 2.055c.; taxes, 0.668c.; depletion of orebodies, 2c.; depreciation, 2.043c.; a total cost of 22.049c. per lb. of refined copper.

Sales of 3,457,320 lb. of copper at 19.11c. or $660,727.62 were made, but a loss of $98,297.73 was recorded, as the following table shows:

Sales:		
3,457,320 lbs. copper at 19.11c.		$660,727 62
Cost of Sales:		
Copper on hand June 30, 1919, at cost	$72,015 16	
Operating expenses at mine as per statement hereafter	600,946 75	
Smelting, freight and New York and Boston expenses	80,818 54	
Taxes, exclusive of income and profit taxes	26,282 40	
Depletion of ore bodies	78,644 50	
Depreciation of equipment, etc	80,333 20	
	$939,040 55	
Less: Copper on hand June 30, 1920, at cost	180,015 20	
		759,025 35
Loss on sales of copper		$98,297 73
Deduct:		
Interest on Liberty Bonds	$24,450 00	
Other interest, etc	2,589 01	
	$27,039 01	
Less: Interest paid, etc	14,766 33	$12,272 68
Net loss for the year		$86,025 05

Three dividends were paid during the year of $30,000 each on the $780,000 capital stock of the company consisting of 31,200 shares of a par value of $25 per share.

Surplus on June 30, 1920, stood at $1,479,582.26, compared with $1,565,607.31 on June 30, 1919.

Shattuck Arizona Copper Co. Shows a Loss for the Second Quarter

Lead, Copper; Arizona

The report of the Shattuck Arizona Copper Co. for the quarter ending June 30, 1920, states that the production of metals for the quarter, especially copper, was badly handicapped as a result of shortage of mine labor. The lead mill operations were nearly normal, but lead production costs were high.

A summary of the production for the quarter is as follows:

Dry tons copper ore smelted	5,318
Dry tons lead concentrates smelted	3,719
Dry tons lead ores smelted	50

Metals Recovered From	Copper Ores	Lead Concentrates	Lead Ores
Pounds copper	631,567		
Pounds lead		1,753,244	
Ounces gold	133	933	7
Ounces silver	21,364	60,139	226

The copper production for the quarter is inventoried at 15c. per pound. The returns on lead are actual smelter settements.

The results of operations for the second quarter are as follows:

Copper ore, bullion and sales		$94,735 05
Copper ores, gold and silver, etc		21,213 15
Lead concentrates settlements		243,186 11
Interest		11,378 62
		$370,512 93
Copper operating expense and development	$172,752 37	
Milled lead expense	193,581 82	
Loss on sorted and direct lead ore settlements	34 07	
Administrative expense	12,811 44	
		379,179 70
Depreciation of mine and mill equipment		$8,666 77
		18,886 35
Loss for quarter, exclusive of depletion		$27,553 12

INDUSTRIAL NEWS

John A. Penton, president of Penton Publishing Co., is a director of the Wellman-Seaver-Morgan Co., Cleveland, Ohio.

Chain Belt Co., Milwaukee, Wis., announces that H. S. Rosenthal is now Southern District salesmanager for its Rex mixers and pavers.

Keystone Steel Co., 997 Union Arcade Building, Pittsburgh, Pa., has been organized to do a general brokerage business in iron and steel products.

The United American Metals Corporation, Brooklyn, N. Y., announce the death of their vice president, William H. Mixer, at his home in Berkeley, Cal. Mr. Mixer was one of the pioneers of his company.

The Jeffrey Manufacturing Co., Columbus, Ohio, announces the opening of a new branch office at 1108 Marine Trust Building, Buffalo, N. Y., to be in charge of H. W. Scott, formerly with the home office.

The Merrill Co., 121 Second St., San Francisco, Cal., call attention to the fact that their eastern office is in the Monadnock Building, Chicago, Ill., from which may be secured copies of catalogs and literature they issue.

F. B. Kirkbride, vice-president, has been elected president of SKF Industries, Inc., 165 Broadway, New York, succeeding B. G. Prytz, resigned, who has been elected managing director of the parent company, with headquarters at Gothenburg, Sweden.

The Blaw-Knox Co., Pittsburgh, Pa., steel products, will have an exhibit of clam shell buckets, water-cooled furnace appliances, and Prudential steel buildings at booth 308 of the American Foundrymen's Association exhibition in Columbus, Ohio, Oct. 4 to 8.

The Fawcus Machine Co., gears and mill machinery, has consolidated all departments in its new office building at 2818 Smallman St., Pittsburgh, Pa. A downtown office for meetings by appointment is maintained at suite 1501, Peoples Savings Bank Building.

D. D. Tripp, vice-president of Pioneer Rubber Mills, returned in May from his trip to China, Japan, the Philippines. He anticipates an unprecedented demand for mechanical rubber goods, and his mills are preparing to take care of a material increase in their oriental trade.

Walter H. Taverner, electrical and mechanical engineer, announces that he has severed his connection with the George A. Fuller Co., and is now with the Walter H. Taverner Corporation, 175 Fifth Ave., New York City, electrical and mechanical constructing engineers.

New York Testing Laboratories, 74-80 Washington St., New York City, L. R. Seidell, managing director, have been awarded the contract for the chemical, physical and electrical testing of approximately 400,000 ft. of signalling cable and wire for the city of Troy, N. Y.

The Koppers Co. and the **Aluminum Co. of America**, both of Pittsburgh, Pa., have jointly purchased the American Tar Products Co. and will operate it together. It is planned to manufacture electrodes for the use of the Aluminum company, as well as to continue the general tar-refining work.

Dwight P. Robinson & Co., Inc., engineers and constructors, New York City, has established a branch office in Youngstown, Ohio, in the Home Savings & Loan Building, in charge of Mr. C. I. Crippen. The Cleveland, Ohio, office has been moved from the *Leader-News* Building to the Citizens Building, and Mr. H. P. Clawson is in charge.

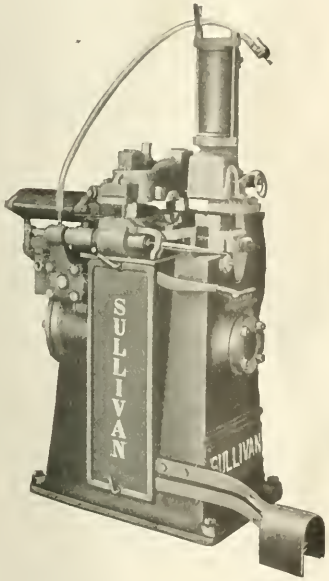
V. C. Kylberg has been appointed sales advisor to the Navy Department. During the period of greatest activity in the disposal of the War Department's surplus property, Mr. Kylberg was Assistant Chief of the Machine Tool Section of the Officer of the Director of Sales. Later he organized the Procurement Division for the Army's vocational training schools. More recently he has been acting head of the Sales Section of the U. S. Shipping Board.

The Oil Engine Manufacturers' Society held its annual meeting Aug. 10, in the club room of the Bessemer Gas Engine Co., at Grove City, Pa. The following were among the officers elected for the ensuing year: President, H. L. Dean, Chicago Pneumatic Tool Co.; Secretary, C. B. Humphrey.

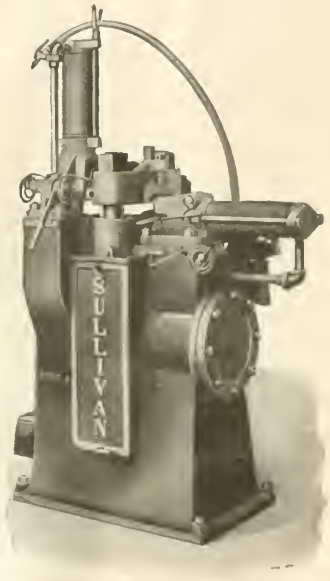
New Small Hammer Sharpener Handles Solid or Hollow Steel

The success attained by the adaptation of the all-hammer process in sharpening and shanking drill steel, as incorporated in the Sullivan drill sharpening machine, has recently induced the manufacturers to design a new model sharpener, embodying the same principles but of smaller and lighter construction, suitable for making and sharpening bits on the steel used in the standard sizes of hammer drills.

This machine, which is shown in the accompanying illustration, is known as the Sullivan Class "B" sharpener, and is designed for handling solid or hollow steel of any section up to 1¼ in. in diameter, and to make bits up to a maximum gage of 2½ in.



SULLIVAN "B" SHARPENER



"B" SHARPENER, REAR VIEW

The Class "B" sharpener weighs 1,500 lb., occupies a floor area of 4 x 2½ ft., and stands 5 ft. high. Its essential features consist of a horizontal hammer cylinder and piston, operating a dolly for upsetting, and a vertical cylinder and piston operating dies for swaging the drill bits or shanks. For upsetting, the steel is clamped in steel dies mounted in the lower, or stationary, and upper, or movable jaws of a yoke or vise operated by a horizontal air cylinder situated in the base of the machine.

The vise, or clamping cylinder and piston are of the differential type, the closing or clamping end being 10 in. in diameter, and the releasing end 4 in. in diameter. The horizontal movement of the piston is communicated to the vertical action of the vise by the air power acting through a toggle, or link. The combined effort of the air power

and toggle leverage is more than 50,000 lb., all of which is applied to hold the steel firmly in the vise.

The action of the vise is controlled by a valve placed in a valve chest on the side of the frame, and operated by a hand lever from the front of the machine. A safety stop is provided, which makes it impossible for the upsetting hammer to start until the steel is securely gripped by the vise.

The two-hammer cylinders are modified Sullivan "DR-6" drills, equipped with floating hammer pistons, and a valve motion which imparts a blow of great strength and liveliness to the dies and dollies.

In order to secure the advantages of the floating hammer piston a novel construction has been employed. Springs are provided to keep the upper swaging dies in a raised position when not in use. The foot lever, which operates the vertical hammer, is kept in a raised position by means of springs. When the lever is depressed, air is admitted to the cylinder and the hammer begins to strike.

In making or resharpening bits, the steel is shifted from one hammer to the other, being alternately upset and swaged until of the proper gage and shape, and the wings, corners, and cutting edge properly drawn out to be uniform, and of the right thickness and angle.

Equipment

The Class "B" sharpener is fitted with a drill steel punch for operating the hole in hollow steel bits and shanks. When the hole has been sufficiently opened, the steel is simply withdrawn and the punch stops operating.

The double taper bits can be accurately formed on the new Sullivan sharpener by means of an adjustable gage plate and dies which are operated by action of the clamping yoke or vise. Sixteen different gages can be provided by means of the gage plate, which is controlled by a key.

For cleaning hollow drill steel an automatic blowgun or jet is provided in the front end of the frame, below and to the left of the vertical hammer. A small nozzle will be noted, against which the hollow steel may be thrust, thus opening the valve, and permitting air to be blown through the steel. Exhaust air is also used for automatic cleaning jets in an ingenious manner from both the horizontal and vertical hammers, so that the working faces of the dies and dollies are kept clean and free from scale and accumulations of dirt and dust at all times.

The Sullivan "B" sharpener, light model, is operated by compressed air at a recommended pressure of 80 to 100 lb. While the machine is much lighter than the Sullivan heavy duty sharpener, it is built very substantially and with ample weight and area of parts where strength is needed, and where stress and strain occur. It will stand much hard work.

Why Foreign Markets Buy Outside the U. S. A.

Walter C. Teagle, head of Standard Oil of New Jersey, recently reported in *System* an important conversation he had on the subject of foreign markets. He gave many illuminating examples of the reasons why the United States fails to develop foreign markets. The most important conclusions he draws are summed up in *Current Opinion* for September, concluding with the admonition to send abroad "the manufacturer himself or at least a high executive who fully knows the business, and can proceed on his own responsibility. . . . A man of resource and imagination. . . .

"One never knows what he is going to run into until he gets on the spot, and one of the reasons that our people so frequently fail in the building of export markets is that they insist on deciding everything ahead of time *and on American experience*, and then not only want matters to move according to schedule but to move immediately. When they fail they blame the market. They should blame themselves."

Outlook for Foreign Trade Better, Says Ingersoll-Rand Official

W. L. Saunders of Ingersoll-Rand Co., who is president of American Manufacturers' Export Association recently reviewed the outlook for foreign trade as follows:

"A few months ago there was cause for alarm in industrial conditions. Prices and bank loans were soaring, and it seemed to conservative business men that the shock of the war was not over; that we were riding for a fall. Being forewarned, the Government, the Federal Reserve Banks and the public determined to exert such reasonable pressure as might forestall drastic results. Restriction of expenditures by the Government, the issue of short-term certificates at market rates, the rise in the discount rate at the Federal Reserve Banks, and the determination on the part of the public that prices must come down or they would not buy, have resulted in a decided readjustment, which is now going on.

Cutting Wire Rope

A section devoted to "hoisting ropes" in the draft of a law to cover mine rules and regulations, proposed by the U. S. Bureau of Mines, is evidence of the extent to which the cutting of wire rope is now required in the maintenance of mine equipment.

The approved method of cutting the rope preparatory to resocketing and reclamping is the well-known oxy-acetylene process. There is no simpler or easier way. A typical outfit that has been found dependable comprises a standard Oxweld cutting blowpipe, a Linde oxygen cylinder, and a tank of Prest-O-Lite dissolved acetylene. With this equipment a competent operator cuts through a two-inch cable in about two minutes.

Dry Power Drills Prohibited in Rand Mines

Regulation Goes into Effect April 1, 1921—Will Affect Many Drills

At a meeting held early in July in the offices of the Government Mining Engineer of the Union of South Africa, representatives of the Transvaal Chamber of Mines, the Mine Managers' Association, Underground Officials' Association, and of the South African Mine Workers' Union agreed that a new regulation should come into effect after March 31, 1921. This regulation, which is an amendment to No. 101 (1) (3) of "Mines, Works and Machinery Regulations," provides that "No person shall in the drilling of holes use or cause or permit to be used any machine drill in which only air is passed into the hole through the hollow jumper of the drill."

As the *South African Mining and Engineering Journal* says, the effect of this order on the mines remains to be seen. There are considerable numbers of dry jackhammers in use today on the Rand and also held in stock, and these will have to be scrapped or converted by the date mentioned. One estimate placed the cost of conversion at £9 per machine.

TRADE CATALOGS

Valves—The Merrill Co., 121 Second St., San Francisco, Cal., have just issued an illustrated 24-page catalog describing the Merco Nordstrom plug valve. The special construction of this valve permits forced lubrication of the sliding surface and the line of special lubricants supplied combine with the construction to make the valve specially interesting to mining and metallurgical companies. The pamphlet may also be secured from the eastern office in Monadnock Building, Chicago, Ill.

Furnaces—The Mine and Smelter Supply Co., 42 Broadway, New York City, and Denver, Col., have issued as their Bulletin No. 63, an elaborately illustrated catalog of 47 pages describing Massco furnaces for melting, hardening, forging, roasting and similar work. These furnaces are designed for low pressure oil fuel, gas or gasoline. Massco burners, blowers, gates, fans and Sil-O-Cel insulation are also described.

Flotation Machines — Southwestern Engineering Co., Hollingsworth Building, Los Angeles, Cal., mining and milling machinery, have issued a very fully illustrated pamphlet describing the K & K flotation machine, giving sample actual flow sheets embracing these machines and useful dots on local and export shipping dimensions. The ore listing laboratory of the company is also fully described. The publication is classed as Catalogue "C."

The Relation of Mining to International Politics

WE of the mining industry at least cannot for a moment ignore our dependence for prosperity on trade relations broader than those of our own comfortable boundaries. The present trying condition of mining, we know, is bound up closely with world politics—more especially with the still grievously tangled European situation. Why are we producing copper at cost when producers of most non-metallic necessities are riding undisturbed on the crest of the still existing inflation and enjoying the fattest of profits? Because the scale of our copper mining and smelting industry is adjusted to the world needs, for supplying Europe as well as America. The researches of our special market editor have shown that the American absorption of copper, so far from being abnormally low, is markedly greater than before the war. But Europe, our old and stable customer, is not buying adequately and cannot do so. She has only enough for her necessities and her luxuries. She is, according to the Spanish writer, Ibañez, now going through the same post-war dementia of extravagance and cheap and easy money from which we are first in trying to emerge. With Europe the war fever was longer and harder, and the compensating devil's-humor of gayety and throwing dull care and dreary common sense to the winds may well be correspondingly deeper and more prolonged. Therefore, they can buy only bread and wine, only firewood and silk stockings, and have only a slight residue for solid improvements such as metals are used for. More than that, their money is no good. With all our bankers' theories as to the solidity of paper or demi-paper currency, they shun paper in practice. We will not sell our copper to Germany for paper marks, nor to Austria for paper krone, nor to France for paper francs. We demand, instead, the good old gold and silver—may Heaven bless them and protect them, and the vital American industries they represent! And the real stuff they do not have. Therefore, with our copper-producing machinery tuned to the world consumption scale, we perforce, to keep the wheels running, produce so much that the supply overtakes the temporary demand, and the price of metal and the cost of metal walk in too close company for our prosperity as miners. And what is true of our mining industry is, of course, true of the world's mining industry.

Therefore, the only remedy is the stabilization of Europe, and that is why our next and chief interest is in European and Americo-European politics, because it is undeniable that just as mad policies have shattered Europe, wise policies can heal her. And Europe least of all is blind to the fact that the policies which dominate her future and well-being are not only those of her own continent and neighboring islands, but those of America. Now, as never before, we need for our happiness and that of the world an intelligent, strong, and wise foreign policy. Now, as never before, we of the mining industry realize that we are simply one of the world's great states, and not to study and act with relation to the other states is in a sense a species of anarchy. From this point of view, the inactivity in international affairs of the United States since the armistice has been criminal negligence—a failure of discharge of duty which in military circles would call for a court-martial of the offenders. As it is, the deadlock apparently will not be thus broken, but only by the Presidential elections. Should these result in a return of democratic rule, of the principle of the submission of the individual and the minority to the need as seen by the majority, of the prudent compromise between different opinions instead of the stubborn deadlock, then we may expect to see such adjustments gradually made that Europe will be assisted to buy and to recuperate. The war is over—let our Government so proclaim it at the earliest moment. Our mining industry needs the markets of all of Europe, on both sides of the line of battle, for its prosperity, provided they have either metal or satisfactory credit to pay with, and provided their governments are fundamentally sound and reliable. This, in general, is true of all western and central Europe. Only, and of course, we shall gain nothing by dealing with freebooters and outlaws, and in this category, by all the evidence, we must place the present government of Russia.

The Attitude of the Banks Toward the Gold Bonus

THE AMERICAN BANKERS' ASSOCIATION recently issued a report of a committee appointed by it to study the proposed bonus on newly mined gold, and in that report the committee was of the unanimous opinion that the contemplated legislation embodied in the McFadden bill would work to the detriment of the public's interest. In view of the fact that the American Bankers' Association is an influential body expressing the financial sentiment of perhaps a goodly majority of banks and bankers in the country, it is surprising to come across a paid advertisement in one of our evening papers by a prominent local bank entitled "The Cost of Gold," which devotes several paragraphs to elucidate the serious decline in United States gold production and the importance of an adequate gold reserve. The concluding paragraph states, "The Harriman National Bank would favor a premium on the use of gold for jewelry, dental needs, window lettering, decoration and a hundred other ways. With this premium upon such uses of gold paid as a subsidy to the mine owner, he could undoubtedly make both ends meet and have legitimate profits wherewith to pay taxes."

This statement is not in keeping with the declaration of the American Bankers' Association and shows out-

spoken dissension from the conclusion reached by that organization. It is pleasing to note such disapproval, and although we have known all along that many bankers, through mature consideration of the McFadden bill, have stamped it as deserving of support, the voices from such quarters have been distressingly silent ever since the A. B. A. issued its report.

It is noticeable that all the adverse criticism directed upon the gold bonus has been destructive in character. It has sought to tear the legislation to pieces, magnifying the untried and supposedly weak points of the measure. If any constructive suggestion has been ventured at all, the statement that deflation would cure existing ills has been stressed the most. Anyone will grant such a statement—when conditions get back to normal the gold miner no doubt will again be able to take up his pick and single-jack—but when will this be? Some economists are of the impression that we shall never again see prices of labor and commodities on the pre-war scale, whereas others estimate a period upward of five years before the situation will be comparable to the pre-war stage. And what of the interval? Is irreparable injury to be done to the highly developed and important gold industry? If not, some arrangement must be made to tide over the gold mines. Perhaps the McFadden bill in its present form is imperfect, perhaps amendments and changes should be incorporated to perfect it—or perhaps other legislation may better meet the circumstances. If so, it is high time to find this out—we need constructive not destructive criticism. The McFadden bill is the best plan so far advanced to assist the gold industry and to strengthen the financial system of the country. Some banks are finding this out and have the courage to air their opinions. More power to their elbows!

Vacationing on the Comstock

IT IS DISAPPOINTING, though not surprising, to hear of the strike that took place at Virginia City, Nev., quite recently when about five hundred workmen employed in the various mines on the Comstock lode quit work after having been refused a dollar increase in pay. Strictly speaking it was not a strike but a "vacation," according to the men themselves, who, feeling sure of their power to make the wheels stop turning, are pleased to jest, doubtless laughing up their sleeves at the neat way in which they get around their contracts and still, to their own way of thinking, preserve their honor.

The strike as a weapon of industrial warfare has become so common that this particular occurrence would ordinarily attract but little comment. The workman in his regal way once more chooses to play the fool. One is reminded of that line in a familiar poem:

> Art thou the king? The king's jester thou.

When will the miner, mucker, or whoever he be come to realize that the strike is a two-edged sword, cutting both ways, injuring not only his employer and the public but himself as well? This is a platitude to all except the striker, who cannot or will not see it.

There is an additional reason, in this recent Comstock strike, for annoyance and disappointment. To those who are interested in the future of the Comstock, the action of the men will seem most inopportune. A new chapter appears to be opening in the history of the famous lode, which of recent years has seemed gradually settling into obscurity. The newly organized United Comstock Mines Co., of which Bulkeley Wells is president, has undertaken the development of low-grade ores at Gold Hill on an extensive scale. Deep diamond drilling is under way at another point on the lode. There has been a shake-up in the management of one important group of mines. A period of change has apparently set in, the chance being that it is for the better and not the worse. And then the workmen strike. If they would have an increased share of the profit they had better wait until it were earned. The companies can scarcely stand an increase in wages with costs already so high. An optimist writes us that the trouble will probably be settled amicably, as is customary on the Comstock. Truly, the striker here is the ass in this bit of asininity. The trouble is said to have a "wobbly" origin. No doubt. Virginia City was once called a place of "Ophirs, gophers and loafers." The last named are evidently still there, as their work is readily apparent.

Concerning Prophecy

WE LIVE in a wonderful age, whose unexpected miracles of science tend to make us broad, receptive and tolerant. Yet, with this there goes hand in hand the scientific caution of waiting for evidence, of not jumping to unwarranted conclusions and beliefs. The bulk of our intelligent citizens do not as of old spring lightly from electricity to "animal magnetism," thence by way of hypnotism and abnormal or unusual psychic conditions to spiritualism, second-sight or prophecy. Our best citizens come from Missouri, and they want to be shown.

We do wrong in these days to speak of the occult and the supernatural. Nothing is supernatural, and if anything is occult, the nature and manifestations of what we call electricity are that; yet electricity has become a familiar demon to us, and gives us none of the terrified thrills its manifestations used to give our forefathers. Psychic phenomena are not occult—they are phenomena illustrative of the set laws of a very well-known system of nerve and brain organs.

Scientifically speaking, the case for prophecy, as we understand it, seems to date to be a poor one. It would be a fine thing—perhaps—were prophecy possible. "Give me a tip on the stock market. I need the money," pleaded a young man to a well-known Wall Street operator. "But I have no knowledge of what the market will do; I can only guess," replied the wizard. "Oh, yes, you do," was the rejoinder. "You know in advance when the market will go up and when it will go down." "Why, you ——— ———," exploded the wizard, "if I knew that 60 per cent of the time, don't you know that I would have had all the money there is in the world before now?" Generally speaking, prophecies make poor reading, both before and after—they are vague and wild, and evidently without moorings.

So far as we can judge, the best forecasts are still scientific, and depend upon the logical reasoning out of results from established facts—of the order of the prophecies of the astronomers who calculate and foretell so accurately the eclipses and the tides. This is supernatural to the savage, but we do not call it "occult."

The forecasts of science in many branches are equally accurate and marvelous. The skilled geological engineer may and often does calculate out, from the geological factors of his problem, the location of a lost or undis-

covered orebody, and shape the course of development in the blind earth so as to uncover it after months or years of burrowing. The same scientific method may be applied with a gratifying amount of success to more variable and elusive problems, even those governing human affairs, and the possession of these ratiocinative and foreseeing qualities distinguishes statesmen from politicians. The man who observes that "one man can see into the ground as far as another" is an ignoramus; and the politician who does not lean on the man capable of drawing future deductions from past and contemporary events, and the application of all the sciences thereto, is in the same foolish category. The forecast of the World War made by H. G. Wells was a famous and accurate one. The sketchy accuracy of Tennyson's vision of a world war fought partly in the air, and a subsequent League of Nations, written nearly eighty years before the war, is astonishing. In his vision of the "world-wide whisper—of the standards of the peoples" rushing to war, he

Heard the heavens filled with shouting, and there rained a ghastly dew
From the nations' airy navies grappling in the central blue.
Till the war-drum throbbed no longer, and the battle flags were furled
In the Parliament of Man, the Federation of the World.

We wonder. Inshallah! as the Arabs say—May God grant it. Yet Tennyson saw something else in the vision.

Slowly comes a hungry people, as a lion creeping nigher
Glares at one that nods and winks behind a slowly-dying fire.

Had the Czar of All the Russias, for example, pinned this under his study lamp as a true prophecy, we should all be happier today.

On the other hand, take imagination unguided by science and logic. Poe is reputed the most imaginative of writers, but he has no reputation for balance or logic In one of his "Tales" he presents an imaginary diary of a balloon voyager, dated a thousand years ahead. It is one of those attempts to construct imaginatively the future, at which Jules Verne did so well. According to Poe, in the year 2800 and something A.D., the principal method of travel would be balloon voyaging, drifting in air currents and with drag-anchors. The imaginary writer gets news of the outside world through newspapers thrown into her balloon from a passing balloon, and when her balloon collapses she can only put her diary into a bottle and throw it into the sea! How flat, after only eighty years, does this "wild" imagination sound, when we are familiar with motor-driven airplanes, the wireless telegraph and telephone, and even know of the wireless-driven motor boats and airplanes!

Sound Industrialism

THERE is something more than typographic and lithographic beauty in the pamphlet issued to commemorate the 175th anniversary of the Taylor-Wharton Iron & Steel Co., at High Bridge, New Jersey. In the present-day seething industrial world of America, beset with giant mushrooms of commerce which in a decade overshadow and perplex the country, with immense bond issues and gigantic bond defaults, with strikes and struggles between leaders and followers—so-called controversies between "capital" and "labor"—a dip into this pamphlet refreshes one as a shady fishing pool after a county fair. The present president is the fifth generation of his family who has directed the mining of iron ore at High Bridge, without, so far as can be discerned, becoming trust magnates or pluto-aristocrats. In his address, the president, Mr. Knox Taylor, observes with proper pride:

"I know of no concern in the line of our great industry which can approach our successful and venerable record. Others may have started sooner, but unless there is some history about which we have been unable to learn, all such beginners have long since dropped out of the race. Since our beginning many have come and gone. Why have we lived on through so many generations? I say in all humility that it is because we have ever been faithful to our trust." . . . "We are, as I have said, so far as we know, the oldest in our line. We are not the biggest; we have never aspired to be. With us it has not been quantity but rather quality." . . . "Such work as ours is not accomplished by great masses of automatic machinery. We need the individual and intelligent and resourceful worker. We need workers who take individual pride in their jobs and the company as a whole. That's the kind of business we do, and that's the kind of employees we are—men and women both."

Among the employees, the president pointed out four groups of three generations each, and twenty men who had served the company close to fifty years, mainly or all of them being representatives of solid old-fashioned American families.

We Always Did Beat the Dutch!

THE Germans who are promoting a company for the extraction of gold from sea water, with a plant to be located on the southeast coast of the United States, had better read up on the history of our country. Like the small boy apropos of scarlet fever, and the high-school girl who was advised to read Shakespeare, we "have had that," and we can't have it again. We have had it, out on our northeast coast, even on the coast of Maine; and does our Berlin friend imagine that what a Yankee clergyman failed to put over he can get away with? Possibly Hans will bite and dig up a few pitchforkfuls of paper marks. He will unless, as we begin to surmise, he is cured of his faith in German efficiency. But this all goes to show that the German genius is to trail along behind the Yankee; though doubtless now they will lay claim to the evolution of the idea. Extry! Great German discovery!

What the "technical and hydrographical reasons" for locating on the southeast coast of the United States are we can only surmise. Probably the United States was selected because it is the only country that still contains a considerable quantity of gold, and the waves that lap the shores of the North Sea contain only a recoverable extract of paper and printer's ink. Doubtless the southeastern coast was selected in order to get as far away as possible from Maine, where the Arctic current proved unfavorable in the Yankee attempt. Moreover, in the vicinity of Palm Beach, what with the higher solvent power of the Gulf Stream, the saline oceanic solutions should be appreciably richer. We suggest to our German friends that if they drive a crosscut under Washington, raise up under the Treasury and flood the vaults with cyanide solution, the waters of Chesapeake Bay and the neighboring high seas will be enriched by the natural convection currents.

WHAT OTHERS THINK

Protect American Citizens

Why not do some propaganda work and agitation for the protection of American citizens and their property in foreign countries rather than so much effort, time, and space in the advertising of the mineral resources of foreign lands? Especially now it seems to be the proper, popular thing of some of our Government departments to advise Americans to go to foreign countries to prospect and develop oil, because our known and prospective resources will be exhausted within the next twenty years.

Judging from the past, what guarantee have we of being able to realize on the investment? Our Government will not protect our lives, to say nothing of our property rights. It is not alone the present administration that refuses to do it, but have we ever done it? Not in Mexico within the last twenty years to my knowledge.

Is there any valid reason why an American in foreign countries is not entitled to protection as much as an Englishman? He is protected and respected in all parts of the world. Over 600 lives of Americans have been lost in Mexico, since 1910, besides many millions of dollars in property, and not a thing has been done. Not only is this true in Mexico but all over the world.

It is more than probable that if, during the past twenty-five years, we as a government had pursued the same policy as Great Britain—a chip on our shoulder, ready to fight to protect our citizens and their property, in all parts of the world—that we as a nation would not have been drawn into the World War.

Germany had no idea that we would fight. Why could not engineers in all classes of each profession and society agitate and work for their own protection in foreign lands as well as for other citizens?

Why not as an organization ask their Congressmen and Senators to define their position on this question? The farmer, as a class, gets what he wants because he has the votes. This is an important subject to the mining profession. Is it not high time that some action was taken?

Organized efforts can accomplish much.

Denver, Col. G. L. SHELDON.

Missouri's Cobalt Industry

I noticed an article in the *Engineering and Mining Journal* of Sept. 4, page 478, referring to Cobalt-Nickel Smelters, in which it is mentioned that a former cobalt-nickel refinery at Fredericktown, Mo., was shut down in 1909, and to the best of your knowledge was not operating at the present time. You will, I am sure, be pleased to hear that the cobalt-nickel industry in Missouri was revived in 1917, and a mill built capable of handling 300 tons of ore per day, with a smelter and refinery for treating the resultant concentrates, and recovering in marketable form the lead, copper, cobalt, and nickel contained. During 1917 and 1918 the plant was under construction, although during the latter part of 1918 some metals were marketed. The main production began in 1919, and the plant is now on a fair operating basis.

The ore milled assays approximately 2.3 per cent copper, 1.5 per cent lead, 0.75 per cent nickel, and 0.55 per cent cobalt. The plant is designed to make a fair recovery on all these metals, so the process is naturally complicated.

The lead is marketed in the form of concentrates from the mill, and as a sludge from the subsequent refining processes; the copper as electrolytic copper; the nickel as metal, or as oxide for the manufacture of nickel salts; and the cobalt as cobalt oxide or as crude hydrate.

The cobalt is the most important product of this plant, as it is an essential raw material of the enameling and ceramic industries, and has lately come into considerable use in the manufacture of driers for the paint industry. It is also the main metal in the alloy stellite, and has a limited market in the manufacture of steel alloys.

The Missouri Cobalt Co. is the only cobalt producer in the United States today, and in view of the increasing demands and the decreasing foreign supply of this metal from the former source, viz., the Cobalt camp of Ontario, Canada, it would appear that the Missouri ores should prove an important asset in the industries of the United States. S. F. KIRKPATRICK,

Managing Director, Missouri Cobalt Co.

Fredericktown, Mo.

[We are glad to publish this letter supplementing the information given in our issue of Sept. 4. It indicates a renewal of an attempt to develop domestic cobalt resources.—EDITOR.]

Smelting Without Fluxes

One does not have to go back to 1851, as is done in the "By the Way" column of Sept. 11, 1920, for an example of smelting without fluxing the ore. In 1905 the citizens of one of our Western towns raised nearly $250,000 to build a local smelting plant. Their ores were highly siliceous—so, to avoid the expense of bringing in basic ores from a distance, their technical advisers, consisting of a lawyer, a dentist and a broker, as I remember it, decided to try a process then being exploited in New Jersey. This consisted of heating the ore in a vertical kiln and then dropping it into cold water (preferably iced.) "The shock of the cold water on the heated ore caused the mineral particles to agglomerate and detach themselves from the gangue. (This is the explanation given to me, and not mine.) "Carbonates and oxides were reduced to metallic form, sulphides were partly roasted and reduced, but might remain unchanged. The entire mass, shattered and disintegrated, was then easily crushed, put over a concentrating table and the rich product sent to Eastern refiners."

Why so plausible a process didn't work seems incomprehensible, but I have never been able to find out that

any bullion or concentrates have ever been shipped from the plant erected to operate under these patents. I believe the original idea of the inventors was to treat the low-grade copper carbonate ores of New Jersey, but New Jersey still figures more as a refiner than as a producer of copper. DONALD M. LIDDELL.

New York, N. Y.

Concerning the Statements of Mining Engineers Abroad

You will not find my name on your list of subscribers for several years past. Constant travel makes it almost impossible to secure your much valued journal when mailed to me direct, so I purchase from the house of Lemare and others and who keep same for me, and I am quite proud of my file extending for more than four years, with only one or two missing numbers.

In the issue of June 26, 1920, appears an article sired by a Mr. Bruhl, stated to be a mining engineer, whose reputation must have been sufficient to allow an excellent half-tone of himself on mule-back "somewhere in Bolivia or S. A." to be published.

It is difficult for us who live our lives in these countries to understand why a journal with the deserved reputation you enjoy can be cajoled into publishing such a sneeringly cynical conglomeration of misstatements as are displayed in this article.

So far as what he says is concerned, dressed in different verbiage it might not hurt. It is possible the celebrated engineer was suffering from liver or "puno" (high altitude) while he was in Bolivia and North Chile, yet he was able to note the "beautiful sunset."

The *Engineering and Mining Journal* is subscribed to and purchased by a large number of Latin-American engineers who are naturally loyal to their own countries. These same acknowledge certain deficiencies in the way of enlightenment, give the hand of fellowship to all foreigners and yearn for information gained by experience and collegiate instruction not obtainable in their own countries. Many of them have studied in the universities of our country, also in Germany and Great Britain, but no one likes to have himself or his people exhibited in print as a group of crooks or damphools as Mr. Bruhl presents them. If Mr. Bruhl presents in his mining reports the same perspicuity as in his Munchausenlike yarn, it is a certainty that he never found anything but country rock and gangue.

Five different Chilean gentlemen brought this article to my attention after I myself had read same, and one of them suggested that had the said Bruhl been less "modest," in place of his own photo he might have shown one taken in our city which he says "is unattractive and in some places smells bad" (*vide* Pell and Mott Streets and some of the N. Y. tenement districts). Not a word about the cleanest, healthiest port on the west coast. No mention of its 64 kilometers of asphaltum paved streets, its wide sidewalks, its 120 kilometers of sewer system, all put down in solid rock, as we have little or no soil here—making it very costly. Nothing is said of its well-lighted streets which would be a credit to any town in the world, of a dozen or more substantial banking and commercial buildings, of the street cleaning department and our own "white wings," compressed-air street-washing machines. Furthermore, there is more than half a mile of a beautiful driveway, to say nothing of an excellent supply of water, brought 327 kilometers by the Antofagasta & Bolivia Ry. Co., and from an elevation of 13,600 ft.

On his trip he also rode in comfortable sleeping cars, not quite as luxurious as the Twentieth Century Limited, but clean and comfortable and with an excellent dining car service provided.

All of this to arrive at just *one* thing. We who live in these countries, and especially in Chile, are kept busy trying to sustain amicable relations with the natives. You never heard of an engineer of English, German, French or Italian extraction breaking into print and offering insults to several countries in one article.

For his one trip as described I have personally made a dozen. In twenty years in Mexico, Peru, Bolivia and Chile I have never locked the door to my room or rooms, have never been robbed of a *cobre*, nor was I ever held up or mulcted by a customs officer in any one of the countries named.

Such an article as this can do more harm than all the beneficent influence of such people as Pope Yeatman, W. S. Morse, W. L. Hamilton, T. S. Hamilton, Frank Aller, H. W. Bellinger, and many others. Why? For the same reason that the good that men do lies buried with their bones and their evil deeds live after them.

If you care to publish this for the "pro amistad" end of the game I will be very glad.

Antofagasta, Chile. ATWOOD BENTON.

Pronunciation

Your Bolshevist editor, as you call him in your issue of Aug. 14, makes a reasonable suggestion in accenting "assay" on the first syllable when used as a noun, and on the last syllable when used as a verb, conforming thus with "essay," which is substantially the same word. This principle also conforms with the double pronunciation of such words as the following list, the accent being shifted as the noun, verb, or adjective form is used: permit, contrast, accent, perfect, project, expert, conduct, frequent, export, import, combat, subject, protest, contest, produce, purport, escort, refuse, abstract present, record, compound, progress, traverse, survey, etc. A few words like "address," which keeps the accent on the last syllable, are exceptions.

However, I stand with your correspondent Roswheel and against the Bolshevist editor in their contention about the word "ain't." This unpleasing word has too bad a reputation, I think, ever to become accepted as good form.

At the end of the note under "By The Way" you say that it is a fool thing to use "rime" for "rhyme," but I believe the shorter form is the older and is a perfectly good word. P. B. MCDONALD.

New York University.

How Do You Assay Bauxite?

The discussion of the proper pronunciation of "assay" makes me think of another word, "bauxite," of which the dictionary pronunciation is miles away from that heard out in the open air. According to the authorities it should be called "bozeite," as if it came from Bozeman, Mont. But whoever heard it called that? Why, even professors of mineralogy call it "lauxite," or at least mine did. AL. U. MINY.

New York, N. Y.

PART OF CREW AT REPLOGLE MINE AT COLLAR OF MAIN SHAFT. RECONSTRUCTION OF HEADFRAME TO PERMIT HOISTING FROM THREE COMPARTMENTS UNDER WAY (NOW COMPLETED)

The Replogle Iron Mine Near Wharton, N. J.

Practically Abandoned for Almost Forty Years, Property Now Has Over 300,000 Tons of Ore Broken in Stopes With Development Progressing Rapidly—Two Concentrators Running and Modern Furnaces and Sintering Plant Under Construction

BY A. H. HUBBELL

ABOUT three miles west of Dover, in the highlands of northern New Jersey, and approximately forty miles from New York, the Wharton Steel Co., or Replogle Steel Co., is opening up one of the numerous deposits of magnetite ore that occur in this region. The work is being done on a large scale with the most up-to-date methods and equipment. The ore is lean and high in silica, running about 36 per cent in iron. It is being concentrated, first in a dry mill by magnetic separators, the tailings then being treated in a wet mill on tables. At Wharton, one and a half miles away, two new blast furnaces are in course of erection, each capable of making 500 tons of pig iron daily. The concentrates from the mills at the mine, which is known as the Replogle mine, are being stored at the furnaces together with Lake ores from the Marquette and Cuyuna ranges, awaiting the completion of the plant. The Wharton company, together with the Wharton & Northern R.R., is entirely owned by the Replogle Steel Co., that was incorporated on Oct. 30, 1919. The last is merely the holding company.

New Jersey was formerly far more important as a producer of iron ore than at present, the peak of production having been reached in 1882, when the output was about 932,000 tons. The decline since then was owing to Lake ore competition at the then low freight tariffs and also to the fact that magnetic separation and other methods of concentration had not been developed to today's high efficiency. At the present time, operations in the state are confined to five companies, including the Wharton (or Replogle) company. The other four are: The Ringwood company, with mines at Ringwood; the Empire Steel & Iron Co., operating at Mount Hope and Oxford; the Thomas Iron Co., working the Richard mine at Wharton, and the Beech Glen mines.

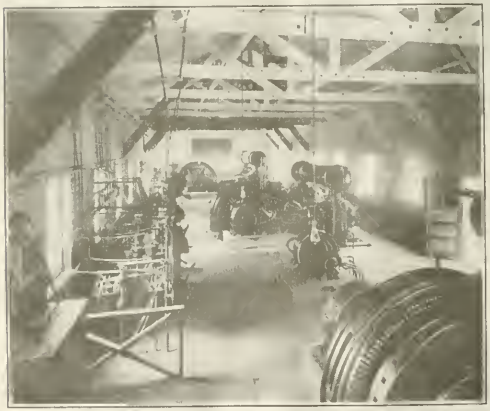
The holdings of the Wharton Steel Co. comprise about 5,000 acres in Randolph and Rockaway townships, of which the fee is owned by the company, and the mineral rights on an additional extensive acreage. In this tract are included about twenty-nine old mines or workings, which with one exception, the Replogle, are closed down. The old Richard mine of the Wharton company, which has been worked for over sixty years and has produced approximately 4,000,000 tons, has been sold to the Thomas Iron Co. Of the properties still included in the holdings the Hibernia has produced over 5,000,000 tons. The Dickerson tract of 385 acres has recently been acquired.

Before the Replogle company took over the Wharton Steel Co. the mine it is now working was known as the Scrub Oaks. The first shallow shafts on this deposit, according to W. S. Bayley, of the New Jersey Geological Survey, were sunk prior to 1868. By 1881 the mine had yielded about 56,000 tons of ore, from which date it remained practically abandoned until July, 1917, when the Wharton company undertook to prospect the ground with the diamond drill. Since then this deposit has been proven to a depth of 1,240 ft. and the probable existence of nearly 27,000,000 tons of iron ore demonstrated. Compared with the present workings and plans the old stope existing prior to July, 1917, is negligible. By the end of 1919, two and a half years later, when the Replogle company took control, the Wharton company had 109,000 tons of ore broken in stopes, no shipments having been made.

Some idea may be gained of the way in which opera-

1. REPLOGLE MINE PLANT, SHOWING ENLARGED HEADER AME AT NO. 1 SHAFT. 2. DWIGHT-LLOYD SINTERING PLANT (SEPT. 15) UNDER CONSTRUCTION AT WHARTON FURNACES. 3. FURNACES AND ORE YARD AT WHARTON, N. J. 4. TAILINGS RECLAMATION PLANT AT REPLOGLE MINE. 5. GENERAL VIEW OF CONCENTRATORS AND CRUSHING PLANT AT MINE, NO. 1 HEADFRAME IN BACKGROUND. 6. NO. 2 SHAFT AND SINKING CREW

tions are now being conducted by the fact that since the first of the year about 200,000 tons has been added to the tonnage broken in stopes, this all on the first level, which has been opened for a distance of about 2,500 ft. from face to face. The second level is in process of being opened up. The main shaft has been enlarged to four compartments, the headframe correspondingly altered, and a hoist capable of working from 1,800 ft. depth has been purchased. The dry concentrator has been supplemented by a wet mill of a capacity of 2,000 tons per 24 hours. About 875 to 1,000 tons of crude ore is being crushed per day at present, which production was doubled commencing Oct. 1. A modern change house to accommodate 500 men is being erected at the mine. Three old furnaces at Wharton have been torn down, one of them scrapped and the two others completely rebuilt on new foundations, at a cost of nearly $3,000,000. The equipment that is being installed is thoroughly up to date. The present operators apparently are optimistic as to the possibilities, all things



COMPRESSOR BUILDING AT REPLOGLE MINE

considered, of these lean ores and are planning on broad lines for the future.

The orebody of the Replogle mine is a lens, or vein, of magnetite in gneiss. It strikes N. 33 deg. 7 min. E., dipping 55 deg. southeast, and pitches 18 deg. northeast. The geology of these deposits of the highlands is discussed at great length by W. S. Bayley in Vol. 7 (1910) of the Reports of the Geological Survey of New Jersey. All the lenses in the mineralized belt have the same general strike. In the Replogle orebody there is no definite contact between the ore and the gneiss, there being instead a gradual change from one to the other. It is claimed that as the magnetite becomes more and more disseminated it is possible to distinguish commercial ore without resorting to systematic sampling.

Considerable diamond drilling has been done by the Wharton company before and since it was taken over by the Replogle interests. The orebody, as stated before, pitches 18 deg. northeast. A hole put down to the southwest has cut ore at a depth of 1,240 ft. measured on the dip. Considering the pitch of the deposit, this represents deeper ore than any yet proved elsewhere. On the Brevoort vein the last hole drilled showed ore at a depth of 600 ft. on the dip and other holes are being put down. All diamond drilling is done under contract by the Sullivan Machinery Co., which has two drills going at the present time.

Non-Magnetic Ore Compelled Erection of Wet Mill

Trouble was experienced in operating the dry mill, where low intensity magnetic separation is employed, the cause of which turned out to be that a considerable part of the iron mineral is martite (Fe_2O_3) instead of magnetite (Fe_3O_4). It was for this reason that the wet mill was erected. The martite and magnetite are so mixed in the ore that it is not possible to mine them separately.

The deposit is opened through two shafts, No. 1 and No. 2, both following the approximate 55-deg. dip of the orebody. No. 1, the main shaft, is now down 311 ft., or 80 ft. below the first level, and is located 100 ft. in the foot wall. It has four compartments, each 6 x 6 ft. in the clear, 10-in. oak timber being used. Sinking is under way on two compartments to the second level, 275 ft. below the first. When the latter is reached and connection made with No. 2 shaft, shaft No. 1 will be completed to this level by raising the remaining two compartments

No. 2 shaft has two compartments, each 6 x 6 ft. in the clear, and was started in ore about 1,400 ft. southwest along the strike from No. 1. It has reached the second level at 506 ft. depth after passing partly through country rock, and a drift has been started toward No. 1. Ore from this development work is hoisted and dumped through an old shaft near by into one of the stopes on the first level. Both shafts are timbered with square sets. In addition, No. 1 shaft is concreted for about 70 ft. below the collar. Aside from the timber used for stope chutes and in the shafts but little of it is used underground.

Shrinkage stoping is employed, stopes being driven the full width of the vein and 400 ft. in length with 50 to 80-ft. pillars in between, in which the manways are carried. There are three such stopes on the first level southwest of No. 1 shaft. In some places the stopes are over 100 ft. wide from foot to hanging wall. Beyond them in the same direction a series of block faults is met which will make stoping difficult where they occur.

Second Orebody Proved Parallel to Replogle Vein

On the other side of the shaft to the northeast the ground is badly broken. After traversing this broken zone for about 800 ft. in a direction approximating N. 65 deg. E. the northeast drift has recently cut a second orebody parallel to the first at a distance of about 400 ft. The existence of this had been shown by diamond drilling. It is known as the Brevoort vein.

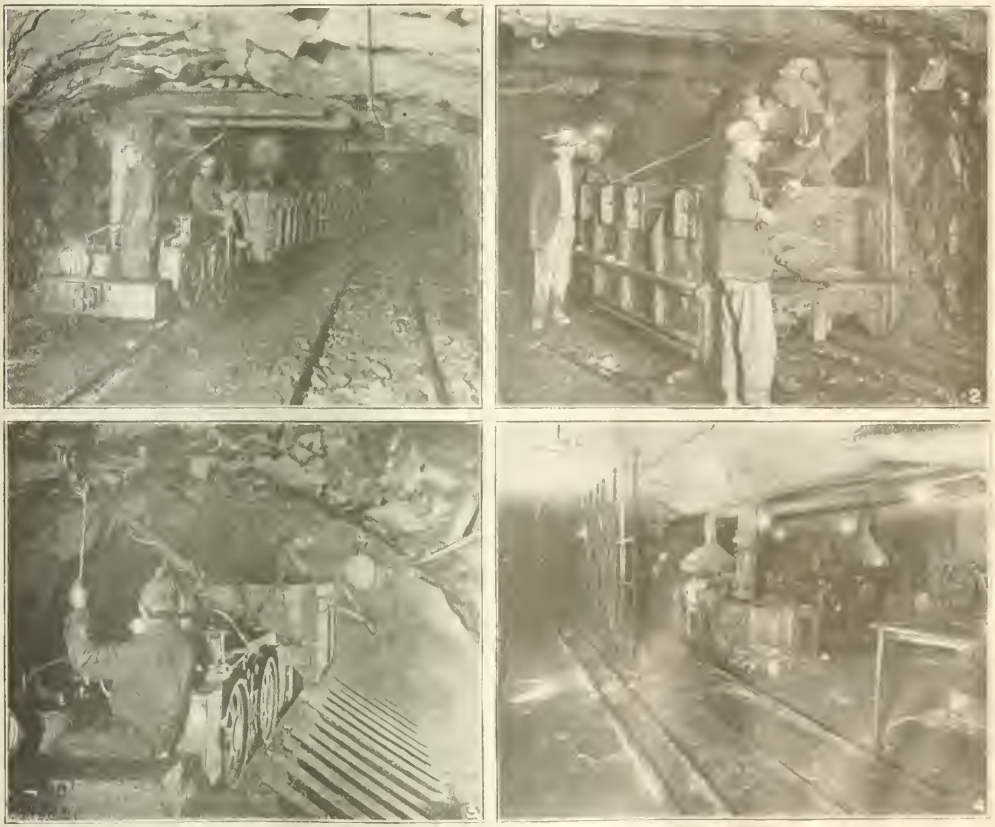
In starting a stope a ten-foot pillar is left over the drift. A sublevel drift is then driven close to the foot wall. Chutes are spaced about 40 ft. apart. Chute grizzlies are made of 105-lb. rails spaced to leave a 10¾-in. opening. Subdrifts were not employed when stoping was first started on this level, so that the muck from the older portions of the stopes must be broken when loading the cars. To obviate the delay in tramming thus caused, the main drift, formerly single track under the stopes, was widened to accommodate two tracks.

At the stope chutes the ore is loaded into 1-ton

70-cu.ft. gable-bottom side-dump mine cars, made by the Easton Car Co., and hauled by electric locomotives to No. 1 shaft, where they are dumped into a 5-ton loading pocket. The grizzly over this consists of 24-in. I-beams cut in half and spaced so as to leave an 11-in. opening.

Three locomotives are in use, one of them being a G. E. 6-ton trolley locomotive. The remaining two are Baldwin-Westinghouse 5½-ton storage battery locomotives which were only recently installed. From six to twelve cars are hauled in a train, the average haul being about 800 ft. Storage batteries are charged once a day under present conditions. The main track is 36-in. gage laid with a grade of 0.5 per cent in favor of the load. Stub switches are used.

All ore is hoisted through No. 1 shaft. The loading pocket is equipped with a measuring box discharging into counterbalanced 2½-ton skips. Hoisting at present is done by a small double-drum geared electric hoist. Equipment is on the way for a new hoisting plant capable of working to 1,800 ft. depth. This will include a Wellman-Seaver-Morgan double-drum hoist, drums being 72 in. in diameter and 60-in. face, with a rope speed of 800 ft. per min. This will be operated by a 350-hp. 2,300-v., a.c. motor and will handle two 5-ton skips in balance. A car for handling men will be installed in the third compartment and will be moved by a single-drum hoist, of 60-in. diameter, and operated by a 140-hp. d.c. motor. Near the shaft, the main drift as it approaches from the southwest branches into two with a pillar between. One track continues straight ahead over the loading pocket. The other passes on the foot-wall side of the pillar and past the underground blacksmith shop and station, connecting again with the first track beyond the pillar. From here the drift runs northeast through the broken ground towards the Brevoort vein previously referred to.

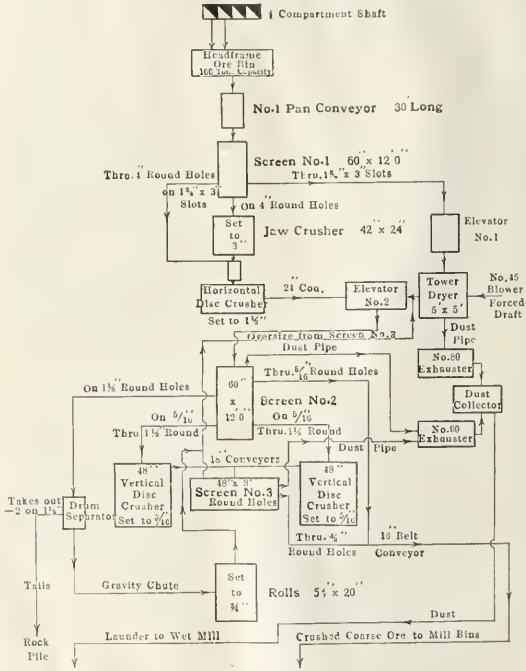


UNDERGROUND VIEWS AT REPLOGLE MINE. 1. MOTOR TRAIN ON FIRST LEVEL (STORAGE BATTERY LOCOMOTIVES ARE ALSO USED). 2. LOADING 4-TON MINE CAR AT STOPE CHUTE. 3. DUMPING INTO LOADING POCKET AT NO. 1 SHAFT. 4. BLACKSMITH SHOP AT FIRST LEVEL STATION

In driving this north (or northeast) drift especially good time was made over a length of 261 ft., which was driven in twenty-six drilling shifts, the formation here being granite. The drift is 9 x 8 ft. in cross section and the work was done with two I-R 24S drills working one shift per day. A wedge cut was used consisting of eight 12-ft. cut holes, the remaining eight holes in the round being 11 ft. long. Sixty per cent gelatine was used in the cut holes and 40 per cent gelatine in the rest. No. 8 caps were used and the round shot with fuse. In drilling, a 24-in. starter was used with a five-eighth-inch

drop in gage and an 18-in. run. A view of the set up in the heading is shown on the front cover of this issue. Powder used averaged 19 lb. per ft. advance. The cut holes were started as close to the rib as possible, the drills being mounted on columns.

All drilling is done by machine. Water Leyners, Denver Turbro and I-R 248 drills are used in drifting, Waugh 73 and I-R—CC 10 drills in stoping, and DDR 13 Jackhamers in sinking. In sinking No. 1 shaft an ordinary pyramid cut is employed, one-inch hex. steel being used with a one-eighth-inch drop and a 1-ft. run. Water for the drills is obtained from a diamond-drill hole from which it is piped to a tank. Compressed air is used to raise the water pressure. The mine makes but little



FLOW SHEET OF CRUSHING PLANT AT REPLOGLE MINE

water, in all about 50 gal. per min., which is pumped out twice daily with a Worthington 4-stage direct-connected electric driven pump, having a capacity of 1,000 gal. per minute. A second pump of the reciprocating type is held in reserve. An Armstrong "Shuveloder" has recently been installed.

Powder is stored underground in a concrete-lined magazine, lighted and heated with electricity. It is kept in separate racks according to grade. Three grades are used, namely 60 per cent gelatine for cut holes in development work, 40 per cent 1¾ in. in stopes, and 40 per cent 1 in. in block holes.

The blacksmith shop is underground. Space has been made for it at the station on No. 1 level. Its equipment includes two I-R 50 sharpeners, two punchers and two Case oil forges (at present using coke). The oil used in tempering the steel is cooled by being pumped through the tank of water used for quenching. The latter is kept cool by being constantly renewed.

The equipment of the power house, which serves the mine and the two mills, includes three motor-driven compressors, namely, one I-R 3,400-ft., 20¼—32 x 24 in.; one I-R 1,900-ft., 15¾—25 x 18 in.; and one Chicago-Pneumatic 1,700-ft., 23—13 x 16 in.; also a 150-kw. 250-v. 60-cycle rotary converter and a synchronous motor generator set consisting of 200-kw., 125-250-v. generator and 290-hp., 2,300-v., 60-cycle motor.

Electric power is supplied by the New Jersey Power & Light Co. Current at 440 v. is used for pumping, at 110 v. for lights and signal system, and at 250 v., d.c., for the electric locomotives and magnetic separators. Mine telephones are in use.

At present about 300 men are employed on operation and construction work at Replogle mine. The mine and crushing plant are running two 8-hour shifts and both mills are working three shifts. About fifteen men are employed on crushing and concentration on two shifts and seven men on the third shift.

The present capacity of the dry mill is 100 tons per hour and of the wet mill 80 tons. Eventually the former will be able to treat 120 tons per hour. The ratio of concentration of both mills combined is 2: 1, though the wet mill, considered by itself, is working under a more favorable ratio. Roughly speaking, out of every 100 tons of crude ore fed to the dry mill 30 tons is removed as dry concentrates, the balance going to the wet plant.

The dry concentrator was built in September, 1918, and has been in commission since then, except for a period of five months in 1919. Poor recovery resulting from the presence of non-magnetic martite, as stated before, led to the building of the wet concentrator, which was placed in operation in March of this year and was run on an experimental basis until June, since when it had been on an operating basis. The flow sheets of both mills and crushing plant are shown in the accompanying illustration. With reference to the crushing plant flow sheet it is planned to install a second Mitchell screen and two more drum separators. It is also intended to do the coarse crushing underground, where a 30 x 42-in. crusher will be installed on the second level.

The wet mill is laid out in eight units, each of which follows the flow sheet given. Every unit is independent of the others. The type of drag employed is the Federal Esperanto. The magnetic separators used in the dry concentrator are of the Ball Norton type and were constructed by the company itself.

Wet and dry concentrates were shipped separately to the furnace until Aug. 1, when they were mixed. For the first eight months of 1920 the concentrates produced ran 0.057 P, 60.18 Fe and 12.07 SiO_2. It is planned to re-treat the tailings that were made by the dry mill before the wet concentrator was installed, the final tailings being expected to run 8 per cent Fe.

In a statement issued with the report of the Replogle Steel Co. for the half year ended June 30, W. H. Brevoort, president, said: "The new freight tariffs will increase the cost of delivery alone on 50 per cent Lake ore to the Eastern District to approximately $5 per ton, which sum is more than sufficient to cover the entire cost of producing Replogle 60 per cent iron concentrate."

Much New Construction Work in Progress

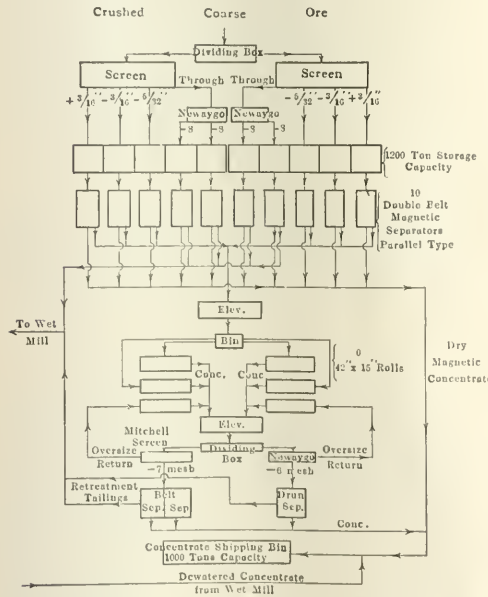
Considerable new construction is under way at the surface plant at Replogle mine. A change house that will

accommodate 500 men and will be as up to date as possible is already partly constructed. A tailings reclamation plant, shown in the photograph, is nearing completion. By means of this it will be possible to draw off the tailings at any point of the dump by means of a belt conveyor that runs the length of the concrete conduit at the base of the trestle. This conveyor will discharge directly into railroad cars. The tailings sands are said to have proved excellent for making concrete, and have been used in the construction work in progress at the Wharton furnaces. It is believed that they can be readily marketed in competition with the output of local sand pits.

Installation of a primary water system is almost complete. By it will be afforded a supply of 300,000 gal. water per 24 hours taken from the mine and a canal in the vicinity. A new system for reclaiming the mill water has also been installed.

Stocking Lake Ores at Furnaces

The concentrates are hauled to the Wharton yards to be weighed and thence to the furnaces, a total distance of 2½ miles. The rail distance to the furnace direct is but 1.3 miles. In the ore yard about 23,000 tons of



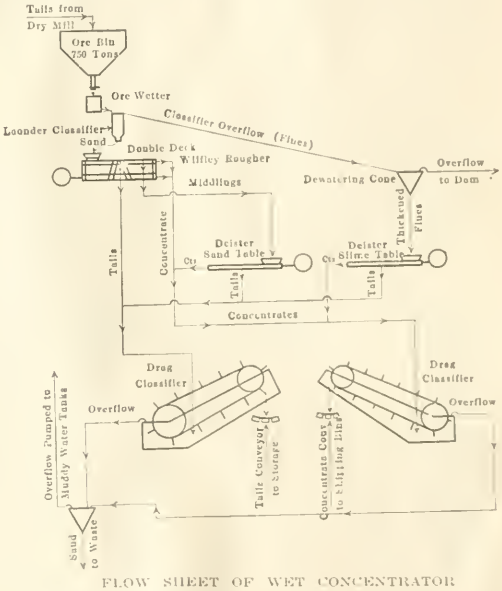
FLOW SHEET OF DRY OR MAGNETIC CONCENTRATOR

concentrates is stocked at present. Lake ores are also being accumulated, about 75,000 tons having been stocked to date. These are of a non-bessemer grade for foundry irons and run about 50 per cent iron.

Remodeling the furnaces at Wharton was started Dec. 12, 1919. The superintendent in charge of construction is S. C. Carter. Prior to the date given the plant comprised two blast furnaces, nominally rated at 500 tons capacity each but actually of smaller output, and one old hand-filled furnace which has been scrapped. The two blast furnaces are being completely rebuilt on new foundations. When completed the plant will have an actual capacity of 1,000 tons of pig iron per 24 hours. A casting machine made by the Pittsburgh Coal Washer Co. will be used. There will be three 100-ton mixer type ladles made by the Treadwell Engineering Co. The ore yard storage capacity is 275,000 tons and an ore bridge is being erected.

A sintering plant of 800-900 tons capacity per 24 hours is under construction. Two Dwight-Lloyd type "B" roasters, each of 400-450 tons capacity, will be installed. These will sinter part of the Replogle concentrates, as well as flue dust from the furnaces. An accumulation of flue dust from several years' operation of the old plant will also be treated.

Twenty 350-hp. gas-fired Sterling boilers are being



FLOW SHEET OF WET CONCENTRATOR

installed in the new boiler plant. The engine room equipment includes six Southwark engines with Iverson air heads, each with a capacity of 384 cu.ft. of air per revolution. These can be speeded up to 50 r.p.m. A new 1,000-kw. Corliss-driven Westinghouse generator is also being installed. The pumping equipment will include one Laidlaw-Dunn-Gordon 1,000,000-gal. pump and three 1,500,000-gal. Worthington pumps.

In all, about 200 men will be employed at the furnaces when the plant is completed. Lime for fluxing will be obtained from the company's quarry at Ogdensburg, N. J., which has a 1,000-ft. face 70 ft. high.

Welfare Work Not Neglected

The Replogle Steel Co. is paying due attention to welfare work. This is supervised by a welfare superintendent, who divides his time between the furnaces and the mine. In the course of his duties he keeps check on living conditions and follows up injured cases. First aid lectures are given once a month at the mine office by the company doctor. A short distance from the mine plant forty houses, constituting the village of Replogle, have been erected. These are four-room structures and are rented to employees at a nominal sum.

The president of the Replogle Steel Co., as well as of

the Wharton Steel Co., is W. H. Brevoort. J. Leonard Replogle is chairman of the board of the Replogle company. L. P. Ross, the vice-president of the Wharton company, is the blast furnace engineer who is to take charge of furnace operations. The members of the mine staff are as follows: A. B. Menefee, superintendent of mines; L. L. Kirtley, assistant superintendent in charge of mills; Warren Davenport, mill foreman; Mr. Van Falkenburg, mine foreman, and William Dressler, master machanic. L. A. Blackner is chief engineer at the mine and W. R. Canton mill clerk. H. J. Briney is furnace superintendent at Wharton. The data given in this article and most of the photographs were readily obtained through the courtesy of the company and the administrative staff at the time of my visits to the property.

South Africa's Mineral Production Increasing

The production of minerals in the Union of South Africa for 1919, according to Vice-Consul Charles J. Pisar, was valued at $247,418,338, or $17,624,484 more than in 1918, when the production was valued at $229,793,854. The production of gold showed a decrease of 86,566 oz. over the previous year, but the output of silver, diamonds, and coal was slightly increased. The

	1918		1919	
Minerals	Tons	Value	Tons	Value

Gypsum	2,638	33,301		
Totals		$229,793,854		$247,418,338

(a) Fine ounces. (b) Carats.

copper output recorded a further decline of nearly 2,000 tons over 1918, and about 15,000 tons over 1917. This was due principally to the closing down in May, 1919, of the mines operated by the Cape Copper Co., in Namaqua Land, on account of the increased operating expenses, the difficulty in obtaining freights, and the fall in the price of copper. The table is a detailed summary of the mineral output for South Africa for 1918 and 1919.

Silver Prices Lower in Canada

The quantity of silver marketed during the first half of 1920 in Ontario, according to the Ontario Department of Mines, was considerably less than the output. An average price of $1.30 per fine ounce was obtained for the first quarter of 1920. For the half year the average New York price was $1.17 for silver in the open market, as distinguished from the fixed price, retroactive to May 13, of $1 per oz. (1,000 fine) under the Pittman Act for metal produced, smelted, and refined exclusively within the United States. For the month of June the average open market price in New York was 90.84c. This disadvantage to the Ontario producer, however, was more than offset by the exchange rate. Since June the export price of silver has risen gradually, until it approaches the quotation for domestic silver.

During the period a total of 4,474,322 oz., worth $5,077,028, was marketed. Of this total 225,513 oz. came from the Miller Lake-O'Brien and Castle properties, at Gowanda, 23,414 oz. from nickel-copper refining operations, and 49,156 oz. from gold ores. Some producers of silver were paid for the cobalt content of ores, concentrates, and residues marketed. In all, $138,317 was received for 296,116 lb.

Extensive Rumanian Salt Deposits

The majority of the Rumanian salt mines adjoin the oil fields, and are situated in the region of the Lower Carpathians, from the Bucovina to the west of Oltenic, a stretch of over 250 square miles. There is sufficient salt to provide for the needs of all the Balkan countries for several centuries. The quality is good.

The Rumanian salt-mining industry, a state monopoly since 1863, is carried on in the following areas, according to *Commerce Reports*: (*a*) Ocna, in the Bakau district, employs about 200 workmen, chiefly prisoners condemned to terms of hard labor. Its pre-war production was about 28,000 tons, at 12 lei per ton. These mines are said to be capable of a total output of at least 400,000,000 tons. (*b*) Ocuele Mari, in the Valcea district, had a pre-war output of 26,000 tons. (*c*) The Slanic mines extend almost unbrokenly for 10 kilometers, and produced before the war 90,000 tons annually. These mines are said to contain about 7,700,000 tons.

It should be realized that in addition to the above mines there are others of lesser importance. A recent calculation places the known salt deposits at more than 10,000,000,000 tons. Owing to lack of organization, the salt export is entirely disproportionate to the production.

Upper Silesia's Metal Production

According to statistics issued by the Upper Silesian Mining & Smelting Syndicate, the number of iron-ore producing undertakings is seven; the production of iron ore, including ore obtained from the lead and zinc mines, amounted in 1919 to 61,469 tonnes, the average price realized being 15.26 marks per tonne. The tonnage produced was less than half the output for the year 1913. The production of calamine was 40,791 tonnes, zinc blende 196,880 tonnes, lead ore 21,950 tonnes, and sulphur pyrites 3,321 tonnes. The output of pig iron amounted to 459,954 tonnes at a cost of 1,581 tonnes of coke per tonne, which compares with 696,146 tonnes pig iron at a cost of 1,395 tonnes of coke per tonne in 1918. The output of the foundries was 20,534 tonnes (29.9 per cent) below that for the preceding year. The production of 50-deg. sulphuric acid in thirteen of the establishments amounted to 121,171 tonnes, as against 260,166 tonnes in 1918. The output of raw zinc was 74,023 tonnes, as compared with 122,961 tonnes in the previous year. The production of lead and litharge was 3,992 tonnes less than the quantity produced in 1918, a fall of 17.7 per cent, and there was also a reduction of 1,098 kilos, equal to 27.1 per cent, in the production of silver.

Hazards Met in Open-Cut Mining

Fewer Dangers at Open-Pit Properties Than Generally Found in Underground Mines—Methods Of Accident Prevention Mainly Those Which Depend on Instruction, Although Safety Appliances Are Used on All Machinery

By D. E. A. Charlton*

SOME years ago, when I was actively engaged in safety work, I made the statement—I do not admit that it was entirely original—that the best beginning that could be made in the development of an accident-prevention program was a careful and systematic study of the accidents which had occurred over a certain period of time at the particular operation or operations where the installation of preventative methods is contemplated. It is to be assumed, of course, that every advantage is to be taken of methods already in practice at similar operations, and for that reason the safety engineer can follow a well-defined plan which will apply to his general problems; but his specific problems, those which are peculiar to his individual operation, will be best determined by the study of the accidents that have occurred about his plant, shop, mine, or whatever the operation engaged in. Having determined the cause, it is then up to the safety engineer to suggest the manner of prevention. Oftentimes it is within his province to put this directly into effect, but at any rate his judgment should be such that possibility a recurrence of a similar accident is reduced to a minimum.

The thoroughness of accident-prevention work in all lines of industry needs no comment here, and it is not the intent of this paper to emphasize what has already been done in the different fields. Those engaged in safety work are all working for a common purpose—the elimination of injury. However, there is the great opporunity for co-operation that we should not lose sight of. If we do so, we become provincial and place ourselves in the class of the man who believes himself sufficient to himself, refuses to accept suggestions, and thereby places limitations upon his accomplishments which are bounded by his own often narrow capabilities. There has been, still is, and will continue to be an immense amount of study given to safety work in every branch of industry, so that it behooves the safety engineer to not only give heed to his own type of accidents and the method of prevention but to those conditions in other fields as well. The idea is simply one which is carried out in any line of work, and its application has been largely responsible for the success that has attended America's industrial progress. By way of illustration: During the recent trip of the American Institute of Mining and Metallurgical Engineers to the Lake Superior region it was most noticeable that the visiting engineers were interested in methods which differed from their own, and the comparison of practices was frequently discussed. This example of course applies to the various branches of mining, but it may well be extended to other industries, any one of which includes features common to all of them.

Open-Pit Accident Percentage Lower Than Other Mining

Open-pit or open-cut mining is free from many of the accidents peculiar to other methods of mining. Although the sources of many open-pit accidents are not present in underground mines, they are, in comparison, in the minority, and it may be said in general that a lower accident rate prevails in open-pit than in underground mines. This is not only true of the average which is based on the number of men employed but also of that obtained on a tonnage basis, for open-pit operations as a rule permit of a greater removal of material than that obtainable through underground methods. The outstanding advantage is, of course, the daylight feature and the relation of this in connection with accident prevention is too well known to the safety engineer to require further comment. It is true that night operations are conducted so that perhaps an additional hazard is introduced. The lighting problem, however, does not present such a serious obstacle as is found in other systems of mining, and present practices have reached a high stage of development, so that there is little difference between the number and seriousness of accidents occurring in the night time and the day time.

In order to obtain an idea of the comparison of the accident rate at open-pit mines and that which holds for all other methods I have reproduced a table which appeared in Technical Paper 252 of the Bureau of Mines, "Metal Mine Accidents in the United States During the Calendar Year 1918," compiled by Albert H. Fay. This shows the number killed and injured in open-pit mines where the ore was mined by steam shovel during the years 1914 to 1918 and includes the returns from typical companies employing about 10,000 men and operating open pits in Minnesota, Alabama,

FATALITIES AND INJURIES AT STEAM SHOVEL OPEN PITS, 1914-1918

	Killed					Injured				
Cause	1914	1915	1916	1917	1918	1914	1915	1916	1917	1918

*A paper read at the Ninth Annual Safety Congress of the National Safety Council, Milwaukee, Wis., Sept. 27 to Oct. 1, 1920.

Nevada, New Mexico and Utah. I have also added the number killed and injured in all methods of mining, (including open pits) per 1,000 300-day workers, for the respective years, these figures being obtained from the same source.

The comparison used is entirely an arbitrary one but sufficiently accurate to show that open-pit mining is not so hazardous as other methods.

It should be understood that the term open-pit mining includes not only those operations where steam shovels are used but those in which other methods of excavation are employed. For our purposes, I shall deal with the former, as I believe all of the hazards met with in the latter will be included in such a consideration. It might be well also, in connection with the above explanation, to add that the development of the electrically-operated shovel will preclude the designation "steam shovel open pits" in any treatment that may be made of open-pit accidents, for the success which has attended the installation of these excavators has demonstrated that they will play a considerable part in the future of the open pits and earth removal.

General Causes of Open-Pit Accidents

In order to consider the various hazards met in open pits, the following classification of causes may be used and each subject can be treated with its relation to the operation as a whole. The scheme of classification follows the subdivision of accident causes which is used by the Bureau of Mines, and it is to the best of my knowledge adaptable to most open pits. All of the accidents can be traced directly or indirectly to all of these causes and a further elaboration will only complicate the study which will be made from the operative standpoint:

Falls or slides of rock or ore.
Explosives.
Haulage accidents (locomotives, etc.).
Steam shovels.
Falls of persons.
Falls of derricks, booms, etc.
Machinery (other than locomotives or steam shovels).
Electricity.
Hand Tools.
Other causes.

Accidents resulting from falls or slides of rock or ore in open pits do not constitute as large a percentage of the total open-pit accidents as do those attributed to a similar cause in a study of those accidents relating to underground mining. The reason for this is quite obvious, inasmuch as the nature of the operation permits better accessibility to the dangerous condition. Not infrequently is ample warning given, the men may be removed to a place of safety, and the necessary steps taken to make the bank safe.

Bank Trimming Prevents Accidents from Falls of Ground

I believe the average slope for stripping banks is 1½ : 1 and it is approximately the same for ore, that is where the overburden is composed of glacial till and the ore is soft such as may be found at the open pits on the Mesabi Range. Rock banks or ore which are of denser structure of course permit of steeper slopes unless the pitch of the strata is such that exceptions must be made. In any event the principal preventive measures which must be taken to avoid this type of accident consist of careful inspection of the banks and proper trimming when necessary. Several factors, such as frosts, blasting, removal of rock or ore from other sections of the pit, etc., may influence falls of banks, but all of these must be carefully guarded against. Several companies employ special men on regular bank inspection work and the results have proved that such precautions have entirely justified the expenditures made. Among the rules which are prescribed by many of the companies who are engaged in open-pit operation is to be found a clause relating to workmen at the front and the bank side of a steam shovel. Although perhaps the rule may apply more particularly to steam-shovel operation, it is most applicable in connection with falls of rock or ore. By remaining on the free sides of the shovel during its operation, the men are assured of safety, and should their work require them to occupy positions between the shovel and the bank a rigid watch should be kept and the men advised of any movements of ground. Such precautions are easily obtainable during the daytime. During the night shift, unless sufficient illumination is procurable, the difficulty is necessarily increased.

The Use of Shelter Houses in Open Pits

Accidents attributable to explosives are many and varied. Before taking up the subject of the handling and treatment of powder, it may be well to consider the dangers resulting from blasting and some of the precautions necessary. It is most essential at all times that men working in the pit are given adequate protection from flying pieces of rock and ore, which often travel considerable distances. There should be ample provision made to properly warn the men, and this is usually done by means of warning whistles which are blown—a series of short blasts from either the steam shovel or locomotive whistles—for some time previous to the blasting. Following this it should be the duty of the foreman and the underbosses to see that all of the men seek proper shelter. There are a number of types of shelter houses which are in use in open pits. These consist of steel frames lined with ties or houses built of steel plate and reinforced. The latter are undoubtedly more serviceable and can be transported from one place to another without much difficulty. In addition to affording protection to the men the shelter also serves as a point from which the blaster may, if he is using an electric battery, explode the charge, and so perform that operation in perfect safety.

Primitive Thawing Methods Tabooed

The lists of "dont's" which have been given publicity by the manufacturers of blasting powders and which appear in every safety rule book should have adequate perusal and digestion, for they have all been written with a purpose, and apply in open-pit mining as well as in any operation where blasting powder is used.

It is quite essential that proper storage be provided for explosives. Powder magazines must be kept dry and well ventilated, separate houses being maintained for the storage of black powder and dynamite and also for blasting caps, electric fuses and exploders. It is generally specified that these should be located not less than 300 ft. from the thawing house or any occupied building. Standard types of thawing houses are pro-

vided by powder manufacturers and these are in general use where climatic conditions require that the dynamite be properly prepared before using. Their specifications provide a separate housing for the heating, which is done by hot water, steam, or exhaust steam, and the thawing house proper where the explosives are stored. Certain precautions regarding the proper care of the thawing house, such as the removal of drawers etc., are stipulated. The many accidents which have resulted from attempts to thaw dynamite by primitive and foolhardy methods have caused rigid rules to be made concerning this particular proceeding, and there are, fortunately, few instances today where attempts are made to thaw powder by methods other than those stipulated by powder manufacturers or operators.

The transportation of powder from the magazine or thawer house to the working place must be accomplished safely and in a convenient manner. At several mines a special slide or lowering device is provided and from the lower end of this the men in special charge of that part of the work convey the powder to the various points where it is to be used. Properly marked boxes should be used and separate boxes provided for dynamite and for caps and exploders.

Gopher Hole Practice on the Mesabi Range

The general practice as relating to the charging of dynamite does not differ appreciably in open-pit work and is too well known to warrant discussion in this paper. The use of black powder is perhaps not as familiar. In this connection, I am sure the following description[1] of "gopher holing" as used in the open pits will be of interest:

"Stripping banks 15 ft. or more in height are shaken up ahead of the shovel by blasting 'gopher' holes. These holes are started at the toe of the bank and are pointed downward at angles of 5° to 10° from the horizontal. 'Gopher' holing, when first used, consisted in making the holes large enough to permit a man to enter and work, but frequent accident caused this method to be abandoned, and 'gopher' holes at the present time have an average diameter of about 15 in. Loose ground is removed with a No. 2 round-pointed shovel blade, the edges of which are slightly turned up, fitted with a 25-ft. handle of 2- or 3-in. diameter. When a hard seam is encountered, it is drilled with a long auger or with a moil and one or two sticks of dynamite are pushed in with a pointed loading stick and fired with a blasting machine. The loose ground is then removed with the shovel. If a boulder is struck while the 'gopher' is being driven, repeated blasting with 60 per cent dynamite will often shatter it sufficiently to allow the hole to be continued. Where it is impossible to blast through a boulder, the hole is bottomed against it, or new hole is begun, few feet away, depending on the length attained. The limit of length of a 'gopher' hole is about 25 ft."

After the "gopher" has been prepared dynamite is used to chamber the hole, and when sufficient time has been allowed for the interior to cool so that no premature explosion may take place, the hole is loaded with black powder, from five to ten kegs of 25 lb. being used. In order to avoid danger from sparks and other sources the powder is poured into the hole by means of a launder device which is provided with a covered hopper. Usually the blasting is done by battery. This and the foregoing description represents Mesabi Range practice and has, from a safety standpoint, proved most satisfactory.

[1] "Steam Shovel Mining on the Mesabi Range," by L. D. Davenport, *Engineering and Mining Journal*, March 2, 1918.

Rolling Stock Should Be Carefully Safeguarded

In considering the hazards which may be involved in the use of locomotives and other rolling stock and the prevention of accidents from those causes, open-pit operators have been guided to a great degree by practices which have been standardized by railroads and other industrial enterprises of a similar nature. The Interstate Commerce Commission in 1910 adopted a number of regulations governing safety appliance standards on locomotives and these are in effect at practically all open pits. They relate to sill steps, hand holds, uncoupling levers, hand rails, hand brakes, running boards and other appurtenaces. It is, of course, essential that a well-arranged system of inspection be maintained in order that the proper persons be advised of any breach of regulations in this particular, and constant work is necessary to keep all rolling stock in a safe condition, as the usage to which it is subjected is by no means one that defies wear and tear. There is considerable variety to the equipment used, and the manner of safeguarding locomotives, stripping cars, ore cars, etc., will be governed by the adaptability of safety devices to the certain types. Having specified the mechanical means for the prevention of haulage accidents, it is further necessary to adopt certain regulations and provisions which will make for the avoidance of accident from other than mechanical sources. In Bulletin 75,[2] issued by the Bureau of Mines, the following rules have been suggested as governing safe practices for the operation of locomotives and ore and stripping trains:

"Precautions are necessary against collisions, against runaway trains on the steep grades and sharp curves that usually exist, and against the danger of running down men who may be walking on the track. To avoid this last danger trails and walks should be provided apart from the railroad tracks and their use insisted upon. Dangerous methods of coupling and dangerous methods of boarding cars or engines should be forbidden. Nobody should be allowed to ride the ore trains except the train crews. Proper clearances over cars and on the sides should be provided and material should not be allowed to be piled so close to the track as to be dangerous. The men selected to work on the track should be intelligent and alert and should be taught extraordinary caution in looking out for trains. Frogs should be blocked and signs provided at crossings. There should be a strict adherence to safe practice in regard to the use of headlights and rear lights on locomotives and trains, to the sounding of whistles, and the ringing of bells." . . . "There is a certain amount of danger attached to dumping the stripping cars, and somewhat less to discharging the ore cars when the contents are frozen or sticky. Dangerous practices in performing these operations should be specifically prohibited."

These provisions are generally carried out in open-pit practice and modifications to fit specific conditions have been made by the various companies.

[2] "Rules and Regulations for Metal Mines," by W. R. Ingalls, James Douglas, J. B. Finlay, J. Parke Channing and John Hays Hammond. Govt. Ptg. Office, Washington, D. C., 1915.

It was stated earlier in this paper that the recent advances made in earth excavation practice admitted of a broader term than that of "steam shovel." The steam shovel still holds it own and steam as a motive force remains a dominant feature. With the increasing use of electricity and other forms of power, and the adoption of the drag-line excavator and other mechanical means for earth removal the more general term of "power shovels" or "power excavators" might be more acceptable. However, with a few exceptions, the safeguarding of power excavators is very much the same and follows the lines carried out in any shop scheme wherein all moving parts are covered; that is, where it is possible to do so. It is hardly necessary to state that the construction of guards must be particularly rugged to withstand the hard usage which the machinery must undergo. A regular plan of inspection, such as is carried out in machine-shops and other plants where mechanical devices are safeguarded, should be instituted and rigidly followed.

It is quite necessary that the area which is occupied by the shovel be kept clear of material. This is not always possible and particularly so where the shovel is "moving up," but it will be found an excellent rule and one which will be the means of preventing a number of slight accidents. Orderliness in open-pit operation is as necessary for accident prevention as in any other work and should not be neglected.

Accidents from Falls of Persons

The responsibility of mining companies for injuries which occur on their property not only includes the safeguarding of their employees but also extends to those who may have no connection whatever with the company. For this reason it is not only necessary to maintain a careful watch around the entrances and banks of open pits but also to see that sufficient fencing and guard-railing is done. Stairways should be substantially built and provided with hand rails. Test pits or other openings should be properly covered. The practice of bank-trimming, which was referred to in an earlier paragraph, is often carried out under hazardous conditions, as it is sometimes necessary that the men, in order to properly trim a bank or slope, must place themselves in a position where a movement of the ground might cause them to fall or perhaps be buried in a run of rock or ore. To safeguard against this the men are provided with ropes which are placed around their bodies and substantially fastened to some safe point above. This practice is also extensively used in the milling method of mining, which may be regarded as a modification of open-pit operation. In the winter it is especially necessary to keep stairways and other such places free of accumulations of ice which may cause falls of persons.

Under the subject, "Falls of derricks, booms, etc." will be included hazards that are somewhat limited in number. The construction of stripping dumps requires that considerable trestle work be done, and it will be found that accidents result from carelessness in the handling of the timbers used in the trestles. At coal-loading stations, water tanks, and other such appurtenances to open-pit mines, arrangements must be made to properly safeguard all devices used, and instructions must be issued as to the proper methods of operation.

There is little machinery used in open-pit mines other than that included under the head of steam shovels and rolling stock. There is, of cource, the machine shop, the blacksmith shop, and the other departments at which the necessary repair work must be done, but the hazards to be found at any of these are well known and do not differ from those met with in general shop practice. The same efforts which are applied in the latter should be the rule in the shops of the open pit. Small hoists, compressors, machine drills, or other auxiliary machinery used in open pits should receive the same attention, both as to operation and safeguarding, as in underground or general surface operation.

High-Voltage Electricity Not General in Open Pits

Electricity as a motive power, either in driving a shovel or hauling ore or stripping trains, is not as yet in general use, so that the dangers resulting from the transmission of high voltage have not become to any great extent a problem of the safety engineer. In open pits which have reached the stage where steam-shovel removal of ore has been replaced by scramming operations and the ore is removed through a shaft, motor haulage is frequent and here it is necessary that the same precautions used in underground mining be observed. In some instances electricity is used as the motive power for pumps and considerable lighting is done by means of electricity, but in both of these instances methods of safeguarding are well defined and follow the trend of general practice.

Hand Tools Cause Many Slight Accidents

There are few serious accidents which may be attributed to the improper use or condition of hand tools, but as a source of the slight accident they are prolific. The prevention of this type of accident can be brought about mainly by inspection and instruction in the proper use of the tools. There is always the mushroom-head drill to be found, the loose or broken hammer handle, the stilson wrench that is not working properly and any number of small defects which should not be permitted if the men are to do their work safely and properly.

Under "Other Causes" may be included a miscellaneous lot of accidents which result from improper handling of material, explosions (other than those due to blasting powder) and others which do not properly fall into those causes already mentioned. It may be well at this point to mention one factor which has a considerable bearing on the frequency of open-pit accidents. That has to do with labor and, as each operator and engineer knows, with the dependence that can be placed on each workman to look out for his own safety. Open-pit labor, with the exception of the foremen, shovel operators, locomotive engineers, train crews, and such men as are required for certain classes of skilled work, is not required to be of the standard usually employed underground, and it has been drawn largely from foreign fields. In some cases there is, or has been, an unfamiliarity with the English language, a certain sluggishness that has been due to either indifference or timidity, and a rather detrimental effect in so far as the best conditions for obtaining prevention of accidents were concerned. In many instances, this condition has been counteracted by the further employment of such men who would serve as instructors, as bosses, and a lower percentage of accidents to the class of unskilled labor has resulted.

The safety engineer will find much to interest him

in the study of accident prevention and the hazards as met with in open-pit mines. The mechanical safeguarding which can be done is limited, but the opportunity for "safety psychology" presents ever an absorbing problem. Such details as "breaking in" a man on the day shift before he is permitted to work at night, transferring one workman to another place for which he is better fitted and following out other plans which can be determined co-operatively with the foremen, are some of the interesting studies that are open to the safety engineer.

Present System of Lighting in Open Pits Is Improvement Over Earlier Methods

The matter of illumination in open pits is receiving considerable attention. Formerly the practice consisted of obtaining only such light as was possible from the locomotives, lanterns, and gasoline burners on the steam shovels. Later the gasoline burners were discarded as being unsafe and the steam shovels were wired and provided with a small dynamo. This practice exists today and is supplemented by the use of carbide flare lights which provide excellent light. The practice of extending wiring into pits for illumination purposes has not met general acceptance, due to the fact that frequent blasting causes breakage of the globes and arc lights.

All open-pit mines make use of signals which are given from the shovels or locomotives. A specified code is used and by means of this the men in charge may be notified of any happening at the particular point where the shovel or locomotive is situated. The value of such a system to accident prevention methods as used at open pits is undeniable.

A treatise on the subject of safety in open-pit mining would be incomplete without pointing out the use for warning signs, safety bulletins and safety rules. These will necessarily be a large part of any safety campaign, but are too well known to warrant further discussion.

In conclusion, the hazards met in open-pit mines are less than those that may be expected from other types of mines. In general it may be said that the three big causes of accidents in open pits are from falls of ground, explosives, and those due to haulage. Similarly these same causes make up the bulk of underground mine accidents, but the manner of prevention in each case is, by reason of the difference in the mode of operation, different.

I realize that much of the information will doubtless be an old story, particularly to those who have had the opportunity to be in touch with open-pit work. The last few years have brought about notable changes. We have today bigger shovels, bigger stripping cars, methods for handling materials on the stripping dumps, compressed-air tie tampers, and other devices which are producing more effective results. All of these are given close scrutiny from the safety standpoint, and so far as their mechanical make-up is concerned, the operator may rest assured that the manufacturers have considered the necessary points to make them safe for the workman. With improved machinery and devices must come the higher type of workman, so that as a higher intelligence is demanded the possibility of accident from causes due to ignorance, indifference, and lack of understanding is decreased. And this in short should mean a marked decrease in the number of open-pit accidents.

Encouraging Outlook for South African Iron Industry

Considerable importance was attached to the establishment of a blast furnace at Pretoria, South Africa, in 1918, according to a report of the Bureau of Foreign and Domestic Commerce, for the purpose of producing pig iron from domestic ore. This furnace has a daily capacity of ten to fifteen tons; and though it was in the nature of an experiment, the results obtained were so successful that the promoters now intend to place the industry on a firm and permanent basis. Several other furnaces began operations in the Transvaal, and a company for the same purpose was organized in Natal during 1919.

In pre-war days nearly all of the pig iron used in South Africa was imported from Great Britain, the price there being so low that it was not profitable to exploit the local resources. The war conditions induced local capitalists to exploit the iron deposits in South Africa, but for a time considerable doubt was expressed as to whether it was economically feasible to produce pig iron in the country.

The industry is said to have passed now beyond the experimental stage, and it is claimed that pig iron can be turned out in South Africa at a lower cost than in the United States or Great Britain under post-war conditions. The promoters express great confidence in being able to supply the domestic demand, besides competing in foreign markets.

Fuller's Earth Production Increased in 1919

About 106,000 short tons of fuller's earth, valued at $2,000,000, or $18.87 a ton, was produced in the United States in 1919, as shown by preliminary returns made by the producers to the U. S. Geological Survey. These figures are the highest yet recorded by the Geological Survey, and show an increase of 217 per cent in quantity and of 563 per cent in value in ten years. The increase in quantity in 1919 compared with 1918 was 25 per cent and the increase in value was 74 per cent. The average price per ton increased from $13.57 in 1918 to $18.87 in 1919. Florida, which has long been the leading producer, made nearly nine-tenths of the output in 1919.

The imports of fuller's earth in 1919 were 13,873 short tons, valued at the port of shipment at $189,711, or $13.67 a ton, an increase of 10 per cent in quantity and of 15 per cent in value compared with those in 1918. The increase in the average price per ton was 54c. The imports in 1919 compared with those of the year of greatest imports, 1914, when the entries amounted to 24,977 tons, valued at $195,083, or $7.81 a ton, show a decrease of 44 per cent in quantity and of 3 per cent in value.

South Australian Barytes Deposits

Important deposits of barytes (99 per cent barium sulphate) are reported by Consul Starrett, Adelaide, as now being developed at Noarlunga, about 25 miles from Adelaide. Certified analysis of samples of this product has proved it to be of unsurpassed purity. Barium sulphate is an established ingredient for many kinds of paints, and the exploitation of these extensive deposits should greatly relieve the prevailing shortage of paint supplies.

A Trip to Porto Rico

Island a Motorist's Paradise, but No Place for Mining Engineers Except on Vacations

By Allen Murray Yonge
Written for *Engineering and Mining Journal*

THE policy of the Spaniards who first came to the rich little island of Porto Rico was heartless from the start. According to historical accounts, they enslaved the natives for field and mine work and drove them so cruelly that, at the end of fifty years, the entire race had either died from overwork or fled from its fate. From this, one would naturally suppose that the island abounded in mineral wealth and especially in the precious metal, gold, but such, however, is not the case, although some mineral does exist and along several rivers of the island placers were once worked. One is led to surmise that the first Spaniards practically made "a clean-up" of all the gold early in the sixteenth century, although the peons living along the rivers named Corozal, Negro Mavilla and Morovis wash the sands of these streams when they have no agriculture

ROAD FROM CARFAÑO TO BAYAMON, PORTO RICO

work. Their recovery of the metal, however, is very small.

There are some small deposits of iron on the island, though none of magnitude, and good copper specimens may also be found. But there is nothing to indicate anything of promise. The occurrences referred to are in the states of Naguabo, on the east, and in San German, on the west. Lignite has also been discovered in the central range of mountains reaching from the town of Moco to Corozal.

My trip to Porto Rico was for the purpose of examining the supposedly large manganese deposits of Juana Diaz, which lie on the southern slope of the mountains, 950 ft. above the sea and about fourteen miles north of Ponce, the southern seaport. Two miles away is the Camino Real, or military road connecting San Juan, the capital of the island, and Ponce.

The ore at Juana Diaz lies on or near the surface in the form of manganese oxides, running from 48 to 56 per cent Mn and occurring in pockets containing from 10 to 1,000 tons. These pockets, or kidneys, are entirely imbedded in the weathered marble, the latter making up the very mountains themselves.

HARBOR OF SAN JUAN, PORTO RICO

The extent of the pockets can only be approximated, and little development can be done in advance of actual mining of the ores. It is my belief that but a small tonnage yet remains to be won, as extensive prospecting has been done and nothing of promise found. About 5,000 tons of manganese ore has been mined, and perhaps an equal amount may yet be taken out. The actual mining is cheap, and workmen are plentiful at from $1.50 to $2 per day. The cost of a ton of the ore delivered in the United States is as follows: Stripping and mining, $2; sacking ore, 75c; sacks, 75c; transportation, pack animals to foot of mountain, $7.50; truck to Ponce, $1.25; lighterage to ship, $2; and ocean freight, $8.50; a total of $22.75. About thirty tons per working day is being mined and shipped to port, but indications are that the ore will be exhausted soon.

Porto Rico is a motorists' paradise, with its network of perfect roads from one end of the island to the other. One can go anywhere beneath an arch of beautiful laurel that also borders a perfectly made macadam road, passing between fields of tobacco and sugar cane, or along cliffs where superb views of the little valleys and picturesque villages below are to be had. The roads are alive with motors and trucks of many kinds and days can be devoted to delightful trips.

Americans should experience great satisfaction in visiting Porto Rico, for they may take a just pride in the evidence of prosperity and contentment to be seen on every hand. Cleanliness prevails everywhere. Through the efficiency and good administration of the resident United States and native officials a new and efficient sanitary system, water supply, electric lights, street cars, schools and wharves have been created.

ONE OF PORTO RICO'S HOTELS, THE VANDERBILT

The Manufacture of White Arsenic

Details of Experimental Work Carried On in an Effort To Obtain a Dense White Product Free From Antimony and Lead — Proper Draft Regulation And Deep Cooling Chambers Found Essential

By E. C. Williams
Written for *Engineering and Mining Journal*

THE objective, in the work to be described, was a dense white arsenic, but in experiments made to secure this, a method for producing refined As_2O_3 (over 99 per cent) in one operation was developed.

The name arsenic furnace will be made to do double duty. Properly, it consists of a small reverberatory furnace connected to cooling chambers. The furnaces were fired with coke and charged with blast-furnace flue dust and Cottrell plant product, assaying as shown in Table I.

TABLE I. ANALYSES OF FLUE DUST AND COTTRELL PRODUCT

Per Cent	Pb	Cu	SiO_2	Fe	CaO	S	Sb	As
B.F. flue dust.....	7 0		5.0	9 0	3 9	3 0	1 2	24.0
	to	0 02	to	to	to	to	to	to
	29 0		10 0	10 0	4 0	3 4	2 0	40 0
Cottrell Product.....	1.5		0 40	0 8	1.0	1 6	1 0	54 0
	to	0 06	to	to	to	to	to	to
	19 0	. .	11 3	1 0	1.2	2 3	2 0	74 0

Three different types of cooling chambers were experimented with. One which will be referred to as No. 1 type consisted of a straight flue 115 ft. long from which five wings, each 33 ft. long, extended at right angles, the first wing having two furnaces connected, the last two double decked. The straight flue had no baffle walls but a butterfly door deflected the fumes through the wings. Each wing was divided by a wall, the fumes entering one side and passing out the other to the straight flue again, giving a travel of 66 ft. in the single- and 132 ft. in the double-decked wings. The wings had baffle walls 5 ft. 6 in. apart, making rooms 54 in. high x 34 in. x 66 in. Whenever height is mentioned, that over 3 ft. 6 in. is meant, this being the height of an archway which the cars passed under to receive the As_2O_3. These "rooms" will from time to time be referred to by the door numbers, each room having a door and each door numbered in rotation, starting at the furnace.

The type of furnace described gave very unsatisfactory results. The fumes had to pass through a tortuous passage, 600 ft. long, before reaching the main smelter flue chamber. As a result, the draft, which was created by motor-driven fans at the outlet, had to be very strong to have the proper effect back at the furnace. The As_2O_3 derived from this furnace carried high impurities, Sb averaging from 1 to 7.50, and Pb 2.0 per cent.

Another furnace, No. 2, had a straight chamber 155 ft. long, 8 ft. 10 in. high x 8 ft. wide; the baffle walls were 4 ft. 6 in. apart, the passageway for the fumes being 30 in. wide and the height of the chambers.

No. 3 furnace was a composite of the other two. The first 65 ft. of the chambers measured 9 ft. high x 7 ft., then sloped down to 6 ft. x 7 ft. for a length of 200 ft. The first part had no baffle walls, whereas the latter part did.

The products of all three furnaces were mixed in one bin and conveyed by a screw-and-belt elevator to the ball mills of the barreling machine. The barrels were of 30-gal. capacity, the average net shipping weight being about 190 kg. The individual barrel weights showed a wide discrepancy, varying from 120 to 250 kg. net. As a first step in an effort to increase the density of the product, a sample barrel was taken from each furnace for several days. No. 2 type showed a consistently high figure, varying from 211 to 242 kg.; No. 1 from 140 to 206, and No. 3 from 170 to 208 kg.

Product Varied Considerably in Density

It was soon evident that the density of As_2O_3 varied in different parts of the chambers, so for several succeeding days the sample barrel was taken from the same door, and far less variation resulted, but each furnace gave different results. Further investigation showed—as was to be expected—that the As_2O_3 which was deposited the quickest, i.e., nearest the furnace and in the greatest heat, was the denser, and the farther it was carried, the lighter it became. This statement, of course, is confined to chamber limits.

Next, the total product from each furnace was weighed separately. No. 1 gave a general average of 167 kg. net per barrel, No. 2, 236, and No. 3, 190 kg.

Faulty Feeding Found Responsible

A great variation was found in the daily average weight per barrel from each furnace; also in the daily production. Most of the trouble was finally found to be in the feeding. The labor employed was thoroughly unreliable, with no sense of responsibility whatsoever. A wheelbarrow held 100 kg. of flue dust comfortably, yet, with the class of labor attracted to this kind of work, a hatful was preferable to a full barrow. From three to six wheelbarrows constituted a charge, and the furnaces were charged some two and some three times each eight-hour shift, but the laborers considered it their duty not to charge a furnace except under compulsion. Under these conditions furnace action was quite irregular.

The No. 1 type was charged for a time from the top by means of cars. A plate was removed and the charge dropped by pulling out a slide in the car bottom. This feed was very unsatisfactory, partly on account of enormous clouds of escaping fumes and partly from the fact that the dropped charge packed in the furnace.

When tests proved that the farther As_2O_3 was carried before depositing, the lighter it became, the fact that draft affected density was indicated. Tests were therefore begun on the draft. Greater reliance could be placed on the actions of the No. 2 type, as it had but one furnace connected and consequently responded more accurately to changes.

Draft Found To Influence Impurities

It had long been the custom to take samples of As_2O_3 from certain doors of each furnace every morning and run them for Sb. This was to help distinguish between off- and high-grade As_2O_3. But every change of draft changed the Sb contents at the different doors,

so this indicated that the draft influenced the impurities as well as the density. The doors at which samples were taken were changed from time to time as indications prompted, until Nos. 7, 10, 14, and 20 were finally selected, corresponding to 39, 52, 70, and 95 ft. from where the fumes left the furnace and entered the cooling chambers. The reason for this was that the draft-changing experiments brought about the condensation of fumes at No. 7 door in greater quantity at No. 10; at No. 14 the height of condensation took place; from there on it decreased until beyond No. 20 there was so little it was unnecessary to clean out the chambers oftener than once a week. From No. 20 on, the As_2O_3 always had to be returned, as it was of reddish color. This was long attributed to Se which was present, but it eventually developed that this reddish substance was only the fume carried in the hottest fire. Insufficient charging with a hot fire always produced reddish As_2O_3 in the No. 1 type (shallow) cooling chambers.

When the fumes were condensed as already described, the As_2O_3 showed a very low Sb content with the peculiarity of slightly higher Sb at No. 20 than at No. 14 door. For example:

Door Numbers	Sb	Sb	Sb
7	0.44	0.39	0.40
10	0.40	0.35	0.34
14	0.34	0.34	0.28
20	0.44	0.38	0.30

Working backward and with an easier and more definite guide, when the draft was set to produce the above-described deposit of Sb, the As_2O_3 was condensed within well-defined limits and the net average weight per barrel was increased from 236 to 300 kg. In other words, the specific gravity was raised from 2 to 2.6. Shipments (carload lots) ran less than 0.35 per cent Sb, where formerly the high-grade had averaged 1.00 per cent Sb.

The interesting feature of draft experiments was that the Sb could be brought to so low a quantity in the chambers, whereas with the same material charged, an extreme like this had before presented itself:

Door Numbers	Sb
7	7.05
10	2.14
14	1.08
20	0.90

Draft Controlled by Antimony Percentage

Such excellent results being obtained on the No. 2 type, the draft was adjusted on No. 3 to produce the same deposit of Sb. This reduced the quantity of Sb to the same as that of No. 2 and raised the specific gravity from 1.7 to 2.5. But No. 3 was not as tractable nor efficient as No. 2, which was attributed to the fact that it had several right-angle turns.

Working on the latter theory, experiments were recommenced on No. 1 type. The two double-decked wings were blocked off, which resulted in much improvement in furnace action. Then the other two wings were cut out; the butterfly doors formerly used to deflect fumes through the wings were set at an angle to aid in detaining fume passage; the draft was changed until the required low Sb was produced, so that this type then gave the same percentage of impurities as the others, and raised the specific gravity from 1.6 to 2.2. However, the hot gases passed so closely over the deposited As_2O_3 that a slight failure in proper charging often blackened the product. Shallow chambers required the closest attention to produce even a fair product.

The presence of 0.40 to 2.20 per cent Pb caused much complaint from consumers. Various efforts were made to overcome this—regulating the fire, reducing the amount of air admitted to the grates and leaving an opening of an inch or two in the second door of the furnace (the furnace was charged through the first door), for the admission of cold air to the fumes. The Pb decreased, but the exact reason is unknown.

Lead in Product Reduced by Resmelting

Complaints over high Pb growing more persistent, refining was ordered. By this is meant putting the product through the furnace again. By this means Sb was brought down to 0.30 per cent and Pb to a trace. A pure white product resulted, heavily crystallized in the first half of the chambers. Brilliantly beautiful crystals were formed and would build up like the roofs of a Chinese pagoda, several inches high and often four inches in diameter. One roof would form on top of another with infinite precision and regularity.

In the efforts to secure high density in the product the Sb control for draft regulation was developed, which, along with better organization, automatically lowered the Pb impurities. At one time the morning samples were run for Pb with the following result:

Doors	Pb
7	0.075
10	0.076
14	0.140
20	1.020

It is plausible to think that if no Sb were present, Pb or some other impurity could be used with which to regulate the draft.

The Cottrell plant product was vicious stuff, catching fire seemingly spontaneously. From the time the plant was started, As took fire in the hoppers. At first it was attributed to chemical reactions induced by water sprays in the smelter flue chamber, but these had been used before with no bad results. One day a shovelful of the product was accidentally dropped in a passageway in a strong draft and soon caught fire. Noting this, the hoppers of the Cottrell plant were made airtight, which removed the fire trouble.

Arsenic Might Be Distilled on a Heated Hearth

The combustibility of this material led to an attempt to distill it with its own heat. Fire was drawn from a furnace, and the furnace was then charged. It performed nicely—while the hearth was hot. This might lead to experiments to introduce heat from below instead of passing it over the charge.

Once, evidently through a demand for greater production, another furnace was built and connected to No. 1 type by a flue 2 ft. 6 in. x 3 ft. x 35 ft. On account of this irregularity experiments were made on it which gave excellent results in regard to density, this averaging as high as 2.5. This was before the draft regulation control was developed. Certain physical conditions caused the abandonment of this end of the plant, which prevented further experiments. Earnest efforts were made to test out this flue connection on the deeper type of chambers, but the management was not experimentally inclined.

Difficulty was once experienced with poor draft on No. 2 type of furnace. The furnace was shut down and many tons of crystallized As_2O_3 barred off the baffle walls and ceiling. This did not give relief, so the fur-

nace was again shut down and a systematic search made. Trouble was located in an unlooked-for spot. A small shelf, a support for a fan bearing, had filled up with As_2O_3, thereby cutting off the draft. This cloud, however, had the proverbial silver lining. The back end of this furnace had two tiers of doors, and in the search for the draft obstruction it was noticed that the furnace had a fair draft when the last (top) door was open. Upon starting up again the smelter stack was depended on for draft, and it proved to be entirely sufficient. With slight changes the other types were placed on the same draft. Discontinuance of motor-driven fans seemed to take most of the "grief" from the plant, besides making considerable saving.

BASIC PRINCIPLES OF FURNACE DESIGN AND OPERATION

In summing up, the results obtained developed certain principles, namely, that draft controls impurities and, to a great extent, density; that deeper cooling chambers produced a denser, cleaner and whiter product; that cooling chambers and furnace should be in a straight line—the furnace possibly connected to the chambers by a flue 2 ft. 6 in. x 2 ft. 6 in. x 20 ft. (the length optional, but 20 ft. probably a mean). By a straight line is meant the elimination of all right-angle turns, thereby procuring as great a draft as is possible on the furnace with a minimum in the chambers, the velocity to decrease the farther the fumes travel from the furnace. To accomplish this, the cooling chamber should gradually be enlarged as it leads from the furnace. Taking No. 2 type as an excellent foundation, superior results could be obtained by applying these principles.

Before concluding, it would not be amiss to mention that the best remedy for arsenic fume burns was found to be boracic acid, either powder or saturated solution, though the powder was found the more effective.

Ontario's Gold Production Increasing

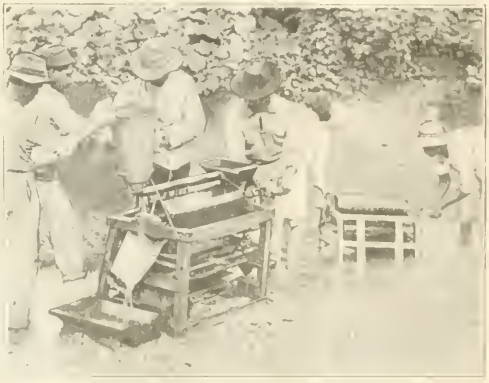
Ontario's position as a producer of gold is becoming increasingly important, according to the Ontario Department of Mines. For the first half of 1920 the output was nearly 22 per cent greater than the 1919 production. Production of gold by individual mines is presented herewith:

Porcupine	
Hollinger	$2,928,079
McIntyre	1,085,298
Dome	989,566
Porcupine Crown	70,017
Dome Lake	46,809
North Crown	31,019
Davidson	13,489
Total	$5,164,277
Kirkland Lake	
Lake Shore	243,977
Kirkland Lake	137,676
Teck-Hughes	125,137
Total	$506,790

From miscellaneous mines the output was $17,138, of which the Argonaut, in Gauthier Township, contributed $16,938. There was also a recovery of gold worth $2,498 from nickel-copper refining operations. In addition, gold mines produced 49,156 oz. of silver, worth $56,364. During the period 673,694 tons of ore was milled. The milling capacity at Porcupine at the end of June was 5,296 tons and at Kirkland Lake 330 tons daily. The 150-ton mill of the Wright-Hargreaves mine at Kirkland Lake is nearing completion.

A Miniature Gold-Washing Plant

The accompanying photograph shows a gold-washing machine used in Cuyabá, which is the capital of the State of Matto Grosso, Brazil. It will be noted that the gold-bearing sands are washed through a contrivance similar to a sand-screen, which carries out the coarse



A 6-MANPOWER GOLD-WASHING PLANT

material, and then they pass downward through a series of sieves or screens, a crude form of various well-known types of mining equipment. The apparatus has the advantage of portability and is somewhat more pretentious than that sometimes found in use by the natives in the backwoods.

Magnesite in New Mexico

A deposit of magnesite that crops out on a steep hillside west of Ash Creek two miles above its junction with Gila River, about thirty miles north of Lordsburg, N. M., was recently examined by R. W. Stone, of the U. S. Geological Survey. The general alignment of the outcrops might indicate that it is a continuous body, 1,000 to 1,500 ft. long and 30 ft. thick, in limestone, but close examination shows that the limestone occurs as a number of detached blocks, none of them more than a few rods long, inclosed in granite and cut by dikes and sills of diabase older than the granite.

The magnesite has replaced certain beds of limestone, but at no place has it yet proved to be 30 ft. thick, as at first indicated. At one place where the deposit has been prospected and has since caved there appears to be a total thickness of 20 to 30 ft. of magnesite and limestone. The best exposure shows only 7 ft. of magnesite in a limestone block 5 or 6 rods long, in which the beds stand vertical. Not all the limestone blocks contain magnesite. The small quantity of magnesite available and the distance of the deposits from a railroad render them of little present commercial interest.

The magnesite is hard, amorphous, and pure white, resembling the variety common in California. It is believed to have been derived from the diabase.

Manganese in Brazil

Deposits of high grade manganese ore totaling 120,000,000 tons are available for development in the State of Matto Grosso, Brazil. The ore is reported to average 45 per cent.

Mining Engineers of Note

John Uno Sebenius

IN NORTHERN MINNESOTA, before the present-day status of open-pit mining was reached, the neophyte referred to the system of mining then in practice as "iron-ore farming." The visitor of today, whether he is familiar with the methods used on the Mesabi or totally ignorant of them, cannot fail to be impressed with the great strides that have been made and the wonderful improvements now in evidence. This is true not only of open-pit practice but in underground mining as well. It is not mentioned in all of the histories of the Mesabi that John Uno Sebenius was in a true sense a farmer—in addition to his other activities—but those who knew him in the early 90's, when the importance of the range was scarcely realized, still speak of the potato patch and the garden that formed a prominent part of his exploration camp at that time. He was one of the first to realize the tremendous possibilities of the district as an iron-ore field, and it is due in no small measure to his efforts and accomplishments that the Mesabi Range has far outlived the "farming" stage and stands today as the greatest iron-ore producing region in the world.

JOHN UNO SEBENIUS

Mr. Sebenius came to the United States in 1888 from Sweden, where he had been graduated from the Royal Institute of Technology and the School of Mines at Stockholm two years previous. The following year he was engaged as geologist and mining engineer for the Ayer estate, of Boston, Mass., and did considerable work in northern Michigan. In 1890, Mr. Sebenius was appointed assistant superintendent of the Witherbee, Sherman & Co. mines at Lake Champlain, N. Y., and for the two years following he had charge of the erection, installation, and operation of their magnetic concentration plant, which at that time was the largest and most successful installation of that type in existence. In the fall of 1892, he went to Minnesota and began a series of extensive trips through the Lake Superior ranges, and it was at this time that his first general examination of the Mesabi Range was made. After serving in a consulting capacity for the Rouchleu-Ray Iron Co., and later for the Lake Superior Consolidated Iron Mines, he became, in 1901, identified with the Oliver Iron Mining Co., the iron mining subsidiary of the newly formed United States Steel Corporation, as mining engineer and superintendent of explorations. In 1905, he received the title of general mining engineer of the Oliver Iron Mining Co. and has occupied the position since that time. During his work on the Mesabi Range, Mr. Sebenius has always been fully informed as to the geology, structure, and developments in that district. His travel and investigation in connection with mining operations have given him ample opportunity to observe practices in other sections, and he is recognized as one of the foremost authorities on iron-ore geology and mining. An evidence of this was his appointment, during last year, as a consulting engineer of the Bureau of Mines. Mr. Sebenius has always taken an active part in public affairs. During the administration of John A. Johnson as Governor of Minnesota he served as a major on his staff, and also held the rank of colonel on the staff of Governors Eberhardt, Hammond and Burnquist. He is a member of the American Institute of Mining and Metallurgical Engineers, the American Society of Swedish Engineers, the Lake Superior Mining Institute, and the Duluth Engineers Club. He also holds memberships in the following clubs: Kitchi Gammi, Commercial, Northland Country, Duluth Curling, Duluth Boat, and the Norroena (of which he is president) of Duluth, and the Minneapolis Athletic and Odin clubs of Minneapolis.

The strenuous out-door life which Mr. Sebenius followed in the early days fostered in him the love of the open, and even today the pleasure of his work is divided, when time permits, with hunting and fishing trips and other outdoor recreation that the North Country so well affords. Mr. Sebenius' keen interest not only in professional but in civic and industrial matters is an example which engineers may well emulate. He is a consistent booster for professional ethics, the bigger fields for the engineer, and the outdoor existence that keeps one physically fit and makes life worth while.

BY THE WAY

A New Use for Explosives

The *Official Gazette* of the Patent Office rivals the old oaken bucket as a source of innocent pleasure. There is always something novel in it. It is the shop window where the latest product of man's genius is laid before the public. Had it been published in Solomon's time he would never have written that there is nothing new under the sun. Everything has come its way or will come sooner or later. It has something in each issue that will appeal to every mood or fancy, whatever be the pursuit of the reader. Were it sold by subscription, what selling arguments were possible! Occasionally a critic may pause to exclaim "Can such things be!" but he immediately resumes, knowing well that they can or they would never have gotten into the *Gazette*. For example, patent No. 1,347,005 covers a device for the prevention of pocket picking. The inventor is Francesco Bini, of Milan, Italy. At once it comes to mind that pickpockets must be numerous in Italy. At any rate, Mr. Bini thinks so well of his invention that he is seeking a patent in the United States. Translating the description in the *Gazette* into English, as nearly as we are able, we find that the device carries an alarm consisting of a charge of detonating material that will go off when the pickpocket inserts his hand into his prospective victim's pocket. This is really clever. How one invention is but the stepping stone to another! Mankind progresses by degrees. This device was truly born of a depth bomb mated with a mouse trap. Let the libraries and archives perish so long as the *Gazette* be preserved and the history of human achievement can be rewritten from its pages.

Dignity Wounded

Speaking of the recent bomb explosion, the *Evening Sun* says: "To destroy Wall Street would require a train of mining engineers." We protest. The phrase used is doubtless correct in a military sort of a way, but now that the great war is over let us have peace. A mining engineer creates and does not destroy. He makes the desert a habitable place and produces earth's riches. Is it not enough that he should be classed with engine drivers after having put in four arduous years at college and winning a beautiful sheepskin—is this not enough, we repeat, or should he now be publicly classified as a sapper or house wrecker simply because of his familiarity with explosives and blasting. The *Evening Sun's* intentions are good, but it should watch its step. It has many mining engineers among its readers and now that they are conscious of their own exceeding worth they are apt to start reading some other three-cent paper. Furthermore, they will have the sympathy and support of the F. A. E. S.—they are organized. Let the offender beware!

Rings Like a Fake

Herr Simons, the German Foreign Minister, is reported to have stated to a correspondent of the *Evening Standard* (London) that a new metal had been discovered at Frankfort. It was of high value, and likely to take the place of copper. In color it was white, like aluminum, and when struck had a "ring like steel."

North Bloomfield Née Humbug

"One of the most noted hydraulic mines was that known as North Bloomfield, some eight or ten miles northeast of Nevada City," says Hittel's History of California." "It was situated near a little creek flowing into the South Fork of the Yuba and between it and the Middle Fork, where, about the year 1851, a prospecting party consisting of two Irishmen and a German discovered a rich deposit of gravel. After working it for some time and finding their provisions running low, they sent one of the Irishmen to Nevada with several hundred dollars' worth of dust for supplies but with strict injunctions to keep silent as to their fortunate strike. The Irishman sold his dust, purchased his supplies and a mule to pack them, and got ready to return. But having some money left, he could not resist the temptation of a little conviviality; and, as one glass led to another, he grew more and more loquacious and at length began to boast of the money he and his partners were making. When asked where his claim was situated, however, he seemed to remember his promises to be discreet and refused to disclose the locality. But the next morning, when he started off, he was followed at a distance by a hundred or more excited adventurers, who succeeded in tracking him to his camp. They prospected for several days along the creek and found a little gold but for some unexplained reason failed to find rich deposits and, returning disappointed to Nevada, unanimously pronounced the creek a humbug; and from that time forward, whenever the place was mentioned, it was called Humbug Creek. Subsequently, in 1853, when hydraulic mining commenced there and a town started, it was also called Humbug from the name of the creek. In 1856, after the place, on account of the great richness disclosed by the deep hydraulic diggings that had been opened, became one of the liveliest and most prosperous towns in the county, the citizens, on the occasion of procuring a post-office, had the name changed to that of North Bloomfield."

The Tommy-Knockers*

When I die (said the mining engineer) do not bury me at all;
Cache me on the bottom level, with a pick beside my pall;
Leave a candlestick and matches, then cave the stopes and drifts,
And I'll be a tommy-knocker for a hundred thousand shifts.
Yes, a jolly tommy-knock, always starting for a walk;
Always pounding on the rock, scaring honest Hunkies with my little tap, tap, tap—
Always listening for the blast 'till the pumps are pulled at last,
And the bloody surface tenderfoots are routed from their nap;
Then the depths of earth will be lighted and we can see right through,
And all the lost bonanzas will be nuts for me and you.
Then we'll dig, dig, dig (If we've been good engineers)
Ore shot with chunks of metal, through all the happy years.
We'll have angels for muckers, who'll never ask for pay,
And the ore will stope itself, over—under—anyway—
Anyway you say!
Oh, boy! Don't wake me up
And say the men are striking and the tax-collector's here,
And the bottom of the metal market's gone,
And how you've lost the ore-shoot, and all the other grief;
Jest let me snooze 'till Gabriel blows his hawn!

—SAMUEL B. ELLIS.

*The tommy-knocker is the gnome of the underground. He is often heard tapping the rock in mines, and superstitious miners do not like to work alone for fear of meeting him.

CONSULTATION

Active Placer Operations

"If you have the information available will you please advise me if there is any placer mining for gold being done on this continent at the present time, and if so, where?"

There is still considerable placer mining being done on the North American continent at the present time in spite of the existing relatively high cost of placer mining compared with pre-war costs. However, the production of the various placer fields is gradually decreasing, due not only to the high cost of labor and supplies but also to the diminished reserves in the placer goldfields and their gradual exhaustion. Many placer mines in California are potential producing localities, but are prevented from operating by the anti-debris laws in effect in that state.

Although we have not a list of all the active placer mines in the country, the following list will give you an idea of the chief producing localities; the figures given represent 1918 production in troy ounces as given by the U. S. Geological Survey, and illustrate how much placer gold the various states produce:

Oz.	
12	Alabama and Georgia—small production.
38,334	Alaska—about 700 placer localities.
33	Arizona—small production, Yuma, Pima, Maricopa and Yavapai Counties.
29,909	California—Yuba, Sacramento, Butte, Calaveras, Amador, Merced, Stanislaus, Placer, Shasta, Siskiyou, San Joaquin, Nevada and Trinity Counties.
6,650	Colorado—Summit and Lake Counties.
3,283	Idaho—Boise and Shoshone Counties.
3,166	Montana—Silver Bow and Lewis and Clark Counties.
3,907	Nevada—Esmeralda and Nye Counties.
21	New Mexico—small production.
17	North Carolina—small production.
4,102	Oregon—Baker, Grant, Jackson, Curry, Douglas, Crook, Josephine and Malheur Counties.
	South Dakota—Lawrence and Pennington Counties produced negligible amounts.
15	Utah—small production.
45	Washington—small production.

In Canada placer gold is being recovered from operations chiefly in British Columbia and Yukon Territory. Mexico and Central America (chiefly Honduras) also produce placer gold.

Silver Standard Countries

"I have heard it stated that China and India are the two chief silver standard countries of the world. What other nations have their currency systems based on a silver standard?"

China is a silver standard country. India is not, but uses what is known as the gold exchange standard which contemplates little or no circulation of the standard metal, gold, but a linking of the circulating medium, silver, to a gold basis. India is a great silver-consuming country, and uses large amounts in coinage, but it is incorrect to say the country is on a silver standard.

A comprehensive list of silver standard countries would include Abyssinia, Afghanistan, China, Eritrea, French Indo-China, Honduras, Morocco, Persia and San Salvador. Other nations that are chiefly using silver in their circulating currency systems but which have a gold exchange standard are British East Africa, Ceylon, former German East Africa, India, Italian Somaliland, Federated Malay States, Nicaragua, Philippines, Siam, Straits Settlements, and Zanzibar. In addition to these countries, Mexico's chief money in circulation ordinarily is silver. It is to be noted that several of the nations listed, East Africa, Ceylon, Italian Somaliland and Zanzibar use the silver rupee, the common coin of India.

Feldspar Potash in Connecticut

"We are interested in a large tract of land in Connecticut containing extensive deposits of feldspar and are informed that this deposit is valuable for its potash content. Will you kindly tell me what the possibilities are of developing such an industry in Connecticut and what attempts have been made to produce the material. What are your quotations on feldspar potash?"

The State of Connecticut does not produce any appreciable amount of potash. No doubt there are extensive geological formations which contain feldspar there, as this mineral is a common constituent of rocks in the East and is found abundantly in the North Atlantic States. However, the use of ground feldspar rich in potash as a fertilizer is only commercially feasible in exceptional circumstances. This has been emphatically demonstrated by tests of the Department of Agriculture. Attempts to extract potash from feldspar are still in the experimental stage, and many patents have been issued covering various processes. If you are endeavoring to develop a prospective potash producing area from feldspar deposits you are doing pioneer work in this line that is subject to the risks attendant upon most untried mining ventures.

Feldspar often contains as much as 14 per cent of potash (K_2O), but a series of unpublished analyses of the U. S. Geological Survey indicates that the average quarry product rarely runs above 7 to 7.5 per cent. The potash feldspar resources of the country are known to be large, but due to the cheaper sources of potash from both domestic and foreign quarters, it appears to be many years before attention will be turned to them and they can be commercially used.

Owing to the fact that potash feldspar is not produced in commercial quantities, we do not quote prices on this material.

Lubricating Grades of Graphite

"In your market report of Sept. 11 you quote lubricating grades of graphite with prices ranging from 11 cents to 30 and 40 cents for higher grades. Will you kindly inform us of the specifications and requirements of graphite that might be termed lubricating grades?"

Lubricating grades of graphite refer to a high grade of graphite of exceptional purity which does not contain any gritty matter such as quartz. As the grain size is immaterial, both amorphus and crystalline graphite can fall in this class. This is essentially the sense in which the term is used by the trade and in the *Engineering and Mining Journal* quotations.

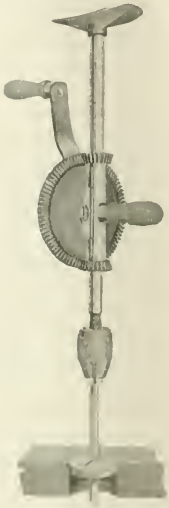
HANDY KNOWLEDGE

Grinding Valves With a Breast Drill

BY C. NYE

Written for *Engineering and Mining Journal*

The common method of grinding valves by means of a screwdriver, oscillated by hand, is slow work and tires the wrist. A practical and mechanically superior manner of performing this operation is to insert the screwdriver blade in a breast drill and then turn the drill handle back and forth. A better result is easily obtained



USING BREAST DRILL TO GRIND VALVES

and in a fraction of the time required by the old method. The drill being geared up, the screwdriver blade turns several times to a single half-turn of the drill handle. Valves that average a half hour by the wrist method are ground with ease in an average of ten minutes by the drill method.

Kerosene To Prevent Slacking of Carbide

That kerosene poured upon carbide will prevent the waste and loss of carbide through premature slacking is maintained by the *Queensland Government Mining Journal*. It is stated that this remedy for slacking is successful and that it takes only a little kerosene to "do the trick," as it spreads rapidly over the whole of the carbide in a tin. Subsequent generation of acetylene is not affected.

Moisture is the great enemy to the preservation of carbide, and it can be seen easily that kerosene or some similar light oil would prevent the moisture taking effect quickly; but kerosene is highly inflammable and what effect the combination of carbide, kerosene, acetylene and the metal of the container exerts on the safety of the combination would seem to us a matter warranting investigation.

Motor-Haulage Block-Signal Protection

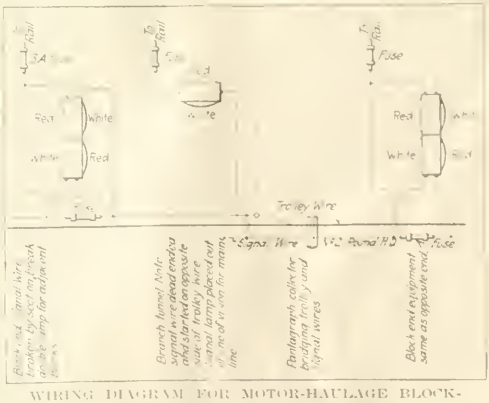
BY T. H. ARNOLD

Written for *Engineering and Mining Journal*

For motor haulages underground where there is a considerable amount of moisture and wet track, a track-circuit signal system is impracticable, as the maintenance cost is excessive and the reliability considerably impaired.

In a simple system devised for the Arizona Copper Co. with pantagraph collectors, a wire of No. 2 hard-drawn round copper is strung parallel with the trolley wire and insulated from it, and spaced two or three inches away. The signal wire is connected at each end of the block to block lamps, which are also connected to the track. The pantagraph collector bridges the trolley wire, and the signal wire thus furnishes current for the block lamps. At frogs and crossings, the wire must be raised over the branch wire, or dead ended and another wire started on the opposite side. The two wires must be carefully aligned for vertical height, which is readily accomplished by means of a double hanger.

The block lamps are usually constructed of galvanized iron and use a 4-in. diameter semaphore lens. At the junction of two blocks a double lamp is used giving a red indication opposing and a white indication back into each block. For branch tunnels not protected with block signals a standard railroad switch lamp is used, giving a red and a white indication. For special uses, three and four signal lamps will be required.



WIRING DIAGRAM FOR MOTOR-HAULAGE BLOCK-SIGNAL PROTECTION

This system, though not giving absolute protection, has many desirable features. The installation cost is low; a moving train is indicated by a flicker of the block lamp; the indication of a train in the block is positive, and the maintenance is negligible. The main defect in the system is that a car standing on the track does not give a signal unless a locomotive is in the block; also, it does not give the direction in which a train is moving, but, on the whole, the operation has been satisfactory.

THE PETROLEUM INDUSTRY

Relation of the Bureau of Mines To the Oil Industry*

THE BUREAU OF MINES is one of three organizations provided by the Federal Government to bring about a greater efficiency in the production and utilization of precious petroleum resources. The Geological Survey provides information for a better understanding of the occurrence and the finding of petroleum; the Bureau of Standards provides means for standardizing instruments for use in the petroleum industry and means for testing and standardizing products manufactured by it.

The Bureau of Mines was established by act of Congress, in 1910, for the purpose of conducting scientific and technologic investigations concerning mining, its various branches and the production and utilization and conservation of petroleum and its products. In short, it has been commissioned by our Government to look after the public interests in the production, manufacture, and utilization of our natural mineral resources.

Its relations to the petroleum industry are advisory rather than supervisory, the only important exception at present being the supervision of drilling and producing operations on Government leased lands. It endeavors to do what is best for the public welfare and looks to ultimate good rather than to the immediate gain. It believes that the ultimate good for the public will prove to be also the ultimate good for the industry and that fundamentally the interests of the public and of the industry are one and the same.

It stands also as an intermediary between the industry and the various departments of the Government—as a sort of consulting board to which matters concerning petroleum and its products are referred by them. In order to faithfully fulfill this function the Bureau of Mines must cover the whole field of the industry and as far as possible those industries allied with the production and utilization of petroleum and its products.

The Bureau of Mines organization for carrying on this particular work is at present divided into four main subjects as follows: Production Technology, Engineering Technology, Chemical Technology, and Oil Shale Technology.

The section of Production Technology handles such problems as (1) methods for drilling wells whereby the various types of equipment may be most efficiently used, to the end that a maximum production may be secured from the sands. This involves the problem of protecting the sands against wastes of oil or gas and against infiltrating water by the use of mud-laden fluid, cements, and like substances; (2) the collection of various data covering the development work as it is carried on which will guide operators in future work, enabling them to avoid serious and costly mistakes and supplying them with information of the repair of producing wells; (3) the collection of such data as the logs of wells, casing records, production records and complementary facts, in order to gain information which may increase the production of the present and future wells and prolong the life of the fields; (4) the valuation of oil lands along a basis which will assist the operator in determining a fair price for the purchase of oil and oil properties.

There are at present engineers of the Bureau who devote their entire time to production problems in Wyoming, California, Oklahoma, and Texas. Great savings already have been effected to the industry through their constructive advice and through the corrective measures that they have recommended.

Co-operative work which was carried on with the Indian Office, under an annual appropriation of only $17,500, resulted, through the proper control of underground waters, in increasing the daily production of one group of oil wells in the Cushing field as much as 3,000 bbl. per day by cementing. At this rate, the increased production for the first year succeeding the repair of the wells amounted to approximately $2,500,000. Operators in the Wyoming fields have recognized the value of the work that the Bureau is doing, and have recently renewed a co-operative agreement whereby $30,000 a year is voluntarily contributed by them and is being spent under the direction of the Bureau for conserving oil and gas on their property.

The Legislature of the State of Oklahoma has recently renewed an agreement appropriating $12,500 of state funds for co-operative work with the Bureau along similar lines. Just recently, an unsolicited fund of $1,000 was proffered the Bureau by the operators of the Hewitt Field, Oklahoma, as a nucleus of a co-operative fund to be expended in conservation work in that field.

Oil Property Taxation

The Bureau of Internal Revenue of the Treasury Department, in endeavoring to arrive at a fair method for taxing oil properties in the United States, called upon engineers of the Bureau of Mines to work out a plan, and, as a result, the Bureau has devised and developed a new and equitable method for estimating the future and ultimate production of oil properties in the United States. This method has been used as a basis for assessing taxes imposed by acts of Congress.

Through its section of Engineering Technology, the Petroleum Division of the Bureau has made valuable recommendations for the transportation and storage of oil. Recently, investigations conducted by it have disclosed that, in many cases, 20 per cent of the volume of the gasoline content of crude oil is being lost by evaporation before it reaches the refinery. The investi-

*Abstract of address delivered at the convention of the Independent Oil Men's Association at Denver, Col., on Thursday, Sept. 30, by F. G. Cottrell, director of the Bureau of Mines.

gation likewise disclosed that probably at least one-half of this loss may be economically saved, and various companies have been induced to make the effort. One tank company recently reported that it had received more inquiries on protection against evaporation losses within the last six months than in the ten years previous. During the ten-year period from January, 1908, to January, 1918, approximately 12,750,000 bbl. of oil and 5,024,506,000 cu.ft. of natural gas were destroyed by fire in the United States, entailing a total estimated property loss of more than $25,000,000. Oil and gas fires had become so common, especially in parts of Oklahoma and Texas, that many people regarded them as an unavoidable evil. In one week, during the summer of 1914, in the Healdton and Cushing fields of Oklahoma, fire destroyed eighty-six tanks, ranging in size from 250 to 55,000 bbl. capacity, numerous oil rigs with equipment, several field pumping stations, besides reservoirs, entailing a total property loss of approximately $1,000,000. As a result of detailed investigations carried on by the Bureau to ascertain, if possible, the causes of these fires, it was found that most of the more disastrous fires resulted from carelessness or from improper storage and transportation facilities. The Bureau has been able to suggest means for successfully combating the most disastrous fires and to entirely eliminate hundreds of lesser fires. Through the adoption of its recommendations, many thousands of dollars have been saved to the industry and enormous quantities of oil and gas have been conserved for use.

A study was also made of methods for increasing the efficiency of the utilization of natural gas. Engineers of the Bureau examined many plants for producing natural-gas gasoline, and through information gathered have been able to make recommendations that have greatly increased the proportion of gasoline recovered from the gas, thereby materially increasing the supply of gasoline. At present a study of the utilization of heavy oils ranging in gravity from 7 to 14 deg. Bé. is being made, and in the near future the Bureau may be able to make recommendation whereby the enormous quantity of tars, heavy oils, and oil-saturated sands known to exist in the United States may be made to yield useful petroleum products.

In the period of under-supply—a condition which is likely to become worse rather than better—when prices of petroleum products have gone up and there have developed serious shortages of gasoline, fuel oils, and other products, the industry is under critical examination and the public demands that justification be shown for these conditions. Without the crude-oil statistics of the Survey and the refined-oil statistics of the Bureau of Mines, there would be most serious misunderstandings between the public and the industry.

A monthly bibliography of petroleum and allied substances is being placed in the hands of trade journals and most of the larger libraries in the United States. In this way, the Bureau hopes to aid in assisting those interested in obtaining accurate and reliable information concerning petroleum and allied substances and to assist in keeping the public in close touch with literature dealing with this subject.

Through the section of Chemical Technology, chemists and chemical engineers of the Bureau are making, every six months, a complete survey of the motor gasoline sold throughout the United States. Samples of gasoline are collected from service stations in various parts of the country, and these samples are analyzed and the results compiled and published. Through these reports, the public as well as the producing companies are kept informed of the quality of the gasoline sold to consumers. A study of the analysis of the most recent survey, July, shows that the volatility of the gasoline put on the market has decreased. This is because the increased demand for the product necessitated the refiner to "cut deeper" into the crude. As commercial gasoline no longer comes up to the Government specifications, the Bureau, believing that these specifications are too rigid, has recommended that they be changed.

At present, a survey is being made of all the crude oils produced in the United States. Results of the analyses will be compiled and published when the survey is completed.

An important activity of the chemical division has been the standardization of testing methods for petroleum products. The gasoline distillation tests adopted as standard by the American Society for Testing Materials were developed by the Bureau and much work has been done on standardizing other tests.

In the work on Oil-Shale Technology, the Bureau has been much handicapped by lack of funds. However, two of its engineers have been able to give most of their time to investigations and experiments connected with this work. The oil-shale industry is at present passing through a critical period. A relatively large amount of money has already been spent by private individuals in endeavors to determine the practical and commercial feasibility of retorting oil from oil shales. However, the industry is faced with a lack of essential fundamental information which it is the province of a government bureau to obtain. There are a multitude of technical problems which are yet to be solved.

The development of the oil-shale industry must necessarily be a matter of years, not only because there must be built up a fund of technical knowledge and practical experience, but because great amounts of capital and labor will be necessary before any considerable proportion of our present and future oil needs can be supplied from our shales. There is no doubt that the industry will be developed into one of the largest in the United States, and it is high time the Government hasten this development by starting immediately the necessary preliminary investigations.

The Bureau is requesting from Congress an appropriation of $170,000 with which it contemplates the establishment of an oil-shale station in some suitable locality, including the necessary grounds, laboratory, and equipment. It contemplates the erection of a one-unit Scotch retort, the design and operation of which are already well understood, to provide a standard. By means of this standard retort it will be possible to compare various processes one with the other, also various methods of retorting, one with another, and various shales, one with another. This standardization will be invaluable to the industry and it is believed can best be done by a Federal agency.

The Bureau has from the first maintained that the production of oil from shale is not for the individual of small means. It is a manufacturing venture involving the handling of large amounts of low-grade raw material and should be undertaken only when substantial backing from capital is to be had and where the best technical skill can be obtained.

NEWS FROM THE OIL FIELDS

State Receipts Increased by the Development of Texas Oil Resources

From Our Special Correspondent

The report of the Texas State Land Commissioner, J. T. Robinson, for the two-year period ended Aug. 31 1920, will show receipts by the state of over $7,750,000 from sales of school land and lease rentals and royalties. This is an increase of more than $2,000,000 over the preceeding period of two years, and was due to the great increase in the development of the oil resources of the state.

The States Oil Corporation, of Eastland, brought in a tremendous gas well on Sept. 18 on the J. M. Radford farm, seven miles north of Eastland. It is claimed that the well came in producing over 50,000,000 cu.ft. daily. Steps were taken at once to prevent undue waste.

The new tank farm, oil-ship unloading, and railway distributing station of the National Oil Corporation, near Galveston, will it is stated be completed and in operation by the middle of October. Three 55,000-bbl. tanks, a 24-tank car-loading rack and trackage have been completed. The 14-in. pipe line from the unloading pier to the tank farm is being pushed to completion.

The most important oil-well completion in the coastal fields recently was the No. 2 Gallagher of the Humble Oil & Refining Co. at Damon Mound, Brazoria County. This well came in flowing 1,000 bbl. by heads from 3,211 ft., and is not only the deepest well in the field but extends the field one quarter mile to the south. At Hull, small producing wells were completed by the Phoenix Development Co., Theis, Wilherson & Parker, and the Humble Oil & Refining Co. The daily production of the field is now over 14,000 bbl. At West Columbia the "big well," No. 1 Abrams of the Texas Co., is still flowing at the rate of approximately 8,000 bbl. daily through the drill stem. It is expected several new wells will be completed in this field soon. One well was completed in the Spindle Top field, the original salt-dome field, by Wilson & Broach, pumping 15 bbl. from about 750 ft.

Homer Field Still Largest Producer in Louisiana

From Our Special Correspondent

Nearly one-half of the Louisiana oil production of about 100,000 bbl. weekly comes from the Homer field. The shallow sand in this field is holding up well, making a steady production and showing little salt water. Some deep wells in the lower sand have made large productions for a short time, but nearly all rapidly sanded up. A well of this nature completed recently was the No. B-1 Shaw of the Oklahoma Gas & Oil Co., which came in making 2,000 bbl. and which rapidly increased to double that amount when bottom sediment began to show.

The Union Petroleum Co., a subsidiary of the Sinclair Consolidated Oil Corporation, is building a compounding plant of 500,000-bbl. capacity and steel storage tanks of large capacity at its Westwego station.

Vinton, Calcasieu Parish, continues to be the largest producer in the Louisiana coastal fields. The Gulf Production Co. recently completed a 100-bbl. pumping well in its No. 34 Vincent well in this section.

Lee County Ranks First as Kentucky Oil Producer

From Our Special Correspondent

Complete reports for August show that Lee County continues to hold first rank in the production of oil in Kentucky. Of the 775,004 bbl. for the entire state its oil runs showed 465,532 bbl. Estill County was next, with 92,693, Allen third, with 86,843, Warren fourth, with 31,393, and Powell fifth, with 26,326 bbl. The price of oil in the state increased recently from $4 to $4.25 a barrel.

Warren County continues to lead in new production, and drilling operations are still centralized there. A flowing well was drilled in on the Phelps lease, six miles south of Bowling Green, on B-1 Shaw of the Oklahoma Gas & Oil air. It was capped after numerous attempts, and is producing 500 bbl. a day.

A second big well was brought in on the Kister lease, in the White Stone Quarry district, Warren County, estimated at 100 to 150 bbl. a day. Johnson, Kerstetter & Stein have drilled in No. 1 on the Briggs lease at 1,155 ft. Oil stood 240 ft. in the hole. A well on the Jefferson lease was shot on Sept. 24 at 1,101 ft. No. 1 on the Porter lease was shot the same day at 1,025 ft. and has an estimated production of 50 bbl.

Well No. 20 on the George Sledge lease, in Allen County, was brought in on Sept. 21 at 292 ft., good for 100 bbl. daily or better. This well proves up the entire acreage of 399 acres.

Lively development is reported in Johnson County. The Seminole Oil Co. brought in its first well in the Weir sand this week. It will be drilled to the Berea sand.

The Heilbron Oil Co. of Tulsa, Okla., has contracted to drill a well before Dec. 1 on the holdings of S. S. Langley and the Eagle Lumber Co. near Ramsey, Dallas County, Ark.

Refinery at Laramie, Wyo., Making Good Progress

From Our Special Correspondent

Construction of the refinery of the Standard Oil Co. at Laramie is progressing rapidly. Eight of the ten stills have been set in place, and the construction work is nearly completed.

The Producers & Refiners' Corporation struck oil at the Wertz camp, Carbon County, on Sec. 7-26-79. Considerable gas pressure was obtained between 3,200 and 3,400 ft. The quantity of oil has not been determined.

No. 2 well of the Iowa-Wyoming Oil Co., in the Bolton Creek field, was completed at a depth of 2,050 ft. and came in flowing considerable oil with the well water. Sufficient gas came with the oil and water to necessitate the moving back of the field boiler to prevent danger from fire. This field is about thirty miles southwest of Casper. Other companies having holdings close to this producing well are the Chappell, Mike Henry, San Juan, and Victor-Wyoming.

In the Piney field, the Petrograd Oil Co. has spudded in and the Associated Oil Co. is preparing to drill a deep test well. The latter company will drill its first well on the C. Freer ranch, and work will be carried on throughout the winter.

The Sand Hills Oil Co. is setting casing in its test well in the Ferris district preparatory to drilling in below 3,100 ft. It is stated that oil is standing in the hole.

Crude-Oil Production Costs in California Show Large Increase

The cost of field operations in the production of crude oil in California has increased 200 per cent, or possibly 300 per cent, during the last five years, according to statistics recently published by the State Mining Bureau. In 1915 the operating cost was generally less than 20c. per bbl., whereas in 1919 the figure was 40c. or more. Decrease in productiveness of wells, coupled with advanced cost of labor and material, are the underlying reasons. The total capital invested in the oil industry is about $320,000,000, upon which dividends of $35,418,851 were paid, or at a rate of about 11 per cent. About two-thirds of the total output of crude oil is refinable, or about a gravity of 18 deg. Bé. The total area of proven oil land is 91,792 acres, or about 143 square miles. Upon this land there are 8,928 producing wells, slightly more than ten acres per well. Future drilling will probably increase the number of wells, until the average amount of land drained by a single well will be seven or eight acres.

COURT DECISIONS IN MINING CASES

By Wellington Gustin

"Implied" Contract Legal and Enforceable

Oklahoma Supreme Court Sustains Gilchrist Drilling Co. in Action Against Tulsa Fuel & Manufacturing Co.

The status of an implied contract is decided in the judgment of the Supreme Court of Oklahoma in favor of the Gilchrist Drilling Co. against the Tulsa Fuel & Manufacturing Co. The Lynna Oil Co. was the owner of an oil lease, and the Tulsa company was the owner of a gas lease on the same land near Tulsa. The Tulsa gas lease was prior to the oil lease, and there seems to have been some agreement between the Tulsa company and the former original owners of the oil lease that either party had the right to drill wells upon the leasehold estate, the oil-lease holder taking over all oil wells, and the gas-lease holder taking over any gas wells, the party so taking a well to pay the expense of drilling.

After the Lynna Oil Co. purchased the oil lease, the Gilchrist Drilling Co. drilled a test well for gas and oil to the depth of 1,275 ft. The well proved to be dry, and the Lynna company paid one-half of the bill and refused to pay the balance, claiming the Tulsa company was liable therefor. The latter refused to pay, and this action was brought to recover.

It was admitted there was no written or oral agreement between the oil and lease holders as to the drilling of the well. However, the testimony showed that the manager for the gas company knew of the drilling and was at the well during the operations; that frequent reports were made him, and that he was consulted as to the best place to drill the well. It appears that the oil company furnished the casing for the well and also the gas to run the machinery.

As there was no express contract between the parties, the plaintiff must rely upon what is known as an "implied contract." The intention of the parties to an "implied contract" is to be gathered from their acts in connection with the surrounding circumstances, and what was said between the parties at the time, the nature of the work done, and as to how the interest of the parties sought to be charged is effected thereby.

It was said the only distinction in this species of contract and express contracts rests in the mode of proof. Both are founded on the mutual agreement of the parties. One must be proved by an actual agreement, whereas in the case of the other it will be implied that the party did make such an agreement as, under the circumstances disclosed, he ought to have made.

Contracts implied in fact must be a reasonable deduction from all the circumstances and relations of the parties, although they need not be evidenced by any precise words, and may result from random statements and uncertain language.

Judgment against the gas company was affirmed.

Texas Court Sustains Legality Of Unilateral Lease

Holds Agreement Not Invalid Through Allowing Lessees To Pay Rent Instead of Drilling Well.

The Supreme Court of Texas has reversed the Court of Civil Appeals in the suit brought against the Corsicana Petroleum Co. for the cancellation of a mineral or oil lease. The lessors contended that the lease was unilateral and therefore void, and that the lessee company had forfeited it by failing to complete an oil well on the premises within one year.

The lease covered "all the oil, gas, coal, and other minerals," with the "exclusive right to drill, mine, and operate on the lands for producing gas, oil, coal, and other minerals." The lessee agreed in the instrument to complete a well on the premises within one year or pay to the lessors a specified lease rental quarterly to the end of the term of ten years, or until the well was completed, or the lease surrendered as provided. A further clause gave the lessee an option either to surrender the lease upon certain payment or to continue it in full force and effect for quarter to quarter by making the quarterly payments.

The court found there was nothing unlawful about such a contract. Acceptance of payments instead of the completion of a well was a matter of agreement and the lease covered the point. But it was contended that such a lease was unilateral and therefore unenforceable. The court said a contract for the grant of an option is necessarily unilateral. An option is granted for the purpose of enabling the lessee to exercise the particular right or not, as he may elect. The value of it consists in that privilege. Owners of property have the unquestioned power to grant such rights with respect to it. They are free to validly make such contracts, and when so made the courts will uphold and enforce them.

In many valid contracts the promise is only on one side. They are unilateral. The inquiry as to such is whether such promise is supported by a consideration. In return for the payment made the lessors herein agreed that the lessee should have the right to surrender the lease on the terms stated. The presence of this provision in the lease did not invalidate it as contended.

Judgment for the Corsicana Petroleum Co. was ordered.

Casinghead Gas Does Not Make A Gas Well

Federal District Court of Oklahoma Rules That It Is a Component Part of Oil

In the action by the Twin Hills Gasoline Co. against the Bradford Oil Corporation, removed from the Oklahoma courts to the Federal District Court, Judge Williams has entered judgment for the Twin Hills company.

The action was based on an oil and gas lease, the controversy arising over the construction of certain paragraphs of such lease relating to "gas wells" and "casinghead gas." The lease provided that the lessor should receive one-eighth part of all the oil produced, that the lessee should pay $200 per annum on each gas-producing well, and that the lessee should have the right to use casinghead gas for the purpose of operating the wells. And the court held that "casinghead gas," which is a component part of oil being produced from wet gas existing only with oil, would not make a well a "gas well" so as to entitle the lessor to $200 per annum, but the lessor would be entitled to his one-eighth part of the casinghead gas separated from the oil and saved.

In construing an oil and gas lease which is ambiguous the court will look to the intent of the parties and the surrounding circumstances.

The court found in favor of the Bradford Oil Corporation as to the plaintiff's claim for $200 for each well produced on the property because the wells were found to be oil wells and not gas-producing wells. But it found plaintiff was entitled to recover one-eighth part of all oil produced on the property, including the casinghead gas.

Reservations of Coal and Mineral Include Oil, Petroleum and Gas

The Court of Civil Appeals of Texas, at El Paso, has denied a rehearing on its judgment in the suit brought by W. L. Parmer against J. E. Luse and another to quiet title to certain mineral claims in Eastland County, Tex. Reservations in the deeds of J. E. Luse to realty "excepting and reserving all coal and mineral and the right to prospect, mine, and remove the same," and "the coal and mineral in said described land and the right to work and remove the same is especially retained" to the grantor, were construed by the court to be reservations of oil, petroleum, and gas. And under such a conveyance reserving oil and gas rights in the grantor, Luse, the grantee, Parmer, is entitled to the ordinary possession of the surface, and such possession alone will not defeat by the statute of limitations the title to the minerals which were reserved.

ECHOES FROM THE FRATERNITY

Future of the United States Zinc Industry*

Unit Cost, Not Furnace Recovery, Plant Manager's Proper Objective—How To Establish Foreign Market

None of us can afford to be deceived about our own affairs. Every zinc man in the United States knows that the stabilization of his industry depends upon increased home consumption and increased foreign demand. Every member of the American Zinc Institute knows if he reads the Institute *Bulletin*, what has been done toward increasing home consumption. Likewise, he knows what remains to be done; in fact, what must be done if that consumption is to be maintained and ultimately increased.

Simply telling other people, orally or through a bulletin, to "Make It of Zinc" is akin to mining for zinc with a sledge-hammer hand-drill crowbar outfit. Neither will the publication and the distribution of architectural service sheets alone create a demand for zinc roofing material. That demand can only be created through backing those service sheets with a substantial amount of advertising, with the publication of a zinc worker's handbook, and with the adoption of all the other methods which are making an ever widening and more unassailable market for other forms of roofing.

So far as increasing the foreign demand is concerned, let us not delude ourselves regarding our European business. Plainly stated, supply war-shackled nations and then competing with war-crippled nations have merely given the zinc men of the United States an incidental European zinc market. Those nations, however, are rapidly returning to a condition of comparative normality.

Trying to measure England's recovery from the war by the daily rates in a disorganized exchange market is about as satisfactory as looking through the wrong end of a telescope. That country, through a series of corporate mergers, is fast transforming and remoulding the fundamentals of world trade. By the end of 1920 Belgium will probably be producing zinc at one-half of her 1913 rate. Even Germany, suffice to say at this time, has begun her renascence in zinc. These nations must eventually discharge their large financial obligations to this country. As far as possible their payments will be made not in money, but in goods of their own manufacture. Such goods will include zinc unless the zinc industry of the United States does not forthwith reform itself.

An export market as tender as our present one has shown itself to be is not an export market in the world's understanding of that term. When world-market conditions recently favored a return of a considerable quantity of United States-made slab zinc no small concern was exhibited by some of the zinc men in this country, and the menace of such dumping was strongly reflected in home-market quotations. This concern and this reflection were by no means unwarranted, for in the world's commodity markets the law of supply and demand inexorably governs.

Frankly, how can an industry expect to prosper even at home when it is guilty of the wasteful practices exposed in Mr. Stone's admirable paper, entitled "Differences in European and American Smelting Practices," read at the 1920 Annual Meeting of the Institute.[1]

Quoting from the summing up of the studies of that authority: "To make the same amount of zinc (432,000 tons) from the same ores with European recoveries and fuel consumption would take 1,084,800 tons of ore and 1,084,800 tons of fuel, a saving of 37,000 tons of ore and 1,000,000 tons of fuel. If we wish to hold our own, and even to avoid going backward, we must do more economical work and reduce our costs below those of other nations." Mr. Stone has clearly pointed out the only way in which the zinc men of the United States can permanently compete in the world's zinc markets, namely, by reducing their costs.

Mr. Schwab said at the 1920 annual dinner of the Institute that he believed "the real returns in business are derived from the economies practiced in that business." It is certain that he had the zinc business as well as the steel and other business in mind when he uttered that modern business truth.

Slab zinc manufacturers are prone to dwell upon the "furnace recovery" element in their work. That factor, though, is only an integral part of their big problem, namely, reduction of their costs. There are some zinc men who must learn that economy is not only the saving, but also the spending of time, money or anything else to the best possible advantage. There are also some zinc men who must stop thinking that a thing is not right because they do not do it, that a method is not good because they do not use it, and that equipment is not the best because they do not own it; in other words, these zinc men must awaken to the fact that the wisest of us has much to learn.

The modern formula for reducing costs is: (1) Gathering and classifying all that is to be learned about each operation; (2) carefully selecting and progressively developing men for the work to be done; (3) bringing the men and the work together.

Is that the formula generally followed in the zinc industry in the United States? It is not! Unit cost, not merely furnace recovery, must henceforth be the objective of the zinc plant manager. The study of materials used, including their handling and conversion, is one of the most important problems confronting the zinc industry of the United States today, as is lucidly set forth in Mr. Stone's paper.

One of the leading zinc companies of the United States quoted in a recent advertisement: "Research is a financial asset. If industry is to continue to guarantee prosperity, it must keep in direct touch with the vanguard of technical knowledge and skill. Modern industry no longer has to take whatever is available. It decides what characteristics are needed in the metals or chemicals, and then delegates the research laboratory to provide the necessary element." That zinc company practices what it commends by reproduction, and prospers accordingly.

The foregoing briefly outlines the fundamental principles underlying the work which must be done to establish and maintain a foreign market for United States-made zinc. This is a work which peculiarly belongs to the American zinc Institute. As the representative of the zinc industry of the United States, therefore, the Institute stands ready to co-operate through its Development of Industry Committee with the zinc manufacturers of the United States in studying, analyzing, charting, diagramming and putting each and every operation in their plants to a test in the light of world practice with a view of reducing their zinc costs below those of other nations.

The zinc men of the United States can reduce their unit cost through such a co-operative movement. If they will do so they will be able profitably to compete in the world's zinc markets when the economic conditions in the other nations return to normal. If they will not do so they will simply continue to supply for a time what will eventually prove to have been an incidental European market. *The future of the zinc industry in the United States of America is in the hands of the members of the American Zinc Institute.*

The Engineers' Club of Northern Minnesota met at the Mohami Club, Virginia, Minn., on Sept. 25. Graham Bright, of the Westinghouse Electric & Manufacturing Co., gave an illustrated talk on the modern electric hoist.

*This article is the leading article in the October issue of the American Zinc Institute *Bulletin*.

Technical Papers

Mining Law—A series of volumes on mining law, embracing the mining law of the British Empire and foreign countries, will shortly be published for the Imperial Mineral Resources Bureau. Address H. M. Stationery Office, Westminster, London, S. W. 1. The purpose of the series is to provide an up-to-date and authoritative exposition of the mining laws in force in different parts of the world, available both for the legal profession and for all those who are in any way interested in mining and minerals. In the first place the mining laws of the British Empire will be discussed and a commencement has already been made with those of Nigeria and of the Gold Coast, which form the first two volumes of the series and will shortly be issued. The price of the former will be 15s. 6d. postpaid. The third volume, which will deal with the Transvaal, is in course of preparation. Each volume will contain a critical analysis of the statute and case law, and will include the full text of the laws, ordinances, proclamations, regulations, rules and notices, which are directly or indirectly material to the subject matter of the work. The volumes will be revised and brought up to date periodically by the issue of supplements.

Molybdenum—Molybdenum has become much more important than formerly. Accurate methods of assaying are necessary, as the old methods left much to be desired. The Bureau of Mines has investigated the subject and has just issued Technical Paper 230 (obtainable from the Superintendent of Documents, Washington, D. C., for 5c.) entitled "Determination of Molybdenum." Improved volumetric and gravimetric methods, more accurate than any previously devised, are described.

Gold in Black Sand—Some tests were carried out by the Alaska station of the Bureau of Mines on the separation of gold from a black sand containing over 90 per cent of magnetite and garnet. The most satisfactory method of treatment was found to be barrel amalgamation in the presence of caustic soda. U. S. Bureau of Mines *Reports of Investigations*, Serial No. 2,158 (five pages), obtainable on request from the Bureau at Washington, tells about the work.

Mineral Statistics—The following separate sections of "Mineral Resources of the United States" have recently been issued by the U. S. Geological Survey, Washington, D. C., and may be obtained without charge: "Clay-working Industries, Silica Brick, etc., in 1918" (pp. 90); "Platinum and Allied Metals in 1919" (pp. 12); "Lithium Minerals in 1919" (pp. 6); "Abrasive Materials in 1918" (pp. 17); and "Cobalt, Molybdenum, Nickel, Titanium, Tungsten, Radium, Uranium and Vanadium in 1917" (pp. 60).

Drill Bits—Walter E. Carr in the September issue of *The Compressed Air Magazine* (11 Broadway, N. Y., 25c.), has a one and one-half page article entitled "Getting Best Results from Rock Drill Bits." Drilling speed can be vastly increased, and the number of bits to be resharpened considerably reduced, by the use of modern drill bits and sharpening equipment.

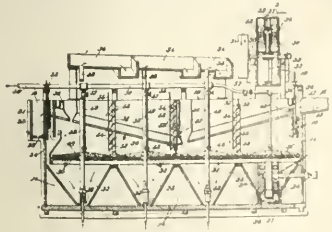
North Dakota Oil—A nine-page pamphlet, Bulletin No. 1, has been issued by the North Dakota Geol. Survey, Grand Forks, N. D. (free) describing the petroleum possibilities of that state. Small amounts of gas have been developed, but few wells have been drilled and no oil in commercial quantity has been found.

Gas in Kansas—The State Geological Survey of Kansas (Lawrence, Kans.) has issued Bulletin No. 5 (32 pages) on the Elk City gas field (free). The first well was drilled July 12, 1918. So far, 52 producing wells have been drilled averaging 27,000,000 cu.ft. daily.

Recent Patents

1,351,096. Apparatus for Separating or Concentrating Ores. David Cole, El Paso, Tex., assignor to Minerals Separation North American Corporation, New York, N. Y. Filed Dec. 4, 1915.

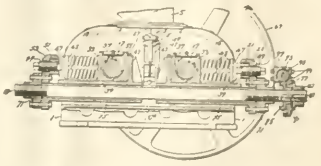
A hydraulic sizer comprising a tank having an inlet at one end, an outlet at the opposite end, and a plurality of sizing compartments at the bottom, said tank being constructed and arranged to permit a free flow of material therethrough in a substantially horizontal direction from said inlet to



said outlet and above said compartments, and a series of vertically disposed spaced sets of shutters within said tank, said shutters having slats downwardly inclined in the direction of flow.

1,350,748. Crushing-Roll Machine. Thomas J. Sturtevant, Wellesley, Mass., assignor to Sturtevant Mill Co., Boston, Mass. Filed Feb. 13, 1917.

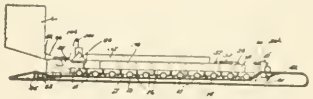
A machine comprising, in combination, a bed, carriages slidably mounted on said bed, a pair of opposed crushing rolls carried by said carriages, a pair of adjusting shafts threaded to both of said carriages, worm wheels on said shafts adjacent one end of said base, a cross shaft having worms meshing with said worm wheels simultaneously to rotate said adjusting shafts to vary the space between said crushing rolls, heads connected to said shafts adjacent one



end of said bed, and means detachably to secure said heads to said bed to confine said adjusting shafts against axial movement.

1,350,440. Apparatus for Agglomerating Ores. Edward W. Davis, Duluth, Minn. Filed Nov. 19, 1918.

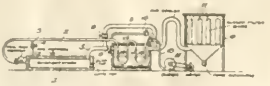
The combination in sintering apparatus of a track, a series of trucks mounted on said track to receive charges of material to be sintered, a vacuum chamber adjacent said track, means for forming an air-tight communication between each of said trucks and said vacuum chamber during the travel of said trucks adjacent thereto, and reciprocating feeding means mounted adjacent



said track and adapted to move said series of trucks by engagement with one of them, said feeding means having a part adapted to engage one of said trucks automatically upon its forward stroke and to pass by said truck upon its return stroke.

1,350,286. Process of Treating Ores. Lewis Bailey Skinner, Denver, Col. Filed Feb. 10, 1919.

The process of treating complex zinckiferous ores carrying precious metal values which comprises preparing a mixture of an oxidized ore of the character specified with an excess of carbonaceous reducing material, the mixture containing matte-forming constituents, charging said mixture on the hearth of a reverberatory furnace, firing the furnace with suitable fuel



and smelting the charge at a furnace temperature of at least about 1,200 deg. C. to produce molten matte and supernatant slag shielded by a non-oxidizing atmosphere, conducting from the furnace fume resulting from reduction and volatilization of zinc from the charge, and continuing the heat treatment of said molten mass until slag tapped from the furnace contains not substantially more than about 6 per cent zinc.

MEN YOU SHOULD KNOW ABOUT

Alfred H. Brooks expected to arrive in Seattle Sept. 27.

R. L. Agassiz, president of Calumet & Hecla Mining Co., has gone to Houghton, Mich., on an inspection trip.

L. M. Prindle is doing geologic field work in the Hoosic-Bennington quadrangle in Vermont and Massachusetts.

R. E. Davis has resigned as director of the Wisconsin Mining School, Plattville, Wis., to engage in private practice.

Ravenel Macbeth, secretary of the Idaho Mining Association, is at the Arlington Hotel, Washington, D. C., for an indefinite stay.

John R. Hall, of Knauth, Nachod & Kuhne, has returned from an inspection of Alvarado Mining & Milling Co., Parral, Chihuahua, Mexico.

J. S. Bradford, mining engineer, formerly general manager at Chiksan Mines, Chosen (Korea) is now at Gensan, Korea, P. O. box No. 14.

F. E. Downs, mill superintendent with the Mexican Corporation, Ltd., Taziutlan unit, has resigned that position and is now in Mexico City.

V. Durand, mining engineer and graduate of Saint Etienne in 1906, has been appointed chief engineer of the Mines de la Chazotte, France.

Warren R. Roberts, chairman of the coal section of the standardization committee of American Mining Congress, is making a visit to western Canada.

U. H. Berthier, mining engineer, who was at Monterrey, is now assistant superintendent at the Mapimi smelter, Durango, Mex., of Cia. Minera de Penoles.

H. N. Lawrie, economist of the American Mining Congress, has completed his trip through the gold camps of the country, and is again at the Washington headquarters.

Donald B. Gillies, vice-president of the McKinney Steel Co., has returned to Cleveland, Ohio., following a visit to the company's mines in the Lake Superior district.

W. S. Bayley, of Urbana, Ill., is at Murphy, N. C., continuing the investigation of the iron ores of North Carolina, begun last summer by the North Carolina Geological Survey.

W. K. McNeill and **W. R. Rogers**, of the Ontario Department of Mines, were in charge of the Ontario exhibit at the National Exposition of Chemical Industries in New York last week.

W. G. Mather, of Cleveland, Ohio, president of the Cleveland-Cliffs Iron Co., and the directors of the company have been on a tour of inspection of the company's holdings in Michigan and Minnesota.

John L. Agnew, general superintendent of the mining and smelting division of the International Nickel Co., is traveling by automobile from the works at Copper Cliff, Ont., to Kentucky.

W. T. Lee, of the U. S. Geological Survey, is completing field work on the coastal plain of Maryland and Virginia. He has made airplane observations of submerged topography.

M. Pigeot, director of mines of Montrambert, who was nominated Chevalier de la Légion d'Honneur recently, has been presented with a rich jewel of the order by the personnel of the Montrambert company.

I. G. Wheaton, during the past four years in charge of operations at Gowganda, for the Crews McFarlan Mining Co., Ltd., has been appointed superintendent of the Wachman Mining & Milling Co., Ltd., Dryden, Ont.

Harris & Ewing, Photo.

EDSON S. BASTIN

E. S. Bastin, now a member of the geologic staff of the University of Chicago, has severed his connection with the U. S. Geological Survey, effective Oct. 31. Mr. Bastin has been teaching economic geology at the University of Chicago since the first of the year, but has maintained a part-time relationship with the Geological Survey.

W. B. Plank, mining engineer, who has been in charge of the Birmingham district for the U. S. Bureau of Mines, has resigned to accept a position as instructor of mining engineering at Lafayette College, Easton, Pa.

L. A. Butler, mining engineer, expected to sail Oct. 2 for West Africa, where he will be engaged in engineering work. His address will be Dun Du, via Pema, care of Caixa 347, Loanda, Angola, West Africa.

William Guggenheim, **J. Leonard Replogle**, of Vanadium Corporation of America, and **Eugene Meyer, Jr.**, of New York City, were among those receiving the decoration of Commander of the Italian Order of the Crown on Sept. 23, at a luncheon by F. Quattrone in honor of Mr. Guggenheim.

John A. Burgess, recently resigned as general manager for United Eastern Mining Co., Oatman, Ariz. He has opened private offices at 648 Mills Building, San Francisco, Cal.

Among the members and guests registering at the Petroleum Section meeting of A. I. M. E., at St. Louis, we noted R. Van A. Mills, Washington, D. C.; F. W. DeWolf, Urbana, Ill.; Arthur Knapp, Shreveport, La.; John L. Henning, Lake Charles, La.; E. W. Ames, Ft. Worth, Tex.; S. O. Andros, Galesburg, Ill.; Winslow H. Herschel, Washington, D. C.; Walt M. Small, Tampico, Fla.; Wallace E. Pratt, Houston, Tex.; Ralph Arnold, Los Angeles, Cal.; Arthur Thacher, St. Louis, Mo.; John R. Roberts, Eastland, Tex.; David White, Washington, D. C.; L. A. Mylius, Urbana, Ill.; J. E. Wallis, Los Angeles, Cal.; Mowry Bates, St. Louis, Mo.; D. F. Sullivan, Chicago; W. J. Howard, St. Paul, Minn.; L. S. Wetzel, Clayton, Mo.; Ralph R. Matthews, Wood River, Ill.; Joseph L. Tweedy, Dallas, Tex.; Edgar Kraus, Houston, Tex.; R. D. Meyer, Denver, Col.; F. J. Fohs, New York City; Wilbur A. Nelson, Nashville, Tenn. and J. W. Gerhard, St. Louis, Mo.

SOCIETY MEETINGS ANNOUNCED

Canadian Institute of Mining & Metallurgy will hold its **Western Meeting** in Winnipeg, Man., Oct. 25, 26 and 27. Headquarters will be the Fort Garry Hotel, in that city. The program includes worth-while papers on the oil, coal, copper, gold and other mining industries of western Canada. Exhibits of all minerals known to occur in Manitoba and the west will be shown.

The Institute extends an invitation to all members and to all others interested in mining to come to Winnipeg for this convention. Those intending to be present should send their names and addresses promptly to the secretary, W. W. Berridge, P. O. box 3076, Winnipeg, Man., Canada.

The New York Section of American Institute of Mining & Metallurgical Engineers holds its regular monthly meeting on Oct. 6, at the Machinery Club, 50 Church St. After the informal dinner at 6:30 the members will hear an unusually interesting address. Courtenay De Kalb will give a talk on "A Visit to Some of King Solomon's Mines." He will refer in particular to the Rio Tinto and the Almaden mines, illustrating his comments with unusual stereopticon views. A general discussion will follow the talk, and many of those present will be expected to take part.

This is the first Fall monthly meeting and a large attendance is expected. Those coming to the dinner ($2, payable at the dinner) are requested to advise at once the treasurer, E. L. Gruver, 25 Broad St. (phone Broad 6768).

Petroleum Section of A. I. M. E. Meets in St. Louis

Two-Day Convention Draws Many Specialists — Paper on Russian Oil Fields Proves of Great Interest — Members Entertained by St. Louis Section of Institute — Anheuser-Busch's Bevo Well Gushes for Occasion

By H. A. Wheeler
Special Correspondent *Engineering and Mining Journal*

The Petroleum Section of the A. I. M. E. held its first independent meeting at St. Louis, Mo., on Sept. 21 and 22, the St. Louis Section of the Institute acting as host to the visitors. By thus convening at a location midway between the financial centers of the East and the field workers of the West, it was anticipated that it would draw a larger and more representative attendance of geologists and oil specialists than do the usual general meetings of the Institute, where the oil section is a minor feature. It was also an effort to attract to the Institute some of the numerous workers in the Western fields, who thus far have not affiliated with the A. I. M. E., many of whom are members of the American Petroleum Association, an essentially Western organization. With this latter object in view Ralph Arnold, chairman of the Petroleum Section, issued invitations to all the members of the latter organization, some of whom took advantage of the opportunity to attend this special oil convention.

The meetings were held in the assembly room of the American Annex Hotel, which was the headquarters of the convention and where ample room was found in spite of a shortage of accommodations in the city caused by a very large convention of retail druggists that was held during the same week.

The petroleum convention was attended by over one hundred members and guests. The first day was devoted to a morning and an afternoon session for reading and discussing papers, with a smoker in the evening that afforded an opportunity for social "section" meetings. The morning of the second day was devoted to papers and discussions, but proved far too short to permit justice to be done to all the papers, and some of the discussions had to be omitted for lack of time. On Wednesday afternoon most of the members relaxed by making a sight-seeing trip about St. Louis, in the course of which they stopped at the very interesting Bevo plant of the Anheuser-Busch brewery and sampled some of the latest product. A hasty visit was also made to the Shaw Botanical Gardens, one of the largest and most noteworthy in this country. Some of the members visited the large new refinery of the Roxanna Oil Co. at Wood River, Ill., and a few inspected the experimental shale oil plant of the Industrial Process Co. of St. Louis.

Twenty papers were presented, some of which evoked very active discussions. The origin of the coastal salt domes came up several times and produced such prolonged discussions as to suggest a special meeting and section on salt domes. The advocates of the volcanic origin of the salt plugs decidedly predominated, their views being in harmony with those accepted regarding similar Mexican coastal pools, in which the dome structure is unquestionably due to vulcanism.

An innovation of the meeting was the presentation of papers by foreign members, these including a paper on Brazilian oil shales and a very interesting review of the rich Russian oil fields, a brief extract of which is hereafter given. The meetings were presided over by Ralph Arnold, chairman, and by E. L. DeGolyer, vice chairman, of the Petroleum Committee of the Institute.

Russian Oil Fields Discussed

The most interesting paper of the meeting was an excellent, comprehensive review of the "Oil Fields of Russia" by A. Beeby Thompson, of London, the eminent oil geologist. These fields are but little known in this country, although according to Mr. Thompson's figures they are the richest that have ever been opened. They have been of very great importance to Europe in the past and are destined to regain this leading position in the future when Russian conditions become sufficiently settled to permit of their being reopened and extended. According to geologic evidence, the future output is likely to exceed the past brilliant record, especially since the recent introduction of American methods that have greatly decreased the cost of drilling and operating.

Two districts have thus far produced most of the oil, of which Baku, on the shores of the Caspian Sea, preeminently leads as a producing, refining and shipping center, while the Grozny field exceeds the combined output of the minor oil fields thus far developed. The oil is of a heavy, asphaltic grade that yields small amounts of gasoline, considerable kerosene and a large amount of fuel oil or residuum. It is this large fuel oil yield that is destined to become very important in the future as a dangerous competitor to the American and Mexican exporters in supplying the European markets when normal conditions again prevail in Russia.

The oil occurs on well defined structures and is produced from eight or more sands of Tertiary age that occur in unconsolidated sediments. The surface seepage of oil, asphalt, gas springs, and mud volcanoes are very noteworthy, and abundant, and some oil has been produced from shallow pits. Submarine gas issues are an interesting feature of the Caspian Sea and have caused such violent ebullitions as to capsize boats.

The wells are mainly shallow and the deepest do not exceed 2,000 ft. They are drilled with rods operated by a walking beam and are cased with "stove-pipe" or riveted casing, the initial sizes being 36 to 42 in. The system is very crude, slow (taking one to three years) and very expensive, the costs per foot ranging from $12 to $25 before the war, in spite of very cheap labor, of which about 50 per cent is for casing. The Russian engineers were unable to use the American cable or rotary systems successfully and have been highly antagonistic to recent attempts to introduce American practice. The system of operating after the wells cease flowing is by bailing with large, high speed bailers, as the excessive amounts of sand produced with the oil, 50 per cent in some cases, renders pumps prohibitory. The cost of bailing a 120-bbl. well was 20c. per barrel in pre-war times. The air lift system has also been successfully used.

Rotary System of Drilling Proved Better

Recent results under American control, after months of obstacles and delays through the excessive jealousy of the Russians, have proved that the rotary system is not only very successful but in offset wells has shown a very great saving in time, costs and freedom from accidents, while the 10-in. screw-joint casing proved vastly more efficient than the huge, costly riveted Russian casing. In the discussion that followed Arthur Knapp stated that where 50 to 75 per cent of the wells put down by Russian methods failed to bottom successfully, the use of American methods resulted in only half as many failures, besides affording a very large saving in time and cost; that he had successfully employed American pumping methods for extracting the oil after the well ceased flowing with a marked saving and much less risk than with the Russian bailing, with its heavy wear and tear of ropes and casing, excessive power and greater risk from accidents. By employing screens below the pump, an innovation in Russian practice, he had greatly reduced sanding troubles.

Output Per Acre Large in Russian Field

The most interesting feature of the Russian wells is the phenomenally large output per acre, as the yields vastly exceed anything known in American practice. The Grozny field has produced 300,000 bbl. per acre and the Baku-

field 500,000 to 2,500,000 bbl per acre. A tract of 250 acres produced over 1,500,000 bbl. per acre where twelve sands were struck that aggregated several hundred feet in thickness. The Balakhany-Saboontchy field of Baku, comprising about 2,600 acres, has outputted 500,000 bbl. per acre and is still capable of enormous collective production, although the output of the individual wells is now small.

Individual gushers or "fountains" have come in at 25,000 to 100,000 bbl. per diem, but the flow lasts only a few days and the gusher period is a thing of the past in the developed fields. The ultimate yield per well declined from 675,000 bbl. in 1892-1896 to 225,000 bbl. in 1912.

A typical well in the Grozny field yielding an ultimate output of 80,000 bbl. is cited as producing 50 per cent of its total production in the first year, 22 per cent in the second, 15 per cent in the third and 7½ per cent in the fourth year.

Russian production started in 1863 with 37,400 bbl. and increased to 203,000 bbl. by 1869 and became very active in 1877. From 1898 to 1901 the Baku fields produced about half of the world's oil output. The approximate output to 1918 is as follows:

	Barrels
Baku district, from 3,600 acres	1,652,610,000
Grozny district, from 8,000 acres	139,858,000
From 7 minor districts	61,526,000
Total	1,853,994 000

The Russian statistics are usually given in the local term *poods* and a barrel is equivalent to 8.3 *poods*.

Deep Drilling of Salt Domes on Gulf Coast Urged

In a paper on the "Urgency for Deeper Drilling on the Gulf Coast," A. F. Lucas urges the testing with very deep wells, under careful geologic guidance, of the salt domes of the coastal region to depths of at least 7,000 ft. He argued that the present high price and assured greater demand for oil warrant such deep exploration, especially as there is considerable promise of it being successful and that improved rotary drilling methods now render such great depths feasible. Capt. Lucas is inclined to regard the salt, sulphur and oil as contemporaneous, and referred to crystals of salt that contain oil, gas and sulphur, in which view Arthur Knapp concurred. Whereas Capt. Lucas formerly regarded the origin of the salt cores as due to crystallization from solution, he is now favorably disposed to the more prevalently accepted theory that they are due to volcanic plugs.

H. E. Williams' paper on "Oil Shales and Petroleum in Brazil" stated that Brazil has encouraging prospects for developing into an oil producer and has extensive amounts of oil shale of good grade that is now being studied and tested by government experts.

Water Problems Considered

The paper on "Oil-field Water Problems" by A. W. Ambrose brought out the great importance of careful observation by production engineers of the source and volume of oil field waters through chemical analyses. Casing records should be kept, he said. Subsequent variations are apt to occur in the analyses of the waters from a given well through changes that occur during the different phases as the gas volume decreases, with a consequent decline in vapor carrying capacity. The paper caused much discussion that brought out the very great importance of not drilling too deep into or too close to the underlying water table that occurs in most Mid-Continent oil fields.

It was shown by Mr. DeGolyer that in Mexico the life of some of the large gushers had been greatly prolonged by throttling down or reducing the output of the flowing wells when water or sediment began to show and to continue throttling or pinching the output as the wells increase in age. It was also thought that a sharp distinction must be made in studying water encroachment in the character of the oil, as the greater the viscosity the greater the danger of condemning and abandoning a well before the available oil was completely recovered through the tendency of the water to advance faster as the oil was recovered by pumping. That with thin, light oils, like the Pennsylvania, with a very low viscosity, the oil and water advanced at about an equal rate to the well, whereas Mid-Continent oils would drag and lag behind the advancing water, which would be still more marked in the very viscous California oils. Mr. DeGolyer cited Mexican wells where a close watch of the temperature has enabled them to forestall water trouble by prematurely throttling before the water appeared, when the oil temperature rose above normal. The underlying water is 14 deg. to 18 deg. warmer than the pure oil and hence warned of its threatened appearance in advance by the increase in temperature. R. A. Conkling, of the Roxanna Company, referred to a well-drilled lease in Oklahoma that had been kept free from water trouble through stopping drilling some distance above the water table, whereas the adjoining leases were making heavy water from the same sand by having drilled too deep and into the water table.

Inefficient Use of Oil as Fuel Pointed Out

The paper by W. N. Best on "Efficiency in Use of Oil as Fuel" brought out an interesting discussion that showed that although many burners now on the market are more or less unsatisfactory and wasteful, this is usually owing to lack of knowledge in using burners under the great range of conditions existing; that if thorough atomization of the oil is attained, whether by steam or air pressure, and if the oil is reliably fed by eliminating sediment and foreign clogging matter, successful results are readily attainable. This requires the oil to be heated to secure a thin, easily fed liquid, if residuum is used, supplied by tanks or pumps.

The short paper by J. E. Hackford, of London, on the "Nature of Coal" was a suggestive and thoughtful study from a purely chemical viewpoint of the marked similarity in the constituents of some coals with some of the oxidized products of petroleum, like albertite, grahamite, gilsonite and others, and he cited the prolonged litigation that has occurred in attempting to distinguish legally between such similarly appearing products as a connecting link.

The paper on "Oil-field Brines," by C. W. Washburne, elicited a keen discussion by R. A. Mills and E. DeGolyer on the coastal salt domes. A corrollary of Mr. Washburne's paper shows that the salt cores could not have been formed by precipitation from salt solutions, as they cut across many open sands that outcrop at a higher elevation farther inland, in which artesian circulation would result from an upward movement at the site of the salt core and consequently the salt cores must be intrusive plugs. This was disputed by Mr. Mills, who maintained that the strong salt solutions would seal up and close the pores of the porous horizons adjacent to the salt core by precipitation.

F. J. Fohs presented an incomplete but comprehensive paper on the "Gulf Cretaceous Oil Fields" that was liberally illustrated by maps of the main structural features of the northern Louisiana oil fields and several local maps of individual structures. This paper will be subsequently enlarged before it is submitted for publication. Lack of time prevented a discussion.

Conditions in Illinois Fields Considered

L. A. Mylius, of the Illinois Survey, presented a brief review of "Present Conditions in the Illinois Oil Fields," which are now producing about 12,000,000 bbl. annually and have shown an annual shrinkage of about 15 per cent since 1908, the zenith year, when 33,686,238 bbl. was produced. He cited the recent deep developments in the old shallow Casey field, where good wells are now being obtained from the Trenton limestone at about 2,400 ft., as compared with the 300 to 600 ft. horizons in the Coal Measure that opened up the eastern Illinois fields.

H. A. Wheeler gave a brief review on "Faulting in the Illinois Oil Fields" that showed that faults had thus far proved destructive on otherwise promising structures through leakage in favorable districts and that faults were much more numerous in the western part of the state, where it was within the zone of the influence of the Ozark uplift of Missouri. He cited an example where oil is migrating today through a heavy fault in the Centralia district, as shown by its marked accumulation in the old, worked-out rooms of a coal mine through which the fault passes.

The local committee on arrangements consisted of H. A. Wheeler, chairman; Prof. W. E. McCourt, secretary; J. E. Caselton, F. V. Desloge, J. D. Robertson and Arthur Thacher.

Special London Letter

The Threatened Strike of Coal Miners—New Minerals in Derbyshire—Mineral Resources Bureau Busy—Katanga To Issue New Capital

BY W. A. DOMAN

London, Sept. 14—The threatened strike of coal miners and the attitude of labor generally are dominating not only the mining world but industrial and political spheres as well. Through the Coal Association the colliery owners are setting out very important facts concerning the earnings, output and slacking of the miners, which certainly do not confirm the altruistic claims of the latter. By their leaders they have refused every avenue of inquiry which would have ensured to them an impartial hearing, and consequently other branches of labor and the public generally are being antagonized. It is the more unfortunate because there is big business in contemplation which capitalists are deferring for the present. For instance, in a mining direction the Chemical & Metallurgical Co. has a plant to erect for one of its processes, and the François Cementation Process is debarred from proceeding with its contracts. Colliery owners are scarcely likely to sink additional shafts and open up new pits with the general position so uncertain.

It is announced that half a dozen new minerals have been discovered in the Peak district of Derbyshire by Mr. Garnett, the most important being cobalt. The others are diabantite, nephrite, cimolite, utahite, sulphur and allophane. The Peak district is one of those wild places that would fit in anywhere; one could even find gulches to satisfy the American promoter. Its geological appearance is such that no one would ever be surprised at the discovery of any mineral there. Lead is being principally worked by small syndicates. The veins, however, are narrow, and their extraction would not support a big company. This is one reason why English capital seeks an outlet at the other end of the world.

The Imperial Mineral Resources Bureau is getting to work. It is issuing pamphlets treating of certain base metals, and is also dealing with the mining laws of the British Empire and of foreign countries. It has a big program, but if carried out it will prove invaluable to the government and traders alike. The war showed us our backwardness in respect of mineral knowledge.

Tin interests are still at work endeavoring to fix a minimum price for the metal. It is argued that as there are only about 150 producing mines and some of them of only secondary importance the thing is quite feasible. There is certainly a "live wire" in it—Oliver Wethered. He is a born optimist.

The Union Minière, which controls the great Katanga copper belt, in which Tanganyika Concessions is interested, is reported to be about to issue new capital at 800 francs in the proportion of one new share for six old. There is ample scope for the employment of additional funds, though the production of copper is about 2,000 tons per month.

For last month the Rand gold output is rather disappointing, for while the value is satisfactory—£3,940,216 against £3,864,520 in July—owing to the high price at which the metal is taken, namely, £5 12s. 6d. per oz., labor is again short as usual at this season of the year. The Far Eastern portion of the Rand continues to contribute the greatest amount of gold, and this time the Brakpan and Spring Mines, which for some months have done rather badly, are well to the fore with increased profits. The Anglo-American Corporation of South Africa is largely interested in these mines, and as their quotations have fallen so has that of the Anglo-American Corporation in sympathy.

WEEKLY RÉSUMÉ

The strike of miners on the Comstock Lode, in Nevada, remains unsettled, except at the Northend mines, in spite of concessions offered by the operators. Likewise in the Slocan, in British Columbia, the men who struck last May are still out and the shortage of labor is hampering operations. Canada Copper's concentrator at Allenby, B. C., is expected to be running soon when shipments will be made to Trail. The recent advance in freight rates in the United States has been discussed at conferences of operators held in Salt Lake City and Phoenix, Ariz. In the iron country a project to explore the western end of the Marquette Range is under way. The Northwestern is planning to increase the capacity of its Ashland ore docks and improvement of the Great Northern's docks at Allouez Bay has been started. Nov. 15 has been set by the Federal Trade Commission for a re-hearing of the Pittsburgh steel basing point case. In South Dakota at Deadwood the Iron Hill tunnel has reached its objective. In Illinois, various companies in the fluorspar district are affected by a strike of their employees. Explosives experts of the U. S. Bureau of Mines at Washington have undertaken to study the recent Wall Street explosion.

From abroad comes word that Katanga is to increase its capital and that the Knight's Deep stamp mill on the Rand has been destroyed by fire.

Knight's Deep Mill Burned

Fire destroyed the engine room and a 400-stamp mill at Knight's Deep, Ltd., East Rand, Transvaal, on Sept. 20. The damage is estimated at £100,000.

Comstock Mines, Except Northend Group, Remain Shut Down

Men Refuse To Accept Operators' Terms Upon Instruction From Union To Stay Out

The following notice was recently issued by the mine operators of the Comstock district of Nevada to the striking employees:

"In order to arrive at a solution of the labor troubles of the Comstock district, the superintendents have considered the following facts:

"First: That there is no operation on the Comstock lode that is at present in a paying condition and that an increase in wages would be disastrous to all.

"Second: That the prevailing high cost of living is working a hardship on many of the families of the district. The operators have already issued a statement setting forth the fact that they are unable to meet the wage increase, and also their belief that the cost of living is now on the decline. It appears that there is some doubt in the minds of the miners as to the merits of this statement.

"The principal grievance or complaint of the miners seems to be that they cannot live on the present wage in face of the cost of living. With the above facts in mind the operators propose a plan which, it is believed, will in every way answer the demands of the miners for lower living costs and at the same time will provide an absolute guarantee on the part of the operators that the cost of living will materially decrease.

"The proposal is as follows: (1) The scale of wages will be the same as that which has prevailed during the past year. (2) Beginning with the day of the acceptance of this proposal miners or their families may go to the operators' general merchandise store and procure any of the commodities carried in stock at a price 20 per cent below present wholesale prices. This will bring commodities a shade below wholesale prices of 1917 and in reality will result in a saving that will average 25 per cent as compared with present retail prices. The operators, in establishing these reduced prices, desire the co-operation of the advisory committee of miners so there may be no dissatisfaction in this arrangement. Under this plan the operators assume the financial responsibility for any losses that aforesaid store may suffer, either through price changes, upkeep or overhead. (3) Room and board, including rooms with bedding and sheets, will be supplied to single men for $39 per month, which is a reduction of over 20 per cent under present living costs.

The operators make this proposal as a guarantee of their belief that the cost of living will decrease and in a spirit of fair play.

"(Signed)

"H. L. SLOSSON, JR.
"GEORGE H. DRYSDALE
"ALEXANDER WISE
"R. A. HARDY
"H. B. BULMER"

After the appearance of this notice on the part of the operators the United Comstock Mines Co. offered to give the miners in its employ contracts instead of day's pay. Under this arrangement a number of the miners returned to work but the following notice from the Gold Hill Miners' Union stopped all further work:

"NOTICE FROM GOLD HILL MINERS' UNION

"That the minimum be a flat scale of $6 for eight hours' work, and that there be no bonus and that men taking contracts receive a minimum of $7 a day and recognition of the union.

"THOMAS ODGERS, president
"W. J. STACK, secretary"

The situation at present is that work has ceased except in the Northend group of mines under Superintendent Alex Wise. At these properties the $6 per day wage has been granted by the superintendent.

Canada Copper's Mill Ready To Start

The Canada Copper Corporation expects that the new power line to its mill at Allenby, B. C., will be delivered to it complete by Oct. 4. It is stated that there will then be no reason why operation of the mill should not begin within a few days thereafter. The full capacity of the concentrator, namely 2,000 tons, will be worked up to as rapidly as possible. Shipments of concentrates to Trail will begin promptly. The plant has been standing idle since its completion about nine months ago. The railroad is completed and in operation and the heavy machinery has now been moved from Princeton up to the mine and is being rapidly installed on its foundations.

Northwestern Ry. To Increase Capacity of Ashland Docks

The Chicago & Northwestern Ry. is to make an addition and improvements to its No. 3 ore dock at Ashland, Wis., on Lake Superior, during the coming winter. The dock will be lengthened 1,000 ft., extending it clear to the harbor improvement line. This will give 340 pockets instead of 200, and the total storage capacity of the company's three docks at that point will be increased to 213,000 tons. All pockets will be operated electrically. The Soo line has one dock at Ashland which has a capacity of 53,000 tons. All of the ore from the Gogebic Range passes through Ashland during the period of navigation and it is expected that this year's shipments from the range will total about 8,000,000 tons. A large increase is looked for next year.

Slocan's Season Output Crippled by Strike Situation

Operators, Except Silversmith Mines, Standing Pat in Refusing to Employ O. B. U. Members

Since the One Big Union called a general strike in the Slocan, in British Columbia, on May 1 last, the operators, excepting the Silversmith Mines, have refused to employ any man who is an O.B.U. They will, however, employ all men who may belong to other unions or are non-union. Under these conditions they have been and still are working very short-handed. In fact, it is said, this strike has crippled the Slocan output for the season, which promised well in the spring. The general feeling, according to the manager of one company, is that now is the time to take a determined stand and once and for all time to break up the O.B.U. by a concerted effort. The strikers had demanded a $1 per day increase, also that the British Columbia Health Regulation Act be strictly adhered to and that all employees be provided with blankets, sheets, pillows and pillow slips.

Winter is approaching and many men will be released from various outside employments and naturally will look to the mines. Many of the mine workers who went out on May 1 went into the woods and harvest fields. These will probably return to the mines when bad weather sets in and the harvest is over. The prospects are not good, however, for securing a fair-sized crew soon, owing to the demand for building materials and lumber, which is likely to continue.

The 100-ton mill of the Noble Five mine at Sandon, erection of which was begun in May, 1919, was started Aug. 23 last and is operating but one 8-hour shift at present.

Effort To Close Cascade Mill at Neihart, Mont., Fails

The effort of Attorney General Ford, of Montana, to close down the Cascade Mines & Milling Co.'s mill at Neihart, Mont., has failed. Some time ago, acting for local interests, the attorney general brought suit for an injunction requiring the company to desist from dumping its tailings into Belt Creek on the ground that the water was becoming polluted. Testimony was brought forward in favor of granting the order, but the company showed that if such an order was granted it would be absolutely necessary to close the mill down and consequently the mining properties of the company, thus throwing out of work a large number of men and injuring the only industry in the district. The judge, after having had the whole question under consideration for some time, has decided to refuse the injunction. The mill, which has only been running at half force since the proceedings were started, is now operating full capacity and more men are being put to work underground.

Mine Managers Testify at Rate Hearing at Phoenix

Gila Copper Sulphide Paying 7½c. Per Ton More for Nine-Mile Haul

"Sick babies" was the designation applied to small producing Arizona mines by Grant H. Dowell, of the Phelps Dodge Corporation, at a State Corporation Commission hearing at Phoenix, Ariz., to pass upon a petition of the railroads to add 25 per cent to their freight tariffs. It was generally agreed that the increase suggested would stop production in a majority of the smaller properties of the state. Mr. Dowell said that smelting costs at Douglas had about doubled already through added transportation charges. Because of this his company in 1919 paid for customs ores $225,000 less than in the previous year.

G. M. Colvocoresses, the general manager of the Consolidated Arizona smelter at Humboldt, told that increase in freight rates would put about 60 of his customs ores shippers out of business. Especially would there be harm to production at the Swansea mine, now under lease to his company.

Percy Williams, manager of the El Tiro lease at Silver Bell, gave figures showing that his company now is making a profit of 80c. a ton on ores that average 130 lb. of copper to the ton. The proposed freight increase would leave the company 45c. "in the hole" for every ton shipped. George Morris, manager of the Gila Copper Sulphide Co. at Christmas, Ariz., included his mine as one of the "sick babies" and aroused interest by showing that the Arizona Eastern had interpreted the 25 per cent raise as increasing his rate for the haul to Hayden from 22½c. to 30c. a ton. The distance is nine miles for about 250 tons a day. He insisted also that the proposed raise would affect the living costs of his workmen, now furnished supplies at cost, and thus wages would have to be raised in the same old unending round. The railroads claim the increase under the Interstate Commerce Commission's recent interstate order.

Inspiration Sues State and County for Tax Refund

About $1,430,000 is demanded from Gila County, Ariz., and the State of Arizona in a suit filed in the Superior Court by the Inspiration Consolidated Copper Co. and the International Smelter Co., of Miami, Ariz., on account of taxes alleged to have been erroneously collected of the plaintiff corporations during the years 1917, 1918 and 1919. The gross sum due the Inspiration is alleged to be $1,264,000, while the smelter corporation demands repayment of $41,824 for 1917, $76,152 for 1918 and $47,511 for 1919. It is alleged that the State Tax Commission, sitting as a board of equalization, raised the valuations unconstitutionally after the tax rate for Gila County had been fixed by the county assessor and county board of equalization.

Utah Operators and Freight Officials Discuss Rates

Smelters Hit by Increase Effective on Outside Ores—Tonnage Decrease Caused

Mine operators of Utah, Nevada and California have been meeting in informal conference in Salt Lake City with freight officials of railroads carrying ores to the Utah smelters in regard to the matter of the increased rates on low-grade ores as ruled by the Interstate Commerce Commission. As has already been stated in these columns, the state public utilities commission of Utah has refused to allow the increase within the state, so that operators here are not materially affected. But the smelters are affected in the matter of ores coming from outside. It is felt that the 25 per cent increase granted will cause many properties to close down and others to curtail their output of low-grade ores. In Nevada there has been a revival of old producers, which are now adding to the tonnage of low-grade ores. Operators in Plumas County, Cal., according to representatives from that district, would have to close down almost entirely.

It was conceded that both smelters and railroads require tonnage to be able to maintain profitable operation. As none of the officials present were empowered to act, nothing was decided at the meeting, which was held in a friendly spirit. It is hoped, however, that the executives of the various railroads will consider the whole question in the near future.

Arizona Commercial Employees Take Short "Vacation"

A few days' "vacation" was recently taken by about 150 employees of the Arizona Commercial Mining Co. at Globe, Ariz., to enforce against Superintendent Plummer a demand that he cease to exercise authority in the employment of shift bosses, backing up the contention of a foreman that such authority was his own prerogative. When the foreman resigned, he was followed by the shift bosses and then by the miners, only the pump men remaining. The men went back to work after listening to a Federal mediator.

Pittsburgh Steel Basing Point Case To Be Re-heard

By a majority vote the Federal Trade Commission has granted motions filed with it for rehearing and re-argument in the matter of the application of the Western Association of Rolled Steel Consumers for the issuance of a complaint against U. S. Steel Corporation, et al., known as the "Pittsburgh Basing Point for Steel Prices" case. The commission has fixed Nov. 15, 1920, at 11 a.m. as the time for such rehearing and re-argument at the offices of the commission in Washington.

Inspiration Wins Long-Drawn-Out Damage Suit

Through a judgment of the U. S. Court of Appeals at San Francisco, reversing a verdict from the Federal court in Tucson, the New Cornelia Copper Co. finally is victor in one of the oddest cases ever known to mining litigation. On Nov. 27, 1918, a number of Mexican employees of the corporation built a fire to warm themselves while waiting for the time they should go to work. The fire was lighted against an old boiler, property of the company, but for some time unused. In the boiler was a quantity of dynamite stolen from the company hidden by thieves. There was resultant explosion of the powder, with consequent injury to the members of the group of men. The widow of Jesus Maria Ochoa, killed, sued for damages, after refusing an offer of settlement by the company, which, however, at no time assumed any degree of responsibility. In the lower court she was given $10,000. The appellate court fails to find where responsibility attached to the defendant for the explosion.

Quebec Asked To Found Radium Institute

The Faculty of Medicine of McGill University, Montreal, Que., has requested the provincial government of Quebec to found an Institute of Radium. The estimated cost is between four and five hundred thousand dollars, including the price of two grains of radium and the installation of a laboratory.

Recent Production Reports

Calumet & Hecla produced 7,520,107 lb. copper in August against 8,312,025 in July. Production by subsidiaries was as follows: Ahmeek, 1,608,200; Allouez, 49,200; C. & H., 4,259,566; Centennial, 0; Isle Royale, 791,351; La Salle, 0; Osceola, 647,629; Superior, 48,600, and White Pine, 115,361.

Burma Corporation produced 4,424,000 lb. refined lead and 243,340 oz. refined silver in August compared with 3,416,000 lb. refined lead and 190,070 oz. silver in July.

Chile Copper produced 10,640,000 lb. copper in August against 9,904,000 in July.

Kennecott Copper produced 11,268,000 lb. copper (including Braden's output) in August, compared with 10,656,000 in July.

Granby Con. M. S. & P. Co. produced 2,471,200 lb. copper in August compared with 2,400,000 in July.

Cie. du Boleo, Santa Rosalia, Baja California, produced 618,390 lb. of copper in August against 781,613 in July.

NEWS FROM WASHINGTON

Wall Street Explosion To Be Studied by Bureau of Mines

Rice Confident TNT Was Not Used—Research Experiments Under Way

The Bureau of Mines has decided to make an exhaustive investigation of the explosion in front of the New York office of J. P. Morgan & Co. A preliminary investigation was made by George S. Rice, chief mining engineer of the Bureau, who happened to be in New York at the time of the explosion. C. E. Munroe, chief explosives chemist of the Bureau, and Spencer P. Howell, an explosives engineer, have been sent to New York to study the explosion. In this connection the Bureau is conducting experiments to determine the exact effect when explosives are detonated on a platform such as was formed by the wagon carrying the charge which wrought such devastation in Wall Street.

Mr. Rice, who made the preliminary examination for the Bureau of Mines, is of the opinion that the damage done by the explosion was equivalent to the destruction which would be caused by 50 lb. of dynamite, but he does not mean that dynamite was necessarily the explosive used in Wall Street. He feels practically certain that TNT was not used. Mr. Rice made observations of the effects of explosives in the battle area in France and was able to use that information in estimating the amount of explosive which had been used in Wall Street.

Iron Ores of North Carolina To Be Studied

Plans have been perfected for a co-operative agreement between the U. S. Bureau of Mines and the North Carolina Geological and Economic Survey to study problems pertaining to the marketing and treating of iron ores in North Carolina. The work will be confined to the magnetic iron ore fields, where it is believed improved methods will make possible a more extensive commercial exploitation of these ores.

Salary Question Still Unsettled in Bureau of Mines

Difficult To Hold Technical Employees at Present Pay—Resignations Continue

The rapid turnover among the technical employees of the U. S. Bureau of Mines is continuing. Officials of the Bureau are convinced that the salary scale must be advanced to practically that which was recommended by the Reclassification Commission. It is a matter of fact that with the recent increases which it has been necessary to pay laborers at the Bureau of Mines some of the laborers were being paid at a higher rate than the technical men engaged in the work.

Alaska has been without a mining inspector for a number of months because no properly qualified engineer will accept the position for $3,000, which is the statutory salary. After an investigation of the matter officials of the Bureau of Mines are of the opinion that the proper man cannot be secured for less than $4,800.

Vocational Board Training Men in Mining Engineering

The Federal Board for Vocational Education is training more than a hundred disabled ex-service men in mining engineering. These men have been enrolled at the following institutions: Harvard University, Huntington School (Boston), Columbia University, Carnegie Institute of Technology, Lafayette College, Lehigh University, Pennsylvania State College, University of Pittsburgh, University of West Virginia, Georgia School of Technology, Michigan School of Mines, Rolla School of Mines, Montana School of Mines, South Dakota School of Mines, Colorado School of Mines, New Mexico School of Mines, University of Utah, Stanford University, University of Arizona, University of California, University of Nevada, University of Washington, and El Paso School of Mines.

Geologic Work in Tropics Attended by Hardships

Government Engineers in Some Cases Loath To Undertake Such Trips for Private Interests

Formerly it was not difficult for private interests to make arrangements with Government geologists and engineers to make trips into Central and South America. Government agencies interested in mining and oil development rather encouraged the practice and extended leave freely for such trips because their technical employee would return with much information of value to his bureau. There has been no change of bureau policy in that connection, but so many of the men have met with physical misfortunes of one kind or another on these trips that it is becoming difficult to persuade the more experienced engineers to undertake such expeditions.

Geologic work in many tropical areas carries with it the greatest of hardships. Not only are the many animal and insect pests to be contended with but there is often the greatest difficulty in securing food which is at all palatable to those accustomed to an American diet. The worst feature of this type of work, however, is the probability of contracting disease. Among the engineers who have gone out from Washington, several on their return have had to fight stubborn cases of malaria and dysentery. There has been one serious case of blood poisoning, while another engineer has had his hearing affected by his stay in the very high altitudes of the Andes. Others have acquired hookworm to say nothing of those who have ringworm on their feet and legs and have had experience with the tropical type of chigger.

Industry Seeking Government Aid More Than Before

Government agencies in general are being called upon by the industries to a much greater extent than was the case before the war. The result of having maintained clearing houses for many industries in Washington during the war period has acquainted these industries with the advantages coming from such an exchange of information and has familiarized them, as never before, with the service the Government bureaus are prepared to render.

War Mineral Awards

Two claims carrying awards aggregating $5,909.53 were made by the War Minerals Relief Commission during the week ended Sept. 18. In the tungsten claim of Frank W. Griffin $5,837.03, which was 41 per cent of the amount claimed, was recommended. In the chrome claim of William S. Moulton $72.50 was recommended. The claim asks for reimbursement to the extent of $311.50.

Awards during the week ended Sept. 11 have been announced by the War Minerals Relief Commission as follows (The claimant, the mineral, the amount recommended, and its percentage relationship to the amount claimed are shown): Edward De Kruso, chrome, $838.60, 49 per cent; D. R. Ridge, chrome, $163.32, 69 per cent; J. J. Skeahan, chrome, $199, 39 per cent. In the claim of Hymer & Rufener an award of $752.19 had been allowed previously but on the presentation of additional evidence a further award of $2,987.61 has been allowed. In the claim of A. J. Schmidt an award of $2,085.19 had been made previously. An additional award of $90.23 has been allowed.

The case of David Taylor vs. Nevada Humboldt Tungsten Mines Co. was on trial before Judge Farrington of the Federal Court at Carson City, Nev., recently. The case involved two points, that of equity to the property and of money judgment. The property involved is the tungsten mines near Mill City which were sold some time ago to W. J. Loring and associates by L. A. Friedman and associates.

NEWS BY MINING DISTRICTS

MEXICO

Coahuila

The Mexican Coal & Coke Co., having its principal mines at Esperanzas, Coahuila, has asked a concession for the free importation of electrical material for the purpose of establishing a transmission line from Esperanzas to the fields at Palau, Coah., where extensive operations are to be started soon. The permission will be granted undoubtedly, with the usual restrictions. The northern coal fields have been pretty well freed recently of professional labor agitators and an increased output of both coal and coke is anticipated.

CANADA

British Columbia

Acute Labor Shortage Hampering Operations in West Kootenays—Claim Staking Activities Along Lardeau River

Sandon—With the exception of Silversmith, at Sandon, no Slocan property is today operating on a scale of magnitude. The Silversmith company, in the face of protests from other operators, made a peace with the "One Big Union" in the spring, and is now manned in large measure by members of that organization, which claims to be purely Canadian labor organization, in contradistinction to the International Union of Mine Mill Smelter Workers, successor to the A. F. of M. The Slocan strike situation has therefore resolved itself into a three-corned contest between the One Big Union on the one hand and the old International and majority of Slocan mine operators on the other. Summer conditions have favored the former, but it remains to be seen whether the strike can be maintained during the winter months. Signs are not lacking that the One Big Union is losing ground. But even if the strike was to be abandoned tomorrow it is unlikely that Slocan operations would be resumed on anything like the old time scale until next season. With the Silversmith maintaining a crew of about fifty or sixty

men, and an equal number divided between Noble Five, Bosun, Cunningham properties and a number of leasing syndicates, it can be readily appreciated how hard the blow is that has fallen on British Columbia's silver-lead producing area, when it is stated the average number engaged in metal mining operations in the Slocan district during the past four years has been approximately 800.

Rossland — Rossland camp, at one time British Columbia's leader in metal production, has between 300 and 400 men working in the various gold-copper properties of the Consolidated Mining & Smelting Co. of Canada. There does not appear to be a possibility of an immediate increase in operating forces, as Rossland, in common with other points, must face the labor shortage and all costs must be materially reduced before production of the bulk of Rossland ores could be maintained at a profit. Future developments must in a large measure depend upon the outcome of the Consolidated's plans with regard to construction of a large capacity concentrator, designed especially to treat the lower grade Rossland ores. Immediate construction of this plant, which is to be located not far from the big smelter works at Trail, will likely be held back by high construction costs, but should these break in the near future the carrying out of plans in this connection may be brought under way sooner than now appears possible.

Nelson—Nelson, the business metropolis of the Kootenays, and whose existence was initiated by the proximity of the old Silver King mine, can report mining activity in only one instance, this in connection with the California group, owned and operated by the California Mining Co., Ltd., and which early in the season began remodeling the Athabasca mill, with a view to treatment there of California ores. A few men are employed, with the mill running on a one-shift basis. Some 200 tons have been treated and results are reported as being encouraging. Some development is anticipated at the Perrier group, also close to Nelson, during the coming winter.

The Blue Bell, on Kootenay Lake, almost opposite Ainsworth camp, and the scene of the earliest operations in British Columbia lode mining, is working a crew of about twenty-five men in mine and mill, and treating a small tonnage of oxide lead ore found close to the surface. Up to three years ago this property maintained a crew of about 100 men, but an inrush of water flooded the lower workings, and until this spring, with exception of maintenance of shipment of crude oxides, the property was practically non-operative.

The Florence, on the opposite side of Kootenay Lake from the Blue Bell, maintains regular operations at both mine and mill. Aside from the Florence no operations of any magnitude are being maintained in Ainsworth camp, although lessees are working at the Krao and the Skyline. Some very high-grade silver shipments were made by the former during the summer.

Development on South Kork of Kaslo Creek continues to be maintained at Silver Bell, Silver Bear, Index, Revenue and Martin groups. These are all silver-lead properties. The Gibson, one of the most promising groups in that locality, continues inactive, due to litigation, and it is likely a receiver will be appointed to get things in shape so that creditors can be paid off. Cork-Province remains inactive, with no immediate possibility of resumption of operations. There is no doubt as to the possibilities of the property, but considerable expenditure must be made in underground development before it can rank as the really large producer expectations warrant.

Some measure of success has attended leasing operations, more particularly in the Slocan and Kaslo districts. A case in point is at the Whitewater, 17 miles from Kaslo, where about twenty-two men have been leasing for several years past.

Renewed activity in the staking of placer claims is reported from along the Lardeau River. The area is thought to have possibilities from a dredging standpoint. Operations of this sort have been already attempted, but failed because of lack of proper apparatus for handling of large boulders that line the river bed.

Ymir—Good progress is being made in opening the Yankee-Girl mine. Operations underground are proceeding satisfactorily. Considerable new development has been done and a substantial body of ore blocked out. John W. Shaw, superintendent, has left for Toronto, Ont., to submit a report to the Mining Corporation of Canada, which is behind the enterprise, and in the meantime A. W. Newberry, of New York, is in charge.

Ontario

Temiskaming Shareholders To Consider Proposed Purchase of Coal Lands

Cobalt—A special meeting of the shareholders of the Temiskaming has been called for Oct. 7 to consider the proposal to purchase from the McIntyre, of Porcupine, a half interest in the Blue Diamond Coal Mines, of Brule, Alta., and the Canadian Coalfields, Ltd., on the Hay River, Alta, recently taken over by the McIntyre.

The Cobalt-53 in the Gillies Limit has encountered high-grade ore in drifting at a depth of 60 ft.

Gowganda—The Reeves-Dobie has gone into the hands of a receiver and 213 bags of concentrates valued at about $100 a bag have been seized in course of shipment on a judgment against the company for wages.

A mining plant has been installed on the Silver Bullion property at Leroy Lake where a shaft is down about 50 ft.

Skead Township—A shaft is being put down by hand drilling on the Crawford Skead, which will be carried to the 100-ft. level on a vein varying from 2 to 6 ft. in width. Several other veins have been opened up on the surface. A three-drill compressor will be installed.

Special Australian Letter

Queensland

Lead-Silver Strike Made in 1918 Near Brisbane Proves Interesting

Brisbane—An occurrence of silver-lead ore accidentally discovered towards the end of 1918 in the outskirts of Brisbane is developing interesting features and proving very profitable at least to the holders of the property on which the find was made. The locale is a residential site on a hill in one of the most picturesque suburbs of Brisbane known by the aboriginal name of Indooroopilly, four miles from the centre of the city of Brisbane. The owner of an allotment of land on which he had built a cottage was digging a hole in which to plant a fruit tree when he came upon some material which a mining friend told him was silver-lead ore, some of which he had previously been using in the making of a rockery. Exploration, involving the removal of the cottage, was for a time carried out on a small scale, and up to the end of last year there had been sent to southern smelters more than 100 tons of selected ore averaging 100 oz. of silver per ton, the total recovery up to that time being over 10,000 oz. of silver besides 61 tons of lead. Ore of about the same quality has been taken out during the present year, but a strike at the smelting works has delayed treatment.

The government geologist, who has examined the locality, describes the ore, comprising earthy cerussite near the surface passing below into galena, as occurring in a brecciated schist. Many mining leases have been taken up in the vicinity; from the adjoining allotment five or six tons of high-grade ore have been bagged, and during the present year promising developments are taking place. Work on this adjoining property has shown the direction in which the ore-bearing breccia dips; and in another holding the silver-lead-bearing formation has been met and followed back on to the felsite dike—a discovery which is considered of great interest and probable importance.

A novel feature connected with this new mining center is that a company now holding several of the leases has called in the aid of a southern concern called the Electrical Mines Surveys Proprietary, Ltd., which has made a survey with improved apparatus and methods based on the Willinms and Daft system; and a map has been published showing the lodes indicated by the electrical survey.

Queensland mineral country certainly extends over a wide area. Silver and lead are being mined a little way from the southern (New South Wales) border near Stanthorpe, about 200 miles south of Indooroopilly, and also in the Cairns hinterland, over a thousand miles to the north.

In the Stanthorpe district is situated the Jiblenibar arsenic mine, one of a number of state enterprises upon which the present government has entered. There are many occurrences of arsenic in this state, but at pre-war prices it

did not pay to work them. The prickly-pear pest, which is overrunning the pastoral and agricultural areas of Queensland, can be held in check alone by the use of arsenic, and only profitably when this poison can be obtained at a low price. War-time rates made it quite prohibitive, and to meet the difficulty the government are now mining and treating arsenic ore at their own mine, and selling it to settlers for pear destruction at £10 per ton, when the market price is about £60. The mine is developing well, and is already turning out over 50 tons per month, the product of 11 per cent ore. It is now proposed to increase the capacity of the works, and consequently the output. A privately owned mine in the same district has produced, besides tin and copper, about 10 tons of arsenic, valued at £400, per month.

MICHIGAN

Showing Good in Arcadian's New Baltic Shaft—White Pine Not Closed Down

Houghton—The management of Arcadian Consolidated is very enthusiastic over the showing in the New Baltic shaft. On the 600-ft. level of this shaft the New Arcadian lode has been opened for about 24 ft. in the crosscut and the mineralization is even better than in the upper levels.

The New Baltic shaft will be sunk about 300 ft. further and the vein explored every 100 ft. The 900-ft. level drift will be driven to meet the same level in the New Arcadian shaft. These shafts are about 4,000 ft. apart and this long drift will explore the vein in good shape.

The management proposes to make good progress in this development during the coming winter.

The ore being removed from Ahmeek No. 2 shaft continues very rich. The crosscut at the 16th level on the famous Ahmeek fissure vein continues to open up rich mass copper. In the No. 3 shaft the grade of ore shows no change from the average maintained by this part of the mine. No. 4 shaft continues to open up richer ore with depth.

The White Pine, a subsidiary of the Calumet & Hecla, was reported as closed down some time ago. This is not so, as it is still producing a small amount of copper and silver with a working force of about 700 men, which is but a nucleus of their former organization. The decreased labor supply has been particularly hard on these smaller properties, situated so far from the centers of population in this district.

Menominee Range

Cleveland-Cliffs Takes Over Wickwire Lease on Virgil

Iron River—The Cleveland-Cliffs Iron Co. has taken over the lease of the Virgil mine from the Wickwire Mining Co. The mine has been idle for several years but is to be reopened and developed extensively. The shaft is down 300 ft. It is likely that the mine will be worked in conjunction with the Spies, which adjoins on the east. The latter is also a Cleveland-Cliffs property and is getting out ore at present. There is a strong demand for the non-bessemer ores of the Iron River district this season and it is believed that the demand will continue next year.

Marquette Range

Captain Fay To Prospect Western End of the Range

Ishpeming—Captain M. F. Fay, a well-known Duluth mining man, has secured a lease on iron lands in the vicinity of Humboldt, on the western Marquette Range, and is to explore for ore. He expects to start several drills at work at an early date. The only mine now operating in the western part of the range is the Republic, a producer of high-grade hard ores.

No announcement has been made as yet by Henry Ford as to whether or not he will reopen the Imperial mine at Michigamme, which contains a large tonnage of limonite ore. Mr. Ford came into possession of this property when he purchased the holdings of the Michigan Land & Iron Co. from an English syndicate. The Imperial has a steel headframe and other equipment in place and it would not be a great task to unwater the workings, which are quite shallow. There is one other known ore deposit on the Ford lands, in the village of Alpha, on the Menominee Range, but no development work has been done there. Considerable territory remains to be explored.

MINNESOTA

Improving Great Northern Docks on Allouez Bay

Duluth—Total shipments of iron ore from the Lake Superior docks up to Sept. 1 were 35,349,874 gross tons, as compared with a total shipment of 29,598,048 on the same date last year, an increase of 19.43 per cent. It is estimated that upward of 60,000,000 tons have been contracted for shipment this season, but it is now doubtful if it will be possible to get this amount of ore down the Lakes before close of navigation. There has been great delay to boats at the lower end of the lakes, owing to car shortage at Lake Erie ports, and it is stated that many boats will not be able to fulfill their season's contracts.

Work has been begun on improvements and additions to the Great Northern ore docks on Allouez Bay, which it is estimated will cost $800,000. Peppard & Fulton, of Superior, have been awarded a contract for wrecking and rebuilding the outer end of No. 3 dock and building approach to No. 1 dock. In the reconstruction of No. 3 dock there will be required 7,500,000 ft. of timber, 70,000 lin.ft. of piling, and 1,245 tons of structural steel; 166 spout hoists will be installed and operated by electricity throughout.

Cuyuna Range

Development of Maroco Property Started—Feigh Mine Stockpiling

Trommald—Active development work has been begun on the Maroco property, leased last winter by the Marquette Ore Co., of the E. N. Breitung interests, from the North Range Iron Co. Stripping of overburden was recently started and is proceeding at an average rate of 5,000 cu.yd. per day. The overburden is shallow, ranging from 45 to 55 ft. in depth, and is being removed by hydraulic methods, using pressure giants and sand pumps. An inclined shaft has been completed to the 210-ft. level and will serve for hoisting ore from future pit. A half-unit washing plant is being completed at the property for treating a large portion of the orebody, which is a fair grade non-Bessemer iron ore. An Allis-Chalmers trommel screen, log washer, and turbo are to be installed. Provision made for later installation of tables if early results show advisability of so doing.

The Merritt Development Co. reports the production of 200 tons of high-grade manganiferous iron ore daily from the No. 4 shaft of Merritt mines. The operators have sold 22,000 tons for this season's shipment, manganese to average better than 20 per cent. Stockpile at No. 1 shaft will be shipped this year, and operations may be resumed underground at the No. 1. It has also been reported that Merritt Development Co. is considering taking over a lease on the Ferro mine property, adjoining the Merritt No. 4 orebody on the west.

Ironton—Held up by lack of boats and dock space the Feigh mine has been forced to stockpile its ore for the past two weeks, and the operators report that they do not expect relief for another week. Concrete foundations have been placed for new boiler and hoist house, 47 x 76 ft., and new change house, 33 x 56 ft. An engine generator set will be transferred from the Carpenter mine, Crystal Falls, for auxiliary power.

Coates & Tweed will start construction on a large combined engine-repair, blacksmith, and carpenter shops, at their Hillcrst open pit mine.

The Mahnomen Mining Co. have started driving exploratory drift south from east end of Mahnomen mine pit to crosscut ore formation on the old Mangan No. 2 mine property, taken over last winter from the Mangan Co.

ILLINOIS

Strike Affects Many Properties in Fluorspar District

Elizabethtown—There is a strike on at the Rosiclare Fluorspar & Lead Co.'s mines, also at Fairview Fluorspar & Lead Co., and the Hill Side Mines. All of these mines are located near Rosiclare, Ill., and about three miles from Elizabethtown, Ill. There has been no trouble and no agreement has been reached. There was a strike at Rosiclare and Fairview about four years ago; guns and ammunition was shipped in and a fight followed, the operators then winning.

Fairview and Rosiclare are operating with a very small force of men and are keeping water out and mining a small amount of ore.

The Hill Side mines are a new concern, located on the Rosiclare vein and not yet doing actual mining. They are erecting one of the finest and largest plants ever placed in the fluorspar country. All work is at a standstill.

The Indiana Fluorspar Co., who are operating a diamond drill in their main shaft, recently lost the drill and are now sinking a small shaft to recover the tools. They have shipped very little ore this year.

The Superior Fluorspar Co. near Hicks and north of Elizabethtown, Ill., are running full blast, and are sinking another shaft. They have just purchased another hoisting engine for this purpose. Considerable high-grade ore has been shipped, and several hundred tons are on the dump and in bins, all being sold.

The Diamond Fluorspar Co., near Karbers Ridge, Ill., are operating with a small force of men. They have shipped three barges of high-grade fluorspar recently and are not effected by the strike.

The Spar Mountain Co., of Cave-in-Rock, Ill., have now about an 8-ft. blanket of ore. They are operating both at the mine and mill and are shipping considerable ore of both medium and low grades.

Several of the mines in and about here are closed on account of poor labor and bad conditions in general. Some have been closed for about a year. The mines are about the only means of employment in this section and men have nothing else to work at. This has not been a union section. The miners at Rosiclare and Fairview recently organized and at once made demands on the companies, which were turned down. The strike followed.

SOUTH DAKOTA

Iron Hill Tunnel Cuts Old Workings—Rescue Car No. 5 at Lead

Deadwood—The tunnel that has been driven for the last two years to tap the old workings of the Iron Hill mine in the Carbonate district has been completed. The old workings were cut at a depth of 300 ft. and the entire mine has been drained and exploration of the once famous silver property started. Active development work will be continued.

Lead—U. S. Bureau of Mines Rescue Car No. 5 in charge of B. W. Dyer, engineer, has arrived in the Black Hills and will spend two weeks giving instructions in first-aid and mine-rescue work.

Galena—Work has been resumed at the mine of the New Silver Queen company under the direction of Robert Scholt and regular shipments of lead-silver ores will be made to the smelter. Electric lines are being extended to the mine and the entire equipment will be electrified. Several shipments of high-grade lead silver ores were sent to the smelter early in the year. Production is expected to increase as the installation work is completed.

UTAH

Tintic Standard Explains Passing of Dividend

Salt Lake City—The Cardiff is shipping up to 65 tons of ore daily and expects to add to this tonnage as soon as some of the lower workings have been unwatered.

Eureka—Tintic shipments for the week ended Sept. 17 amounted to 147 cars.

The North Standard is continuing shaft sinking, working two shifts. The shaft is expected to reach the 800-level in six weeks.

A statement issued by Tintic Standard officials explains the passing of the quarterly dividend for the quarter just ended as having been due to making the final payment for the new railroad and to paying 60 per cent of the cost of the mill now being constructed, the total amount paid out amounting to about $360,000. The working force is stated to have been for the last three months 60 per cent of what was required. A dividend is promised at Christmas, after production has been speeded up by the addition of workmen available at the end of the harvest season. It is further stated that development has been hampered by lack of labor, and that some work, such as the sinking of the proposed new shaft, has been given up for the present. Development in general, however, is well ahead of production.

American Fork—The American Consolidated, a merger of the old Bog and Earl-Eagle properties, has taken a bond and lease on the Silver Dipper, lying above the Bog in American Fork Canyon.

Bingham Canyon—The Utah Consolidated is completing its new machine shop and the new change rooms for the men. Grading and concreting for the company's new concentrator in Pine Cañon near the International smelter is being done with a large working force.

IDAHO

The Cœur d'Alene District

Bryan Strike Continues Interesting—Federal Seeks Writ in Star Case

Wallace—The Imperial Mining Co. is starting to raise 700 ft. from the lower tunnel to connect with a winze sunk 50 ft. from the upper tunnel. This winze has been sunk on the vein that shows several feet of ore that assays as high as 6 per cent lead. The lower tunnel, which is 4,200 ft. long, was run with the expectation of cutting this ore body, but failed to do so after two crosscuts had been run aggregating 500 ft. The raise is expected to give a line on the course of the ore and permit its development on the lower level.

The strike on the Bryan, reported several weeks ago, continues to be the center of much interest. Since the discovery was made the ore has been crosscut 15 ft., showing continuous lead-silver ore of good milling grade, some of which will pay to ship crude.

PORTAL OF IRON HILL TUNNEL, DEADWOOD, S. D.

Control of the Bryan is owned by E. R. Day, of Wallace. The minority interest is owned by Charles Burns, also of Wallace, who was preparing to work the property under lease. The Bryan is located in the East Cœur d'Alene district, about five miles from Saltese, Montana. Development will now proceed with every indication that the property will prove up well.

The Sunset mine is being unwatered as a means of entering the West Sunset, formerly known as the Portland group, which is now owned by the West Sunset Mining Company, of which the Days are the controlling factors. The Sunset and West Sunset have a common end line, from which the Sunset shaft is about 250 ft. This shaft has been sunk vertically 800 ft., from which levels have been run both east and west, showing up much low-grade lead-silver and zinc ore. The Sunset is owned by Senator W. A. Clark, of Butte, from whom the Days have secured permission to enter the West

Sunset through the Sunset shaft. The purpose of the Days is understood to be merely to take advantage of this means of investigating the orebodies of the West Sunset at a greater depth than has been obtained by tunnel, and if the showing justifies to drive a deep tunnel for a permanent outlet from some point on Beaver Creek, which will give a depth of 2,000 ft. or more. With the mine unwatered it is believed that the Days will give it a thorough inspection with the view to purchasing and consolidating it with the West Sunset.

The final step in the apex litigation between the Star Mining Company and the Federal Mining & Smelting Company has been taken by the Federal. Having had its application for a rehearing denied by the court of appeals at San Francisco, Federal has now appealed to the Supreme Court of the United States for a writ of certiorari.

MONTANA

Philipsburg District Actively Producing Manganese Ore

Butte—Successful extraction of lead values from residue from the electrolytic zinc plant at Great Falls is proceeding at an old copper stack remodeled to meet the necessities of lead reduction. Fifty tons of residue daily are being treated, but with the success attending the venture it is deemed likely that the tonnage will be increased.

Philipsburg—More than one thousand men are engaged in the production of manganese and silver ore here at the present time. A good sale is being had for all high-grade manganese. Of interest is the fact that Montana is leading the nation in the production of manganese, with the Philipsburg district in the van in the state.

Scratch Gravel District—Reorganization of the Scratch Gravel Gold is under way and it is expected to resume operations within several weeks. The property is located about three miles northwest of Helena.

Comet District—Operations will soon be resumed at the Comet mine, near Wickes, Mont., with a new treatment process for the complex silver-zinc ores.

Libby District—The Lukens-Hazel power plant will be in operation within a few days and it will be possible shortly to begin milling operations.

WASHINGTON

Power Shortage Hampers Work in Oroville-Nighthawk District

Nighthawk—Mining activity in the Oroville-Nighthawk district is being seriously hampered by power shortage. The Similkameen Power Co., which furnishes power to the mines of the district, is building a large power dam across the Similkameen River and planned to furnish additional power by May, 1921. Failure of delivery of the large water wheel for the plant has held up the work and it will be several months before the power will be ready for the mining companies. The new 75-ton mill for the Ruby mine is fully completed and will be put in operation as soon as power can be secured.

At the Kaaba mine the southern extension of the vein is being explored from the 200-ft. level; this work is adding appreciably to reserves.

The Four Metals Co. have sunk a vertical shaft 100 ft. on the Shamrock vein which they encountered in a 30-ft. drift from the bottom of the shaft. On the Alice vein, owned by the same company, a 135-ft. incline shaft has been sunk on the vein and from the bottom of this shaft drifts are being extended to develop a tonnage of ore sufficient to warrant erection of a mill.

OREGON

War Eagle Company, at Gold Hill, To Erect Quicksilver Furnace — Gold Quartz Discovered Above Oakridge

Gates—The storeroom, cook and bunk houses at the North Queen gold property in the Quartzville mining district, southwest of Gates, was recently burned, the loss being about $4,000. The property is owned and operated by A. M. Hammer and John McChesney, Albany, Oregon.

Oakridge—A vein of gold-bearing quartz was recently discovered in the upper Willamette River country, twenty-six miles above Oakridge, where gold has never been found before. The find has caused the usual excitement at Eugene, the nearest shipping point.

Gold Hill—The Chisholm quicksilver mine in the Gold Hill district, which has been closed for several months, has resumed with a small crew. It is equipped with a 12-pipe furnace. Negotiations are still under way for its sale. The prospective purchasers talk of erecting a Scott furnace of large capacity. The War Eagle Mining Co., owners of adjoining property, are assembling material and equipment on the ground to erect a furnace of this type. This will be completed within sixty days. Their present equipment consists of several 12-pipe furnaces.

CALIFORNIA

Reinmiller Claims at Engelmine Being Surveyed

Engelmine—George W. Lloyd and Charles J. Worden have a contract to survey the fifty-six claims owned by the Reinmiller Copper Mines Co. and are now engaged in the work. The claims extend for three miles and include sites for a reduction plant and sawmill. The road to the portal of the tunnel that is to be driven is now being graded and a boiler and compressor will soon be installed. John Reinmiller, president of the company, was in charge of the Engels from 1915 to 1919, when it was developed from a prospect to a dividend-paying mine.

M. H. McKelvey, superintendent, is planning to start driving a tunnel which will cut at about 1,000 ft. depth the big mineralized area on the Plumas Copper King mine, adjoining the Superior mine of the Engels Co. on the south.

NEVADA

Commissary in Tonopah and Divide Districts Cuts Living Cost

Tonopah—In the Tonopah district there is a shortage of skilled miners in the larger mines. Wages are high and living conditions excellent, and the healthy condition of the camp in general is indicated by the ever increasing number of houses that are being moved into town from Goldfield. The commissary established by the companies of the Tonopah and Divide districts is operating successfully and has cut living costs about 20 per cent. The volume of business handled is direct evidence of appreciation by the workmen of these districts.

The Tonopah Mining Co. shipped 1,500 tons last week, which is normal tonnage for the present time. In the Silver Top section of the mine ore is being broken in stopes near the surface, and development and stoping is being done on the Mizpah fault vein, the MacNamara vein and the Mizpah vein with good results.

The Tonopah Belmont mine is producing about 350 tons of ore per day, and in addition the mill is handling an irregular tonnage of custom ore from various parts of the district. No new developments of importance are reported with regular development work being performed from the 700, 800, 900, 1,000, 1,100, and 1,200 levels on several veins.

West End shipments for the last week were about 1,400 tons. Development work was accomplished on the 500, 600, and 800 levels on the West End, Footwall and Ohio veins with normal results.

The Tonopah Extension report shipment of 1,750 tons of ore for last week which is a little higher than usual for the past few months. Sinking of the Victor shaft is progressing satisfactorily and the water flow is being handled with little trouble. Development work was done in the Victor, McCane and No. 2 shaft sections of the mine on different levels, with no discoveries reported.

Divide—In the Tonopah-Divide mine stations on the 800 and 1,000 levels are complete and crosscutting is to be started in a few days. On the upper levels development faces are reported to be looking exceptionally well and a considerable portion of the regular ore shipments is coming from development. On the 165 level the vein is being crosscut at three points about fifty feet apart in ore. Other work on the 270, 375, 480 and 575 levels was done, the majority being reported as being in ore of milling grade.

Pioche—The Pioche Metals Mining Co. recently leased their Point property to Arthur Reall and associates of Pioche. Operations have been started.

The Victoria Nevada recommenced sinking their main working shaft Sept. 10. The shaft at present is 165 ft. deep and will be put down to the 200 ft. point before further drifting is done.

Everett Wade of Salt Lake City, Utah, has taken a lease from the Bristol

Silver Mines Company on the May-Day mine at Bristol.

William Willoughby and Cy Thomas are operating in the Zero territory and are taking out good silver-lead ore. Returns on their last car netted about $500.

At the Deerfoot mine recent prospecting has shown up a promising new orebody which should yield considerable ore of shipping grade. Average assays across the body show 30 oz. in silver, which is the principal value. The Deerfoot is credited with a production of 385 tons during the last eight months.

Arthur Reall, of Pioche, has started operations with a small force of men at the Telephone mine. Recent examination of the underground workings has demonstrated the presence of a body of lead-silver ore which can be opened up with a small amount of development.

The Prince Consolidated is shipping at present over 5,000 tons per month and has produced from Jan. 1, 1920, to date the large total of 36,151 tons. The ore is of the usual fluxing grade, 75 per cent of the total tonnage being derived from the prolific Davidson bed and the remainder being mined from the big bed of the Prince. Arrangement will shortly be completed for resuming sinking of the main shaft to the lower beds. A pleasing improvement is being noticed in the greater efficiency of the underground labor employed. Production is being maintained with fewer men, who are showing a spirit of loyalty to the company which insures economy of operation.

The Virginia-Louise is doing a large amount of development work and the orebodies are proving to be of greater extent than anticipated and well up to average grade. A large tonnage is being shipped and with an improving lead market the product is bringing a satisfactory return.

The Pioche Silver Corporation, whose property adjoins the Virginia-Louise Mining Co. to the south, is planning a development campaign to pick up the extension of the Virginia-Louise ore beds. It is expected that operations will be started in the next sixty days. Charles Lee Horsey is president.

Uncertainty of the application of the new freight rate caused a slight decrease in the tonnage shipped.

Construction work is proceeding at the Southern Nevada mill, which is next to the Pioche R.R. depot. It is expected the plant will be in operation within the next two months. Delay in delivery of some of the essential equipment has entailed much hardship on the management. When completed this plant will treat the milling ores now available in the properties of the Pioche Mines Co., and such other ores as are suitable to the flow sheet.

Como—As a result of a recent boost in the cost of electric power, the high cost of labor and mining supplies, together with discovery of theft of bullion from the mill, Gurney Gordon, manager of the Como Consolidated, has decided to shut that property down for the present at least. The pumps will be pulled.

Tybo—The furnace at the Tybo smelter has been shut down temporarily, as Fred W. Draper, manager found it impossible to get enough miners to produce on a scale that would keep the furnace going and to do development work. He is planning to cut down the size of the furnace, but before doing so wishes to see if the approach of cold weather will not improve the labor situation. The mill is running steadily three shifts and about eight tons of $100 concentrates are shipped daily.

Piermont—A hydro-electric plant for power and lighting is being installed at the Piermont mine in Spring Valley, White Pine County.

Tule Canyon—W. J. Loring, manager of the Silver Hills company, has decided to let leases on the company's property in Tule Canyon, 40 miles southwest of Goldfield.

Jean—The directors of the Christmas Consolidated mine, which is located nine miles southwest of Jean, recently engaged Henry M. Adkinson, a geologist of Salt Lake City, to examine their property and outline a program of development. Mr. Adkinson suggested that the production might be increased by leasing the old workings where much high-grade ore is still to be mined. Special attention was paid to the vanadium deposits which have been uncovered at the Christmas mine and, following Mr. Adkinson's complete report, it is planned to enter upon an active development campaign.

Battle Mountain—Eight sets of lessees are at work on the property of the Maysville Consolidated, 15 miles south of Battle Mountain, and all are said to be in silver ore of shipping grade. Rollins & Williams shipped a carload from their lease in August which ran better than $200 per ton.

Copper Basin—Frank B. Keever is operating the Bentley mine at Copper Basin, south of Battle Mountain, under bond and lease. He is reported to have developed considerable $35 to $40 ore and ships what is taken out in development.

Pyramid Lake—The Nevada Western Gold & Silver Mining Co. are preparing for active operations on their property near Pyramid Lake and have bought a hoist, a Chicago Pneumatic compressor and a Cochise drill from the Western Engineering Co., of Reno. H. W. Dawes is general manager.

Leadville—The mill at the Leadville mine, 40 miles north of Gerlach, which was developed by Johnny Harnan, is again being remodeled and a flotation system is being installed.

Contact—Ed Gray is developing a property at the copper camp of Contact. Contact will be on the line of the proposed railroad from Twin Falls, Idaho, to Wells, Nev., the actual building of which is expected to begin shortly.

ARIZONA

C. D. Ridgeway Takes Over Arabia Mine in Mohave County

Stockton Hill—The C. O. D. shaft has reached the 400-ft. level where station and skip pocket are being cut. The first carload of machinery for the new mill arrived in Kingman on Sept. 15. This shipment included crusher, rolls and ball mill. Hauling to the mine and installation is under way.

The I. X. L. has installed a larger compressor and a contract has been let for sinking the shaft another 100 ft. The new auto road to Berry on the main line is now in use.

Mineral Park—The Golden Star has made a 50-ton test shipment to the smelter of ore recently cut. The ore, while extremely high grade in spots, is variable. Results from this shipment will determine average values.

Chloride—The Pay Roll crew are making good progress in cleaning up and retimbering the shaft. It is hoped that conditions will permit resumption of sinking in the near future.

The Hidden Treasure has added a night shift. Drifting continues along the main vein and a good grade of milling ore is being opened up.

The Dardanelles shaft is now down 175 ft. Hard rock and pumping problems delayed progress during August. It is hoped that crosscutting for the vein on the 200 level will be under way soon after Oct. 1.

The Arabia mine in the Union Pass district has been taken over by C. D. Ridgeway and associates. The mine camp is being overhauled. Grading for new hoisting equipment at the old shaft is under way. The workings will be unwatered and an underground crew put to work as rapidly as possible.

Paradise—The Cochise Mineral Mines Co. have driven their main tunnel 700 ft. Several veins showing upon the surface have been cut so far showing good values in lead-silver. A good vein of manganese has also been cut. H. D. Buford is general manager in charge.

NEW MEXICO

Octo at Lordsburg Cuts Sulphide Vein at 300 Level

Lordsburg—The Octo has cut a strong vein in copper sulphides carrying some red oxides at 170 ft. east of the main shaft on the 300-ft. level, which so far shows a width of 5 ft. with the opposite wall not yet struck. This is the deepest ore showing on what may be termed the north side of the district and confirms favorable surface indications. Fred C. Semmek is manager.

Exploration work on the lead-silver veins on the Monte Rica property is showing excellent results. The veins are strong and the values well disseminated. Tentative arrangements have been made with Virginia parties that may lead to the erection of a mill, which would be well justified by the mineral showings. Lawrence Boyd is manager.

THE MARKET REPORT

Daily Prices of Metals in New York

Sept.	Copper Electrolytic	Tin 99 Per Cent	Tin Straits	Lead N Y	Lead St L	Zinc St L
23	17.90@18.35	41.50	43.50@43.75	7.25@8.00	7.65	7.60@7.70
24	17.80@18.25	41.25	43.50@43.75	7.25@8.00	7.65	7.60@7.75
25	17.75@18.20	41.25	43.25@43.50	7.25@8.00	7.65	7.60
27	17.75@18.15	41.75	43.25@43.75	7.15@8.00	7.65	7.55@7.60
28	17.75@18.10	41.75	43.00@43.50	7.15@8.00	7.65	7.50
29	17.75@18.00	41.50	42.75@43.25	7.15@7.75	7.50	7.45@7.50

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point. All prices are in cents per pound.

Copper is commonly sold on terms "delivered," which means that the seller pays the freight from refinery to buyer's destination. The delivery cost varies, and it would be confusing to figure net prices on individual transactions. Consequently, an average deduction of 0.15c. is made from the "delivered" price to arrive at the New York price. When copper is sold f.o.b. or f.a.s. New York, of course no deduction is made.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Sept.	Copper Standard Spot	Copper Standard 3 M	Copper Electrolytic	Tin Spot	Tin 3 M	Lead Spot	Lead 3 M	Zinc Spot	Zinc 3 M
23	96⅛	97⅛	112	268¾	273¾	34⅞	35	41	42⅛
24	95¾	97⅛	112	268¾	274	34⅝	35	40⅞	41¾
25	....	....	....	....	....	....	....	....	....
27	95⅛	96⅛	113	271	276½	34⅞	35	41½	42
28	93⅜	94⅞	113	271⅜	276¾	35	34¾	41⅛	42⅛
29	94	95	113	268½	274½	34⅞	34¾	40¾	41¼

The above table gives the closing quotations on the London Metal Exchange. All prices in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Sept.	Sterling Exchange	Silver New York, Domestic Origin	Silver New York, Foreign Origin	Silver London	Sept.	Sterling Exchange	Silver New York, Domestic Origin	Silver New York, Foreign Origin	Silver London
23	349⅜	99½	94	59⅞	27	349	99½	93	59⅛
24	347½	99½	93	59⅜	28	349⅜	99½	93	59⅝
25	347	99½	93	59½	29	348¼	99½	92¼	59⅜

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States. This quotation is retroactive to May 13.

Metal Markets

New York, Sept. 29, 1920

The industrial reaction which has been such a pronounced feature of the last week's news has not been without its influence on the metal market. Practically all buying except on a hand-to-mouth basis has ceased. Consumers are looking for lower prices on everything, and the fact that many metal prices are already at or below the cost of production is considered no argument why the market should not drop further. The tone of the producers and selling agencies is hopeful, but in almost all instances large tonnages would be sold at markedly cut prices if buyers could be found. The prompt market is quiet, but demand for forward delivery is absolutely dead.

Copper

The larger producers have apparently decided that the time has come when it will no longer be advisable to continue production without selling, and are willing to meet the market half way. No one is now asking more than 18½c., delivered, and this price has to be shaded to attract even small business.

Some electrolytic copper has been sold for export, and the London price has advanced. Five thousand tons of December copper was offered at 18c., delivered, late last week, but found no takers. Many normal buyers of copper whose business is good are not in the market, because they are using scrap metal, large stocks of which continue to be available. Rumors of a pronounced cut in the price of copper sheets have been heard, the normal differential of 3 to 4c. from the price of unfinished forms having been considerably exceeded in recent months.

Lead

Last Thursday the A. S. & R. reduced its contract price from 8⅛ to 8c., New York, and a further reduction to 7¾c. was made today. This should tend to cut off foreign importations, which continue unabated. Imported lead on the dock here was offered late last week at 7.75@7.50c., and early this week at 7.40c. Prompt shipment from Germany is offered at 7c., duty paid. The tone in the Middle West is also easier. Many cancellations and postponed deliveries are being requested, and producers who have been turning away inquirers for the last few months are now scurrying after business. Spot lead continues in fairly active demand for small lots, and quick deliveries obtain a slight premium over our quoted prices.

Zinc

A fair demand has existed, but only at decreased prices. With the freer movement of sheets, demand from galvanizers was expected, but it has not come. Apparently the only galvanizing business demanding zinc is that of wire. One large producer predicts 7c. zinc in the near future. This would of course mean that production would be curtailed, but this would be offset by the absence of export demand, which has been normally about 8,000 tons per month.

Tin

Consumers are being advised to buy a supply of tin at current low prices, as dealers predict an upward tendency soon. Whether the wish is father to the thought remains to be seen. Anyway, the market continues very dull. Some small sales of electrolytic have been made at or fractionally under the price of spot Straits. Producers of high-grade 99 per cent are not willing to sell at present prices.

Straits tin for future delivery: Sept. 23d, 44.25@44.75c.; 24th, 44.50@44.75c.; 25th, 44.25@44.50c.; 27th, 44.25@44.50c.; 28th, 44@44.50c.; 29th, 44.00c.

Arrivals of tin in long tons: Sept. 22d, London, 25; 27th, London, 225; Singapore, 450.

Silver

The silver market remains quiet and dull, with small purchases for China account. India, however, continues to keep out as a buyer. The London quotation today is 59½d., with the market reported sentimentally weaker on the Indian government ceasing to sell sterling drafts on London. Purchases of silver to date by the U. S. Government under the Pittman Act amount to about 16,000,000 oz.

Mexican Dollars—Sept 23d, 71⅞; 24th, 71; 25th, 71; 27th, 71; 28th, 71; 29th, 70¼.

Gold

Gold in London on Sept. 23d, 117s. 6d; 24th, 117s. 9d.; 27th, 117s. 11d.; 28th, 117s. 11d.; 29th, 117s. 9d. Correction: Gold on Sept. 15th, 118s. 6d. instead of 117s. 4d.

Foreign Exchange

The market for European exchange has been very thin, and on that account fairly wide fluctuations during a day's trading are not particularly significant. No important changes have taken place in the last week. On Tuesday, Sept. 28, francs were 6.71c.; lire, 4.19c.; and marks, 1.63c. New York funds in Montreal, 10⅝ per cent premium.

Other Metals

Aluminum—For 50-ton lots: ingot, 99 per cent and purer, 35c.; 98@99 per cent, 34.8c. Virgin metal still obtainable in open market at about 32.5c. for 98@99 grade.

Antimony—Spot metal, 7¼@7½c. per lb. Cookson's "C" grade, 12½c. Chinese and Japanese brands, 7¼@7½c. W. C. C. brand, 9@9½c. Chinese needle antimony, lump, firm at 7½c. per lb. Standard powdered needle antimony (200 mesh), 11½c. per lb. Market dull.

Bismuth—$2.55 per lb., 500-lb. lots, and $2.57 per lb., 100-lb. lots. Market quiet.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady. Probably no change before Jan. 1.

Cobalt—Metal, $6 per lb.; black oxide, $4.10 per lb.; sulphate, $1.60. Market probably firm for some time.

Iridium—Nominal, $350@$400 per oz. Heavy demand, but small supplies.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb. for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]**Molybdenum Metal** in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.

Monel Metal—Shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$100@$110 per oz.

Platinum—Firm at $115 per oz.

Quicksilver—Market quiet; $75 per 75-lb. flask. San Francisco wires $75. Unchanged.

Ruthenium—$200@$220 per troy oz.

[1]**Selenium**—Black powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]**Thallium Metal**—Ingot, 99 per cent pure, $20 per lb.

[1]**Tungsten Metal**—$35@$60 per kilogram, according to purity and gage.

Metallic Ores

Bauxite—About 52 per cent alumina content, less than 2 per cent iron oxide, up to 20 per cent silica and artificially dried to contain not more than 4 per cent free moisture, $10 per gross ton at mine; 54 per cent alumina and about 15 per cent silica, $11; averaging 57 per cent alumina, 8 to 12 per cent silica, less than 3 per cent iron oxide, $13 on basis of 8 per cent free moisture. Ores of very low silica content suitable for the manufacture of aluminum oxide and hydrate of alumina command a fancy price.

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a maximum of 6 per cent silica, 70@80c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 70@75c.

Manganese Ore—65@75c. per unit, seaport; chemical ore (MnO_2) $70@$90 per gross ton, lump; $80@$100 per net ton, powdered.

Molybdenum Ore—85 per cent MoS_2, 70@75c. per lb. of contained sulphide, New York.

[1]**Tantalum Ore**—Guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots, against recent price of 65@70c.

[1]**Titanium Ores**—Ilmenite, 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $6 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, 85, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[1]**Zircon**—Washed, iron free, 5c. per lb.

[1]**Zirkite**—$90@$100 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

Zinc and Lead Ore Markets

Joplin, Mo., Sept. 25—Zinc blende, per ton, high, $48.55; basis 60 per cent zinc, premium, $45; Prime Western, $15; fines and slimes, $42.50@$40; calamine, basis 40 per cent zinc, $35. Average settling prices: Blende, $46.15; calamine, $38.27; all zinc ores, $46.09.

Lead, high, $101.15; basis 80 per cent lead, $90@$80. Average settling price, all grades of lead, $94.09 per ton.

Shipments for the week: Blende, 11,560; calamine, 81; lead, 2,030 tons. Value all ores the week, $727,590.

Shipments for nine months: Blende, 430,516; calamine, 7,312; lead, 67,598 tons. Value all ores nine months, $28,164,660. The shipment is 72,223 tons blende and 13,676 tons lead excess over last year, with calamine 2,798 tons less.

Reports from the smelting area south and west indicate more labor trouble early in October.

Lead prices have dropped $32.50 per ton in three weeks. A number of mines have made profit principally from lead sales, and this extraordinary decline will put some of them below the profit line.

Platteville, Wis., Sept. 25—Blende, basis 60 per cent zinc, $49.50 base for high-grade. Lead ore, basis 80 per cent lead, $90 per ton. Shipments for the week: Blende, 1,311; calamine, 30; lead, 40 tons. Shipments for the year: Blende, 51,326; calamine, 2,429; lead, 4,248; sulphur ore, 1,241 tons. Shipped during the week to separating plants, 2,871 tons blende.

Non-Metallic Minerals

Asbestos—Crude, No. 1, $2,400@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15 all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax.

Barytes—Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $24@$30 in bags, carload lots; (off-color) $22@$26 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $12 per gross ton; ground (white) $23@$25; ground (off color) $16@$19 per net ton, f.o.b. Cartersville, Ga. Crude, 88 to 94 per cent, $23; ground (white) $45; ground (off color) $30@$32 per net ton, less than carload lots, f.o.b. New York. Crude, not less than 98 per cent, $11@$11.25 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—Domestic, extra light, 5@6c. per lb.; light, 4½@5½c.; heavy, 4@5c; English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin)—Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground, $15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$18 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $80@$35, car lots, f.o.b. Baltimore; ground, $17@$21, f.o.b. North Carolina points; $17@$21 per ton, No. 1 ground, f.o.b. New York State; $21@

[1]Furnished by Coote Mineral Co., Philadelphia, Pa.

$23 per ton, ground, f.o.b. Maine. Crude spar very scarce.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Gypsum—Plaster of Paris in carload lots sells for $4.25 per 250-lb. bbl., alongside dock, New York.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $75@$85 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—India block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20 @$1.40; No. 4, $2@$3; No. 3, $4.25@ $5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $4; No. 3, $5.75, No. 2, $7; No. 1, $9; A1, $14; extra large, $25, all f.o.b. New York; ground, $100@$150 per ton, Philadelphia. Domestic, uncut, f.o.b. Franklin, N. C., as follows: Scrap, $45 @$50 per ton; punch, 4@5c. per lb.; circle, 15@25c.; 1½ x 2 in., 75c.; 2 x 2 in., $1.15; 2 x 3 in., $1.65; 3 x 3 in., $2.10; 3 x 4 in., $2.50; 3 x 5 in., $2.75; 3 x 6 in., $3.75; ground 165 mesh, $240 per ton; ground roofing mica, $60; mica washers, 75c.@$2 per lb.; 1¼-in. disks, No. 1, $1.60 per lb.; No. 2, $1.30.

[1]**Monazite** — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses. Tennessee production sold up months ahead.

Pumice Stone—Imported, lump, 4@ 50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish fines, per unit, 12c., c.i.f. Atlantic seaport; furnace size, 17c.; Spanish lump, 14@16c.; domestic fines, f.o.b. mines, Georgia, 12@14c. Market improving.

Quartz—(Acid tower) fist to head, $10; 1¼ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines. F.o.b. Wausau, Wis., the price is $16 per ton in car lots, and $22 in less quantities, including bags.

Sand (Glass)—Dry glass sand, $4 per net ton, f.o.b. cars Mapleton, Pa. Sand, f.o.b. Ottawa, Ill., is $3 per ton; $2.50 on annual contracts. Sand at Klondike, Gray Summit and Pacific, all in Missouri, is $2.50 on contract; some outside sales have been made at $4.

Sulphur—$18 per ton for domestic; $18@$20 for export, f.o.b. Texas and Louisiana mines. Market quiet.

Talc — Paper making, $12@$22 per ton; roofing grades, $9.50@$15; rubber grades, $12@$18, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $12@$15 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60 @$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $2.25 @$2.50 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15 to 18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 18½@19c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c., f.o.b. works.

Ferromanganese—For 76 to 80 per cent, prompt delivery, $175@$180, freight allowed; last half, $170; English, $170@$175, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $80@$85, f.o.b. furnace.

Ferromolybdenum—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2.50@$3 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $82.50@$85; 75 per cent, $150@$160.

Ferrotungsten—70 to 80 per cent W, 90c.@$1.05 per lb. of contained tungsten, f.o.b. works.

Ferro-uranium—35 to 50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium—Basis 30 to 40 per cent, $6.50@$9.50 per lb. of V contained, f.o.b. works.

Metal Products

Copper Sheets — Current New York price, 29½c. per lb.; wire, 22½@23c.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver—Unchanged at 39½c per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 26⅜c.; sheathing, 25⅜c.; rods, 8 to 3 in., 23⅜c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Refractories

Bauxite Brick—56 per cent alumina, $160 per 1,000, f.o.b. Pittsburgh.

Chrome Brick—$100@$110 per net ton, carload lots, eastern points; 9-in. straights, f.o.b. Baltimore, $100@$105.

Clay Brick—First-quality fire clay, f.o.b. New Jersey, $75 per 1,000; second quality, 9-in. straights, f.o.b. Pennsylvania, Ohio and Kentucky works, $50@ $55.

Magnesite Brick — 9-in. straights, f.o.b. Baltimore, $110@$120 per net ton.

Silica Brick—9-in., per 1,000, $65@ $70, Chicago district; $65 Mount Union, Pa.

Iron Trade Review

Pittsburgh, Sept. 28, 1920

Though transportation conditions as affecting the steel industry have been improving as a whole, there are fluctuations from week to week and not a few bad spots. The accumulations of steel at mills have been reduced at least two-thirds, perhaps more, from the high point, and as this reduction has occurred almost wholly within the last four or six weeks, while production has at the same time increased, deliveries of steel have been much heavier. This by itself would account largely for the extreme stagnation in the steel market, but of course there are contributing influences, including the feeling that prices of many commodities are going to decline, while the rate of actual steel consumption is likely to decrease materially before it increases again.

The steel industry is not perturbed by the reduction in automobile prices that has occurred, and resents the conclusion reached in some uninformed quarters that reductions in steel prices will be necessitated thereby. Automobiles sell at 50c. to $1 and more per pound, not all the weight being steel, and the Steel Corporation or Industrial Board prices range from 2.35c. a pound on bars to 5c. to 7c. on special grades, such as cold-rolled strip, special finished sheets, and like forms. Fancy prices 10c. or higher applied only on small tonnages, and, moreover, disappeared some time ago.

Buyers are still taking deliveries freely in most lines of steel, and the mills still see full operation ahead, though for an uncertain period of time. Prices show little change, except that delivery premiums continue to decrease.

Pig Iron—The market is absolutely stagnant, with practically no inquiry for either prompt or forward. Prices are nominal, based on last sales: Bessemer and basic, $48.50; foundry and malleable, $50, f.o.b. Valley furnaces, with $1.96 freight to Pittsburgh.

Steel—Market inactive. Last sales of sheet bars, $65, Pittsburgh. Nominal mill quotation on billets, $60, with resale lots offered at $58 or less.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $16@$16.50; foundry, $17@$18.

COMPANY REPORTS

Broken Hill Proprietary Co. Shows Profit

Lead, Zinc, Iron; Australia

The report of the Broken Hill Proprietary Co. for the year ended May 31 states that the net profit amounts to £517,663. The sum of £377,614 has been expended on plant at the steel works, and £500,000 was transferred from profit and loss to reserve, which now stands at £1,065,000, leaving a credit balance of £528,943. Liquid assets total £971,560, exclusive of 200,000 shares in the Broken Hill Associated Smelters Proprietary and 720 shares in Zinc Producers' Association. Outstanding debentures total £748,100, and the credit balance of the sinking fund is £11,622. Owing to the shortage of coastal shipping, the steamship "Iron Prince" and steamship "Iron Baron" were purchased at a cost of £275,000. Owing to a strike at Broken Hill which occurred on May 5, 1919, and which still continues, no productive work was carried on. A conference has just begun at Sydney, and the directors are hopeful that a settlement will be reached.

Maritime troubles extending over eighteen weeks were responsible for much dislocation of the operations at the Newcastle works, resulting in diminished output and increased costs of production. The rod mill is giving excellent results. The works of John Lysaght, Ltd., for the manufacture of corrugated plain galvanized and black steel sheets, should be ready to start operations next month. Rylands, Ltd., are starting works for the manufacture of wire netting and similar products, and have entered into arrangements to take raw material from the company. Further iron-ore leases in close proximity to the Iron Knob tramway have been secured from the government of South Australia, comprising a total of 560 acres, and are now being opened. The two large blast furnaces produced jointly 169,409 tons of pig iron. The foundry furnace produced 1,730 tons of pig iron, 12 tons of spiegel, and 1,271 tons of ferromanganese. Pig iron sold totals 39,677 tons. The openhearth furnaces produced 166,772 tons of steel, the blooming mill 151,681 tons, the 28-in. mill 73,667 tons (including 54,200 tons rails), the 18-in. mill 60,760 tons, the 12-in. mill and 8-in. mill 21,816 tons, and the rod mill 23,011 tons. An additional blast furnace with a daily capacity of 500 tons is being erected with necessary coke ovens.

Las Dos Estrellas Mining Co.

Gold-Silver; Michoacan, Mexico

The annual report of Las Dos Estrellas Mining Co. for the year 1919 states that the production of gold amounted to 3,451.52 kg. and that silver production amounted to 42,307.6 kg. The average price obtained for silver during the year was $1.1216 per oz.

The average cost of all operations, including development work, was 11.55 pesos per dry metric ton. Total operating costs, including development work, amounted to 4,236,751.37 pesos. The net income from operations was 3,369,247 pesos. Dividends paid in 1919 amounted to 763,145.08 pesos, making a total of 34,682,411.89 pesos distributed to the end of 1919. The original capitalization of company was 300,000 pesos, which was refunded to shareholders in 1909. The 1919 production was 366,820 dry metric tons, of an average content of 10.2 grams gold and 168 grams silver per ton. Recovery of metals amounted to 20,783 pesos per ton. The various reserve funds of the company at the end of 1919 amounted to practically six and a half million pesos, whereas there was additionally voted the sum of 500,000 pesos for the purpose of investigating new mining properties.

Tincroft Mines, Ltd., an Example of High Tin Production Costs

Tin; Cornwall, England

The report of the Tincroft Mines, Ltd., operating in the Cornwall tin area of Great Britain for the first half of the present year, shows a loss of £2,435 17s. 5d. The directors call attention to the serious situation of the industry in stating that "at the date of the last meeting in February the price of tin was £380, and a small profit was being made. A fall of more than £150 per ton caused the gravest anxiety to all engaged in the industry, and although prices have improved somewhat of late, it is unreasonable to expect any industry to succeed with its product fetching only 25 to 40 per cent above pre-war levels, while coal, power, and other operating charges average 200 per cent higher. . . .

"Owing to existing prices, practically all development has had to be suspended, despite the fact that at the bottom of the mine a good section of ground is only waiting the necessary funds in order to be opened up."

September Mining Dividends

The following is a partial list of dividends paid by mining companies during September, 1920:

U. S. Mining and Metallurgical Companies	Situation	Per Share	Totals
Ahmeek Mining, c	Mich.	$0.50Q	$100,000.00
American Smelting & Refining	U. S. & Mex.	1.00Q	609,980.00
American Smelting & Refining, pfd.	U. S. & Mex.	1.75Q	875,000.00
Calumet & Arizona Mining, c	Ariz.	1.00Q	642,520.00
Chino Copper	N. Mex.	.37½Q	326,242.50
Consolidated Interstate Callahan, z.l.	Idaho	.5CQ	161,651.50
Copper Range Co.	Mich.	.50Q	200,000.00
Daly-West Mining	Utah	.25Q	62,500.00
Federal Mining & Smelting, pfd.	Idaho	1.75Q	209,757.00
Golden Cycle, g	Col.	02K	30,000.00
Hecla Mining, ls	Idaho	15Q	150,000.00
Iron Cap Copper Co.	Ariz.	.25K	35,526.50
Judge Mining and Smelting	Utah	.12½Q	60,000.00
Kennecott Copper	Alaska	.50QX	1,393,530.00
Nevada Consolidated Copper	Nev	.25Q	499,864.25
Oroville Dredging, g	Cal. & Mex.	9d.Q	£25,745.175
Ray Consolidated Copper	Ariz.	$0.25Q	$394,294.50
St. Joseph Lead	Mo.	.50Q(a)	704,734.00
Utah Copper	Utah	1.50Q	2,436,735.00

(a) Further stock dividend of one share to each ten shares held, ex Sept. 27.

Canadian, Mexican, Central and South American Companies	Situation	Per Share	Totals
Cerro de Pasco Copper	Peru	$1.00Q	$898,229.00
Hollinger Consol. Gold	Ont.	.05X	240,000.00
McIntyre Porcupine, s	Ont.	.05Q	182,014.15
Mexico Mines of El Oro, g.s	Mex.	4 sh.Q	£30,000.000
Mining Corporation of Canada, s.	Ont.	$0.12½Q	$207,506.25
Pato Mines, Ltd., g	Colombia	3½sh. Q	£17,500.00
Holding Companies			
Yukon-Alaska Trust		1.00Q	203,433.00

Q, quarterly; K, semi-annual; X, includes an extra dividend

Isle Royale, of Michigan, voted to pay no dividend at this time owing to production costs and the relatively low market price of copper. The company's last dividend was 50c., paid in September, 1919. Cresson Consolidated also passed its dividend, owing to low grade of ore being mined. Iron Cap Copper Co., however, was feeling easier and declared its first common stock dividend since February, 1919, when it stopped paying 25c. monthly; and Golden Cycle Mining & Refining Co. also resumed, after omitting three monthly payments.

National Lead Co. paid its regular quarterly dividends of 1¾ per cent on the common and 1¾ per cent on the preferred shares.

The Gospel of Manual Work

A CORRESPONDENT from Japan charges the Japanese engineers with having a training that is entirely mental, and one in which the manual experience which we in America regard as necessary and complementary is omitted. If this is true, it means that Japan is following out the European handicap, instead of conforming to the practice which has put the United States foremost in engineering and industry—the good old gospel of the two-fisted.

The development of the human hand by evolution has enabled man—otherwise a clumsy animal—to perform an infinite variety of work, and so eventually to shape all nature to his uses. Mental culture followed manual accomplishment, and this relation is so deeply ingrained that education will always be best accomplished along these lines. For this reason, American education, and specifically American mining engineers, have always found that the best engineers were produced from those who began with manual education and kept it up while their mental development was proceeding.

If we want to teach a student a principle of chemistry, an experiment which he performs himself will accomplish at once what repeated memorizing of results obtained by some one else's manipulation will never achieve. The student of agriculture who reads agricultural books exclusively, without putting his hand to the plow and the pruning knife, is, as is well known, wasting his time. If we must choose between the exclusive education through practice and that exclusively through study, we shall always wisely choose the former—hence the general respect in which the "practical" man is held.

There is something deeper than efficiency in this. The sulks of the old world are based upon the friction between these two classes—that consisting of the knights of the horny palm, too often ignorant and improperly developed mentally, and the lily-white palms of the class who are seeking to stultify their heritage by avoiding contact between their hands and the world. In the United States, the general high standard of education makes it the rule rather than the exception that the man who specializes in his hands is as well educated and fundamentally as well poised as the great clerical or white-collar class, who labor mainly with their brains. It also is common that the latter class are quite competent manually, and have passed through an excellent course in the use of their muscles.

The American idea, is, therefore, for an engineer to have personally become competent in the manual work which he has to direct, and be able to take the place of any man under him and show him how his work is to be done. Thereby he incidentally earns the subordinate's respect and loyalty, instead of his antagonism.

Manhood respects manhood. How many of our mining engineers have been trained in the manual craft of mining? We believe that the large majority will qualify. At any rate, it is our universal creed; and we recommend it to Europe and Japan, as not only a technical and an industrial, but a sociological remedy. Thus, we shall become leader and follower—which is an arrangement bred in the heart of human nature—rather than capital and labor. Many of those who in this country, fed full and daft with Old-World ideas, seek to rouse "labor" against the citizen in general, are themselves of the lily-fingered Old-World variety and unacquainted with that healthy manual craft and exercise which go to make the best type of man!

"Passing the Buck"

THERE is in a Western city a sign which has attracted our attention and which made a sufficient impression at the time to be readily recalled. It is:

> Try Murphy's famous drink!
> With beans, roll and frankfurter.
> All for 10c.

An economic lesson is back of the placard and its commercial fulfillment. The individual making this liberal plea to the wayfarer had to made a readjustment in his affairs when prohibition swept the country. Murphy did not strike. Murphy did not starve himself to death. On the contrary, he figured out an acceptable ration; cut his profit to a narrow margin; had his placard painted by some hungry sign painter, no doubt, and went out for business.

Though we don't know Murphy we like his courage and applaud his ingenuity. In sharp contrast is the attitude of some mine workers. A case in point is the strike which is now on at Virginia City, Nev. On Sept. 5, the miners, disregarding their agreements to give the operators the customary thirty days' notice, walked out and signified their willingness to walk back if the ruling wage was increased $1 per day. The operators pointed out their inability to meet this increase, owing to the fact that the properties under their control were not making expenses or were in the preliminary stages of development. They offered to meet the men more than half way. One company offered the men employment on a contract basis which proved sufficiently acceptable to some of the miners to cause them to return to work. The Gold Hill Miners' Union promptly interfered, and work stopped. The operators also, as a group, offered the miners a substantial reduction in living costs by giving them the privilege of buying any of the commodities carried in stock at their general merchandise store at a price 20 per cent below present wholesale prices and thus bring living costs to the level existing in 1919. At latest accounts this has not proved acceptable. In fact, it was indignantly spurned.

Every one has suffered from the high cost of living. "Passing the buck" has been resorted to until the "buck" has been worn out. The Virginia City and Gold Hill miners have passed the "buck" onto the operators in expectation that the operators would pass said buck on to the stockholders. We are glad that the operators in

question, with one exception, refused to go to their stockholders for further increases.

The situation has its critical phases. The stockholders, unless they are different from other men, will not go on indefinitely putting their money into unprofitable enterprises. Operation on the Comstock is dependent upon excellent management and economical operation. At best the profit margins are low, and unless active co-operation is secured from the workers the operations cannot be successful.

We feel that if the workers would attack their own difficulties in the same spirit as the individual whom we have quoted in the beginning of this editorial, there would be measurably less difficulty and more opportunity for work. After all, opportunity for work is one of the greatest blessings that comes to mankind. Anything that destroys that opportunity will eventually reduce the prosperity of a community.

"Passing the buck" has not brought a solution of our economic problem. It will not solve the problem for the miners of the Comstock. Only the spirit of active co-operation and the desire to make individual readjustment can do this.

Bolshevism at Home and Abroad

THE Red Terror at the moment is the most important question on Earth; and, therefore, the one that we first have to consider in looking ahead for business and making our plans for mining. We must look at events dispassionately, and neither tilt back in our rocking chairs in a fool's fancied security, nor be stampeded by a few despicable terrorists. Will our governments and our existing social and financial systems be overthrown? It seemed unbelievable for Russia, yet the thing is done. Italian workmen recently confiscated industrial plants on a wholesale scale, held them uncontested, and only delivered them back for a substantial consideration. In England, the labor organizations frankly support the Russian Reds, and are exerting themselves, with considerable success, to align England with the Bolshevists, through the pussy-footing policy of Lloyd George.

What of the United States? It is our opinion that the danger is past; that the test came last year when the various strikes were declared, to paralyze industry, and failed. American organized labor considered attentively the Red Dragon which had crept into its councils, and cast it out wholeheartedly. Greater intelligence and more widespread education achieved their victory, and common sense took secure possession of workman, farmer, and merchant. If some of us criticise at times some of the attitudes of organized labor, let us not forget to be grateful that it stood between the liberty of our country and the radical, and really made America "safe for democracy." Laying prejudice aside, it would be hard to find a more trenchant and intelligent verdict as to Bolshevism than that repeatedly delivered by American "labor":

"We are living in the Republic of the United States of America, a country by no means perfect, in which, all too frequently, injustice is done. But it is a republic based upon the principles of freedom, justice, and universal suffrage. Our men and women are not likely to throw these rights and principles into the scrap heap for the dictatorship of Moscow's Lenine and Trotzky."

Who shall deny the writer or writers of a proclamation like this a place among American statesmen? There is no ruffling of the surface by details like the anarchistic expulsion of the Socialistic members from the New York Legislature, for it is known and understood that those violators of constitutional freedom who committed the expulsion have been adequately condemned by American public opinion. So much for the safety of the United States then, and radical plotters may set off their bombs and commit their sporadic crimes without long getting even the attention of the respectable citizen.

We note, however, that these insensate doctrines and wild acts are more likely to appeal to the ignorant. The few plotters in our country are largely foreigners, and in countries where the masses are ignorant this get-rich-quick scheme of Lenine's gathers in millions of suckers. Accordingly, we note also the relative success among the Italian and the British workmen, and the failure to make much impression in the Scandinavian countries, Germany, Holland, Belgium and France.

We of the mining profession will, therefore, do well, while concluding that the United States and Canada are fundamentally sound, to consider Mexico, where the years of revolution have not eliminated the difficulties, where the mass of the population is ignorant and foot loose, and where a throttling agrarian system not dissimilar to that existing under Imperial Russia still offers a problem that none of the temporary governments have dared to attack. Lenine's propagandists and spies, working under disadvantage in the United States, have easier sledding in Mexico. Already, we understand, the province of Yucatan is in the hands of the Communists; and they revelled in incendiary public speeches the other day in Mexico City and hoisted the Communist flag without being disturbed. Among the practical suggestions offered by the orators were the construction of barricades in the streets, the sacking of food shops, and the dynamiting of the Archbishop's palace. Truly, when you cross a Russian Bolshevist with a Mexican, you get a fearsome hybrid, a sort of hippopotato.

Another suggestion, to which we are totally opposed, was the erection in the Central Plaza of a guillotine for all journalists. As a mark of our disapproval, we shall postpone the tour of investigation of Mexico which we had planned. Surely, dear Brotherhood, not *all* journalists? There are some we could mention that it might not hurt to guillotine—we doubt if they would realize it anyhow—but there are others of finer mould who are sensitive to a thing like that. And consider the inefficiency—a whole guillotine for half a dozen measly journalists—surely an extravagance; but if you would chop up the guillotine into safety razors it would go much further, and the beneficial effects might be more universal.

Art in Mine-Building Construction

SINCE the inception of mining, the primary thought of the mine operator has been the winning of the ore from the earth. He has followed, in most cases, a well-thought-out plan whereby the margin of profit would be such as to compensate for the effort; he has enlarged upon his scale of operations as the conditions permitted, and in general pursued the course adopted by those engaging in any line of industry.

Consider for the moment the case of a successful operator, a company which has reached a point where its continuance is assured and the policies that have been followed are such that no unsurmountable handicaps stand in the way of advancement. The employees receive broad and liberal treatment, the plants and methods represent the most modern ideas, and the entire organization is a credit to the originators and to the

community. Such a concern exerts a potent influence on other mining companies, and the latter, to a considerable extent, must conform in their ideals to those already established by their contemporary.

For many years little thought was given by mine operators to anything but the business of mining—of getting out the ore, of preparing it for treatment and for the market. Methods were studied and advances in practice were made, and the business was judged purely from the standpoint of mechanical production. Later came the development of an idea which at first appealed to some as being too "élite" for such a vigorous pursuit as mining. "Human engineering," we have pleased to call it, and although the term is somewhat general, it is now fairly well understood and covers a vast amount of work which is being done by all progressive mining companies. The benefits of such welfare work cannot be computed on a dollars-and-cents basis, but that it is a paying proposition is admitted, and further proof is clearly shown by the fact that the movement is growing.

Under this general head comes the construction and improvement of mine buildings with a view to their greater utility and economy. Shall we not go further and include beauty? The artistic mission architecture at Ajo, Ariz., is a convincing example of the utility of beauty; likewise the Cliffs shafthouse at Ishpeming, Mich., and the Quincy hoist house in the copper country. Certainly, if a building is a makeshift or an eyesore, the structure offends us and does not add to our sense of well-being; therefore, a well-planned design can be considered as a part of the general welfare work.

Permanent mine-plant construction requires stability, but does this imply ugliness? How frequently we notice at mine plants that the buildings are solidly constructed, but with absolutely no thought given to general appearance. Need this be so? We are told that stresses, strains, and other functions of the walls and roof eliminate any possibility of securing an artistic effect. But we don't believe it, and one has only to look about in many of the mining districts today to see that the old order is changing and an attempt is being made to discard the earlier types of engine and shafthouses and other mine buildings, and to adopt those designs which are pleasing to the eye. Such ideas are characteristic of the successful company—the builders of standards and those who exert influence.

Who Suffers from Increased Freight Rates?

WHEN you make a big strike or a new hoisting metal sellers, particularly in the East, were kept busy determining just how much the advances would amount to per pound of metal sold. It was rightly pointed out that the changed rates would affect not only delivery charges, which in the case of copper, are paid by the seller, but also would make it more expensive to bring the unrefined metals East, and would increase the cost of materials and equipment necessary to smelt the ores. The total extra cost was of course almost impossible to estimate but it was variously figured at from one-half to one cent per pound of metal sold. Selling agencies considered it no more than right that consumers should stand this expense. This, however, was not to be. Had any producers added even half a cent to their previous prices for copper, for example, they would not have sold a pound. Lead also, owing to importations from Europe, had begun to show an easier tendency before the freight rates took effect. In a buyer's market small possibility existed of marking up prices to offset increased costs no matter how definite or how plausible the reason may have been.

The only alternative, if the smelting and refining companies were not to suffer the loss, was to charge the ore producers more for smelting; or what amounts to the same thing, deduct a certain sum from the quoted price of metals on which settlements are made. This is what has been done by some of the companies. One quarter of a cent is being deducted from the quoted price of lead and copper and one cent from the price of silver. This may or may not be an equitable figure; at any rate it will help to recompense the smelting companies for the increased charges, which, by the way, should be more than offset at no distant date, by the improvement in transportation service which should result.

There remains the poor producer with no one on whom to pass the advance. He cannot say to the miner, "I get less for my concentrates, so you will get 50c. less a day." If he did, the ore would not be mined. As a result of the decreased profits rumors of shutdowns are prevalent, for many small producers were running close to the line. We would urge, however, that the small producer take heart. Prices in many lines are definitely falling and it is almost certain that it will cost him gradually less to operate. His products, however, are not likely to decrease in value, with the possible exception of lead. If he can break even this fall, or can afford to lose a little, it will pay him, we think, to carry on.

Just as You Write to Bill

WHEN you make a big strike or a new hoisting record you enjoy sitting down and writing friend Bill about it. No stilted style nor long letter is required. You simply put down the plain facts in every-day language that Bill will understand. Under the same circumstances, why not do the same thing with those thousands of other engineers who are interested in you and your work and with whom you should be constantly in touch for mutual assistance? New technical developments, minor improvements in method, little devices that mean large savings—all should soon become the property of the profession as a whole, that by mutual helpfulness the entire industry may profit.

You can write about these things just as you would in a letter to your best friend. There is no need of formal style nor literary elegance. Perhaps the most valuable report will be the one which least resembles the classical literature of the essayist.

What your friends want is a clear, simple, and, above all, short description of what you did and why; what you accomplished and what it will save, in either money, time or inconvenience. If you will bear in mind your duty thus to pass on your achievements, you can count upon your fellow-workers to do their share for you in return.

E. & M. J. Index

THE INDEX for Vol. 109 of the *Engineering and Mining Journal* is now ready for distribution and will be mailed only to those who request it. Those who wish a copy of the Index, are requested to send for it promptly. A postcard will do.

WHAT OTHERS THINK

Anarchy in Siberia

As an American mining engineer and constant reader of the *Engineering and Mining Journal* and, moreover, as an engineer of long and intimate experience in Siberia, I feel it my duty to write you this letter on the subject of Bolshevist propaganda. Please accept my assurance that I am writing in no captious spirit, and that I am animated only by the desire that a leading professional publication should not be misled on a vital subject, and thereby, through its authoritative position, mislead its readers.

In your issue of Aug. 14, 1920, you publish a contribution headed "The Mining Opportunities in Siberia Under the Present Régime of Zemstvo-Soviet Government." The article purports to come from the pen of "Ivan Narodny," which, when faithfully rendered into the English language, is "John the Communist," and no more a typical Russian name than "Jack the Ripper" is a typical American name. The article from beginning to end appears to be purely Bolshevik propaganda, and is replete with misinformation, to use no stronger term.

The aim of the article in question is plain. It is an attempt to utilize American abhorrence of the worst features of the Czarist régime to claim for the "Zemstvo-Soviet Government" credit for all the constructive work of the Czar's government, which I can assure you was the only construction work ever done in Russia as it exists. As a matter of fact, there is in Siberia today no government save the few commissars controlling the railway centers. The peasants are in sporadic revolt. It would be easy to refute in detail the statements of "Ivan Narodny," but a few examples will suffice. He states:

"The local co-operative societies had already started the establishment of tanneries, canneries, soap factories, and flour mills."

The truth is that such institutions, both co-operative and private enterprises, have been in existence for decades. He also says:

"The butter produced in the Omsk, Semipalatinsk, and Tobolsk regions only would be twice as much as that of the United States."

The truth is that in 1913, the year of largest output, the whole of Siberia produced 90,000 tons of butter, or 2 lb. per year for each inhabitant of the United States. "Narodny" says, further:

"At many places we can give mines and mills which were operated by the past régime or its favorites. . . . But we will not tolerate criminal exploitation as used to be, or corruption and all the methods of an autocratic government."

I personally know of no "criminal exploitation" nor "corruption" in mining operation in the past, but presume that "Ivan Narodny," as a Communist, believes that all exploitation by private capital is of a criminal nature. By a curious contradiction, however, he makes it plain in the first sentence of this quotation that the alleged opportunities for the investment of foreign capital in Siberia are to be largely provided by property which has been stolen from other foreigners who had courage to try to develop Siberia's resources in the past.

I personally know of such foreign property worth considerably over $100,000,000 and belonging to many thousands of small investors in foreign countries which has been forcibly confiscated, or, to use the Bolshevik term, "nationalized." Although "nationalized," none of these properties are working. The morality of utilizing a theft from one set of foreign investors as a bait for soliciting capital from other foreign investors appears to be as dubious as the failure of such a policy will be certain when once the truth concerning present contentions is made known.

Without going further into details, I would again point out that the *Engineering and Mining Journal* has apparently been made the unwitting instrument of a cunning attempt at mendacious Bolshevik propaganda. I especially regret this at a time like the present when the so-called government of "Ivan Narodny" holds as prisoners many American and other foreign mining engineers and refuses to release them. The facts as to these engineers are known to the Department of State in Washington. Y.

Boston, Sept. 29, 1920.

The "Human Engineering" Number

I wish to congratulate your people in getting out such an issue as you did get out on such a hopelessly inexact and inscientific a thing as "Human Engineering." Psychology is a thing that every newspaper man learns with the ABC's of his business—only he probably would not recognize it as such. And your "human engineering" is, after all, nothing in the world but applied psychology. If the employer of men would only take as good care of the human machinery that is producing his dividends as he does of his lathes and punches and laboratory equipment, he wouldn't have any strikes on his hands. But by "taking as good care of his human machinery" I don't mean handing out a lot of gifts, liberally exuding hot air or "giving" people libraries, gymnasiums, "sanitary homes," and such gratuitous benefits. The proper sort of an upstanding man does not want a whole lot of things "given" to him by someone else.

You know, of course, that Shakespeare is commercially impossible in the theatre. You also know, of course, that Shakespheare wrote the most appealing and most human plays that have ever been written in the English language. Now, why is it that these plays are impossible commercially? Because they have been torn, twisted, dissected and macerated by high school and college professors and students to a point where the average man or woman who has been to school goes out into life weary of Shakespheare and all his works.

I was tickled to death to see such a wide departure from exact science as "Human Engineering" have a place in your magazine. Do it again. That publication is actually becoming one of the most interesting I read.

Chicago, Ill. HUMANIST.

Mineral Wealth of the Kingdom of Jugoslavia

Deposits Worked Since Neolithic Age—Region Is Rich in Base Metals and Has Gold, Silver, And Coal—Repressive Policy of Central Powers Long Held in Bondage The Nations Comprising the New State

By Captain Gordon Gordon-Smith*
Written for *Engineering and Mining Journal*

ONE of the results of the World War has been the creation of a number of new states, the names of which sound unfamiliar to American ears. One of these is Jugoslavia, or, to give it its official title, the Kingdom of the Serbs, Croats, and Slovenes.

The new state has been created by the union of all the countries inhabited by the Serbo-Croatian race. These have grouped themselves around the Kingdom of Serbia, which is the "Piedmont" of this Slav "Resorgimento." These countries were the Kingdom of Montenegro and the former Serbian-speaking provinces of the Austro-Hungarian Empire: Croatia, Bosnia, Herzegovina, Carniola, Carinthia, Slavonia, Dalmatia, part of the Hungarian Batchka, the Baranya, and a part (roughly speaking, one third) of the Banat of Temesvar. The last three sections, made up of, probably, the most fertile region in all Europe, are generally grouped together under the title of the Voivodina.

CAPTAIN GORDON GORDON-SMITH

Jugoslavia Has Population of Thirteen Million

The Voivodina is the most densly peopled portion of the new state, counting eighty inhabitants to the square kilometer. Serbia proper counts sixty; Bosnia thirty-seven; Croatia fifty-five; and Dalmatia and Montenegro have but twenty-five inhabitants to the square kilometer. This gives an average of fifty inhabitants for each of the 260,000 square kilometers the country contains, or a total population of thirteen million, a people closely knit together by race, language, and national aspirations.

If Jugoslavia is to be enabled to fulfill her high mission she needs all the aid and support that the United States can give her. Not political aid or military support. Only in her absolute independence can Jugoslavia fulfill her great destinies. By developing the resources of the country, increasing its wealth and production, its independence will be secured.

Jugoslavia is rich. She has everything that makes a country great. She possesses twenty million acres of virgin forest only awaiting the axe of the lumberman. Her mineral wealth is great. She has gold, silver, mercury, copper, zinc, lead, coal, and iron.

In her mountain streams and her swift-flowing rivers she possesses a reserve of electric force running to the millions of horsepower.

As a railroad center Belgrade has no rival in all Europe. No more favorable field exists for the investment of American capital.

But why, if all this be true, does it come that for half a century no attempt has been made to develop the natural resources of the country? The answer to this is—the dead hand of Austro-German policy.

Serbia lay right athwart the path of German ambitions, and while she remained independent and unsubdued brought the whole grandiose plan to naught. For thirty years, in consequence, nothing was left undone to prevent her increasing her independence by developing her resources.

Now Jugoslavia turns to the United States for aid. For this there are two reasons. The first is political. If Jugoslavia handed over to any European power the development of her immense economic resources she would at once arouse the jealousy of the others, as they would fear that the according of economic advantages would only be the thin end of the wedge for securing political influence and guiding the foreign policy of the new kingdom. No such fear is felt in the case of the United States. The intervention of American capital would be a cold commercial proposition without any *arrièré pensée* of political advantage. The whole matter would resolve itself into dollars and cents, and the Jugoslav people would be able to realize its political ambition, "friendship with all; alliance with none."

A second reason why Jugoslavia looks to the United States is that America is the one country which has not physically suffered from the war and which has all its powers and sources of supply, professional skill, and material and financial resources intact. Without professional skill Jugoslavia is helpless to work out her own salvation. Serbia's intellectual *élite*, men trained abroad in the schools and universities of Austria,

*Intelligence section, Headquarters Staff, Royal Serbian Army.

Germany, France, and England as engineers, electricians, doctors, and professional men generally, were, *noblesse oblige*, all officers of reserve in the army, and were killed off, almost to the last man, in six years of ceaseless war. It is for this reason that she has to appeal to the energy and professional skill of the United States to aid her in the development of her resources. One of the chief of these is the exploiting of her mineral wealth.

The archives of the newly annexed Austrian provinces are still in Vienna, so that I have not at my disposal such exact data as I have in the case of Serbia, but my readers may take my word for it that the mineral wealth of the former Austrian provinces is hardly inferior to that of Serbia and that they offer an attractive field for American mining enterprise. This article, however, will deal with Serbia.

In regard to the mineral wealth of Serbia a great deal of data is to be had, notably a report by Dr. Demetrius J. Antula, the distinguished Director of the Ministry of Mines. Dr. Antula is a geologist and mining authority whose reputation has spread far beyond the frontiers of Serbia.

It is known that the working of the mineral resources of Serbia dates from the most ancient times. The archaeological remains found in the old mercury mines of Avala, near Belgrade, bear evidence that these have been worked from as far back as the Neolithic Age. There are many traces to be found of Roman workings and debris heaps which testify to a large development of the mining industry in Serbia in the ancient past.

MAP SHOWING GENERAL DISTRIBUTION OF MINERAL DISTRICTS OF JUGOSLAVIA

After the fall of the Roman Empire the mining industry disappeared, and was restored only in the thirteenth century, at the time of the Namanya. At the opening of the fourteenth century the industry attained great development. The mines were the principal source of wealth of the ancient Serbian state of the Middle Ages. With the Turkish invasion the mining industry in Serbia, as also in the neighboring countries, began to diminish rapidly. Only the iron industry, on a very small scale, was continued in one or two places. During the Austrian occupation in 1718

mining work was resumed, after an interruption of three hundred years, but came to an end again in 1728. With the restoration of the Serbian state at the beginning of the nineteenth century mining was started at many points, and keen interest was awakened by the favorable results obtained by prospecting the copper, gold, and coal deposits.

Until a few years ago all that was known about gold in Serbia was that placers existed in the gravels of the Timok and the Pek, and of their tributaries. Lode deposits were recognized only in the first years of the present century. There are three principal types:

Gold in Serbia

1. *Gold-Quartz Veins in Crystalline and Granitic Rocks*—Gold occurs in the crystalline rocks of the Department of Kraina, and prospecting has been carried on at various places, especially between Neresnitsa and Maidanpek. There existed in 1911 two mining concessions in this region, besides several prospecting rights. One concession was given to the Serbian Dredging & Mining Syndicate, Ltd., in Neresnitsa, in 1903, extending over 7,500 hectares (18,250 acres), and the other to MM. Georges Weifert and Felix Hofmann at Blagoyenkamen, in 1902 (the St. Barbe concession), covering 410 hectares (1,025 acres). Prospecting established the existence of numerous mineral-bearing quartz veins, containing sulphides of lead, copper, iron, and zinc. All these sulphides, especially the galena, are auriferous.

Quartz veins with auriferous sulphides were found near Ram, on the Danube; near Bela Palanka; and near Stanitchinci, at the foot of the north slope of Kopaonik. In the crystalline schists at Vratarnitsa, near Zayetchar, similar auriferous quartz veins were also found. Auriferous copper deposits are to be found in the granite formation of the districts of Tanda, Crnajka, and Isvor.

2. *Gold-Quartz Veins Occurring in Serpentine and Gabbro*—Gold formations in serpentine rocks are known only in the region of Deli-Yovan, where there are ancient workings, the most important of which is at Rusman-Gindusa, and is eight kilometers in extent. Several parallel veins have been discovered in this ground. These veins in general direction strike north and south, but in certain parts, as in the workings of Gindusa, they spread into a great number of small veins, and the gabbro itself is often impregnated with auriferous pyrites. The workings at Rusman have shown the continuation of a well-defined cross-vein for a length of 300 meters, and this vein extends at least 35 meters below the old workings.

In 1901 a concession was granted on this field covering 2,500 hectares (6,250 acres). The concessionaire built at Rusman a ten-stamp mill for testing the treatment and concentration of auriferous pyrites. The yield of gold in the ore was approximately 9.6 dwts.[1] to the ton.

3. *Gold in Volcanic Rocks*—The presence of gold in the volcanic rocks was proved by the placer workings of the Crna-Reka and its numerous tributaries. Traces of gold have been found in the andesitic rocks themselves, which are impregnated with pyrites. This shows that the andesitic formation of the Timok contains gold deposits whose nature recalls very much the gold deposits of Hungary, but of which it has not yet been possible to ascertain the importance. The extent of the ancient workings in this eruptive formation, however, shows that it would be worth while to investigate further.

Placers

Placer deposits have been discovered in the gravels of the Pek and its tributaries, in the valley of the Mlava, in the basins of the Poretchka and the Timok, and in the valleys of the Plavnitsa and of the Jassenitsa, in eastern Serbia; also in southern Serbia, at the base of Kopaonik, at Stanitchinci, Poppina, and in other places. No systematic research has been made except in the valley of the Pek, on the concession of the Serbian Dredging & Mining Syndicate, and in the valley of the Bela Reka, upon the prospecting concession of M. Weifert.

Tests of the gravels in the valley of Pek showed that these contained a workable quantity of gold; on an average one franc's worth of gold is found in each cubic meter of sand. The gold is found to a depth of five to six meters, which is very suitable for washing. In the valley of the Pek the area which was investigated will suffice for working during twenty-five years by four dredges, which treat about 3,000 cubic meters of gravel per day. The Serbian Dredging Syndicate had two dredges working at the beginning of 1905, which produced ninety-two kilograms of gold. During that year two more modern dredges arrived and began work.

The cost of the extraction of the gold was reduced to 30 centimes per cubic meter, and it may therefore be concluded that these workings will give satisfactory results. The tests made in the valley of the Bela Reka also showed that the gravels of this river contain a considerable quantity of gold. Here also the gold is found to a depth suitable for dredging, and over a sufficient area to make profitable operations possible. Dredges suitable for the washing of gold were set to work in 1905 in this valley. In view of the considerable extent of placer gravels, and the evident importance of ancient exploitation, the government began in 1905 tests of the gravels of the basins of the Poretchka and the Timok.

Mercury Deposits

The gold deposits are far from being the most valuable part of the mineral wealth of the country. There exist, for example, very considerable mercury deposits. Cinnabar is found at Avala, near Belgrade, and in the villages of Brajici, Bar, and Donja Treshnica. The mercury deposits at Avala were the first to attract attention. For some time work was carried on with considerable success, but later all the workings were abandoned. The cinnabar, together with metallic mercury, baryte, and pyrites, is found at Avala in a porous quartz in serpentines.

From 1885 to 1891 a total of 7,796 tons of mercury ore was treated, containing on an average 1.416 per cent of mercury, which produced 79,823 kilograms of mercury.

Lead Mines

Lead deposits are frequently found throughout the country, and some of them contain also silver and gold. They are generally found in the Mesozoic limestones, and especially the volcanic rocks of recent age, or in irregular masses in the limestones, near the igneous rocks. Deposits of lead ore have also been found in old workings, at the contact of alaskites with slates.

[1] Approximately $9.89.—Editor.

THE KATCHANIK PASS IS AN OPENING BETWEEN THE CHAIN OF THE KARA-DAG AND THAT OF THE SCHAR. HEMMED IN BETWEEN HIGH WALLS OF ROCK, AT THE FOOT OF WHICH FLOWS THE LEPENAC, A TRIBUTARY OF THE VARDAR, IT UNITES THE PLAIN OF SKOPLIE TO THAT OF KOSSOVO. THERE IS HARDLY ROOM ENOUGH FOR A ROAD WHICH IN PLACES RUNS ALONGSIDE BUT GENERALLY ABOVE THE RAILWAY LINE

There are several important centers of lead mining which merit being studied separately. These are those of Podrinje, Avala, Kosmaj, Rudnik, Kopaonik, Ruplje, and Kucajna.

At Podrinje the lead ores have been worked continually for centuries. The deposits are worked by the state. The center of these workings is the mountain of Krupanj, lying sixty-three kilometers from the landing stage at Shabats, on the Save, where there is a smelter. In these works the lead ore from Postenje was also treated, and all the lead and antimony ore of the surrounding region was smelted (such as the lead ores of Zavlaka and the antimony ores of Kostajinik and Zayetchar.) At Postenje, a distance of fifteen kilometers from Krupanj, the lead ore is found on limestone near serpentine, in a vein varying in width from a few centimeters to two meters. The ore is carbonate, with some residual primary galena. It is very easily smelted.

There are also important deposits at Selanats, not far from the Drina. Here some veins of mixed sulphides (galena, chalcopyrite, blende, iron pyrite, in quartz and in calcite) are found near igneous rocks and in the schists. The lead from this ore contains from 0.02 to 0.237 per cent of silver. Work was carried on from 1874 to 1900, with few interruptions, and in all 1,548 tons of lead was extracted.

At Avala there are traces of Roman workings, and others of more recent date. Ruins, drifts, shafts, and dumps prove the importance of the old mines. At Ljuta Strana, in the Valley of Tapavac, seven kilometers from the station of Ripanj, lead-bearing veins were found at the contact of Cretaceous limestone and rhyolite. These veins were followed to a depth of 120 meters below the lowest level. The veins contain principally galena, with some blende, pyrite, and chalcopyrite.

Silver-lead deposits are also found in similar geological formations at Zuce and on the Creveni Breg, near Avala. At this latter place the French company Société des Valeurs Industrielles et Minières obtained a concession of 400 hectares (1,000 acres) in 1901. Several rhyolite dikes striking east to west have been followed by the ancient workings, for the deposits themselves are closely related to these rhyolitic veins, being found either in them or at their point of contact with schist and limestone. These veins resemble closely the ore of Ljuta Strana, but with a greater proportion of silver, amounting to from 0.183 to 0.4308 per cent of the lead. A chain of similar deposits leads from Avala toward the south via Kosmaj, Rudnik, and the valley of the Ibir to Kopacnik.

At Rudnik there is a mining field well known in ancient times, where copper, lead, silver, and gold were extracted. Mixed sulphide ores at Rudnik are found at the contact of the alaskites with the Cretaceous limestones and sandstones. Two concessions, amounting to 4,530 hectares (11,325 acres), were given in 1894 to M. Mihailovitch, a former Director of the Mining Section. The work done proved important mixed sulphide deposits, and tests were made with regard to the concentration of the ore.

The mountain of Kopaonik and its mountainous district, near the southern frontier of Serbia, abound in mineral deposits, but these have not been closely studied. Lead deposits and old workings have been found in many localities.

Near the village of Ruplje there are veins at the contact of the alaskites and mica schists. Generally these contain galena, but sometimes blende and pyrites predominate. These ores contain a variable amount of silver, estimated at from 0.3 to 0.4 per cent of the lead. A concession of 800 hectares (2,000 acres) (Djurina Sreca) was granted to M. Weifert and to the French Société Industrielle et Metallurgique.

The workings of the lead deposits of Kucajna go back to a very remote date. The ancient miners apparently knew how to work the high-grade lead carbonate ore and leave the poor ore containing much pyrite and blende. They also ignored all the galena, which was worked by the owner of the mines from 1864 to 1892. The mining field extends to about four square kilometers. The deposits occur rarely in regular veins, more often in lenticular masses of different forms, found at the contact of the Cretaceous limestone and igneous rocks, or between the limestone and a volcanic breccia, or in the limestones themselves.

In these ores lead, iron, and zinc sulphides predominate, as well as the products of their alteration—cerussite, limonite, and calamine. Gold and silver are contained in the ore. From the results of the smelting work it is apparent that 1,081 tons of mineral ore were treated in eight years, which produced 265 tons of lead, 62.5 kilograms of gold, and 1,092 kilograms of silver. The quantity of gold varied considerably from 6 to 650 grams per ton of ore, averaging 57 grams per ton of ore. The average percentage of silver was 1.112, or 455 grams per 100 kilograms of lead. Compared with other lead ores in Serbia, those of Kucajna are the richest in gold and silver; and these metals are associated with the pyrites and blendes. The deposits (of 160 hectares) were granted in 1862 to M. Hofmann.

Zinc Ores

Serbia is rich in zinc. Zinc ores are found in connection with galena, pyrite, and chalcopyrite in many deposits, of which the most noted are those of Kucajna, Zavlaka, and the mountains of Rudnik. The calamine deposits of Kucaja are fissure veins, and calamine is also found in the form of incrustations on the metallic sulphides. The calamine is often pure, and contains from 50 to 55 per cent of zinc, and it is usually associated with limonite. During three years from 1891, 291 tons of zinc ore were treated at Kucajna, with a yield of 121 tons of zinc, which gives an average percentage of zinc of 21.5 in the ore. These zinc deposits were granted in 1862 to M. Hofmann.

Zinc ore is found in many parts of the mountains of Rudnik, occurring with lead. These deposits are sulphides containing 10 to 30 per cent of zinc. Similar deposits are also found between the villages of Zavlaka and Srpulja in irregular masses, in the Triassic limestone, and in proximity to outcrops of trachytic rocks. The proportion of zinc varies from 24 to 56 per cent. It is interesting to note that cinnabar in thin incrustations is found with the calamine of Zavlaka.

Copper Deposits

Copper deposits are found in Serbia, especially near serpentines, in lenticular masses of chalcopyrite and iron pyrite, together with oxides, and also often in association with other minerals in the trachytic rocks, or at the contact of these rocks with the limestone or with the crystalline schist. They also occur in the red sandstone in the form of a copper impregnation.

Copper ore is found in the whole of the serpentine

mass forming the mountains of Suvobor, Maljen, Bukovi, and part of the northern base of Povlen, in the Department of Valjevo. These generally occur at the contact of the serpentine with Cretaceous limestones. These depoosits are lenticular, but because of their constant strike from southeast to northwest they present many of the characteristics of veins. They contain sulphides and oxides of copper. At the mine of Rabelj, in 1903, 3,820 tons of copper ore was treated and 151 tons of black copper obtained—that is to say, 3.5 per cent of copper. In the limestone at its contact with the serpentine irregular masses of cuprite and of chalcocite have been found in the village of Planinitsa, and there

especially in the period of the medieval Serbian state before the Turkish invasion. Documents which are in the archives of the mines of Oravitsa show that the work in the mines of Majdanpek began again during the Austrian occupation, that the production of copper was considerable at that time, and that the ore contained an average of 8 to 10 per cent of copper.

Many authorities who later studied the deposits came to the conclusion that they possessed great importance; in fact, soon after the establishment of the Serbian state the development (1850 to 1860) on a large scale of the iron and copper industry at Majdanpek began. Much money was spent, and at this time Majdanpek was

THE BABOUNA PASS SEEN FROM THE DEFILE. THIS PASS IS THROUGH THE PICTURESQUE MOUNTAINS WHICH DIVIDE THE HEADWATERS OF THE TERNA RIVER FROM A TRIBUTARY OF THE VARDAR

are often masses of native copper weighing from 100 to 150 kilograms.

All the work which has been done as yet is in the nature of prospecting, although the analysis of specimens has shown that they contain a fair amount of copper. On the highland of the Department of Tchatchak there are copper ores in serpentine, and here are found many ancient workings and old dumps. East of Kniajevats there occur in the gabbro rocks quartz veins with chalcopyrite, iron pyrite, and bismuth.

The mineral area of Majdanpek is marked by gossan. It stretches from north to south for more than four kilometers, and its greatest width is about 600 meters. The deposits appear in the form of irregular masses and broken veins, and also as impregnations, which occur at the contact of the andesite with the limestone and the crystalline schists, or in the altered andesite.

Numerous ancient workings and dumps show to what an extent the ancient workings of Majdanpek extended. It was certainly worked in the time of the Romans, and

recognized to be the best organized mine of the east of Europe. Owing, however, to an interruption in the production of iron, the state was discouraged and disposed of the deposits to private individuals. Today the iron industry is completely abandoned, only the copper ore being worked.

At Majdanpek are found ores of copper and iron sulphides and oxides, together with a small amount of zinc and lead sulphates. The chalcopyrites are usually to be found together with iron pyrites and magnetite. There are often great masses of iron pyrites near which are situated masses of covellite containing a great percentage of copper. The decomposition of the primary deposits has produced copper and iron oxide ores. It is in this way, also, that the important limonite deposits which were utilized for a long time for the production of iron were formed. The oxidized ore contains generally more copper than the unchanged sulphides. This is the reason why many of the deposits of iron pyrites have been abandoned, as they contain only from 0.3 to

0.5 per cent of copper, whereas in the oxide deposits there are from 6 to 12 per cent.

The Majdanpek mines, covering 16,000 hectares (40,000 acres) were leased in 1902 to a Belgian limited company. From 1870 to the end of 1903 upward of 115,000 tons of ore were treated, giving 4,350 tons of copper. The average proportion of copper in the ore is therefore 3.78 per cent. The black copper when refined at Brixlegg in 1901 gave 94.10 per cent of copper, 48.6 per cent of iron, 10 grams of gold, and 270 grams of silver per ton of copper. An analysis of the black copper in 1904 gave the following: Copper, 96.4 per cent; iron, 2.10 per cent; sulphur, 0.67 per cent; zinc, 0.53 per cent; silver, 411 grams per 1,000 kilograms; gold, 39 grams per 1,000 kilograms.

There are numerous quartz veins of auriferous chalcopyrite in the granite mass of the Department of Krajina, near the villages of Tanda and Luka. Copper ore occurs in the form of isolated masses in the limestone to the east of Golubats, on the mountain of Ridanj, which is undoubtedly a continuation of the mining region of the Banat, and also extends far toward the south to Vukan, where there are very large dumps, as well as outcrops of copper ore.

The copper deposits of Bor and Krivelj, in the Department of the Timok, occur in connection with the andesitic rock. Here there are also ancient workings, which form the best indication for the study of the various deposits. The ancient galleries and shafts are arranged in a linear direction, and may be grouped into several parallel zones. Their direction is, in general, from north to south, with slight deviations toward the northwest. The general direction of the ancient workings, which follow the metallic veins, is parallel with the general direction of the volcanic dikes which may be followed for a distance of 300 kilometers in Serbia and the Banat.

There are indications in the old workings of this region that the presence of gold had been recognized, and that gold has been recovered by washing. It is therefore probable that the ore interested the old miners only as a source of gold, and that they abandoned the work when they reached the primary ore, which is found at the shallow depth of twenty-five to thirty meters.

The prospecting work has demonstrated five parallel veins, which may be followed by their outcrop, and by the old workings, for a distance of ten kilometers and a width of two kilometers. The most important workings occur in the village of Bor, and had for object the determination of the depth of the deposits. A drift was begun at Bor, thirty-two meters below the ancient workings, and following their direction through a propylitized mass of andesite. The propylitization was so far advanced that only a quartz skeleton remains of the original rock, in which there often occur cavities with the shape of feldspar and ferromagnesian minerals. The percentage of copper in the ore was favorable. Of the thirty analyses made, taken from each meter of the mass of ore, twenty-six gave 8 to 25.6 per cent of copper, eleven from 5 to 8 per cent, and only two 3.2 per cent. All the analyses showed gold from traces to ten grams per ton of ore. The volume in sight amounted to 85,130 cubic meters, or 255,390 tons.

The mineral deposits of Bor are related by their geological conditions and by the period of their origin to the copper deposits of Majdanpek, and also to those of the interior zone of the Carpathians, and they show a certain semblance to those of Nevada and Colorado. On the other hand, the deposits of Bor differ from all these by their mineralization and resemble rather the well-known pyritic masses of Europe (Roros, Ramelsberg, and Huelva). A concession of 2,400 hectares was given in 1903 to a French company. Its exploitations showed that it was one of the richest copper mines in Europe. It was in full operation at the time of the German invasion. During the period of occupation the Germans extracted thousands of tons of copper.

Impregnations of copper ores, malachite and azurite, are found in many parts of the country, but only in small quantities. There are also other outcrops of different kinds of copper ore in various districts, but these have not been carefully studied.

Antimony

Antimony is found in great quantities in Serbia, and the most important deposits have been discovered in Podrinje. At Zayetchar there are two kinds of antimony deposits. The proportion of antimony in them varies greatly. A concession for these deposits, extending over 1,660 hectares (4,160 acres), was granted to a Serbo-French company in 1898. From 1901 to 1903 this company treated 13,537 tons of ore, containing 12 to 14 per cent of antimony, with a yield of 1,460 tons of oxide of antimony, which was transformed into 825.5 tons of regulus. There are also deposits of antimony in other parts of the country, but these have not been studied.

Nickel

Nickel ore occurs in such small quantities as not to be worth working. Chrome exists in the form of chromite on the mountain of Suvobor and near Kraljevo, where it appears in isolated masses in serpentine. Analysis has shown that the ore, of which several hundreds of tons have been obtained, contained an average of 50 per cent of chrome oxide. There are also other chrome deposits, but none have been worked systematically.

Deposits of Iron

The iron industry has not yet come into existence in Serbia, apart from some attempts which have failed, although the country is rich in iron ore. Investigations have been made only on a small scale, and it is impossible to judge the exact nature of the deposits. The most important deposits are of magnetite in the crystalline rocks. There are also iron deposits in irregular masses in the serpentine ore, in conjunction with other minerals, near the eruptive rocks, and isolated deposits in large or small masses or in layers in the sedimentary formation, principally in the cretaceous limestones.

Manganese

There is no doubt that a considerable amount of manganese ore exists in Serbia, generally associated with limonite, but these deposits are as yet little known. One of the deposits of the Department of Kragujevats is, however, known to contain up to 42 per cent of manganese. Natural sulphur is rare in Serbia, and it is never found in masses sufficient for working. Bituminous schists are found in many parts of the country, and many of them deserve to be studied further because of the quantities of bituminous matter they contain.

Coal

There are four kinds of coal fields in Serbia, which should be considered according to their geological age

—coal of the Carboniferous period, Liassic and Cretaceous coal, Tertiary brown coal, and Tertiary lignitic coal. In the Carboniferous basin lying between the Save and the Pek there are several beds of coal, but owing to the lack of adequate study it is impossible to estimate the exact value of these coal beds, which are, however, composed of coal of excellent quality. The fossil plants found in these coal deposits show that this coal is of the same age as that of Moravia, upper Silesia, and the basins of the Saar and the Rhine. Of the many deposits of Liassic coal, several are being worked. These are the mines of Dobra, lying on the Danube opposite to the Drenkova mines in Hungary. The coal formation extends over a length of four kilometers. There are three principal seams, with varying widths of from one to ten meters. Unfortunately, there are layers of sandy clay among the coal, which make it necessary to wash the coal in a special manner, resulting in a loss of 28 per cent. This mine, covering 1,200 hectares, was leased in 1887 to a company, and from 1900 to 1903, a total of 61,491 tons of coal was extracted. Another mine which is being worked is near Zayetchar, the deposits having a length of ten kilometers. There are several beds, but only one, varying from 2 to 3½ meters in width, which is fit for working. From 1888 to 1904 the total production amounted to 275,059 tons.

To the east of the mountain of Rtanj outcrops of coal are found over an area of over forty kilometers in extent. At Boljevats, in the department of the Timok, coal beds one to eight meters in width have been discovered. The coal is of good quality and gives 80 per cent of coke. There are also known coal beds at Vina and Podvis. In the latter place a coal vein of two to three meters has been opened, and analysis shows that the coal possesses 7,000 calories.

Extensive Tertiary Coal Beds

Coal beds of the Tertiary period occur all over Serbia, in basins in the Cretaceous rocks or along the Drina, the Save, the Morava, the Danube, and the Timok. In these river basins only recent lignites are found; outside them there is brown coal. The principal mines of this coal are at Senje. Here is a bed of brown coal having from seven to eight meters as an average width, and with a known length of 900 meters. This mine was opened by the government in 1889, and in 1897 it was handed over to the railway administration, which now possesses a concession of over 450 hectares. From 1897 to 1904 the production of coal amounted to 522,770 tons, and in 1904 the production was nearly 100,000 tons.

In the neighborhood of Senje a coal bed of much greater value has been found, as there is a known quantity of coal of over 2,000,000 tons. There are similar coal beds in all the regions surrounding Senje, especially those of Dilje and Cicevats. At Jelasnitsa, near Nish, and at Jarandol, there are also important deposits, the coal at the latter place being among the best in Serbia. In the valleys of the Drina and the Save there are few known coal beds, although there exist in various localities outcrops of lignite. In the valley of the Morava there is much lignite, and this is worked at several places, notably at Kraljevats, by a Belgian company. The valley of the Danube is much richer, and at Kostolats there is a mine of lignite producing about 20,000 tons annually. The valley of the Timok is also richer in lignite, but has not been seriously studied.

Serbia is remarkable for the wealth and variety of its commercial and industrial stones. There are a great number of kinds of granite, marble, lithographic stone, and millstone, which are in great quantities, and which compare in quality with the best foreign varieties. Largely because of the lack of roads and railways, little has been done in the working of this source of wealth, but it will inevitably develop with the means of communication. Of special interest for other countries is the great amount of lithographic stone, which in one place covers an area of over 95 hectares, with a depth of 200 meters. There are many places where limestones occur suitable for the production of cement, and in Ripanj and Ralja cement plants already exist.

The Control of Mines in Serbia

In all matters relating to mines and mining the administrative and judicial authority is vested in the Ministry of Agriculture, Commerce, and Industry, which acts through the Service of Mines and the Mining Council. All concessions for mines are granted by the Minister. He also introduces the necessary laws, and imposes penalties according to the reports of his special departments. The supreme court of appeal is the Council of State. Concessions are of two kinds—prospecting rights and working rights. The former are divided into simple rights and exclusive rights, and these rights have been granted over an area of 200,000 acres. The concessions granted are comparatively few as yet, and cover about 40,000 acres. The grant of prospecting rights carries with it the ultimate possibility of obtaining a concession if the requisite work is done within the necessary period, if sufficiently rich mineral deposits are located, and if the individual or company applying for the concession can show satisfactory evidence that it possesses financial means to carry on the undertaking.

Despite the undoubted wealth of Serbia in mineral resources, it must be said that the mining industry has not yet begun, and this although 634,000 francs' worth of mineral products in 1895 had increased in value in 1907 to over 3,500,000 francs. This, as I have said, is to be attributed in a large degree to the constant hostility of the Central Powers and their efforts to hamper Serbia's economic progress.

The most interesting development has undoubtedly been the increase in the production of coal, ten years having recorded a production of 1,400 tons of hard coal transformed into an output of over 53,000 tons, and 41,000 tons of brown coal becoming 172,000 tons. The exploitation of the great copper deposits promises in the future an enormous increase in the mining industry of Serbia. What is needed is foreign capital intelligently utilized.

South Australian Iron Ore

The iron ore produced in South Australia, according to Consul H. P. Starrett, comes from the mines at Iron Knob and Iron Monarch, situated thirty-four miles from Hummock Hill. This ore forms two hills, which enables it to be worked by open quarrying. It is estimated that there are about 110,000,000 tons of ore in sight. It is a hematite, 66 per cent metallic iron, with no excess of sulphur, phosphorus, or titanic acid. The ore is not treated in South Australia, but is shipped to the steel works at Newcastle, New South Wales, and it is the chief supply of that plant. It is stated that the amount of ore available is sufficient to meet all Australian requirements for many years.

CAMP AT RED ROVER MINE, CAVE CREEK DISTRICT

Ore Deposits of Cave Creek District, in Arizona

Geology of Area Twenty-eight Miles North of Phoenix Described — Only Deposit Developed of Present Importance That of Red Rover Mine — Characteristics of Principal Type of Outcrops Discussed

By Alfred Strong Lewis
Written for *Engineering and Mining Journal*

WITHIN the last two years I have made several professional trips to the Cave Creek mining district, in Maricopa County, Ariz., for Eastern clients holding mining interests therein. In passing over and through the district, and in connection with my examination of certain specific properties, I was greatly impressed by the appearance of the general surface conditions, and therefore determined to make a careful examination, with the purpose of preparing a geological map of the district. This article is based on such survey and examination.

First I made a thorough search of all possible sources for information relating to the district, but found nothing except that its northeast corner was included in the quadrangle covered by the Bradshaw folio of the U. S. Geological Survey. Careful study was made of the Government geological maps and other data relating to the developed districts both north and south of the Cave Creek district, in which the same surface conditions are disclosed as I found to exist in the latter.

Mapping the District

Having completed the study of the adjoining territory I proceeded to examine the Cave Creek district about July 1, 1919, and by Oct. 1, 1919, I had gone over all of the country which had exposures of the older pre-Cambrian formation. I found large areas within the district to be covered by volcanic agglomerate, which was not mineralized and was therefore of no economic importance. These areas I simply sketched in and did not attempt to differentiate. The final results of my work are embodied in the geological map on page 714.

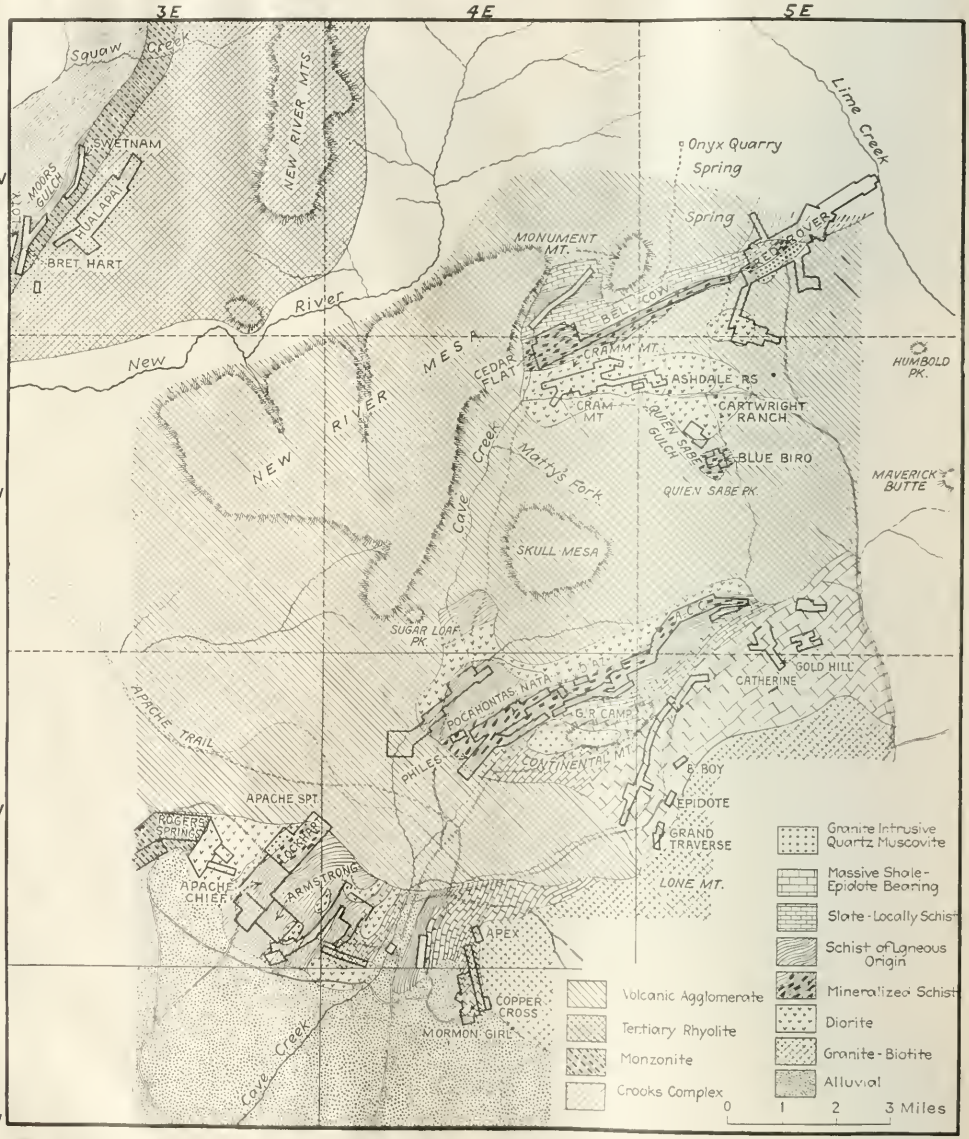
The Cave Creek district is twenty-eight miles due north of Phoenix, Ariz. The road leading out of Phoenix is paved for the first eight miles and from that point passes through the Paradise Valley with slight grades. The elevation of the district varies from 2,100 ft. in the lowest part of the basin to a maximum of 5,000 ft. at the higher peaks. The main outlet for the drainage of the entire district is Cave Creek, which has an average fall of 200 ft. to the mile. At its headwaters near the Red Rover mine it has an elevation of about 4,000 ft. and twenty miles from here it emerges into the desert at an elevation of 2,000 ft.

Evidences of Great Erosion Apparent

Following up Cave Creek, a rim of low mountains is first encountered through which the stream has cut its course. This rim forms the southern boundary of the district. These mountains are abruptly covered at the base of their southern slope by the alluvial material of Paradise Valley. At the foot of the northern slope they are covered by volcanic agglomerate, which covers a basin-like area about three miles wide, feathering out to the east, but widening to the west. High ridges and mesas then succeed one another for several miles. Cave Creek has cut a deep gorge in this part of its course. The ridges and mesas finally give place to open country with an average elevation of about 3,500 ft. and the creek branches out into numerous small washes and ravines. Erosion has been very great, as evidenced by the great depth of the fill in Paradise and Salt River valleys. These hills, which now stand out alone and disconnected, were once part of an enormous mountain system extending from the interior of Mexico diagonally across Arizona and continuing through Nevada. Many thousands of feet have been torn from this mountain system by powerful forces of nature operating through millions of years. This material has been washed down into the great chasms at their feet. The chasms have been filled and leveled into broad valleys of great agricultural activity, and the once lofty peaks have been

dwarfed and diminished into low hills of insignificant size. These tremendous destructive natural agencies have finally exposed at the surface mineralized zones which were originally conceived at profound depth.

The geological ages represented in the district by agglomerate, are for the most part in their original position and are non-mineral bearing as far as known. The Paleozoic beds elsewhere developed in Arizona are entirely absent here. Rocks of igneous origin, however, represent volcanic activity in many geologic periods.



RECONNAISSANCE MAP OF AREAL GEOLOGY OF CAVE CREEK MINING DISTRICT, MARICOPA COUNTY, ARIZ.

sedimentary deposits are confined to the oldest and the youngest of all exposures in Arizona. The pre-Cambrian sediments, which have been highly altered, metamorphosed, folded and finally compressed into shales, slates, and schists, are mineral bearing, but the Tertiary (or Quaternary) deposits, composed of volcanic

Granites of Algonkian age are present; siliceous porphyries originally bedded in pre-Cambrian oceanic sediments, and now forming nearly vertical zones of schist: later granite intrusions in the schists diagonal to its strike: greenstone bedded with the schists and diorites in large marginal masses as well as small and

large dikes irregularly intruded into the schists; and narrow granite prophyry dikes developed for miles in length and running with the strike of the schists, some highly sericitized, some highly siliceous.[1] At certain points as many as six of these dikes running remarkably parallel and spaced from 300 to 600 ft. apart are exposed.

Upon the southeastern margin of the districts is exposed a coarse-grained biotite granite batholith which covers an area of about 2,000 square miles. The granite weathers into peculiar shaped boulders which have almost the identical appearance of the boulder batholith granite exposures of Butte, Mont. The batholith, if of post-Paleozoic age, may have doomed and broken up the Paleozoic beds, rendering them easy prey to the erosive action of the Verde and Salt rivers. Deformation is evidenced by highly contorted rocks in many localities, as well as the change in the strike of the schist zones. There is a remarkable persistency in this strike. The normal strike seems to be N 42° E, and the deformed strike in almost all cases is N 60° E.

Quartz Lenses and Stringers Prominent in Schists

At certain points the schists contain large and small lenses, stringers, and bands of jasper and quartz. Some of these lenses are prominently developed. They are usually from 10 to 50 ft. wide and from 200 to 500 ft. long. They do not occur in straight lines, but are offset in a somewhat regular manner and occur in the softer, more highly sericitized and bleached zones of schist and usually in proximity to the acid-porphyry dikes. Throughout these mineralized zones are distributed many small outcroppings of copper, silver, and gold minerals.

The exposures in the Cave Creek district are similar to those found at the surface in the proven districts of Arizona. An examination of the ore outcrops throughout the district discloses clearly the fact that, in the main, the gold, copper, and silver have been leached, leaving occasional shoots or kidneys of ore which have escaped leaching by reason of some topographical or other condition unfavorable to leaching. Such residual oreshoots are found to carry values in gold, silver, and copper running from $10 to $60 per ton.

Red Rover Deposit Only One of Importance to Date

There is only one property in the district which has done sufficient development work to uncover anything worthy of the term "ore deposit." This property, known as the Red Rover mine, is in the schist zone. The deposit at the surface is in an irregular inclined seam and shows copper carbonates carrying as high as 2,000 oz. of silver per ton. The ore occurs as lenses in the schist and has been developed so far to a depth of 500 ft. A very interesting occurrence is to be seen in the shaft which passes through about 30 ft. of schist impregnated with native copper in the form of thin scales, bright and wonderfully distinct until tarnished by exposure to the air. The principal deposit opened up on the 300- and 500-ft. level shows masses 3 to 4 ft. wide, of copper glance carrying 400 to 700 oz. silver per ton. The other properties in the district have nothing but outcrops to recommend them.

It has been stated many times in recent mining literature that the mines of the future must be found by the application of geological deduction based upon surface and other data available. It therefore seems proper to describe the general characteristics of the principal types of outcrops exposed in this district. For convenient description the district can be divided into three zones.

Copper Carbonates Frequent Along Batholith Contact

The first zone is from one mile to two miles wide and borders the northwestern contact of the granite batholith. It is composed of highly metamorphosed banded shales. Blocky epidote rock is extensively developed in this zone, and in places there are ledges composed of epidote, quartz, and dolomite intimately mixed. This zone gives place to slates along its western margin. Copper carbonates carrying several dollars per ton in gold and silver outcrop at many points within this zone, always in association with quartz or epidote.

The Mormon Girl deposit, in this zone, is formed in contact with and just above an inclined foot wall of

GRANITE POINT—A PREHISTORIC "LOOKOUT" IN THE CAVE CREEK DISTRICT

barren quartz. This quartz is 6 to 8 ft. thick and represents two generations of silicification, one of white quartz, which has been crushed into angular fragments, and the other a dark quartz, which has been deposited around the irregular fragments of the white quartz making the present hard compact foot wall. This foot wall is smooth, continuous, and unbroken. On top of it has been deposited copper-gold-silver-bearing quartz of an average value of $40 per ton and from 4 to 5 ft. thick. A few hundred feet below this the ore disappears.

Little Copper in Second Zone

The second zone begins at the edge or border of the slates and extends to the contact of diorite and igneous complex. It is several miles wide and is all schist. Within this belt is a narrow, highly mineralized area that is exposed for about fifteen miles and is 600 to 1,200 ft. wide. It consists of highly altered soft sericitized schist in places highly twisted and contorted. In coloring it ranges from pearly white through the various shades of yellow and occasionally is deep red. In

[1] The Pre-Cambrian rocks are designated on the accompanying map as "Schist of Igneous Origin," "Mineralized Schist" and "Crooks Complex." The latter formation, shown in the northwestern corner of the map, is the equivalent of the formation so named by the U. S. Geological Survey, in the Folio of the Bradshaw Mountain Quadrangle. It comprises irregular bands of diorite, granite, aplite and schist, with some breccia.—Editor.

other places, it is bleached or gray and full of innumerable quartz stringers. Very little copper is in evidence in the outcrops, but several location cuts exposed copper stain a few feet beneath the surface.

Elsewhere in this area many huge silicified outcrops occur, showing jasper and siliceous hematite. In connection with these there are innumerable outcroppings of carbonate, oxide, and some sulphide of copper occurring in patches or irregular impregnations.

The third zone lies along the contact of the schist and the diorite and other igneous intrusions and is the western part of the mineralized section of the district. There are several brecciated siliceous zones, from 50 to 300 ft. wide and of undetermined extent, which contain ore averaging $2 to $5 in gold per ton. Ore averaging as high as $12 per ton has been taken from narrower enriched channels within the main low-grade orebodies.

In the diorite there are many outcrops showing strong shearing action. In these zones impregnations of copper carbonates are common. One of these at a depth of 225 ft. was crosscut for 30 ft., showing chalcopyrite and bornite disseminated in a hard greenish diorite which carried 1 to 3 per cent copper.

Dimensions and Area of the United States

The gross area of the United States is 3,026,789 square miles. The land area amounts to 2,973,774 square miles, and the water area—exclusive of the area in the Great Lakes, the Atlantic, the Pacific, and the Gulf of Mexico within the three-mile limit—amounts to 53,015 square miles. These and other data determined or compiled by the U. S. Geological Survey, to show the limits of the continental United States, contain some interesting facts.

The southernmost point of the mainland is Cape Sable, Fla., which is in latitude 25° 07′ and longitude 81° 05′. The extreme southern point of Texas is in latitude 25° 50′ and longitude 97° 24′. Cape Sable is therefore forty-nine miles farther south than the most southern point in Texas.

A small detached land area of northern Minnesota at longitude 95° 09′ extends northward to latitude 49° 23′.

The easternmost point of the United States is West Quoddy Head, near Eastport, Me., in longitude 66° 57′ and latitude 44° 49′; the westernmost point is Cape Alva, Wash., in latitude 48° 10′, which extends into the Pacific Ocean to longitude 124° 45′.

From the southernmost point in Texas due north to the forty-ninth parallel, the boundary between the United States and Canada, the distance is 1,598 miles. From West Quoddy Head due west to the Pacific Ocean the distance is 2,807 miles. The shortest distance from the Atlantic to the Pacific across the United States is between points near Charleston, S. C., and San Diego, Cal., and is 2,152 miles.

The length of the Canadian boundary line from the Atlantic to the Pacific is 3,898 miles. The length of the Mexican boundary from the Gulf to the Pacific is 1,744 miles. The length of the Atlantic coast line is 5,560 miles and that of the Pacific coast line is 2,730 miles. The Gulf of Mexico borders the United States for 3,640 miles.

Nearly all maps of the United States show the parallels of latitude as curved lines and are likely to lead the ordinary observer to believe that certain eastern or western states are farther north than some of the central states that are actually in the same latitude. For this reason, one who is asked which extends farther south, Florida or Texas, is very likely to say "Texas," but, as stated, the mainland of Florida is nearly fifty miles farther south than the southernmost point in Texas. For the same reason errors are likely to be made in estimating position or extent in longitude. Few realize that the island of Cuba, for example, if transposed directly north, would extend from New York City to Indiana, or that Havana is farther west than Cleveland, Ohio, or that the Panama Canal is due south of Pittsburgh, Pa., or that Nome, Alaska, is farther west than Hawaii.

Ontario's Metalliferous Production Increasing

Returns received by the Ontario Department of Mines for the six months ending June 30, 1920, are tabulated below, and for purposes of comparison the quantities and values are given for the corresponding period in 1919. Tons throughout are short tons of 2,000 lb.

Product	Quality 1920	Quality 1919	Value 1920	Value 1919
Gold, oz	277,656	231,729	$5,690,504	$4,666,759
Silver, oz	4,474,322	5,744,172	5,077,028	5,951,362
Platinum metals, oz	184.45	30.08	12,443	1,805
Cobalt (metallic), lb	113,239	59,337	266,045	93,157
Nickel (metallic) lb	4,854,979	5,147,745	1,696,687	1,825,347
Nickel oxide, lb	3,491,544	5,503	814,070	1,567
Cobalt oxide, lb	388,318	202,912	645,783	301,791
Other cobalt compounds, lb.	1,417	26,289	1,029	16,164
Nickel sulphate and carbonate, lb	159,183	133,732	15,308	15,531
Lead, pig, lb	749,820	1,481,204	71,006	54,802
Copper sulphate, lb	89,939	.....	4,497	.....
Copper, blister, lb.	2,918,153	3,080,492	470,949	452,055
Nickel in matte exported tons	9,527	7,072	5,338,120	3,535,915
Copper in matte exported (*a*) tons	4,434	4,341	1,241,520	1,128,753
Iron ore, exported (*b*) tons.	2,189	5,804	18,512	44,309
Iron, pig (*c*) tons	28,771	24,095	738,079	670,512
Totals			22,101,580	18,759,829

(*a*) Copper in matte was valued at 13c. and nickel at 25c. per lb. in 1919. For 1920 the values have been placed at 14 and 28c. per lb. respectively. The total matte produced contained 15,030 tons of nickel and 7,705 tons of copper.

(*b*) Total shipments of iron ore were 13,962 short tons, worth $74,073.

(*c*) Total output of pig iron was 321,826 tons, valued at $8,255,916. Figures in the table represent proportional product from Ontario ore

The aggregate output from metalliferous mines, smelters, and refining works of the Province of Ontario for the six months ended June 30 shows a considerable increase in value over the 1919 figures. For the first time since 1903, when the Cobalt silver camp was discovered, the output of gold exceeds that of silver in value. The new electrolytic refinery of the British America Nickel Corporation is now in operation at Deschenes, near Ottawa.

Japan's Mining Industry Slack

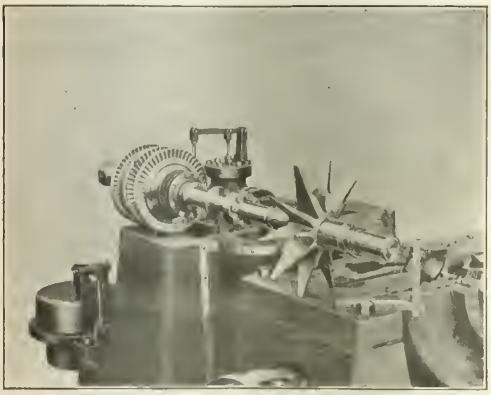
Japanese mining industry, in which more American capital is invested than in any other line of business activity in Chosen, experienced an unusual slackness during 1919. The Mitsubishi Iron Foundry, at Kyomipo, was forced to reduce its output, as was also the Suan mine, worked by the Seoul Mining Co., and the Kapsan copper mine, worked by the Kuhara Mining Co. The reasons for this were difficulties experienced in the matter of transportation through the outbreak of rinderpest among the cattle and which totally stopped all transport, and the heavy death rate among the miners from cholera. The continual rise in the cost of supplies and living expenses gave added cause for the reduced output.

A New High-Speed Turbo Compressor

Many Interesting Features in Machine Designed for an Argentine Copper Smelter—Notable Reduction in Manufacturing Cost of Air Compressors Possible—Low Capacity For Its Type and Wide Range of Volume

By Bancroft Gore
Written for *Engineering and Mining Journal*

IN NORTHWESTERN Argentina, on the eastern slope of the Andes, near Chilecito, at 5,500 ft. above sea level, the Corporacion Minera de Famatina operates a copper smelter. This plant has been recently overhauled and new equipment added to conform to the latest metallurgical practice. Two converters of the Peirce-Smith type are used for the production of blister copper from blast furnace and reverberatory matte.



ROTOR SHAFT OF TURBO COMPRESSOR

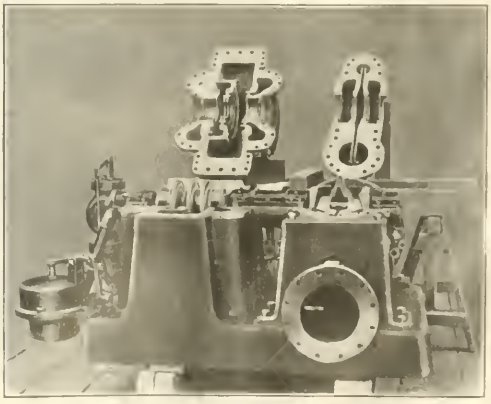
Air enters the tuyères at 12-lb. gage pressure, and the volume required fluctuates from 3,000 to 5,000 cu. ft. per min., according to variations in the operating conditions of the converter department.

As steam, at a pressure of 150 lb. with 100 deg. F. superheat, is available from waste-heat boilers, it was suggested that a turbine-driven blower would be the most desirable substitute for the belt-driven reciprocating unit, which was worn out and of insufficient capacity when both shells were blowing freely. Although the turbo blower, for capacities considerably in excess of these requirements, has generally supplanted cumbersome steam-driven reciprocating units, considerable difficulty was found in placing the order for the machine shown herewith. Owing to its relatively low capacity and the wide range of volume needed to meet the operating conditions it was the general opinion of engineers, all specialists in the design of air compressors, that the first cost of such a machine would be out of proportion to the many advantages easily obvious in the larger units, and that, in addition to its excessive steam consumption, it might result in an unfortunate experiment to the customer.

The design and construction of the machine were finally undertaken by the Rateau Battu Smoot Co. About the time the machine was set up for testing purposes at Ridgway, Pa., one of an almost continuous series of freight embargoes was effective, preventing shipment to the port of New York for export. Advantage was taken of this delay to give the compressor a rigid test, extending over a period of nearly two months. Mechanical engineers designing this class of equipment, who were invited to study the performance of the machine, were much interested.

A notable advance had been made in the construction of air compressors by an aggressive use of peripheral wheel speeds that in a unit of this size had been looked upon by conservative designers as either impossible or extremely risky for continuous operation. As a result of the somewhat unusual shaft velocity, which varies from 22,000 to 26,000 r.p.m., the cost of material used in the construction of the machine and the shop work had been cut to a pre-war basis, considering the capacity. A large proportion of the shop work was chargeable directly against the rotor element, which weighed only 138 lb. Further, it would be but one step more, by use of a two-stage effect on the air end of the rotor, to develop an air compressor for mining requirements that would be remarkable for compactness and weight when compared with a more conventionally designed machine of equivalent output.

In a general way this turbo compressor follows a design adopted in the construction of a blower which has been operating as a gas booster at Omaha, Neb.,



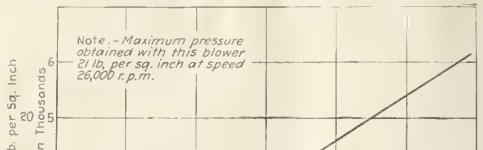
TURBO COMPRESSOR, SHOWING WHEEL CASINGS THROWN BACK

for two years at 20,000 r.p.m. The design of bearings for extreme velocities was much simpler than had been anticipated and the fool-proof qualities of a turbo blower were found actually to increase with the speed of the rotor.

The practical result of this experience applied with further refinements of design to the Famatina compressor is best known by comparison of it with a recip-

rocating machine of standard construction and approved type, rated at 4,000 cu.ft. per min. at 15-lb. gage pressure: Turbo compressor, selling price at factory, one-half; net weight, one-eighth; floor space occupied, one-seventh; concrete for foundations, one-fifth; railway and ocean freight to mine, one-seventh; erection cost, one-third. Aside from these features the blower has an efficient volumetric capacity of 25 per cent over and under its rating of 4,000 cu.ft. at 13-lb. gage pressure.

The general construction of the machine is shown in the accompanying views. The rotor is made of two rigidly coupled sections, forged and machined from nickel-chrome steel having an elastic limit of 80,000 lb. per sq.in. The turbine is of the Rateau two-stage impulse type, the first wheel taking the steam at initial pressure, from which it flows in parallel to each of the low-pressure wheels. The compressor is mounted directly over a Wheeler condenser, giving a vacuum of



STEAM CONSUMPTION AND PRESSURE-VOLUME CURVES

4 in. of mercury, absolute. One view shows the wheel casings thrown back, revealing the method of taking care of the smooth flow of air which enters and leaves the one-stage impeller chamber at a velocity above 1,200 ft. per sec. The bearings are ordinary babbitt-lined, but carry special groovings for the flow of lubricating oil, which circulates under a pressure of 10 lb. per sq. in. from an overhead tank at the rate of 8 gal. per min. This tank is kept overflowing, and an alarm attachment sounds when the oil supply to it fails.

At the maximum speed of 26,000 revolutions the operation of the machine is without vibration, owing in large measure to the satisfactory dynamic balance of the rotating element and the massive construction of the casing and bedplate.

The basic feature governing the smooth running of the compressor is that its critical speed is well above the running speed, in this case the critical speed being above 30,000 r.p.m.

The floor space occupied is 4 x 7 ft. and the height above floor level 4 ft.

Speed regulation is obtained by attaching to the end of the turbine shaft a small control fan, the air pressure from which is proportional to the square of the speed of the rotor. This operates a static regulator controlling the steam supply. Adjustment covers a considerable range of pressure and volume. An automatic stop valve, also controlled by the fan, shuts off all steam at the desired speed limit. A hydrostatic gage from the control fan indicates on a calibrated vertical scale the speed of shaft rotation.

The rate of steam consumption for a fixed speed of rotor, but with variations in the aperture of the air orifice, is shown in the graph in the opposite column. The comparative flatness of the curve between 3,000 and 5,000 cu.ft. shows the remarkable flexibility of the machine when it is operating under varying loads.

Chromite in Asia Minor

Chromite deposits are widely scattered through many parts of Asia Minor. All the orebodies are found in schistose and decomposed serpentine in groups of lens-like or irregular bodies.

The chromite mines of Asia Minor have produced important quantities of ore. From about 1870, when Turkey began to supplant the United States as the world's principal producer of chromite, to near 1900, Asia Minor furnished the bulk of the chromite for the world's consumption. Most of the ore mined has come from the mines in the Brussa region, on the south and southwest slopes of the Mysian Olympus, and from the mines of the Macri region. The Brussa and Kutahia deposits are said to have produced an average of about 20,000 tons annually for many years, of which the Daghardi mine is said to have furnished nearly three-fourths. This deposit consists of high-grade ore, averaging 51 to 55 per cent chromic oxide, and has been estimated to contain about 10,000,000 tons of ore. Probably this is somewhat an exaggeration, although doubtless the deposit is large and important if developed by modern methods.

It has been the policy of Turkey not to allow her mineral properties to fall into the hands of foreigners. Even while the exploitation of the chromite deposits was most vigorous, therefore, the mines, although in many places worked by foreign firms, were largely owned by the Turkish government or by Turkish subjects who leased them.*

French Iron-Ore Production

French production of iron ore during the first quarter of 1920, according to *Commerce Reports*, is given as 3,084,115 tons, by months as follows: January, 990,495 tons; February, 974,847 tons; March, 1,118,773 tons. Owing to the strikes in April the production fell to 613,028 tons.

There were imported into France during 1919 a total of 303,295 tons of iron ore, valued at 22,747,000f. ($3,116,627, at 7.20f. to the dollar, the average rate of exchange for the year).

Countries of origin and amounts were as follows: Belgium, 1,473 metric tons; Spain, 214,983; Italy, 9,113; Algeria, 10,398; other countries, 67,328.

The exports of iron ore during 1919 amounted to 1,697,171 metric tons, valued at 127,288,000f. ($17,436,712 at the above rate of exchange). The countries of destination are not given, but it is presumed that the majority of the iron ore exported went to Germany

*E. C. Harder in "Political and Commercial Geology," McGraw-Hill Book Co., 1920.

A Picturesque Mining Experience—V.

The Last Bucket

By Lt.-Col. George Sydney Binckley

IT WAS a snowy day, a good many years ago, when I sat by a fireside up in Sutter Creek, and heard from Mr. Knight this story of the early days of quartz mining in California. We had been discussing a recent accident, and for a while the old gentleman pulled thoughtfully on his pipe.

"While it wasn't just the same kind of a mess, somehow that brings to my mind a curious thing that happened not far from here away back when I was a youngster," he began. "There had been some work done on the property a good while before—in fact, I believe that this was one of the first quartz mines in California—but it had been abandoned a long time before the new crowd came in, sank a vertical shaft a bit over in the hanging, and put in a steam hoist. The rock looked pretty good, and at the time I speak of they had the shaft down about four hundred feet, were drifting on the three hundred level in search of an ore-body that showed in some of the old workings above, and had opened a small stope a short distance from the shaft above the four hundred level.

Caught by Poison Gas

"They were getting on pretty well but were bothered with poor ventilation, and I was over there putting in a ventilating fan and a small engine to drive it. They hadn't struck much water—an hour or so a day of bailing kept the sump clear—and, as I say, the main trouble was powder smoke. So that morning as I was rushing the work on the blower outfit over close to the shaft, I heard them shoot a round in the drift on the three hundred at the regular time. But even before the last shot let go—I instinctively counted them—something ugly happened. There was a sudden roar of falling water in the shaft, and almost immediately there was belched up to the surface a sickening gust of foul gas. The effect was fairly stupefying. There was a sudden rush toward the shaft from all over the place, and as sudden a falling back as the foul, poisonous gas spread. For an instant no one could form any idea of what had happened, but it was plain that no man could be left alive in the mine."

The old man paused a moment, as the full recollection of that sudden horror came back to him. He spoke very slowly as he looked into the fire while the snow whirled outside. "I hardly know how to make you understand how I felt," he began. "In an instant all was quiet—the white-faced men who crowded around the shaft were as quiet as the timbered hills lying there in the sun. From the shaft we could hear the tinkle of a little stream of water that made deeper the silence of those who had died.

"And then the women came—there weren't many children yet—and at once came a clamor to go down and bring up the dead. Dazed as I was along with the rest, I kept my head enough to realize that it was death to go ten feet into that shaft, and I persuaded them to wait until I could get the blower to work and clear the shaft of foul air. Yes," remarked the old man with the ghost of a smile, "I persuaded them. I wore a six-shooter in those days, for it was a handy tool, and could save life as well as take it.

A Swift and Strange Death

"Well, it took but a short time to fix up the blower so it could run (fortunately the pipe was already in place), and soon after we started it up the air was clean enough to let the men go down to the three hundred and bring up those who had been working there. They found them in the little cross-cut where they had gone when they were ready to fire the round of shots that had broken through into a forgotten stope, hidden by an old, waste-covered bulkhead at the bottom of a winze from one of the old levels above. The bodies had not even been washed out by the rush of water as it swept past on its way to the shaft, but the foul gas from the rotting timbers killed all six as they stood. It was a swift and strange death.

"There was a sad and quiet crowd around the collar of the shaft after the six bodies had been brought up and taken to the cabins, and we began to bail out the shaft so as to get at those caught by the water on the four hundred. It wasn't a long job, for there had not been any very great amount of water in the old stope, but it was coming on dusk when we got the water down toward the level, and we saw that soon we could send men down for the bodies there. Then the bailing bucket was lowered for the last time and allowed to fill."

The old man was staring into the fire. Then he looked up at me. "Can you see it? The dusky hills around, the silent white-faced crowd, the black mouth of the shaft? Can you realize the state of mind and body we were in after ten hours of desperate toil, and horror and nervous tension?

Miraculous Escape

"Try and see it all as it was, and then try and imagine the effect on that crowd when, from the bottom of the shaft, from the hands of dead men, slowly, solemnly as the tolling of the bell of Death, came the signal to hoist men! Stroke after slow stroke the gong in the hoist-house gave out the signal . . . . and the crowd melted away. Babbling terror, the Irish hoistman made for the woods, and—I admit it without shame—my knees shook under me as I took his place and brought the bucket to the surface. In the half-light, four men stepped off—to me it seemed in the dusk that I could see the headframe through their bodies, but I guess this couldn't be so, for they were four very solid Cornishmen, who had merely been trapped, with plenty of good air, in the overhand stope on the four hundred. As a matter of fact they suffered little inconvenience, and simply waded out when the water was low enough, climbed on the bucket, and signalled to hoist."

This was the tale told on that snowy day in Sutter Creek, and few stranger tales have I ever heard than this of the early days of the Mother Lode.

The Barman

By C. M. Campbell

THE accompanying pictures represent a phase of mining work of a somewhat more spectacular nature than usual. They show the removal of an unsafe piece of rock from the nearly vertical east wall of the glory hole at the Granby mines, at Phoenix, B. C., recently abandoned.

MORE difficult conditions prevailed underground. The physical character of the ore was such that shrinkage stopes were hardly ever necessary, the method actually employed involving large open stopes with the roof supported by pillars. The backs of these stopes had to be examined as the work progressed, and the lot of the barman who attended to this matter would not seem to be a happy one. There was, however, no lack of applications for these positions, and it is worthy of record that, during the twenty years the mines were operated, neither a fatality nor even a serious accident occurred among the barmen.

AS MAY be seen, each of the men makes use of a rope, one end of which is firmly fastened to a point above the work, the other being placed about the waist of the barman. Should he lose his footing he may be, for the moment, inconvenienced, but the rope is always the means of preventing a nasty fall and offers a safe method of carrying on the work of barring down.

Mining Men of Note

Adolph Lewisohn

FATE picked Butte as the scene of Adolph Lewisohn's entry fifty years ago into the business of mining copper, when, in 1870, the newly organized firm of Lewisohn Bros., of which he was a member, took over the property of the Montana Copper Co., controlled by Behr & Steiner, who had fallen into financial difficulties. Mr. Lewisohn, who was then only twenty-one years old, went to Butte to look over the new acquisition of his company. He found the superintendent pessimistic, and decided to have the mine examined. He chose for this work a distinguished engineer, whose report proved none too glowing. There was some copper, it stated, which perhaps it would pay to take out before shutting down. But operation was continued in the belief that the property had merit, which proved to be the fact, and eventually the Lewisohns organized the Boston & Montana Consolidated Copper Co. Later, when this company was taken over by Boston interests, Lewisohn Bros. contracted to refine and market its copper, and upon the organization of the Amalgamated converted this refining and selling business into the United Metals Selling Co., of which Adolph Lewisohn was president for a number of years.

ADOLPH LEWISOHN

As the original firm prospered it acquired other interests, among them being the Old Dominion, at Globe, Ariz., and the Tamarack and Isle Royale mines, in the Michigan Copper Country, which properties eventually were sold. At this time Lewisohn Bros. had two copper refineries, one at Pawtucket, R. I., and a small one in Connecticut. The growing demand for electrolytic copper caused the firm to build the Raritan Copper Works in 1898—a modern electrolytic refinery. About the same time the firm organized the Tennessee Copper Co., which continued under its management for the next decade. Adolph Lewisohn, however, withdrew from the firm within a few years and opened offices of his own, also continuing as head of the United Metals Selling Co. At present he is the head of Adolph Lewisohn & Sons.

In 1905, Mr. Lewisohn organized the General Development Co., which successfully floated the Miami Copper Co., of which he has been president from the start. The operating control of the Kerr Lake Mining Co., of Cobalt, was also purchased. In 1917, he again took control of the Tennessee Copper Co. and with others helped organize the present Tennessee Copper & Chemical Corporation. A few years ago, in association with the present firm of Lewisohn Bros., who are sons of the late Leonard Lewisohn, he formed the South American Gold & Platinum Co. Mr. Lewisohn's career has been distinguished by a capacity for business and a genius for organization that are apparent in all his achievements. But there is another side to his character that is quite as striking. He is widely known for his philanthropies, especially to a large part of the New York public. He is actively interested in many charitable and educational undertakings. Prominent among his gifts to various institutions is the building of the School of Mines of Columbia University; the great stadium of the City College, in New York, presented by him to the city, which turned it over to the college, and the building and equipment of the new pathological laboratory of the Mount Sinai Hospital in New York. Mr. Lewisohn is one of the reorganizers of the Hebrew Sheltering Guardian Orphan Asylum, to which he gave a large part of the financial needs for the building of its new cottage plan home in the country, where it takes care of dependent children in a model way. He is still president of this institution and is also honorary president of the Hebrew Technical School for Girls, which is doing a great work for the ideal education of girls after they leave the public schools. He is chairman of the Prison Survey Committee, appointed by Governor Smith, and of the National Committee on Prisons and Prison Labor, and has published an essay, "Prisoners: Some Observations of a Business Man." He is also a director in the National Child Labor Committee and the International Child Welfare League.

Mr. Lewisohn is now seventy-one years old, having been born in 1849 in Hamburg, Germany. His genius as an organizer, his example as a useful and honored citizen, and his benefactions as a philanthropist form a fitting memorial of his character and distinction.

By The Way*

Slippery Going

In protesting against the recent increase in freight rates, George D. Morris, manager of the Gila Copper Sulphide Co., at Christmas, Ariz., said that his company "had one foot in the grave and the other on a banana peel." Probably a sliding scale based on market conditions would be more suited to a company in this condition.

Not a Vegetarian

"They do say as 'ow tha price o' food stuffs be droppin'," sez Cap'n Dick, "an', dam-me, I mus' say as 'ow tha news be pleasin' to some. 'Ere a bit ago some o' tha men wuz grumblin' baout 'ow everythin' wuz so 'igh an' any nummer o' schemes were tried h'out to h'economize. Some worked an' some didn't. Jan Tregar's missus tried somethin' on 'im that didn't gaw very well with Jan. One moornin' 'e starts for tha mine, an', dam-me, 'e wuz feelin' pretty good, for 'e naws 'e 'ad a bit o' pasty in 'is dinner bucket. Come along h'eatin' time, an' Jan sits daown to 'ave a bite. H'after 'e'd taken a few bites o' 'is pasty 'e naws somethin' is wrong, for, dam-me, tha pasty doesn't taste right some'ow. An' before 'e's through 'e naws bloody well tha missus 'as lef' h'out tha meat. So 'e wuz mad, an' that night tha firs' thing 'e says to 'is missus, ''Ere, Mary Jane; w'ot's, tha matter with my pasty?' 'W'y, Jan,' sez she, 'w'ot's that matter with un?' 'Well,' sez Jan, 'thee need'nt think thee can make any bloody root-'ouse out o' my stummick. Nex' time, min' you, I want some meat in my pasty.'"

Science and Health

A certain American mining engineer has resided so long in the Republic of Colombia that the natives regard him almost as one of the family. Not long ago while domesticating after a particularly strenuous experience in the field, he felt indisposed to the point of craving a little sympathy. As his wife strove to entertain some callers, the afflicted one reclined in an easy chair and from time to time passed his hand across his brow, muttering *"Aaaie! Aaaie de mi. Aaa---ie!" in the* characteristic manner of Latin-Americans. The clacking of tongues became somewhat hushed; giving way to murmers of pity and promises to the hostess of various home remedies to be dispatched by couriers at the earliest moment. After the room had cleared, the patient's faint self-congratulatory grin faded as Mrs. Gringo turned on him with a playful tirade. "Now, see here, Enrique. I think a good bath and a shave will make you feel all right in *poco tiempo*. I know there is nothing much the matter with you at all. I know it pos-i-tive-ly, because never, never in the world was there anyone really sick who would groan in a foreign language."

EDITORIAL NOTE*

This page is not to be taken seriously. If our attempts at occasional humor are not detected as such, we at least wish to disclaim all responsibility. Our chronicling in a recent issue of the new German scheme for extracting gold from sea water has brought us in an honest offer to raise money for subscriptions. We have thought of labeling each of our whimsical paragraphs "Joke," but have concluded that perhaps a general notice will serve.

Early Operations in Arizona

"Of mining operations in Arizona, during any portion of the Spanish or Mexican period, nothing is practically or definitely known," says H. H. Bancroft in his History of Arizona. "The records are barely sufficient to show that a few mines were worked and that the country was believed to be rich in silver and gold. In several districts have been found traces of these early workings; and these with traditions arising from the Planchas de Plata find, at Arizona proper just south of the line, are for the most part the only foundation for the many lost mines of which much has been vaguely written and more said. I have already remarked that modern writers have greatly exaggerated the country's former prosperity in mining and other industries, and it may be added that they have as a rule given the wrong date to such prosperity as did exist, by assigning it to the earlier years of the Jesuit period. Contrary to what has been a somewhat prevalent impression, there are no clear indications of prehistoric mining, that is, by the Pueblo Indians, when their towns extended over a large part of the territory; and there is no proof either that the Jesuits ever worked any mines, or that in their time there were ever carried on any mining operations except on a very limited scale near the Tubac presidio, though in occasional prospecting tours it is probable that some discoveries were made. In Franciscan times for over two decades the same state of things continued. But from 1790 for twenty or thirty years, the period of comparative peace with the Apaches, the veritable era of Arizona's early prosperity, there can be no doubt that many mines were opened from time to time and that some were profitably worked, though we have no definite record of particulars, and though there is no reason to believe that there were any very extensive or wonderfully rich developments. It is to this period almost exclusively that we must trace the old workings discovered in later years, and also all the traditions of lost mines that have any other than a purely imaginary foundation."

The Peanut Press Replies

As we believe in letting both sides of a question be heard, or as many sides as the question may have, we reprint the following letter, which has been received from an observing reader.

Greeting:

In your Aug. 28 issue I had occasion to observe two important items that should have had additional publicity in your following issue. One item referred to the possibility of raising snakes in Arizona for commercial possibilities and the other article states that the blow-off that hatches and breeds in the unworked or closed mines is a menace to cattlemen of southeastern Arizona. For the benefit of all concerned it should be remembered that since prohibition was cast upon us snakes are becoming prominent and more numerous, hence the commercial possibility of a byproduct in the reptile. Also be it further resolved, that if those cattlemen who are also bankers in Arizona would invest a nickel in legitimate mining once in a while, especially in their own country, the blow-fly would soon blow away, or else get run over with an ore car at a producing operating mine. No—the cattleman will come to the city after he has cleaned up about $50,000 on a roundup, and will let some one clean him up. Then he goes back home and discovers that some of his bulls got killed by a blow-fly—then the big yell "Close the mines tighter!" Let us have a little yelling about opening them up. What do you say boys?"

Yours sincerely,

"PEANUT PRESS."

CONSULTATION

A Prospective Mining Career

"I am a young man seventeen years old, having had only a grammar-school education, and from since I could remember I always wanted to be a mining engineer, but do not know how to go about it; so will you help me by answering the following questions:

"1. I haven't the time to go to college to learn mining engineering, as I have got to work. Do you think I could learn mining engineering through a correspondence course?

"2. Must one pass a state examination to become an engineer?

"3. Will there be a great demand for mining engineers in the next twenty-five years or so?

"4. How much do prospectors and assayers get as a yearly salary?

"5. What must one know to become a prospector and assayer, and what are the necessary qualifications?

"6. Do you think I could learn mining engineering by working in a mining engineer's office, at the same time taking a course in the same?"

The *Engineering and Mining Journal* frequently is called upon to essay the difficult and responsible task of advising young men about to embark upon the career of mining engineer as to their prospects in the profession and concerning the kind of education best suited to their needs.

In this case it will be difficult for the inquirer to enter a mining school, owing to his probable inability to pass the entrance examinations on merely a grammar-school knowledge. Supplementary study will be necessary before the usual rigid requirements of the various universities can be met. There is a choice of studying in spare time, with the object of ultimately entering some mining school or starting a career in the mines immediately, and supplementing the direct experience gained with correspondence-course studies or otherwise, and depending upon sheer determination and ability to succeed. In view of your youth, you can well afford time and mental effort in an attempt to pass the college entrance requirements. Such an effort will be found to pay in any future work. Although many men have become eminent and highly successful mining engineers without a degree attached to their names, the fundamental knowledge acquired through mining-school study cannot be deprecated. Many young men have worked their way through college and benefited by the necessity.

To answer the questions in detail:

1. Mining engineering undoubtedly can be taught through a correspondence course, but a regular program of studies pursued at a recognized mining school, with actual instructural contact, is much more to be desired. If you have time and money to devote to a correspondence course you should be able to find time for a more extended regular curriculum.

2. A few states, such as Oregon and Colorado, require a state examination and license for practicing mining engineers.

3. It is difficult to prophesy the demand for any particular professional service, but as long as the world needs metals and minerals there will be an insistent call for mining talent.

4. Prospectors as a rule do not work on a salary basis but prospect for themselves. In some cases they are "grub-staked"—that is, in return for their "grub" they agree to allow a certain party or parties a portion of their discoveries. Assayers get variable salaries. We note a call for some at $150 per month and others for less. It depends on conditions and circumstances.

5. To learn either prospecting or assaying exclusively, a university education is not essential—both can be readily grasped by practice and a little study.

6. It would be of substantial aid in this case to work in a mining engineer's office, but unless the work were supported by actual field practice it would not be of great benefit.

The following list of books and papers has been compiled by Engineering Council in response to requests, especially from parents and vocational advisers of high-school boys, for information concerning the principal branches of engineering, the education and training requisite therefor, and the possibilities for making a livelihood therein. It is valuable to anyone contemplating an engineering career:

"Engineering as a Career." Edited by F. H. Newell and C. E. Drayer. D. Van Nostrand Co., 1916. A collection of papers originally published in the *Cleveland Plain Dealer* and the *Scientific American* on various phases of engineering work.

"Opportunities in Engineering." By Charles M. Horton. Harper & Bros., 1920.

"Engineering as a Vocation." By Ernest McCullough. David Williams Co., 1911. Subject matter based upon a series of addresses given before technical schools and associations of engineer assistants. Published for information of parents.

"Engineering as a Career." By Percival and A. A. Marshall. P. Marshall & Co., London, 1916.

"Addresses to Engineering Students." Edited and published by Waddell & Harrington, consulting engineers, Kansas City, Mo. Second edition, 1912. The purpose of the book is to give engineering students a broad conception of the profession.

"Engineering as a Profession." By Milo S. Ketchum. Bulletin of the University of Colorado, 1916; No. 6. General Series No. 98.

"Engineering as a Profession." By Dean William G. Raymond, University of Iowa. University Extension Bulletin No. 3. New Series No. 73. April 11, 1914.

Manganiferous Zinc Residuum

"Will you kindly tell me where and how much manganiferous zinc residuum was produced in the United States during 1919?"

According to the U. S. Geological Survey, there was produced 80,418 long tons of manganiferous zinc residuum in 1919, compared with 146,796 long tons in 1918, which came from Franklin Furnace, N. J., and was made by reducing the complex manganese-zinc mineral franklinite, occurring in the district. A mechanically and electrostatically separated franklinite product is roasted with anthracite to eliminate the zinc, and the residue, containing about 15 per cent manganese and 40 per cent iron, is smelted to spiegeleisen.

THE PETROLEUM INDUSTRY

The Petroleum Industry in Mexico

Numerous Factors Have Retarded the Full Development of Oil Possibilities Exports for the First Half of 1920 Show an Increase, and Extensive Exploration Is Now Being Done*

A COMPARISON of figures on the production of oil in Mexico, in the United States, and in the world since 1912 shows that the Mexican production has multiplied more than three times in the last seven years. Though in 1913 Mexico supplied only one-fifteenth of the world's production of oil, in 1918 it furnished more than one-eighth.

Statistics show that the world's actual production of oil in 1918 was about 515,000,000 bbl. The potential production of Mexico during 1919 was 547,000,000 bbl. By the term "potential production" is meant the amount of oil that would be produced if each well were permitted to flow without any restraint being placed on it. In 1919 Mexico was potentially able to produce 32,000,000 bbl. more oil than was actually produced in all other countries in 1918, and 170,000,000 bbl. more than the United States production of 377,000,000 bbl. in 1919. The potential production of the wells already drilled and producing in Mexico is estimated at from 1,500,000 to 1,900,000 bbl. daily. But only about 12 per cent of the potential capacity of the wells in Mexico is being actually produced. The full development of the potential possibilities of the industry in Mexico has been hindered by the lack of transportation both for oil and materials, by the lack of sufficient storage facilities, and by the disorganized political conditions of the country. The application of new legislation to the industry, the effect of which it has not been possible to fully ascertain at this time, has tended to halt development operations. Yet the exports of oil from Mexico in the first half of 1920 show a notable increase over the shipments in previous years.

COMPARISON OF MEXICAN AND AMERICAN WELLS

The output of the wells in Mexico can best be illustrated by a comparison with the wells in the United States. The oldest wells in this country are in the Appalachian region and number about 100,000, with an average daily yield of less than two-thirds barrel per well. The newest region is the Rocky Mountain, with 400 wells and an average per well of 40 bbl. daily. The Mid-Continent field of America, with nearly 50,000 wells, averages 9 bbl. daily. The California field, with an annual production of about 100,000,000 bbl., yields an average of 30 bbl. daily per well.

The known oil-producing areas of Mexico may be divided into three main regions, as follows:

The Tampico Region.—The Ebano field is situated forty miles west of Tampico. The oil from this field has a very heavy percentage of asphaltum, and averages about 12 deg. Bé. (0.986 specific gravity). The Panuco field, comprising the productive areas between the Tamesi and Panuco Rivers, is twenty to thirty miles southwest of Tampico. The Panuco or Topila product is a heavy, viscous oil of from 10 to 15 deg. Bé. This field is noted for relatively few failures in drilling. The Huasteca field is south of Tampico and north of the Tuxpam River. This is a field of big producing areas, such as Casiano, Cerro Azul, and Potrero del Llano. The oil is lighter than the Ebano and Panuco grades, averaging from 19 to 21 deg. Bé. (0.9395 to 0.9271 specific gravity).

The Tuxpam Region.—The Tuxpam field is situated south of the river of the same name. The oil is lighter than in the regions farther north, being 19 to 22 deg. Bé. The wells are characterized by long periods of productivity. The Furbero field is about forty miles southwest of Tuxpam. The oil is 24 deg. Bé., but the yield has not been large, and the field is not now producing.

The Tehuantepec-Tabasco Region.—The Tabasco-Chiapas field is noted for the quality of its oil, which has a paraffin base, is very light, and contains a large proportion of illuminating oils. Exploitation of this field has not been active since 1917.

Isthmus of Tehuantepec field produces an oil of from 25 to 32 deg. Bé. The field is characterized by the short period of productivity of the wells and the shallow depth to oil. Operations in this field have not been of great importance in the last few years.

The temperature of the oil as it comes from the various wells in Mexico ranges from 105 deg. F. at Ebano to 165 deg. F. in the water and oil of the Dos Bocas. The pressure per square inch varies from 285 lb. in the Casiano well to 850 lb. in the Potrero gusher.

HISTORY OF MEXICAN OIL DEVELOPMENT

The earliest reference to oil as an industry in Mexico occurs in pamphlets issued in 1857, which record the agreement of a group of merchants in the village of Macuspana, Tabasco, to furnish cacao in exchange for "sheets of forged iron" to be used in storing "illuminating oil" which flowed from a spring near the village. In 1865 the government issued a permit authorizing a certain Spaniard to exploit the deposits of bituminous and oleous substances near San Jose de las Rusias, Tamaulipas. The favorable results obtained by this Spaniard led to the organization of the Development Co. of the Gulf of Mexico in 1868 by a group of Mexican planters for the purpose of exploiting the petroleum seepages and springs situated near Furbero, Papantla, Vera Cruz. This company failed because of financial difficulties. An attempt by Dr. Autrey to continue the development of this field in 1878 was unsuccessful also.

The failure of all these enterprises and those

*Abstract from Latin American Circular No. 71, prepared by the Bureau of Foreign and Domestic Commerce.

immediately following produced a period of pessimism regarding the oil industry in Mexico lasting until about 1900. In that year American oil men, headed by E. L. Doheny and C. A. Canfield, purchased some land at a place now called Ebano, in San Luis Potosi, near the Vera Cruz boundary. In the spring of 1901 a camp was established and drilling began on the first of May. In just two weeks the first profitable well was developed, although its yield was only 50 bbl. a day. There followed three years of continuous and fairly successful drilling by this company, under the name of the Mexican Petroleum Co. A so-called "gusher," yielding 1,500 bbl. daily, was brought in on April 6, 1904, and this well is still flowing at the present time, production being about 800 bbl. daily. The total production of oil in Mexico in the first year of success—1904—was 220,000 bbl.

Early American and British Oil Investors

The development work of the Mexican Petroleum Co. proved so successful that a policy of expansion and exploration was adopted. In 1906 the company acquired several tracts of land situated from 60 to 100 miles south of Tampico. The two English companies holding part of the tracts had failed to discover oil in paying quantities. In July, 1910, a 14,000-bbl. well was brought in by the Mexican Petroleum Co., and the production of oil on a large scale was begun in Mexico. Exports of oil from that country began in 1911.

Soon after Doheny began his operation in the Ebano region an English company, S. Pearson & Son, Ltd., started exploitation on the isthmus of Tehuantepec, and in 1906 extended its activities to the fields south of Tampico. The first well on the isthmus was brought in in 1904, and in 1910 the famous Potrero del Llano was developed in the Huasteca field. This well had a possible daily production of 100,000 bbl. when brought in, and flowed until December, 1918, when it went to salt water. In 1906 S. Pearson & Son, Ltd., contracted with the Mexican government to exploit government lands in the states of Chiapas, Campeche, Vera Cruz, Tabasco, Tamaulipas, and San Luis Potosi. This company has continued to acquire oil lands in Mexico.

Explorations for New Fields of Production

Increasing attention is now being given to the exploration of various other parts of the republic for the discovery of oil. A recent report of the Mexican Petroleum Department, of the Department of Commerce, Industry, and Labor, Mexico City, places the zone of possible production in the Gulf Coast States at over 80,000,000 acres, on the Pacific at about 50,000,000 acres, and in Lower California at about 18,000,000 acres, a total of 148,000,000 acres, or 230,000 square miles. Of this immense area only about 6,500,000 acres have been investigated, which illustrates the scope offered for wildcat operations in Mexico. The combined area of the fields now being exploited in Mexico does not exceed 800 square miles.

The discovery of what is believed to be extensive petroleum deposits on some islands in the Gulf of California has been officially announced by the Mexican government. These islands are close to the shore of Sinaloa, due west of Hermosilla, and the deposit is said to extend to the mainland on the peninsula of Lower California. The southern district of this peninsula has given indications of an extensive petroleum zone, and it is being thoroughly explored.

Exploration is also being carried on in different parts of Mexico, as follows: Durango, in the neighborhood of Mapimi; Colima, in the vicinity of Santa Rosalia and of Manzanillo; Chihuahua, in the vicinity of Casas Grandes, Guzman, Trinidad, Santa Maria, southeast of Ojinaga, and near Juarez; Coahuila, at Ubalde, near Piedras Negras, and at Nuevo Laredo; Chiapas, in the departments of Palenque and Mezcalapa; San Luis Potosi, in the Valles district; Jalisco, vicinity of Lake Chapala; and in various parts of Yucatan.

Ownership of Mexican Wells

Of the total investments in the oil industry of Mexico 97 per cent is held by foreigners. In the petroleum industry of the United States but 4 per cent of the total amount invested is held by foreign capital. In 1918 there were twenty-seven companies in Mexico which produced oil in commercial quantities, seventeen of these being owned by Americans, five by Spanish-Mexican capital, three by Dutch, and two by British interests. Of the total of 63,828,326 bbl. produced in Mexico in 1918, the American interests produced 73 per cent, British 21 per cent, Holland 4 per cent, and Spanish-Mexican 2 per cent. In 1919, however, the British interest materially increased their production. Only American and British interests shipped oil from Mexico during 1918, the oil exports having been 79 per cent American and 21 per cent British.

The refining plants in operation at the present time consist of four in Tampico, one in Tuxpam, one in Vera Cruz, and the oldest one of all in Minatitlan. These refineries have a total capacity of approximately 100,000 bbl. daily. Not more than 22 per cent of the oil exported from Mexico is sent out in the refined state. The future will probably witness the establishment of several new plants of large capacity.

The exports of oil from Mexico in the first six months of the calendar year 1920 amounted to nearly 60,000,000 bbl., representing an increase of 72 per cent over the exports in 1919. If this rate of increase is maintained throughout the year, the total exports for 1920 will reach 135,000,000 bbl., in comparison with 78,000,000 bbl. in 1919.

Destination of Mexican Oil

Of the total exports in June, 1920, the shipments from the Tampico district amounted to 10,566,181 bbl. From Puerto Lobos the shipments were 3,384,513 bbl., and from Tuxpam 1,472,553 bbl. The United States took 71 per cent of the total, South America 8 per cent, Great Britain 4 per cent, Cuba 3 per cent, and Mexico itself 4 per cent, the small remainder going to various countries of North America and Europe. In accordance with its usual record the Huasteca Petroleum Co. was the largest shipper, its exports for the month of June totaling 2,189,750 bbl. Production was somewhat curtailed in June by floods in the lower country, which damaged the oil fields.

The total imports of oil from Mexico into the United States in the fiscal year ended June 30, 1920, reached the record figure of 2,821,693,174 gal., or 67,183,170 bbl. (at 42 gal. to the barrel). This shows a gain of 991,598,069 gal., or 23,609,478 bbl., over the imports of the 1919 fiscal year, which amounted to 1,930,095,105 gal., or 45,954,645 bbl. The gain was 100 per cent over the imports of 1918, when the imports were somewhat more than 1,000,000,000 gal.

NEWS FROM THE OIL FIELDS

Recent Rains in Texas Fields Cause Production Decline

From Our Special Correspondent

In the North and North Central oil fields a considerable decrease in production was recently evident. This was due largely to interference with development work by recent heavy rains. Production changes in these fields lag only slightly behind changes in development. The fields principally affected were Burkburnett, those of Stephens County, and Desdemona, in Eastland County. The Eastland-Ranger district of Eastland County made an increase in production over the preceding week. In and around Burkburnett a number of wells were completed, but all of them were small producers, and their combined production was not sufficient to offset the natural decline in the older wells.

It is reported that Walker & Perkins have sold a 40-acre lease out of the Goodwin tract, one and one-half miles northeast of Breckenridge, for approximately $1,500,000. This lease includes one producing well that came in two months ago making 5,000 bbl. of oil daily. Completions have been made in the Breckenridge Townsite field by the Virginia Oil Co., Ibex Oil Co., Plateau Oil Co., and others, all of these companies bringing in good producers. In some cases the wells were brought in after shooting. Acreage in the northern part of Stephens County in the vicinity of the Leydon field is being leased for as high as $1,000 per acre in some cases.

The Killeen-Mellon well in Bell County is reported to have struck oil and gas in the black lime below 1,850 ft. This is in wildcat territory, and any discovery here will be of considerable importance.

In the Gulf Coastal section the Hull field made the largest increase in production during the week ended Sept. 25, reaching about 18,000 bbl. per day. The Republic Production worked over its No. 20 Dolbear, getting a flow of 4,000 bbl., and completed Nos. 37 and 40 Dolbear, which made initial productions of 1,500 and 350 bbl. respectively. These are all in the 800-acre Dolbear tract. The joint well of the Sun and Texas companies was drilled to 4,070 ft. and then pulled back and casing set from 3,570 to 3,680 ft. The flow gave 300 to 400 bbl. oil and 1,200 to 1,500 bbl. salt water. This is one of the deepest wells in the field and the most southerly.

Interest at West Columbia still centers on the No. 1 Abrams well of the Texas Co. which continues to flow 7,000 bbl. through the drill steam. Three wells immediately north of this well are now down below the depth of the Abrams No. 1 without results. These are the Monarch Oil & Refining Stribling well, over 3,280 ft., No. 1 Masterson of the Gulf Production Co., over 3,200 ft., and the No. 1 Robinson of the Humble Oil & Refining Co., 2,900 ft. plus. Production from the West Columbia field was over 20,000 bbl. daily during the week ended Sept. 25. The Humble Oil & Refining Co. completed its No. 28 Japhet well at West Columbia recently. The next morning it was flowing at the rate of 15,000 bbl. daily or better. This well is a little less than 3,400 ft. deep, and is on the northeast corner of the Japhet lease.

An interesting deep test was made in the Goose Creek field by the E. F. Simms Co in its No. 33 Ashbel Smith well which was deepened and tested below 4,000 ft. Considerable gas was obtained and an oil spray. This is the deepest hole in the field. Goose Creek is one of the few sections in the Gulf Coast country believed to be salt domes where salt has not yet been found.

New Well in Mule Creek Field

From Our Special Correspondent

The Western States Oil & Land Co. completed a well in the Mule Creek Field recently, making the third producing well completed during September. Other wells are being drilled in this section. This company also brought in a 350-bbl. well in the Salt Creek field a short time ago.

It is reported that oil has been struck at 400 ft. in a wildcat well being drilled on the Ziller ranch near Cumbe land, Lincoln County, by Oregon men. The oil is said to be of high grade.

The Standard and Midwest refineries at Casper will be supplied with gas for fuel as soon as the 12-in. main can be laid across the Platte River and connections made. The gas will supplant the oil now being burned.

The Sunset Oil & Land Co., it is reported, has struck oil at 3,700 ft. in its well on Sect. 6 of the Lance Creek field. This well is a considerable distance southwest of any previous drilling.

In this same field, the Western States well on Sec. 28, on the far east side of the field, tried to change itself from a pumper to a gusher; two high heads of oil were made on successive days.

The Producers & Refiners Corporation has struck oil in its No. 2 well in the Osage field at 1,500 ft. The well will be drilled in deeper and placed on the pump. This well is 2,000 ft. southeast of the company's No. 1 well. This company is also drilling a wildcat well in the Williams Park district, near Hayden, Routt County, Colorado. The first casing has been set.

Activities in the Tampico Region

From Our Special Correspondent

The damage done by the fire which threatened the Cia Mexicana de Petroleo, "El Aguila," refinery is now estimated at nearly one million dollars. There were five 55,000-bbl. storage tanks, and a 2,000,000-bbl. reservoir of asphalt destroyed before the flames were extinguished. The fire started early Monday morning, September 13, one of the tanks being struck by lightning, and was not controlled until Tuesday evening after the hardest kind of fire fighting. No foamite or steam was available. The entire tank farm and refinery were in serious danger for several hours, as there were a number of gasoline tanks within a hundred yards or so of the flames.

The Aguila company recently brought in another big well in the Los Naranjos field on Lot 134 Chinampa. It was controlled in six and one-half minutes. The well is estimated at 60,000 bbl daily.

There are several new holes being put down on lot 114 Chinampa and there is a great deal of interest in the drilling to see who gets to the pay first. There are already six producing wells on this lot varying from 20,000 to 50,000 bbl. daily.

The tests in Zacamixtle are being closely watched by many, as some of them are starting to look doubtful. This field was reported on by geologists, and is on line between the Amatlan-Chinampa field and the Cerro Azul pool

Deep Pool To Be Tested in Warren County, Ky.

From Our Special Correspondent

Geologists who have conducted a two months' investigation of deep strata in Warren County report that a deep pool lies there which operators will test out soon. A dual structure is said to underlie the field, indicating that a well touching this level will quadruple the present average production per well and will show a depth of sand twice as great as in the present shallow depths. The intersection of the dual structure occurs at Sand Hill and extends two and one-quarter miles in all directions.

The Callis Oil Syndicate brought in a 50-bbl. well Sept. 29 on the George Sledge lease in Warren County. No. 2, on the Jackson lease, one mile south of Bowling Green, has been brought in, pumping 20 to 30 bbl. a day. Both No. 1 and 2 on this lease indicate that the are on the edge of a pool above the shale. Several deep wells will be drilled.

Kerstedder brought in a well Sept. 27 on the Briggs lease, five miles west of Bowling Green, estimated at 25 bbl.

Denver Convention of Independent Oil Men Draws Large Number

Jobbers, Refiners and Supply Men as Well as Producers Discuss Papers Presented--Van. H. Manning's Address a Feature—Many Companies Have Part in Exhibit—Story of Petroleum Shown in Films

BY GEORGE J. YOUNG

THE term "oil man" is as inclusive as the term "mining man." However, it has the significance, when used by the Independent Oil Men's Association, which held its convention in Denver, Col., from Sept. 28 to Oct. 1, that it excludes all companies which are affiliated in any way with the Standard Oil group and includes in its membership companies, that are essentially jobbers, refiners, and supply men. Indirectly producers and the petroleum industry generally are interested in this association because it has to do with the marketing and handling of petroleum and its products. The membership of the association consists of 300 companies. T. J. Gay, of the Gay Oil Co., of Little Rock, Ark., is president.

The organization is not a militant one in so far as the Standard Oil group is concerned. On the contrary, it co-operates with this group in many ways that are important to the welfare of the petroleum industry. Its chief purpose is to fight improper trade standards, improper competition and to advance the interests of both producers and marketers of petroleum products as well as the industry generally.

By the evening of Sept. 27 the badges of the association became conspicuous in numbers. The way the convention opened might be compared with the bringing in of an oil well. First, a rush of water, and then gas, and finally the oil spouts. Although from the announcements in the program the subject of oil was expected to be reached on the first day, the important speakers, Governor S. Bamberger of Utah and Dr. Cottrell of Washington, did not arrive and substitutes took their place. At the luncheon President Gay presided and introduced Governor Oliver H. Shoup of Colorado and D. C. Bailey, mayor of Denver, who welcomed the delegates to Denver. At the conclusion of the addresses all adjourned to the Auditorium, where an interesting exhibit of marketing appliances, motor trucks, tanks, metal hose, pumps and oil-testing apparatus was on display.

The afternoon session was held in the Auditorium, with President Gay in the chair. E. R. Harper, former lieutenant-governor of Colorado, was the first speaker. He discussed the potential resources of Colorado in the large deposits of oil shale and pointed out in an emphatic way the need for almost unlimited capital to carry the oil shale possibilities to commercial success. In closing he briefly touched upon the subject of unfair freight rates, which, in his opinion, discriminated against the users of petroleum products in Colorado. Harry S. Botsford, manager of the Puente Oil Co., of Los Angeles, Cal., was the next speaker. His address was on the subject of the vital need of better American citizenship.

Fred W. Freeman, president of the Elk Basin Consolidated Petroleum Co., then spoke. He said: "The oil business is a wonderful business. This is principally on account of the number of 'experts.' It's the only business that can register 100 per cent. I can prove that there never was a dry well in the United States. It is the tradition of success that lingers around an abandoned well or else the story of the Standard Oil buying up the well and closing it down just when it was ready to produce that proves my assertion. Once I drilled two wells, prospects. One developed a little gas and the next one was a beautiful salt water artesian well. Some years later I was in the same locality and found that attempts were being made to develop oil on the strength of a report that the wells I drilled had been purchased and closed down by a large oil company." He closed his address by calling attention to the large number of grafters afflicting the oil industry and said that it is the duty of the association to put the stamp of disapproval upon the men who exploit the people in the name of the industry.

"FORTY-NINE" ENTERTAINMENT ARRANGED FOR DELEGATES

The entertainment of the evening of Sept. 28 was a "humdinger." Whoever had the arrangements in charge was an expert in human psychology and particularly the psychology of oil men. It was called a "forty-nine" evening. The cathedral room of the Albany Hotel was the stage and all who attended were participants. Of course there was a little outside talent from the "Midnight Follies." There was something doing every minute from the time each eager delegate tied his red bandana about his neck and grasped his corncob pipe, handed to him as he entered, until he cut his way through the smoke-laden air to the door on his way to his hotel. Probably none thought of what an old "forty-niner miner" would have thought if he had had the good fortune to have been present, but we can picture his amazement and we know that, if he retained any power of speech, he would be just able to say "some night, oh boy!"

Wednesday opened up another fair day and the convention began to get down to business. President Gay introduced T. F. Kuper, of Chicago, secretary and treasurer of the Mideo Oil Sales Co., who made an eloquent plea for the establishment of a workable code of ethics for jobbers and refiners. He offered a resolution to the effect that the association appoint a committee to confer with the various divisions of the oil industry and work out a suitable code for adoption by the association.

In the discussion that followed W. F. Farish, of Chicago, called attention to the work already done and in progress by the American Society of Testing Materials. Mr. Kuper in reply stated that the association's committee would work in harmony with the society.

O. W. L. Coffin, of the White Co., Cleveland, Ohio, the next speaker, presented the subject of "Motor Truck Supervision, Lubrication and Maintenance." He went to the heart of the problem by stating that the selection of proper equipment was fundamental and that next was the human element. Good supervision in handling both men and trucks intelligently reduced maintenance. Lastly lubrication conscientiously carried out and controlled by inspection is the remaining factor necessary to keep maintenance at a minimum. W. F. Parish read a carefully prepared paper on the subject of "Specifications and Nomenclature of Lubricating Oils." Colonel H. C. Boyden, of Chicago, closed the morning's program with the subject of "Concrete Tanks for Oil Storage." He pointed out the wide use of such tanks in the California oil fields and the advantages of their use in other oil districts.

BUREAU'S PETROLEUM FILMS SHOWN

In the afternoon the long delayed moving pictures of the Story of Petroleum, a film made by the U. S. Bureau of Mines in co-operation with the Sinclair Oil Co., were shown. These were elementary in nature but gave the general public an excellent idea of the great divisions of the industry and some of the important details. E. E. Grant, secretary and treasurer of the association, presided and introduced L. F. Moore, traffic manager of the association, at the conclusion of the film story.

Mr. Moore briefly discussed the confusion that is now existing in the freight situation due to the recent increase in freight rates. The distribution of oil products is greatly disturbed by great changes in the relativity of rates. This has operated to give some companies undue advantages over others and to make it impossible for other companies to compete in territory which they regularly served. The amount of feeling displayed in the short discussion indicated that our present situation in freight rates is due for a drastic overhauling before it can be considered equitable in its operation.

Felix Renick, secretary of the New York Petroleum Exchange, made the next address on the subject of the "Relation of the New York Petroleum Exchange to the Industry." Mr. Renick rapidly reviewed the work of the exchange in providing a market for oil securities. The plans of the organization provide for the establishment of a market place for trading in oil securities, a rating bureau which shall receive reports from the companies, a statistical department that will collect information from companies and general sources, and a National Petroleum Club, limited to 1,000 life members, with a library and oil map collection as adjuncts. The plan of the organization is similar to that of the New York Stock Exchange, and its operation will be like it, with the difference that it will be confined to the oil industry. Mr. Renick was of the opinion that the exchange would broaden the market for oil securities, reduce the cost of providing capital for enterprises of a legitimate nature and reduce the fraudulent operations of unscrupulous promoters.

J. O. Lewis, chief of the petroleum division of the U. S. Bureau of Mines, presented the subject "Crude Petroleum and the Ever-Increasing Demand for Petroleum Products." He pointed out the inadequacy of the domestic petroleum production to meet the demand without assistance from foreign sources. The solution of the existing problem, he said, was to be found not in any one thing but in a number of things, such as the recovery of existing supplies in oil fields exhausted by present methods, the development of foreign fields, the discovery of new fields, greater economy and efficiency in the use of products, the development of shale oil deposits, the retorting of bituminous coals and the elimination of all preventable losses in storage and transport.

C. B. O'Hare, manager of the *Petroleum Magazine*, of Chicago, followed with a brief plea for co-operation between refiner and jobber. The afternoon session was closed by a summary of the work of the U. S. Bureau of Standards in investigating lubrication. The paper was written by W. H. Hershell and John E. Schulze and was read by H. C. Dickenson.

At the evening session George E. Collins, of Denver, presided. Mr. Collins called attention to the increasing importance of good engineering in the oil industry in introducing A. W. Ambrose, in charge of the Bartlesville experiment station of the U. S. Bureau of Mines. Mr. Ambrose spoke on the subject "Engineering Applied to Oil Field Production Problems."

Dr. V. C. Alderson, of the Colorado School of Mines, was then introduced and briefly presented his impressions of the Scotch shale oil industry.

The next paper of importance was by Martin J. Gavin, of the petroleum division of the U. S. Bureau of Mines, on the subject of "Possibilities of Oil Production from Shale." Mr. Gavin gave a thorough analysis of the conditions under which the shale oil industry is operating in Scotland. He presented an analysis of conditions applying to the exploitation of oil shales in the United States. He stated that all American shale oil so far produced was much poorer in quality than the Scotch shale oil but that there was some hope of remedying such deficiency, in part at least, by further research as to proper conditions for retorting and refining. He pointed out the need for extensive research but expressed the opinion that in the course of a few years results of commercial importance are to be expected. He emphasized the point so often expressed that large capital was necessary and technical direction essential to the successful working out of the complicated problems involved.

Third Day's Sessions Opened

The meeting on the morning of Sept. 30 was opened by M. J. Byrne, president of the Connecticut Oil Co., of Waterbury, Conn. A. H. Callaghan discussed ethical trade practices. John C. Howard followed with a short but interesting review of the history of oil development in Wyoming. In closing, he briefly referred to oil developments in Utah, stating that while the northern part of the state held forth nothing promising, the central and southern parts are the scene of much activity and some of the large operating companies are giving serious attention to the more favorable localities. F. A. Bean, of Ft. Wayne, Ind., discussed the operation and maintenance of filling stations and C. P. Bowie, of the U. S. Bureau of Mines, closed the morning session with a paper on "Oil Storage and Transportation."

In the afternoon E. E. Somers, of the Somers Oil Co., Denver, Col., presided. He introduced J. O. Lewis, who, in the absence of Dr. F. G. Cottrell, read his paper on "Relation of the Bureau of Mines to the Oil Industry."

The next speaker was Dr. Van. H. Manning, of the Petroleum Institute. Dr. Manning discussed the international aspect of the petroleum industry, and in concluding proposed the following:

"1. To make a careful study of the oil resources of the world and the laws and regulations governing these resources (as described).

"2. Congress should enact a general reciprocity measure covering all trade relations with foreign countries.

"3. To encourage our nationals to acquire and develop and market oil in foreign countries: (a) By an assured adequate protection of our citizens engaged in securing and developing foreign oil fields; (b) By promotion of syndication under a charter of the United States of our nationals engaged in foreign business, in order to effectually conduct oil development and distribution of petroleum and its products abroad."

Sheldon Clark, of the Sinclair Refining Co., Chicago, followed Dr. Manning and pointed out the need for American exploitation of foreign oil fields and the necessity for the Government to get back of the oil industry. P. F. Walker, dean of the school of engineering, University of Kansas, discussed methods for conserving oil and gas in the field. A paper by H. H. Hill, of the Bureau of Mines, on "Refinery Problems," closed the session.

In the evening a banquet was held at the Albany Hotel. President Gay presided. The speakers were Senator Charles S. Thomas, Governor Oliver H. Shoup and James C. Berger. A musical program and songs interspersed the program.

At the business meeting on Oct. 1 the following officers were elected: President, T. J. Gay, Little Rock, Ark.; sergeant-at-arms, Albert J. Squier, New York; new directors: W. H. Barber, Minneapolis, Minn.; G. I. Sweeney, Peoria, Ill.; M. W. Collins, Philadelphia, Pa., and J. T. Barry, Kansas City.

The following resolution was unanimously adopted: "Resolved, that the present percentage advance in freight rates is ruinous to the independent oil industry throughout most of the country; that application to the railroads and to the Interstate Commerce Commission should be immediately made to revoke the recent percentage advance in freight rates on petroleum products and to revise the same on a basis of a flat advance in cents per hundred pounds to maintain the market differential between the large pipe line oil companies and the independent oil companies; that questions arising on intra-state freight rates on crude petroleum delivered from fields to refineries in the same state present problems individual to each of the representative states and these questions should be handled on their respective merits by the individual state commissions, and this association urges the immediate attention of the state commissions to those problems."

On Friday afternoon the delegates and their friends were taken on an automobile trip of seventy miles through the mountain parks in the vicinity of Denver. Luncheon was served on one of the high peaks of the Rockies. The closing feature in Denver was a dinner given by the president of the association to the Colorado State Oil Convention Committee. On Saturday a party left on a special excursion to the shale deposits at DeBeque.

National Safety Council Holds Ninth Annual Congress Sept. 29 to Oct. 1

Record Attendance, Number and Variety of Papers and Discussions, and Increased Interest Mark Meeting of Safety Enthusiasts at Milwaukee Mining Section Holds Sessions Which Cover Coal and Metal Mine Methods and Plans Extension of Activities

STAFF CORRESPONDENCE

THE Ninth Annual Safety Congress of The National Safety Council established a new record for large attendance, the registration having exceeded 2,500 on the last day of the conference. There was also a greater number of papers which were presented at the various sessions and it was very evident that added interest has been and is being shown in the safety movement which is being so well promoted by the Council. Following the custom established by the Council, the meeting was made the occasion of a "No Accident Week" in Milwaukee and it was later announced that only one accidental death had occurred as against seven in the corresponding week the year previous.

At the annual meeting held on Monday morning, Sept. 21, an address of welcome was delivered by Mayor Daniel W. Hoan. This was followed by reports of the president, the general manager, and six committees, and then the election of directors. In the afternoon a public mass meeting, of which George P. Hambrecht of the Wisconsin Industrial Commission was chairman, was held. Marcus A. Dow, general safety agent of the New York Central Lines, gave an address on "Safety Service," and Dr. Franklin C. Wells, medical director of the Equitable Life Assurance Society, spoke on the subject, "Human Conservation." Both of these speakers were well received. In the evening a reception and informal dance was held at the Auditorium Arena. Tuesday's meetings opened with a general "Round Table" discussion which was participated in by members of all sections. Following this, there were the sectional meetings which occupied the balance of the day and took up the greater part of the time during the remaining days. The following is a list of the sections which held meetings: Public Safety, Public Utilities, Employees' Publications, Foundations of Safety, Health Service, Mining, Automotive, Cement, Chemical, Construction, American Association of Industrial Physicians and Surgeons, Meat Packers, Metals, Paper and Pulp, Rubber, Steam Railroad, Textile, Woodworking, Safety Bulletins, Education, Engineering, Women in Industry, Electric Railway, Employees' Benefit, and Boy Scouts. No attempt will be made to cover the meetings other than those of the mining section, although many of them were of interest to mining men.

The first session of the Mining Section was held Tuesday afternoon, there being about sixty present from various sections of the country. C. A. Mitke's paper, "Vocational Training as Influencing Safety and Efficiency," was read by the chairman, B. F. Tillson. Mr. Mitke's paper stated that during labor shortages it was difficult to obtain the results from vocational training that were procurable under normal conditions. He recommended that the training should be carried on not only in the classroom but on the actual work underground, and pointed out the success that had been met with in the plans which had been followed to obtain a standardization of drifting and stoping methods. In the discussion of this paper, E. E. Bach of the Pennsylvania Americanization Bureau said that his company was at present conducting a campaign for "English First," and that this step should be promotive to the vocational training idea. J. W. Reed of the Consolidation Coal Co. told of the success his company has had in the establishment of schools, and said that in addition to the courses in reading, speaking and writing English their mining course had attracted considerable attention from the men.

The next paper, "Industrial Nurses in Mining Communities," was read by the author, George Martinson, safety inspector, Pickands, Mather & Co. The following is an abstract:

INDUSTRIAL NURSES IN METAL MINING COMMUNITIES

It has been established beyond any doubt that a contented workman is more efficient than one who is discontented. Inasmuch as the success of an industry depends upon the efficiency of its employees, it is therefore wise to consider their happiness and contentment. If it is within the power of an organization to remove any causes of inefficiency and unrest, it should be done. There are numerous causes of unrest and they present as many problems and remedies. Not the least of these problems is that of keeping the family contented.

The larger proportion of the miners in the Lake Superior districts are of foreign birth. They have settled in the mining communities with their families. Their wives, being of foreign birth, have come to this country, usually leaving their relatives across the water. They have no warm friends, they have missed the social life to which they were accustomed in the country from whence they came. Finding no social life, it seemed to them that an insurmountable barrier prevented the enjoyment of the social diversions they craved. If this condition existed for a considerable period, what would be more natural than to have them become disgusted with America and its industries which, to their minds, was responsible for their unhappiness. This unhappiness would eventually affect the work of the husband, for instead of finding his helpmate waiting for him with a smile, he would be greeted with a tale of dissatisfaction. With these conditions prevailing, it makes no difference how good the working conditions, or how large the pay check, the man will eventually leave the community for one in which he thinks his family will be satisfied. They will move and find conditions in their new home about the same. After a few more moves, always looking for that better place but never finding it, the workman becomes dissatisfied also, and he begins to feel that the industry is responsible for his unhappiness. When this idea begins to enter his mind, he becomes a comparatively easy prey for the sleek-tongued agitator.

It makes no material difference upon whom the responsibility for this condition rests. It concerns the operators as an industry, and they must prevent it. In other words, they must help supply the joy and happiness which will supplant the tears with laughter, the first requisite of the true life.

It is advisable to employ a person who will be able to fulfill the duties of a nurse and social worker as well. By virtue of her professional training, the nurse can be of service to the workers at the time when they are in trouble and most responsive to kindness. After having gained their respect and love in this way, she can begin her social duties.

A brief explanation of the plan followed by Pickands, Mather and Co. in the Lake Superior district might be of interest. The nurses are members of the safety department, and do their work under the direction of the safety inspector. They are also, of course, responsible to the general superintendent or manager of the group of mines in the district in which they work. Their responsibility to the physician concerns only the cases which he is caring for.

In the discussion which followed the presentation of Mr. Martinson's paper, Mr. Tillson desired to know if any

absenteeism on the part of the miners was investigated by the nurses. To this Mr. Martinson replied that such work was done by the local safety men. Mr. Reed also stated that the work of the nurses in his company was purely that of welfare. Much of the discussion following centered about the actual duties that visiting nurses should perform as most of those present were in agreement concerning the employment of such. The "Round Table Discussion" which was scheduled for this session, was postponed owing to the lateness of the hour.

"Smile Party" Substituted for Smoker

In the evening a "Smile Party" was held in the Arena of the Auditorium, and was attended by about two thousand. Several vaudeville acts were staged, a light lunch was served, and the gathering was concluded with an excellent burlesque on the various industrial sections. Several creditable numbers were rendered by the local Elks' chorus and that of the Federal Rubber Co. under the direction of Otto Singenberger.

First Aid Standardization Advisable

The first paper presented at the Wednesday morning session was "Standardization of First Aid Contests," by Major M. J. Shields of the American Red Cross. Major Shields stated that in view of the large labor turnover at mines it was difficult to maintain efficient first aid work unless a permanent plan of standardization in methods was followed. He advocated as standard the prone-pressure method of resuscitation, the use of iodine with a sterile dressing, the prohibition of the washing of wounds and the application of external heat for the treatment of shock. In the matter of judging first aid contests he recommended that all judges should be men who have had experience in the teaching of first aid work or who had previously judged such contests. In order to eliminate the employment of incompetent judges and an extended prolongation of the contest, Major Shields stated that the meets should not be participated in by more than 50 teams and that not more than 20 teams shou'd take part in the final contest. A questionnaire which was sent out to 45 mining companies brought the following returns: 42 gave first aid training to their men; all agreed that first aid was of value; 14 favored, as a textbook, the Red Cross, Miners' Edition; 11 the Bureau of Mines, Advanced First Aid; 15 had no preference; 3 favored other textbooks, and 12 returned no answer. Thirteen companies declared that 5 per cent of their men were trained in first aid; ten trained 10 per cent; two trained 15 per cent; three, 25 per cent, and three other companies extended the training to as many as 50 per cent of their men.

In the discussion following, D. Harrington of the Bureau of Mines, Denver station, expressed himself as being in favor of standardization of first aid contests for he stated that erratic judging had been the means of placing contests in disfavor in some sections. George Martinson said that the reaction which followed contests was, in general, detrimental to the work, as many of the men showed a disinclination to practice. Orr Woodburn of Globe, Ariz., took exception to this and said that on the contrary the men were stimulated by the contests and that this was one method of reviving interest. B. F. Tillson declared in favor of contests and compared them to baseball in that the best team did not always win. Further discussion was participated in by J. W. Reed, Dr. W. H. Lynott, R. H. Seip, Dr. E. R. Hunter, and C. E. Julihn.

The next paper was that of L. F. Mitten, engineer of the Vulcan Iron Works at Wilkes Barre, Pa., "Safety Devices on Winding Engineers."

Examination of Hoisting Engineers Should Be Compulsory

In discussion, Horace F. Lunt of the Colorado Bureau of Mines said that in Utah a physical examination was required of all hoisting engineers, as it was found that many of the men so engaged were deaf. Martin Flyzie of the State Safety Board, Olympia, Wash., said that the safety of men being hoisted was of the greatest importance, and rigid requirements were made of all the hoisting engineers in his district. The men must be suited physically, mentally and temperamentally for the work. William Conibear of the Cleveland-Cliffs Iron Co., Ishpeming, Mich., stated that at the mines of this company the safety of men being hoisted was in the care of the cage-riders. Further discussion was given by Mr. Tillson, Sim C. Reynolds of the Aetna Life Insurance Co., and John T. Bradley.

Following the discussion a paper, "Signalling from Moving Cages," by Carl A. Allen of the Salt Lake station, Bureau of Mines, was read. This paper is an elaboration of an article which Mr. Allen has already published in the Bureau of Mines "Monthly Reports," an abstract of which appeared in the July 31 issue of *Engineering and Mining Journal*.

In discussion, Mr. Conibear stated that he opposed the idea of having the hoisting of a cage interfered with by anyone on the cage. In contrast to this opinion Mr. Harrington quoted the instance of the North Butte fire where the men were unable to signal when attempting a rescue as the landing to which they were lowered was burned out. Other discussion was offered by Mr. Woodburn, Mr. Seip, Mr. Lunt, Mr. Reed, W. W. Gidley of the Phelps-Dodge Corporation, and Mr. Reynolds.

Engineers Visit Local Plants

No session was held in the afternoon, but several members of the section availed themselves of the opportunity to visit the Cutler-Hammer plant. A number of special switches and controllers were shown to the visitors Others visited the plant of the Milwaukee Coke and Gas Co. where a model of a new loading machine invented by S. H. Hunt, chief engineer of the company, was on exhibition. This machine claims to load 116 cars of 2½ tons capacity in eight hours.

Prevention of Gas Explosions Discussed

On Thursday, Sept. 30, the mining session was opened with the paper, "General Rules for Gas Explosion Prevention in Bituminous Coal Mines," by R. A. Walter, superintendent of the Mulga Works, Woodward Iron Co., Mulga, Ala., and this was followed by the reading of the paper, "General Rules for Gas Explosion Prevention in Anthracite Coal Mines," which was prepared by Joseph J. Walsh, District State Mine Inspector, Nanticoke, Pa. Both of these papers were discussed, particularly by those interested in coal-mining fields.

The paper, "Mine Rescue and Recovery Operations," was read by the author, Orr Woodburn, director of the Globe-Miami District Mine Rescue and First Aid Association, Globe, Ariz. Mr. Woodburn outlined the considerations necessary to handle mine fires and other disasters and emphasized the need of proper equipment and organization. He gave a brief summary of the plan which is followed by his association at Globe and detailed the equipment which is maintained by each of the mining companies participating in the association. The general rules to be observed in the event of a mine fire were also given.

Following Mr. Woodburn's paper, Robert H. Seip, Safety engineer of the New Jersey Zinc Co., Franklin, N. J., presented his paper, "Requirements of Rescue Training for Metal Mines."

The Annual Banquet

The annual banquet was held Thursday evening in the Arena on the first floor of the Auditorium and was well attended. The program was arranged with special thought of the historic significance of the occasion, for it was at Milwaukee that the National Safety Council came into being eight years previous. Phil A. Grau, business manager of the Milwaukee Association of Commerce acted as toastmaster. After introducing members of the organization committee and the first executive committee of the Council who had been invited to occupy seats of honor at the speaker's table, Mr. Grau called upon Major H. F. Doidge, who was in attendance as the personal representative of Lord Leverholme, the head of the British Industrial Safety First Association. Major Doidge told of the safety movement in Great Britain and stated that the knowledge of the accomplishments of the Council and their co-operation had been of great assistance in the work. He also read a letter of greeting and congratulation from Lord Leverholme to members of the Council. Arthur T. Morey, president of

the Commonwealth Steel Co., was the next speaker. Mr. Morey characterized the safety movement as the spirit of service and unselfishness and paid special tribute to those men who were instrumental in the formation of the National Safety Council. He then introduced R. W. Campbell, chairman of the Central Safety Committee of the Illinois Steel Co., who was the first president of the National Safety Council. Mr. Campbell outlined the history and the rapid growth of that organization and stated that much of the progress of civilization depends on the continuation of the safety movement. It is necessary, he said, that the idealism of safety be made practical. The toastmaster then introduced H. Walter Forster of the Independence Associates, Philadelphia. Mr. Forster was asked to speak on "Impressions," and in addition to adhering conscientiously to one interpretation of the subject he made a decided impression on those present. He spoke in a light vein and called the attention of his hearers to certain proclivities and peculiarities of his fellow members of the executive committee, all of which was taken in good part. A. T. Morey announced the officers for the ensuing year as follows; president, Charles P. Tolman; first vice-president, W. H. Cameron; second vice-president, W. E. Worth; third vice-president, L. A. De Blois; fourth vice-president, J. A. Oartel; general manager, C. W. Price; secretary and chief engineer, S. J. Williams; treasurer, W. H. Frater; assistant secretary, R. T. Solensten. Following this announcement, Mr. Tolman, the new president, spoke briefly on the aims of the organization. He stated that the American safety movement was a democratic one, and as evidence of this called attention to the fact that there are now in this country about 50,000 workmen on safety committees. Following the adjournment an informal dance was held.

At the fourth session of the mining section, which was held on Friday morning, the papers, "Accidents from Falls of Roof and Ground in Metal Mines," by John L. Boardman and W. S. Bates of the Anaconda Copper Mining Co., and "Accidents from Falls of Roof and Ground in Coal Mines" by H. A. Kudlik, chief safety inspector, Delaware-Hudson Coal Co., Scranton, Pa., were read by Chairman B. F. Tillson. An abstract of the former paper follows:

Accidents From Falls of Rock or Ore

The driving of drifts and crosscuts include mining operations which should, on the face of things, be the least hazardous with reference to falling ground. These operations are usually performed in virgin ground; the back or roof is always within a reasonable distance of the miner and easily reached for barring down. Timbering is simple and easy and all other conditions should tend to make this the safest mining operation. However, figures show that the very safety of this class of work actually tends to a larger accident rate.

Square set stoping, which from the nature of the work should be considered more hazardous and which is estimated at 70 per cent of the total mining work, has caused only 63 per cent of the falling ground accidents. Rill stopes where no timber is used, and where the working floor is on a slope corresponding very nearly to the angle of repose of broken ore, which is estimated at 9.5 per cent of mining work, caused only 10.3 per cent of falling ground accidents. Timbered rills and stull stopes, which on account of the timber used should be considered safer, are responsible for 3.3 per cent of the underground mining and caused only 1.29 per cent of the accidents. Back filling stopes, which are not timbered and where the working floor is on broken ore, are responsible for 1.07 per cent of the mining work and only 0.88 per cent of the falling ground accidents.

From this information it may be deduced that in the more dangerous mine workings the miner by increased vigilance renders himself less liable to injury than does the man working in the "safe place," who puts too much trust in the ground holding up.

In the discussion which followed, Mr. Conibear asked for expressions of opinion concerning the effect on accidents of timber scarcity. Mr. Gidley replied that the scarcity of timber had an appreciable effect upon accidents in the mines of his company and that it was necessary that at all times there be an adequate supply. Mr. Flyzik of the State Safety Board, Olympia, Wash., stated that although there was a good supply of timber in his section it was essential that the delivery of timber at the mines is such that the men can procure it for their working places with a minimum of effort. Mr. Conibear outlined in a general way the plan of safety inspection followed by his company and emphasized the need of contact between the shift bosses and the officials. Each shift boss is virtually a safety inspector and each receives a prescribed course of training in the school that is maintained by the company. Mr. Martinson stated that in the mines of his company the shift bosses were held responsible for the safety of the men in their charge. B. F. Tillson said that excellent results had been obtained in the mines of the New Jersey Zinc Co. by offering inducements to the foremen obtaining the lowest accident records.

During the past year the mining section has given consideration to the need for a paid technical secretary, and Mr. Tillson outlined at this meeting the steps that had been taken. It has been suggested that an employee of the Bureau of Mines be detailed for this work and that the additional expense be defrayed by such allotment as is necessary from the mining section of the National Safety Council. The matter has already been taken up with F. G. Cottrell, director of the Bureau, and he has agreed to give the matter full consideration. C. E. Julihn of the Minneapolis station of the Bureau of Mines said that it was quite essential to bring the work of the Bureau home to the industry. He expressed himself as being in favor of the plan proposed by the mining section and said that such an idea would necessarily accomplish that and also aid in the work that the National Safety Council was doing.

"Hazards Met in Open Cut Mining" was read by the author, D. E. A. Charlton. This paper appeared in the *Engineering and Mining Journal* of Oct. 2. "Hazards Met in Anthracite Stripping," by F. S. Gallus, district superintendent of strippings, Lehigh Coal and Navigation Co., Lansford, Pa., was read by Mr. Tillson. Following this, Mr. Martinson spoke of the method of flood lighting which is now being used in the open-pit mines of his company on night work. Fusees, similar to those used by the railroads, are also used to indicate points in the pits where blasting is being done at night so that the men are advised and can seek proper shelter. W. W. Adams, statistician of the Bureau of Mines, made a plea for prompt statistics on accidents. He told of the work of collecting statistics and added that the work of that part of the Bureau would be greatly facilitated if the reports were sent in promptly.

Medal Offered By Mining and Metallurgical Society

Announcement was made by Chairman Tillson of the gold medal which is to be awarded by the Mining and Metallurgical Society of America for distinguished service in increasing the safety of men in mining and metallurgical operations.

R. Dawson Hall, chairman of the nominating committee, read the report of his committee and named the following officers for the ensuing year: B. F. Tillson, chairman; Dr. A. F. Knoefel, first vice-president; George Martinson, second vice-president; and Guy J. Johnson, third vice-president. The report was accepted and a unanimous ballot cast for the slate as offered by the committee. Before adjournment a vote of thanks was tendered to Mr. Tillson and the other officers for their service during the year.

Of no small interest to the visitors and members of the Council was the Safety Exhibit which was held in Machinery Hall of the Auditorium and remained open during the entire week. Over 200 booths had been prepared and in these were shown most of the safety devices that are on the market today, either as models or full-size working exhibits. Many of these applied to industrial fields other than those of mining, but all were worthy of attention. Among the exhibits shown were mine rescue, breathing, and resuscitating apparatus, safety lamps, electrical safety switches, controlling devices, metal safeguards for machinery, safety goggles, first aid material, safety signs, anti-slip treads for stairways, portable projectors for showing safety work, and drinking fountains and other sanitary equipment.

ECHOES FROM THE FRATERNITY

SOCIETIES, ADDRESSES, AND REPORTS

Anniversary of Discovery of Gold Celebrated at Dawson

The twenty-fourth anniversary of the discovery of gold in the Klondyke, held at Dawson City under the auspices of the Yukon Order of Pioneers, was specially notable. On the same day the aviators engaged in a flight from New York to Nome, Alaska, arrived at Dawson and Right Reverend Bishop N. O. Stringer, known and respected among Yukon pioneers, delivered an interesting address.

Bishop Stringer's speech sketched the history of the north country and truthfully interpreted the spirit of its present residents. He said, in part,

"All honor to the pioneer. We feel a thrill of pride at the thought of the perseverance and endurance and optimism of the trail blazers of bygone days. The experience of the war proves that the present generation shows no deterioration. That men and women are capable of doing great things now as in past ages. It needs only the occasion and demand to bring out the greatest attributes of mankind. So also the qualities that go to make up the pioneer are not extinct. We have today men and women in this country who are as capable and resourceful as the pioneers.

"This is the second Discovery Day celebration since the conclusion of the war. . . . This time of peace is a day of opportunity. The future is before us. We possess a land full of resources and boundless possibilities. Who would have thought in the days when the Harpers, McQuestens, Ladues, Mayos and, later, the O'Briens and many others, wandered over this virgin land seeking for gold, that the time would come as it did when, within eight years (1898-1905) a hundred millions in gold would be taken from the tributaries of the Klondyke, mostly by primitive methods. When and where we shall have another Klondike no one can tell . . . we hope it will be Mayo, but, wherever it is, I believe it will be only the forerunner of other discoveries in days to came. . . . We take it as a matter of course, that this district can produce potatoes and other vegetables successfully, and that certain grains can be ripened, but many people outside are still astonished to hear this and some will scarcely credit it. . . We are only at the beginning of things agricultural.

"I look forward also to the time when the great barren lands of the North will teem with reindeer and other animals suited to the conditions of the country and climate. Whatever success this country may encounter in the future it will be largely due to the pioneers who led the way and who will still carry on in spite of all obstacles."

"How appropriate it is that at this celebration of pioneers we should now be about to welcome the pioneers of the air who alight in our midst for the first time. This feat is prophetic of the time when we shall no longer be isolated from what we call the outside world, when the difficulties of navigation in air will be overcome and when the words "outside" and "inside" shall have lost their meaning and when we shall be connected with the world generally by steel on land and by wings through the air. It is an epochal day for Yukon and for the North generally. All honor to the birdmen.

Gold Premium Bill Endorsed by Colorado Bankers Association

At the annual meeting of the Colorado Bankers Association in Denver, the alarming decrease in gold production was a subject of discussion. The merits of House Resolution No. 13201, known as the Gold Excise or Premium Bill (or McFadden Bill) was considered and the following resolution adopted:

WHEREAS, the constantly shrinking volume of gold available for monetary purposes is attracting the attention of bankers throughout the country and believing this matter to be one which is of serious import, and with a view to stimulating the production of new gold within the borders of the United States, we unqualifiedly endorse House Resolution No. 13201 of the Congress of the United States, known as the McFadden bill, and urge its passage. We consider it of the highest importance that the gold mining industry of this country be fostered and encouraged, to the end that a basis for credit and currency be not curtailed, and public confidence be maintained in our circulating medium;

Therefore, BE IT RESOLVED, that the Colorado Bankers Association, in convention assembled, endorse the McFadden Bill, and urge our representatives in Congress to do all in their power to obtain its passage, and that a copy of this resolution be sent to our representaives in the Senate and in the House.

Coal Deliveries Conforming to Spa Agreement

The French Ministry of Public Works has confirmed a recent statement by *L'Echo des Mines et de la Métallurgie*, to the effect that the coal deliveries by Germany to France are conforming to the Spa agreement. During August these deliveries exceeded 1,600,000 tons (metric). The agreement required 1,550,000 tons. It is stated by the same authority that this proportion held during the early part of September.

Canadian Institute of Mining Meets at Stewart, B. C.

The North Coast Division of the Canadian Institute of Mining & Metallurgy held a two-day meeting recently at Stewart, B. C., and was attended by representatives of all the important mining centers of the section.

E. J. Conway presided and among the speakers were vice-president E. E. Campbell and Peter E. Peterson, both of whom are connected with the Granby Consolidated Mining & Smelting Co. at Anyox. Mr. Campbell declared that the men most needed now were miners and metallurgists who could mine for a dollar when there was but $1.25 in the ore. He reviewed some of the work being done at Anyox and asserted that the operations there were being carried on at a lower cost per ton than at any other mine in the Dominion. The company concentration work, which Mr. Campbell characterized as unique, was dealt with by Mr. Peterson, who described the concentration methods and stated that these not only were adaptable to the treatment of the ores of the Stewart and Alice Arm zones but ultimately would be in use at those places. A. C. Garde of Prince Rupert, discussed the evolution of the mining industry of the Pacific Northwest.

Dr. J. A. Bancroft, professor of geology, McGill University, emphasized the value of the trained geologist in practical mining. He said that the big national mission of the geologist in the mining field was to work out the geology of districts before the coming of the prospector, thereby saving much useless work by indicating where mineral bodies were not to be found.

The session closed with a banquet at which Pat Daly, prospector and mining operator, referred to the closing down of the Big Missouri in the Salmon River district of Portland Canal. Mr. Daly was not inclined to accept as final the negative results of the limited amount of diamond drilling there and the decision to abandon work.

"Pilgrim half dollars," commemorating the tercentenary of the landing at Plymouth, Mass., in 1620, were issued by the Director of the Mint about Oct. 1. On one side the coin bears the head of a typical Pilgrim and on the reverse a view of the "Mayflower" under full sail. The price has been fixed at $1 each, and coins should be ordered through a bank from the distributing agent, the National Shawmut Bank, Boston, Mass. Any balance from the sales will be turned over to the Pilgrim Tercentenary Commission in official charge of permanent memorials at Plymouth, Mass.

MEN YOU SHOULD KNOW ABOUT

W. Young Westervelt, of New York City, has returned from a recent trip.

B. Britton Gottsberger, former general manager of the Miami Copper Co. was in New York City on Sept. 28.

F. A. Blakeslee, of the Institution of Mining & Metallurgy, London, is reported to have gone from England to California.

Cornelius F. Kelley, president of the Anaconda Copper Mining Co., who has been spending the summer at Swan Lake, has returned to New York.

Harry J. Wolf, consulting mining engineer, who has been in Butte, Anaconda, and Great Falls, Mont., recently, has gone to Sudbury, Ontario.

Alan M. Bateman, mining geologist, has been engaged in professional work in Alaska and British Columbia, and has now returned to New Haven, Conn.

Frederic R. Weekes has returned to New York from a two-month professional trip to the Portland Canal and Alice Arm districts, British Columbia.

H. W. Young, research engineer of the gas department of the Midwest Refining Co., Salt Creek, Wyo., attended the Independent Oil Men's convention at Denver.

Frederic Bradshaw, general manager of Tonopah Belmont Development Co., has gone to Colorado to inspect the Belmont-Wagner property of his company.

C. M. Weld, consulting mining engineer, of New York City, has moved his offices from 66 Broadway to new quarters at 2 Rector Street. (Phone: Rector 1421 and 1422.)

Millard K. Shaler, mining engineer, 66 Rue des Colonies, Brussels, left there on Oct. 1, to be absent about six months on an inspection trip to the Belgian Congo.

F. M. Van Tuyl, who has been examining oil lands during the past few months, has resumed his duties as head of the department of geology at the Colorado School of Mines, Golden, Col.

Homer Guck, for many years correspondent for the *Engineering and Mining Journal* at Houghton, Mich., is now associated with the Detroit Life Insurance Co., as assistant to the president.

Prof. Benjamin L. Miller, head of the department of geology, Lehigh University, Bethlehem, Pa., has returned from Panama, where he was engaged in the examination of some manganese deposits.

Hon. Clifford W. Robinson, of Moncton, N. B., formerly premier of New Brunswick, has been appointed Minister of Mines for that province in succession to Dr. E. A. Smith, who resigned recently.

N. L. Stewart, plant engineer, and **A. H. Richards**, both of the Garfield Smelting Co. of Utah, have returned to Garfield, Utah, from a visit to the Stepto plant of the Nevada Consolidated Copper Co.

John D. Galloway, resident engineer for north-eastern British Columbia, has completed an examination of mica property near Tête Jaune Cache, and the Taltapin property on Babine Lake. He has returned to Hazelton, B. C.

J. P. Hutchins, mining engineer, of New York City, has recently spent three months in Italy, including a trip to some of the ancient mines of the Trentino. Mr. Hutchins' present address is care of Hispano-American International Corporation, Juan de Mena, 10, 2do., Madrid, Spain.

Prof. Stanley M. Graham, formerly of Halifax, N. S., and a lecturer on the mining staff of Queens University, Kingston, Ont., two years ago, has been appointed head of the Department of Mining Engineering in that institution. He is the successor to the late Prof. J. C. Gwillim.

Dr. Charles E. Munro, chief explosives chemist, and **Spencer C. Howell**, chief explosives engineer of the Bureau of Mines, are in New York City on detail connected with the recent explosion in front of the U. S. Assay Office in Wall Street.

J. B. McArthur, a British mining engineer connected with the Associated Gold Mines of Western Australia, Ltd., is visiting mines in northern Ontario and will shortly leave for Australia and China, where his associates have extensive mining interests.

A. C. Watts, chief engineer of the Utah Fuel Co., has gone to the Sunnyside mine, at Sunnyside, Utah, to supervise the reopening of the property, and the reclaiming of that part of the mine which has been sealed off for the past month on account of fire.

G. J. Loughlin, the chief of the Division of Mineral Resources of the U. S. Geological Survey, is making an inspection trip to the Western offices of that bureau. He will also study the newly developed ore deposits in the Tintic and Morgan districts of Utah.

Henry N. Thomson, formerly head chemist for the Anaconda Copper Mining Co., and later superintendent of the Tooele smelter, International Smelting Co., has been appointed professor of metallurgy in the University of British Columbia, Vancouver, B. C.

Waldemar Lindgren, professor of geology in the Massachusetts Institute of Technology, has been in Wallace, Idaho, in connection with the pending apex litigation between the Federal Mining & Smelting Co. and the Hecla Mining Co. Professor Lindgren has been retained by the Federal company.

Donald G. Campbell, mining engineer, has returned to Seattle, Wash., after a year spent at Lost River, Seward Peninsula, Alaska, where he has been superintending the erection of several new concentrating mills. His address is care of Campbell, Wells & Elmendorf, Prefontaine Building, Seattle, Wash.

U. S. Bureau of Mines men at the Independent Oil Men's Association convened at Denver, Col., last week, included among others, F. G. Cottrell, director; J. O. Lewis, petroleum technologist; M. J. Gavin, A. W. Ambrose, Roy Collom, H. W. Bell, L. C. Karrick, C. P. Bowie, Frederick Tough, and H. H. Hill.

Collier Cobb, head of the department of geology at the University of North Carolina, is devoting a year's leave of absence to the study of the relations of certain shore line problems to harbor development along the Pacific coast. He spent a part of the summer in Alaska, and is now engaged in field work along the Washington coast.

OBITUARY

Burroughs Edsall, for some years in charge of the Rochester Merger Mines Co., died recently at Dansville, N. Y., after a lingering illness. Mr. Edsall was born in New York City and a graduate of Columbia College and also of Freiburg University, Germany.

Jacob Charles Denton, of Los Angeles, Cal., and formerly general manager for the Grand Pacific Co., of Superior, Ariz., disappeared mysteriously about June 1. His body was recently found buried in a cellar room of his Los Angeles house. He had been shot on an upper floor with a pistol found there. Just previous to the murder Mr. Denton had made telegraphic arrangements to meet friends in Phœnix, Kansas City, and Chicago on his way east on business. He was forty-six years of age.

SOCIETY MEETINGS ANNOUNCED

American Association of Engineers will hold a conference on employment and education at the Congress Hotel, Chicago, Ill., on Nov. 12. All free employment bureaus and agencies, as well as representatives from engineering societies and colleges, are invited to attend. The meeting purpose is to consider the general problems of employment, and a number of significant addresses have been promised. National headquarters is at 63 E. Adams St., Chicago, Ill.

American Mining Congress and affiliated bodies announces its twenty-third Annual Convention will be held at Albany Hotel, Denver, Col., Nov. 15 to Nov. 19, inclusive. It is planned to make this specifically a producers' meeting "for an open, frank, and unhampered discussion of the peculiar problems facing all industrial undertakings in the United States at this time."

THE MINING NEWS

The Mining News of ENGINEERING AND MINING JOURNAL is obtained exclusively from its own staff and correspondents, both in the United States and in foreign fields. If, under exceptional conditions, material emanating from other sources is published, due acknowledgment and credit will be accorded.

LEADING EVENTS

Tjosevig-Kennecott Suit Before U. S. Court of Appeals

Rowe and Tjosevig Fighting Extradition to New York

The U. S. Circuit Court of Appeals, which opened at Seattle recently, took as its first hearing, the case of George Francis Rowe and Christian Tjosevig, indicted by a grand jury in the southern district of New York for alleged use of the mails to defraud the public in regard to certain representations of mining stock in Alaska. The defendants are fighting extradition to New York to answer the indictment.

About fifteen years ago, according to a review of the case, Christian and Nels Tjosevig, brothers, located a group of claims in Alaska opposite the famous Bonanza and Jumbo copper mines of the Kennecott Copper Co. In 1916 Rowe and others became interested and organized the Tjosevig-Kennecott Copper Co. The stock was offered on the New York Curb and was advertised as one of the finest copper properties in Alaska. A large share of the stock was sold.

In October, 1919, following complaints as to the affairs of the company, indictment by the grand jury of the Southern District of New York followed. After a local legal battle Federal Judge Neterer, of Seattle, ordered the removal of Rowe and Tjosevig to New York to answer the indictment. It is this order that is now being appealed.

Anaconda and Granby Shipping Copper East by Water

Both the Anaconda Copper Mining Co. and the Granby Consolidated Mining Smelting & Power Co. are shipping copper to the East by water. Anaconda has several hundred tons in transit which has been sent by rail to Seattle and thence by water through the Panama Canal to its eastern refinery. Granby has arranged with the Robert Dollar Steamship Co. to carry its copper from Vancouver, B. C., to Brooklyn, where it will be lightered to the Laurel Hill refinery of the Nichols Copper Co. Both companies will continue to ship in this manner under present conditions. It is said that the water route is cheaper and also quicker than the overland haul.

Mine rescue car No. 5, of the U. S. Bureau of Mines, will be at Tonopah, Nev., until Oct. 30, and at Goldfield, Nev., on Oct. 31.

WEEKLY RÉSUMÉ

Both Anaconda and Granby have started to ship their copper to the East via Panama instead of by the overland route, expecting thus to save both time and money. Anaconda has closed three mines, whose production is said to be unimportant. The property of the Nenzel Crown Point Mining Co., at Rochester, Nev., has been ordered sold at public auction. In the Coeur d'Alenes, the labor situation is said to be better. Steady improvement in mining conditions in Mexico is also reported from across the border. Purchase of the Croton Magnetite Mines Co. at Brewster, N. Y., has been effected by the Nipissing Mines Co., of Cobalt, Ont. From London comes word that Burma Corporation, Santa Gertrudis and Broken Hill Proprietary are issuing new capital.

It is reported from Washington that Director F. G. Cottrell of the U. S. Bureau of Mines is anxious to resign and various candidates for the position are talked of.

Northwest Mining Convention To Meet Next Winter

The Northwest Mining Convention will be held in Spokane, Wash., as usual next winter. Owing to the annual meeting of the A. I. M. E., in February, which draws many of the Northwest members, it has been decided that the convention will be held during the week of Jan. 31 to Feb. 5, 1921, closing ten days prior to the New York meeting.

The convention has become such an important event that there has been a complete reorganization of the controlling body. A committee of control has been made up of two members from each of the following bodies: Northwest Mining Association, mining committee of the Chamber of Commerce, Columbia Section of the A. I. M. E., Associated Engineers, Washington State Metal Mining Association and Spokane Stock Exchange. The committee's personnel is as follows: L. K. Armstrong, chairman; M. E. Poole, secretary; Sidney Norman, F. M. Smith, Frank A. Ross, Frank C. Bailey, R. S. Ord, A. D. Butler, Ivan De Lashmutt, E. H. Knight, C. E. Mallette, and Elmer G. Watson. Subcommittees from this list and additional members of the societies will be named, a convention hall and exhibit space will be selected and exhibitors will be asked to indicate their intentions.

Nipissing Acquires Iron Mines

The Nipissing Mines Co., of Cobalt, Ont., has purchased the control of the Croton Magnetite Mines Co., at Brewster, N. Y. The property is said to have large reserves of lean ore that can be readily concentrated.

Britain Gaining Supremacy as U. S. Ignores Gold Question, Says McFadden

Production Here Steadily Falling While That of Empire Increases Owing to Premium Paid

In an interview given out Oct. 7 Representative Louis T. McFadden, chairman of the Committee on Banking and Currency of the House of Representatives, has asked the following pertinent question with reference to the gold situation: "Is the United States to continue to ignore the problem of gold production, thus permitting the British Empire to gain an unquestioned supremacy?" The substance of the interview follows:

An estimate of the gold production of the United States based on the output for the first six months of this year indicates that the production for 1920 will be less than half the amount produced in 1915. In 1915 the United States produced 21.5 per cent of the total world's gold output, and the British Empire 3.7 per cent. In 1919 the United States produced but 16.6 per cent of the world's total gold output, while the British Empire produced in excess of two-thirds. Since July 24, 1919, the British Empire has been paying an exchange premium as high as 50 per cent to the gold producers of South Africa, where the bulk of the British gold is produced, while in the United States no assistance has been rendered the gold mining industry. This year the contribution of the United States to the gold production of the world will probably be not more than 12 per cent, about half of that which it contributed in 1915, while the stimulating effect of the exchange premium will probably increase the quota which the British Empire will contribute to 75 per cent.

REASON FOR DECLINE OF UNITED STATES PRODUCTION

As compared to 1914, the purchasing power of the dollar in terms of all commodities in 1919 was 47c. The gold producers' ounce in 1914 had a purchasing power of $20.67, whereas during 1919 the same ounce could purchase in terms of all commodities but $9.70. Since the price of gold is fixed by statute at $20.67 an oz., the gold producer is in the same position as a person who received the same income in 1919 as in 1914 and finds that a $2,000 income has shrunken in purchasing power to $970. "This is the principal reason for the decline of the gold production of the

United States from $101,000,000 in 1915 to less than $50,000,000 this year," said Mr. McFadden.

"The United States Mint sold for industrial consumption during 1919 nearly $22,000,000 more gold than was produced from the mines of the United States, while this year the drain on the monetary gold stock will probably be $40,000,000. The American Bankers Association passed a resolution on Oct. 2, 1919, urging upon the Government the necessity for maintaining a domestic production of new gold in sufficient volume to satisfy the industrial requirements of the arts and trades. To comply with the specifications of this resolution, the soundness of which cannot be questioned, I introduced H. R. 13,201 on March 22, 1920."

Consumers Now Subsidized

Since the industrial consumers of gold are the only ones in the country receiving raw material at the pre-war price, while the general increase in all commodities was 112 per cent in 1919 as compared with 1914, it is evident that they are being heavily subsidized. Mr. McFadden emphasizes that the imposition of this excise tax merely adjusts the cost and price equation between the producer of new gold and the consumer of gold in the industrial arts, and is free from all monetary entanglements. A free gold market is maintained under the provisions of this bill for the reason that the excise tax is collected on the finished product as sold, and not upon the bullion which is sold to the manufacturers. There is nothing in the bill which in any way alters the number of grains in the standard dollar, the unit of our monetary system. The bill creates the governmental machinery by which the consumer of gold in the industrial arts may pay more nearly the cost of production for his raw material. The stimulus to the gold producer specified in this bill is equal to the excise tax imposed, and is no greater than the exchange premium paid by Great Britain in the latter part of 1919 to the South African producer, whose operating conditions are more favorable than those in the United States.

Heavy French Tax Levied

In addition to paying the exchange discount, which in the case of the French industrial consumer of gold would amount to 100 per cent more in francs than the price paid before the war, the French government has imposed a sumptuary tax for the use of gold in the fabrication of articles (other than money) of 60 francs per hectogram ($3.73 per fine ounce) by law of June 25, 1920. Previous to that date the guarantee tax was 37 francs, 50 centimes per hectogram. The French Government justifies this tax in a formal document transmitted by the U. S. Bureau of Foreign and Domestic Commerce, as follows: "Moreover this tax, striking as it does luxury goods, or unessential articles, enters into the category of a sumptuary tax, the levying of which is admitted a legitimate procedure."

It is important that the gold mining industry be kept alive for fear that with greatly reduced production there will be difficulty in retaining the gold standard during a popular campaign for credit restriction accompained by declining prices. The continued depletion of the gold stock by excessive exportation and industrial use will seriously impair the public confidence in the Nation's finance and currency unless a normal gold output is insured.

The gold mining industry will be completely shut down unless constructive aid is provided without delay, in which event it will take years to develop a normal output of gold at a very much greater expense. To allow the gold mines of the United States to cave in and fill with water entails a waste of developed gold resources, which in a most critical hour of financial need will cause want. No argument can be made in favor of waste. The time to act is now before the industry is shut down.

Leadville Mines Co. in Nevada Installing Small Mill

The Leadville Mines Co., 39½ miles north of Gerlach in Washoe County, Nev., is installing a 50-ton concentration plant. An existing plant which consisted of tables has been torn out and new machinery installed. The unit consists of a Marcy No. 54 ball mill operating in closed circuit with a Dorr Simplex classifier, the 48-mesh overflow of which flows to a Colburn vacuum flotation machine. The concentrates from this are partially dewatered in an 8-ft. Callow cone, the thickened concentrate discharge being drawn off by a Dorrco pump and further dewatered by a 3 x 2-ft. Oliver filter. The concentrate cake is directly sacked without drying. The tailings from the flotation machine are dewatered in a 24 x 8-ft. Dorr thickener and discharged to waste. The overflow, together with all overflow from vacuum and cone, is collected in a sump and used again.

The ore is a silver-lead zinc ore which by water concentration gave a ratio of 7 or 8 to 1. With the flow sheet as described the ratio will be from 10 to 12 to 1 with a recovery of 93 per cent of the lead and silver and with the zinc content of the concentrates below the penalty limit. By adjustment of the flotation machine the grade of the concentrates can be closely controlled. This is a matter of considerable importance, as the concentrates have to be hauled 39.5 miles to rail.

The power unit consists of an 80-hp., 4-cylinder engine using distillate and two semi-diesel engines of 100 and 75 hp. respectively. Owing to the altitude the power delivered by the engines is less than the rated power and is 64, 80 and 62 hp. respectively for the three engines. The power plant supplies both the mine and the mill. The mill and plant are being installed by Lindsay Duncan and Curtis Lindley, Jr., mining and metallurgical engineers of San Francisco, Cal.

Mexican Mining Situation Improving Steadily

Six Hundred Companies Added to List of Operators in Last Ninety Days—Extension of Railways Planned

The general mining situation throughout Mexico has greatly improved during the last three months and finds itself at the beginning of October in a much more satisfactory condition. The fact that silver, Mexico's leading mineral product, has maintained itself between 90c. and $1 per ounce establishes a much more stable basis for mining men to figure on and it is eminently more satisfactory than the boom prices which prevailed at the beginning of the year. Especially are conditions more satisfactory to the smelters, which are also heavy mine owners and operators, and upon whose general movement a great deal of the prosperity of the mines depends.

Labor conditions have also improved notably as a whole, in that they have become more normal. This is due in part to the rapid growth of the demand for mine labor, which is exceeding the supply. The natural consequence is an automatic advance in wages. With better wages and reasonable assurance of steady employment the Mexican miner lends small ear to the harpings of labor agitators and professional trouble organizers. Mining camps in this country now furnish barren soil for anything like Bolsheviki propaganda, although considerable headway is being made by the Russian "wing" as well as the I. W. W. in some of the larger centers and in the oil fields, where a great many foreigners are employed.

The recent order of the Secretary of the Treasury removing all Federal taxation on low-grade propositions in order to enable them to temporarily overcome many natural obstacles encountered in a period of reconstruction has heartened the small operators and literally hundreds of small properties, which have been idle for years, are being opened and development is being pushed. The treasury department has appointed a commission to keep "tab" on the general economic situation, with particular reference to mining activities, that is, fuel, transportation, imports, etc., and it is the evident intention to grade the mining taxes according to conditions from time to time.

In a statement just issued by the Secretary of Commerce and Industry of Mexico it appears that there are now in round numbers 30,000 mining properties with proper titles, out of which 4,000 and some odd are actually being exploited. This is an increase in working mines of over 600 in the last ninety days. Most of the renewed activity is in the northern states, though considerable life is shown in the central part of the country, particularly in Guanajuato, Zacatecas and Jalisco.

The same department of Commerce and Industry is giving especial attention to the extension of railway lines in territory which will produce heavy mining outputs. Contracts have been

let, for example, for extension of the branch from Parral, into the Inde and El Oro district, from Rosario, the present terminus; also for an extension of the Mexican Northern, which leaves the Central at Conejos, to the barranca fronting the Inde region; also an extension of the National Line in Durango into the Guanaceví district; also extensions in Zacatecas; from Durango to Mazatlan (now working); from Toluca through the state of Mexico and the state of Michoacan to the Pacific Ocean. In addition to railway extension projects several score contracts have been signed for extending automobile roads where railway lines are impractical or too costly. It will probably be possible by the first of the year to make a run from the City of Mexico to Acapulco, in auto, and return the next morning.

With the exception of cyanide, which has advanced slightly, there has been no appreciable change in prices of mining supplies during the last thirty days. There has been a slight drop in local market prices, that is, in beans, corn, meat, rice and sugar.

Coeur d'Alene Labor Situation Reported Improved

Men Returning from Surface Jobs as Winter Approaches—Open Shop Maintained

A steady improvement in the labor situation in the Cœur d'Alene district of Idaho is noted, and the prediction is made that the next few weeks will find the mines generally working with normal forces and with a corresponding increase in output. The chief difficulty has been that during and since the war the rate of wages for outside work has been as high or higher than that paid in the mines, and in that situation men naturally prefer surface work while weather conditions are favorable, and return to the mines only when driven to it by cold or otherwise disagreeable weather. Before the war wages in the mines were generally higher than for similar classes of work outside, and the increased pay acted as an offset to the objections to underground work. Another good feature of the situation in the Cœur d'Alenes is that the district is comparatively free from radical agitators. The firm attitude of the operators in maintaining the "open shop" system, together with the activity of the peace officers in the enforcement of the Idaho law against criminal syndicalism, have combined to bring about a very satisfactory condition throughout the district.

Kuskokwim River District Makes Record Gold Shipment

Marking a new epoch in northern mining development and representing the largest shipment ever sent out of the Kuskokwim River district between Seward Peninsula and the Aleutian Islands, a consignment of $150,000 in gold dust arrived in Seattle recently. This shipment represents the pioneering of placer miners panning the streams tributary to the Kuskokwim River.

Talk of Starting B. C. Steel Industry More Definite

President of Canadian Collieries Goes East in Interest of Project

By Robert Dunn

In the last few weeks there has been much talk and the indications are that there will be some action with regard to the establishment of an iron and steel industry in British Columbia. For some time H. A. Fleming, president of the Canadian Collieries (Dunsmuir), Ltd., has been in the province investigating local conditions with respect to the iron ore resources of the country and the market that may be relied upon for such a Pacific Coast enterprise. Recently he interviewed William Sloan, minister of mines, in regard to the assistance that might be expected from the government in the event of his company entering upon the enterprise. The minister and Mr. Fleming went into the matter thoroughly and subsequently the latter issued a public statement the purport of which was that he felt convinced that conditions were opportune for making a start along the lines indicated. He said that he was leaving for the East, and would take immediate steps to get the matter forward. It was his hope that within a short time it would be possible to make a definite announcement.

The foregoing incident occurred after it had been announced from Vancouver that Nichol Thompson, a prominent resident of that city, who for some time has been interested in the promotion of an iron and steel industry for his province, had appeared before the Tariff Commission, now touring the Dominion and had there given evidence that there exists on the Pacific Coast a market up to 1,500 tons a day for iron and steel manufactured in British Columbia. It was stated by Mr. Thompson that he had reliable information on which to base this assertion, having just completed a tour of the Coast, made for the special purpose of inquiring into these particular market conditions. Mr. Thompson urged that in the interest of mining in this province the tariff existing on drill steel before the war should be continued. This permitted free importation of steel costing more than 3½c. per lb.

Talking about his experiences while on tour, Mr. Thompson affirmed that there existed a daily demand of from 1,000 to 1,500 tons of pig iron. In answer to inquiries Mr. Thompson explained that 20,000 tons of Texada Island ore had been treated at Irondale, in Washington, and that it had been used in conjunction with other ores in the manufacture of steel for two United States warships. The latter method had proved that the ores of British Columbia could be used to produce iron and steel without importing fluxing ores. The difficulty which had retarded production in the past had been the market.

Merrimac Co., Near Boston, Gets Returns on Silver-Lead Ore Shipment

The Merrimac Development Co., which is operating at Newbury, Mass., 32 miles from Boston, received returns averaging $67 per ton in gold, silver and lead on a car of silver-lead ore on Oct. 2 from the American Smelting & Refining Co. Further shipments are in progress. A new shoot of copper ore cut Oct. 1 on the 220-ft. level east has demonstrated the existence of a new deposit. Todd C. Woodworth is president of the Merrimac company.

Proposed Steel Deal Ratified

Shareholders of all companies concerned have ratified the proposal to sell out to the British Empire Steel Corporation, according to a press dispatch, and consummation of the contracts will be made immediately upon the $25,000,000 preference stock of British Empire Steel Corporation being sold, and the funds becoming available for the use of the new corporation. There has been considerable opposition from the finance department at Ottawa and from other interests in Canada against raising this money in Canada, and it is understood practically the entire $25,000,000 is being underwritten in London, subject to the clearing up of certain legal matters.

Tripoli Mining Near Seneca, Mo., Attracting Attention

Increased interest in the tripoli mining industry is promised for this district. About a year ago the Barnsdall Corporation of New York bought the Seneca Tripoli Co.'s plant and mines near Seneca, Mo., about 15 miles south of Joplin. For several months past, under the name of the American Tripoli Co., it has been combining the two tripoli mills that heretofore had been used in making the filters and tripoli powder, and now has this work virtually completed. The new and enlarged mill is located at Seneca.

This week announcement was made of the organization of the National Tripoli Co., and the purchase by it of a 253 acre tract of land south of Baxter on which an extended run of tripoli has been located, about five feet beneath the surface. Dr. T. A. Smith, formerly of Topeka, Kan., now of Joplin, is at the head of this organization, which plans the immediate construction of a tripoli mill on its lands.

Recent Production Reports

Phelps Dodge produced 7,998,000 lb. copper in September compared with 8,365,000 in August.

Inspiration produced 6,500,000 lb. copper in September compared with 7,200,000 in August.

The shipments of the Consolidated Interstate-Callahan in September were as follows: 4,230,000 lb. zinc concentrates, 2,180,000 lb. lead concentrates, and 21,800 oz. silver; which compare with 4,452,000 lb. zinc, 2,014,000 lb. lead and 20,140 oz. silver in August.

Iron Industry of Germany Reviving

Increase in Orders Slight But Gives Hope That Market Conditions Are Changing for Better

By Our Vienna Correspondent

Vienna, Sept. 10—After months of inactivity in the German iron industry there has recently developed a very slight increase in orders. Slight as it is, the circumstance arouses the expectation that the unsatisfactory market conditions have been overcome, and that by fall more active business will develop and serve to bring the factories safely through the winter. The revival is based on increasing orders of domestic consumers as well as on a very recent increased demand from abroad. There has been considerable decrease recently in stocks held by direct consumers and by dealers who had very considerable supplies a few weeks ago. As the traffic through second and third intermediaries has suffered a considerable decline it is natural that consumers should lose some of their diffidence. At present, however, most of the business has been in the form of inquiries to try out the market conditions, but in view of recent occurrences it may be safely assumed that 15 to 20 per cent of the queries will lead to actual orders. The reaction on the individual products of the market varies: Pig iron needs will be but partly met, chiefly because of the recent greatly diminished deliveries possible from the victor countries; rod, strap, and heavy sheet iron enjoy a continued strong demand; but the trade in light sheet iron continues very depressed. Contracts that had previously been closed at 9,000 or 10,000 marks per ton (metric) are now being made at as low as 4,000 marks. This will hinder the starting of new enterprises. The same holds for the piping market, since the cessation of building operations has stopped the demand for gas-piping. Further lowering of prices is the less to be expected since Exchange has further fallen and the contract prices for pig iron have risen considerably. Deliveries are usually demanded within two or three weeks, which the works rarely can meet.

Numerous orders for export are being received from the northern countries by way of Hamburg, in individual cases amounting to as much as 10,000 tons, and are in very many cases meant for deliveries to Russia. At present Switzerland and Holland are not so strong on the German iron market. In the case of the Netherlands this is due in part to the cheap freights in the German ports. Contracts for the building of 100 railway locomotives of the heaviest type will be closed with Russia, a deal involving 175,000 tons of steel and similar materials. The agreements concerning the delivery of rolling stock to France and Belgium are also on the point of being concluded. The mean degree of activity of the German industry as a whole cannot be estimated.

However, one may safely state that up to about 50 per cent of the normal peace time production and deliveries can be attained. Of late the labor problem has, happily, begun to show considerable improvement. The worst of these difficulties has been passed.

NEWS FROM WASHINGTON

By PAUL WOOTON

Cottrell Anxious To Resign as Bureau of Mines' Head

Several Mentioned as Possible Successors—Position Should Go to Mine Operator, It Is Held

A change in the directorship of the Bureau of Mines is expected to take place in the near future. At the time the present director, Dr. F. G. Cottrell, accepted the place, he made it very clear that it was to be for a short time only. Dr. Cottrell is understood to be very anxious to take up the duties of chairman of the Chemical Division of the National Research Council, to which he recently was appointed to succeed Wilder D. Bancroft, who has returned to his work at Cornell University.

The suggestion that Pope Yeatman be tendered the place has met with favor among officials in Washington, but it is understood that Mr. Yeatman cannot be induced to accept the office. An effort was made to induce Herbert Hoover to accept the position. Mr. Hoover admits that the place tempts him but he is not in a position to accept it at present.

J. Foster Bain, formerly assistant director of the Bureau, has been sounded out but he has cabled from China that he cannot consider the proposition. His answer is not to be regarded as final, however, and additional efforts are being made to induce him to accept the place.

It is clearly recognized that the mining industry is very desirous that the place go to a man who has been prominently identified with the mining side of the industry. The demand seems to be for a seasoned man with a record of success as a mine operator—one who has shown resourcefulness and vigor and who is familiar with underground mining as distinguished from surface and financial operations. At the same time it is realized that any director of the Bureau of Mines must have an appreciation and leaning toward the scientific matters which are involved in mining. In addition he must be a man who can handle his labor problems in a sympathetic manner. Since the salary of the director is only $6,000, it is recognized that practically any man of that type who takes the position will have to make a decided sacrifice.

A man who will measure up to the foregoing specifications is said to be F. W. Denton, the vice-president of the Copper Range Consolidated Co. Mr. Denton's name has been submitted for consideration but since it was stated by those submitting his name that Mr. Denton had no knowledge of the matter, there is no certainty as to whether he would accept the place if offered it.

There is an increasing tendency on the part of Cabinet officers to look with favor on filling vacancies by promotion within the Bureau. It is known that consideration is being given to such promotions in connection with the selection of a new director for the Bureau of Mines. George S. Rice has seen many years' service as the Bureau's chief mining engineer. E. A. Holbrook is assistant director, the position from which Van. H. Manning was promoted to the directorship. Dorsey A. Lyon, the supervisor of stations, while a metallurgist, has had long experience in intimate contact with other phases of the mining industry. O. P. Hood, the Bureau's chief mechanical engineer, has had a long and successful period of service with the Bureau. His experience has been chiefly with the mechanical problems of mining, which is ninetenths mechanical engineering, it has been said. Speaking generally, there is a desire on the part of division chiefs to round out their service as chief of the bureau, but in the case of the Bureau of Mines succession, none is entertaining the hope that he may be chosen since they are very familiar with the general feeling in the industry that the directorship should go to such a mining man as has been described above.

Silver Purchases Under Pittman Act Proceeding Smoothly

The Director of the Bureau of the Mint is particularly gratified with the satisfactory way in which silver purchases are being made under the Pittman Act. No efforts have been discovered of any attempt to represent foreign silver as being of domestic origin. Now that the procedure of marketing silver under the Pittman law is generally understood, the whole transaction is proceeding smoothly.

Reserve Board Reports on Mining in September

In its report on business conditions during September, the Federal Reserve Board has the following to say in regard to metal mining:

"Metal mining during the period in question still shows some stagnation. The output of gold in California and Nevada continues to fall off on account of the low purchasing power of the metal. Silver mines in Utah and Idaho are working on a basis which will probably be slightly ahead of 1919. Higher prices of silver early in the year probably stimulated production somewhat as compared with present conditions. Copper from the Arizona region will probably be produced in larger vo ume than in 1919. Elsewhere there is no substantial change. The lead output in Utah and Idaho has been small but some mines which were idle are now resuming operations, so that the yield for 1920 may exceed that for 1919. District No. 10 (Kansas City) reports that in the Colorado district there has been very little change during the month of August, but the recent advance in freight rates has produced some discouragement, while increased costs of supplies may further lower production. Zinc and lead, however, have shown considerable improvement in August, both in the volume shipped and the price paid, in the Missouri, Oklahoma and Kansas fields. Shipments of zinc ores increased 20 per cent over the preceding month and lead 12 per cent, the average price of zinc ore advancing $1 and lead $14 per ton. Stocks, however, have increased about 2,000 tons during the month in spite of increased shipments. A car shortage continues to be a serious problem in the shipments of ore, while the new freight rates will result in an increased cost of $4 per ton for slab zinc."

Gold Bonus a Financial Matter Bureau of Mines Holds

The Bureau of Mines is asked from time to time to support plans holding out inducements for greater gold production. In this connection it is pointed out at the Bureau that such matters as a bonus on gold is a financial rather than a Bureau of Mines matter. Half of the country's present gold production is not affected by present conditions, since the recovery of the gold is incidental to the mining of other minerals. The other half of the production may be regarded as teetering in the balance, but since that involves only $35,000,000 it necessarily must be secondary, the Bureau feels, to the effect which will be exerted on the whole business structure which might follow changes in the unit of value. It may be said, however, that the Bureau of Mines is very anxious to assist in eliminating waste and securing greater efficiency in gold mining operations.

War Minerals Awards

Awards in war minerals relief cases were recommended during the week ended Sept. 25 as follows (the name of the claimant, the mineral, the amount recommended and its percentage relationship to the amount claimed are shown): Florence Doty, manganese, $5,316.06, 56 per cent; J. B. Tilford, tungsten, $3,477.50, 68 per cent; Edmonds & McCurry, manganese, $1,774.96, 68 per cent; M. H. Cutter, manganese, $23,911.42, 66 per cent; East Tennessee Mining Co., manganese, $4,620.09, 79 per cent; Newport Mining Co., manganese, $10,551.20, 60 per cent.

Reconsideration was given to the chrome claim of M. A. Dellano, which had been disallowed. An award of $2,956.10, or 74 per cent of the amount claimed, was recommended.

NEWS BY MINING DISTRICTS

Special London Letter

Broken Hill Prop., Santa Gertrudis and Burma Corp. Issue New Capital

BY W. A. DOMAN

London, Sept. 21—Three mining companies are making issues of capital for the purposes of their undertakings, namely, the Broken Hill Proprietary Co., the Santa Gertrudis, and the Burma Corporation. On the question of financial methods, however, a fourth company comes on the screen this week. This is the Northern Exploration Co., formed comparatively recently to deal with coal, iron and marble deposits in Spitzbergen. The promoter was Mr. Salisbury-Jones, and he with a certain banking institution held absolute control of the company. Although substantial cash offers were put forward, no independent finance house could secure a footing. This seemed to prove the confidence of Mr. Salisbury-Jones and his associates in the future. The price of the shares went to the neighborhood of £4, a figure that evidently was too tempting to be resisted, for it is now stated that the control has changed hands. But Mr. Salisbury-Jones hopes to recover it. There are rumors that the Norwegian Government wishes to buy out the English coal companies operating in Spitzenbergen, with the result that Northern Exploration shares which have languished in the neighborhood of 10s. are nearly 20s. again. Certain persons, among whom is said to be Mr. Salisbury-Jones, have circularized the shareholders offering them 1s.—not 1s. a share mind—for the option to call their shares until the end of the year at £2. There is no need to point out who will make money on this arrangement, even if new capital be guaranteed.

Although still very important the mining branch of the Broken Hill Proprietary Co. plays second fiddle to the Newcastle Iron & Steel Works. Upon this undertaking the directors have expended over £3,750,000, and now in order to extend it, are about to issue £1,500,000 of debentures, and 420,000 shares out of 900,000 in reserve at the rate of one for five now held. There are already £748,100 debentures in issue. Until last year the operating results of the mine and of the steel works were shown separately in the accounts; they are now merged, which prevents shareholders from ascertaining whether the steel works are yielding a profit. That there is a fine future open to the works is undoubted, for two or three important English companies are establishing factories in the neighborhood to take advantage of the steel products.

Methods of finance change in mining as in other branches of industry. Years ago a mining company would never have attempted to raise capital on "notes," and it is only relatively recently that this method of providing funds has come into vogue. In one way and another the Santa Gertrudis has big business on hand, for it is about to ask for £300,000 in notes carrying 8 per cent interest, to be issued at 98 and to be redeemable at 115. There is, of course, much that is speculative in the offer, but it is pretty certain to go, for the company is sound and the premium is an attraction.

The Burma Corporation has just raised £1,000,000 in 8 per cent convertible first mortgage debenture stock at par. It is redeemable between 1925 and 1930 at 110. This, again, is distinctly attractive, for the ore reserves, proved and probable, at the property controlled, have a metal value at conservative prices of £100,000,000. The company is removing its domicile to the East in order to escape the high taxation of this country.

Business in mining shares is very quiet, being upset by Paris sales in order to provide funds for the new French loan.

MEXICO

Sonora

San Julian Co. Stoping at Tres Piedras—Remodeling of Mina Mexico Mill Almost Complete

Sahuaripa—Operation of the San Julian mill in the Sahuaripa district continues at one shift. A 90-per cent molybdenite concentrate is being made. Some first-class hand-picked ore is

also being produced. Ore and concentrates are brought from the mine to Nacozari, a distance of 210 miles, by mule-pack trains. The San Julian Mining Co. has recently acquired the Tres Piedras property, which is located about four miles north of the company's main holdings. Stoping operations have been commenced there and the ore is packed over to the mill.

Mina Mexico—At the Mina Mexico the mill is being remodeled. This work is about completed and its operation will shortly be resumed. It is reported that this company has a considerable tonnage of milling ore blocked out. There is also a considerable amount in mine dumps and in the old tailing dumps.

San Xavier—It is reported that the United States Smelting Co. has taken an option on the Los Animos mine at San Xaxier. They are examining the property and doing some development work at this mine and also at the Santa Rosa mine, an adjoining property. Operations by Loughlin and Schroder, owners of the latter property, are continuing as usual.

Suaqui—Work continues at the Progresso property near Suaqui. The mill is being run mainly on ore from the dumps and ore purchased from several small native operators.

Mr. Royer has an option from A. McFarlane on the Promontorio property near Suaqui. Development of the property is being undertaken, it is reported, in the interest of Guggenheim Brothers. The outcrop on which work is being done is a brecciated silicious mass approximately 500 ft. long by 200 ft. wide, the whole of which runs from 10 to 14 oz. of silver per ton.

Alamos—Two churn drill are being taken from Navajoa to Alamos. It is reported that they are to be used in drilling the La Verde property near Alamos.

Wilson and Obermiller are working the La Junta mine in the Minitas district, about 30 miles from Alamos. They are running a five-stamp mill.

Zacatecas

El Oro Investment Co. Contracts for Victoria Group—Option on La Noria Extended

The El Oro Investment Co., an English Corporation with large holdings in Mexico, has signed a contract with G. C. Palmer for the Victoria group of mines in Zacatecas. The property produces a medium grade silicious ore suitable for cyanide process.

The Fergus Allan Corporation has been granted an extension till Nov. 15 of their option to purchase La Noria property in the Sombrerete district. La Noria is one of the well known *antiguas* of this section. It has a vein extending over four kilometers with an average width of about thirty feet carrying silicious lime ore averaging 20 oz. of silver and some gold. The lessees finished unwatering the property on Sept. 15 and are now making active exploration.

CANADA

British Columbia

Lightning Peak Section Being Opened by Trail

Stewart—It is reported from the Alaska side of the Salmon River section, Portland Canal, that considerable interest now is being taken in the development of mining properties in this locality. It is likely that at least three properties will be working all winter. The New Alaska is to be opened up and a diamond drill is being used in exploration work on the property of the Fitzgerald Brothers. This property is located on Fish Creek. On another group of mineral claims, controlled by the Fish Creek Mining Co., a promising vein of ore has been encountered, and it is hoped that it will be possible to ship ore this winter.

Greenwood—The Lightning Peak mining section is being opened up by the construction of a trail, under the terms of the Mineral Survey and Development Act. The Provincial Government has been busy on this during the last season, and the work now is reported to be practically completed. Lightning Peak has an elevation of about 7,500 ft. In this locality are situated a number of mining properties which give promise of developing into importance. Among these is the Waterloo mine in which Greenwood people are interested. With the completion of the trail it will be possible to make the trip with pack horses from Greenwood to the peak in four days.

Victoria—A small force has been employed since last March on the Gabbro Copper Mines, Ltd., situated at Jordan River, Vancouver Island. Several large open cuts have been made. These have established a width of from 5 to 25 ft. of mineralized material having a length of 300 to 400 ft. There is a fair sized orebody averaging 3 per cent copper.

Trail—Shipments received at the Consolidated smelter during the week ended Sept. 21 totaled 8,810 tons. Shippers are given in the following table:

Mine and Location	Gross tons
Bluebell, Riondel	174
Josie, Rossland	223
Mandy, Le Pas	65
Monarch, Field	45
North Star, Kimberley	224
Ruth, Cedar Creek	108
Silver Bear, Zwicky	28
Skyline, Cedar Creek	37
Velvet, Velvet	31
Yankee Girl, Ymir	29
Company Mines	7,846

Ontario

Kerr Lake Finds More New Veins—La Rose Recovers Stolen High Grade

Cobalt—The Kerr Lake has found two new high-grade veins over a width of 8 ft. These veins will probably enter the Crown Reserve ground.

The Mining Corporation has dropped its option on the radium-bearing claims in Butt Township. This company will diamond drill the Foster property in Cobalt, which it has under lease, in order to gain geological information. Steady shipments of mill rock are being made and some high grade has also been found.

Last week $1,500 worth of high grade which had been stolen from the University property of the La Rose was recovered and one of the high graders arrested. There has been a good deal of high grading going on in the camp lately, regularly organized gangs obtaining and disposing of the silver.

The Carr Silver Mines in Carr Township will make a shipment of five tons of ore which is expected to run about 500 ounces a ton. A fair tonnage of high grade mill rock is being broken and a small mill is talked of.

The Tretheway company operating in Gowganda has struck a new vein carrying high grade ore. Ontario smelters which now control the market for Cobalt metal and oxide have raised the price of the metal from $3 to $6 a lb. It remains to be seen if the miners producing the ore will benefit.

Kirkland Lake—Kirkland Lake's August production was $35,261 from 1,281 tons of ore , or an average recovery of $27.50 a ton.

Porcupine—The Vipond mine in Porcupine is to be unwatered, and men are being assembled to start development work.

It is stated that the Associated Gold Fields of Larder Lake is contemplating an increase of capital from $5,000,000 to $30,000,000 on an exchange basis which would leave 10,000,000 shares in the treasury.

Manitoba

Herb Lake—The Bingo Mines, Ltd., have just completed the sinking of a shaft to the 50-ft. level. Another contract has been let to continue the shaft to the 200-ft. level, and also to crosscut at the 100-ft. level. The object of this crosscutting is to determine the value of four veins which appear on the surface within 60 ft. of the main vein.

CALIFORNIA

Plymouth Con. Cuts New Ore—Argonaut Improving Surface Plant

Plymouth—The Plymouth Con. Mining Co. has cut a 12-ft. vein of ore assaying from $10 to $15 per ton on the 3,050-ft. level, and development work so far done on it indicates its likelihood to yield well for some time to come.

Sutter Creek—Drifting north and south from the vein recently cut on the new 3,900 level of the Central Eureka is in progress and ore of good grade is being sent to the mill from this new development. Ore from the 2,700 level is also being profitably milled.

At the Old Eureka (Hetty Green's old property) development work under way on the 3,500 level has uncovered ore of better character than any encountered thus far on other levels since re-opening. The present company has spent a large sum of money in equipping and unwatering and much develop-

ment work has been done. T. C. Gorrie is in charge of operations.

Colfax—The Rising Sun mill has been forced to close until normal power conditions prevail. In the meantime the management is developing the new ore recently cut on six levels.

Scales—Drilling has apparently located the channel on the Poor Boy and Bella Union claims. It will be necessary to tunnel for 3,000 ft. to tap the channel. This will require the installation of compressed air machinery, power plant and other equipment if the plans of the management are to be carried out.

Auburn — Herbert Whittemore, of Newcastle, and E. C. Montgomery, of Auburn, have opened the Old Elizabeth mine near Penryn, which has been closed since 1862.

Jackson—Steady progress is being made at the Argonaut and Kennedy mines in lowering the water. In the meantime the Argonaut is completing extensive improvements at its surface plant. What is practically a new hoist will be installed. The Knight Company, of Sutter Creek, has turned out a large part of this new equipment. All new equipment is at the mine.

Nevada City—The lifting of the ban on the use of electric energy for new mines is awaited with much interest by H. H. Estee, manager of the St. Louis mine, at Willow Valley, who reports that the new mill and the hoist are ready for operating, and that ore on the dump will keep the mill going for two months. The ledge is being developed.

NEVADA

Nenzel Crown Point Holdings To Be Auctioned—Pilot Mill for Eureka Holly

Virginia City—In a winze sunk from the 2,150 level of the Con. Virginia an orebody 5 to 8 ft. wide has been developed for 100 ft. in length, the values running very high, according to Alex Wise, the superintendent.

Simon—A face of good ore was struck in the southwest crosscut on the bottom level of the Simon Silver-Lead mine on Sept. 23, according to a telegraphic announcement sent out by the management. In the initial unit of the reduction plant soon to be erected a combination of wet concentration for the coarse material and oil flotation for the fines is expected to produce the most efficient results. Lloyd White, of Burch, Hershey & White, is consulting metallurgist.

Cortez—The main pipe line of the Consolidated Cortez mine, which extends seven miles to the south of the camp, has been overhauled and an elaborate water supply system installed at the property.

Rochester—All the property of the Nenzel Crown Point Mining Co. is to be sold at public auction on Nov. 17 under a deed of trust given to secure an authorized issue of $300,000 face value first-lien 7-per cent convertible equipment gold notes, the company having defaulted on payment of principal and interest. The Anglo-California Trust Co., of San Francisco, is trustee.

Eureka It is reported that the Eureka-Holly will erect a small pilot mill at the mine which will be used as an experimental plant to perfect a volatilization process for the treatment of carbonate lead ores. The process has met with success in laboratory tests made by W. H. Layng, the company's metallurgist.

Pioche—Ore shipments from the Pioche district for the week ended Sept. 23 totaled 2,555 tons from following shippers: Prince Consolidated, 1,330 tons; Virginia Louise, 780; Combined Metals, 210; Black Metals, 100; Bristol Silver Mines, 95; and Magnolia, 40.

The recently incorporated Silver Horn Mining Co., with property 23 miles northwest of Pioche, will shortly erect a 30-ton cyanide plant. Material has been purchased and will be on the ground in October.

Earl T. Godbe, who recently had charge of the Pioche Assay Office, has associated himself with Everett Wade of Salt Lake City in the May-Day lease. Work will be confined exclusively to the mine and the lease on the May-Day dumps will be operated by Lee Battles as heretofore.

The Pioche Bristol Mining Co. has levied an assessment of one quarter of one cent per share on all outstanding stock to provide funds for deepening its shaft 100 ft. This assessment will be delinquent Oct. 20, 1920, sales date Nov. 12.

ARIZONA

White Metals Mill at Pioneer Completed—Power Shortage Hampers Operations at Some Bisbee Mines

Kelvin—The No. 1 diamond drill hole of the Ray Boston company is down to 1,415 ft. with 35 ft. to be driven to complete the contract. Since passing the 1,240-ft. mark the work has progressed very slowly due to the bad ground passed through. It is expected that the No. 1 hole will be finished by Oct. 10.

John Cresap has recently opened up a promising vein of gold ore on his claims adjoining the U. S. Vanadium Development Co. A streak a foot wide on the foot wall has yielded some spectacular specimens of free gold. The full width of the vein is nearly two feet. The ore carries silver as well as gold.

Kennard & Bierce, engineers of Los Angeles, have completed the mill for the White Metals Mining Co. at Pioneer. The mill is a modern flotation plant of 50 tons capacity and will treat the ores from what was known in the early mining history of Arizona as the Pioneer mine. J. C. Devine is resident manager.

Morristown—Frank Wright is operating under a lease in certain parts of the original Black Jack workings of the Montzuma mine. High-grade lead-silver ore is being taken out for shipment.

The Plomo King continues the extraction of lead-silver ore for shipment to El Paso. About twenty men are now employed and the newly installed mining equipment is operating satisfactorily.

Sombrero Butte—Surveys for patent have been approved on twelve claims belonging to the Magma Chief Copper Co., in the Bunker Hill mining district.

Bisbee—Operations at several of the outside properties in this district have been curtailed or suspended temporarily because of the lack of electric power. The Bisbee Improvement Co. furnishes electric power to the Boras and Night Hawk Leasing Co., the Shattuck concentrator and other operators. Because of a shortage of fuel oil the power company has been forced to discontinue supplying power and is conserving their small supply of oil for making ice and supplying the city with lights. These properties are therefore shut down. Oil is on the way but it will be several days before conditions will be normal and operations can be resumed.

The Night Hawk Leasing Co. has made a new strike on its 650 level. An important body of carbonate ore running from 10 to 12 per cent copper is being opened up. Development work continues on the 750 level.

The Wolverine & Arizona has not yet completely resumed operations. Some repair work is being done in the mine. Their machinery is being thoroughly overhauled. A cylinder of one of the engines has been sent to El Paso for reboring.

The new sulphide orebody on the Boras Leasing Co.'s 600 level continues to open up. The body is now 60 ft. long and 30 ft. wide and averages about 7 per cent copper. Its vertical extent is not yet known. The fourth monthly disbursement of 10c. per share has recently been made. Production is being maintained at approximately 1,250 tons of 8 per cent copper ore per month.

COLORADO

Mary Murphy Finds Rich Silver Ore—Cripple Creek August Output Averages $13 per Ton

St. Elmo—Recent development work in the Mary Murphy mine has opened an 8-ft. vein of ore assaying high in silver.

Cripple Creek—Lessees Boyle and Duar have opened at a depth of 35 ft., on the Hardwood property of the United Gold Mines Co., a flat vein of high grade gold ore. Four 30-ton carloads of the ore have been shipped recently. The ore runs from $130 to $200 a ton.

The production of Cripple Creek mines for August was 36,991 tons, yielding $477,604, or an average of about $13 a ton for all ore including material from mines and dump.

The Forest Queen will sink its shaft to the 1,000-ft. level. An electric hoist has been installed at the 800-ft. level.

Victor—A small vein of high-grade ore has been opened on the 1,600-ft. level of the Cresson, at a point 700 ft. west of the shaft.

MONTANA

Tuolumne Copper Installing New Pumping Equipment—Anaconda Closes Three Mines

Butte—The Tuloumne Copper Co. is installing pumping equipment which represents pioneer work so far as the use of centrifugal pump under high head in the Butte district is concerned. It is planned to install two 5-stage pumps, connected in series, and driven by a centrally located motor, to pump 500 gal. per min. against a head of 1,200 ft. The pumps are made by the Cameron Pump Co.

The Davis-Daly Copper Co. will raise a new ventilating shaft to connect the 1,700 level with the surface. This shaft will be a noteworthy achievement in point of rapid construction, and will present some novel features in so far as timbering and general design are concerned. It will be about 50 ft. from the main hoisting shaft. It will be driven by raising from several levels at the same time, and will be of circular form and cribbed solid with 8 x 8-in. timber, arranged with the horizontal section octagonal in form. The shaft will have a large cross section in proportion to the frictional resistance to air current, and the proposed system of timbering and lining will be more economical than a rectangular shaft lined with square sets, of equivalent ventilating capacity. James L. Bruce is general manager.

The Tropic, Orphan Girl and East Colusa mines of the Anaconda company have been closed. No appreciable amount of ore has been hoisted from any of these mines in the last few months. The men that had been employed at the three properties have been transferred to other mines.

SOUTH DAKOTA

Dakota, Imperial and Reliance Properties Merged

Deadwood—A consolidation of three of the important mining properties in the Bald Mountain district has been perfected. This merger includes the Dakota, Imperial and Reliance mines. The properties will be operated by the Ofer Mining Co. The acquisition of the Reliance property gives the Ofer company a treatment plant and a total of 700 acres of mineral ground, 500 acres of which is situated in the mineralized section of the district. The Reliance cyanide plant will be remodeled and enlarged. The railroad will be extended from Juno spur to the mill and will greatly facilitate the handling of ores from distant mines. A comprehensive plan of mine development will be undertaken and among other things a working tunnel will be driven to cut the various properties and make possible the removal of most of the ore through one opening. The plans also call for the complete equipment of the entire property with modern machinery.

JOPLIN-MIAMI DISTRICT

Oklahoma-Kansas-Missouri

Goodeagle Mine Near Tar River Sold —Bethlehem Mill To Be Moved From Quapaw to Treece

Treece, Kan.—The Bethlehem Zinc Co. has arranged to move its big mill, located just east of Quapaw, Okla., to a site south of the Tampa mine, west of Treece. At its Quapaw location the mill was operated only a short time, very little ore being produced.

Tar River, Okla.—Temple Chapman has sold the Goodeagle mine to the Hartford Mining Co., Harlan H. White, manager. The consideration is understood to have been approximately $250,000. Shortly before the option was taken a field shaft at the mine had been sunk into unusually good ore. This strike was carefully followed up by the Hartford Co., and a large tonnage of dirt has been hoisted to the surface. There is a good mill on the property.

Hockerville, Okla. — The Federal Smelting & Refining Co. has taken over the Farmington mine, and has made a good producer out of it. The Lucky O. K., its local subsidiary, also recently took a 30-day option on the Acme properties, including two mines and one mill east of Picher, and is testing the ground.

The Empire Development Co. is drilling its tract northeast of the town, while maintaining steady operation.

The Hawkins Mining Co. has opened up a second shaft to the north of the shaft where it recently encountered one of the richest lead deposits opened in the district for many months, and is preparing to move a mill from the Sunnyside camp to this shaft.

MICHIGAN

The Copper District

Michigan Smelting Co. To Instal New Pulverized Coal System—Mill Tailings for Roads

Houghton—The Michigan Smelting Co. at its plant at Coles Creek just west of Houghton have started the erection of a new building in which will be installed the Holbeck pulverized coal system devised and manufactured by the Bonnot Company, of Canton, Ohio. The pulverized coal will be conveyed to the large reverberatory melting and refining furnaces replacing the present use of the best grade of bituminous coal. This is the first of such installations in the copper country of Michigan and is considered a distinct advance in the prevalent metallurgical practice.

Concentrator tailings, locally known as "stamp sand," are being largely used as a highway building material in this vicinity. It is used as a top dressing together with crushed rock in tar and water bond macadam construction for roads subject to heavy traffic. For light traffic country roads the "stamp sand" alone is used. It is especially effective when spread on a clay road bed, the clay acting as a cementing material. It is also largely used as railroad ballast, producing a road bed that is practically dustless. It is also employed as a back-fill in old stopes and is ideal for this purpose in as much as it can be blown into the stopes with compressed air, following South African practice in this respect. The long distance of most of the concentrators from the mines here, involving excessive freight charges, has limited the use of tailings for this purpose.

A rough screen analysis of this material is as follows: All through ⅜-in. or ¼-in. diameter round holes; on 10 mesh, 30 per cent; on 20 mesh, 15 per cent; on 40 mesh, 15 per cent, and through 40 mesh, 40 per cent.

Calumet—The 4th level south drift of the Seneca is within about 40 ft. of the Ahmeek Mining Co.'s boundary. The 5th level plant is being cut preparatory to drifting both north and south on this level.

At the Gratiot shaft the 13th level north drift is 850 ft. from the shaft and about 300 ft. from the Mohawk property line.

Chronology of Mining, September, 1920

Sept. 5—Miners at Virginia City and Gold Hill, Nev., struck for $6 per day. Gold Canyon Dredging Co., Silver City, Nev., started dredging near Dayton, Nev.

Sept. 6 — National Tax Association opened annual convention at Salt Lake City, Utah. Rising Sun Consolidated Mines Co., Colfax, Cal., cut its rich main ledge lost years ago.

Sept. 7—Dome Mines Co. stockholders ratified the purchase of Dome Extension Co.

Sept. 9—International First Aid and Mine Rescue meeting opened at Denver, Col.

Sept. 13—Oklahoma State School of Mines, Miami, Okla., opened for its initial session, Lloyd B. Drake president.

Sept. 16—U. S. Assay Office, New York, damaged by bomb explosion, apparently caused by Reds.

Sept. 20 — Alexander McDougal vs. Oliver Iron Mining Co. suit for infringement of a patent came before Federal Court, Duluth, Minn.

Sept. 27—Ninth annual safety congress of National Safety Council opened in Milwaukee, Wis.

Sept. 28—Annual convention of Independent Oil Men's Association opened in Denver.

THE MARKET REPORT

Daily Prices of Metals in New York

Sept	Copper Electrolytic	Tin 99 Per Cent	Tin Straits	Lead N Y	Lead St L	Zinc St L
30	17.75@18.00	41.25	42.25@42.75	7.15@7.75	7.50	7.50
Oct 1	17.65@17.80	42.00	42.75@43.00	7.45	7.45	7.45
2	17.40@17.75	41.50	42.75@43.00	7.45	7.45	7.40
4	17.40@17.60	41.50	42.75@43.00	7.40	7.40	7.40
5	17.25@17.50	41.25	42.00@42.25	7.40	7.40	7.40
6	17.25@17.45	41.50	42.50@42.75	7.35	7.35	7.35

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point. All prices are in cents per pound.

Copper is commonly sold on terms "delivered," which means that the seller pays the freight from refinery to buyer's destination. The delivery cost varies, and it would be confusing to figure net prices on individual transactions. Consequently, an average deduction of 0.15c. is made from the "delivered" price to arrive at the New York price. When copper is sold f.o.b. or f.a.s. New York, of course no deduction is made.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c per lb.

Quotations for zinc are for ordinary Prime Western brands. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Sept.	Copper Standard Spot	Copper Standard 3 M	Copper Electrolytic	Tin Spot	Tin 3 M	Lead Spot	Lead 3 M	Zinc Spot	Zinc 3 M
30	94¼	95¼	113	268	274	34½	34⅜	40¾	41½
Oct 1	94¼	95½	111	271½	276½	34⅜	34¼	40¼	41¼
2	...								
4	96¼	96½	111	271¾	277½	34⅝	34⅜	40¾	41⅞
5	96⅜	96⅝	111	270	275	34⅝	34⅝	40⅞	41⅝
6	97½	97	112	269½	274½	34½	34⅝	40⅝	41¾

The above table gives the closing quotations on the London Metal Exchange. All prices in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Sept.	Sterling Exchange	Silver New York, Domestic Origin	Silver New York Foreign Origin	Silver London	Oct.	Sterling Exchange	Silver New York, Domestic Origin	Silver New York, Foreign Origin	Silver London
30	346¼	99½	92	59⅞	4	348	99½	90¼	58¼
Oct 1	347½	99½	91½	59	5	348	99½	89⅛	57⅝
2	348¼	99½	91	58¾	6	350½	99½	88⅝	56¾

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States. This quotation is retroactive to May 13.

Metal Markets

New York, Oct. 6, 1920

Metal markets for many weeks have been unusually dull, but the week just past was one of those in which quietness was especially emphasized. Practically all producers and consumers report a lack of interest in the metals. Price recessions where they have occurred have failed to induce more business, and, as is usually the case in a falling market, purchasers are refraining from participating more than to cover their immediate requirements. The tendency last week was downward as reflected by our quotations. The prompt market is quiet and little interest is manifested in futures.

Copper

The market was particularly quiet Producers report few inquiries, as consumers are evidently content to run on a minimum amount of supplies. It takes a particularly strong producing company to withstand the present low prices. The large producers have come down to 18c., delivered, but without being able to negotiate many sales. These are hard times for high-cost copper producers, who, should this condition be maintained, will have to suspend operations. Copper for forward delivery is being quoted at ¼ to ⅛c. below our quotations.

Lead

It has been conservatively estimated that some 18,000 tons of pig lead entered the United States during September, causing the recent recession in the market. Producers are "catching up" in their shipments, but only a small number of inquiries are coming in. In fact, since the first of the month the market has been exceptionally dull, despite the fact that neither consumers, producers, nor dealers have excess stocks to speak of. Consumption in paint, cable and foil manufacture is good, but pipe and battery consumption has fallen off. The price of lead is now close to that of zinc, and the abnormal disparity between the two metals is disappearing. Spot lead is in little demand. Futures are nominal.

Zinc

Demand from galvanizers has picked up and there has been an increased activity in the market but only at decreased prices. Although zinc is in an excellent statistical position in the United States, the influence of the European market is important, as the United States cost of producing spelter is a secondary consideration with those countries which want to literally convert all their marketable zinc into gold.

Tin

Sales have been made below import costs, little interest is exhibited in futures, and there have been heavy losses in the forced liquidation of speculative tin supplies.

Straits tin for future delivery: Sept.

Monthly Average Prices for September

Copper:	
New York Electrolytic	18.144
London Standard	96.381
London Electrolytic	111.905
Lead:

30th, 43.25@43.50; Oct. 1st, 43.50@44.00; 2nd, 43.50@43.75; 4th, 43.75@44.00; 5th, 43.25@43.50; 6th, 43.50@43.75.

Arrivals of tin in long tons: Sept. 28th, Singapore, 75; 30th, Singapore, 575; total arrivals for the month of September, 5,335 tons; Oct. 1st, Penang 50; 4th, Singapore, 600; London, 350.

Silver

The silver market since our last report has continued to drop, owing to the weakness of Eastern exchanges, and at the close the tendency is still weak. It has been reported that shipments of Indian rupees have been made to China. Purchases of silver to date by the U. S. Government under the Pittman Act amount to about 18,000,000 oz.

Mexican Dollars—Sept. 30th, 70¼; Oct. 1st, 69⅞; 2nd, 69½; 4th, 68¾; 5th, 68; 6th, 67⅞.

Gold

Gold in London on Sept. 30th, 118s. 4d.; Oct. 1st, 118s. 4d.; Oct. 4th, 118s.; Oct. 5th, 117s. 10d.; Oct. 6th, 117s. 1d.

Foreign Exchange

The European exchange market continues to be steady and fluctuations are relatively small. On the whole the market showed a slight downward tendency. On Tuesday, Oct. 5th, francs were 6.68c.; lire, 4.03c.; and marks, 1.59c. New York funds in Montreal, 9 per cent premium.

Other Metals

Aluminum—For 50-ton lots: ingot, 99 per cent and purer, 35c.; 98@99 per cent, 34.8c. Virgin metal still obtainable in open market at about 32.5c. for 98@99 grade.

Antimony—Spot metal, 7c. per lb. Cookson's "C" grade, 12½@13c. Chinese and Japanese brands, 7c. W. C. C. brand, 8½@9c. Chinese needle antimony, lump, firm at 7@7½c. per lb. Standard powdered needle antimony (200 mesh), 9½c. per lb. Market dull.

White antimony oxide, Chinese, guaranteed 99 per cent Sb_2O_3, wholesale lots, 10c.

Bismuth—$2.55 per lb., 500-lb. lots, and $2.57 per lb., 100-lb. lots.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady.

Cobalt—Metal, $6 per lb.; black oxide, $4.10 per lb.; sulphate, $1.60.

Iridium—Nominal, $350@$400 per oz.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb. for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]**Molybdenum Metal** in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.

Monel Metal—Shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$100 per oz.

Platinum—Firm at $105 per oz.

Quicksilver—Market quiet; $72 per 75-lb. flask. San Francisco wires $73@$75. Market weak.

Ruthenium—$200@$220 per troy oz.

[1]**Selenium**—Black powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]**Thallium Metal**—Ingot, 99 per cent pure, $20 per lb.

[1]**Tungsten Metal**—$35@$60 per kilogram, according to purity and gage.

Metallic Ores

Bauxite—About 52 per cent alumina content, less than 2 per cent iron oxide, up to 20 per cent silica and artificially dried to contain not more than 4 per cent free moisture, $10 per gross ton at mine; 54 per cent alumina and about 15 per cent silica, $11; averaging 57 per cent alumina, 8 to 12 per cent silica, less than 3 per cent iron oxide, $13 on basis of 8 per cent free moisture.

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a maximum of 6 per cent silica, 75@85c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 70@75c.

Manganese Ore—60@70c. per unit, seaport; [1]chemical ore (MnO_2) $70@$90 per gross ton, lump; $80@$100 per net ton, powdered.

Molybdenum Ore—85 per cent MoS_2, 70@75c. per lb. of contained sulphide, New York.

[1]**Tantalum Ore**—Guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots.

[1]**Titanium Ores**—Ilmenite, 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $6 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $4.50@$5, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[1]**Zircon**—Washed, iron free, 5c. per lb.

[1]**Zirkite**—According to conditions, $70@$90 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

Zinc and Lead Ore Markets

Joplin, Mo., Oct. 2—Zinc blende, per ton, high, $48.40; basis 60 per cent zinc, premium, $44; Prime Western, $42.50; fines and slimes, $42.50@$40; calamine, basis 40 per cent zinc, $35@$30. Average settling prices: Blende, $45.04; calamine, $32.92; all zinc ores, $44.08.

Lead, high, $98.30; basis 80 per cent lead, $80@$75; average settling price, all grades of lead, $93.40 per ton.

Shipments for the week: Blende, 14,431; calamine, 275; lead, 1,978 tons. Value, all ores the week, $843,670.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

It is admitted that 1,000 tons of Prime Western blende was purchased on Monday, $45 basis, yet buyers assert it was a purchase on last week's market. Another decline in lead totals a decrease of $37.50 in four weeks. Much of the lead now loading out was sold on $100@$112.50 basis. Purchases on the lower basis offerings of the last three weeks are smaller each week. Sellers claim they cannot produce ore in the face of a continued lowering of the market.

The Van Buren smelter was closed Oct. 1 by a walkout of smeltermen. A repetition is looked for at Fort Smith Tuesday and Wednesday.

Six agencies bought no ore this week, the purchase dropping to 7,500 tons, against 11,500 tons last week.

Platteville, Wis., Oct. 2—Blende, basis 60 per cent zinc, $49.25 base for high grade. Lead ore, basis 80 per cent lead, $80 per ton. Shipments for the week: Blende, 1,276; calamine, 30; lead, 50 tons. Shipments for the year: Blende, 52,602; calamine, 2,459; lead, 4 298; sulphur ore, 1,241 tons. Shipped during the week to separating plants, 2,383 tons blende.

Non-Metallic Minerals

Asbestos—Crude, No. 1, $2,000@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax.

Barytes—Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $24@$30 in bags, carload lots; (off-color) $22@$26 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $12 per gross ton; ground (white) $23@$25; ground (off color) $16@$19 per net ton, f.o.b. Cartersville, Ga. Crude, 88 to 94 per cent, $23; ground (white) $45; ground (off color) $30@$32 per net ton, less than carload lots, f.o.b. New York. Crude, not less than 98 per cent, $11@$11.25 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—Domestic, extra light, 5@6c. per lb.; light, 4½@5½c.; heavy, 4@5c; English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin)—Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground, $15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$18 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $30@$35, car lots, f.o.b. Baltimore; ground, $17@$21, f.o.b. North Carolina points; $17@$21 per ton, No. 1 ground, f.o.b. New York State; $21@

$23 per ton, ground, f.o.b. Maine. Crude spar very scarce.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Graphite—The 90 per cent crucible grade is held in Alabama for 9c. per lb. and 85 per cent grade is practically unobtainable, prices being 7@9c. The higher lubricating grades sell for 11@40c., according to carbon content. In Ceylon, some of the largest producers have closed their mines until prices advance to meet increased production costs, and stocks at Colombo were lowered only 3,000 tons in the first five months of 1920. Surplus stocks on Jan. 1 amounted to 20,000 tons.

Gypsum—Plaster of Paris in carload lots sells for $4.25 per 250-lb. bbl., alongside dock, New York.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $75@$85 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—India block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20 @$1.40; No. 4, $2@$3; No. 3, $4.25@ $5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $4; No. 3, $5.75; No. 2, $7; No. 1, $9; A1, $14; extra large, $25, all f.o.b. New York; ground, $100@$150 per ton, Philadelphia. Domestic, uncut, f.o.b. Franklin, N. C., as follows: Scrap, $45 @$50 per ton; punch, 4@5c. per lb.; circle, 15@25c.; 1½ x 2 in., 75c.; 2 x 2 in., $1.15; 2 x 3 in., $1.65; 3 x 3 in., $2.10; 3 x 4 in., $2.50; 3 x 5 in., $2.75; 3 x 6 in., $3.75; ground 165 mesh, $240 per ton; ground roofing mica, $60; mica washers, 75c.@$2 per lb.; 1¼-in. disks, No. 1, $1.60 per lb.; No. 2, $1.30.

Monazite — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses. Tennessee production sold up months ahead.

Pumice Stone—Imported, lump, 4@ 50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish fines, per unit, 12c., c.i.f. Atlantic seaport; furnace size, 17c.; Spanish lump, 14@16c.; domestic fines, f.o.b. mines, Georgia, 12@14c. Market improving.

Quartz—(Acid tower) fist to head, $10; 1¼ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines. F.o.b. Wausau, Wis., the price is $16 per ton in car lots, and $22 in less quantities, including bags.

Sand (Glass)—Dry glass sand, $4 per net ton, f.o.b. cars Mapleton, Pa. Sand, f.o.b. Ottawa, Ill., is $3 per ton; $2.50 on annual contracts. Sand at Klondike, Gray Summit and Pacific, all in Missouri, is $2.50 on contract; some outside sales have been made at $4.

Sulphur—$18 per ton for domestic; $18@$20 for export, f.o.b. Texas and Louisiana mines. Market quiet.

Talc — Paper making, $12@$22 per ton; roofing grades, $9.50@$15; rubber grades, $12@$18, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $12@$15 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60 @$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $225 @$250 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15 to 18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 18½@19c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c., f.o.b. works.

Ferromanganese—For 76 to 80 per cent, prompt delivery, $170@$180, freight allowed; last half, $170; English, $170, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $82.50@$85, f.o.b. furnace.

Ferromolybdenum[1]—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2@$2.50 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $82.50@$85; 75 per cent, $150@$160.

Ferrotungsten—70 to 80 per cent W, 90c.@$1.05 per lb. of contained tungsten, f.o.b. works.

Ferro-uranium—35 to 50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium[1]—Basis 30 to 40 per cent, $6.50@$8.50 per lb. of V contained, f.o.b. works.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Metal Products

Copper Sheets — Current New York price, 29½c. per lb.; wire, 22½@23c.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver—Unchanged at 39½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 26⅜c.; sheathing, 25⅜c.; rods, ⅜ to 3 in., 23⅜c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $160 per 1,000, f.o.b. Pittsburgh.

Chrome Cement—40@45 per cent Cr_2O_3, $55@$60 per net ton, and $65 in sacks, carload lots, f.o.b. eastern shipping points.

Fire Clay—First quality, 9-in. shapes, $55@$60 per 1,000, Pennsylvania, Ohio and Kentucky. Second quality, $45@ $50.

Magnesite Brick — 9-in. straights, $110 per net ton; 9-in. arches, wedges and keys, $121; soaps and splits, $134

Silica Brick—9-in., per 1,000: Chicago district, $65@$70; Birmingham, Ala., $56@$61; Mount Union, Pa., $55 @$60.

Iron Trade Review

Pittsburgh, Oct. 5, 1920

In a few instances mills have slightly decreased operations on account of customers requiring less steel than was formerly shipped to them, but as to the great bulk of the steel industry, production has been increasing, on account of better transportation and weather conditions, and it is possible that this month's steel output will break the record that has stood since October, 1918.

Finished-steel prices are not declining to any extent. Special premiums for prompt shipment have disappeared, but the independent market generally is almost as far above the Steel Corporation price schedule as at any other time. The strength of sheets is particularly noteworthy, they being $50@ $60 a ton above the Steel Corporation prices, at about 6.75@7c. for black sheets and 8.50@9c. for galvanized.

Pig Iron—The market is so sluggish that it is not developing the new and lower prices that must come on account of changed conditions. Bessemer and basic remain nominally quotable at $48.50, Valley, although buyers will no longer pay the price. It is reported that two steel interests have offered basic at $45.96, delivered Pittsburgh, or $44, Valley equivalent; also that a middleman has sold over a thousand tons at only a shade above this figure.

Steel—Nominal mill quotations are $60 for billets and $65 for sheet bars, but it is believed $5 under this could be done on a firm bid.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $16.50@$17; foundry, $18.

The Price of Zinc

We have been much interested in the comment on our zinc prices for the week ending Sept. 29 which has been made by the editor of the *American Metal Market*. We are glad to mention the subject at greater length because we have found this publication to be one of the most reliable and honest of the journals devoted to the marketing of metals. The prices quoted by *American Metal Market* are likely to be somewhat higher than ours, but we believe that this is because they represent, in general, small lots, and because those responsible for their compilation are not always in the position to be advised of the actual prices at which large tonnages are marketed. Wholesale prices, as we might call them, are naturally lower than retail.

The editor of the *American Metal Market* in his issue of Sept. 30 questions our prices as being too low and takes us to task for being unwarrantably bearish in our attitude. In his issue of Oct. 1, he is more inclined to dismiss the first charge, for he admits that "there are reports that a certain interest has indicated a willingness to sell Prime Western at 7.50c., St. Louis basis." These interests, we might add, were not only willing to sell but did sell a considerable tonnage at that figure, and it was upon these sales that our quotation was based. Then follows an intimation that the dull demand was brought about by our report of a leading producer who predicted 7c. zinc. We believe the demand is no duller than it has been for some time. If it *is* quieter, we feel flattered that any comment of ours should have so serious an effect on the market. We wish that our optimism on copper a few months ago had had a better effect on the demand for that metal. The editor has also been inquiring about to find out who predicted 7c. zinc. In this, of course, he was unsuccessful, although it was not because he did not write to the proper people. The man who made the prediction naturally does not care to make himself known.

The reason zinc is being pushed down, if it is being pushed down, and not just falling down, as a result of the old law of supply and demand, we suspect is because domestic producers are doing their best to keep foreign metal out of this country. If this is the case, it would probably redound to the advantage of the domestic zinc industry in the long run. If importers lose money they will hesitate about trying the same game again. If we could control things, we would boost up the prices on all metals: it would result in better times for our clientele and, therefore, more profit to ourselves.

This matter brings up the subject as to whether we should abstain from publishing all bearish reports and always be sunny and optimistic regarding the future; or, if not that, at least keep still. This is small-town stuff. We consider it our duty to publish the market gossip as we get it, even though our informants have long black hair and claws. We believe that our metal industry generally has progressed beyond the stage where it must be fed on sugar-coated pills.

Japan's Mineral Production

According to figures published by the Tokyo Chamber of Commerce, the output of minerals from the leading Japanese mines for the first four months of the year was generally lower than for the same period of 1919, with the exception of coal, the figures being as follows:

	1919	1918
Gold (momme)	613,411	677,504
Silver (momme)	13,518,115	17,567,640
Copper (kin)	41,475,533	46,056,032
Iron (kin)	22,450	29,249
Coal (ton)	8,538,245	8,261,462
Petroleum (koku)	608,209	690,832
Sulphur (kin)	12,146	23,237

A momme is the equivalent of .008267 lb.; a kin is 1.323 lb.; and a koku is the Japanese denomination of liquid capacity or 39.7032 gal.

Foreign Trade in Metals and Ores for July

Imports and exports of the more important metals and ores, as reported by the Department of Commerce for July, 1920, and the figures for July, 1919, as finally revised, are as follows:

IMPORTS, JULY, 1919, AND 1920
(In pounds, unless otherwise stated)

	July, 1919	July, 1920
Antimony ore, contents	226,246	152,720
Antimony matte, regulus or metal	1,219,458	2,267,058
Copper:		
Ore, contents	4,756,444	1,389,399
Concentrates, contents	2,902,900	2,548,425
Matte, regulus, etc., contents	5,758,470	123,607
Imported from (in part):		
Canada	3,610,480	1,030,824
Mexico	4,029,810	2,606,275
Chile	3,186,163	359,758
Unrefined, black, blister, etc	18,033,812	14,781,480
Refined, in bars, plates, etc	3,116,315	7,938,249
Composition metal, copper chief value	12,177	525,391
Lead:		
Ore, contents	2,711,964	1,346,980
Bullion, contents	12,575,262	9,971,247
Imported from (in part)		
Canada	1,376,588	458,079
Mexico	12,758,243	8,389,023
Chile	385,878	11,042
Pigs, bars, and old	561,053	2,305,038
Manganese ore, long tons	15,585	18,447
Imported from (in part):		
Brazil	9,750	12,462
British India	None	1,600
Tungsten ore, long tons	452	71
Pyrites, long tons	63,088	56,753
Imported from (in part)		
Spain, long tons	36,099	34,874
Canada, long tons	24,889	21,879
Tin ore, long tons	1,975	1,938
Tin bars, blocks, pigs, etc.	113,120	17,584,167
Imported from (in part):		
United Kingdom	None	4,029,725
China	None	167,881
Straits Settlements	113,120	10,097,914
Hongkong	None	2,318,059
Zinc:		
Ore, contents	4,225,849	1,974,322
Imported from (in part):		
Canada	196,515	164,955
Mexico	2,160,540	1,802,826
Blocks or pigs, and old	None	18

EXPORTS OF COPPER, LEAD AND ZINC
(In pounds)

	July, 1919	July, 1920
Copper:		
Ore, contents	3,000	392
Concentrates	None	None
Unrefined, black, blister, etc	3,600	83,277
Refined, in ingots, bars, etc	42,373,791	40,051,623
Exported to (in part):		
France	13,917,000	17,797,752
Belgium		536,638
Germany		5,634,824
Netherlands		191,463
Sweden	7,008,518	3,465,284
United Kingdom	7,676,212	9,200,750
Canada	1,406,066	1,523,997
Japan	7,592,248	940
Composition metal, copper chief value	25,408	6,972
Pipes and tubes	334,563	444,316
Plates and sheets	436,843	2,522,007
Wire, except insulated	6,208,843	3,647,668
Lead:		
Pigs, bars, etc.:		
Produced from domestic ore	637,855	171,202
Produced from foreign ore	4,664,547	574,595
Exported to (in part):		
France		493,315
United Kingdom	3,472,560	112,089
Canada	119,650	13,280
Zinc:		
Dross	72,000	5,980
Spelter		
Produced from domestic ore	18,715,545	16,196,507
Produced from foreign ore	1,103,124	863,622
Exported to (in part):		
France	5,683,424	3,992,888
Italy	112,000	67,238
United Kingdom	11,442,341	10,678,762
Canada	340,494	14,512
In sheets, strips, etc	1,978,580	3,082,276

Algerian Mineral Exports

Mineral exports from Algeria last year were as follows, according to the *Mining Journal*, London, the figures for 1918 being given by way of comparison:

	Metric Tons, 1918	Metric Tons, 1919
Antimony ore	7,920	2,160
Copper ore		1,000
Iron ore	759,217	782,885
Lead ore	17,831	8,316
Zinc ore	29,288	4,261
Mercury (native)	15	8
Natural phosphates	198,539	242,186
Superphosphates	4,852	14,576

INDUSTRIAL NEWS

Chemical Industries Exhibit Manifold Accomplishments

The Sixth National Exposition at New York Drew Many Visitors—Some Exhibits Noticed

The chemical industries of the United States and Canada held their most extensive and pretentious exposition in the Grand Central Palace, Lexington Ave. and 46th St., New York City, during the week ended Sept. 25, 1920. The more than 750 booths fully occupied the four floors of the great building, and every booth carried an attractive, interesting display, with its message of one or more successful American applications of chemical science to industrial needs. Every afternoon and evening of the week brought a steady stream of visitors, including the public, teachers, students, and industrialists, representing most of the nations of the globe. Exposition officials estimate the total attendance at 125,000, and every visitor found something worth his attention. The talks and illustrated lectures, but more especially the cinematograph demonstrations of actual plants in operation, drew crowds far exceeding the capacities of the space allotted. Future shows must follow suit.

In the following paragraphs brief note is made of some of the exhibits having special interest for the mining, metallurgical, and allied industries.

William Ainsworth & Sons—This well-established firm of instrument makers exhibited a group of assayer's balances, all of which had varying degrees of sensitiveness and corresponded to their standard grade of balance. There was also shown a compact theodolite with solar attachment.

American Metal Co., Ltd.—This mining company's chief exhibit was a group of raw and finished metallic products, such as zinc ore and zinc slabs, entering into their manifold mining and smelting activities. Manufactured and commercial forms of copper were also shown, and the variety of chemicals made from copper and other ores was illustrated.

Anaconda Copper Mining Co.—A diversified exhibit was presented by this company, and served to indicate the many fields of endeavor included in its operations. Copper, zinc, and lead commercial forms were shown, as well as many rarer metallic and chemical products. Not the least interesting feature of the exhibit was the $11,660 bar of gold (a metal rarely seen nowadays), inclosed in a glass case. The Anaconda Lead Products Co. and the Anaconda rolling Mill Department, allied and subsidiary organizations, joined in the display.

Eagle Picher Lead Co.—As this company's chief product is paint or paint pigment, its exhibit comprised many colored samples of lead pigments contained in an artistic arrangement in glass bottles.

International Nickel Co.—Monel metal, an industrial alloy of nickel, was displayed in many manufactured forms. Nickel chemicals and commercial forms of nickel also received much attention and combined to make an instructive exhibit of the nickel industry.

Lunkenheimer Co. showed a large line of valves and brass specialties of use to the chemical engineering trade which although by no means a complete line of its products, served to indicate the field covered by its activities.

Raymond Bros. Impact Pulverizer Co.—Several well-constructed models of pulverizing machinery were exhibited. One model illustrated the method used by the company to pulverize coal for use in reverberatory furnaces and another showed how a similar apparatus could be used for grinding and separating soft non-metallic minerals such as talc.

Western Electric and Manufacturing Co.—A few switchboards and motor generator sets were the chief display of this company. To have exhibited everything manufactured for use in chemical work would have necessitated much more space than was available.

Worthington Pump & Machinery Corporation—The several lines of centrifugal and direct acting pumps made by this company were given prominence, and various models exhibited.

De Laval Separator Co.—This company, of pastoral origin, demonstrated the great efficiency of its special machines for separating, or reclaiming and purifying all kinds of oil combinations, as its display of tubes of oils made clear. The separator at work was sorting machine oil out of colored water, and of course held the attention of many who are fascinated by these canny devices.

Lead Lined Iron Pipe Co.—It is difficult to make a lively display of such deadly heavy objects as lead-lined pipes, joints, and elbows. This company did as well as could be expected with its complete line of fittings.

Sullivan Machinery Co.—Air lifts, by their nature, are lively devices. This company's display of an air lift of two stages, at work, took advantage of this fact and the transparency of glass to catch everyone's attention and interest. The whirr of the compressor motors and the rush of bubbling waters was most interesting.

Magnesia Association of America.—When fire and heat are under control man needs the insulating coverings provided by this company to maintain his supremacy and direct the chained giant's efforts. This company's display of snowy, high-grade magnesia insulation was capped by a block of 85 per cent magnesia compound.

Mine Safety Appliance Co.—Walking in safety, if not comfort, through the great building, it was hard to realize the conditions of work that sometimes require the use of the complete Gibbs apparatus displayed here. The glistening collection of various pieces of gas-testing apparatus and the multi-colored canisters of absorbents for the Burrell mask seemed particularly to interest those who had experienced gas attacks in the Great War.

Chapman Valve Manufacturing Co.—This firm displayed a very complete line of bronze and iron valves tastefully arranged on either flank of and pointing to a great handsome bronze 28-in. gate valve. The design and general appearance of this centerpiece made it a fitting salesman for the valve builders.

Thwing Instrument Co.—The "hump" method, and particularly the decalescent recording device, were admirably demonstrated by this company's exhibit, where both were shown actually at work. The festoons of graphic records and the glowing little furnaces, with their thermocouples, always caught the eye.

Titanium Pigment Co.—Outdoor weather and indoor factory or mine atmospheres are all inveterate enemies of iron, steel, and wood structures, and the comparative panels displayed by this company seem to show that their "Titanox" paint is a splendid defense against them. Both by weight and by volume this coating shows a superior hiding power. The display of the usefulness of the company's products was heightened by an exhibit of attractive tiles decorated with its terra-cotta titanium pigments.

Herold China & Pottery Co.—The perfection attained by some American makers of chemical and scientific porcelain wares was well illustrated here in a display of carefully made forms ranging from the simplest pestles to complicated and delicate patterns of all sizes.

Magnetic Manufacturing Co.—The uncanny intelligence displayed by electromagnetic machinery is always interesting, and the selective action of this company's ingenious rotating disk, as shown by the half-size working model, attracted much attention when it was in action.

Midwest Engine Co.—The problem of conveying and pumping acids and other corrosives seems to have been solved in an economical way for the rotary pumps made by this company. Certainly they stood up well in contrast with the comparison test pieces displayed beside them.

Becker Christian, Inc.—A line of highly finished analytical balances of various sizes in glass cases is always an attractive showing. In this company's display contrasts were made use of by placing a man-high bullion balance of fine workmanship in the midst of its smallest relatives. A 1-kgm. weight, accompanied by U. S. Bureau of Standards certificate showing it to have no error, emphasized the quality of this firm's work.

The New Jersey Zinc Co. displayed its zinc products and many manufactures of zinc for making which the possibility of using zinc is not generally known. A section of roof covered with zinc shingles, together with leaders and gutters of zinc, caught the attention of the discriminating, though the casual visitor was possibly more attracted by the zinc meter cases, coins, bread trays, lighting fixtures, and the like.

Nichols Copper Co. took advantage of the blue, green and red of its products of copper and nickel sulphates and copper oxide to arrange a striking and artistic exhibit. Pyramids of these colors flanked on each side a larger pyramid made of successive lavers of copper ore, concentrates, matte, blister, and metal. Specimen ingot, wire, and wedge bars and other shapes of refined copper were shown.

The W. S. Tyler & Co. of Cleveland, Ohio, made its presence known over a wide area, from time to time, through the agency of one of its 6-ft. "Hummer" electro-magnetic vibrating screens, which is some hummer when working at its maximum vibration. The familiar displays of woven-wire screen, double-crimped wire cloth, and other products were also shown.

The Refinite Co., of Ardmore, S. D., demonstrated the manner in which it can soften any kind of water with its product, a zeolite mined and prepared in South Dakota. Filters for domestic and commercial use, made by the company, were also displayed, as well as some Phoenix hosiery which is "processed' in Refinite water.

Dings Magnetic Separator Co. attracted the passer by, who usually stopped to test his strength against that of the magnetic pulley which held several monkey wrenches fast against its face. A Rowand-Wetherell E No. 1 X high-intensity separator was also shown, also a type M magnetic separator.

Cleveland-Cliffs Iron Co. was present in its capacity as a manufacturer of wood chemicals. It displayed samples of alchohol (methyl), acetate of lime, and other products, including sulphuric acid. Its factories for making these are at Marquette and Gladstone, Mich., and at Goodman, Wis.

United Lead Co., N. Y., and Georgia Lead Works—The protective lining of pipes, elbows, junctions, and valves, with a heavy lead sheath impervious to corroding fluids, was well illustrated by the many forms of construction displayed by this company.

Nash Engineering Co.—The small-sectioned working model of the "Hytor," a combined air compressor and vacuum and water pump, was an interesting demonstration of the principles of this compact and efficient device. The small volume of the 300 cu.ft. per min. pattern displayed attracted some attention by its compact efficiency.

Allis-Chalmers Manufacturing Co.—The "snapping" bags of this company's dust collector and spray drier usually attracted the attention of the passerby, and the sound of dashing water in the working "Air Conditioner" drew one to a grating whence poured forth a stream of cool, moistened air. Both devices suggested the comment that out-door weather is in the hands of Providence, but indoors Man may largely be the controlling factor.

The Lungmotor Co.—The well-polished aluminum twin cylinders of the Lungmotor hand pump attracted everyone's interest. This portable and simply safeguarded device for rescuing persons overcome by gas or drowning presents many advantages in manipulation.

Foamite Firefoam Co.—The terrors of fire uncontrolled, as shown by lurid pictures and constantly changing stereopticon views, drew everyone's attention to the booth of this company. The sizzling reaction at the table where actual demonstrations of "foamite" were given kept the aisle crowded.

America La France Engine Co.—A bright array of warning and guiding metal placards covered the walls back of the interesting display of the firefighter's aids. Various styles of fire-fighting masks, clothing, and fire extinguishers attracted the interest and attention that these devices always receive.

General Chemical Co.—An attractive feature of this exhibit to mining men, was the diminutive Herreshoff roasting furnace. This was an iron model standing about 7 ft. high, opened and illuminated for inspection. Although not heated, the furnace was in operation, and complete even to the small blower, Herreshoff furnaces have been successfully used at many smelters, notably that of the Calumet & Arizona at Douglas, Ariz.

Groch Centrifugal Flotation, Ltd.—Many were disappointed at not having the opportunity to see this successful Canadian machine. The shipment was delayed in transit.

Hardinge Co.—The Hardinge mill is so well known that an exhibit would seem almost superfluous. The principle of operation was well shown in a small glass model filled with nuts of assorted sizes. A larger iron model about five feet long was also revolving merrily.

Huff Electrostatic Separator Co.—The principle of operation of this company's separator was well shown in an open model about six feet high. The snapping discharge attracted considerable attention.

The Merrill Co.—This exhibit of the Merrill Co. was confined principally to the equipment designed by this firm. Of special interest of course was the new Merco Nordstrom plug valve, of which it can be truly said that "it can't stick and it won't leak." Whether cyanide solutions, lime emulsions or scale-forming fluids are to be handled, the Merrill engineers seem to have solved the valve question.

The Mine & Smelter Supply Co.—An exhibit in motion is always attractive and a laboratory flotation machine built of glass is particularly adaptable for show purposes. The model of the Ruth machine shown attracted wide interest. The small Wilfley table was also a feature and even experienced millmen liked to watch the shower of black concentrates coming off the end.

Oliver Continuous Filter Co.—The Oliver filter is adapted to exhibition purposes as well as to mill operation, particularly when a nice white filter cake can be provided. The model in operation was of about 3-ft. size and gave an excellent exemplification of the way these standard machines work in practice.

Stimpson Equipment Co.—No one who reached the third floor could help but investigate the Stimpson exhibit, so alluring was the whirr of the new, electrically vibrated Mitchell screen. This new type promises to revolutionize mill screening in the finer sizes. That the vibration was there, many were willing to get greasy hands to find out.

Corning Glass Works—This company is one of the leading exponents of the manufacture of American laboratory glass ware. An unusually complete line of standard and intricate forms was exhibited. It was a happy thought to include a demonstration of glass bending, blowing, and sealing. When the operator faced his roaring blowpipe flame, a crowd of fascinated boys and men soon gathered there.

The Dorr Co.—Working models of the Dorr thickener, Dorrco pump, and Dorr agitator were of sufficient size to attract considerable attention. Other exhibits showed that this company does not confine its activities to mining, a working model of a system of sewage purification being a feature.

Foote Mineral Co.—The rare minerals are always interesting. Both crude and refined products were shown in an attractive display.

United Filters Corporation—The disk type of filter is still of sufficiently recent introduction to be critically inspected by mining men. The working models shown plainly exhibited how simply the filter segments could be changed and the large capacity considering the size of the machine.

American Metric Association—At an exposition of chemical industries, a booth devoted to the advantages of the metric system of weights and measures, seems a superfluity, as the pure and the applied science underlying the whole exposition uses that system almost exclusively. A representative was on hand, however, and presided over a display of familiar canned food containers whose weights were given in ounces and in grams on their labels. Two sheets of the International Map, scale 1:1,000,000, published by the United States, also displayed the advantages of the metric scale.

The Bureau of Mines Directorship

THE novel idea of having someone who is familiar with mining from actual experience, contact, and practice as head of the Bureau of Mines, when in the future the time comes for a new selection to be made, has been taken up with great favor by the mining industry. The Bureau needs such a man, for only such a one can understand and classify in the proper order of priority the different demands which the industry will make upon the Bureau which represents it. It needs such a man, with the business experience of having handled mining enterprises with a view toward economy and efficiency, to expend the large sums which are annually allotted to the Bureau, and secure the maximum results per dollar of the public's money expended.

It matters little who the practical engineer is who will be called upon or who will consent to take charge of the Bureau's affairs and devote his thoughts to perfecting plans for organization. We have already mentioned Pope Yeatman, whose record of experience and ability leaves little to be desired. Other excellent suggestions have included Arthur Thacher, Robert M. Raymond, and Allen H. Rogers. All these gentlemen are familiar with organization, efficient administration, and the whole range of mining problems; all are expert captains of men, with histories which guarantee success to anything they undertake.

The Function of Government

THERE is a rumor in Washington, which has been reported in our columns by our Washington correspondent, to the effect that a party from the Interior Department is in Alaska investigating smelter charges and that the plan to install in that region a Government mill or smelter is receiving consideration.

We may question whether such an investigation is within the function of the Bureau of Mines or the Geological Survey. At first glance it would seem to fall under the redoubtable Federal Trade Commission, if anywhere. If the Interior Department has the right to investigate supposed industrial monopolies and prescribe a remedy therefor, the idea is novel. If not, is it proper to spend Government money even in the investigation? Granted the propriety, however, of the investigation, is it permissible to consider the solution of a Government-owned smelter or mill?

In a spineless commonwealth, as we conceive of it, the people lean on the government; in an ideal democracy, the government would lean on the people. In our Government today we see both tendencies. A large class of people are yearning to become Government paupers, demanding from the Government that they be babied from birth till old age. "The world owes us a living," was the old remark of the loafer. "The Government owes us a living," is the present-day theory. But for every bone that is thrown to a man by the Government on such a system, a substantial bit of his freedom and liberty is taken away. Suppose the Government is to smelt the miner's ore, or mill his ore. If this is to be done in Alaska, by all means let it be done in Colorado, Arizona, and Montana. Any Government official who imagines that the Government can do it for a substantially less cost than the present average charges is unfamiliar both with custom smelting and milling and with Government administration. It would be done, then, below cost, in order to help out the miner; and the deficit, as in the case of the Government administration of railroads, would be saddled on the taxpayer.

But the Government, if it smelts the miner's ore, must grind the farmer's wheat and refrigerate his beef, must operate all public utilities to rescue the citizen from the "grinding corporations," must by all means dig and transport his coal for him. In short, it must take charge of and direct all big business. This is what is commonly called socialism. We are not here arguing for or against this system, except to point out again that, apart from the question of practicability of business being conducted honestly and efficiently by an ever-increasing swarm of bureaucrats, every coddling function of the Government carries with it a corresponding loss of individual liberty.

As for us, we believe in the maximum of individual liberty consonant with the general welfare. Therefore, we should like to scrutinize carefully each project which makes toward socialism and attacks individualism. If, however, the opposite theory is to hold, we should like to get on the band wagon while the going is still good. We should like to see a bill for the pensioning of editors of mining journals, and will agitate also for a 2-cent subway fare in New York, a Government housage program whereby each citizen can get eight rooms and bath at a nominal rental, and Government remission of all taxes to fathers of families of more than two children.

The Provincialism of Engineers

IT IS A CURIOUS fact that mining engineers to a great extent carry out in practice a theory which is diametrically opposed to certain fundamentals which they absorbed in their early technical training. The study of elementary geology revealed the fact that there are certain fixed laws with regard to the formation of rock strata. We learned, among other things, that there are movements of the earth's crust which cause various phenomena; the actions of ascending and descending solutions produce metals and ores, and certain effects are produced by contact. Contact, as we understand it, and as later studies and investigations showed, was highly important. What is true in a geological sense also has its application in a general way, namely that the law of "contacts" is a most important factor in the existence of the mining engineer—but how many consider it so, or, at any rate, put it into practice?

The engineer, by reason of the fact that much of his work deals with certain concrete facts and with fixed natural laws, is provincial. He takes things as he finds them, applies his acquired knowledge to further his ends, and seeks to obtain a result which is satisfactory to himself and his employers. He takes a pride in his work, and to him one of the greatest pleasures obtained from any accomplishment is the satisfaction of originality. All of which is laudable, justifiable, and eminently proper in one sense, but not at all times advisable.

The story is told—it is ancient history to some perhaps, but we only read of it recently ourselves—of a smelterman who did not know that copper matte could be safely turned into granulated material if a spray of water were properly directed upon it as it flowed from the furnace. He thought that it would cause an explosion, just as it does when the matte is allowed to flow into water. At a neighboring plant, less than twenty miles away, matte had been successfully granulated for some years in the manner described. In the former case, coarse crushing was used, followed by treatment in a ball mill, and a result obtained which was satisfactory to the operator, but at a comparatively high cost. The idea was, to a considerable extent, original, but in comparison with the simpler method which was pursued at the neighboring plant it was an unjustifiable waste.

There exists today a greater realization among engineers of the value of "contacts" and the need of getting the "other fellow's" viewpoint and way of doing things; but there is still room for improvement. Perhaps the best evidence that mining men appreciate the need for this co-operation is shown by the fact that there is a greater tendency toward publicity of mining, milling, and metallurgical methods. More encouragement is offered to engineers to visit other plants, to attend technical meetings wherever operative details are discussed, and to present their views to the technical press. But, as we have before stated, the engineer is by nature inclined to provincialism, and it needs not only the urging of his "boss" but of his fellow engineer as well to pry him from his shell.

On Taking Losses

THERE is no doubt that the consumer will come into his own; a recession in prices has occurred, and in some commodities so rapidly that the rubber balloon called inflation has almost collapsed, as if by a puncture. From a producer's market, conversion has taken place to a buyer's market, and the smooth and exhilarating passage from the valley to the mountain peak of high prices has given way to a rather bumpy and uncomfortable journey to lower levels. The journey up was easy and entailed no worry—the journey down is a different story, and already many business houses have found themselves in a bankrupt condition due to the abrupt turn of affairs.

To ascertain just how metal prices are being affected by deflation, the following table has been prepared, listing a few representative basic agricultural and mineral commodities which reflect the general commodity price level. The table is primarily intended to show how certain of the metallic commodities, such as copper and zinc, are bearing and have borne the brunt of the economic movement downward.

The outstanding feature of the table is the small margin of present copper and zinc prices over 1914 prices. Lead is notably higher, and pig iron is far above its 1914 level. This great trade barometer has shown little inclination to drop, but that other extraordinary price barometer, silver, pointed the way last spring for the general downward movement. The fluctuations in the price of silver have been unusually accurate gages of the general commodity trends, but the peculiar situation in the white metal at the present, whereby the entire United States production is removed from the market, precludes using it as a reliable index.

COMPARATIVE TABLE OF COMMODITY PRICES

	Average 1914	Sept. 1920	Inflation Per Cent
Cotton—Middling, spot, New Orleans, per lb	$0 11¼	$0 28¼	+ 148
Hides—Calfskins, No. 1 Chicago, per lb.	0 21	0 28	+ 33⅓
Wheat—No. 1 Northern Spring, Chicago, per bu	0 97	2 46	+ 154
Wool—Ohio fine delaine, per lb	0 61	1 50	+ 146
Rubber—Plantation, per lb	0 58	0 25	— 57
Hogs—Good merchantable, Chicago, per 100 lb	8 50	16 20	+ 90¾
Petroleum—Kansas-Oklahoma, per bbl.	1 03	3 50	+ 240
Coal—Anthracite stove, f.o.b. mines, per ton.	3 80	8 00	+ 137
Pig Iron—Basic, Pittsburgh, per ton	12 87	50 46	+ 292
Copper—N Y (1910-1914 Av., 0 141 per lb.)	0 136	0 181	+ 33
Lead—N Y (1910-1914 Av., 0 0429 per lb).	0 038	0 082	+ 110
Zinc—St. L. (1910-1914 Av., 0 0567 per lb.)	0 055	0 077	+ 40

Rubber is the only commodity listed which has been deflated below its 1914 level. Although practically all items have exhibited in the last few months a tendency to the normal level, their prices are still markedly high. From hogs to cotton the story is the same—prices have dropped, but are still in the clouds.

For the copper and zinc industry, deflation has meant much financial hardship. Many producers of these metals are taking losses and have been doing so for some time, and there are certain ones whose activities were encouraged by the high price of the metals during the war that are in too weak a position to continue operations. Even the larger corporations are living on the surpluses they were able to accumulate during the war and are undergoing a test of their financial strength. They are progressively becoming leaner—should the process continue ribs will begin to show—and all are receiving a severe lesson in how to take losses. However, as the vice-president of one of our large banks recently pointed out to an editorial conference, the ability to take losses is foreign to the constitution of many organizations, despite the fact that it is part of every-day commercial life to take losses as well as gains.

The business man well schooled in the matter of taking losses and able to judge the market is in an infinitely better position to emerge from this period of deflation with a whole skin than a person so constituted as to be unable to weather a loss. When sugar took its recent tumble we noticed many retailers holding at 20c. when the market was 18c. and less. How much better it would have been to sell at 18c. with a relatively small loss than to have held the product in the face of daily decline, only to unload subsequently with a much greater loss at 16 and 15c.

The same proposition holds true for other business lines, and the shrewdest business acumen will be necessary to weather this period of contraction of prices.

The Artificial Preservation Of Mine Timber

A RECENT inquiry by us in several places indicated that little attention has been paid to the preservation of mine timbers by chemical treatment before placing in the mines. There is field for investigation of this problem, especially in districts where timber is costly. We do not emphasize the additional argument covering the preservation of our forests, for the demands of the

mining industry on the timber supply are relatively not large.

The mine manager, in considering this problem, finds that in many instances the function of mine timber is to withstand an increasing strain, which in the end proves irresistible and crushes the timber long before material decay sets in. Artificial treatment against rot would not increase efficiency in such cases. In the square-set-and-fill type of mining the functions of the timbers are to support the crushing strain of the walls during that period before the fill is complete, and thereafter it is of no importance whether the timber rots or not. In many other stoping operations only a relatively temporary support is economically desirable. Stulls or other forms of timbering are needed only until the ore is extracted, and rot does not progress during that period. Indeed, in many instances it may be said that where timbers last long enough under crushing strain to rot, no timbering is required. Falsely judged timbering is familiar to all of us, as evidenced where the props or stulls have finally rotted away while the walls or roof stands immovable.

Exceptions to this, where the long life of a timber is desirable, are in gangways or travel channels of all kinds, whether shafts, adit tunnels, drifts, permanent crosscuts, manways, or chutes. These may require timbering, often including lagging, when the strain is slight. In such cases the life of the timber under slight strain may be prolonged by guarding against rot.

The careful student of economy will doubtless again discriminate as to the exact conditions. Water acts as a preservative of timber in mines, whereas moist air passing over the wood brings on the growth of fungi which produce the so-called dry rot. It is, finally, in the last condition that the problem of timber preservation may be studied. Probably the timbering of shafts will be the most common example. In instances of this sort the preservative may be creosote or other chemical means, the timber being treated before being placed. A spray of magnesium chloride has been tried and found to be efficacious after the timber is set if it is available for the spray from all sides. Under similar conditions, the thin layer of cement spread by the "Cement Gun" may also be efficient in sealing the wood from the air, which is the rotting agent.

Will the Zinc Industry Respond?

THE American Zinc Institute has taken a practical and commendable step. In the October issue of the *American Zinc Institute Bulletin* appears an article entitled the "Future of the United States Zinc Industry" (reprinted in our issue of Oct. 2), which is a frank discussion of the precarious position of the domestic zinc producers, the underlying causes, the exceptional opportunities facing the industry, and the remedy for existing conditions. The necessity of readjusting the zinc business to meet the changed world economic condition, and the urgent need of meeting lower foreign smelting costs and more efficient working, if the United States is to enter the export market, is properly emphasized, and the suggestion is made—the crux of the article—that "the Institute stands ready to co-operate, through its Developments of Industry Committee, with the zinc manufacturers of the United States in studying, analyzing, charting, diagraming, and putting each and every operation in their plants to a test in the light of world practice, with a view of reducing their zinc costs below those of other nations." Splendid! But does the industry realize fully that this plan, if followed, means abandoning the secretive and narrow-minded policy of some of the zinc producers—a policy well known to the trade—and which at times has led to attempts on the part of competitors to resort to unscrupuleus means in obtaining each other's trade secrets?

It appears that the seed sown by the speech of Charles M. Schwab at the annual 1920 banquet of the A. Z. I., in which this exponent of team work expressed surprise at the attitude of the zinc producers in failing to compare production costs, to their mutual benefit, has taken firm root. Will it grow? Will each member of the institute, by doing his share, help nourish it? For their own good they will do so. Few people besides themselves will benefit by a new tendency on the part of the producers. Should the idea perish, and the wheels of the industry slip back into the old rut, one of the greatest opportunities faced by the United States zinc industry will be lost—foreign trade will be relegated to foreign producers, who will supply that trade, hands down, by lower production costs, if for no other reason.

One of the important and as yet intangible fruits of the war that has come to this country of ours, is the prospect of a highly enlarged foreign trade—an expansion undreamed of a few years ago, but which an increased merchant marine, the havoc and destruction of the war, and enlarged domestic production facilities have brought within our reach. The nation does not know what to make of this international aspect of its markets, and many difficulties must be overcome before a place in export favor and trade can be won. The problem peculiar to the zinc industry can be duplicated in many other lines—not only metallic.

If the zinc producers avail themselves heartily of the timely effort of their representative organization to make co-operation replace isolated endeavor, the announcement of the American Zinc Institute noted will herald a new era, for then no longer will there be, as in pre-war days, a balance of domestic production and consumption, because a new factor, that of foreign trade, will have been introduced. But to compete in the world's zinc markets means a concerted co-operative spirit, which can readily be achieved only by the action proposed. "If they (the producers) will not do so," so the statement goes, "they will simply continue to supply for a time what will eventually prove to have been an incidental European market."

Will the zinc industry change its behavior?

Engineering and Mining Journal Quotations in South America

MR. V. L. HAVENS, editor of *Ingenieria Internacional*, who has just been on an extensive tour of South America, relates that while he was in Buenos Aires a judge requested him to procure a file of *Engineering and Mining Journal* to assist him in making a decision. A dealer in Buenos Aires had purchased tungsten ore from Bolivia, which was shipped from time to time, and there was a legal dispute as to the price. The judge ruled that settlement was to be made according to the *Engineering and Mining Journal* quotations at the time of each shipment. We have, before this, chronicled rulings in the United States courts where our quotations were accepted as standard and a basis for legal decisions, and it is gratifying to note that South American courts have followed the precedent.

WHAT OTHERS THINK

Engineers on the Witness Stand

If a young man may comment critically on the professional and public actions of his elders, I should like to register an impression that I have received from reading the testimony of several prominent engineers when testifying before important governmental bodies. During the spring of 1918, W. R. Ingalls, editor at that time of the *Engineering and Mining Journal*, was requested to come to Washington and express his opinion about the War-Minerals bill before the Committee of Mines of the House of Representatives. The conservative Mr. Ingalls was strongly opposed to any interference by the Government with the sacred law of supply and demand, and spoke at every opportunity against the bill. But the point that I wish to emphasize was the uncoöperative and sarcastic attitude which he assumed toward the poor Congressmen, who scarcely knew enough about mining to ask intelligent questions. The following is a sample of Mr. Ingalls' replies[1]:

Mr. Hamlin was trying to understand the position which arsenic plays as a byproduct of the copper industry. He compared it with the production of oleomargarine in its relation with the cattle business. Mr. Ingalls said: "I wish you would cite some analogy which is more in my line." Mr. Hamlin asked: "It (oleomargarine) is a byproduct of the steer, is it not? Is that not a fact?" Mr. Ingalls: "I do not know about that." Again, the chairman remarked: "The emergency is here. What are we going to do about it?" Mr. Ingalls replied: "What is anybody going to do?"

My impression from reading the testimony was that Mr. Ingalls made things difficult for the committee. Many of his replies were curt, and he apparently showed little tact or willingness to help matters. Now, much has been said recently about the need for engineers mingling in more friendly fashion with people in general, and establishing a respect for their profession among public men. Such an attitude as Mr. Ingalls' seemingly would antagonize more than it would conciliate, and would even arouse resentment about engineers in the minds of Congressmen who were present.

During the past several weeks the editor of the *Mining and Scientific Press*, T. A. Rickard, was called before the Federal Trade Commission in San Francisco to testify about the Minerals Separation companies and the flotation patents. His attitude, as is evident from reading the testimony,[2] was flippant at times, as when he suggested that a man could be born in a stable and yet not be a horse, or as when he remarked that it would be well for the questioning lawyer if he had had as much literary experience as had Mr. Rickard.

The attitude of both Mr. Ingalls and Mr. Rickard contrasts with that of another prominent engineer, the late Hennen Jennings, who testified in 1918 before the Committee on Ways and Means of the House of Representatives in regard to the menace to gold mining. At that time Jennings held a position with the Bureau of Mines, but the service was largely from patriotic motives, as was shown recently by the large fortune left on his death. In reading his testimony[3] one cannot but be impressed by his extraordinary patience in striving to have the Congressmen understand what they were talking about. Mr. Rainey, for instance, appeared to think that the German control of iridium would affect the use of gold as a standard of exchange, because iridium is more precious than gold. Jennings explained tactfully why this was not so, although such a foolish question is difficult to answer tactfully. Another questioner, Mr. Sloan, said of platinum: "It don't burnish like gold, it is not as desirable for the vision as gold, and it yields to certain acids (anything that has lead in it), so that it may be lost in a very short time?" Now, what engineer could reply seriously to that? Yet Jennings said: "It is really more valuable in the arts now for electrical purposes, and chemical purposes, and in laboratories—and it is very useful."

The question is, is it not better for engineers, when called to testify before governmental bodies, to take a tactful and coöperative course than to be sarcastic or flippant?

P. B. MCDONALD.

Engineering in the Tropics

Under "News From Washington" in your issue of Oct. 2 was published a half column of complaint from someone of the "greatest of hardships" in tropical areas, and for that reason "it is becoming difficult to persuade the more experienced [Government?] engineers to undertake such expeditions." This seems to me to be hardly an authoritative statement, and as an impression might be made on some younger engineer contemplating such a trip which would cause him to miss a very interesting and valuable experience, I protest against such rot, for I have had many years of experience and enjoyment of examinations in the tropics.

The animals and insect pests may be avoided, and with them most of the exposure to disease. Any man who does not sleep under a net where there are mosquitoes is exposing himself to malaria, and the net should be the close woven net of the tropics, not the one for use against our larger mosquitos. Proper boots and clothing guard against many other pests and, in bad cases, putting the legs of cots and chairs in cans full of water or kerosene keeps away prowling insects. To drink unboiled and unfiltered water or to eat fresh salads and vegetables in cholera time without thoroughly washing them first is to invite disaster.

Work in the tropics is somewhat of a special character and should not be undertaken by engineers without experience—"tenderfeet," in other words—except under some experienced man, but there is no reason whatever that any engineer in good health, with some regard to sanitation and the well-being of his body, cannot undertake such a trip without misgivings. I speak from an experience embracing paddling through rainy seasons in the Philippines, Venezuela and Nicaragua, and various wanderings all over South America and the rest of the globe.

PACKING WATER BY BURRO TRAIN TO CARNOTITE MINE LOWER SAN MIGUEL RIVER DISTRICT

Carnotite Mining in Southwestern Colorado

Estimated Ore Resources Larger Than at One Time Anticipated—Extensive Use of Diamond Drill for Discovery and Outlining Ore Deposits—High Mining Costs and Difficult Transportation—Experimentation With Milling Methods

BY BLAIR BURWELL
Written for *Engineering and Mining Journal*

PRODUCING radium, vanadium, and uranium during the year 1919 valued in excess of five and one-half millions, and with a total production, including the year 1919, of approximately 29,000 tons of carnotite ore averaging 1.90 per cent U_3O_8 and 5.80 per cent V_2O_5, the carnotite field of southwestern Colorado is at present producing the bulk of the world's radium ore. With little of the publicity that usually attends the initial success of a Western mining camp, the region promises, in the course of a few years, to exceed the gold production of the State of Colorado in the value of its output[1].

Carnotite has been found over a wide area in western Colorado, eastern Utah, and even in northern New Mexico; but at present the bulk of the mining is carried on in the semi-arid basin country in Colorado, along the course of the Dolores River in the west ends of Dolores, San Miguel and Montrose counties, and in the southwest corner of Mesa County. This belt of country is roughly divided into districts whose degree of development is dependent upon transportation facilities, operations at present being centered in the Paradox Valley, Long Park, and Lower San Miguel River districts tributary to Placerville, Col. To the south the Bull Cañon and McIntyre regions and to the north the Mesa Creek, Grubstake, and Gateway districts constitute a vast mineralized area that awaits transportation facilities.

The eight producing camps in the region are operated by the Standard Chemical Co., the Radium Co. of Colorado, and the Radium Luminous Materials Corporation. The Standard Chemical Co. is by far the largest operator, mining approximately 75 per cent of the region's output. The Radium Co. of Colorado produces 10 per cent and the Radium Luminous Materials Corporation 8 per cent of the total production.

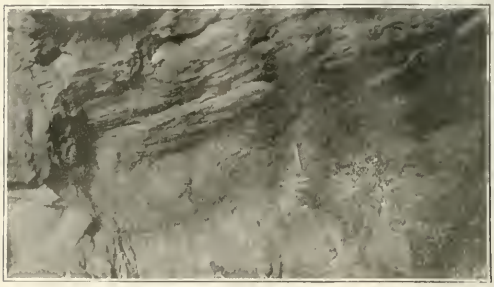
Horizontal and slightly dipping Mesozoic sediments overlie the region. The present drainage has exposed the cliff forming Cutler and Dolores red beds (Permo-Triassic) in the cañons that deeply dissect the region. Above the red beds occurs the prominent La Plata sandstone (Jurassic), with a distinctive white top. Above the La Plata sandstone occurs the carnotite-bearing McElmo series (Jurassic) of sandstones and clays, in which erosion has created a series of rims and flats, capped by the bold cliffs of the so-called "Dakota series of conglomerates" and sandstone. The McElmo formation varies considerably in thickness, but averages about 700 ft.

GEOLOGICAL CHARACTERISTICS

The ore deposits are exceedingly irregular as to size, shape, distribution, and grade of ore. It is believed that the thick series of clays and impure sandstones at the top of the McElmo formation, containing uranium and vanadium minerals widely disseminated, were the source, as traces of these elements are found throughout this member and not in any overlying formation. A downward migration of uranium and vanadium took place in ground waters containing sulphates, with a formation of crystalline gypsum and the precipitation of vanadium and uranium under the influence of carbonaceous matter. In many cases the vanadium was precipitated first, and the uranium subsequently partially replaced the vanadium, thus forming carnotite. In some parts of the district the ready solubility of uranium and vanadium, when exposed by erosion to

[1] In Bulletin 103, U. S. Bureau of Mines, may be found a detailed résumé of mining and other conditions in this area.

ground waters containing carbon dioxide, has resulted in four successive migrations and the formation of four ore levels in favorable precipitating horizons. However, the bulk of the deposits are found in a fairly definite sandstone and clay member of the McElmo formation, about 200 ft. from its base. This member is predominantly æolian in origin and probably represents a sand-dune region where local patches of vegetation and occasional overwhelmed trees, now replaced by ore, followed the pitches and undulations of the dune surface.



CARNOTITE OREBODY, DOLORES CAMP, STANDARD CHEMICAL CO.

CARNOTITE. STOPE IN YELLOW JACKET MINE AT CLUB CAMP, STANDARD CHEMICAL CO.

The orebodies are found throughout this member without any special relation to present cañons, faults or minor dislocations, their distribution being governed by the presence of carbonaceous matter and the lenticular nature of closely associated clay formations.

Two ores are recognized: One, which is the most widely distributed, a black oxide ore of vanadium, carrying a small amount of uranium; and carnotite, which contains a variable proportion of uranium to vanadium, ranging from 1 to 1 for an ore containing 8 to 18 per cent U_3O_8 to 1 to 3 for an average ore containing $1\frac{1}{2}$ per cent U_3O_8. Carnotite frequently carries large amounts of calcium vanadate as well as other variable constituents. This is especially true of deposits found under heavy cover, where in some cases carnotite forms the outer shell of masses of calcium vanadate. In this connection it is interesting to note that calcium vanadate is usually formed from interaction of vanadium solutions and gypsum, and often occurs as a pseudomorph after the latter mineral.

In size the orebodies vary from pockets containing a few hundred pounds to deposits yielding as much as 1,800 tons in exceptional instances. As there are often no indications leading to an orebody, prospecting by jackhammers or by diamond drills is resorted to in advance of mining operations. When the overburden is less than twenty-five feet, the jackhammer is the cheapest method of prospecting, and for this purpose portable gasoline-driven compressors are used. However, as most of the mining operations are being carried on under increasing cover, the diamond drill, with its superior core information, is taking the place of the jackhammer. The practice in prospecting with a diamond drill is to run a line of holes thirty to sixty feet deep and from fifteen to fifty feet apart across the area to be prospected. Upon striking ore or mineralization, drilling is concentrated until the body is roughly defined.

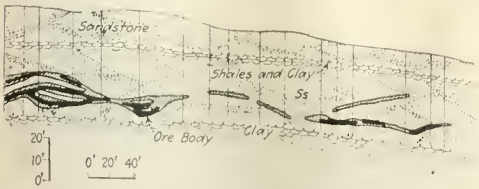
At the Club Camp of the Standard Chemical Co., situated on the west rim of the San Miguel Cañon, four miles above its junction with the Dolores, 45 per cent of the region's total production is being mined from ore located by diamond drills. Three drills are in operation continuously during the drilling season, and 1,000 holes have been completed in an area of approximately 200 acres. The ore is mined from four inclines and four adits, and a total of 10,000 ft. of drifts and crosscuts have been driven.

MILL OF THE STANDARD CHEMICAL CO. ON THE LOWER SAN MIGUEL RIVER

ORE-SORTING CHUTE, CLUB CAMP, STANDARD CHEMICAL CO.

The irregular nature of the orebodies makes it difficult to follow a definite plan of mining, but the usual procedure is to drive haulage drifts below the lowest ore horizon shown by the drills. Raises are then made into the ore, and the waste and ore from stoping are wheeled or shoveled into chutes, from which the cars on the haulage level are loaded. In stoping, what might be termed a room-and-pillar method is followed, the poorer portions of the deposit being left as supports. The waste is stripped from below, and the ore care-

fully shot down on canvas or on a swept floor. In the usual mining operations, from five to ten tons of waste are moved for each ton of ore mined. The roof is usually good, and as a rule little timbering is required, which is fortunate, as the local piñon and cedar are of poor quality. For purposes of mining, the ore is divided into three grades: Low grade, covering up to 0.7 per cent U_3O_8 and usually 2.5 per cent V_2O_5, which is left in the mine or dumped separately for possible future



TYPICAL CROSS-SECTION OF CARNOTITE OREBODY

use; milling ore, assaying from 0.7 to 2 per cent U_3O_8; and high grade, which is carefully mined from the richer portions of the deposit and carries up to 35 per cent U_3O_8.

Hand sorting on the dumps from specially designed sorting chutes is taking the place of the early methods of spreading the ore on a flat rock and picking out the waste. The ore from the mine is dumped into chutes, which discharge upon a breaking platform, where the waste is rejected. The ore then drops into chutes beneath the platform, from which it is sacked and loaded upon wagons for haulage to the company's mill on the San Miguel River, a mile and a half distant and eight hundred feet lower than the mines.

The equipment of the camp consists of a 50-hp. Ingersoll-Rand two-stage compressor, driven by an electric motor with a Foos gas engine in reserve, and a 25-hp. compressor, also motor driven. Power is supplied from the company's hydro-electric plant on the San Miguel River, in which supplementary units consisting of two 200-hp. Fairbanks & Morse "Y" engines have recently been added. A motor-driven triplex pump and pipe line to the camp from the river are installed.

Typical of the smaller camps is the Dolores, also operated by the Standard Chemical Co., and situated on the east rim at the junction of the Dolores and San Miguel rivers. The camp is reached by a trail that climbs five hundred feet above the road, over which water, supplies, and ore are packed by burro trains. Prospecting by drills has not been as intensive as at the Club Camp, but a number of orebodies have been located, and a steady production of about three tons of carnotite ore per day is maintained. Six adits have been driven from the rim, and orebodies located under seventy feet of cover. A Sullivan Compressor with a 25-hp. Foos gas engine has been installed.

From the San Miguel River southward the formations rise with a two-and-a-half-degree slope to the north rim of the Paradox Valley. Here is found a park-like area known as Long Park, in which are the camps of the Radium Co. of Colorado and the Radium Luminous Materials Corporation. Two roads give access, one from the San Miguel River and the other from the Paradox Valley. Long Park has to its credit a total shipping production of about 4,200 tons of carnotite ore averaging 2 per cent U_3O_8, and at present is producing at the rate of about five tons per day when all the camps are in operation. Mining is carried on in open cuts, tunnels and inclines, and jackhammers and diamond drills have been used in prospecting. A number of camps—Saucer Basin, Jack Rabbit, Julian, Outlaw, and the Hieroglyphic—have been established on the sloping country between Long Park and the San Miguel River, but the general scarcity of water in the region has hindered prospecting by drills, and, as a consequence, the majority of the camps lie idle after having exhausted the exposed orebodies.

On the south side of the Paradox Valley a number of claims are located on a faulted segment of the carnotite strata. The most important camps are the Jo Dandy and Monogram, which are owned and operated by the Standard Chemical Co. At the Monogram Camp, reached by trail from the Paradox Valley, mining operations are carried on by hand, due to the difficulties of packing machinery. However, a road to the camp from the Paradox Valley is now under construction.

THE MOTOR TRUCK HAS NOT ENTIRELY REPLACED THE FREIGHTERS' "SIX" HAULING ORE OUT OF THE PARADOX VALLEY

Three adits are worked and several extensive orebodies have been found.

The Jo Dandy claim, early mined by the General Vanadium Co. and declared exhausted, is now a steady producer. Due to broken ground and lack of water, diamond-drill prospecting has not been attempted, but three development adits with connecting crosscuts have opened up a number of orebodies, which are being worked in some cases under 140 ft. of cover. From the operations here, evidence is strong that the carnotite orebodies will be found under the heavier cover of the overlying formations as well as under the shallow overburden of the flats and benches on which operations in the district have so far been confined.

Utilization of low-grade ores is one of the problems in the district. Considerable experimentation is being done with various methods of concentration. The Standard Chemical Co. operates a 50-ton mill on the lower San Miguel River, and at present is the only company concentrating its ores. A simple method of crushing the ore and recovering the mineral in the slimes by a classifier is used. The carnotite and vanadium is friable, slimes readily, and the sand is rejected as tailings. Extensive tests are being made by this company to improve the mechanical details of its process.

Cost

Cost, of course, varies widely with the camp and its condition. The average mining cost per ton is as follows:

Labor—Mining and mucking	$24.35	
Sorting and sacking	2.60	
		$26.95
Powder, fuse and caps		2.25
Other supplies		6.66
Laboratory expense, boarding house loss and general overhead		19.24
Depreciation and replacement on mining equipment		5.22

To which prospecting and transportation charges should be added as follows:

Diamond-drilling prospecting	5.78
Wagoning to Placerville	30.00
Total	$96.10

Where packing is necessary, the cost per ton varies from $3 to $5. Freighting is usually done at the rate of 50c. per ton-mile.

Diamond-drill costs, with the light type of rig used, vary from 80c. to $2 per ft., an average cost being as follows:

Wages	$0.56
Gas and oil	0.05
Repairs	0.10
Depreciation, machine and diamonds	0.07
Overhead and interest	0.16
Total	$0.94

To this must be added the cost of supplying water, which varies from 7c. to 50c. per ft.

The labor supply is scanty and of poor quality, due to the distance of the region from the railroad and the attractions of a town. Miners and muckers are paid $4.50, ore sorters $5.50, and drill runners $7 per shift, with board at $1 per day.

Market

Practically all the operators treat their ore in plants in Denver, or in the East, under secret processes, and market their products as ferrovanadium, ferrouranium, and radium. Owing to the costs involved, little mining is done by the small prospector.

A uranium assay is one on which very few laboratories can check, and the difficulty of reconciling the assays of the miner's inaccurate sample against the pessimistic assay of the buyer causes constant trouble. Ore has changed hands on a basis of $2.75 per lb. of U_3O_8 contained, with a minimum of 2 per cent ore, and some deals are made with a flat rate of 75c. per lb. for vanadium oxide and a sliding scale for the uranium oxide, based on grade.

Excessive transportation costs over roads that are impassable three months of the year comprise one of the limiting factors in the development of the region. Plans are being made to build a road from Naturita to Placerville, the principal shipping point, a distance of forty miles, by the co-operative efforts of the mining interests with state and county aid. This proposed road will follow the course and grade of the San Miguel River, and will greatly stimulate the opening up of the district.

Taking the average tonnage per acre on ground systematically prospected by diamond drills as a basis, and multiplying this into the number of acres in located claims, exclusive of territory mined out, which show equal surface promise of production, and for safety dividing this by five, gives an estimate of 100,000 tons of carnotite ore containing 1.5 per cent UO_3 and 4.5 per cent V_2O_5, which may possibly be termed as the ore resource of the region. The located claims cover only a small fraction of the mineral-bearing territory, and include none of the vast areas where the carnotite sandstone is covered by heavy overburden. Consequently, it is evident that the carnotite region of southwestern Colorado possesses great potentialities for future production.

Chromium Ore in Russia

The most important producers of chromium ore are South Africa (Rhodesia), New Caledonia, Asiatic Turkey, and Russia. Generally speaking, chromium is rarely found in commercial quantities; therefore it has a good market, especially at the present time, when the production of various kinds of steel is increasing. Most of the consuming centers are a great distance from the centers of production. The United States is the most important consuming country, using over 50 per cent of the world's production.

The most important beds of chromium ore in Russia, according to *Commerce Reports*, are found in the Urals (from south to the extreme north), mainly on its eastern slope. All these beds have been only superficially explored; therefore, their supplies cannot be estimated. But the great number of these deposits and their nearness to metallurgical centers give them much importance. It can be expected that a considerable amount of chromium ore will be exported when conditions are again normal and proper methods of exploitation are adopted. Prior to the war the mining of this ore was considered of minor importance in the Urals, but the increasing demand for it may aid in the development of its mines. Chromium ore has been obtained from twenty to thirty small mines, but mostly by primitive methods. In addition to the Urals, chromium ore is also found on the northeastern banks of Lake Goktcha, Government of Erivan, Transcaucasia, where the supply is considered rather large, and also along the Gazimur River, near the Kultuminsk silver-lead mines, Transbaikal region. These beds are all undeveloped.

The Shattuck-Arizona Mill for Concentrating Silver Lead-Carbonate Ores

How a Low-Grade, Truly Oxidized Ore Is Concentrated at a Profit—Exceedingly Fine Crushing Necessary—Table Treatment and Sulphidizing Followed by Flotation Gives Satisfactory Lead Recovery

By Glenn L. Allen
Mill Superintendent, Shattuck Arizona Copper Co.

Written for the *Engineering and Mining Journal*

THE Shattuck-Arizona Copper Co., of Bisbee, Ariz., has probably the most unique and successful plant in operation today for the concentration of silver lead-carbonate ores. The plant and process represent a new departure in the art of dressing low-grade oxidized ores of lead and constitute a real advance in a new and rapidly developing form of metallurgy. This mill is designed for treating a class and grade of ore heretofore considered impossible of profitable treatment.

GLENN L. ALLEN

The most abundant economic mineral in the Shattuck ore is cerussite, or the carbonate of lead. The ore contains in addition silver chloride or cerargyrite, and gold. Sulphate of lead is present but in very small quantities. The major gangue constituents are silica, specular iron, and limonite. Lime, alumina and manganese together represent less than 1 per cent by weight of the ore. The sulphur content is about 0.1 per cent, so the ore is truly oxidized. A typical analysis of the mill feed is Au, 0.06 oz.; Ag, 5 oz.; Pb, 5.3 per cent; Fe, 13 per cent; "insoluble," 71 per cent.

The mill has a nominal capacity of 400 tons in 24 hours and employs both gravity concentration and flotation, as shown on the flow sheet. Flotation of the carbonate mineral depends upon a sulphidizing process wherein the silver chloride and lead carbonate are lightly coated with a film of sulphide and thus made amenable to oil flotation such as is commonly practiced with the natural sulphide minerals. The reagents and chemistry of sulphidizing have been described in detail elsewhere.[1]

Gyratories and Rolls Used for Crushing

Ore from the mine, 800 ft. deep, is delivered to the mill in 50-ton side-dump cars and dumped directly into the coarse-ore bins (1) having 1,000 tons' capacity. Eight Jeffrey stationary steel apron feeders (2) deliver the run-of-mine ore into one movable hopper car which feeds a 20-in. conveyor belt (3). This belt delivers to a 20-in. inclined conveyor belt (4) provided with a magnetic head pulley. The grizzly (5) on which this belt discharges is spaced 1.5-in. between bars and delivers the oversize to a No. 5 Telsmith gyratory crusher (6) set at 1.5-in. opening. The undersize of the grizzly joins the gyratory product at the boot of a Jeffrey continuous bucket-and-chain elevator (7) which discharges over a Hummer electrically vibrated screen (8). This screen is equipped with a heavy wire cloth having a rectangular opening $\frac{5}{8}$ in. wide. The oversize, after passing through the 42 x 16-in. Traylor rolls (9), is returned to the boot of the elevator (7). The undersize of the screen is sent to the fine-ore bins by a Jeffrey 16-in. conveyor belt (10) inclined at 21½ deg. Another conveyor belt (11) drives a self-reversing automatic tripper (11) which beds the crushed ore in either of two 400-ton bins (12). These bins feed the ore by means of six Challenge feeders to 16-in. belts (13 and 14). The next belt (15) passes over automatic weighing scales (16) and delivers the crushed ore into the mill. About 20 per cent of the crusher product will remain on a 3-mesh screen, 75 per cent is coarser than 48 mesh, and 14 per cent will pass a 200-mesh sieve.

About half of the ore is too coarse to concentrate, so it is sent to a Whip-Tap vibrating screen (17) screening dry through a 4-mm. opening. Water is added to the undersize to carry it to primary Butchart tables (18), two operating. These tables produce a finished concentrate. Their tailings are deslimed and dewatered in a 12-in. drag classifier (19) operating at 75 ft. per min., and ground in a 4 x 10-ft. Allis-Chalmers ball tube mill (20) in closed circuit with the drag classifier.

The oversize of the screen (17) is a coarse, hard, siliceous material and is laundered nearly dry directly

[1] "Flotation of Oxidized Ores of Lead," Glenn L. Allen, *Chem. and Met. Engg.*, Vol. 20, No. 4, Feb. 15, 1919, and "Innovations in the Metallurgy of Lead," Lyon and Ralston, 1919, 157, U. S. Bureau of Mines.

THE SHATTUCK ARIZONA MILL, BISBEE, ARIZ.

to the scoops of two 6 x 4½-ft. Marcy mills (21) in closed circuit with 5-ft. Dorr duplex classifiers (22). The overflow of these classifiers joins the overflow of the drag classifier (19) and is laundered to 6-ft. Allen sand cones (23) for sand and slime separation.

Sizing the mill feed through a 4-mm. screen has distinct advantages. It gives the primary tables an enriched feed of finer material, on which they do good work; it eliminates much wear of linoleum and riffles on the tables; and it provides a minus 4-mm. feed for the 4-ft. tube mill. For the 6-ft. Marcy ball mills the screen oversize provides a dry feed of minus ⅝-in. and plus 4-mm. material and allows a high percentage of solids in the mills. Sizing the mill head thus virtually gives a modified two-stage grinding wherein the larger sizes are ground in large diameter mills with larger steel balls and heavy ball charges. The smaller sizes are ground in a smaller diameter mill using small cast balls and cheaper cast liners. This permits of finer grinding, easier and closer control of the size of the material in the overflow of the classifiers, and a higher percentage of solids in the mills. Economy in balls and liners is probably secured and power per ton milled is materially less.

The ball charges in the Marcy mills are replenished with 85 per cent 4-in. and 15 per cent 3-in. forged steel balls. When the occasion offers, the balls smaller than two inches are sorted from Marcy mill charges and fed into the 4-ft. tube mill. This mill is regularly charged with 2-in. and 1.5-in. cast balls, although a small percentage of 3-in. balls appears to give the mill more grinding capacity. The tube mill makes 31 r.p.m. and the ball mills make 25 and 23.5 r.p.m. All are belt driven from a line shaft which is driven by a 220-hp. synchronous motor.

Referring again to the flow sheet, the products of the mills are finely ground and ready for desliming. The tube mill furnishes a product 68 per cent of which is plus 200 mesh and the ball mills grind to 55 per cent through 200 mesh. Both products are combined and deslimed in two 6-ft. Allen cone classifiers (23). The

DISTRIBUTING ORE IN FINE-ORE BINS

overflow of the cones is about 90 per cent through 200 mesh and is laundered to a 34 x 12-ft. Dorr thickener (24) to thicken it for flotation. The underflow of the cones contains about 15 per cent through 200 mesh. This 200-mesh material contains a large percentage of lead carbonate which, though very finely ground, is still granular and is recovered in the subsequent tabling operation.

The two secondary Butchart tables (25) treating the underflow of the Allen cones are similar to the primary tables except that they use shallower riffles and higher speed. The same highly developed system of riffling found most effective with lead carbonate ores is used on both primary and secondary tables. These secondary machines produce a finished concentrate about 30 per cent of which is minus 200 mesh. The tailings are again classified in an Allen cone (23-*A*), and re-treated on Butchart tables mostly for gold and silver because virtually all the lead has been removed in the previous tabling operation. The last two tables (26) produce finished tailings and a middling product that is returned to the tube-mill circuit for regrinding.

Pulp Treated With Sodium Sulphide Previous to Flotation

Virtually all of the slime portion of the minus 200-mesh material, whether primary or resulting from the action of the mills, collects in the thickener (24). The underflow of this thickener is sulphidized with a weak solution of commercial sodium sulphide, then pumped to an agitator (27), where primary oiling takes place. From the agitator the pulp, which is now well sulphidized and oiled, is distrubuted to six K. & K. and two Rork flotation cells (28) arranged in four series of two 10-ft. cells each. The froth concentrate from the first cell in each series is run to the concentrates dewatering plant and the low-grade concentrate from the second cell in each series is returned to the agitator (27). The tailings from the second machine go to waste. The low-grade concentrate from the secondary cells was formerly re-treated in a separate cleaner machine, but this practice was abandoned in favor of returning to the head of the system.

The sodium sulphide used for sulphidizing is the ordinary commercial 60 per cent Na_2S fused in iron drums for convenience in shipping. For convenience the sulphide is dissolved and held in steel storage tanks. The dilute solution is drawn from the tanks and added to the flotation circuit at the rate of about 3 lb. per ton of ore treated by flotation.

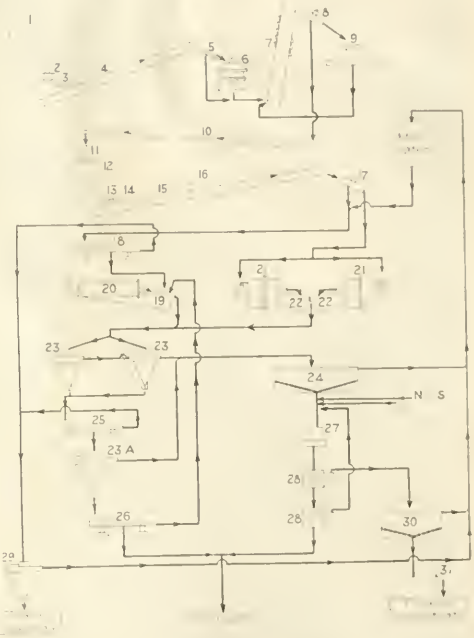
The primary flotation oil consists of a mixture of coal-tar creosote and hardwood creosote. The secondary oil usually consists of a mixture of oil tar, coal creosote, wood creosote and sometimes a little pine or eucalyptus oil.

The usual percentage of solids in the flotation pulp at the head of the primary machines is 30 and at the foot of the secondary machine about 28. Fine grinding seems essential to good flotation work. The usual grinding is all through 100 mesh, 2 per cent on 150 and 90 per cent through 200 mesh.

Flotation Machines Are Particularly Sensitive

The flotation operator controls the work of the flotation machines by varying the amount and kind of oil used, pulp density, pulp-level adjustments, and by varying the amount of sulphide solution used. The work of the machines is very sensitive to changes in the amount of sulphide, so that every precaution is taken to have the flow of the sulphidizing solution under ready and positive control by the operator. Although flotation requires close attention of expert operators, the results obtained are good and remarkably consistent; especially so when it is remembered that the ore treated is entirely oxidized and contains no natural sulphides of the minerals recovered.

All gravity concentrates are combined and laundered to Allen cone classifiers (29) for dewatering. These machines are automatic and entirely satisfactory. The spigot discharge of the cones, containing 21 per cent moisture, is caught in concrete bins having a sand-



THE MILL FLOW SHEET

filter bottom which further reduces the moisture to about 10 per cent. The clear water overflow of the cones is combined with the overflow of the flotation concentrate Dorr thickener and returned to the mill for reuse. The concentrate is shoveled from the bins onto shuttle-type conveyors which load the cars for shipment to the smelter.

Ratio of Concentration Almost 6 to 1

The flotation concentrate is thickened in a 20 x 12-ft. Dorr thickener (30). A 3-in. diaphragm pump ele-

AVERAGE ANALYSES

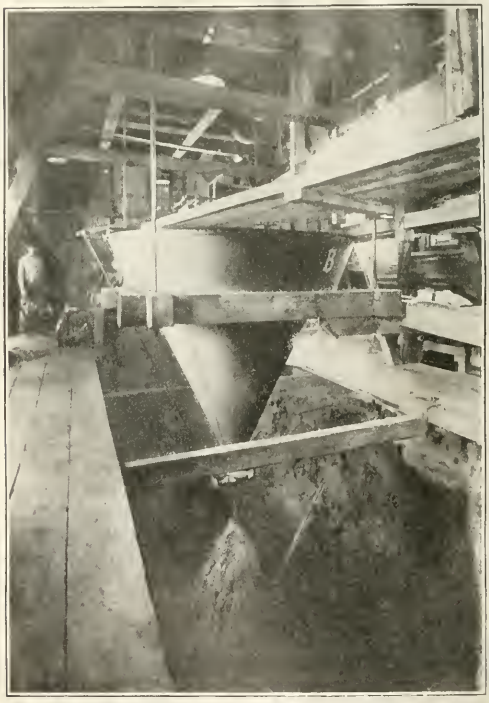
Mill head	0.059	7.22	6.27	13.73	63.99
Concentrate	0.227	28.53	32.92	20.6	22.3
Mill tailings	0.022	2.52	0.43		
Recovery, per cent	69.4	71.3	94.4		

vates the thick pulp underflow of the thickener to the hopper of an 8-ft. diam. x 6-ft. face Oliver filter (31) which discharges its cake into a concrete bin ready for loading.

The metallurgical efficiency of the process is well shown by the average analytical results of a recent period. During this time the ratio of concentration was 5.56 to 1 and the grade of ore was good. The recoveries were calculated from the average assays as noted.

The mill was designed for 400 tons' capacity, but has handled up to 500 tons with but little loss in efficiency. The buildings are all frame structures with corrugated galvanized iron sides and asbestos roofing. The floors and all foundations are of concrete. The mill was built during the World War at war prices at a cost of $275,000. All of the metallurgical work incident to the Shattuck milling enterprise, including the development of the sulphidizing flotation process, was done by Glenn L. Allen, who also designed the mill and supervised its construction.



DEWATERING GRAVITY CONCENTRATES
SHATTUCK ARIZONA MILL

Each shift in the mill consists of two millmen and two helpers, the ball-mill operator having charge of the shift. In addition to the operators the mill organization consists of a superintendent, foreman, clerk, samplers, millwright and mechanics. The crushing, loading of concentrates, unloading of ore, and general surface work requiring unskilled labor is done by Mexicans under the direction of an American surface foreman.

For permission to publish this account I am greatly indebted to L. C. Shattuck, general manager of the Shattuck Arizona Copper Co., to whom acknowledgment is duly accorded.

Difficulties of South African Mines

In spite of the premium on gold, the low-grade gold mines of the Rand (Witwatersrand) are finding it difficult to continue operation, in view of the mounting cost of production, according to Trade Commissioner R. A. Lundquist. For the year 1914 the average working cost for the mines of the Rand district was 17s. 1d. ($4.16) per ton milled. For the first three months of 1920 the costs averaged 25s. 9d. ($6.30 at normal exchange).

The increase in working costs has been due partly to higher wages and partly to the increased cost of all materials, and, in addition, the burden of the mines has been increased through the heavy exchange charges imposed by the banks. At present (May, 1920) the banks charge 8 per cent on London sight drafts.

The closing down of many of the low-grade mines seemed imminent last year, in view of the rising working cost, but the premium on gold temporarily eased the situation. However, the prices of all commodities soon began to rise in even greater proportion than the premium on gold, and, furthermore, while the premium on gold has receded to about 26 per cent, as against a maximum of 44 per cent of a few months ago, the cost of labor and commodities has not been reduced.

Many of the mines, therefore, are now operating at a loss and are faced with the proposition of taking out ore only from the richer sections of the property in order to continue. However, some of the mines are unable to carry on this selective mining, and the Princess, the Jupiter, and the Simmer Deep have already announced that they will close down, and Roodepoort United is considering doing so. At several other mines, the Durban Roodepoort, Deep, the Aurora, the New Goch, and the Luidpaardsvlei Estate, the managements have arranged to cut down the number of white miners to a minimum, and are endeavoring to increase the production per man.

Joint meetings of mine officials and of mine labor leaders are being held to consider the situation, which is regarded locally as serious. Nothing has been announced as to the results of the meetings, but it is reported that the labor leaders and the miners themselves appreciate the gravity of the situation, and that the mine workers' union will take steps toward an increased production per man.

The closing down of these low-grade mines will to a considerable extent affect the mining machinery and materials market, but the effect will be lessened by the increased activity on the East Rand, where new mines are being developed. However, the idle equipment of the mines being shut down will be available for the mines coming into development, and this will reduce the demand for any equipment on the East Rand to no small extent. The general economic unsettlement due to the closing down of mines will also, no doubt, react seriously upon the importation of American goods generally.

State Aid for Australian Lead Producers

A relatively large proportion of the Australian production of lead, zinc, and silver is produced by the various mines at Broken Hill, New South Wales, all of which is handled through the State of South Australia, the lead and zinc being treated at Port Pirie by a producers' association which owns the reduction plant there.

Revival of the Colquechaca Silver-Tin District, In Bolivia

Ancient Mines in the Andes Mountains Which Have Yielded High-Grade Silver and Tin Ore From Narrow Fissure Veins in Igneous Rocks Are Being Reworked —Present Operations Contemplate Using Flotation To Recover Both Metals

BY JOSEPH T. SINGEWALD, JR.*

Written for *Engineering and Mining Journal*

DESPITE the well-known productivity and importance of the Colquechaca district in years gone by, geological and mining literature on the region is particularly meager. The only readily accessible account is a résumé by R. Peele, Jr., published in the *Engineering and Mining Journal* in 1894, of a private report made by him in 1892. This deals primarily with the operating conditions and treatment of the ores at that period, and was written at a time when only the silver ores were known. Since its publication, the district has passed through a long period of desuetude in silver mining, toward the close of which there was a brief boom in tin mining. It is now in the early stages of what promises to be an important revival in both silver and tin mining. The time seems opportune, therefore, to give an account of the main features of the ore deposits as they are known today and of the new operations that are being initiated.

The close association of silver and tin ores in many of the Bolivian veins has attracted much interest for a number of years. At the beginning of tin mining in Bolivia, there was considerable discussion as to the conformity or non-conformity of the Bolivian tin veins to the normal tin-vein type of Europe. Only in recent years has the completion of the Bolivian railroads made the Bolivian mining districts reasonably accessible, so that the participants in this early discussion were usually familiar with a restricted area only, and were prone to generalize on the basis of what they saw in that area. Thus, some observed no essential difference between the Bolivian tin ores and the European; others could discover no essential points of similarity. Attempts were made also by some investigators to differentiate two distinct types of deposits with different areal distribution.

It has been my privilege in the course of several trips to South America in the last five years to visit almost all of the important mining districts of the Bolivian Andes. My observations indicate with increasing certainty that the mineralization of that range is a genetic unit, and that its exceedingly diverse expressions at different points are only local facies of one general mineralization. At some points, or even over certain large areas, a typical tin mineralization has taken place. As those deposits have been more closely observed, telltale traces of the silver or bismuth minerals often have been noted. At other points, the silver and tin minerals or the bismuth and tin minerals are essential constituents of the ores and are so intimately intermingled as to leave no doubt of their genetic unity. On the other hand, in the light of present scant knowledge concerning them, there are other places where the silver mineralization does not seem to have been accompanied by the deposition of tin or bismuth ores, and where, consequently, a distinct and unrelated mineralization may have occurred.

When consideration is accorded the fact that many of the old silver districts of Bolivia are today producers of silver and tin, with the latter in many instances of predominating importance, and that most of the apparently tin-free silver districts are those that have been quite dormant since the inception of tin mining in Bolivia, suspicions are aroused, and the investigator wonders whether a reopening of those old mines would not disclose tin ores, just as has happened in such districts as Oruro and Potosi. If such were not the case, why should not a tin-free silver mineralization repre-

*George Huntington Williams Memorial Publication No. 4.

sent one extreme, just as the silver-free tin mineralization of such a region as the Quimsa Cruz range represents the other, of a single metallogenic province?

Colquechaca has seemed to stand out as a representative of the tin-free silver type, noted particularly for its great accumulations of the ruby silver ores. It is true that a tin production has been reported from the Colquechaca district for some years, but nothing was known concerning the relation of the tin veins to the old silver veins, and it is probable that the tin ores may have come from other veins in the vicinity, as it is known that such tin districts as Ocuri and Maragua were not far distant. A visit of several days at Colquechaca proved, however, that the Colquechaca veins are both silver-bearing and tin-bearing, and that beyond question they belong to the mixed type of silver-tin ores so abundantly represented in Bolivia.

Colquechaca lies at an elevation of 14,000 ft. at the fork of a deep valley cut into the southern flanks of a group of peaks which rise to an elevation of 2,800 ft. above the city. It is most conveniently reached from Chalapata, a station on the Antofagasta & Bolivia Ry., between Uyuni and Oruro, with which it is connected by a road eighty miles long, which is now traversable by

FIG. 2. SKETCH MAP OF COLQUECHACA MINING DISTRICT, SHOWING THE LOCATION OF THE PRINCIPAL MINES

automobile. Colquechaca lies a little north of east of Challapata. Sucre is situated about sixty miles to the southeast, and Potosi about one hundred miles in a direction east of south.

The great antiquity of the Colquechaca mines is attested by the fact that the San Bartolomé tunnel, the longest in the district, was begun before 1700. The city of Colquechaca is the third mining town that has sprung up on the flanks of this group of mineralized mountains. In the canyon between Santa Barbara and Flamenca peaks are the ruins of the completely abandoned town of Anconaza, about which are evidences of ancient workings of considerable extent. South of the Cerro Gata, in the canyon between Animas and San Matias peaks, are extensive ruins of the town of Aullagas, which, except for the presence of a few Indian families, is likewise abandoned. About thirty years ago, Colquechaca had a population of 8,000. A period of decline to almost extinction of the mining industry then set in, so that by 1900 the population of the town had dwindled to a few hundreds, and in 1915 it was mainly a town of roofless walls.

With the increasing activity in the Bolivian mining industry incident to the rising prices of silver and tin during the war, a revival set in at Colquechaca, and the district recently has been the scene of more active operations. The former population is returning in constantly increasing numbers and the bare dobe and rock walls along street after street are again being roofed and converted into habitable houses. The town now presents the curious spectacle of a central inhabited part with newly whitewashed houses surrounded by outlying sections of abandoned walls.

General Features of the District

The prevailing rocks for miles around Colquechaca are a great series of red sandstones, quartzites, and shales, which Steinmann has called the Puca sandstone, from the Quecha word for red. The series is generally made up of three fairly distinct divisions—a lower consisting of red sandstones; a middle, made up of red clays, with which are often associated salt and gypsum; and an upper, which, like the lower, is prevailingly sandy. These beds are for the most part unfossiliferous. Near the base of the shaly division, however, are often fossiliferous limestones, which near Miraflores and between Miraflores and Potosi have yielded Cretaceous forms.

Colquechaca is on the contact between these red sediments and a mass of igneous rock which constitutes the group of peaks in the vicinity of the town on the north, and which has been intruded into and through the Cretaceous strata. The igneous rock is a rhyolite which ranges in texture from a distinctly porphyritic rock, in which there are large phenocrysts up to an inch in diameter, to a rock with very small phenocrysts. The phenocrysts are quartz, feldspar, and hornblende. The quartz crystals are generally less than $\frac{1}{8}$ in. in diameter and quite abundant. The feldspar is usually a glassy orthoclase, and frequently shows zonal structure. Many individuals are over $\frac{1}{4}$ in. in diameter and some are as much as an inch, but most of them are smaller. In some places the rock contains patches of radiating acicular crystals of tourmaline, many of which have pyrite in the center. Often the tourmaline in part replaces the feldspar phenocrysts. Small fractures are also filled with veinlets of tourmaline, but the mineral was not seen in the ores. Locally there is an abundance of inclusions of fragments of sedimentary rocks, chiefly sandstones and quartzites, in the form of rounded pebbles.

All of the workable veins of the Colquechaca district lie within the igneous rock. The most famous and productive has been the vein which to the southeast is called the Embudo and to the northwest the Gallofa. It has been worked through the San Bartolomé, Amigos, Huainacucho, Progreso, Begoña, and other tunnels, almost continuously along the strike for a distance of two miles, and over a vertical range of 2,000 ft. The outcrop of the vein runs in the direction N. 35 deg. to 60 deg. W. near the crest of the mountain on the south side, from the pass between Flamenca and San Matias

FIG. 3. LOOKING DOWN THE COLQUECHACA VALLEY OVER THE LOWER PART OF THE CITY
The rocks are strata of the Puca sandstone series

peaks. Its dip is usually steep to the north, but equally steep reverse dips are found. It has yielded only silver ores, and has been especially noteworthy for phenomenally high-grade oreshoots.

The vein is generally a well-defined but narrow fissure filling, rarely over four to eight inches wide. Over most of its extent it consists of low-grade or barren filling, frequently gouge and sphalerite. Irregularly distributed are the small shoots of rich silver ores. The most important ore mineral has been ruby silver. Associated with it, particularly in druses, is wire silver. Argentite and tetrahedrite are also of common occurrence. The most abundant sulphide is sphalerite. Galena is found only locally, and iron sulphides are not abundant. The principal gangue mineral is quartz.

Descubridora Vein Now Worked for Tin

About 300 ft. northwest and parallel to the Embudo vein is the Descubridora, which has also produced large quantities of silver but is now worked primarily for tin. The southeast end of the vein lies on the north side of the crest of the mountain, but toward the northwest it crosses to the south side. It was not encountered in the San Bartolomé tunnel, but was an important vein in the mines west of it as far as the Manjon tunnel. The average width of the vein is eight to sixteen inches, but it attains to widths of three feet or more. On the other hand, it frequently splits up into small stringers to such an extent as to be unworkable. Most of the ore has a massive and compact texture, but locally it is drusy and crustified, and has a banded structure. The gangue minerals are quartz and a little siderite. Sphalerite is the most abundant ore mineral, with cassiterite second.

Much more pyrite occurs than in the Embudo-Gallofa vein, and also a little chalcopyrite and pyrrhotite.

Galena is found in sufficient abundance locally as to necessitate sorting it out of the tin ores to be concentrated. The average grade of the hand-sorted ores is about 15 oz. of silver and 9 to 18 per cent tin. Small pockets and shoots of rich silver ore are frequently encountered that yield a half ton to a ton of ore, with several ounces in silver. The principal silver mineral is the ruby silver. There is considerable similarity, therefore, between the Embudo-Gallofa and the Descubridora veins. The differences are that the Descubridora sliver shoots are not as abundant or large as those of the other vein, and there has been sufficient deposition of tin in the Descubridora to bridge over the gaps between the silver shoots with workable ore and thus make the vein important as a producer of tin ore.

Another Producing Vein

In the Begoña and Progreso tunnels a vein is encountered parallel to the Gallofa but at a distance of 1,000 ft. to the northeast, which is called the San Carlos. In the absence of a vein in the expected position of the Descubridora, the San Carlos is believed by some to be the northwestward continuation of the Descubridora. The filling of the vein is mineralogically the same as

FIG. 4. ONE OF THE REHABILITATED STREETS OF COLQUECHACA. ANIMAS PEAK AT THE HEAD OF THE STREET. HERMOSO PEAK IN THE BACKGROUND

that of the latter vein, but sphalerite and quartz are more abundant, cassiterite is less abundant, and the silver shoots are lacking. Only a small part of the vein is rich enough in cassiterite to yield workable ore under existing conditions.

The Embudo-Gallofa, Descubridora, and San Carlos are the only veins producing at present, but a number of other veins have been worked, some for silver, others for tin, and some for both metals, several of which have yielded large productions. Prospecting is being carried on, and doubtless other productive veins will be developed. By far the most important part of the district has been the side of the mountains facing Colquechaca. On the east side much work has also been done, and considerable production has come from the mines on that side. The north side of the mountains has been but little worked, and the west side still less.

Aliada Mine Formerly Prolific

In Gato and San Matias peaks, on the east side, is the Aliada mine, now idle, but which about 1910 was producing at the rate of 100 tons of 60 per cent concentrates annually from hand-sorted ore carrying 25 per cent tin. The value of the tin production of this mine is said to have aggregated over two million dollars, a figure that is doubtless exaggerated. Lower down in the same canyon in which the Aliada mine is situated, is the Gran Poder mine, which is not now being worked, on account of the complexity of the ore. The Lora is the principal vein in this mine. The tin tenor is said to be high, but the vein is only four inches wide, and carries so much galena that the production of clean tin concentrates is difficult. The Rosario vein, at right angles to the Lora, carries less galena but more sphalerite. The Porfyr vein, northeast of the Gran Poder mine, is being developed by Simon I. Patiño. As thus far opened up and developed it is a narrow vein with highly pyritic ore.

The wall rock of the Colquechaca veins has undergone considerable alteration. For some distance from the vein, it is soft and kaolinic in appearance and impregnated with pyrite. At the vein walls, it is often typical gouge, and shows evidence of mashing, which may warrantably be assumed to be due to slipping along the fractures.

Tin Ore Concentrated Locally in Present Operations

The production of the district comes from the Huainacucho, Santa Teresa, Manjon, and the Gallofa mines. The position of the Huainacucho mine is shown on the sketch map. It is the property of the German commercial firm of Moerch, Bauer y Compañia. Rafael C. Campos and Luis Calvo have operated the mine under lease since early in 1919. Up to August of that year only ten tons of high-grade tin ore had been shipped, the rest of the production being stored at the mine awaiting facilities for milling. At that time they leased La Cruzada mill, situated in the valley a short distance below Colquechaca. The production last year was at the rate of 400 tons of crude ore per month, all from the Descubridora vein.

The Santa Teresa mine is owned and operated by the Gumucio Brothers, and has been worked about three years. The workings are likewise on the Descubridora vein, and lie to the east of and above those of the Huainacucho mine. During the latter part of 1919, the daily production had been brought up to 1½ tons of high-grade ore and 4½ tons of concentrates. The company has rented a small mill at the lower end of the city, to which the ore is brought down on llamas. After a preliminary hand-sorting at the mine, the tin content of the ore sent to the mill is 18 per cent. Concentration with hand jigs makes a preliminary product of 35 per cent tin. This is ground in a Krupp ball mill and classified into three sizes, 2-4 mm., 1-2 mm., and less than 1 mm. The two coarser sizes are concentrated on jigs. The smallest goes to a spitzkasten, the settlings of which are treated on a Wilfley table and the overflow in buddles. The jigs and table make a pyritic middling, which is roasted and reground in a buhr mill, and then reconcentrated. The final concentrate contains 62 to 65 per cent tin. The silver content is such that the concentrates carry 12 oz., the middling 60 oz. and the tailings 20 to 24 oz.

The Gallofa Consolidada is a Bolivian stock company, with headquarters at Sucre. It is operating the Manjon mine and the Gallofa mine, which includes the Progreso and Begoña tunnels. In the Manjon mine only the

Descubridora vein is being worked, and operations are on a small scale. The San Carlos vein is being worked in the Begoña tunnel, and the ore is treated in a small mill equipped with hand jigs and buddles at the Progreso tunnel. The output is 30 to 40 tons of concentrates monthly. In the Progreso tunnel the high-grade silver shoots of the Gallofa vein are being worked. The company is erecting a new mill of 40 tons' capacity a quarter mile below the tunnel to treat the lower-grade silver-tin ores. The ore will pass from a crusher to ten stamps with ⅜-in. screen. The stamp pulp will go to a hindered settling hydraulic classifier. The overflow from this will continue to a Dorr thickener, and the settlings to trommel, which will make a more than 20-mesh product and a less than 20-mesh product. The greater than 20-mesh size will be concentrated in a four-compartment jig, the first two compartments making tin concentrates, the last two middlings, and the tailings being discarded. The less than 20-mesh size will be concentrated on a Deister table. The jig and table middlings will be reground in a Hardinge mill. This mill pulp and the settlings of the Dorr thickener will be concentrated in a Kraut and Kolberg flotation machine. The flotation tailings will be concentrated on Deister and Overstrom tables, roasted, and reconcentrated on slime tables. The ore to be concentrated in this mill is estimated to contain 45 oz. of silver and 5 per cent tin. Flotation experiments with it yielded a 360-oz. concentrate.

The most productive part of the Colquechaca district in the past was that of the Compañía Colquechaca Aullagas de Bolivia, which last year was acquired by Simon I. Patiño, the owner of the Uncia, Huanuni, and other mines in Bolivia. This property is also known as La Unificada, because it represents the consolidation of the workings of the Flamenca, San Bartolomé, Amigos, and other tunnels in their vicinity. It is the purpose of Patiño to reopen these old mines and push their development.

The possibilities of this plan for the rehabilitation of the mining industry of Colquechaca can be grasped by a consideration of a few production figures given in Peele's report. In the twenty-seven years subsequent to 1865, the San Bartolomé tunnel produced $21,000,000 in silver, and from 1884 to 1892 the Amigos tunnel produced $5,700,000. During the first ten months after the consolidation of the properties in 1892, the combined output was 809,000 oz. of silver.

Colquechaca District Has a Bright Future

From the foregoing description, it is evident that the veins of the Colquechaca district are persistent laterally and vertically, but are very narrow. Mineralization is not uniform, but, on the contrary, is very irregular. The veins are characterized by the occurrence of rich oreshoots, between which the grade of the ore in low. This is particularly true of the silver veins with little or no tin content, in which the mineralization is practically devoid of values between the oreshoots. It is true to a less extent in the veins in which the value of the tin exceeds that of the silver

In the days when only the silver ores were worked, the existence of the mines was precarious. A company was prosperous for a period; then followed a long barren spell, against which resources had not been sufficiently conserved, and a collapse followed. Now that the tin ores are also being utilized, and provision can be made for the recovery of both tin and silver values of the mixed ores, that state of affairs has been considerably ameliorated. Nevertheless, the nature of the Colquechaca veins is such that their successful exploitation can be accomplished only by companies with a far-sighted policy and adequate resources, working on a program that carries them over the lean periods as well as through seasons of prosperity. The performance of these veins in the past, and the developments of the present, make reasonably sure a successful outcome with such a program. The Patiño management, especially, is capable of and has the resources for operating on such a basis, so that Colquechaca should soon again take high rank among Bolivia's mining districts.

U. S. Quicksilver Production Declined in the Second Quarter of 1920

From April 1 to June 30, 1920, inclusive, 3,685 flasks of quicksilver of 75 lb. net was produced in the United States, according to F. L. Ransome, of the U. S. Geological Survey, who obtained the figures from the producers. This is 1,214 flasks less than was produced in the first quarter of 1920 and 255 flasks less than was produced in the second quarter of 1919. Only thirteen mines were reported as productive—eight in California, one in Nevada, one in Oregon, and three in Texas. California produced 2,704 flasks, Texas 952 flasks, and Nevada and Oregon together 29 flasks.

The chief cause of the decrease in production during the second quarter was the destruction by fire on June 20 of the reduction plant of the New Idria mine, in California, and the consequent loss of quicksilver already reduced during the earlier part of that month. Because of this misfortune the production for the third quarter of 1920 will probably be still smaller than that for the second quarter. Reconstruction is in progress, and it was thought that the plant would be in partial operation in August or September of this year. Other causes that contributed to the decrease in production were a shortage of efficient labor and a reduction in the average grade of the ore.

At a time when initiative in the quicksilver-mining industry is at a low ebb and the tendency is rather to abandon enterprises already begun than to embark on new ones, it is of interest to note that the former productive Klau mine, in San Luis Obispo County, Cal., has been reopened under capable management as the Carson mine, and that its 50-ton furnace has been put in repair, so that the mine is likely to become a considerable producer.

The Styrian Iron Industry

A few weeks ago, according to *The Ironmonger*, the last blast furnace of the Alpine Montan Co., in Styria, was blown out. Styrian ore, the chief product of the country, can no longer be smelted locally, because not enough coke is coming from Czecho-Slovakia. The Styrian iron and metal industry is now entirely dependent upon foreign iron, and Czecho-Slovakia, taking advantage of the situation, recently raised its prices of iron for delivery in Austria by 16,000 Austrian kronen per ton, and a further increase is under consideration. The Austrian government has been asked to take speedy measures to obtain supplies of fuel, to avert the complete ruin of the Styrian iron industry.

The Declining Quicksilver Production

Drop in United States Output of Mercury Especially Marked During the Summer—World Production Also Has Been Declining, but Present Prices Make It Difficult To Operate Domestic Properties Profitably

By Murray Innes
Written for *Engineering and Mining Journal*

THE Geological Survey has estimated the United States quicksilver production for the first quarter of 1920 at 4,900 flasks. The estimate for the second quarter has not yet been published, but cannot fully reflect the decline in production during June, July, and August, which has been so rapid as to indicate a collapse of the industry. Two-thirds of the mines that were producing in the first quarter are no longer operating. The extensive works of the New Idria mine were destroyed by fire in June, and the California output has declined to 300 flasks monthly. The total United States monthly production is now less than 700 flasks, and though the New Idria Co. will gradually rebuild, it is doubtful if the United States output for the second half of the year will average 1,000 flasks monthly, which compares with 3,000 flasks per month during 1917 and 1918.

A Comparison of Cost of Production and Prices

The cost of mining and reduction has steadily increased. As a rule twelve to fifteen tons of ore are mined and roasted to produce a flask of quicksilver, and thus any increased cost per ton is multiplied in like ratio.

The present New York price (about $75) compares with $105 to $125 per flask during 1917 and 1918, and therefore, though the average cost of production has doubtless increased at least $25 per flask, the market price has declined even more, and as a result there is now no incentive to operate even a well-developed and well-equipped property.

During 1919 the average selling price was somewhat higher, and the average costs of labor, fuel, and other items, considerably lower than at present, but even under the conditions then prevailing the profit of the largest producer on a production of 7,400 flasks amounted to only $1,051.81, or about 15c. per flask.

The New York market has lately been depressed by the dumping of Italian metal, made possible because of exchange conditions, and also from the dumping of re-sale metal from Japan, where a financial crisis has prevailed, and even from the dumping of the small stock held by our Navy Department, amounting to about 1,400 flasks. It would seem (at least to the quicksilver miner) that there was no urgent need of sacrificing this metal at $25 per flask below what it cost the Government.

Prior to the war the average quicksilver consumption in this country was about 2,500 flasks monthly, and at present the country is producing about a quarter of this amount, with small likelihood of permanent increase.

The Attitude of Interested Parties

The position of the miner is simple. He can no longer operate. The Western metal miner is an optimist, but there is usually a limit to the period in which he can operate his mine as a charitable institution.

The position of the quicksilver importer is also simple. The smaller the domestic production, the larger the imports and the larger his business and profits. In other words, he profits by the death of the domestic industry.

The position of the manufacturers of explosives and mercurials and the other larger consumers, who have always the lion's share of profits from quicksilver, has been, I think, rather shortsighted and for the following reasons:

Notwithstanding war demand, the quicksilver production of Europe has also shown a considerable decline during the last few years. For example, the annual production of Spain, including the great Almaden mine, was 23,300 flasks in 1916, 24,300 flasks in 1917, and 16,600 flasks in 1918, or an average of 21,000 flasks for this three-year period. This compares with an average of over 40,000 flasks prior to 1912. As far as figures are available, the production of Italy and Austria also shows a decline, with mine operation becoming increasingly difficult, owing to strikes and Bolshevist activities.

As compared with the United States production of 1917 and 1918, our output at the present rate will show an annual decrease greater than the entire output of Spain, and the United States consumption on a pre-war basis would absorb not only our present output but also the entire output of Spain.

The Question of the Tariff

With declining world production, it might therefore profit our large consumers, now that the domestic production is in collapse, to look about and insure their future requirements. Domestic stocks are negligible, and as most of the European supply is in strong hands, there is a possibility that those who control it may some day decide to do much manufacturing in Europe. If this should happen, the ultimate consumer will doubtless pay through the nose.

The production of quicksilver is not a large business, and the few engaged in it have no influence; but it is a fairly useful metal to have in the country, and when war comes it is an essential. Possibly in a year or two years some old-fashioned protectionist may suggest that it might do no harm to keep the industry alive. Right then we will doubtless hear from the importers and also from the assorted blatherskites who will raise a howl about taxation for the benefit of a few wealthy mine owners. It is to be hoped that the consumers will, if only for their own benefit, take a broader view and show more of the spirit of live and let live than they have shown in the past.

[Since this article was written the quicksilver production estimate of the U. S. Geological Survey for the second quarter of 1920 has been received and will be found on page 767 of this issue of *Engineering and Mining Journal*. It confirms the decline in United States quicksilver production mentioned in Mr. Innes' paper.—Editor.]

Mining Engineers of Note

Pope Yeatman

POPE YEATMAN told a story on himself at a dinner given by the Mining and Metallurgical Society of America, on March 21, 1918, at which time he was presented with the Gold Medal of the society for Distinguished Service in the Administration of Mines. The story was to the effect that he had admitted to his young son that he had never killed a bear, an elk, or a man. His son thoughtfully replied, "Too bad; you're not much of a hero." From this we gather that we may be judged by different standards. Although Mr. Yeatman may receive the same opinion from his fellow engineers with regard to his heroic qualities in the use of firearms, there is little doubt as to how he stands professionally and in the esteem of his colleagues. Mr. Yeatman was born in St. Louis on Aug. 3, 1861. After receiving his degree from Washington University in 1883, he was first employed at the plant of the St. Genevive Copper Co., near St. Louis. From there he went to New Mexico, Mexico, and then Colorado, where he engaged in mining. Later he accepted the position of superintendent of the mine, mill and smelter of the Doe River Mines, in Missouri, and in 1891 took charge of the properties of the Empire Zinc. Co., at Joplin, Mo. In 1895 he went to South Africa, where he remained until 1904. During this time he was successively assistant consulting engineer for the Consolidated Gold Fields, general manager of the Robinson Deep mine and later of the Simmer and Jack mine, and finally consulting engineer and general manager of the Ranfontein Estates Gold Mining Co., Ltd. The nine years spent in the Transvaal by Mr. Yeatman were eventful ones in the history of the gold-mining industry of that country, and his part of the development during that time was most notable.

POPE YEATMAN

Returning to this country, Mr. Yeatman entered consulting work. This was at a time when the copper industry was undergoing a change and methods of mining and treating low-grade ores were receiving attention. In his administration of the Nevada Consolidated Copper Co. he demonstrated that excellent ability for organization which also characterized his work at the Braden and Chuquicamata mines, in Chile.

When the Great War arrived, Yeatman was one of the first engineers to offer his services to his country, for he comes of a military family; and he took steps to enter the Engineering Corps of the Army. At about that time Bernard Baruch was organizing and developing the War Industry Board into a great system which eventually kept track of and controlled the industries of the whole country. He got J. Leonard Replogle, head of the Replogle Steel Co., to come to Washington and take charge of iron and steel problems, and then he cast around for a suitable head for his division to take charge of the other metals — copper, lead, zinc, and such trifles. Yeatman was the man who seemed best fitted, and Baruch asked him to contribute his services. Mr. Yeatman explained to Baruch that he wanted to enter the army, but would go where duty called him, although a desk at wartime did not at first impression arouse in him much enthusiasm. Baruch thereupon had Yeatman appointed a Lieutenant-Colonel of Engineers in order to try to please his new division chief, but when Yeatman heard of it he refused the commission and said he had least of all the ambition to be a swivel-chair officer. So it is *not* Colonel Yeatman, but we love him the better for it. His war record, as it was, left nothing to be desired in the way of being the right man on a big war job.

It is such a record in a Government position, combined with his signal achievements as an engineer, organizer, and operator, that has led many of the mining fraternity throughout the country to hope for a man of his type to head the Bureau of Mines. Those who have worked with him testify to the breadth of his knowledge of details as well as principles, whether it was the detail of sampling procedure or the geology of such a complicated problem as Chuquicamata.

Among the societies in which Mr. Yeatman is a member are the A. I. M. E., the A. S. C. E., the Institute of Mining and Metallurgy, and the Mining and Metallurgical Society of America.

By The Way

Too Much Variety

"These days, m'son," said Cap'n Dick, "a man mus' naw jus' w'ot 'e's doin', an' it does'nt 'ardly do to confuse 'is work so that 'e becomes one o' these 'ere jack-o'-h'all-trades. This is tha h'age o' specialization, they do say, an' tha business o' tryin' to do too many things at once does'nt work h'out some'ow. Sometimes a chap gets h'all h'upset h'over tryin' to suit h'everybody. Take tha case o' Jan Williams, tha blacksmith. W'y, 'e were a good blacksmith too, but they bloody near spoiled 'e w'en they tried to give 'im somethin' to do besides blacksmithin'. 'Ere's 'ow it 'appened. The super, one day, h'asks Jan to keep track o' tha time 'e puts on h'each job in tha shop so that they could make tha right h'appropriations in tha h'office. So Jan said 'e would, but, dam-me, tha more 'e tries tha worse 'e gets tha charges mixed h'up. Tha chief clerk kep' after 'im to get tha h'accounts straight, but Jan wuz poor at figgers, so 'e could 'ardly make 'ead or tail out o' they. Finally one day Jan gets mad, an' after swearin' aroun' 'e sez to tha chief clerk, ''Ere, you, be I a blacksmith or be I a bloody book-keeper?'—an', dos't thee know, m'son, they let 'im alone h'after that for 'e come mighty near quittin'."

Reviews of 1920

Those who hold that engineers should take a more active interest in what is going on about them, aside from their own particular work, will be glad to learn that the U. S. Bureau of Standards has recently issued a paper on the subject of "Adjustment of Parabolic and Linear Curves to Observations Taken at Equal Intervals of the Independent Variable." It is high time that our scientists turned their attention to the national game, the ins and outs of which are readily seen to be susceptible of much investigation. Such manifestation of interest will also serve to awaken in the esoteric a keener appreciation of its finer points and, on the other hand, will perhaps imbue those of the exoteric class with a desire to become esoteric, thus tending to raise standards throughout the country. This is where the Bureau comes in. Lack of space unfortunately prevents quotations at length from this admirable paper. Let it suffice that it starts out with "$Y = A + BX$," to which we echo "Y indeed," and after a reference or so to the "Theory of Errors," that umpire's handbook, arrives at the expression $Y = 0.0285 + 0.009141\ X$. Here is the answer, then, and the reason why only a few become proficient in curves is readily apparent. We have but one criticism to offer, and that is that the author spends too much time on "least squares." Some authorities hold that this should be "diamonds" rather than squares, and there are some who go even further and sweepingly declare that there is nothing square about the thing at all. The pamphlet costs but five cents and may be obtained from the Superintendent of Documents at Washington.

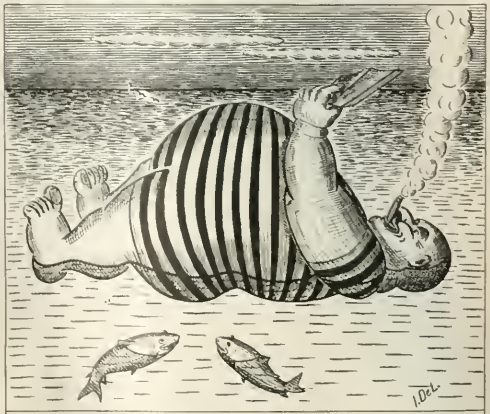
Another paper that is worthy of more than passing comment is Professional Paper 128-A of the U. S. Geological Survey, entitled "The Fauna of the Cannonball Marine Member of the Lance Formation." It is one of the shorter contributions to general geology, being only sixty-six two-column pages in length. The title has a post-bellum sound, but this is merely an accident, the article being a discussion of all the known animal fossils from the Cannonball member. The fauna is strictly marine. Among the good things which all will be glad to hear about are the Solemya bilix White, the Fasciolaria (Mesorhytis) dakotaensis Stanton, and the Otodus obliquus Agassiz and their numerous faunal relations. Those interested should apply to the Director for a copy of this pamphlet.

A Consulting Food Expert

"Dr. Beef, the well-known lady authority on food values, has accepted an invitation from the Rand Mines, Ltd., to visit the mines and report on the question of mine natives' food," says the *South African Mining and Engineering Journal*. Thus opens a vista of jobs for the jobless, not to say beef for the beefless.

Equality

"Next to the tendency of life in the mining regions to remove all restraints and bring into prominence all the vices that were lurking, perhaps unknown to themselves, in the breasts of many of the first comers," says Hittel's "History of California," "one of the most noticeable features of the times was the extraordinary leveling tendency of that life—a tendency upon the effects of which have been based to a great extent the readjustments and developments on new lines that have constituted the peculiarities of California civilization. Every man, finding every other man compelled to labor, found himself the equal of every other man; and, as the labor required was physical instead of mental, the usual superiorities of head-workers over hand-workers disappeared entirely. This condition of things lasted several years. Men who had been governors and legislators and judges in the old states worked by the side of outlaws and convicts; scholars and students by the side of men who could not read or write; those who had been masters by the side of those who had been slaves; old social distinctions were obliterated; everybody did business on his own account, and not one man in ten was the employee, and much less the servant of another."



"Metallurgical Term: "Easy to Float."

CONSULTATION

Method of Marketing South African Gold

"It is not quite clear to me exactly how the South African gold producers market their gold so as to obtain the benefit of the 'gold premium' in London. I can readily understand that it is due to the depreciated currency of Great Britain and the relatively high gold price in the United States that a premium exists, but the exact manner in which the result is brought about is unknown to me. Can you enlighten me upon the subject?"

Without entering into a discussion of the history of the gold premium, a subject which has frequently appeared in the columns of the *Engineering and Mining Journal*, suffice it to say that the South African gold producers are enabled to realize a premium over the normal local currency value of their gold by being allowed to sell their product in the general world market and receiving in exchange the equivalent of $20.67 per troy ounce in their own depreciated *paper* currency.

In marketing their gold, the South African gold mines rely on an agreement made on July 24, 1919, between the Imperial Government, the Union Government, and themselves, whereby they agree to ship all gold refined and unrefined which has been produced by them, to England, consigned to the Bank of England, with, naturally, the exception of such amounts of metal as are necessary to meet local currency requirements. The unrefined exported gold is refined upon arrival at the Bank of England by the gold producers' refiners. The sale of all the refined gold is negotiated by the producers' agents at the best market price obtainable. The fluctuations in the London price of gold reflect the discount on foreign exchange; when exchange is low the price of gold is correspondingly higher, and vice versa.

The Bank of England has authority from the Treasury to issue licenses for the re-exportation of the gold at any time within the period of five weeks from the date of its arrival at the bank. Under ordinary conditions, a period of five weeks is assumed to be amply sufficient to allow the gold to be disposed of to the best advantage. Furthermore, as the amount of each shipment is cabled to London, additional time is afforded in which to market the gold, a total of possibly eight to nine weeks. The assurance is given the producers that in the event of interruption in export facilities due to unforeseen circumstances, an extension of time will be granted. Should sovereigns be required for export, the Bank of England will make payment in sovereigns for gold sold to it at 77s. 9d. ($18.89 at par of exchange) for the standard ounce of gold, .916⅔ fine. All charges for freight, insurance, refining, assaying, and marketing are borne by the gold producers. Another provision whereby the Bank of England undertakes to advance an amount equal to 76s. ($18.46) per standard ounce, subject to interest, is included in the agreement.

This arrangement is of great benefit to the producers. In contrast to the 77s. 9d. received before and during the war, about 117s. is now being received for the standard ounce.

Abnormal Relation Between the New York And St. Louis Lead Markets

"For six days the price of pig lead is quoted at less in the New York market than f.o.b. St. Louis, and this we cannot understand, because all the lead comes from the West, and the price generally is higher in New York than out here [Missouri]. Is it due to the fact that imported lead has weakened the New York market to this extent?"

The abnormal disparity between New York and St. Louis lead markets was due solely to the fact that heavy importations of foreign lead were laid down in New York alone, which was offered at lower prices than lead transported from the Middle West to the Atlantic seaboard. It is estimated that about 11,000 tons of foreign pig lead were received in the port of New York during the month of September, and more is still arriving. Under such a state of affairs the New York and St. Louis markets are influenced by another market element, one that does not ordinarily assume such importance—importations of lead. In fact, these importations are still influencing the trade and neutralizing the normal differential between the two markets. Attention was directed to this situation in the market report for the week in question. The disparity will gradually adjust itself as the domestic price of lead meets the London quotations and makes the cost of importing lead unprofitable.

In 1916 a similar condition arose, with this exception: exportation of lead from the Pacific Coast to Asiatic points was taking place, so that the New York lead market necessarily had to lower its level in order to meet the competition of the Middle West, where producers took advantage of the shorter haul westward.

Uses and Production of Calcareous Marl

"I have been unable to get much information regarding calcareous marl. What it is used for, prices and production? Any information you can give me will be appreciated."

The calcareous marl industry is relatively small. An idea of the production for the past four years can be obtained from the figures of sales given by the U. S. Geological Survey, with average prices:

CALCAREOUS MARL SOLD IN THE UNITED STATES

Year	Quantity (Short Tons)	Value	Average Price per Ton
1916	58,088	$144,768	$2 49
1917	73,900	165,223	2 24
1918	98,894	261,082	2 65
1919	91,437	327,294	3 58

Calcareous marl is of both marine and fresh-water origin. In 1916 and 1917 the entire output was used in agricultural work. In 1918 and 1919 a part of the production, about 15 per cent, was used in the neutralization of acid waters and the preparation of patent fertilizers. Production jumped during the war.

The method of preparation for marketing is usually simple screening and drying, but rotary kiln drying, crushing, screening, and pulverizing may also be used.

California, North and South Carolina, Pennsylvania, Virginia, West Virginia, and Arkansas are the chief producing states.

THE PETROLEUM INDUSTRY

The Prospects for Petroleum Production In Peru and Bolivia

The High Cost of Development, Difficulties of Transportation, High Royalties Asked, and an Objection to Long-Term Concessions Are Drawbacks to the Exploitation Of Oil Possibilities in These Countries

BY CHARLES S. HALEY
Written for *Engineering and Mining Journal*

SINCE the close of the war, the opportunities in the South American field for mining and oil investment have been attracting the attention of American and English capital. Considerable money has been invested there in the last two years, and it seems that more interest is being taken with regard to future development possibilities than has ever been evinced before.

The importance of this field should not be underestimated, nor should its disadvantages be overlooked. It is with the intention of giving a brief survey of the good and bad points of the situation, more especially with regard to the two most prominent republics from a mineral standpoint, Peru and Bolivia, that this article is written. Both of these countries have been famous for centuries for their mineral production, and justly so. Potosi Hill, in Bolivia, has a recorded production valued at more than seven billion dollars, and has been in continuous operation for more than three centuries. Other and less known districts in Bolivia have been adding their steady contribution to the wealth of the world for many decades and even centuries.

PERU IMPORTANT MINERAL PRODUCER

Peru, from a mineral standpoint, is one of the most attractive countries in the world today. The greater portion of the country is occupied by the high Andes and the river valleys between their slopes. Much of it is inaccessible to ordinary methods of travel, and a large portion of it has never been traveled by anyone save the natives. In the colonial days of Spanish rule, many mines were worked at a tremendous profit by means of slave labor, amid difficulties of transportation and operating conditions which would stagger attempts at production even now. And still the heart of the country is as yet unknown and practically unprospected, from a mining standpoint. All over the country one encounters tales of old colonial mines which were abandoned at the time of the revolution, when the colony of Peru threw off the yoke of Spanish dominion. In many places the natives are making an easy living from the crudest forms of placer mining; and what work has been done by the Peruvian government engineers has shown that there exist in that country deposits of almost every known economic mineral within the range of civilization's present horizon.

The petroleum possibilities of Peru have long been known, as have those of Bolivia. Denouncements and concessions have been made in both countries for many years, but as yet the only field of economic value that has been developed has been a very limited one on the northern portion of the Pacific coast of Peru. This field at present produces around one-half of 1 per cent of the world's total production of petroleum.

PROSPECTIVE PETROLEUM FIELDS INACCESSIBLE

The reason for this apparently small development of what appears a great prospective field is obvious. The principal prospective petroleum fields of both Peru and Bolivia lie in the most remote and inaccessible portions of both countries. This does not impress the governments of either of these countries as it should, and still less is it taken into consideration by the average owner and holder of concessions. The main thing that appeals to this individual is that—according to everything he reads—the world's visible supply of petroleum is steadily growing less. He has petroleum, or at least he thinks he has, under the surface of his ground. Therefore the world must come to him and tamely submit to being his oyster. And the petroleum—if it is there—still lies under the ground, and lies, and lies, and lies.

One of the most attractive prospective fields is that extending in eastern Bolivia southerly from the Santa Cruz region through the Azero into the Argentine. Seepages can be found over the entire distance from Embarcacion, in the Argentine, to the north of Santa Cruz, and the structure seems favorable. Until a careful examination can be made, and a few holes put down, that is all that can be said. To date, the presence of slightly productive oil sands has been proven by two shallow wells. The cost of a careful examination of the country is greatly enhanced by the fact that most of it is several hundred miles from the nearest railroad, and the expense of getting material in for development is bound to run from three to five hundred dollars per ton up—as there is absolutely nothing but muleback transportation into the country. Supplies are correspondingly high, and the native labor is notoriously uncertain and inefficient. The result is that in beginning operations in the country, without considering the enormous cost of getting the oil out to a world market, a tremendous overhead is thrown upon the work from the start, in the way of interest and amortization.

DRAWBACKS OF TRANSPORTATION

The most feasible route for the transportation of the oil to a market is by way of the Rio de la Plata. To avoid rehandling and towing of barges—a condition which

makes costs prohibitive when the back haul is considered—a pipe line of from three to four hundred miles in length would have to be built from the most accessible part of this field—this, through a country absolutely without roads or other feasible means of transportation. Such represents the overhead with which the pipe-line company would have to contend. A prohibitive charge for the transportation of the product of the development company would have to be made to amortize the pipe line within a reasonable time.

Product Would Compete With Mexican Oil

After the oil has been safely delivered to tankers of sufficient draft to navigate the Atlantic, geographic troubles enter in. The world's principal petroleum market is the United States, and will be for some time to come. And from the mouth of the Rio de la Plata it is three thousand miles to the east of the market, and eight thousand miles to the south of it. How much of this oil—which by this time represents an investment that approaches in cost the perfumes of Araby—will one have to expend in pushing the rest of it on a back track to the market, and how is the operator going to compete with Mexican petroleum produced at the very front door of the United States?

Considering taxes and royalties, the standard royalty in the United States has for years been 12½ per cent of the gross production. This condition exists in a country where railroad facilities are excellent, where a constant supply of skilled labor is to be had, and where the principal materials for development are produced within easy distance of the property. The Bolivian government is demanding a 15 per cent royalty on gross production, applied universally over the country on all government lands, and private owners are naturally following its lead. So petroleum still lies under the promising prospective territory.

Value of Field Purely Prospective

The entire value of this ground, as has been stated before, is purely prospective. The extent of the territory is so enormous, and its geological history is so favorable, that it seems likely that some day in the future very productive fields may be developed. But this is all indeterminate at present. No corporation which has not been deprived of its financial reasoning powers is going to the expense of making a careful and detailed geological examination of the country, and to the further enormous expense of sinking the first few wildcat wells, until it is assured of at least having a chance for fair return on the investment. In negotiating with private owners, a very definite trend is noticeable toward hard and immediate cash in hand—and the more immediate the better. This tends to disillusion the confiding purchaser as to the owner's faith in the future production of the property.

The attitude of the government is largely influenced, of course, by the political situation. As soon as a large concession is granted, some patriotic individual will come out with a passionate appeal in the papers to the people at large not to permit their political masters to sell their inheritance and birthright for a mess of pottage—and such emotions, properly fanned, may mean revolution. In other words, it is better to have a stable government in an undeveloped and povery-stricken country, than a revolution in an effort to better conditions.

The metal-mining situation in Bolivia is much better. For some reason, the government does not have to contend with the same popular attitude that it does in regard to oil, and the taxation scheme introduced in 1920 seems rather fair and liberal, although a bit too hastily devised. It is perfectly possible to secure a good title to mining property in Bolivia, although the recent revolution has undoubtedly stirred things up to some extent, and to work a small high-grade property, or a large low-grade, on conditions which compare favorably with those in the United States. The attitude of the government which existed until July of this year was both friendly and liberal, with regard to mining.

The same applies to mining conditions in Peru. Peru probably has the most liberal mining laws of all countries in the world. The government is stable—in spite of some revolutions it always recognizes the foreign obligations of former governments—and the general policy of the present administration is to encourage foreign capital by every means possible to come into the country. The continued existence and strength of the powerful and prosperous Cerro de Pasco company through various changes of government demonstrates clearly the possibility of absolutely stable conditions.

Personnel of Peruvian Government Excellent

The present president of Peru, Sr. Augusto B. Leguia, is probably the most capable and able leader that Peru has had in a generation, and the people as a whole seem to be solidly back of him. He has been fortunate in being able to surround himself with a body of ministers whose efforts show that they have the best interests of their country sincerely at heart. In Peru, also, a system of propaganda, instituted by Sr. Oscar Salomon, is being given aid and support by the government, with the idea of educating the people up to the necessity and desirability of getting foreign capital into the country. This propaganda is bearing fruit; and my impression is that the attitude of the Peruvian nation in general toward the United States is the most friendly of all the Latin American republics.

Peru Objects to Long-Term Concessions

The petroleum situation in Peru is not so difficult from either a geographic or a governmental standpoint as it is in Bolivia, but a tinge of the same attitude—that the world must come to them—is visible in certain circles. This tendency, fortunately, is held in check by the wiser and more far-seeing heads of the government. The inaccessibility of the best prospective field—on the drainage of the Amazon—is fully recognized, and excessive royalties are not expected. The government will not charge duty on machinery brought in for development, and will grant all facilities in its power as to right of egress and appropriation of natural resources of power and timber. The chief drawback seems to be a hesitancy to grant long-term concessions—an absolute necessity, in view of the enormous first cost involved—and an unwillingness to give a sufficient time for preliminary prospecting, with a cautious expenditure of money until the ground is sure. This reluctance can be readily understood in the case of fly-by-night companies and irresponsible individuals, who should of course be discouraged from the pre-emption and holding of large territory at all times. But in the case of a well-known production company, of undoubted financial strength and responsibility, it hardly seems necessary or advisable to take these precautions.

The geographical situation of the most promising prospective petroleum territory of Peru—that of the *montaña*—though more favorable in many respects than that of Bolivia, is still far from being ideal. In fact, it is in its own way more or less prohibitive. Practically all the territory of this field is tributary to the Amazon and its headwaters. These are navigable to a far greater extent than those of the Plata, and barges of five- to seven-foot draft can come directly to the region of some of the best seepage indications. This, of course, merely affects the handling of machinery, for barge transportation is out of the question in handling oil, on account of back haulage.

This field is much closer to the west coast of South America than are the Bolivian fields, and as the west coast of Peru is almost due south of New York, the transportation problem is much simpler from there on. But the question which causes the greatest difficulty, and which seems on first consideration to be an insurmountable obstacle to the development of these fields, is the problem of getting this oil to the west coast.

Inaccessibility of Peruvian Oil Fields

The main *cordillera* of the Andes forms a barrier from 14,000 to 17,000 ft. high between this oil and the coast, under the most favorable conditions that can possibly be selected. The distance is only 300 or 400 miles—compared to 4,000 miles by the other door (the Amazon)—but the enormous cost of installing a pipe line with successive pumping stations to overcome this lift is appalling. The country through which the pipe line would have to pass is absolutely without transportation facilities. It takes from one to two months of steady muleback travel to even reach it from the coast. A railroad could not be developed into a financially paying venture, owing to the thin population of the district and the primitive character of the major portion of the inhabitants. Wagon roads and truck roads would have the same drawback. How, then, is the heavy material required in a pipe line of this character to be brought into the country? Discarding Zeppelins and other ultra-modern ideas, there remains transportation by main strength and awkwardness—in other words, by trail. The cost of four hundred miles of such an installation is so extremely high that it could be justified only by the discovery and careful development of a field which would be rich enough and extensive enough to surpass any at present known to the world.

There is, of course, a possibility that on the eastern slopes of the lower Andes such a field may exist. That, however, is highly problematical, and would require many years of careful prospecting and the drilling of many wildcat wells to be susceptible of proof. Again, the spectre of overhead comes in even before the pipe line can be considered. Transportation of complete blacksmith and machine shop equipment 4,000 miles up the Amazon, and transshipment on barges, will make the first oil produced—if it is produced—worth much more than its weight in gold.

It would then appear that it is absolutely imperative that time should be given to prospect carefully and feel the way before money be wasted needlessly. All necessary guarantees should be exacted, but the mere tying up of a corporation's money in prospecting, not to speak of development work, should be the greatest guarantee of all. The more money that is spent in successive years, the more the company will be loath to leave it. A long-term concession is absolutely necessary to give the development company a chance to get its money back. This does not take into account the still longer time which would be necessary before the pipe-line portion of the work could begin to exhibit a profit.

These conditions I believe the Peruvian government will realize, as it appears to have the best vision of all of the Latin-American republics of South America. But the Bolivian attitude appears hopeless for some time, unless the new government which has recently come in adopts an attitude far different from that of its predecessor.

Latin America Should Utilize Foreign Capital

In brief, the situation is this: Now is the accepted time for the Latin-American republics to use our capital—as well as that of England, the only European nation which has it to spare—in the development of their own natural resources and the transformation of themselves into prosperous industrial communities, such as their immense natural resources seem undoubtedly to warrant. Mexico is beginning to realize this fact, and under the new and progressive government has already made great strides toward regaining the confidence of American capital. In the next few decades she will begin to reap the reward of this enlightened and progressive policy.

It is entirely up to Latin America. For years she has neglected to take advantage of her opportunity, partly because of a distrust of the United States, which seems to have been partly justified by some of the acts of our Government in the past, but mostly on account of lack of vision among the statesmen of the Latin republics.

Supplementing the vision of her public men, she must educate her people up to the standpoint where they do not take the vision for the reality. Otherwise the petroleum resources will still continue to lie where they are. To convert any vision into reality, the effective presence and co-operation of hard cash is needed and absolutely essential. To invite this co-operation, and the confidence of pioneer capital, liberal facilities must be offered, and exaggerated ideas of undeveloped riches must not be too strongly held; or, rather, the fact that they are undeveloped, and will continue to be unless such facilities are offered, must be impressed on the minds of the people. Latin America, and more especially Peru and Bolivia, have a brilliant future just around the corner, if they will but recognize their opportunities and give the United States a chance to work with them for our mutual benefit.

A Record Well

In a recent issue of the Standard Oil *Bulletin*, information is made public of the Packard No. 1 Well in California, which is the deepest well in the state, having reached a depth of 6,240 ft. The well turned out to be a "dry hole." Drilling was begun in July, 1919, and completed in March, 1920. The "deepest well in the world," the Lake No. 1, drilled by the Hope Natural Gas Co. on the Lake farm, twelve miles east of Fairmont, West Virginia, was sunk for gas and was abandoned at 7,579 ft. when gas was not found. Europe's deepest well at Czuchow, Silesia, is 7,345 ft. in depth.

NEWS FROM THE OIL FIELDS

Oil Company Sued for Violation of R.R. Commission Rules

State Gas Survey To Be Made in Texas —Recent Completions in Breckenridge, West Columbia, and Hull Fields

From Our Special Correspondent

Suit has been filed in the fifty-third district court of Travis County, Texas, by County Attorney John W. Hornsby, for the State of Texas, against the Montour Oil Co., a corporation of Delaware, with Texas headquarters at Fort Worth, for $870,000. This sum represents penalties for alleged violations of several of the rules of the Railroad Commission, these violations having taken place after March of this year. This is the second suit of this nature filed against the same company. The first, filed in March, asked for penalties amounting to $1,000,000.

A survey of the gas industry of the state will be made by R. D. Parker, newly appointed chief engineer of the gas utilities division of the Railroad Commission. An attempt will be made to fix a fair price for gas sold by the eighteen gas companies placed under the supervision of the commission by the Cox gas law.

The new 18-in. gas main, twenty miles long, from Joshua Junction to the Dallas-Fort Worth trunk line, has been completed, and an additional supply of 50,000,000 cu.ft. of gas will be furnished by the West Texas fields to these cities. It is believed that this increase in supply will prevent any shortage of gas in Dallas this winter.

Recent completions in the townsite pool at Breckenridge, Stephens County, have been made. The W. G. Harding well, a joint well of the Cooper Henderson Co. and employees of that company, located just north of town, came in making 4,000 bbl. It caught fire, but was quickly extinguished. The Cooper Henderson Co. well No. 1 Walker Caldwell, on the east edge of town, has 2,000 ft. of oil standing in it. The Stoker No. 4 well of the Gulf company was shot, and its flow increased from 350 bbl. to 1,500 bbl. daily.

West Columbia holds the attention of all the operating companies on the Gulf Coast. Recently the Humble Oil & Refining Co.'s. No. 28 Japhet well came in making about 15,000 bbl. of oil. The Monarch Oil & Refining-Stribling No. 1 Smith well came in at 3,287 ft., making over 1,000 bbl. of oil. This well is about 1,300 ft. north of the Texas Co.'s Abrams No. 1 well.

At Hull several producing wells were recently completed, including the No. 4 Thomas well of the Gulf Production Co. flowing initially over 2,500 bbl. The total production of this field has been steadily increasing the last few months and is now nearly 15,000 bbl. daily.

Damaged Valve Causes Losses in Mexican Oil Field

From Our Special Correspondent

Well No. 4 of the Transcontinental Petroleum Co. on Lot 134, Chinampa, is running wild, making about 40,000 bbl. a day. The well was flowing under heads at regular intervals, when just before it was brought in one of the gate valves was damaged by the drilling tools; and the other was blown out by the well pressure while the operatives were trying to close in. Temporary pumps and boilers have been set up in an effort to save as much of the oil as possible. About two thousand barrels a day are being saved.

Special apparatus will be necessary gain control of the well, and it is probable that the well will continue wild for a week or ten days at least. The task of getting a new valve on the well is a very difficult one, as the material used is necessarily heavy and has to withstand great pressure. The workmen also have to contend with the gas given off by the well. This gas suffocates, and in some cases proves fatal. This accident will not help the Amatlan-Chinampa pool; as this great daily draught will aid the encroachment of the salt water.

It is reported that one of the International Petroleum Co.'s tests in Zacamixtle has brought in salt water, and that the Aztec hole is drilling in brown limestone at 2,806 ft.

British Interest in Roumanian Oil Development

A new British oil company has been organized to complete, with French and Roumanian groups, a syndicate to acquire a controlling interest in the Steaua Romana Oil Co, according to *Commerce Reports*. The British group will be called the British Steaua Romana Co. and will be floated jointly by the Anglo-Persian Oil Co., Stern Bros., and James Dunning & Co. The French members of the syndicate will be La Banque de Paris et des Pays-Bas, Mirabaud et Cie., La Société d'Etudes et d'Entreprises, Mallet Frères et Cie., and an industrial group represented by M. Mercier. The Roumanian group will include La Banque Marmorosch Blank, La Banque Romanesca, La Banque Générale, and La Banque du Crédit Roumain.

The Technical Sub-Committee of the Committee on Standardization of Petroleum Specifications, appointed some time ago by President Wilson, will hold a meeting at the offices of the Bureau of Mines, Washington, D. C., on Oct. 18, to give further consideration to Government specifications on gasoline, kerosene, fuel, and lubricating oils.

Shallow Well Completed in Poison Spider, Wyo., Field

From Our Special Correspondent

Gas has been turned into the mains of the New York Oil Co. from the Poison Spider field, in Wyoming, for delivery to the oil refineries at Casper. Mains in Casper are also being laid. The completion of the New York Oil Co.'s No. 9 South Casper Creek well at shallow depth on its 2,000-acre lease, making 75 to 100 bbl. of oil, is considered an important development.

The Consolidated Royalty Oil Co., at its annual meeting held in Casper recently, declared the regular quarterly dividend of 2½ per cent payable Oct. 20 to stockholders of record Oct 15. New officers elected were: B. B. Brooks, president; T. A. Dines, vice-president; C. B. Richardson, vice-president; R. N. Matson, secretary and treasurer; R. S. Ellison, H. D. Schoonmaker and S. A. Lane, directors.

The Sage Creek Petroleum Co. has spudded in for a second well on the Winkler Dome, Fremont County. This well will be drilled on the side of the formation. The first well, on the apex, came in as a large gas well. The same company will also resume drilling at 2,420 ft. in its Buffalo Basin well, Fremont County. It is stated that some oil and gas showings have been obtained here.

The Producers' & Refiners' Corporation has struck a third gas sand in its well at the Wertz camp, between the Ferris and Lost Soldier fields. The first sand was at 3,200 ft., the second at about 3,400 ft., making 2,000,000 cu.ft., and the third at 3,440 ft. with a flow between 7,000,000 and 9,000,000 cu.ft. This same company has completed its No. 2 well in the Osage field at 1,525 ft. making 150 bbl. by pumping. No. 1 well is making good progress and will be completed soon.

The Western States Oil & Land Co. has completed its No. 31 well on Sec. 5-39-78 of the Salt Creek field at a little over 2,300 ft., making an initial production of about 500 bbl. The oil-bearing sand is said to be over 60 ft. thick.

Oil in Alberta Sands

That oil in sufficient quantities to supply the world for 600 years will be released when the problem of separation of oil from oil sands lying to the North of Edmonton has been solved is the opinion expressed by Dr. H. M. Tory, principal of the University of Alberta. Dr. Tory stated that a member of the faculty of the university has been working on the problem of separation for ten days, and that if he continues to make progress as rapidly as he has done hitherto, the problem will be solved in six weeks.

COURT DECISIONS IN MINING CASES

By Wellington Gustin

Principles for Determining the Legality of Unsigned Contracts

West Virginia Court Propounds Conditions Under Which Reduction to Writing of Verbal Agreements Is Necessary.

In these days of innumerable leases on oil, gas, and mineral properties, their proper execution may well be considered. The Supreme Court of Appeals of West Virginia determined the legal aspects of such issues in deciding the case of Herndon et al vs. Meadows, affirming judgment of the land owner.

The facts appear that after some negotiations a conclusion was reached to the effect that Meadows would lease his land to his grandson, Tolley, and Herndon upon certain terms. A writing was prepared purporting to be between Meadows as one party and Herndon and Tolley as second parties, with provision for the signatures of all parties to the contract. Meadows signed and acknowledged it before a notary. It was subsequently signed by Herndon, but Tolley never did execute the instrument. Herndon had a lease prepared according to the terms of the contract, but Meadows refused to sign this, and sold the land to others. Thereupon Herndon brought this action for breach.

In its opinion the Supreme Court says that where the parties to a contract reduce their agreements to writing, with the purpose and expectation that the same shall be signed by all the parties before the agreement is completed, the failure or refusal of one party thereto to execute will excuse all of the parties from performance. Where, however, the agreement of the parties is complete, and the writing is simply treated as a memorial of the contract already entered into between them, and its execution not necessary to the completion of the contract, the parties will be bound.

The court found the writing in this case to be in a form which contemplated execution by all of the parties, and further, one as is required to be in writing to be enforceable under the statute of frauds. It was said that where a contract in writing is executed by only one of the parties, and the other party waives the execution by accepting performance, or by doing something under the contract which shows that the parties did not contemplate its complete execution as a prerequisite to a valid contract, it will be binding; but where a contract is reduced to writing, and the subject matter is such that people do not ordinarily contract in regard to it without expressing their agreements in writing, and the paper on its face indicates that it is the intention that all the parties shall execute it, and nothing is done under the contract to indicate that the parties intend their agreements to be binding, whether the writing is signed or not, it will be held that there is no completed contract, unless all the parties thereto execute the same.

Therefore judgment for the land owner was upheld, for the reason that there had never been a completed contract between the parties.

Upper Locator Liable for Damages to Lower

Judgment in Favor of Allison's Mines Co. Reversed by California District Court of Appeals

The District Court of Appeals of California has reversed the judgment rendered against J. W. Dripps in his action to recover damages for injury to his placer mining claim, situated in Laurel Gulch, Los Angeles County, by the Allison's Mines Co. The Allison company located its mining claim to the north of Dripps' claim and further up the gulch. Plaintiff's evidence was that tailings from defendant's mill accumulated on plaintiff's land along the stream the entire length of his claim, and from six inches to two feet in depth; that large rocks and boulders, aggregating many tons, rolled down the steep sides of the gulch; that this was caused by the trail built and used by defendants; that it would cost $25,000 to remove the rocks, and several thousand dollars to remove the tailings, necessary to work the claim; that the water in the stream is made "muddy and riley" by the tailings from defendant's mill; and that this "gums up the riffles," so that this placer mining claim cannot be worked profitably.

In reversing the judgment the court said it was now settled that the first locator on mining ground has no right, by custom or otherwise, to allow tailings to run free in the gulch and render valueless the mining claims of subsequent locators below him. And where the land of the lower locator is actually invaded by "tailings," "slickens" or other material from the claim of the upper locator, it makes no difference how carefully the latter may have worked his mine. If his work in fact injures the property of another, he is none the less liable.

As for the water, the prior locator cannot insist that the stream above him shall not be used by subsequent locators for mining purposes; neither may the subsequent locator so conduct his operations as unreasonably to interfere with the fair enjoyment of the stream by the prior locator. The reasonableness of the use is a question of fact in each particular case. The spirit of the law is "live and let live."

Dey Loses Action To Recover Laurel Canyon Mines

Failure to Appeal from Former Judgment in Favor of Arizona Mining Company Renders Later Action Void

In the action brought by Richard V. Dey against the Laurel Canyon Mining Co., in Graham County, Ariz., to recover possession of certain mines and improvements, the grounds alleged were that the mining company had forfeited its lease of the premises by breaching certain covenants of the lease. But shortly after this was begun, Day instituted another action under the Landlord and Tenant Act of Arizona, to recover possession of the mines. This case was tried and resulted in a judgment in favor of the Laurel company, which was never appealed, and therefore became final.

The lease was a working lease with option of sale. It contained covenants to pay lessor certain royalties and to keep mill in continuous operation, and to keep same and other improvements in repair; to work the mines in a miner-like manner, and to timber, where necessary; to pay promptly all debts incurred; and to keep property free from liens, and similar charges. The violations of these covenants were alleged as the grounds for suit. The court found the violations cover the period in both suits, that the object of both suits was the same, both being possessory actions to dispossess the Laurel company. In the last case brought, the court said Dey was unable to establish the breaches claimed, and a final judgment in that case, therefore, has forever settled his contentions.

American Metals Co. Denied Removal of Suit to Federal Court

Federal Judge Smith of the District Court at El Paso, Tex., has remanded the suit instituted by the Compania Minera y Compradora de Metales Mexicano, S. A., against the American Metal Co. and the Compania de Minerales y Metales, S. A., to the Texas state court from which the American Metal Co. sought to remove it.

The plaintiff in this case seeks to recover of the defendant, Compania de Minerales y Metales, S. A., damages for an alleged breach of contract between them, and alleges that this company, in making and breaking said contract, was acting as the authorized agent of the American Metal Co.

Grounds for removal of a cause from a state to a Federal court are purely statutory, and Judge Smith ruled that no proper showing was made bringing the suit within the statute.

ECHOES FROM THE FRATERNITY

SOCIETIES, ADDRESSES, AND REPORTS

Safety Devices on Winding Engines*

Nearly all accidents in hoisting are due to two general causes: Failure of the hoist machine to function, and failure of the hoist operator or engineer to act correctly.

Failure of the hoisting machine to function is caused by faults in design, defective material, poor workmanship, overloading and neglect. No safety devices can prevent the failure of a hoist under any of these conditions, but they can prevent to a large extent injury to life and property due to hoist failure from such causes. But in some cases the finest of safety apparatus will be powerless to prevent accident unless backed up by sufficient strength, proper design, and care of the hoisting machine. With respect to strength, however, a factor of safety of not less than five should be used. Most hoist drums should be provided with an indicator positively driven by chain or gearing from the drum or other hoist part having motion coincident thereto.

Of the utmost importance are adequate brakes, and every hoist should have at least one efficient brake applied to the drum. For long hauls or for deep shafts where heavy loads are lowered by gravity, two brakes are advisable, to be used alternately in order to prevent overheating and probable breakage due thereto.

The hoist operator should be protected as much as possible, and the operating levers should be so placed as to keep him out of the way of a possible flying rope. Safety devices or other mechanism that cause operators' levers to move are dangerous and should be avoided.

The hoist should be designed for the maximum load it will be called upon to handle, and this load should be known to operator and cage tenders. Before men are handled on any hoist, trial trips should be made to test the equipment for possible flaws in materials and workmanship.

The most common dangers incident to hoisting may be enumerated as follows: Cage or trip passing prescribed or safe limits, traveling beyond a prescribed or safe speed, starting the hoist in the wrong direction, improper application of brakes, failure of brake to hold, accidental release of clutched drum, backing away of hoist due to power failure, and inability to stop hoist in emergency.

Protection from these dangers cannot be had without some form of power-operated brake engine, which automatically applies the brake and brings the hoist to rest through actuation of the safety devices. Such brake engines may be of steam, compressed air, or oil type, according to the power available or preference of the hoist owner. Usually they are of the weighted type, the engine being provided with two cylinders, each having a movable piston, the piston being fitted to a common rod to which, by suitable means, a set of weights is attached, and which also acts to move the brake bell crank. In one cylinder the motive field acts to keep the weights in a suspended position ready to be released for application of the brake. The other cylinder contains oil, which is by-passed through an adjustable valve from one end of cylinder to the other, effecting a smooth motion of the piston rod. There is a valve provided at the power end of the brake engine to release the pressure against the piston, allowing the weights to apply the brake. When weighted brakes are not used, the brake is both held in the released position and applied by direct fluid pressure on the engine cylinder. Either type of brake is normally controlled by the operator by means of hand lever or valve which governs the admission of motive fluid to the brake engine cylinder and its release therefrom. But when the operator fails to act properly, the safety devices take control of the brake from him and use it according to their functions.

*Abstract of a paper by L. F. Milten delivered at the Ninth Annual Safety Congress, Milwaukee, Wis., Sept. 27-Oct. 1, 1920.

Requirements of Rescue Training for Metal Miners*

It is of vast importance that the men to be selected for places on the rescue crews should be given careful consideration. It is just as essential to have physical fitness in rescue or recovery work as it is to have mechanical fitness in the type of apparatus which is used. Each of these factors is dependent on the other, and each without the other is dangerous, not only to the one man but to the entire crew. Therefore, each candidate should be subjected to a thorough physical examination prior to any instruction. Inasmuch as a considerable part of actual emergency work with apparatus is dependent upon the absolute understanding and execution of instructions, men who are to be selected for the training should be mentally as well as physically efficient.

All candidates should be thoroughly familiar with the mine workings, and should know the conditions existing in each level and ladder-way. It is also important that they should be able to do any of the various kinds of work underground as might be necessary, such as timbering, constructing brattices, drilling, mucking, etc.

With apparatus and men selected, the next thing to be considered is the place of training. The preliminary instructions should be given on the surface, so that any room large enough to accommodate the number of men in training will serve this purpose. Also, the first couple of days can be spent in the open air until the men become familiar with the apparatus and "get the feel" of it while wearing it in the preliminary work.

Following this period many instructors take the crew into the mine for further practice. The course of training is for the purpose of teaching the men something entirely new, a phase of mining work that requires courage, and one that is not without hazards. Therefore, the work must be done in a manner and under conditions that will instill in the men absolute confidence in their machines and in their ability to use them. It is important that they should be able to carry on their work under similar conditions as exist underground. To this end the training chamber, or smoke room, should be constucted to meet these conditions, and most metal mine conditions can be represented here.

An arrangement of apparatus which offers practically all of the mine conditions, eliminates the generation of smoke and fumes in the mine, and, further, establishes confidence in the men during the training period, has been designed and built in the First Aid building of the New Jersey Zinc Co. at Franklin, N. J..

Five half days, at least, should be allotted for the preliminary training. Six half days are not too many. This preliminary course endeavors to carry the candidate gradually from an understanding of the fundamental principles of rescue work to as thorough a knowledge of the details as is possible in the time allotted. It is natural that, in the training period, many unforeseen things will occur that the men will not understand. Reducing valves will require adjustment, by-pass valves will accidentally become opened, men will overexert themselves, etc. It is the duty of the instructor to explain carefully the reasons for all such occurrences and instruct the men how they may be corrected or prevented.

It is advisable that a half-day each month be allotted to each crew for practice. In these periods the apparatus should be worn for at least one and one-half hours and the work should be varied so as not to become monotonous.

*Abstract of a paper by R. H. Selp delivered at the Ninth Annual Safety Congress, Milwaukee, Wis., Sept. 27-Oct. 1, 1920.

Special Committee of National Tax Association Reports on Mines Taxation*

The Committee on a Model System of State and Local Taxation recommends for general adoption by the states three principal taxes, viz, a personal income tax, an ad valorem tax on tangible property, and a tax on business. Concerning the taxation of mines it said "We are agreed that mines should pay, under whatever method may be adopted, a tax commensurate with that paid by other real estate in the same taxing jurisdiction."

How should the tax on mines be imposed and collected? Our answer is in precisely the same manner that taxes are imposed and collected on other real estate. The Committee on Model System would retain the ad valorem tax on other forms of real estate with modernized administration. In our opinion the equalization of the taxes on mines with those on other real estate requires that no exception be made in the case of mines.[1]

The populations of the typical mining communities of the United States are almost entirely dependent on the mines. So long as the mines exist other real estate has value, but when they are exhausted it has no value or only nominal value. The mines must pay most of the taxes, it matters not under what system they are levied.

If the ad valorem tax on mines is abandoned in favor of a tax on income or product, the local community will lose control of its main source of revenue, and in lieu of the ad valorem tax it will receive such portion of the tax on income or product as may be prorated to it by the state, and this portion will be an annually fluctuating sum. In periods of low income the main burden of the taxes would fall on other property. The effect would be that the tax rate on other property would fluctuate inversely with the productivity of these taxes.

The interests of the local taxing jurisdictions are paramount in any system of taxation devised for the American state. The bulk of the public expenditures is made by the cities, villages, townships, school districts, and other local jurisdictions. The tax on property has been the mainstay of the local community. It would be under the proposed Model System. Taxes based on the production or on the income of mines are ill adapted to the requirements of the local communities. The necessary control of the rates of such taxes by the state deprives the local mining jurisdiction of control over its own finances to an embarrassing degree, and imposes on it a tax system which would starve the treasury in some periods and flush it in others.

The property tax, the elastic element in the Model System, will practically disappear if mines are excluded from its provisions in the typical mining jurisdictions where the value of the mines comprehends from 50 to 95 per cent of the value of all property.

We believe that mines should be taxed for revenue only and condemn the super-taxation of mines on the one hand, and exemption or under-taxation on the other. A classification of real estate for taxation opens the door to exploitation of the numerically weaker elements in the population by the dominant elements. We find no reason why city property and mines should pay more taxes in proportion to *value* than rural property.

It is the outstanding merit of the Model System that all able-to-pay elements of the population will be reached and fairly taxed.

There are no insurmountable obstacles in the way of taxing mines as other real estate is taxed, and the rule of uniformity should govern. Subsidies on the one hand and penalties on the other, administered to industry through the device of taxing, are a dangerous perversion of the taxing power of the state. It is opposed to inter-state comity in taxation, fostered in the provisions of the Model System, and introduces an unnatural disturbing element in the economics of the internal commerce and development of the country.

It is assumed that mines and other real estate will be subject to both state and local taxation. It is not conceivable that the local jurisdiction can dispense with the tax on mines, but if the state abandon the property tax, the principle of equalization of the tax on mines would require that it also abandon the tax on mines.

We believe that ad valorem taxation of mines by state and local jurisdictions under direct administration by a state tax commission or tax commissioner is a thoroughly practical method of taxing mineral wealth. If the assessments are made by township, city, and village assessors, it cannot be operated satisfactorily. But the Model System contemplates a state tax commission or tax commissioner in every state, with power of original assessment of certain property and presumably with power to maintain such expert assistance as may be necessary. Such a centralized administration is indispensable for a satisfactory administration of the ad valorem tax on mines. It has proved its worth in several states.

Approved methods of determining mining values for taxation should not differ in principle from those used in ordinary commercial transactions, for whatever a property is worth commercially, it should also be worth for taxation. The value sought should be the amount which the mine should command in the event of sale at the time of assessment. In this connection we may add that prescription by state legislatures of formulae for the valuation of mines is a usurpation of an important function of the Tax Commission or Tax Commissioner.

In our opinion idle mines ought to be taxed if they are valuable. There is no more reason why idle mines should be relieved of taxes than non-productive property generally should be. Neither are we impressed with the often voiced opinion that ad valorem taxation for revenue only, at the same level as other real estate, restrains, too seriously, the development of ore reserves and discourages development of new mines. The tax is merely an element of cost and will be reckoned with precisely as other costs are. Of course, there is no pyramiding of the taxes on unmined mineral as an actual fact of accounting and financing. Obviously, all charges in excess of or advance of income are capitalized, and taxes are no exception.

Summary

Summarizing the recommendations, your committee approves the principle of equalization of taxation of mines and other real estate, opposes the classification of real estate (including mines) for taxation at different levels, or by different methods, and advises the inclusion of the ad valorem system of mines taxation, under centralized state authority and control in the Model System of State and Local Taxation.

*An abstract of the report by a committee of the National Tax Association, presented at its thirteenth annual conference on taxation, held in Salt Lake City, Sept. 6-11, 1920, to appear (in full) in vol. 13 of the annual proceedings of the Association.

New York Section of A. I. M. E. Hears Discussion of Ancient and Modern Mines

The first of the fall meetings of the New York Section of the American Institute of Mining and Metallurgical Engineers was held at the Machinery Club the evening of Oct. 6. Following the regular dinner, E. P. Matheson, chairman of the section, introduced Courtenay De Kalb, who spoke on the subject "A Visit to Some of King Solomon's Mines." Mr. De Kalb, as a special commissioner in the Bureau of Foreign and Domestic Commerce, spent some time in Spain, and while there visited the different mining sections of that country. The first part of his talk was given over to that period of early Biblical history pertaining to the mines of the ancients, and he quite definitely established the fact that many of the mines in Solomon's time which were of great value are the same properties that are worked today in parts of Spain. Following this introduction a number of stereopticon views were shown of the Rio Tinto and Almaden mines and also of some of the iron-ore mines and plants near Segundo. During the showing of the pictures, Mr. De Kalb gave a most interesting talk on the geology, history, and development of the mines. Further views of the Rio Tinto mine were shown by Col. A. S. Dwight, who related his experiences on a visit to the property in 1903. Both of the speakers were well received, and the attendance and interest indicate a most successful series of monthly gatherings to be held this season.

Technical Papers

Mineral Statistics—Recent separates of the *Mineral Resources* series issued by the U. S. Geological Survey, Washington, D. C., and which may be obtained on request, include: "Thorium, Zirconium and Rare-Earth Minerals in 1919," pp. 32; "Magnesium in 1919," pp. 4; "Bauxite and Aluminum in 1919," pp. 7; "Gold, Silver, Copper, Lead, and Zinc in Colorado in 1918," pp. 56; and the "Preliminary Summary of Mineral Resources in 1919," pp. 128.

Tennessee Oil—The oil and gas resources of the northeastern part of Sumner County, Tenn., form the subject of a thirty-nine page booklet recently issued by the Tennessee Geological Survey, Nashville, Tenn. To the date of writing, no oil had actually been discovered in Sumner County, but several wells were producing in Allen County, Ky., adjoining. This report deals principally with geological conditions.

Manganese Ore—Two pamphlets have been issued by the U. S. Geological Survey on this subject. Bulletin 715-C (pp. 3) describes a small deposit in the Laramie Mountains of Wyoming, and Bulletin 715-D (pp. 12) discusses several occurrences in Colorado. They may be obtained on request. *The Mining Magazine* for September (Salisbury House, London Wall, London, E. C. 2.; price 1s. 6d.) contains an illustrated six-page article on the manganese deposits of Tchiaturi, Caucasus. The deposit there is probably the largest producing property in the world. Methods of mining and milling and economic conditions are described.

Air Lift Pumping—The continuous air lift requires a depth of submergence which often does not make it feasible. The lift may, however, be made in sections and operated with low-pressure air, a device of this kind having possibilities for unwatering or regular pumping work, which could only be reached with mechanical plants at greater cost both of installation and maintenance. The advantages and methods of installation and operation of the low-pressure air lift are discussed in a three-page article in the August number of the *Mining and Oil Bulletin* (Los Angeles, Cal., 25c.).

Flotation—*The Boletin de Minas* for June 30, 1920, contains a fifty-eight-page article in Spanish describing the general principles of the flotation process and the machines used therein. Some space is also given to the Murex process whereby oil is mixed with pulverized magnetite before being brought in contact with the sulphide minerals, the latter then being separated from the gangue by a magnetic process. A copy of the *Boletin* may be obtained on request from the Escuela de Ingenieros, calle Calleo 5a. (Espiritu Santo) Apartado de correo: 1301, Peru.

How To Get Government Publications

United States—Each of the various departments of the U. S. Government issues its own publications, which are printed at the Government Printing Office. These departments include, among others, the Bureau of Standards, the Geological Survey, and the Bureau of Mines. A part of each issue is ordinarily reserved to the branch which publishes it, for free distribution in the United States. Requests addressed to the individual bureau at Washington, D. C., within a reasonable time after publication, will usually secure a free copy, or one may be obtained from a congressman. The remainder of the issue is customarily kept in stock by the Superintendent of Documents, and sold by him at a price to cover the cost of printing—ordinarily 10 or 15c. Remittances should be made in advance to the Superintendent of Documents, Government Printing Office, Washington, D. C., by coupons, postal money order, express order, or New York draft. Foreign orders should be accompanied by international money order or New York draft. Postage stamps, coins defaced or worn smooth, foreign money, and uncertified checks will not be accepted. Coupons that are good until used in exchange for Government publications sold by the Superintendent of Documents may be purchased from that office in sets of twenty for $1. No charge is made for postage on documents forwarded to points in the United States, Alaska, Guam, Hawaii, Philippine Islands, Porto Rico and Samoa, or to Canada, Cuba, Mexico, or Shanghai. To other countries the regular rate of postage is charged.

The only publications furnished free by the Superintendent of Documents are the lists of the various department publications, with their prices. Separate price lists are devoted to such topics as Mines, Engineering and Surveying, Chemistry, Labor, Maps, Finance, Transportation, Health, Agriculture and Geography and Geology. These lists are revised once or twice a year.

Those who wish to be advised of all new publications issued by any department should write to the department in question and ask to have their name put on its free mailing list for announcements. Those who wish to be advised of all new Government publications should subscribe to the Monthly Catalogue of U. S. Public Documents, the subscription price of which is 50c. domestic and 75c. foreign, from the Superintendent of Documents.

State Publications—In addition to the above, each state bureau publishes numerous books and pamphlets, e.g. the State Mining Bureau, San Francisco, Cal.; the Kansas Geological Survey, Lawrence, Kan., or the Oregon Bureau of Mines and Geology, Portland, Ore. These bureaus may be situated at the state capital, at the leading city, or at a state-endowed university. In general, the publications issued may be obtained free on request, or a list will be supplied by addressing the bureau in question. Those who wish to be advised of all state publications as issued should subscribe to the Monthly List of State Publications, price 50c. per year domestic or 75c. foreign, from the Government Printing Office, Washington, D. C.

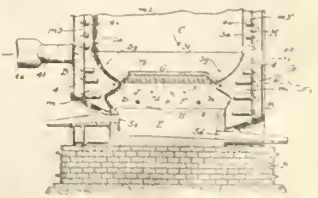
Canada—As in the case of the United States, both the central government and the individual provinces issue books and pamphlets. There is, however, no general catalogue issued, and no central office from which publications may be obtained. Requests for publications should be sent to the individual bureaus, as the Canada Department of Mines, Mines Branch, Ottawa; the Geological Survey, Ottawa; the Ontario Bureau of Mines, Toronto, and the British Columbia Department of Mines, Victoria, B. C. Ordinarily, Canadian government publications are supplied free of charge. Regular monthly lists of new publications are mailed on request by some of the departments.

Great Britain—Most British publications are sold through His Majesty's Stationery Office, Imperial House, Kingsway, London, W.C. 2. That office issues frequent free lists as well as annual lists of all government publications. The publications of the Geological Survey can be purchased from the Director General of the Ordnance Survey, Southampton.

Recent Patents

1,351,451. Smelting Furnace. Randolph G. Ward, New York, N. Y., and William R. Ward, Bethlehem, Pa., assignors to Independent Mines Smelting Co., Inc., New York, N. Y. Filed Oct. 4, 1916.

The combination of a horizontally elongated charge chamber having the lower part of its walls downwardly and inwardly curved to form a furnace hearth provided with a central elongated hearth opening having a width greater than its vertical depth; and oppositely disposed upwardly and inwardly pointing coacting burners arranged under said hearth and disposed in opposed pairs and adapted to combine their flames at a point just beneath said opening and to project the concentrated flames up through said hearth opening to points considerably above the opening.



MEN YOU SHOULD KNOW ABOUT

A. H. Brooks has returned to Washington after three months in Alaska.

Arthur Keith is making a study of the structure of the Taconic Belt in Vermont.

Norman Carmichael, general manager of the Arizona Copper Co., is in New York for a short time.

E. C. Pierce, of Los Angeles, is inspecting the mill of the Cora Miller mine, near Tyrone, N. M., which he designed.

W. L. Creden, mining engineer, is now manager for the Cascade Mines & Mills Co. in the Neihart district, Montana.

Edwin J. Collins, mining engineer, has returned to Duluth, Minn., from an inspection trip in New Mexico and California.

K. C. Heald is inspecting the Geological Survey's field parties in the oil fields of the Big Horn Basin and the Lost Soldier region.

William J. Hamilton, of Westmount, Que., general manager of the Cerro de Pasco Copper Corporation, sailed for Peru on Oct. 6.

C. Erb Wuensch has returned to Golden, Cal., after four and one-half months spent in Salvador, C. A., in geological examinations.

L. Salazar Salinas, director of the Geological Survey of Mexico, is in Washington studying the methods and organization of the U. S. Geological Survey.

E. L. Hawes, mining engineer, who has been the copper country representative of the Ingersoll-Rand Co., will leave soon for South America for the same company.

J. C. Martin is engaged in field work for the U. S. Geological Survey in Connecticut, where he is continuing the study of the high-calcium and dolomitic limestone.

H. M. Robinson, formerly a member of the U. S. Geological Survey, is in Washington making a compilation from the files of the section of foreign mineral resources.

E. J. Ruh is now at the U. S. Bureau of Standards as research assistant, appointed by the International Nickel Co. to assist investigations on the properties of nickel alloys.

S. Z. Krumm, formerly assistant professor of metallurgy at Colorado School of Mines, has accepted a similar position with Case School of Applied Science, Cleveland, Ohio.

P. J. Creighton and **John McPhilips** of Syracuse, N. Y., have been in Butte, Mont., on their return home after an inspection of the Brady Development Co. property in Idaho.

A. W. Newberry, mining engineer, has returned to New York City from a recent trip to Canada. He has moved his offices to 2 Rector St., that city (Phone, Rector 1421).

Herbert Hoover has been appointed by Secretary Payne to serve as consulting mining engineer on the advisory board of the Super-Power Survey authorized in April, 1920.

J. T. Pardee, of the U. S. Geological Survey, was a recent visitor in Seattle, Wash. He is now engaged in working out certain glacial problems in Montana and in eastern Washington.

William B. Milliken, graduate of Colorado School of Mines in 1883, is reported dead. Mail addressed to him at Ipoh Perak, Federated Malay States, via China, has been returned so marked.

W. H. Webster, assistant general manager of the Copper Queen branch, Phelps Dodge Corporation, has returned from a visit to the principal mining camps of Grant and Hidalgo counties, N. M.

Alfred W. Stickney, the geologist reported to have been roughly treated by the Bolsheviki in Moscow, has reported from Riga to the Department of State that he is safely out of Soviet territory.

R. D. Idema, of Grand Rapids, Mich., formerly with the Tennessee Coal, Iron & Railway Co., has taken a position with the engineering staff of Pickands, Mather & Co. on the Gogebic Range, Michigan.

W. C. Bridgeman, M. P., has been appointed the first Secretary of Mines under Great Britain's new Mining Industry Act. He has selected **E. A. Gowers** as Permanent Under-Secretary for Mines.

J. W. Russell, manager of Oxford Cobalt Mining Co., and member of the staff of Woodstock College, Woodstock, New Brunswick, Can., has been appointed professor of geology at Western University, London, Ont.

W. Z. Price is the newly appointed assistant professor in mining engineering and **W. A. Copeland** has been appointed instructor in metallurgical and mining engineering at the Carnegie Institute of Technology, Pittsburgh, Pa.

Charles Hoyle, general manager; **W. A. Gardiner**, superintendent; **Joseph Dietrich**, mine foreman, and **Forest Godden**, assayer, of the Esperanza Mining Co. of El Oro, Mexico, captured and held by Pedro Zamora, a bandit, have all been released or escaped from detention.

Harry O. Robinson, mining engineer, is in New York City on a brief visit from Venezuela, where he is engaged in professional work. His address is care of American Institute of Mining and Metallurgical Engineers, 29 West 39th St., New York City.

E. Martin Thorniley, mining engineer, of 625 I. W. Hellman Building, Los Angeles, Cal., is sailing for Jamaica, B. W. I., where he will spend several weeks in the examination of a copper property for British interests. Mr. Thorniley will go from Jamaica to London, and expects to return to Los Angeles early in 1921.

W. B. Plank, formerly with the U. S. Bureau of Mines, has been appointed to the Markle professorship of mining engineering and head of the department of mining engineering at Lafayette College, Easton, Pa. Recent reports erroneously stated that Professor Plank was an instructor there.

C. J. Whittlesey has been appointed by the Gypsum Industries Association as a research associate to work at the U. S. Bureau of Standards. He will study particularly the technical data regarding gypsum now available, and assist in further investigations of the properties of this material.

Albert H. Fay, consulting mining engineer, formerly with the U. S. Bureau of Mines, is now a valuation engineer, Oil and Gas Section, Internal Revenue Bureau, Washington, D. C.

Rolland C. Allen, geologist and vice-president of Lake Superior Iron Ore Association, Cleveland, Ohio, is chairman of the special committee on mines taxation appointed by the National Tax Association. The committee includes Ralph Arnold, J. Parke Channing, Celcus P. Link, C. M. Zander, Samuel T. Howe, Ernest L. Bogart, and L. E. Young.

The delegates to the Stewart, B. C., meeting of the Canadian Institute of Mining & Mettallurgy included H. M. Roscoe, secretary of the North Coast Division of the Institute; J. Tuttle, Jr., mine superintendent at Hidden Creek; N. E. Nelson, field engineer; John Dillon, Anyox smelter; W. L. Wetmore, mechanical engineer; William Weir, chemist; A. B. Wing, superintendent at Swamp Point, Granby Co.; Dr. Stuart A. Scofield, Canadian Geological Survey; and G. W. Bain.

OBITUARY

Spencer W. Clawson, who died lately in Los Angeles, was best known in the Southwest as superintendent of mines for the Copper Queen at Bisbee for twenty-three years. He went to Arizona in 1880, then connected with the Contention, at Tombstone. After leaving Bisbee he had an office as consulting engineer in Los Angeles, Cal. For a time he was in charge of a gold mine near Parral, Mexico, before being driven out by revolution.

SOCIETY MEETINGS ANNOUNCED

The California Metal and Mineral Producers Association meets at San Francisco on Oct. 24.

THE MINING NEWS

The Mining News of ENGINEERING AND MINING JOURNAL is obtained exclusively from its own staff and correspondents, both in the United States and in foreign fields. If, under exceptional conditions, material emanating from other sources is published, due acknowledgment and credit will be accorded.

LEADING EVENTS

New Mexico Chapter of American Mining Congress Organized

C. T. Brown, of Socorro, Governor, and Burton Bunch, of Silver City, Elected Secretary

Organization of a New Mexico Chapter of the American Mining Congress was completed Oct. 4 by the naming of fourteen directors, election of officers and adoption of the Arizona Chapter's constitution and by-laws as a temporary guide. The officers elected were: C. T. Brown, Socorro, Socorro County, governor; I. J. Stauber, Lake Valley, Grant County, first vice governor; I. R. Kirchman, Silver City, Grant County, second vice governor; Powell Stackhouse, Jr., San Antonio, Socorro County, third vice governor; Ira. L. Wright, Silver City, treasurer; and Burton Bunch, Silver City, secretary.

A committee on constitution and by-laws was appointed composed of Percy Wilson, Silver City; Frank W. Vellacott, Silver City; and John M. Sully, Hurley. The finance committee is as follows: D. W. Boise, Hurley; Donald G. Miller, Tyrone; and J. B. Gilchrist, Silver City. The personnel of other committees was not announced.

The fourteen directors elected were: C. T. Brown, Socorro; E. M. Sawyer, Tyrone; J. M. Sully, Hurley; Ira L. Wright, Silver City; Powell Stackhouse, Jr., San Antonio; B. B. Hanger, Albuquerque; S. J. Kidder, Mogollon; M. W. Porterfield, Silver City; J. H. McCutcheon, Chloride; L. M. Kniffin, Fierro; Norval J. Welsh, Gage; F. W. Vellacott, Silver City; I. J. Stauber, Lake Valley; and R. I. Kirchman, Silver City.

Dispute Over Engineer Group at Atlin, B. C., To Be Heard

The question of ownership of the Engineer group of mineral claims in the Atlin district, B.C., is expected to be brought before the courts for decision about Oct. 20. Because the property is valued at considerably more than $1,000,000, being rated as one of the most promising of the lode gold mines of the province, the suit will be followed with much interest. The action has some interesting features. In the first place the original stakers will seek to establish their right to title. It is understood that it will be alleged that the late Captain Alexander, the accepted owner during his lifetime and whose heirs will be the defendants, occupied the ground before it had become vacated.

WEEKLY RÉSUMÉ

In Utah an attack on the powers of the State industrial commission under the workmen's compensation act has been begun by the Utah Fuel Co. In the extreme southern part of the state, the McQuatters Corporation, of New York, is reopening the old property of the Silver Reef Consolidated Mines Co., about forty miles from a railroad; this was formerly a producer of high-grade but is probably a milling proposition now. In Nevada, the Bullfrog-Goldfield railroad has been taken over by the Tonopah & Tidewater, and to be continued in operation. In the Coeur d'Alenes of northern Idaho, financing of the U. S. Copper Co. has been provided for; the Kill Buck stockholders have elected a new directorate controlled by the Interstate Callahan; and the development is on the two Flynn groups are being pushed by the Coeur d'Alene Syndicate. In British Columbia the dispute over the ownership of the Engineer group at Atlin is to come up in court soon. In the Southwest, the advisability of licensing engineers is again urged. The docks of the Texas Gulf Sulphur Co. at Galveston, Tex., were recently burned.

At Washington a general economic study of the mineral resources of Alaska has been completed by Alfred H. Brooks and O. C. Ralston.

Silver Reef Being Reopened by McQuatters Corporation

The McQuatters Corporation, of New York, took over the property of the old Silver Reef Consolidated Mines Co. in Washington County, southern Utah, in the last few months and is engaged in putting it in shape for operation. Tests have been made on the ore and diamond drilling is to be undertaken. The property was formerly a producer of high grade but is now probably a milling proposition. It is about 40 miles from Leeds, the nearest railroad point, which is on the Salt Lake route.

Butte Ballaklava Property Sold at Sheriff's Sale

The property of the Butte-Bullaklava Copper Co., at Butte, Mont., including buildings and machinery, has been sold at public auction by the sheriff to satisfy a judgment obtained by John G. Williams and other bondholders residing in Duluth. The sale was made to the bondholders' committee for $225,000, which is approximately $5,000 less than the claims of the judgment and costs. It is the intention of the bondholders to reorganize the company and start operations at the property just as soon as all details can be arranged. The company had defaulted on payment of interest.

Northern Mexico Under Peace Conditions

Good Times Ahead — Crops Can Be Harvested—Banks Again Opening —Labor Scarce

Special Correspondence

Chihuahua, Sept. 18—People are still wondering who surrendered, Villa or the government. At all events everyone is well satisfied and Northern Mexico is in peace for the first time in eleven years. People are coming into the towns in buggies, wagons and on horseback, disclosing vehicles and saddles that have been in hiding for a long time. The roads are now free and one can even take a ride or walk in the outskirts of a town or city and get back without being deprived of his clothes by some underfed and unpaid Carranza soldier. The present federal soldiers are of a better class and are constantly being improved, better clothed and fed and, for a wonder, being drilled. The improvement is very marked. The markets also show an improvement.

Villa reached the main line of the old Mexican Central railroad at Bermajillo on Tuesday, Aug. 31 with six hundred men, about seven hundred horses and mules, a Ford and a U. S. Army wagon. Wednesday he sent two hundred men north under General Aranda and made his people a farewell address. In the afternoon he received a party of Americans and told them that he had no ill feeling toward the Americans in Mexico in that he felt that they were in no way responsible for the acts of their government, that he did not think that he had any enemies in the U. S. except one and having been double crossed by that particular person he could not regard him as anything but an enemy. Friday morning he left for Mapimi where he spent a day as guest of an American mining company. Saturday he left the railroad for his new home with over two hundred men, fifty fully armed and all officers with side arms. It was as good as a county fair to see all the fine horses and mules that he had with him and the men in gala attire and in a happy mood. Villa closed all the saloons wherever he went and was very strict in compelling good order.

He was hard pushed in Chihuahua and made one of his remarkable moves, crossing the worst desert in Mexico, the Bolson de Mapimi, and turned up unexpectedly in an important region that had few federal troops at a time when the Secretary of War was away, thus

enabling him to deal directly with the President. Crossing the desert he traveled forty-five leagues (120 miles) in twenty-nine hours without water, losing 172 horses and no men. At Sabinas he took the town and after enquiring for the names of the richer merchants assessed them twenty thousand pesos. He paid cash to all the smaller dealers for what he required of them He compelled the telegraph operator to put him in direct communication with provisional President de la Huerta and arranged for the surrender that is so satisfactory to everyone in northern Mexico.

There seems to be no doubt that the country is in for an era of rebuilding and improvement. Crops can be harvested and marketed this fall without molestation. It will require some years for the herds to accumulate. There never was such pasture, gramma grass thick enough to be cut with a mowing machine. With no stock on the ranges and the abundant rains of the last three years the grass has re-seeded and is remarkably heavy. Work animals turned out on it now will not even eat their grain, as they like the gramma better.

Ten years ago a prospect was hardly in ore before some "expert" was on the ground. Now even small profitable mines that gave promise are idle and filled with water and rubbish. Some have been robbed of visible ore and others have had shots put in them in such a manner as to make the extraction of ore impossible without some preliminary work. The smelters are nearly all operating but are short of the rich siliceous ores that have been hand sorted from the smaller mines, mines that could not afford a mill.

Labor is scarce, the more energetic of the working men having gone to the United States. Even now the trains are crowded with them going north. The demand for labor is constantly increasing and, of course, wages, particularly of those who have some mechanical experience, are increasing. The day wage for eight hours, except along the border, is from one and one half to two pesos.

Banks are opening in the larger towns but there is no such use of checks as has become the practice in the north. The people have had such an experience with paper money that it will be years before it will circulate again. At one time men were receiving the equivalent of four cents American money per day and five dollars would buy a ticket that entitled one to a ride on the railroad from the City of Mexico to El Paso. There is very little small change—a few coins of one, two, five, ten and twenty cents made of copper, fewer nickels and very little silver. The principal coinage is gold, two, two and one-half, five, ten and twenty pesos coins. In the north, American money is in circulation and it is now reaching well south along lines of communication. American nickels pass for ten centavos and a dollar for two pesos.

The railroads are bady run down both in regard to the track and rolling stock. The shops cannot turn out the repair work fast enough. The military carry no tents and are living in trains. The large smelting companies are operating their own trains largely using rebuilt cars. The merchants are bringing in their goods by express which adds to the H. C. L. The native still gets off light with his tortillas and beans.

Protection Against Outside Competitors Asked for Trail Smelting Industry

The attitude of the management of the Consolidated Mining & Smelting Co. of Canada with respect to protection against metal imports was forcibly presented to the Canadian Tariff Commission which recently toured British Columbia. J. J Warren, president of the company, complained of the removal of the 7½ per cent war tax, asserting that, in the confident belief that this impost would remain in force, the company had made investments of a substantial character. Over $250,000 had been expended in developing fluorspar deposits and commitments of equal amount had been assumed in the construction of a rod mill and other additions to the plant at Trail. He declared that there was no protection against Great Britain or the United States and, although competition from the latter source was not keen at present owing to properties having been overworked and little development having been done during the war, under normal conditions the competition for the Canadian market would be active. The United States duty was $1.50 per ton and he felt that Canada should have at least the same protection.

The company's output in lead was about equal to the Canadian consumption, he said. Until 1919 the Canadian tariff was the normal 15 per cent plus the 7½ war tax as against a United States rate of 25 per cent. Last year the whole was removed and a specific duty of 1 per cent per pound imposed.

It was stated by Mr. Warren that his company had paid $150,000 in taxes in 1919, over 16 per cent of the net income. Half a million of the 10 per cent dividends had been taken from reserve funds.

The increase in railway freight rates, Mr. Warren contended, was a direct contribution to the railways because no corresponding increase in selling price could be made. The Trail Board of Trade submitted to the commission a memorandum emphasizing the importance to the Trail smelting industry of adequate protection.

Texas Gulf Sulphur Co.'s Docks Burned

The sulphur-loading docks of the Texas Gulf Sulphur Co. at Galveston, Tex., were recently destroyed by fire, together with about 50,000 tons of crude sulphur, forty freight cars, and a great deal of surrounding property.

Chinese-American Company Working in Yunnan Province

Engineers of Yunnan Ming Hsing Mining Co. Engaged for Some Time in Northwestern Part

"The government of Yunnan Province, China, and the Orient Mines Co. of New York, have jointly formed a Sino-American company called the Yunnan Ming Hsing Mining Co. for the development of mining property in Northwestern Yunnan," says *Millard's Review of the Far East*. "Thirty-odd American engineers have been working there with J. W. Finch, as engineer-in-chief. Silver and lead in large quantities have been discovered.

"American activities in that province are being favored by both the people and the provincial government. Large sums have already been spent by the American partners during the last three years in investigation and development work. The first group of American engineers sent from America to prospect for silver and lead began work in March of 1918. Finding that the property was worth developing, a company was formed in September, 1919. It was a Sino-American undertaking, but it is a purely Chinese corporation operating under a Chinese charter.

"The Yunnan Ming Hsing Mining Co. is the first attempt really to operate a mining enterprise under a Chinese charter. Its promoters declare that thus far it has been successful, and do not believe they will encounter any difficulty in dealing with the Chinese authorities. In their opinion, all Chinese-American enterprises should be run upon that basis and on no other if genuine co-operation of the Chinese is desired.

"The president of the company is Wu Shih-shun, former chief of the Yunnan Bureau of Finance, a man of considerable modern business experience although he has been in contact with foreigners for only a short time. Its engineer-in-chief is Mr. Finch. One of the best known mining engineers in America, Mr. Finch, has been general manager of some of the largest mining enterprises in the United States All credit for the successful formation of the company belongs to him. Having been in China for a number of years investigating mines, he has come to know the Chinese people thoroughly. This knowledge of the people among whom he is now working has helped him greatly in his negotiations with the Yunnan authorities with regard to the formation of the company. Had it not been for his able handling of the negotiations, they might have ended in failure.

"It is interesting to know that as a result of the growth of American influence in that remote province in recent times, Yu Yun-lung, former Civil Governor of Yunnan, several months ago made a trip to the United States, accompanied by C. Y. Chiu, an American returned student, who has held several important positions in Peking,

one of them being English Secretary to the Senate when C. T. Wang was Vice-Speaker after the death of the late President Yuan Shih-kai. The trip of Mr. Lu to America was undertaken to study conditions in that country. Since the arrival of so many American engineers in Yunnan, the interest of the people in that province in commercial conditions in America has been greatly aroused.

"Besides working the silver-lead mines, a number of American engineers are investigating the tin mines in Cochiu and the Tungchwang copper mines, both of which are famous as they are supposed to contain the largest quantity of tin and copper, in the belief of foreign engineers, who have made a study of them. The Americans plan to eventually develop those mines together with the silver-lead ones. Dr. H. Foster Bain, the famous mineral authority, is in charge of the investigation of both the Cochiu and the Tungchwang mines.

"America is destined to play a part—an important part—in the opening up of Western China, and in the development of her mineral resources. When the development work of the Yunnan Ming Hsin Mining Company is well under way, railway communications will undoubtedly be introduced to facilitate transportation of ores. The need has been already deeply felt, the authorities of the company experiencing difficulty in sending a sufficient number of coolies to the region where their property is located. The mining region is mostly unpopulated, and for this reason the import of labor becomes a necessity. The transportation question is now being tackled. Its solution means that Yunnan will be more accessible to the outside world, and its general development will be accelerated.

"Reports from Yunnan indicate that the Yunnan government is appreciative of the fair spirit manifested by the American partners of the mining company. The Chinese own half of the interest, but they do not have to bear the initial expenses such as expenses for purposes of investigation and for the sending of American engineers into Yunnan. Nearly a million dollars have been spent upon the investigation work, which made possible the formation of the company.

"The capitalization of the company is two million dollars to begin with. The company's by-laws provide that it can be increased to any size the board of directors may decide in the future. It has five directors, three of whom are Americans, and there is one auditor-in-general who checks all the expenditures. Many American returned students are being employed to assist the American engineers, and are getting much practical training in mining gineering.

"There appears to be no surer way of insuring the independence of China and maintaining her sovereignty than by encouraging foreign investment in her land and especially the investment of American money. It is said that if America or Great Britain had invested one hundred million dollars in Shantung, the issue of the Shantung question at the Paris Peace Conference would have been entirely different. General Tang Chi-yno, Military Governor of Yunnan, who is the real ruler and authority in that province, seems to understand this situation, and, understanding it, has gone into full co-operation with one of the largest mining companies in the world, the Orient Mines Co. of New York, in which many big American financiers are interested.

"Following the break-up of the age-long idea of spheres of influence which all the enlightened nations are detesting, Americans, Britons, Frenchmen, or other foreigners can go anywhere in China and help the people to develop natural resources. Americans have apparently thrown in their lot with Yunnan, which province is, however, large enough to accommodate activities of other foreigners. In the meantime, the interior provinces such as Szechwan, Sinkiang, Mongolia, and Tibet are awaiting development. They would welcome more men of Mr. Finch's caliber if the latter would go to them in a spirit of helpfulness and friendliness.

"Yunnan, situated on high table-lands, abounds in minerals. Covering 146,718 sq.mi., it is next to Szechwan in size, but it is the least populous province of China, its inhabitants being about 12,721,500 or 86 to the square mile. The extraction of ores, tanning, the preparation of tea, and the mining of copper, iron and tin, occupy a large number of the Yunnan people. In Yunnan, four cities are open to foreign trade, namely, Mengtze Hsien in Linngan Fu, Hokow in K'aihwa Fu, Szemao Ting in P'ueul Fu and Tengyuch T'ing in Yungchang Fu. The treaties provide also for the opening of Yungchang Fu itself.

"Numerous routes radiate from Yunnanfu, the provincial capital of Yunnan. Starting from the city, the following, according to Richard's Comprehensive Geography, deserve to be mentioned: The road to Kweichow, via K'utsing Fu; the road to Szechwan, via Tungchwan Fu and Chaotung Fu; the road to Burma, via Tali Fu and Yungchang Fu; a road forks off at Tali, and leads to Tibet, via Atentze; the road leading to the Laos country, via P'ueul Fu and Szemao T'ing; the road to Tongking, via Mengtze hsien and Manhao; the road to Kwangsi, via Kwangnan Fu. The new railway line, which will bring Yunnan into direct and rapid communication with Tongking, starts from Laokwi, follows the Namti valley, and has its terminus at Yunnan Fu, via Mengtze hsien, and Ami Chow."

The Tintic district in Utah, lying in Juab and Utah counties, produced over half of the total silver output of Utah in 1919, according to the U. S. Geological Survey, having produced 6,815,008 oz. as compared with 11,649,961 oz., for the entire state. The Chief Consolidated at Eureka was the largest producer in the district and in the state.

Utah Fuel Co. Attacking Powers of Industrial Commission

Claims Body Acting Under Workmen's Compensation Act Is Usurping Judicial Functions

The powers of the Utah industrial commission as conferred by the amended workmen's compensation act of 1919 are being opposed by the Utah Fuel Co. on the ground of unconstitutionality. The case will shortly come before the state supreme court, which alone, according to the amended act, is empowered to review the proceedings of the commission. It is held that review by the district courts as permitted under the Act of 1917 would result in frequent appeals, which would be prejudicial to the proper functioning of the law.

The case in point concerns an award of $12 weekly to be continued throughout the period of disability that was made to a former employee of the Utah Fuel Co., who is now supposed to be suffering from progressive or creeping paralysis. The fuel company holds that there is no evidence to connect the man's present condition with his employment with the company about a year ago before the hearing was held, and that the evidence proves the disease to have attacked the employee in question before the time of his entry into the service of the company. The fuel company challenges the right of the commission to make decisions between litigants as to ultimate liability, holding that the commission, an administrative body, is thus usurping judical functions, and that if the law as amended, does attempt to give it such judicial power, this would make it in legal effect a court, and that the law would therefore be unconstitutional and void. Contention is made also for the right of appeal to district courts.

Tonopah and Tidewater Acquires Bullfrog-Goldfield Road

The Bullfrog-Goldfield railroad, which is 75 miles long and extends from Goldfield to Beatty, in Nevada, will be operated in the future by the Tonopah & Tidewater railroad, the control of the stock having been recently bought from the Althouse-LaGrange syndicate, of New York. The road was built during the boom days of Goldfield and of late years has been far from a paying investment. When the Althouse-La Grange syndiate secured control it was with the intention of scrapping the line and selling the equipment at the high prices then prevailing for such material. This was prevented and the road has now passed into control of those who are interested in having it continue operations, and it is expected that a much improved service will result.

The Bullfrog-Goldfield R.R. Co. has been re-organized with R. C. Baker, president, and C. B. Zabriskie, vice-president and treasurer. The general offices will be in Los Angeles. Mr. Baker, the new president, is also president of the Pacific Coast Borax Co. and the Tonopah & Tidewater R.R. Co.

Chisholm, Minn., Seeks More Taxes from Wellington Mine

Steel Corporation's Property Said to Contain Million Tons of Ore—Drilling Results Concealed from Tax Commission

Alleging under-assessment of mining property a petition was recently filed with the state tax commission of Minnesota asking that the commission make a full examination and re-assessment of the Wellington mine, owned by the United States Steel Corporation on the Mesabi Range. The petition states that this property has paid only nominal taxes during the last thirteen years and that the state is entitled to more than $100,000 in additional taxes from the property.

It is alleged that this property was thoroughly drilled in 1907, but that the results of drilling were not disclosed to the tax commission. From 1907 to 1919 the Wellington mine was assessed on the basis of approximately 140,000 tons of ore reserves and on a valuation not to exceed $14,000 in any one year. The annual taxes never exceeded $610, when it is claimed, they should have reached $10,000.

The petition is filed by George H. Spear, attorney of Duluth, and signed by J. Austin, president of the village council of Chisholm, Minn., and E. Drew, president of the school board. The mine is located in the village limits of Chisholm.

The Oliver Iron Mining Co., the iron mining subsidiary of the U. S. Steel Corporation, is now sinking a shaft on the property preparatory to opening up the mine for operation. It is alleged that the mining company has admitted to the board of equalization of the village of Chisholm that the property contains more than 1,000,000 tons of ore.

Licensing of Engineers Urged in Southwest

Mining and civil engineers of Arizona and New Mexico are to try to pass through their next legislative sessions bills for the licensing of engineers. It is urged that the profession assuredly is as technical as that of the law, the bar and of teaching, all of which have strict license regulation that protects the individual and the state alike. The legislatures will be asked in each state to create a board of engineering examiners.

Would Open All Indian Reservations to Mining

The support of engineering and mining societies and much official aid have been enlisted in support of the movement to throw open for mining all the Indian reservations of the nation. Especial interest attaches to this movement in Arizona, which state has large deposits of coal on the Navajo reserve, asbestos on the Apache reserve and mica on the Pima reserve, while on all are understood to be valuable prospects of copper, gold and silver.

Wage Scale Agreed on Last May Still Effective in Slocan, B. C.

The wage scale effective at present in the mines of the Slocan district, British Columbia, is given as follows:

MINE WORK

Class of Work	New Scale
Miners	5.75
Muckers	5.25
Timbermen	6.25
Timbermen's helpers	5.75
Blacksmiths	6.25
Blacksmith's helpers	5.75
Carpenters	6.75
Compressor men (steam)	6.25
Compressor men (other than steam)	5.75
Tramway operators (head end)	6.25
Mule drivers (underground)	5.75
Brakemen on mule trains	5.25
Teamsters	6.25
Common labor	5.25

MILL WORK

Jig men	6.25
Table men	5.75
Flotation men	5.75
Roll men	5.25
Crusher men	5.25
Common labor	5.25
Carpenters	6.75
Repair men	6.75
Repair men's helpers	5.75

This scale became effective May 12, 1920, following the strike called by the O. B. U. on May 1, at which time the men demanded a wage increase of $1 per day and other concessions as given on page 688 of the *Engineering and Mining Journal* of Oct. 2. On May 12 the operators of the district, excepting the Silversmith Mines at Sandon, made an agreement with the International representatives granting an increase of 75c. per day but also increasing the price of board 25c. per day. They also agreed not to employ any I.W.W. or O.B.U. members but reserved the right to employ non-union men.

"As matters now stand four months since the strike was called," says one of the operators, "nearly all the mines have resumed, but, most of them are still shorthanded, though labor has recently become more plentiful. The strike is meeting the fate of all movements founded on misrepresentation and false promises, and, is dying a natural death. Conditions will probably return to normal by the spring of 1920.

"One of the most deplorable features of this trouble particularly from the standpoint of international good feeling has been the spectacle of the ex-District Attorney of Spokane coming to British Columbia, and, making an arrangement which gives aid and comfort to the avowed enemies of established government, for the sake of putting a few dollars in his pocket."

According to the State Mine Inspector, Arizona now is employing about 20,000 men in its mining industry, compared with 30,000 a year or so ago.

Labor Survey Now in Progress in Northern Ontario

Mines Short of Men—Operators See Importation of Foreign Labor Only Relief

Despite the fact that large numbers of men are being laid off in the various industries in southern Ontario, the mines of northern Ontario are very short of men. Unfortunately, men who have been employed in shops and factories are not generally suited for the mines, and it is doubtful if the operators will be benefited to any great extent by this surp'us. Practically every company operating in northern Ontario reports a shortage and a slowing down in development and exploration, and, in many cases, of production. The labor turnover has been high and in the Cobalt camp will undoubtedly average 25 per cent a month. This is due to the fact that there has been no immigration of foreign labor, and that the Government has been consistently opposed to such immigration. An official of the Labor Department from Ottawa is now making a survey of this northern country in order to get first-hand information, and it is hoped that some definite action may be taken. Unless the operators are allowed to import foreign labor they can see practically no hope of relief for the future.

Recent Production Reports

Calumet & Arizona's September production was 3,038,000 lb. copper compared with 3,650,000 in August.

New Cornelia produced 3,314,000 lb. copper in September against 3,842,040 in August.

North Butte produced 1,434,159 lb. copper in September against 1,286,137 in August.

Shattuck Arizona in September produced 166,513 lb. copper, 921,912 lb. lead, 57,008 oz. silver, and 523 oz. gold compared with 194,003 lb. copper, 563,452 lb. lead, 34,661 oz. silver and 406 oz. gold.

Oriental Consolidated, in Korea, reports its September cleanup as $76,500, compared with $75,500 in August. The entire property has been operated with hydro-electric power since July 13. The Tongkol mine has been unwatered and the Chintui mine is now being pumped out. Labor shortage is holding up prospecting work. Exchange continues unfavorable. Chinese labor continues absent and Koreans are more difficult to handle than formerly.

Greene Cananea produced 3,500,000 lb. copper, 159,600 oz. silver and 910 oz. gold in September. The August output of copper was also 3,500,000 lb.

U. V. Extension produced 3,327,644 lb. copper in September as compared with 5,805,568 lb. in August.

Anaconda produced 11,100,000 lb. copper in September against 11,800,000 in August.

Phelps Dodge produced 7,998,000 lb. copper in September, compared with 8,365,000 in August.

Mining in Alaska Less Affected Than Elsewhere, According to Col. A. H. Brooks

Loss of Experienced Miners Worst Feature of Situation; Scarcity of Common Labor Next

The most careful general economic study ever made of the mineral resource of Alaska just has been completed by Col. A. H. Brooks, in charge of Alaskan mineral resources of the U. S. Geological Survey, and O. C. Ralston, of the U. S. Bureau of Mines. This comprehensive study of the entire Alaskan situation from the mineral standpoint, was made at the instance of the Secretary of the Interior, in connection with the program of stimulating Alaskan activities so that sufficient tonnage may be found to make the Alaskan railroad pay. There is also the general consideration of speeding up the development of this territory which has been so generously endowed by nature.

One of the matters to which particular attention is given is the increasing demand in Alaska for a Government smelter. That phase of the matter will be reported on by Mr. Ralston on his return Nov. 1.

Considering the world-wide depression in gold and copper mining, Colonel Brooks was of the opinion that the mineral industry in Alaska is doing very well indeed. Although both gold and copper mining has been affected very seriously by the depression in those metals, Colonel Brooks believes that Alaska has been less affected than any other mining region depending largely on those metals. The fact that Alaska seems to be better off than other mining regions is regarded as an indication that Alaska possesses a fundamental vitality which is certain to exert itself as the situation improves. The worst feature of the situation, in Colonel Brooks' opinion, is the loss of experienced miners. Many of these men have been working in Alaskan camps for twenty years and are thoroughly familiar with conditions. Now a great many of them have returned to the United States and find that they can do better in this country. A great many of them have been attracted by the petroleum industry since the lure of oil carries with it more chances of reward than does gold mining under present conditions.

Another serious feature in the Alaskan situation is the loss of common labor. These men have returned to the United States in great numbers. It was from their ranks that most of the prospectors in Alaska was drawn. It is going to be very difficult, Colonel Brooks believes, to induce these men to return or to get men of their type to take their place.

Despite the depression in gold mining, Colonel Brooks reports great activity in prospecting for gold lode claims in southeastern Alaska. Promising discoveries have been made in the Sitka district. The success of the Chichagoff mine is also having an important influence. It is interesting to note that the Sitka district was the scene of great prospecting activity nearly half a century ago. After a long period during which it was practically abandoned by prospectors it again is the scene of the greatest activity.

At the special request of Secretary Payne, Colonel Brooks made a general survey of the oil possibilities of the territory. He calls attention to the fact that geologic conditions are particularly good for the occurrence of oil at a number of places in Alaska. In addition there is the direct evidence of oil seepages. Due to the increased price of petroleum and to the enactment of the new mineral leasing law, Colonel Brooks expects active drilling to start at a number of points in Alaska next spring. Colonel Brooks visited the Katalla field where drilling and refining are in progress on a patented claim containing 160 acres. This is a field of small pumping wells, but a superior grade of gasoline and distillate are being produced. The petroleum is coming from sands at depths of 300 and 800 ft. In Colonel Brooks' opinion, these wells will continue to produce for a long time to come. There is a ready market locally for all that this field can produce, especially since the product is superior to the imported gasoline.

War Minerals Awards

Awards aggregating $5,812.25 were recommended during the week ended Oct. 2, by the War Minerals Relief Commission. The awards were as follows (the name of the claimant, the mineral, the amount recommended, and its percentage relationship to the amount claimed, are shown): E. E. Taylor, chrome, $300, 100 per cent; Frank M. Liscom, chrome, $148, 16 per cent; W. S. Tolbard, manganese, $5,364.25, 31 per cent.

With the foregoing awards, 239 war minerals claims have been allowed in full or in part. The total amount claimed in these 239 cases was $5,938,748. The amount recommended for award was $1,912,368.23, or 32.2 per cent. In all the commission has acted on 1,032 claims.

The administrative expenses of the commission, on Oct. 2, totaled $302,248.14, or 2.22 per cent of the total amount of the claims settled.

Geologic Study of Homestake Mine, at Lead, S. D., Completed

Sidney Paige Follows Up Earlier Work for Government by Comprehensive Examination

A thorough geologic study of the Homestake mine at Lead, S. D., has just been completed by Sidney Paige. This is the first comprehensive study ever made of this mine by a Government engineer. Due to the fact that the Homestake deposit is unique in the United States, there has been the greatest interest in its geology. It has been the policy of the company, however, not to permit of studies of its ore deposits by outside agencies. An exception was made in 1913 when Mr. Paige was allowed to make limited observations underground. During the present visit, however, Mr. Paige was given every opportunity to make a careful study.

As a result of his study in 1913, Mr. Paige published a short paper on the origin and structure of the ore deposit. His latest examination supports the ideas which he published at that time.

"The mine is really a replacement deposit of a closely folded pre-Cambrian series of schists and carbonate rocks," says Mr. Paige. "The ore, in the main, is confined to beds which probably comprised magnesium and calcium carbonate layers. An important zone of shearing and faulting determined the locus of the ore in this series of carbonate beds. The folding of the beds in large measure determined the shape and pitch of the orebody."

Rumors to the effect that gold existed in the Black Hills became current early in the 19th Century. Owing to the hostility of the Indians, few efforts were made to prospect the hills. In 1874, however, General Custer made a military reconnaissance of the region in an effort to establish whether rumors of gold had foundation. The Custer expedition was accompanied by N. H. Winchell, a geologist. Gold was found to exist in the stream beds of the Harney Peak region. A further examination was made by Government geologists in 1875, but the party did not reach the region of the Homestake mine.

The facts concerning the discovery of the Homestake deposit are not known but it is said that the Homestake and Old Abe deposits were discovered by two French boys, Moses and Frederick Manuel. The property was mentioned in print as early as 1876. Its real worth was established in 1877. Since that date more than $100,000,000 in gold has been taken from the Homestake orebody.

NEWS BY MINING DISTRICTS

Special London Letter

Mining Companies Finding Difficulty in Obtaining Funds—West Rand Consolidated in Sorry Plight

London, Sept. 28—At least half a dozen mining companies acknowledge that they are in need of funds, and five of them are specifying the amount that should be raised. Four of the companies own tin areas, one is a gold mine, and the last, the Broken Hill Proprietary, which owing to demands made upon it is compelled to extend its iron and steel works. Three tin mining companies, namely, the Killifreth, the Dolcoath and the Grenville United are in Cornwall, where the industry is sadly in need of additional financial resources. While tin was selling at a high price and wolfram and arsenic were in great demand the mines of the Duchy earned fairly substantial profits; but since the war, and owing to the action of the Government in regard to the price of the metal, coupled of course with increased wages, the rise in coal, transport rates and raw materials, matters have become much less rosy. Attempts were made to induce the Government to loan £100,000 for development purposes; the authorities, however, refused, deciding that the mining industry must find its own capital. The famous old Dolcoath wants something like £100,000; Grenville United, which for some months worked from hand to mouth, experiences great difficulty in obtaining funds; while Killifreth, which has acquired two adjacent properties, is compelled to provide £20,000 additional capital, and is creating 50,000 new £1 shares.

Money is by no means plentiful, and can only be procured on onerous terms; in fact large lenders of capital to mining companies in the past are deciding to sit still and do nothing because, where machinery is required, early delivery cannot be guaranteed, and they argue that if money is raised on debentures the interest will be paid out of the money that is provided.

An illustration of the unfavorable effect of increased cost of labor, transport, materials, etc., is acorded in the case of Northern Nigeria (Bauchi) Tin Mines. This company designed a hydro-electric plant at the Kwall Falls, to be erected by Messrs. Vickers. The original estimated cost was £85,000, and it will be exceeded by no less than £65,000. To complete the mine equipment will require another £75,000, making £225,000 in all. The directors have expended £100,000, of which £45,000 is borrowed, and they must now raise £125,000. Ten thousand tons of tin concentrates is proved, having an estimated value at the current price of tin of £1,680,000, on which the profit should be £600,000. The issued capital is approximately £300,000.

The Broken Hill Proprietary proposes to spend £3,500,000. It has rather over £1,000,000 in reesrves; it will issue £1,500,000 in 7 per cent debentures at 97 and 420,000 shares at £2 5s. For the iron and steel works this sum is fairly certain to be found.

The West Rand Consolidated Mines is in a very sorry plight, for it needs money and has decided to postpone for three years payment of interest on its debentures, and also redemption of the debentures. Further, it will suspend the first charge of the debenture holders to enable the company to raise up to £100,000 at 8½ per cent on a floating first mortgage. The General Mining & Finance Corporation will advance the money, but only as and when required. The property is a low-grade area in the western part of the Witwatersrand, about which great things were predicted some years ago. The mine, however, has never come up to expectation.

Peregrina—The Peregrina mill continues operating on a reduced scale pending the conclusion of important development work which it is expected will open up a large tonnage of very good ore. W. T. Kendall is superintendent for the company of both mine and mill.

La Luz District—The Guanajuato Reduction & Mines Co. is building a mill and cyanide plant on its properties at San Pedro in the district of La Luz. The plant is designed to handle 200 metric tons per day and was laid out so as to permit of the tonnage being readily increased. The counter-current system is to be used with Dorr thickeners and agitators. Precipitation will be effected by the Merrill zinc dust system, using the Crowe vacuum process in conjunction with same. The ore from the crusher will be screened, the fines going direct to 5 by 6-ft. Allis-Chalmers driect-driven ball-mill; the coarse being passed through twenty stamps before going to the ball mill. Three 5 by 16-in. tube mills are to be used for the fine grinding, working in closed circuit with Dorr classifiers. Construction work is progressing.

A new three-compartment shaft is being sunk in the south end of the Rosario mine, to be used as the principal hoisting shaft for operations in the Rosario, Purisima and San Pedro mines. The old Rosario shaft is being timbered through caved ground, for use as an auxiliary shaft. An adit is also being driven north in the Pili mine at the north end of the company's La Luz group. This mine will be connected with the others by a surface tram. The company expects to have its mill in operation early in November, unless something unforeseen arises.

GROUP INCLUDES CHARLES HOYLE (1), MANAGER OF ESPERANZA MINING CO.; W. A. GARDINER (2), SUPERINTENDENT, AND THREE OTHER EMPLOYEES OF COMPANY, WHO WERE RECENTLY CAPTURED BY PEDRO ZAMORA, BANDIT, IN JALISCO, MEX., AND HAVE SINCE ESCAPED OR BEEN RELEASED

MEXICO

Guanajuato

San Matias Mill Running After Two-Year Shut Down—Guanajuato R. & M. Co. Erecting 200-Ton Mill

Guanajuato—On Sept. 8, the San Matias mill of the Mexican Milling & Transportation Co. resumed operations after having been closed down for over two years. The mill has been entirely overhauled and some important changes made in the flow sheet and system of treatment, which brings the daily capacity up to over 300 tons. The ore is being supplied from the Esperanza group of mines by an aerial tramway 11,000 ft. long, which has recently been installed. P. R. Hudson is mine superintendent and O. W. Johnson mill superintendent.

Durango

Mining Active in Avino and Panuco Districts

Mining is becoming very active in the Avino and Panuco districts in Durango. They are located near each other and at one time were the most flourishing camps in the state. A large amount of English capital was invested there.

Gabriel Segura, of Durango City, has filed on a number of delinquent claims in that vicinity and is preparing to operate them.

The Avino Mines Co., Ltd., are seeking to obtain from Juan F. Flynn, former manager, the titles to the Maverick group of mines near Avino.

CANADA

British Columbia

Re-definition of Canada-Alaska Boundary Progressed During Summer—Opening Berniere Mines

Victoria—Dr. V. Dolmage, of the Canadian Geological Survey, has returned after a summer's field work which has resulted in the obtaining of the information necessary to complete the geological map of the west coast of Vancouver Island. Dr. C. H Clapp and Dr. G. N. Dawson have already completed the geological survey of the southern and northern sections of the west coast of the island.

Vancouver—The re-definition of the Alaska-Canada boundary line, particularly in the Portland Canal and Salmon and Unuk River regions, make considerable progress during the past summer. J. D. Craig, head of the Canadian party, has returned and states that he worked north and westward from the town of Stewart and that the United States surveyors, led by Jesse Hill, worked south by the Unuk River. The duty of these parties was to indicate the boundary clearly by means of monuments and by the cutting of timber where there is timber. It is stated that some miners and prospectors have made the mistake of staking in American territory and recording the same with Canadian officials and that the error has been as frequently made conversely.

Trail—Ore shipments received at the Consolidated smelter during the week ended Sept. 30 totaled 12,744 tons, coming from the following shippers:

Mine and Location	Gross Tons
Emerald, Salmo	33
Florence, Princess Creek	95
Iron Mask, Kamloops	45
Josie, Rossland	448
Monarch, Field	78
North Star, Kimberley	224
Paradise, Athalmer	57
Providence, Greenwood	47
Queen Bess, Alamo	40
Sally, Beaverdell	37
Twin, Princess Creek	26
Velvet, Velvet	28
Washington, Sandon	37
Company mines	11,549
Total	12,744

Revelstoke—The Berniere Mines, situated near Scott Creek, Camborne, are being opened up and a contract has just been let for the construction of cabins, blacksmith shop and other buildings, it being the intention to continue work this winter. The Beatrice Mines, of the same district, are shipping silver-lead ore to the Trail smelter.

Ontario

Temiskaming Shareholders Ratify Coal Mine Deal—To Continue Sinking at Vipond

Cobalt—F. C. Sutherland & Co., of Toronto, have taken an option on the Penn Canadian mine, which has been closed since the strike last year. There is about 8,000 tons of ore broken in the mine and about 150,000 tons of old tailings, which, it is believed, can be retreated at a profit.

At a general meeting of the shareholders of the Temiskaming mine a deal for the purchase of a half interest in the Blue Diamond coal mines in Alberta was ratified. The coal property is being taken up jointly by the McIntyre and the Temiskaming. Four hundred and fifty thousand dollars has already been paid on the purchase price. It is stated that the mine is already making a profit, which will be largely augmented when the new equipment ordered is on the ground.

According to the terms of the agreement between the Dominion Reduction Company and the Peterson Lake, for the retreatment of old tailings belonging to the Peterson Lake, the Dominion Reduction is to receive 35c. per ton over the cost of treatment, and one-third of any profit remaining after this.

The Casey Cobalt Co., which has produced 2,500,000 oz. of silver, has gone into voluntary liquidation.

Porcupine—Following the decision to reopen the Vipond mine, it has been decided to continue the shaft from the 600 to the 1,100-ft. level. A big program of development work has been outlined.

Elk Lake—The Matachewan Gold Mines in the Elk Lake district has recently concluded 15,000 feet of diamond drilling. The results of this drilling, together with the underground development that has been done, is sufficient to satisfy the management as to the orebodies. It is probable that the property will not be opened up in a large way until hydro-electric power is available.

It has been officially stated that the shareholders of Dome Extension will participate in the dividend of 25c. per share on Dome stock, payable Oct. 20. The deal for the purchase of the Dome Extension property by the Dome on the basis of 30 shares to one was recently ratified

Manitoba

Herb Lake—The Rex is working three shifts per day underground and the mill running 24 hours per day. Ore reserves have been blocked out ensuring steady operation of the mill

ALASKA

Rae Wallace Co. in Willow Creek District Installing Gibson Mill

Allen G. Kennedy, of Wallace, secretary of the Rae-Wallace Gold Mining Co., recently returned from an inspection of the company's property in the Willow Creek district, Alaska. Most of the stock of the company is held in the Cœur d'Alene district and the manager in charge at the mine, Don S. Rae, has been in Alaska twenty years and prior to that time was engaged in mining in the Cœur d'Alenes. The development on the Rae-Wallace at this time consists of a series of tunnels which have proved the vein for a distance of 3,500 ft. and exposed enough ore to keep the 50-ton mill, which is now being erected, running for several years. However, the company plans to drive another tunnel just above the mill site which will open up the vein to a depth of 1,200 ft. and then increase its milling capacity. A Gibson mill in two units of 25 tons each is now being installed, and it is hoped to have one unit running before the mining season closes this fall. The ore is free milling and Mr. Kennedy estimates that from $40 to $50 per ton will be recovered by amalgamation.

CALIFORNIA

Construction of 500-Ft. Tramway Begun at Kelly Gold Mine at Quincy

Quincy—Construction of a 500-ft. tramway to connect the mouth of the tunnel with the stamp mill at the Kelly gold mine on Crescent Hill, near Quincy, began on Oct. 1. The work is under the supervision of H. C. Martin, building contractor, who has just completed several other large construction jobs in this district. Martin will also erect an ore storage bin and other buildings. The Kelly mine embraces 180 acres containing nine claims and now employees a force of nine men. The plant is hard to reach by tractors or trucks as in order to get machinery and supplies to the mine a 27-per cent up grade must be overcome.

Sutter Creek—Morris Brinn, of San Francisco, has completed an examination of the Central Eureka property in which he is heavily interested. Power shortage has curtailed the output, but large reserves are being developed.

Jackson—The water in the Kennedy shaft has been lowered to a point below the 2,800 level, with a corresponding progress in the connected Argonaut workings. Last week some delay was caused by one of the large water skips getting caught in the shaft and tearing out some of the timbers. The pumps are working steadily in both mines in addition to the water skips. The shaft as thus far unwatered is in first-class condition. The greater part of the east shaft of the Kennedy is in hard greenstone and is not affected by the water. James Spiers, superintendent, is looking after the present work, which is being done at the expense of the Argonaut company, the Kennedy not desir-

ing to resume operations on its own account during present abnormal conditions.

San Francisco—Fletcher Hamilton, state mineralogist, has been touring the mining districts of the state and giving addresses on the development of mineral resources. H. A. Jenison, geologist for the United States Geological Survey, is engaged in making a survey of the principal copper mines of the state, starting with the Engels and Walker mines in Plumas County.

Engelmine—R. A. Kinzie, present manager of the Engels Copper Co. states that on the No. 6 level, or 600-ft. level, of the Engels upper mine one new tramway, which is now in operation, according to J. R. Walker, who is interested in the company. These concentrates are said to be worth over $80 per ton at the present price of copper. The Walker company is making the camp and headquarters for operations close to the mill,

NEVADA

Cactus Nevada Silver Makes First Shipment

Cactus Peak—The first shipment of ore by the Cactus Nevada Silver Mines Co. was recently made, going to the Goldfield Development mill at Goldfield. A new vein is reported to have been

necessary equipment the driving of the Arctic tunnel at the Cortez Consolidated mine is progressing steadily. It is now in 1,400 ft. from the portal and within another 600 ft. is expected to cut the downward extension of the main vein at a vertical depth of 600 ft. below where the latter was mined in the No. 1 tunnel. Geo. L. Kaeding is in charge.

Tonopah—The Tonopah Extension report satisfactory progress in sinking their Victor shaft, which is now 100 ft. below the 1,760 level. Present plans are to sink 75 ft. before crosscutting, the last 50 ft. to be used as a sump. The McCane shaft workings have been connected to the No. 2 shaft workings and

MILL AND MACHINE SHOP OF ENGELS COPPER MINING CO., PLUMAS COUNTY, CAL. DEPOT OF INDIAN VALLEY R.R. IN FOREGROUND

orebody is 840 ft. long with on average width of 70 ft. Another to the south is 200 ft. long and 60 ft. wide, while two other known orebodies have both been developed sufficiently to have their limits known. These bodies average between 2.75 and 3 per cent copper as they are broken down, also carrying gold and silver.

The Reinmiller Copper Co. has about completed the road leading to the site for the crosscut tunnel which will tap the main vein so far developed at a depth of 400 ft. below the collar of the shaft. A boiler and compressor are on the ground and will be installed at once, after which the tunnel will be rapidly pushed with two shifts until it reaches its objective.

Portola—Between 8,000 and 9,000 tons of concentrates is at the Walker mine at this time ready to ship over the opened up in the east drift on the 265-ft. level.

Goldfield—The winze from the 900 level of the Spearhead is down over 200 ft. and will be continued to a depth of 500 ft. It is being sunk on an incline of 76 deg. and is going through a series of faults, the formation being alternately quartz and alaskite.

Gold Hill—Crosscutting on the 475 and 575 levels of the Co. Imperial is in progress. When the vein has been crosscut, sinking of the shaft will be resumed. Twenty men are at work at the portal of the haulage tunnel on open cut work and construction of buildings to house machinery and supplies. The United Comstock Mines Co. is employing 78 men altogether.

Cortez—With the completion of the installation of a compressor and other after some delay in repairs this shaft is to be sunk to the level of the 1,540 of the Victor. In development work fair progress is reported and mill tonnage from the mine is given as 1,750 tons.

In the Tonopah Belmont mine drifts have been started on the 729 vein from what has been designated the 550 level. This is an intermediate level from a raise driven from the 700 level. The drift shows two feet of fair ore. Regular development from the 700 to the 1,200 levels has disclosed nothing new of importance, ore showings and tonnage mined being normal.

In the West End mine development on the West End, Footwall and Ohio veins has proceeded with few changes. August profits were $47,466.64 from 4,396 tons of mine ore and 496 tons of Jim Butler lease ore mined from the

West End shaft with a total gross value of $112,775.79.

The Rescue continues regular shipments of ore of good grade and it is said that a substantial treasury is being accumulated.

Divide—In the Tonopah-Divide mine conditions are stated to be very good. On the 165 level a crosscut at a point 350 ft. southeast of the original strike on this level has shown the vein to have a width of 36 ft., 12 ft. of which is shipping grade ore and 24 ft. ore of milling grade. Development workings in the vein on other levels have satisfactory showings and crosscutting on the 800 and 1,000 levels has been started.

Pioche — Shipments from the district for the week ended Sept. 30 show a steady reduction on account of the freight increases and it is only hope and assurances of an adjustment in the rates that is keeping the majority of the properties on the active list. Many shutdowns will result in the near future unless some action is taken. Shipments in the week referred to totaled 2,995 tons from the following shippers: Prince Con., 1,700 tons; Virginia Louise, 650; Combined Metals, 245; Bristol Silver, 200; Black Metals, 100; Campbell-Bristol Lease, 50, and Con. Nev. Utah, 50.

ARIZONA

C. & A.'s New Air Shaft in Operation —Considerable Leasing in Tombstone District

Bisbee—The Irish Mag Leasing Co. has finished its first six months' period of operation. The Irish Mag shaft has been opened and retimbered from 40 ft. below the 450 level to a point 20 ft. below the 750 level. Work of opening the shaft and retimbering will be continued. It is planned to start prospecting on the 950 and 1,050 levels. Approximately $17,000 has been spent in repairing the shaft, which work was started April 1, 1920. Two shifts have been working in the shaft continuously.

The Boras and Night Hawk leasing companies have resumed operations after a week's shutdown due to a lack of electric power. The Bisbee Improvement Co., which furnishes these mines with power, was forced to curtail due to a shortage of fuel oil. This is now being received and no immediate shortage of power is anticipated.

At the Calumet & Arizona the new air shaft near the Briggs mine has been connected with the fire area and is now being used for ventilation.

Tombstone—There is considerable leasing going on in the Tombstone district. The Bunker Hill Mining Co. is at present doing no company work. Small leases have been given both on the surface and underground in several of the mines. It is reported that the Mellgren property, comprising about 60 claims, has been examined by Eastern interests. The property is said to be bonded.

The Winter's property has been sold to Boyd, Hughart & Bloodworth, who have formed a closed corporation to develop it. A new shaft is being sunk as the old one has not been found suitable. The present mill will not be operated.

Altogether there are about thirty different operators including lessees in the Tombstone district.

Swansea—The Swansea is now employing more than 100 men, mainly Mexicans, and producing about 140 tons of ore per day. Most of this is milled, yielding a 24-per cent concentrate which is shipped to Humboldt, as well as a small quantity of high-grade ore that is valuable in the furnaces because of its high iron. The Swansea lease has been taken from the Clark interests by the Consolidated Arizona Smelting Co. of Humboldt, as recently stated.

NEW MEXICO

Bonney Con. Makes Strike of High-Grade Copper Oxide

Lordsburg—Frank M. Manson, who recently made an investigation of the possibilities of southern Arizona, southwestern New Mexico and northern Sonora, with the object of locating ore-buying agencies in this section, has announced the intention of the Western Ore Purchasing Co., of Reno, Nev., to establish a number of agencies in this section, which will buy all kinds of salable ores in any quantities. One or more sampling mills will be erected at points later to be decided upon.

A new strike of very high-grade red oxide of copper has been made at a depth of 35 ft., on the Manilla claim of the Bonney mine. Work has been started to cut this from the 100-ft. level of No. 1 shaft.

Ore shipments from the Lordsburg district in September totaled 89 cars, or 4,072 tons, valued approximately $61,080.

White Signal—At Camp Kithil mining of torbernite ores has ceased. The representative of the Radium Company of Colorado, who has been here for several weeks, has returned to Denver. The Merry Widow shaft has been sunk to a depth of 200 ft. and various other openings made which has demonstrated an ample quantity of ore. It is understood however that considerable difficulty has been experienced in perfecting a process for handling the torbernite which differs from the ores heretofore used by the Radium company in the production of radium.

COLORADO

Silver Mountain Mines Suspends — Guadaloupe Mine Changes Hands

Ouray—Silver Mountain Mines has suspended work and is reported to be offering its equipment for sale. The equipment of this property was good and a fair start was made, but subsequent mine development was neither very effective nor successful.

James A. Lannon, of Ouray, formerly manager of the Atlas M. & M. Co., has taken over the Guadaloupe mine for a group of outside men and is actively engaged in equipping it. The construction of a line to transmit electric power to the mine is under way and mining machinery will be installed soon. The mine has been sporadically worked for years but never well developed; the new operations promise to give the mine a good try-out and the prospects are good for success, the mine having produced ore of very good grade at intervals.

Camp Bird has continued active development ever since the new crosscut tunnel, two miles long, was connected with the old workings above by a 400-ft. raise for ventilation. The intervening ground around this raise was opened up by several levels, then the vein was explored on the main tunnel or crosscut level. Drifting over 2,000 ft. east was first done, and now drifting west along the vein is in progress out under the most productive of the old workings. Ore encountered is stored in a stock pile at the tunnel portal. The intermittent manner of adding to this pile indicates that no large or continuous orebody, as compared with the old mine, has been encountered. Considerable ore has been encountered, however, and undoubtedly the mill will again be operated some time in the future.

UTAH

Utah Sulphur's New Leaching Plant Ready Soon—Seek Injunction Against Tintic Standard

Morissey—The new leaching plant of the Utah Sulphur Co. is expected to be in operation early in November. The new plant will have a daily capacity of 250 tons, and with the retorts and sublimer also working, the total capacity, it is stated, will be 350 tons daily. The latter have been doing satisfactory work, but the leaching plant can produce sulphur at a considerably lessened cost, it is said. The sublimer is used only for making the highest grade of sulphur. It is reported that the company is arranging also to produce fertilizer made of sulphur and phosphate rock combined, and that it is going to construct a plant having a capacity of 150 tons daily for this purpose.

Eureka—Tintic shipments during the week ended Oct. 1 totaled 131 cars as compared with 143 cars the week before.

An injunction is being sought against the Tintic Standard by the East Warm Creek Irrigation & Canal Co. to prevent the former from using water from Warm Springs and Warm Creek near the site of its mill which is in process of erection.

Park City—Shipments for the week ended Oct. 1 amounted to 2,153 tons coming from six mines, the Ontario and Silver King Coalition heading the list, with 704 and 554 tons respectively.

Alta—The South Hecla shipped 35 cars of ore during August and the September output is expected to amount to about 25 cars. Labor is scarce.

IDAHO

Cœur d'Alene District

Cœur d'Alene Syndicate Installs Compressor—Financing of U. S. Copper Arranged — Kill Buck Reorganized

Wallace—The Cœur d'Alene Syndicate, of which Rush J. White, mining engineer, is manager, has completed the installation of a large compressor to be used in developing the two Flynn groups which the syndicate has under option. The development consists of the extension of the Black Bear tunnel into the Flynn ground. This has now been extended about 700 ft. since crossing the common line, making the distance from the portal about 4,500 ft. A crosscut is being run south to the Flynn vein which is expected to be cut at any time. The great depth from the surface, 2,000 ft., and the fact that there are no intermediate workings, make it impossible to estimate accurately the position of the vein.

The United States Copper Co. is to be financed by E. R. Day, of the Grasselli Chemical Co., and J. W. Munroe, both of Cleveland, Ohio. Both these gentlemen inspected the company's holdings about a month ago in company with H. V. Edwards, of Wallace, manager, with the result that a permanent wagon road is now being built to the property which will enable the delivery of a compressor and all necessary equipment and building material early in the spring. A vein from 5 to 40 ft. wide outcrops for a distance of over 3,000 ft. A prospect tunnel has been driven 200 ft. on the vein, showing an average of 3 ft. of ore ranging from 2 to 30 per cent copper and some gold. In the spring a crosscut will be run about 1,200 ft. which will cut the vein 350 ft. below the present tunnel.

The Kill Buck stockholders have elected the following directors: Donald A. Callahan, James F. Callahan and Dr. L. E. Hanson, of Wallace; C. W. Newton, of Interstate, and John Borg, of New York. Control was recently purchased by the Consolidated Interstate-Callahan from Senator W. A. Clark, of Butte. The meeting of stockholders was called for the purpose of effecting re-organization with the representatives of the Interstate-Callahan in control. The directors are also identical with those of the Chicago-Boston Mining Co., also controlled by Interstate-Callahan. The two properties adjoin and will be developed through the same shaft, although operated by independent companies.

MICHIGAN

The Copper District

C. & H. Subsidiaries to Get Power From Lake Linden—Tamarack Reclamation Plant Site Cleared

Houghton—Sinking of the New Baltic shaft of the Arcadian Consolidated has been resumed, and at this writing is about 20 ft. below the 600-ft. level. The corner is in the lode.

The steel for the addition to the Calumet & Hecla flotation plant at Lake Linden is expected to arrive soon. This building is being erected by the American Bridge Co.

The site of the Tamarack reclamation plant is practically cleared of the old Tamarack stamp mill and equipment. Excavation for the flotation and leaching buildings are well under way.

Gogebic Range

"C" Pabst Shaft Lining Being Repaired

Ironwood—"C" shaft of the Pabst mine will be shut down for two or three weeks while repairs are being made to the shaft lining. Three shifts will be put on and the work pushed as rapidly as possible. The shaft is vertical, starts in the hanging and passes into the footwall near the 17th level. The pillar left to support the shaft was not adequate and the ground has caved until the shaft is several feet out of plumb. It is now crushing where it passes through the ore and dyke, and has to be retimbered between the 9th and 13th levels.

Menominee Range

McKinney Steel Electrifying Tobin and Dunn Mines Owing to High Cost of Coal

Crystal Falls—The McKinney Steel Co. is to re-equip the Tobin and Dunn mines and will move all the equipment at the Odgers property, all three of which are in the Crystal Falls field. The present steam plants at the Tobin and Dunn are to be scrapped and replaced with new electric hoisting engines and compressors. The present electric hoist at the Odgers will be moved so as to serve the new shaft which was recently completed. The hoisting engines at all of the properties will be housed in new buildings of brick construction. The high cost of coal was the determining factor in causing the company to discard the steam equipment and substitute electric machinery. The work of moving the Odgers equipment has been under way for several weeks and will soon be completed. In addition to erecting a new engine house at the Dunn, the company will also build a new change house for the men and put up a new steel headframe.

MINNESOTA

Cuyuna Range

Armour No. 2 Begins Stockpiling—Transfer of Hopkins Expected

Ironton—The Armour No. 2 mine, operated by the Inland Steel Co., has completed its season's shipments and has begun stockpiling. This property, one of the largest on the range, had the advantage of an early start, three boatloads of Armour ore having reached the lower lakes in May, and is the first to complete its schedule. Most of the Cuyuna Range properties are somewhat behind schedule at this time owing to the delay in boat and car service during the summer.

Irondale Township—The Hopkins mine, located on the NW¼ of SE¼ of Section 3, is expected to pass into the hands of new operators soon. This property was leased to the E. N. Breitung Ore Co. in 1915 and was opened and developed by them as an underground mine. A 3-compartment shaft was sunk to a depth of 171 ft. and development work proved up about 475,000 tons of available iron ore and manganiferous iron ore. In 1918 the operators shipped 37,257 tons of manganiferous ore and in 1919 loaded their stockpile of 5,849 tons. The mine has been idle since the winter of 1918-19.

ALABAMA

Quest for New Ore in State Continues—Prospecting for Gold in Clay County

Birmingham—Satisfied that there is considerable iron ore in Alabama that has not heretofore been considered, engineers and geologists are at work prospecting, mainly in the Birmingham district. The Sloss-Sheffield Steel & Iron Co. has been core drilling on the southern end of Red Mountain, near Parkwood, on the main line of the Louisville & Nashville. This will be a deep mining project if operation be decided upon. The same company has been prospecting on the upper end of the mountain also, not far from what is known as the Ruffner mines in the vicinity of Trussville. This is another deep mining proposition.

The Gulf States Steel Co., after three or four years of development work at the Shannon mines, expects to be obtaining a good supply of ore by Jan. 1. It has been stated that when the Shannon mines are in full operation the company will not only have a visible supply of ore for its own use for years to come but will be able to go on the open market with some of its ore. Smaller mines now supplying the Gulf States will be given up when the Shannon mines are producing as anticipated.

The Tennessee Coal, Iron & R.R. Co. has done some drilling and private parties are now dickering for acreage, on which boring has shown good ore, near the Parkwood property of the Sloss-Sheffield company. Brown ore mines at Cave Springs, Ga., on the northeastern Alabama-Georgia boundary are being operated and the ore is being hauled by trucks to a point of consumption. Other negotiations are on in the state in further prosecution of ore development.

The Woodward Iron Co. reiterates that the shaft sunk to ore during the last 12 months, some distance from its mines on Red Mountain, will be held in reserve until more ore is needed.

Clay County—Prospecting for gold in Clay County, Ala., is again under way, Louisville people being interested, and there is some talk of erecting a mill. The Kentuckians are asking for no financial assistance and appear to be well equipped in that respect to handle the project, which is being done quietly and effectively. For some years prospecting for gold has been under way in the eastern part of Alabama but the results have been encouraging.

THE MARKET REPORT

Daily Prices of Metals in New York

Oct.	Copper	Tin		Lead		Zinc
	Electrolytic	99 Per Cent	Straits	N. Y.	St. L	St. L
7	17.10	40.50	42.25@42.50	7.20@7.25	7.20@7.30	7.35
8	17.10	40.50	42.25@42.50	7.15	7.15	7.25@7.30
9	16.85	40.50	42.00@42.25	7.15	7.15	7.25@7.30
11	16.75	40.25	41.00@42.00	7.10	7.10@7.20	7.25
12	.....	.....	.....	.....	.....	.....
13	16.50	39.25	39.75@40.00	7.00@7.10	7.00@7.20	7.25

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point. All prices are in cents per pound.

Copper is commonly sold on terms "delivered," which means that the seller pays the freight from refinery to buyer's destination. The delivery cost varies, and it would be confusing to figure net prices on individual transactions. Consequently, an average deduction of 0.15c. is made from the "delivered" price to arrive at the New York price. When copper is sold f.o.b. or f.a.s. New York, of course no deduction is made.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Oct.	Copper			Tin		Lead		Zinc	
	Standard		Electro-						
	Spot	3 M	lytic	Spot	3 M	Spot	3 M	Spot	3 M
7	98½	98	112	267	272½	34⅜	34½	40⅞	41⅞
8	98	97	110	266	270⅛	34⅜	34¼	40⅝	41⅜
9	....	....	...	...	....	....	....	...	...
11	96½	95½	109	263¾	269	34⅜	34½	40½	41⅞
12	95	94	109	259	263½	34⅛	34⅜	40⅛	41⅜
13	96½	94½	108	256	260¾	34⅛	34	40	41⅛

The above table gives the closing quotations on the London Metal Exchange. All prices in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Oct.	Sterling Exchange	Silver New York, Domestic Origin	Silver New York, Foreign Origin	Silver London	Oct.	Sterling Exchange	Silver New York, Domestic Origin	Silver New York, Foreign Origin	Silver London
7	349	99½	87	56⅛	11	349½	99½	83	53⅜
8	350	99½	87½	56⅛	12	....	...	..	54⅛
9	350½	99½	85⅜	54⅞	13	348½	99½	87	56⅛

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States. This quotation is retroactive to May 13.

Metal Markets

New York, Oct. 13, 1920

The metal markets record another week of trade dullness. All the major metals remain comparatively inactive, and the sales reported are relatively small. The importance of general financial and economic conditions is especially pronounced in the metal trade, and the effect of strained credit is forcing many producers to create a market at a loss, and as consumers, for similar reasons, are not overly anxious to participate in the market, the tendency is still downward. The market is evidently seeking a new level from which trading can be resumed with confidence by both producer and consumer. The London market in copper and tin took a decided slump during the week, whereas the market for lead and zinc remained at substantially the same level.

Copper

The downward trend of last week has continued. Large producers are no longer holding aloof and are entering into the market at prices representative of the lower level. Large quantities can be bought today at 17c. or less delivered, and it seems as if the copper-consuming industry is attempting to close the year with as small a copper stock inventory as possible. Price concessions have not reached a level which has induced much business, bearing out the impression prevalent in the trade. The summer and fall seasons for construction work are closing, and the demand for copper products is slackening, which partly accounts for the lack of interest in the market. The low price at which the red metal can be obtained is creating a low level for the year and making it increasingly difficult for some producers to operate. There is little interest in futures.

Lead

The official A. S. & R. price remains at 7.75c., N. Y., which is a wide deviation from the general market. There have been few inquiries in the lead market, and the dullness noted last week still prevails. This respite from the recent pronounced activity in the market is enabling producers to complete their unfilled orders and contract deliveries that have long been delayed. Consumers are buying only small quantities and manifesting little interest in the market. The metal can be obtained at practically the same price in both the New York and St. Louis markets. Quotations in the Western market are nominal, and there is little interest in futures.

Zinc

There has been a further decline in the market in spite of a statistical position that is inherently good. The demoralization of the automobile trade is looked upon as of benefit to the zinc trade, in that it will deflect black sheets used by the automobile factories to the galvanizing trade, which has hitherto felt a shortage in supply. On the other hand, there is the unchanged European situation, the foreign-exchange question, and the determination of European nations such as Germany (which was formerly a large zinc-consuming country) to market all available supplies of the metal in order to realize cash. These tactics on their part have acted and are acting as a depressing influence on the domestic market. Interest in futures is largely nominal.

Tin

The effect of the slump in the London price of tin amounting to about £11 for the week has practically killed all interest in a dull market. Supplies of tin are still being liquidated.

Straits tin for future delivery: Oct. 7th, 43.25@43.50; Oct. 8th, 43.50@43.75; Oct. 9th, 42.75@43.25; Oct. 11th, 42.75@43.00; Oct. 13th, 41@41.25.

Arrivals of tin in long tons: Oct. 5th, Penang, 125; 8th, Hongkong, 5.

Silver

The cessation of the sale of Reverse Council Bills in India previously reported has had a weakening effect on Indian exchange, which in turn has had an influence in the lower price of silver. Exchange rates on China have also continued to fall, so that support from China banks at higher prices has been lacking, although buying from that quarter continued moderately.

The result has been a continued fall in the price of silver to 53⅜d. in London on Oct. 11 and on the same day in New York to 83c., which is the lowest figure since June 16. At these low rates, however, it is reported that speculative buying has developed in London, with a resultant sharp advance to 54¼d. and 56¼d. on the 12th and 13th respectively. The New York market has also risen in sympathy.

Mexican Dollars—Oct. 7th, 66½; 8th, 66⅜; 9th, 65½; 11th, 63½; 13th, 66⅜.

Gold

Gold in London on Oct. 7th, 117s. 3d.; Oct. 8th, 117s.; Oct. 11th, 117s. 3d.; Oct. 12th, 117s. 6d.; Oct. 13th, 117s. 6d.

Foreign Exchange

The European exchange market has generally been steady, but slightly downward for the week, with no pronounced fluctuations. On Monday, Oct. 11th, francs were 6.58c.; lire, 4.01c.; marks, 1.52c.; New York funds in Montreal, 8.4 per cent premium.

Other Metals

Aluminum—For 50-ton lots: ingot, 99 per cent and purer, 35c.; 98@99 per cent, 34.8c. Virgin metal still obtainable in open market at about 32.5c. for 98@99 grade.

Antimony—Spot metal, 7c. per lb. Cookson's "C" grade, 12½@13c. Chinese and Japanese brands, 7½@7¾c. W. C. C. brand, 8¼@9c. Chinese needle antimony, lump, firm at 7@7½c. per lb. Standard powdered needle antimony (200 mesh), 9¼c. per lb. Market dull.

White antimony oxide, Chinese, guaranteed 99 per cent Sb_2O_3, wholesale lots, 10c.

Bismuth—$2.55 per lb., 500-lb. lots, and $2.57 per lb., 100-lb. lots.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady.

Cobalt—Metal, $6 per lb.; black oxide, $4.10 per lb.; sulphate, $1.60.

Iridium—Nominal, $400@$450 per oz.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb. for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]**Molybdenum** Metal in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.

Monel Metal—Shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$100 per oz.

Platinum—Firm at $105 per oz.

Quicksilver—Market quiet; $72 per 75-lb. flask. San Francisco wires $72.50 @$75. Market weak.

Ruthenium—$200@$220 per troy oz.

[1]**Selenium**—Black powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]**Thallium Metal**—Ingot, 99 per cent pure, $20 per lb.

[1]**Tungsten Metal**—$35@$60 per kilogram, according to purity and gage.

Metallic Ores

Bauxite—About 52 per cent alumina content, less than 2 per cent iron oxide, up to 20 per cent silica and artificially dried to contain not more than 4 per cent free moisture, $10 per gross ton at mine; 54 per cent alumina and about 15 per cent silica, $11; averaging 57 per cent alumina, 8 to 12 per cent silica, less than 3 per cent iron oxide, $13 on basis of 8 per cent free moisture.

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a maximum of 6 per cent silica, 75@85c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 70@75c.

Manganese Ore—60@70c. per unit, seaport; [1]chemical ore (MnO_2) $70@$90 per gross ton, lump; $80@$100 per net ton, powdered.

Molybdenum Ore—85 per cent MoS_2, 70@75c. per lb. of contained sulphide, New York.

[1]**Tantalum Ore**—Guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots.

[1]**Titanium Ores**—Ilmenite, 52 per cent TiO_2, 1¼@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $6 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $4.50@$5, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[1]**Zircon**—Washed, iron free, 5c. per lb.

[1]**Zirkite**—According to conditions, $70 @$90 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

Zinc and Lead Ore Markets

Joplin, Mo., Oct. 9—Zinc blende, per ton, high, $46.50; basis 60 per cent zinc, premium $41; Prime Western, $40@$37.50; fines and slimes, $37.50@$35; calamine, basis 40 per cent zinc, $32@$30. Average settling prices: Blende, $44.86; calamine, $36; all zinc ores, $44.49.

Lead, high, $97.90; basis 80 per cent lead, $75. Average settling prices, all grades of lead, $93.53 per ton.

Shipments for the week: Blende 10,120; calamine 343; lead 2,205 tons. Value, all ores for the week, $672,760.

The labor situation at the Arkansas smelters is unchanged, with negotiations still pending. Fire at Henryetta consumed the Victor Metal company's roaster, putting that company out of smelting for three weeks. Production at the mines continues strong, with buying declined to around 9,000 tons per week. Several buyers offered only $37.50 basis this week and over 500 tons were purchased on that basis. Aside from 500 tons purchased Monday, reported as last week's purchase on $42.50 basis, the bulk of blende sold on $40 basis.

No further decline was made in offerings on lead ore.

Platteville, Wis., Oct. 9—Blende, basis 60 per cent zinc, $45 base for high grade; lead ore, basis 80 per cent lead, $75 per ton. Shipments for the week: Blende, 1,099; lead, 4,398; sulphur ore, 43 tons. Shipments for the year: Blende, 53,701; calamine, 2,459; lead, 4,398; sulphur ore, 1,284 tons. Shipped during the week to separating plants, 2,052 tons blende.

Non-Metallic Minerals

Asbestos—Crude, No. 1, $2,000@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax.

Barytes—Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $24@$30 in bags, carload lots; (off-color) $22@$26 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $12 per gross ton; ground (white) $23@$25; ground (off color) $16@$19 per net ton, f.o.b. Cartersville, Ga. Crude, 88 to 94 per cent, $23; ground (white) $45; ground (off color) $30@$32 per net ton, less than carload lots, f.o.b. New York. Crude, not less than 98 per cent, $11@$11.25 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—Domestic, extra light, 5@6c. per lb.; light, 4½@5½c.; heavy, 4@5c; English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin)—Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground, $15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$18 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $30@$35, car lots, f.o.b. Baltimore; ground, $17@$21, f.o.b. North Carolina points; $17@$21 per ton, No. 1 ground, f.o.b. New York State; $21@

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

$23 per ton, ground, f.o.b. Maine. Crude spar very scarce.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Graphite—The 90 per cent crucible grade is held in Alabama for 9c. per lb. and 85 per cent grade is practically unobtainable, prices being 7@9c. The higher lubricating grades sell for 11@40c., according to carbon content. In Ceylon, some of the largest producers have closed their mines until prices advance to meet increased production costs, and stocks at Colombo were lowered only 3,000 tons in the first five months of 1920. Surplus stocks on Jan. 1 amounted to 20,000 tons.

Gravel—No analysis guarantee, f.o.b. Roseview, Ill., $25 per ton; gravel suitable for acid, chemical or enameling purposes, $60.

Gypsum—Plaster of Paris in carload lots sells for $4.25 per 250-lb. bbl., alongside dock, New York.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $75@$85 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—India block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20 @$1.40; No. 4, $2@$3; No. 3, $4.25@ $5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $3.50; No. 3, $5, No. 2, $6.50; No. 1, $8; A1, $10; extra large, $25, all f.o.b. New York; ground, $150 per ton, Philadelphia. Domestic, uncut, f.o.b. Franklin, N. C., as follows: Scrap, $45 @$50 per ton; punch, 10c. per lb.; circle, 15@25c.; 1½ x 2 in., 75c.; 2 x 2 in., $1.15; 2 x 3 in., $1.65; 3 x 3 in., $2.10; 3 x 4 in., $2.50; 3 x 5 in., $2.75; 3 x 6 in., $3.75; ground 165 mesh, $240 per ton; ground roofing mica, $60; mica washers, 75c.@$2 per lb.; 1¼-in. disks, No. 1, $1.60 per lb.; No. 2, $1.30.

[1]**Monazite** — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses. Tennessee production sold up months ahead.

Pumice Stone—Imported, lump, 4@ 50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish fines, per unit, 12c., c.i.f. Atlantic seaport; furnace size, 17c.; Spanish lump, 14@16c.; domestic fines, f.o.b. mines, Georgia, 12@14c. Market improving.

Quartz—(Acid tower) fist to head, $10; 1¼ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines. F.o.b. Wausau, Wis., the price is $16 per ton in car lots, and $22 in less quantities, including bags.

Sand (Glass)—Dry glass sand, $4 per net ton, f.o.b. cars Mapleton, Pa. Sand, f.o.b. Ottawa, Ill., is $3 per ton; $2.50 on annual contracts. Sand at Klondike, Gray Summit and Pacific, all in Missouri, is $2.50 on contract; some outside sales have been made at $4. St. Louis, open market, at $3.50; contract price on large quantities, $2.50; on small quantities, $3.

Sulphur—$18 per ton for domestic; $18@$20 for export, f.o.b. Texas and Louisiana mines. Market quiet.

Talc — Paper making, $12@$22 per ton; roofing grades, $9.50@$15; rubber grades, $12@$18, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $12@$15 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60 @$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $225 @$250 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15 to 18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 18½@19c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c., f.o.b. works.

Ferromanganese—For 76 to 80 per cent, prompt delivery. $170@$180, freight allowed; last half, $170; English, $170, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $82.50@$85, f.o.b. furnace.

Ferromolybdenum—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2@$2.50 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $82.50@$85; 75 per cent, $150@$160.

Ferrotungsten—70 to 80 per cent W, 90c.@$1.05 per lb. of contained tungsten, f.o.b. works.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Ferro-uranium—35 to 50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium[1]—Basis 30 to 40 per cent, $6.50@$8.50 per lb. of V contained, f.o.b. works.

Metal Products

Copper Sheets — Current New York price, 29½c. per lb.; wire, 22½@23c.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver—Unchanged at 39½c per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 26¾c.; sheathing, 25¾c.; rods, ⅜ to 3 in., 23¾c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $160 per 1,000, f.o.b. Pittsburgh.

Chrome Cement—40@45 per cent Cr_2O_3, $55@$60 per net ton, and $65 in sacks, carload lots, f.o.b. eastern shipping points.

Fire Clay—First quality, 9-in. shapes, $55@$60 per 1,000, Pennsylvania, Ohio and Kentucky. Second quality, $45@ $50.

Magnesite Brick — 9-in. straights, $110 per net ton; 9-in. arches, wedges and keys, $121; soaps and splits, $134.

Silica Brick—9-in., per 1,000: Chicago district, $65@$70; Birmingham, Ala., $56@$61; Mount Union, Pa., $55 @$60.

Iron Trade Review

Pittsburgh, Oct. 12, 1920

Production of steel ingots in September was at the same rate as obtained in August, about 42,700,000 tons per annum. Physical conditions affecting steel production had improved and the failure of production to increase confirms recent reports of some mills slackening their operation on account of cancellations of orders and suspensions of deliveries. The individual mill prefers to do this rather than cut prices in a search for additional business, since the cutting of prices tends to jeopardize the contract business on books.

Pig Iron—Quotable prices on pig iron decline only as purchases are made, fixing new levels, and purchases are rare. Following the decline shown in Valley foundry by a small sale, from $50 to $47, Valley, a sale of 3,000 tons of Valley basic is reported, at $45, furnace, setting the market quotation at this figure against $48.50 formerly quoted. Bessemer remains nominally quotable at $48.50, Valley. Freight to Pittsburgh is $1.96.

Steel—Steel mills call the market $60 for billets and $65 for sheet bars, but these figures have not been tested lately, and a firm bid at $5 less might result in a sale.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $16.50@$17; foundry, $18.

Market for Phosphate Rock

Production Confined to the South, in Florida And Tennessee — Export Trade Particularly Heavy

PHOSPHATE ROCK, used principally by the fertilizer trade, is mined in Florida, Tennessee, and to a limited extent in Idaho and South Carolina. In Florida, which is the chief center of production, there are two kinds of rock—Florida land pebbles and hard rock. The pebbles vary in size from grains up to "fists," are found in a matrix of sand or clay, and are recovered by placer mining. After being washed down, they are picked up by pumps and sent direct to a washer, which removes all extraneous matter except 6 or 7 per cent—insolubles. The pebbles amount to about 20 per cent of the material mined, and are 68 to 79 per cent tricalcium phosphate. They are found chiefly in Polk County, about forty-five miles west of Tampa. The mines produce from 150 to 3,000 tons each per day.

The hard rock is found about 100 miles north of the pebble fields, in Florida, and is mined by dipper dredges. Production at the various properties averages fifty tons per day. The rock is of higher grade than the pebbles, running from 77 to 89 per cent tricalcium phosphate.

Production of Tennessee

Tennessee produces two kinds of rock—brown Tennessee lump, which looks like brown sandstone but is softer, disintegrating easily, and blue rock, which is hard and dense and of a slate blue. The blue rock occurs in veins two to three ft. thick, and shows 70 to 72 per cent tricalcium phosphate, against 72 to 78 for the brown lump. Both grades are recovered by steam shovel or by pick and shovel. Present demand and high prices make this work profitable, but in normal times the cost is too great to encourage production.

Deposits of phosphate rock have been found in Idaho and neighboring states, but have not been developed importantly as yet. The tonnage from South Carolina also is negligible.

Algiers and Tunis produce a pebble running about 56 per cent tricalcium phosphate. There are deposits also in France and Belgium which supply the home consumption.

Fertilizer Makers Principal Buyers

Perhaps 95 per cent of the demand for phosphate rock is from fertilizer manufacturers, the rest going to the chemical trade, baking-powder manufacturers, and for minor uses generally. The demand from the fertilizer makers extends from October until February, when the manufacturing and shipping season opens.

The principal nations importing from the United States are the United Kingdom, the Scandinavian countries, Holland and Spain. Previous to the war Germany was the leading foreign buyer, but that country has not entered the market since. The foreign demand is particularly heavy at the present time.

The market is very strong. The Tennessee product is sold up months ahead, and much the same situation exists in Florida. The recent car shortage was acute in Florida, seriously interfering with shipments, which, however, are now going forward.

Producers Market Own Product

Most of the business in phosphate rock is carried on directly between the producers and the fertilizer manufacturers. Of course, some tonnage is handled through brokers in fertilizer materials, but for the most part producers market their own product. A thousand tons is considered a small sale, the usual contract being for 2,000 tons and up, on ninety days to a year. A fertilizer plant producing 12,000 to 15,000 tons of acid phosphate per season is rated small. Acid phosphate, sometimes called superphosphate, is made of about equal parts of 50-deg. sulphuric acid and phosphate rock.

Discoverers of new phosphate rock deposits in Tennessee might be able to mine and market the rock themselves under the present favorable conditions. In Florida, however, the situation is different. There a power plant costing $2,000,000 or more is required for commercial operation, with electric-driven mining outfit, dredging pumps, and motors for the mills. The discoverer of a new deposit in Florida would ordinarily try to interest one of the ten or twelve large operators by making test borings and submitting samples for analysis.

Phosphate Production in the Society Islands

Phosphate is the only mineral produced in or exported from the Society Islands, according to Consul Howard F. Withey, in *Commerce Reports*. It is produced and exported by one company, the Compagnie Francaise des Phosphates, a French corporation with head offices in Paris, and with a capital stock formerly of 6,000,000 fr., all French owned, except for a relatively small amount held in Tahiti. The capital stock is now 11,000,000 fr. This concern, organized in 1908, has the exclusive mineral rights of the Island of Makatea, which is about 120 miles north of Tahiti and has an area of roughly 1,200 acres. Two piers about 300 meters long, a part of which length however is on shore, have been constructed. Mooring buoys and lighters are used by the loading vessels.

The phosphate, as exported, is virtually the soil itself, which is dug with pick and shovel and loaded on cars on a short narrow gauge railway and drawn to the works, where it is put through crushing and drying processes. It is sold on a moisture percentage basis. After going through the drying process the product is stored in bins awaiting shipment. Most of the machinery used is of French manufacture.

At the present time nearly all the phosphate is exported to New Zealand. Before the war much of it went to San Francisco, some to Europe, particularly France, and a considerable quantity to Honolulu. It is expected that in the future the product will recover the markets of the prewar period.

The phosphate soil shipped runs about 80 per cent phosphate, according to the statement of the manager of the company. Before the war the annual production was from 80,000 to 90,000 metric tons. In 1919 the production was approximately 40,000 metric tons, and it is reasonable to expect that the production will rapidly increase.

The great difficulty encountered in this enterprise, as in all enterprises in this colony, is the difficulty of procuring suitable labor. At present the company employs about 500 workmen and employees, many of whom are Japanese. The French government recently enacted a decree providing for the importation of foreign labor and fixing the conditions of such importation. It remains to be seen whether it will prove profitable to import such labor under the conditions prescribed, but the probabilities are that it will, at least for the phosphate company.

Latest Rand Gold Production

During August, the gold production of the Rand, in South Africa, amounted to 702,083 oz., a decrease in output from the July figure, 736,099 oz. A table summarizing production since 1917 follows:

RAND GOLD OUTPUT 1917-1920

(Fine Ounces)

	1920	1919	1918	1917
January	670,503	676,059	714,182	782,634
February	625,330	636,728	659,750	721,321
March	707,036	712,379	696,281	787,094

December		650,191	641,245	722,419

COMPANY REPORTS

American Smelting & Refining Co's. Earnings Increase

The report of the American Smelting & Refining Co. for the six months ending June 30, 1920, shows a decided improvement over a similar period in 1919. The net income for the six months, after deducting depreciation, ore depletion and bond interest, aggregated $4,030,840.88. Preferred-stock dividends aggregating $2,115,417 were declared. Dividends upon the common stock, on the basis of 1 per cent quarterly, have been declared, aggregating $1,219,960.

The six months in question show a profit, over and above dividends and bond interest, of $695,463.88, as against a deficit for the corresponding period of last year of $1,195,463.84, or a net betterment of $1,890,927.72. The earnings for the last six months of last year, over and above the same dividends and bond interest, amounted to $109,806.16. The earnings of the first six months of this year, therefore, were better than the last six months of last year to the extent of $585,657.72. The increased earnings have been due to the better conditions of the Mexican operations, the increased volume of business in the United States, and to increased treatment charges on many ores, more nearly comparable with our present costs. There are still some old, long-time contracts which are unsatisfactory.

The usual charge has been made to the profit-and-loss account for depreciation and depletion of ore reserves, and provision has been made for the estimated Federal income taxes for the period.

Mexico is now experiencing the general increases in wages and other costs which have been so prevalent in the United States during the last few years. The company is, however, glad to note that the prospects of a stable government in that country look brighter at present than at any period since the revolution of 1912. It is believed that at last a steady operation of Mexican properties is reasonably certain. Incidentally, it may be remarked that the military activities attending the end of the Carranza government commandeered most of the railroad equipment owned by the company, with consequent disruption of service and loss of earnings for a considerable period. The equipment has now been restored, and railroad conditions are as good as can be expected.

A statement summarizing operations follows:

SUMMARY OF CONSOLIDATED INCOME AND PROFIT AND LOSS, AMERICAN SMELTING & REFINING CO.

	Six Months Ended June 30, 1920	Six Months Ended June 30, 1919	Comparison
Net earnings of smelting and refining plants and industries immediately dependent thereon	$6,678,412 10	$5,285,698 03	Inc. $1,392,714 07

Tonopah Belmont Development Co.

Gold, Silver; Nevada

The Tonopah Belmont Development Co. has issued the following statement covering operations for the quarter ending June 30, 1920:

OPERATING RESULTS

Received and receivable for ore	$384,594 12
Mining, milling and administration expenses	302,967 12
Net earnings for three months	$81,627 00
Miscellaneous income	7,433 32
Total net income for three months ended June 30, 1920	$89,060 32

AVAILABLE RESOURCES, JUNE 30, 1920

Due from smelters	$198,791 46
Due from others	13,324 83
Liberty bonds	22,250 00
Loans on collateral	50,000 00
Cash in banks	48,478 17
Total	$332,844 46

The net earnings for the quarter ended June 30, 1920, of the Belmont Surf Inlet Mines, Ltd., of which stock this company owns 80 per cent, were $77,535.28.

Output of Mexican Mines

Statistics showing the production of metals in Mexico from 1916 to September, 1919, have been published in "Iniciativa de la Ley de Ingresos" for the fiscal year 1920. The following table, taken from the publication mentioned, gives the production of 1916, 1917, 1918, and 1919 (January to September), quantities being stated in kilos of 2.204 lb. each:

Metals	1916 Kilos	1917 Kilos	1918 Kilos	1919 Kilos
Gold	11,748	23,543	25,313	22,944
Silver	926,142	1,306,988	1,944,542	1,949,673
Copper	28,411,248	50,985,923	70,223,454	50,893,612
Lead	19,970,986	64,124,752	98,837,154	67,378,353
Zinc	37,449,226	14,757,333	20,698,995	8,665,413
Antimony	828,767	2,646,544	3,268,546	627,704
Tin	292	9,214	13,537	2,117
Tungsten	12,250	187,637	140,485	29,292
Molybdenum			27,371	2,356
Manganese		73,387	2,878,383	2,849,979
Mercury		33,132	163,598	113,865
Arsenic		1,284,820	1,881,011	2,188,333

	Current	One Year Ago
New York	30%	50–10%
Chicago	50%	50%
Cleveland	50%	60–10%

MACHINE BOLTS—Warehouse discounts in the following cities:

	New York	Cleveland	Chicago
½ by 4 in. and smaller	+20%	25%	20%
Larger and longer up to 1 in. by 30 in.	+20%	25%	10%

WASHERS—From warehouses at the places named the following amount is deducted from list price:

For wrought-iron washers:

New York	List	Cleveland	$2 50	Chicago	$3.00

For cast-iron washers the base price per 100 lb. is as follows:

New York	$7 00	Cleveland	$4 50	Chicago	$4.75

CONSTRUCTION MATERIALS

PREPARED ROOFING—Standard grade rubbered surface, complete with nails and cement, costs per square as follows at manufacturing points:

	New York — 1-Ply c.l.	New York — 2-Ply l.c.l.	New York — 3-Ply c.l.	Philadelphia — 1-Ply c.l.	Philadelphia — 2-Ply l.c.l.	Philadelphia — 3-Ply c.l.
No. 1 grade	$2 50	$3 00	$3.55	$2 40	$2 90	$3 45
No. 2 grade	2 25	2 70	3.20	2.15	2 00	3 10

Slate-surfaced roofing (red and green) in rolls of 108 sq.ft. costs $4.25 per roll in carload lots and $4.50 for smaller quantities.

Shingles, red and green slate finish, cost $8.75 per square in carloads; $9.00 in smaller quantities, in Philadelphia.

ROOFING MATERIALS—Prices per ton f.o.b. New York and Chicago:

Tar felt (14 lb. per square of 100 sq.ft.), per roll	$3 55
Tar pitch (in 400-lb. bbl.), per 100 lb	2 25
Asphalt pitch (in barrels), per ton	56 50
Asphalt felt (light), per ton	132 00
Asphalt felt (heavy), per ton	138 00

HOLLOW TILE—

MINING AND MILLING SUPPLIES

HOSE—

	FIRE	50-Ft. Lengths
Underwriters' 2½ in.		$0 85 per ft.
Common, 2½-in.		30%

AIR

¼-in. per ft.	First Grade $0.60	Second Grade $0 40	Third Grade $0.30

STEAM—DISCOUNTS FROM LIST

First grade..... 20% Second grade.... 30% Third grade..... 45%

LEATHER BELTING—Present discounts from fair quantities (½ doz. rolls):

Light Grade	Medium Grade	Heavy Grade
30%	25%	20%

RAWHIDE LACING—For cut, best grade, 25%, 2nd grade, 30%. For laces in sides, 79c. per sq.ft.; 2nd, 75c. For semi-tanned: cut, 40%; sides, 83c. per sq. ft.

MANILA ROPE—For rope smaller than ½-in. the price is ½ to $0 02 extra while for quantities amounting to less than 600 ft. there is an extra charge of $0 01. The number of feet per pound for the various sizes is as follows: ¼-in., 8 ft., ⅜ in., 6; ½-in., 4½; ⅝-in., 1½-in., 2 ft. 10 in.; 1¾-in., 2 ft. 4 in. Following is price per pound for ¼ in. and larger, in 1200-ft. coils:

New York	29	Kansas City	$0.30½
Cincinnati	.35	Seattle	.28
Chicago	.27½	St. Louis	.26½
Minneapolis	.29½	Denver	.30
San Francisco	.27	Los Angeles	31

PACKING—Prices per pound

Rubber and duck for low-pressure steam	$1.00
Asbestos for high-pressure steam	1.70
Duck and rubber for piston packing	1.00
Flax, regular	1.20
Flax, waterproofed	1.70
Compressed asbestos sheet	.90
Wire insertion asbestos sheet	1.50
Rubber sheet	.50
Rubber sheet, wire insertion	.70
Rubber sheet, duck insertion	.50
Rubber sheet, cloth insertion	.30
Asbestos packing, twisted or braided and graphited, for valve stems and stuffing boxes	1.30
Asbestos wick, ½- and 1-lb. balls	.85

RAILWAY TIES—For fair size orders, the following prices per tie hold:

Material	7 In. x 9 In. by 8 Ft. 6 In.	6 In. x 8 In. by 8 Ft.
Chicago—Plain	$2 00	$2 25
Chicago—Creosoted	2 25	2 50
San Francisco—Douglas fir, green	1 35	96
San Francisco—Douglas fir, creosoted	2 50	1 92

Prices per tie at Missouri mills; St. Louis prices about 25c. higher:

Untreated A Grade White Oak 6x8x8		Untreated A Grade Red Oak 6x8x8	
No. 1	$0 80	No. 1	$0.60
No. 2	90	No. 2	.70

Gossip: How Wags the World?

THOSE mining men who are in remote districts may be interested in the bird's-eye views or impressions of those who are situated at the nerve centers of modern life.

Looking out over the world on a fine October morning, we perceive that the wild onrush of historical events which has characterized the last six years is still progressing. The war between Poland and Russia draws at least to a temporary close with the defeat of the Reds. It was a great war, with vast armies involved; yet on our stunned perceptions it has made little impression. Future historians will celebrate the turning back of the Reds by the Poles as like the stemming of the German tide by the Belgians, or the turning back of the Turks at Vienna in the Middle Ages.

The rest of Europe is in a ferment—political, social, commercial, financial. Germany is busily spreading propaganda calculated to release her from paying the bills for the calculated damage that she wrought during the years that she had the upper hand, and apparently is having some little success here and there. The French are presenting a firm front to the Teutonic propaganda, and, having aided in the victory of Poland, now continue the pressure on the Reds; while Lloyd George apparently is still trying to figure which way England will make the most money.

Foreign travelers tell us Americans and English are popular in Germany, the former for the deeds of mercy of the Quakers and others, the latter because of a prospective trade alliance; and the Americans are unpopular with all the Allies, who consider them cocky and stingy. The old rule still works: if you want to lose a friend, lend him money.

To call a nation "a nation of shopkeepers" used to be a reproach. Yet shop—commerce, trade, economics—has run away with all and sundry; and what shall we eat, and if we shall drink, and wherewithal shall we be clothed, is our chiefest if not our only thought; also, how we shall maintain ourselves in comfort against our neighbor's effort to do likewise against us.

The world in general has spent all its money and exhausted all its credit, and now is facing the inevitable bills, and the threat "No pay, no eat." Russia finds the paper-money game played out, and is starving, and Austria, having tested this banking device to an equal extreme, is in almost as bad a way. Germany is treading the same primrose path. What of the rest of Europe?

The United States is relatively rich and really very prosperous, but she, too, has to liquidate and make good on her inflated dollar. The world is in liquidation, and we must share. It is said that the Federal Reserve system will prevent our having a panic, but it will not prevent Europe having one, nor can it prevent our feeling it acutely if Europe slumps still further. Anyhow, we are engaged in the fundamentally necessary surgical operation of paying up—deflation.

The products of the mines and the mining industries go with the current, with wool, cotton, hides, wheat, automobiles and the rest. Europe cannot buy sufficiently to sustain business—her money is no good, and her credit is not sound. On a declining market the psychology is not to buy; therefore our own industries hold back. So the prices of metals slide downward, and no buying is attracted. Nobody wants a thing when it is cheap. Yet for a long view ahead this would be the time to buy and equip mines, and be ready for the upward swing which will come in time. Adjustment took a long time after the Civil War, but we do those things more swiftly these days.

The greatest step for the healing of the world would apparently be a sound constructive foreign policy on the part of the United States. This, of course, will not occur till after the new President is inaugurated, but it may be foreshadowed. Harding lost some votes on account of a careless presentation of his opposition to "the League," but his subsequent proclamation of his belief in "a league" helps. Indications are strongly for his election; and there is no doubt that the people favor "a league."

Altogether, while storms still rage, and the tempest has scarcely passed its height, the outlook for Old Mother World is better than for some time past—even with declining markets and metal prices.

Concrete Hearths for Roasting Furnaces

WE ARE glad to see that the information which we recently published in the Consultation section on concrete hearths has brought forth considerable discussion from those who have had experience in this form of furnace construction. We are publishing three of the letters this week. We originally stated that concrete furnace hearths had been generally found wanting, although we mentioned that they might have been a success at Great Falls. Mr. Wiggin then informed us that they did good service in the McDougall furnaces, but that brick had been used in the new Wedge furnaces. One of our readers, on hearing this, suggested that this looked like another exemplification of the old wheeze about the patient who died, although the operation was perfectly successful. W. W. Taylor, who superintended the construction of the Braden furnaces in Chile, says that concrete hearths were a failure there, although considerable care was taken in their construction. Possibly the proportions were wrong, inasmuch as 1 part of portland cement was mixed with 2½ parts of granulated slag. No sand was used, and we would have anticipated better results with *crushed* slag. Frank Corwin comes to the defense of concrete for this purpose, as we hoped that he would. Mr. Corwin was one

of the originators of this type of construction and a patentee, and will make a success of it at Humboldt if possible. Metallurgists will watch the results there with interest, for this type of construction, if it can be made to stand up, will permit a considerable reduction in the original cost of roasting furnaces and also lower repair charges.

Our Declining Foreign Commerce

IT TAKES only a boat trip across New York Harbor forcibly and visually to impress upon one the fact that increased imports are coming to the United States. A few days ago, on such a trip, we counted over fifty merchant and tramp steamers anchored in the harbor alone, with more vessels at berths alongside the many docks and piers constructed to receive them. In fact, it looked to us as if there were a little congestion in New York's great bay and that the anchorages almost interfered with the regular ferryboat traffic in the harbor lanes. Some of these ships, no doubt, recently brought part of the lead and zinc to this country that had such a profound effect in lowering the market for those metals, and all of them are factors in a sweeping world trade readjustment, which is being reflected in the nation's trade balance, as figures covering our foreign commerce indicate.

Without giving a dry statistical table, it may be stated that, compared with the year 1913, our preponderance of exports over imports in 1919 *increased almost six times*, for reasons plain to everyone. At the same time the trade balance of the large majority of other nations, chiefly the warring ones, fell sharply. France, to take one example, had an *adverse* trade balance in 1913 which was multiplied almost fourteen-fold in 1919. Such disparities cannot continue for an extended period, for in the long run all trade between countries becomes neutralized, or balances—no one is giving anything away for nothing. This phase of readjustment is progressing at this time, and it is for that reason that current export and import figures are of prime importance. Thus, the foreign-commerce figures for August, consisting of exports valued at $584,000,000 and imports at $519,000,000, indicate the smallest monthly excess of exports shown for several years and compare with average excess exports for the earlier months of this year of over $200,000,000.

The year 1919 was a banner one in regard to favorable trade balances, because of the unabated foreign demand for our raw materials, regardless of exchange and high prices immediately after the war, but the tide ebbs as well as flows, a change slowly but surely is setting in, reversing the flow, and consequently it would appear that our export balance in 1920 will be less than half of the 1919 figure.

Expressed in other words, we must be prepared to receive a larger number of European commodities, as Europe gradually progresses with reconstruction, and at the same time we must realize that our exports cannot continue on the exaggerated war and post-war scale. Agricultural and mineral producers may complain that a decline in the volume of exports is unwelcome, and the trade inclination can easily be viewed with misgivings, but when the true significance of this trend of foreign commerce and its compensating effect on the high cost of living in the United States is understood, the result is more than gratifying. Although the nation's external trade suffers, the great consuming public gains by the increased domestic supply, and if any subject is more pressing, or, rather, oppressive today, it is the burdensome living cost.

City and Country

THE CENSUS BUREAU announces that the present population of the United States is 105,683,108, an increase of 13,710,842 since 1910. Outlying possessions and citizens now abroad, will, it is estimated, bring the total number under the American flag to 118,000,000.

During the last decade it is shown that there has been a strong flow of population from the country to the city, a trend that has been very much accentuated as compared with the previous decade; for the first time in the history of the country, 51 per cent, or more than one-half, of the total population live in cities.

This does not impress us as a healthy condition. Doubtless it has been brought about largely through the war, with the consequent high wages paid to industrial workers, and the resultant rich "pickings" by merchants and the whole urban tribe who struggle to share in the rewards of industrialism and production. The farmer tends to forsake the farm and find work in the factory, where he can earn more and spend more. Doubtless this has in part been artificial, and with the letting down or deflation which is now going on, with lowered wages or unemployment in towns, there may be a certain ebb "back to the land," to the farms, the forests, and the mines. The automobile boom in Detroit drew five or six thousand miners away from the copper country of Michigan. Will not some of these go back?

But something more than this deflation will be needed to foster the healthy growth of the country, whose prosperity is the best guarantee of the nation's welfare and stability. The farmer leaves the farm because the city dweller has the best of it. The natural urge toward the land is strong, but many a wage worker leaves his job and undertakes farming only to find he cannot earn a living at it; and, defeated, he goes back to the industrial ranks. As a farmer, he finds that the cards are stacked, and that the organization of the urban population is arrayed against him. If he triumphs over natural obstacles and accidents and produces a crop, he often finds that he cannot market it at a fair profit. In the greatest apple year of recent record in New York State, apples are offered four for fifty cents in New York streets. Rural organization, to match urban organization, is needed, if our abundant vacant fields are to be progressively cultivated. Similar fair and even favorable conditions are necessary for that other great basic industry, mining. The predominant city dwellers must concede a fair deal to those who produce the metals, whether gold, zinc, or copper, so that prospecting, enterprise, and production will be encouraged. Off this production, from farm, forest, and mine, all the population lives. Let the urbanite see that he does not let the cow that gives him the milk he lives on dry up under too little nourishment.

The Divining Rod Improved

A CORRESPONDENT interested in our recent editorial on the divining rod sends us in a long clipping from the *St. Louis Post-Despatch*, whereby we perceive that our earlier account of the divining rod was not up to date.

It appears that in the spring of 1919 there arrived in Pierre, S. D., an elderly man named Switzer, who prospected around and then informed the mayor that he had "positively located a spot where a large deposit of gold could be found." Some unusual interest seems to attach to getting Switzer's name right, which we do not rightly comprehend. We have heard it said that each one must be "a man, a mouse, or a piece of cheese," and if the name had been Schweitzer (and we suspect it) we should have had a clue. Anyhow, next the story of how the gold came there.

It appears that a barge laden with gold bullion bars was brought down the Missouri in 1850, "being attacked by a large force of Sioux Indians"—but you know the rest. The crew, being hard pressed, scuttled and sank the boat, hoping to return in happier days and dig up the gold. But, alas! all were killed. The same bunch hid their treasure, and were killed about this time, all over North America, and up and down the East and West coast.

The treasure near Pierre now slumbers awaiting the Prince Charming—and after just forty years in the wilderness he arrives—no other, impatient readers, than Mr. Roquefort. Schweitzer-Roquefort bore with him a magic device presumably given him by the Goddess of Cheese, the gentle Fromage de Brie—a "mineral indicator"—a divining rod, if you please. This led him on and on and on and on from Wyoming into Dakota. "Starting from Wyoming he approached Pierre, and as he neared that portion of South Dakota the indicator (he said) pointed ahead of him. Arriving at the St. Charles hotel in Pierre, the needle swerved in a southerly direction."

We have a correspondent in Boston that uses his divining rod mainly for locating whiskey; and we suggest to Mr. Cheese that the coincidence of arriving at the St. Charles hotel and the agitation of the faithful needle is too significant to be overlooked. Anyhow, his wanderings led him away from the hotel (we wonder why), and finally his needle settled on one spot—whereupon "Switzer departed," making it look more like black magic than ever. Next he apparently reappeared in a different form, as one Embrey, oil expert. We are inclined to suspect this a slight camouflage for Embryo oil expert. At any event, he had an indicator on the same principle as Limberger's, and he struck the same scent and settled on the same spot. Next came the digging, which is now going on—but whether for gold á la Welsh rarebit, or petroleum á la embryo the chronicler of the *Post-Despatch* does not inform us.

Romance has gone out of business, but not mining. We have the tommy-knocker, the busy little gnome woodpecker of the underground. We have heard him ourselves. And we have the divining rod, short-range and long-distance, as marvelous and intangible a fairy gift as seven league boots or cloak of invisibility. We have known several mines where the spirits instructed the owner in detail, periodically, what to do—"turn your tunnel to the left and drive fifty feet, and then crosscut west sixty-three feet and six inches." In one such case the patient owner, after driving like this for a year, broke into his own tunnel near the mouth—and who could do this without supernatural help?

We have only one suggestion for the *St. Louis Post-Despatch*—that it print these tales under "Bedtime Stories for Children."

Americans in Russian Jails

A RECENT dispatch to The Associated Press records the release from a Moscow jail of an American mining engineer, Dr. Alfred Wood Stickney. He was held only for a fortnight, and the excuse was that he was held pending identification. And for that reason he was kept in jail! The Russians have always been famous for their hospitality, and their reluctance to speed the parting guest is proverbial; but why lodge their guests in the jails?

The dispatch mentions by name a number of other Americans who still languish in the unsanitary jails in Moscow, and look forward to the rigors of a Russian winter.

There was a time in the history of the United States when the strong arm of the American navy (of sailing ships only) reached into any corner of the world where American rights were disregarded. American armed frigates descended on the coast of North Africa, at a time when the great European nations prudently stayed at home, sailed into the harbor at Tripoli and brought to terms the freebooters who had been attacking American commerce. This was the period when Thackeray offered America as a model which England would do well to emulate in this respect.

The second stage of America's defense of Americans abroad was the unhappy one from which we have just emerged, where the United States, grown rich and powerful but timid, with a vanished merchant marine, refused to accord any protection to the citizens abroad, and went so far as to inform them that they should have stayed at home! while England, following Thackeray's recommendation, made it uncomfortable for anyone who unfairly injured a British subject, anywhere.

Apparently we have now arrived at the third stage, when excessive caution characterizes both the United States and England. As a contrast, the other day France advised the Bolshevist-dictators, that if the French prisoners were not repatriated within twenty-four hours, the French Black Sea fleet would turn its guns upon Odessa, whereupon Lenine ironically but sincerely replied, "We bow to brute force."

As Thackeray once held up the United States as a model to England, we now hold up intrepid France as a model to both.

Our Foreign Service

WE HAVE recently made arrangements with Mr. W. A. Doman, mining editor of the *London Financial News*, for a weekly London letter covering high points of activity in the mining field which centers in London. We are publishing a monthly letter also from Mr. Sigmund Silberstein, chief editor of the *Hungarian Mining Journal*, in Vienna, giving the chief features of the mining and metal situation in Central Europe. We have special correspondents in Melbourne and Brisbane, Australia, from whom we publish a monthly general letter. We have correspondents in South Africa, and are arranging for a regular letter from that section. For Mexico and Canada, of course, we have the same extended system of correspondents that we have in the United States, and we are extending this system to South America. We wish to call these facts to our readers' attention, that they may be aware of the thought and expense that are being constantly devoted to building up the news service of the *Engineering and Mining Journal*.

WHAT OTHERS THINK

Concrete Hearths Successful if Properly Constructed

I have read with interest the criticisms in the Consultation section of the Aug. 28 issue of the *Engineering and Mining Journal* relative to the use of reinforced concrete for replacing brick in the construction of roasting furnace hearths. As this is a subject to which I have given considerable study during the past eight years, I take this opportunity to state some facts regarding the performance of this type of arch during this period.

The scheme for using reinforced concrete in a monolithic construction to replace brick in roasting furnace hearths originated and was patented by J. H. Klepinger and myself, the first hearths being installed in the McDougall furnaces at the Great Falls Reduction Works of the Anaconda Copper Mining Co. in 1912. Six hearths were installed at that time in two furnaces, the third, fourth and fifth hearths being selected as the ones that would receive the most severe treatment. After these hearths had been in service for over a year they showed no signs of wear whatever, and in a paper written by S. S. Rodgers and myself entitled "Increasing the Efficiency of McDougall Roasters," for presentation at the Butte meeting of the A. I. M. E. held in August, 1913, we made the statement that we considered the reinforced-concrete hearths practically indestructible. Now, after a period of eight years, I have a telegram in response to an inquiry made to A. E. Wiggin, general superintendent of the Great Falls Reduction Works, to the effect that the six reinforced-concrete hearths installed in 1912 are still in good condition, and were operated continuously up to April, 1919, when the roasting department was shut down.

I am aware of the adverse criticism that has been published from time to time, and I am also familiar with the experience that some of the smelting companies have had with the hearths. The information given out, however, has been somewhat misleading, as I have been connected with some of the companies where these hearths have been tried out. It is absolutely essential that care be given to the preparation of the concrete, and that the proper proportions of one part portland cement, two parts tailing sand and four parts crushed slag are intimately mixed and poured on the forms before any setting action takes place in the mixture. Then, after the concrete has set thoroughly and the forms removed, a light fire should be started on the lower hearth of the furnace and the arch thoroughly dried before the furnace is operated. Cement manufacturers have spent considerable sums of money during the last few years in the distribution of information relative to the proper handling of their product, but irrespective of this, concrete construction is usually turned over to some foreman whose only idea is low cost of construction. As these hearths, when properly constructed, will outlast any number of brick hearths, and can be constructed for one-half the cost of brick, it surely pays to give their construction the proper supervision.

We "blew in" our Wedge roasting plant here in February, 1918, and lost our first arch in February, 1920. Our furnaces receive severe treatment owing to the frequent change in the sulphur content of our charge, which makes it necessary intermittently to burn oil, and I consider that two years is good service for a brick arch in a furnace operating with frequent changes in temperature. We replaced the arch with reinforced concrete and it has been in service now over three months and shows no signs of wear whatever. The arch is just above the burners, and when oil is used the flame strikes the under surface of the arch. We have one other arch under construction and will replace all of the brick with reinforced concrete as soon as the brick arches "cave in." We are forced at times to operate all of our roasters at full capacity, and cannot take the time to shut down to replace brick arches, so we are following this plan, feeling satisfied that when we have all of our furnaces equipped throughout with reinforced concrete our arch troubles will be ended. As for the arches rising in the center and causing trouble, it is a very simple matter to allow a little more clearance between the surface of the arch and the rabble blades when the arch is being constructed.

FRANK R. CORWIN.

Humboldt, Ariz.

Concrete Hearths a Failure in Chile

In 1919 the Braden Copper Co. installed, in an extension to its acid plant at Sewell, Chile, a 22-ft. 6-in. seven-hearth Wedge roasting furnace. The construction of this plant was in charge of the writer.

As the cost of brick was very high, due to the ocean freight rates prevailing at that time, it was decided to try two experimental hearths of concrete, and, accordingly, the two upper hearths were so built. The concrete section was about the same shape and size as the other brick hearths, well reinforced with ⅜-in. and ½-in. rods, both radial and circumferential, to make it as strong as possible.

Concrete consisting of native portland cement (which had proved very satisfactory on other work) and granulated slag from the copper blast furnace was used, the proportion being about 1 to 2½. The material was well mixed and placed, the whole job being subject to very rigid inspection. Plenty of time was allowed for the concrete to set, and the furnace was warmed up very slowly, a period of a month elapsing between the time of placing the concrete and putting the furnace in commission.

After about one week of service the lower of the two hearths failed completely. The concrete cracked very badly, and the arch sagged down onto the rabble arms below. Upon examination the concrete was found to be badly disintegrated by the heat, so both hearths were removed and rebuilt with brick.

In regard to the materials used the granulated slag was the subject of a thorough test extending over a year and was used in placing some 30,000 cubic yards of concrete in Chile. It gave higher results even than standard Ottawa sand. The cement is the only other factor. Apparently it contained considerable free lime, but an analysis could not be obtained from the manufacturers, nor were our own laboratory facilities adequate for making one.

F. J. Brulé, construction engineer for the company, and who built the first successful concrete hearths for the Anaconda company, told me that those were the only successful hearths that he knew of, all the others having failed. As he was greatly interested in this matter he had complete data on a great many installations of like character.

I was quite confident at the time that the concrete hearth would be successful. In fact, the trial was made at my request, as I had previously built concrete furnaces to burn sulphur in Tennessee, using identical materials. These concrete furnaces, though subject to temperatures as high as 2,200 deg. F., were very satisfactory.

I regret that I have not my notes available so that I could give fuller details as to our construction. Under the circumstances, I am inclined to doubt the success of concrete hearths of a diameter exceeding 10 or 12 ft. W. W. TAYLOR.

Milwaukee, Wis.

More Information Wanted

The question and answer in regard to Concrete Furnace Hearths that appeared on page 411 of your issue of Aug. 28 was very interesting to me, because whoever wrote it seemed to have a great deal of unpublished information, but it does not refer to the only published statement on the subject except through the allusion to Hofman's "Metallurgy of Copper." In Vol. 46 of the Transactions, pages 419 and 420, Corwin and Rodgers describe the converting of furnaces at Great Falls to concrete hearths, and give the results of the six months' run, which are quite contrary to the general tenor of the reply made to your correspondent. I hope some further statement in regard to this will appear, for I shall be interested to know whether a more extended experience at Great Falls contradicted the conclusions given by Corwin and Rodgers. T. T. READ.

Washington, D. C.

[Mr. Wiggin advises us that the concrete hearths used in the McDougall furnaces at Great Falls gave very satisfactory service but that these furnaces have not been in use for some time. The zinc concentrate, which is the only material now being roasted at Great Falls, is treated in Wedge furnaces with brick hearths. —EDITOR.]

Mineral Statistics for the Census Bureau

A statement on the work of the census of mines and quarries appearing in the article on p. 525 of *Engineering and Mining Journal* for Sept. 11, requires an explanation. The statement is as follows:

The work has gone far enough to determine that 47 per cent of all mining and quarrying operations have as their object the securing of oil or gas. The remainder of such operations is divided as follows: Coal, 18 per cent; gold, silver, lead, copper, and zinc, 21 per cent; quarries, 11 per cent; iron, 2 per cent; all others, 1 per cent.

The percentages given are merely a sorting of establishments or enterprises, that is, of individuals or organizations, engaged in or interested in the various mineral industries as shown by the census lists prepared as a guide for the census canvass. These figures have no relation to the number of actual operations, the number of men engaged, the quantity or value of output, or the scale of operation measured by any standard. The lists from which these figures were obtained are based on U. S. Geological Survey records and lists from state mining and geological bureaus, industrial registers, state gazetteers, and other published directories and indices of various kinds. The figures will be very materially modified when the results of the canvass are compiled and tabulated.

Washington, D. C. FRANK J. KATZ.

The Formation of the Sevier Valley, In Utah

I have just read the review of "The Ore-Deposits of Utah," by B. S. Butler, G. F. Laughlin, V. C. Heikes, and others, as published in the Aug. 28 issue of *Engineering and Mining Journal*.

Although I agree with you that "geological literature is rotten with faults that 'ain't there'," as well as a lot of other things that "ain't there," I must differ with you about the Sevier Valley not being a structural depression, for if it has not been in large part produced by faulting, there are no such things as structural depressions.

Although the whole of Sevier Valley is undoubtedly a depressed area, it is more particularly evidenced from the vicinity of Marysvale, south to the south end of Circle Valley, a distance of almost thirty miles. Both to the east and west of Marysvale the evidences of faulting are clear, on the east there being two eastward-tilted blocks forming the foot-hills to the main mountains, and to the west immense walls of quartzite practically vertical for hundreds of feet. It is in the mountains around Circle Valley that the faulting in the Tertiary volcanics is best exemplified. The stratification of the rock here is more marked than further north, and tilting and displacement are more easily followed than was possible in contiguous formations.

I would say, however, that there are more than two faults which formed the valley. From the edge of the plateau country on each side there are a number of faults stepping down the country to the valley floor, and below. A noticeable feature is that the formation on the east side of the valley dips to the east, and that on the west side dips to the west, as though the axis of the valley had once been the axis of a low arched anticline.

In Alaska, I have seen wide, flat-bottomed valleys with vertical and steep sides which were mostly, if not wholly, formed by the cutting effect of glacial ice streams. That an ice sheet once covered this country is not to be denied, and Sevier Valley may, in part, have been shaped that way; but there is no doubt of the faults of recent displacement which now are to be seen on its east and west borders, and which from all the trustworthy evidence at present available would appear to be the main factors in the valley's present geological development. JACOB W. YOUNG.

Marysvale, Utah.

Mineral Resources of the Belgian Congo

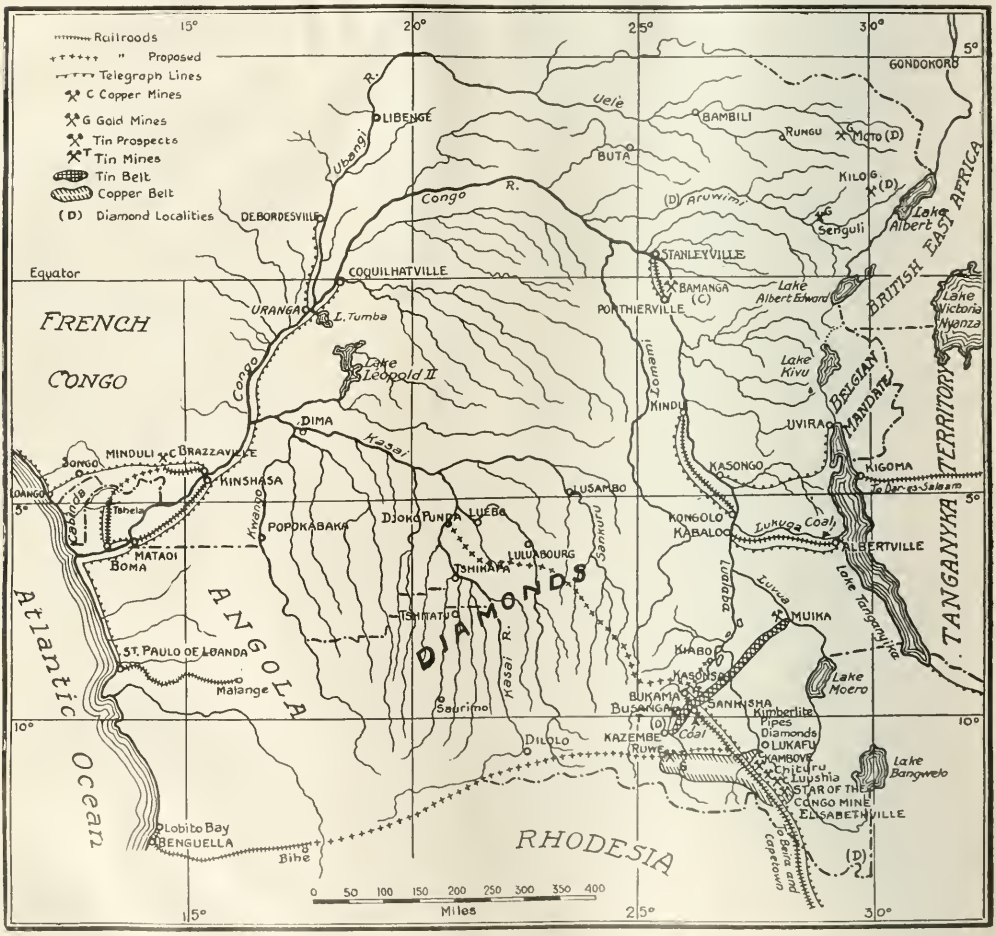
Development Formerly Much Hindered by Inaccessibility of the Colony, but Now Being Actively Pushed—Copper the Chief Product, but Gold, Tin, and Diamonds Also of Importance

BY SYDNEY H. BALL AND MILLARD K. SHALER
Written for *Engineering and Mining Journal*

BELGIUM, in her central African colony, the Belgian Congo, has a treasure house of natural resources from which raw materials, essential to stricken Europe, are being sent in increasing quantities to the mother country. The Belgian Congo comprises the greater portion of the Congo River basin, roughly one-third of its area lying north and two-thirds south of the Equator. The colony itself has an area of 909,000 square miles, and, in addition, the Belgians hold a mandate over 46,000 square miles in the northwestern part of what was formerly German East Africa. The combined area is a quarter that of the United States and Alaska.

Disregarding the narrow coastal plain, the colony lies on the African plateau, and consists of a basin, the centre of which is about 1,000 ft. above sea level. On the north frontier of the colony the elevations are from 2,500 to 4,200 ft., and to the south approximately 1,000 ft. higher. To the east are the high mountains of the lake region, Ruwenzori having an altitude of 16,800 ft.

Contrary to general opinion, one-half of the Belgian Congo is savanna, the great equatorial forest being



THE BELGIAN CONGO

confined largely to the south side of the great horseshoe bend of the Congo River. Heavy rainfall, high humidity, and relatively high temperature characterize the climate.

Interior transport, as in many countries, is the weak link which retards development. At present high freight rates permit the export of only relatively valuable raw materials and burden the cost sheets of all companies. Interior transport follows the Congo and its tributaries, the navigable stretches being linked to one another by railroads. Within the colony are over 9,000 miles of rivers navigable to steamers of light draft, but the service is slow and costly. Larger and faster steamers, channel improvements and loading facilities are necessary and are being provided.

Over a Thousand Miles of Railroad Built

The colony has 1,020 miles of railroad, and one can step off a boat from Antwerp at Matadi and from that port travel across the continent by all rail and steamer routes either to Cape Town, Beira, or Dar-es-Salaam. The building of the Bas-Congo-Katanga railroad between Bukama and Charlesville (Djoko-Punda), on the Kasai, would open up a fertile country, which is not only one of the best labor reservoirs in the Congo, but also is a diamond field of importance. It is not unlikely that construction of this line will begin soon from the Charlesville end. Eventual rail connection between Charlesville and Leopoldville is projected, which would furnish an all Congo rail route for the Katanga copper. The construction of one of the two proposed routes connecting the Congo and Nile rivers would better the transport facilities of the gold fields lying in northeast Congo.

Hydroplanes Used for Passenger, Mail, and Express Service

Fifteen hydroplanes with crews have been provided for the colony, and four are already in service. The program includes carrying passengers, mail, and express between Kinshasa and Stanleyville, a distance of 1,800 miles. It is expected that the round trip can be made in seventy hours, in place of the fifteen days which the river steamers take. Since June 1, a regular six-hour bi-monthly service between Kinshasa and Coquilhatville (360 miles) has been organized. The expansion of hydroplane service in the future is certain.

The climate, although tropical, should have, to a red-blooded person, none of the terrors which the story writers are prone to ascribe to Africa. White men, if proper care is exercised in their selection both as to physique and temperament, can serve their employers well during a continuous period of two years, the usual term of service in the colony, and that, too, without reason to regret later their sojourn in Africa.

Labor Is Cheap, but Natives Do Not Enjoy Work

The wage for common labor is low, varying according to the district from 5 to 10c. a day, although the companies also furnish food, lodging, medical care, bedding, and clothing in part. As a result, although general mining costs, for reasons other than labor, are high, certain types of work (shoveling of gravel and overburden for example) are done at small cost. As in most tropical countries, labor shortage is a chronic cause of complaint. This is due less to the lack of labor than to the unwillingness of many natives to work, and to the fact that some of the mining districts are relatively sparsely inhabited and lack means of easy and direct transportation from more densely populated regions.

Mining in the colony is mostly in the hands of ten or twelve companies and their associates and subsidiaries. Many of these companies are in a strong financial position and possess large concessions. A large number of the concessions held give the right to prospect large territories over a considerable period, at the expiration of which a certain number of smaller but still large mining claims may be staked out. The colony, in return for such rights, is given a participation in the mining companies varying from one-third to one-half of the stock issued. In addition, the colony is paying 2 per cent export tax on all minerals produced, and there is an import tax on supplies entering the colony. A graduated profit tax is proposed. The Katanga was thrown open to individual prospectors before the war, and eventually the whole colony will presumably be opened to general prospecting.

Since the war nationalistic tendencies have marked the policies of all European countries. With countries which have suffered as has Belgium, the policy is right and natural. The Congo gold is now all sent to Belgium, and used either in coinage or reserved for the use of Belgian goldsmiths. Part of the Katanga copper is being directed from England to Belgium, and this will be refined, as will be the Congo gold, in the Hoboken works near Antwerp. A large proportion of the Kasai diamonds must be sold to Belgian cutting works. Further, the mining companies must offer employment to Belgian engineers, and they are encouraged to purchase their supplies in Belgium.

As indicated, mining costs in the colony are relatively high, due to the following factors: high taxation, distance from the home office, slow transportation, high freight rates, and inefficient labor. Several of the operations are, however, carried on at an excellent profit.

Geology of the Region

The coastal plain is underlain by sandstones, limestone and shales of Cretaceous and Tertiary age, which dip gently toward the Atlantic. To the west is a belt of closely folded and ancient gneisses and schists of both sedimentary and igneous origin, intruded by granite bosses and diabase dikes. The central zone is composed of Devonian (?) limestone and the eastern belt is of red, flat-lying Permian (?) sandstones and shales. The interior basin is underlain by flat-lying interbedded sandstones and shales of Jura-Triassic age. As the north, south, and east frontiers are approached these sediments feather out, and rocks similar to those of the geologically complex Crystal Mountains outcrop. To the east, recent lava flows cover considerable areas north of Lake Tanganyika.

Many of the gold- and iron-ore deposits and some of the less important copper deposits are genetically related to the supposedly pre-Cambrian intrusions. The ancient African plateu has been deeply eroded, and these ore deposits are either replacements, fissure veins, series of linked lenses, magmatic segregations, or pegmatitic veins. The tin lode deposits of the Katanga are, however, dependent on the earlier of two Paleozoic

ROCKING SCREENS ON DEVELOPMENT WORK, KASAI DIAMOND FIELD

granites, whereas Studt ascribes the Katanga copper deposits to the latter. The origin of these deposits, however, remains a moot question.

Important mineralization apparently ceased by mid-Carboniferous times. Coal, oil shales, and diamondiferous conglomerates occur in the flat-lying shales and sandstones of the central basin, and it is possible that oil seeps in the coastal plain may lead to the discovery of petroleum.

The three important mining districts include the Katanga, to the southeast, with copper and tin and less important gold, coal, and diamond deposits; the Aruwimi-Uelle region, to the northeast, with gold deposits; and the Kasai region, to the southwest, with diamond deposits.

Extent of the Katanga Copper District

The Katanga copper belt is not only the site of the most important mining industry in the colony but its operating company, the Union Minière du Haut-Katanga, is one of the twenty most important copper producers in the world. Its reserves, proved and potential, warrant the belief that its future importance will be even greater.

The Katanga copper belt lies in the southeastern part of the colony, and, indeed, its lower tip extends into Rhodesia. Two hundred copper deposits have been discovered in a belt from 25 to 40 miles wide and about 200 miles long. The belt extends from east to west.

The ruggedly dissected plateau ranges in elevation from 3,900 to 5,200 ft. above sea level. The copper deposits were relatively easy to locate, as they usually rise above the surrounding territory as cones or ridges bare of verdure. The local natives were also familiar with the location of the numerous pits sunk by the old copper miners.

The copper-bearing rocks (probably of middle Silurian to Devonian-Silurian age) include sericite schist and quartzose rocks, ranging from shaly sandstone to quartzite, and less frequently slate, talc, limestone, and dolomite. The rocks are closely folded, and strike parallel to the extension of the belt, the predominant dip being north. Granites and basic igneous rocks occur in the vicinity. The orebodies are associated with sharp folding, faulting, and brecciation and an unusual degree of metamorphism. The orebodies are tabular masses conforming usually to the bedding planes but in instances to schistose planes cutting the former. Malachite and chrysocolla are the predominant minerals; azurite, copper pitch ore, and melaconite are less abundant; and cuprite, dioptase, native copper, lunite, libethenite, olivenite, and cyanotrichite are rare. Diamond drilling shows that copper sulphides (chalcopyrite, chalcocite, bornite, and covellite) and pyrite occur in several orebodies.

Although figures as to reserves are not available, substantial tonnages are practically in sight, and the amount of the ore which will eventually be developed will be very large. A number of deposits are large, as, for example, Kambove No. 2, reported to be 3,000 ft. long, and, so far as developed, from 240 to 400 ft. wide.

High-grade ore, containing 15 per cent or more copper, and suitable for direct blast-furnace smelting, is in relatively small amounts compared to 6½ to 7 per cent ore. Most of the ore is highly siliceous, although some is high in alumina and still other is dolomitic. Some of the ore carries appreciable quanties of precious metals. The cobalt content is high, and the Katanga copper belt could produce as a byproduct practically all the present world demand.

The copper belt is the property of the Union Minière du Haut-Katanga, in which the Tanganyika Concessions, Ltd., a British corporation, holds a 39 per cent stock interest.

Mining was begun in 1910, and smelting in June, 1911, the production in metric tons being as follows:

Date	Tons	Date	Tons
1911	998	1916	22,167
1912	2,492	1917	27,462
1913	7,407	1918	20,238
1914	10,722	1919	23,004
1915	14,041		
		Total	128,531

The drop in production in 1918 was due to transportation difficulties, labor shortage, and an influenza plague, whereas the production in 1919 was adversely affected by shortages of supplies and a strike of the white employees.

Americans Hold Important Executive Positions

The staff consists of about 800 whites, several of the more important positions being held by Americans, and a labor force of 12,000 to 13,000 natives. Mining is predominantly open-cut work by pick and shovel or steam shovel, although in several of the mines the ore

HAND-PICKING CONCENTRATES, RAMONA, KASAI DIAMOND FIELD

is milled down chutes to main haulageways. The less rich ore is either hand sorted or washed before reaching the smelter.

The Star of the Congo Mine, formerly the principal producer, produced in 1919 but 20 per cent of the ore; 65 per cent of the production came from the Kambove mine and 15 per cent from the Likashi and Chuturu group. The latter mines were opened up in 1918. To the end of 1919 the Star had produced 888,000 tons of smelting ore, besides the greater part of the dolomite used as flux until recently, when it has been supplanted by Kakontwe limestone. Kambove between June, 1913, and Dec. 31, 1919, furnished about 635,000 tons of smelting ore, and Likashi-Chituru 128,000 tons. The Fungurume mine is being opened up, and the Luishia, Luiswichi, Kakanda, and M'sesa mines have been satisfactorily developed. Development, particularly by diamond drilling, has been pushed in the western group of mines in 1920.

The ore is smelted in blast furnaces at Lubumbashi, near Elisabethville, to black copper containing from 96 to 97 per cent of the metal. In 1916, about 195,000 metric tons of ore, 70,000 tons of iron flux, 52,000 tons of dolomite and 2,700 tons of limestone were smelted, the coke consumed being about 70,000 tons (54 per cent Wankie Rhodesia coke and 45 per cent coke made in Katanga from Wankie coal). In 1919 a total of 189,169 tons of 16 per cent ore and 163,000 tons of flux were smelted. About 73 per cent of the copper content of the ore is recovered. Seven furnaces are in operation, of a theoretical total capacity of from 35,000 to 40,000 tons of copper per year. The plant was therefore running at about 50 per cent capacity during 1919.

A 4,000-ton mill to concentrate the malachite stringers in the lower-grade ore is being built this year near the Likashi and Chuturu mines, and will probably be put into operation during the second half of 1921. The tailings are to be stored for later treatment by a leaching plant. An experimental leaching plant (100 tons copper per month) was planned to be erected this year, and this pilot plant will be superseded, within the next three or four years, by one of a capacity of 55,000 tons of copper yearly. Its probable location is near N'Zilo, where hydro-electric power can be generated. In prewar days, the copper was sold in Germany, but during the war most of it went to England. Since 1919, part of the production is shipped to England and part to Antwerp, where it is refined at the Hoboken plant. The Union Minière holds a 25 per cent interest in this 20,000,000-fr. refining corporation.

Cupriferous quartz veins and lenses, lenses of chalcopyrite, magmatic segregations of chalcopyrite, and cupriferous beds in red sandstone occur in the older rocks of other portions of the Congo basin, but of the copper deposits those of the Katanga are alone known to be exploitable. Ten years ago a few tons of high-grade ore was shipped from quartz-chalcocite lenses at Bamanga, near Ponthierville. The Simkat is to continue development of the Kapulo copper mine, near Lake Mwero, a deposit found during the war.

The Belgian Congo produced to the end of 1919 from its placers about $16,626,255 worth of gold, or 24,750 kg.

GOLD PRODUCED IN BELGIAN CONGO TO END OF 1919

Property	Kg.	Property	Kg.
Kilo-moto	23,213.617	Nebula	(a)50.775
Sengule	17.797	Ruwe	530.000
Babeyru	750.000		
Kanwa	158.000	Total	24,750.189

(a) Figure of the Colonial Office.

The placers now worked are situated in the northeastern part of the colony, although gold is widely distributed around the rim of the basin and is even an occasional clastic constituent of the interior sandstones.

THE LUBUMBASHI SMELTER, KATANGA COPPER BELT

The northeastern part of the colony is a region of ancient rocks, which have undergone deep weathering and erosion, resulting in the concentration, in present-day streams, of gold once widely distributed in stringers and other non-exploitable bodies. The bullion runs about 93 per cent gold and 7 per cent silver.

The colony owns and operates the two important placers, namely Kilo and Moto, in the Ituri and Uelle basins. The two placers, which are about 100 miles apart (and this in Africa, due to difficulties of communication, is the equivalent of a thousand miles in America), were operated by a single management in Africa, but in 1918 the two mines were placed under separate African managements. In March, 1920, the Colonial Ministry placed the management of these placers in the hands of a committee sitting in Brussels and composed of experienced engineers and colonials, who are to be responsible for the mines paying a return on an assumed capitalization of 100,000,000 fr.

The gold is chiefly sold in England, and a part of it is reserved to Belgian goldsmiths. Recent production has been from one to two thousand kilograms a year each from Kilo and Moto.

The country rock at Kilo is diorite, schist, syenite, and granite. The gold probably originates from quartz-pyrite stringers in the diorite itself and along the diorite-granite contact, as the streams become barren as they pass from the diorite into the granite. The average depth of gravel is 2.75 ft. at Kilo and 1.85 ft. at

Moto. The bottom at Kilo is a greenish clay, an alteration product of the diorite into which the gold penetrates for four and in places over eight inches. Operations began in 1905. Excavation is largely by pick and shovel, although a small giant is used, and more machinery should by now have arrived at the mine. The gold is chiefly recovered in sluices. A dredge has been working the wash of Chari River since 1918, and gave for the year 1919 a production of 96.514 kg.

deposits at Kilo and Moto, and a sample of serpentine yielding platinum has been found at Kilo. The gold region is relatively sparsely settled and labor is difficult to procure. During the war there was a shortage of white staff, and since the armistice the region has suffered from several epidemics.

The Moto placer began operating in 1911. The country rock is reported to be granite, diorite, and hematitic schist. The Senguli placer of the Kasai company, also

PANORAMA OF KAMBORE MINE, KATANGA COPPER BELT

In 1918 the gravel treated averaged $2.17 per cu.yd., and costs are reported to be about $1.25 per cu.yd. Details concerning the two exploitations during 1919 follow:

	Kilo	Moto
Production	1,740.697 kg.	1,618.598 kg.
Cubic meters of gravel washed	350,436	700,000
Gold contents per cubic meter	4.96 g.	3.32 g.
Cubic meters of overburden	273,447	800,000
Number of native workmen	2,900	5,600
Number of white agents	37	23

The reserves now determined can be estimated at about 10,000 kg. for Kilo and 5,000 kg. for Moto. Part of the territory is not yet prospected.

Lode Deposits Also Known

Lode deposits have been found at Kilo, and these are soon to be exploited, as machinery is said to have arrived in the fields. The Colonial Office reports that about 432,000 tons of quartz, containing approximately 5,550 kg. of gold, or $7.50 per ton, has been developed. Certain lodes have been cut at a depth of 60 to 120 meters. Their thickness averages about one meter and they strike nearly E.-W. along a distance of over one kilometer. At Moto, lode prospecting is not yet sufficiently advanced to permit an estimate; however, the results obtained are encouraging.

Some diamonds have been discovered in the alluvial in the northeastern part of the Belgian Congo, was opened in 1919, and its production for the year was about 18 kg. of gold. The discovery, in May, 1919, of a new placer in the northeastern part of the Uelle basin, was also reported. West of Moto mines in the Uelle, and near Niangara, the bed of the river is reported to contain paying gold. The Orientale company (since taken over by the Intertropical) has located a placer in the Ituri region. Small placers derived from two of the Katanga deposits (the copper ore, as already stated, is slightly auriferous) were formerly worked; at Kambove very little gold has been extracted. The placers of the Forminière at Kanwa and Babeyru have been temporarily abandoned because of low grade and high working costs. The production from these mines totaled 908 kg.

The Ruwe mine structurally resembled the copper deposits, and, indeed, its ore contains some copper. The ore shoot is reported to be about 1,400 ft. long and to average 7.5 ft. wide. The ore was reported, prior to the war, to average $14 per ton in gold, platinum, palladium, and silver, equivalent, at present metal prices, to at least $28. There are rumors that it is soon to be worked. Between 1904 and 1908 about $330,000 worth of gold was washed from a detrital deposit derived from the weathering of this lode.

On the northwest face of the dissected plateau known as Monts Mutumba, in the Katanga, is a tin belt 250 miles long and of considerable promise. The strike of the belt is northeast to southwest. The rocks are mica-schist, tourmaline-bearing quartzite, and slate of pre-Cambrian or Cambrian age, which are intensely intruded by biotite granite and pegmatite of Ordovician age. The cassiterite occurs in pegmatites and greisens, but the commercial deposits are detrital and to a less extent stream deposits. The southern 175 miles of the belt is owned by the Union Minière du Haut-Katanga, the central portion by the Geomines, and the north end by the Simkat.

In 1906 the Union Minière smelted ten tons of tin concentrates at the Busanga mine in a locally constructed furnace. This mine was reopened in 1916. The company has contracted the mining, its engineers merely superintending the exploitation and doing development work. An epidemic of grippe and delays in road construction have held the work back, but it is hoped that the two contractors will soon be producing monthly the fifty tons of cassiterite (65 to 75 per cent) for which the contract was made. The first shipment of concentrates reached Elisabethville in April, 1920. The better gravel is said to carry about 1 per cent of cassiterite, and the reserves now developed contain approximately 10,000 tons of that mineral.

The Geomines is exploiting the Manono and three smaller placers near Kiambi, using giants and sluices. About ten white men and 600 natives are employed. From 15,000 to 20,000 tons of cassiterite in low grade gravel (0.1 to 0.01 per cent) have been blocked out. In 1917 a total of 103 tons of concentrates were sold, and in 1918, 274 tons. The concentrate carries 74 per cent tin and is highly prized by British smeltermen. The company's other tin placer at Naulongo-Kikondja is not now being exploited. Exploitation was begun in 1915, and to June 30, 1918, the production totaled 443 tons.

The Simkat is reported to have started work on its placer at Muika. The lode is reported to contain from 0.2 to 0.5 per cent and the placer from 0.05 to 0.07 per cent of cassiterite.

The reported tin production in metric tons follows:

Date	Carats	Date	Carats
1915	48,935	1918	164,000
1916	53,910	1919	215,000
1917	100,000		

Diamonds are widely distributed in the Belgian Congo. They exist at two alluvial occurrences and as constituents of several kimberlite pipes in the Katanga, as alluvial diamonds over an area of 45,000 square miles in the southwestern part of the Belgian Congo called the Kasai diamond fields, and at six places scattered over the northeastern part of the colony.

In the Kasai diamond fields are the only exploitable deposits so far found in the colony. The region consists of a foundation of ancient (pre-Cambian?) schists, gneisses, and granites, on the peneplaned surface of which rest flat-lying sandstones, shales, and conglomerates of Jura-Triassic age. The conglomerate lenses contain diamonds, in instances in commercial quantities, and in consequence the diamonds are much older than those mined from the South African pipes. The deposits now being exploited are, however, creek and terrace deposits, which are in instances rich. The stones are generally small, averaging about one-tenth of a carat; and the largest stone yet found weighs about 32 carats. In quality, the diamonds resemble those of the Southwest African Protectorate, and a large portion of them are suitable for cutting.

TAKING OFF OVERBURDEN IN THE GRAVEL PIT AT M'PESO, KASAI DIAMOND FIELDS

The field was discovered in 1907 by the Forminière, a Belgian corporation in which American capital is interested. Production began in June, 1913, since when 620,000 carats have been produced. Recent production follows:

Date	Metric Tons	Date	Metric Tons
1913	19,368	1917	103
1914	30,947	1918	274
1915	10,250	1919	163
1916	0,025		

From eight to ten different placer mines are under exploitation. Excavation is largely by pick and shovel, and concentration by pan plants, or (after sizing by rocking screens or trommels) by jigs. Fifty white men and 8,000 blacks are employed. The capital of this company has recently been increased from 8,000,000 to 16,000,000 fr. On Oct. 1, 1919, the company declared 6 per cent dividends on the preferred stock, covering the period from 1909 to 1913 inclusive. In 1919, the government requested that three-fourths of the production, as a minimum, be disposed of in the Belgian market.

The staff of the Forminière is prospecting the concessions of six other companies and syndicates in the Kasai diamond fields, of which the Beceka, a mining

company subsidiary to the Lower Congo-Katanga R.R. Co., will in 1920 begin to exploit at least one of the deposits which it has found to be northeast of the Forminière concessions. The Kasai company has also located some promising deposits and is forming a subsidiary company, which will soon start exploitation. These exploitations as well as further prospecting work will be carried out under the auspices of the Forminière. Capitalists associated with the Forminière have also obtained diamond prospecting concessions in the northern part of the Katanga, where prospecting work has begun.

In the southern part of the Katanga are about forty pipes composed of a rock resembling kimberlite, and, indeed, these pipes may well be contemporaneous with those of South Africa. The largest has an area of forty-five acres. Many of these pipes are known to be diamondiferous. Several hundred stones have been obtained from the Luanza pipe.

Fourteen known pipes are owned by the Simkat, others by the Geomines, and by the Kundelungu Exploitation Co., the latter a subsidiary of the Katanga Special Committee, and the Tanganyika Concessions, Ltd. Now that the war is over, further washing tests will be undertaken on certain of these pipes.

Colony Also Has Coal Deposits

The Geomines has uncovered coal beds at Kilometer 262 on the Kabolo-Lukuga railroad. Five seams of coal from four to six feet thick occur in rocks of Karoo age, which formation includes the coal-bearing strata of South Africa. The beds vary from horizontal to vertical. The weathered coal is reported to contain 61.9 per cent of carbon and 13.25 per cent of ash, and produces 5,891 B.t.u. Although it clinkers badly, it can doubtless be used locally on the railroads. The coal is known to underlie a considerable area.

The Geomines, Simkat, and the Paris Banks Consortium jointly own the Luena field, also in the Katanga. The coal is about four feet thick and the outcrop has been traced for thirty-two miles. The Luena field is twenty-six miles south of Bukama and a mile from the railroad. The field is to be immediately prospected.

The Union Minière du Haut-Katanga and the Compagnie du Chemin de Fer du Bas Congo au Katanga have taken up several circles for coal near Sankishia (on the Katanga railway), and methodical prospecting was started several months ago. Several drill holes and shafts have already been put down. They have proved the existence of an aggregate of coal beds approximately fifty feet in thickness containing approximately fourteen feet of clean coal in five seams. Two of the seams, as far as known, vary in thickness from three to five feet. One of the bore-holes struck the coal at about 225-ft. depth.

The outcrop of the overlying formation can be traced along a considerable distance, which justifies the conclusion that the coal field is of great extent. The coal is something between a true lignite and bituminous coal, and is non-coking where sampled. The volatile matter varies from 18 to 32 per cent; the ash from 22 to 41 per cent; and the sulphur from 1.4 to 4 per cent. Part of it is probably suitable for use in stationary boilers, locomotives, gas producers and reverberatory furnaces, either as it is or after pulverization.

It is anticipated that the discovery of this coal will facilitate considerably the fuel problem of the Union Minière and the Katanga railroad, which are at present using wood fuel exclusively for their stationary boilers and locomotives. The total monthly consumption of wood for this purpose is estimated for next year at not less than 50,000 tons, which could be replaced by 8,000 to 10,000 tons of coal. This substitution of coal for wood would release a considerable number of whites and native workmen.

Very impure coals have been found at several other places in the Katanga.

The Simkat is preparing to construct a cement plant in the Katanga, and another company (Société des Ciments du Congo) is to burn lime and manufacture cement bricks and other building materials in the Katanga. The Simkat and Geomines, besides their activities mentioned, form part of a syndicate for which the Forminière is prospecting for diamonds in the Kwango and Kasai regions. They are both to continue prospecting their mining blocks in the Katanga.

The above notes cover the Congo mining activities. Among the colony's undeveloped resources may, however, be mentioned considerable bodies of iron bauxite, manganese, tungsten, molybdenum, and lead ores, and uranium and radium minerals are also present. Monazite is a relatively common constituent of certain of the stream gravels, and thorianite is also reported.

In addition to diamonds, a number of other precious stones, including chrysoberyl, rose tourmaline, ruby, sapphire, meerschaum, cyanite, and amethyst, occur, although none so far as known are present in commercial quantities. Oil shales outcrop in the vicinity of Ponthierville. Apatite, fluorspar, barite, asbestos, muscovite, and strontianite, although occurring in fair quantities, are not exploited.

Branch of the Royal Mint Established

The creation of a mint in the Union of South Africa was provided for in legislation passed by the Union Parliament in June, 1919. The mint will be a branch of the Royal Mint so far as gold coinage is concerned, according to *Commerce Reports*. This insures that the output will be legal tender throughout the British Empire.

The gold mines in South Africa exist entirely by selling their gold. They strongly urged the creation of a mint, as it would have, under normal conditions, added to their profits and would have relieved them from the many difficulties which beset the industry during the past few years. Work on the mint is now proceeding, but with the high premium on gold which the mining companies are receiving since the placing of gold on the open market, minting at present would not be profitable. Until the premium disappears no advantage will be gained by minting locally.

Exports of Gold Dust, Graphite and Corundum From Madagascar

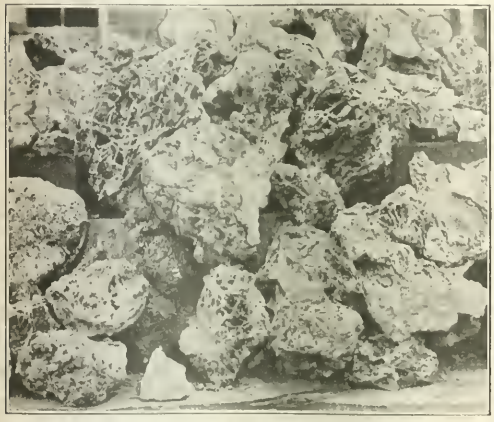
For the nine months ending Sept. 30, 1919, according to Vice Consul Feibelman, 725 metric tons of corundum, 13,278 troy ounces of gold dust and 2,363 metric tons of graphite were exported from Madagascar. During the last quarter of 1919, 99 metric tons of corundum, 4,501 troy ounces of gold dust, and 1,687 metric tons of graphite were exported.

Zinc Ores of the North Arkansas Field

Smithsonite and Calamine Are Easily Mined, and the Milling Methods Used Are Simple—Ores Are Especially Desirable in Chemical Industry for Manufacture Of Zinc Oxide, Lithopone, and Zinc Chloride

By Tom Shiras
Written for *Engineering and Mining Journal*

THE growing scarcity of smithsonite, or carbonate of zinc, and calamine, or silicate of zinc, in the United States, is creating a new interest among big consumers of these ores in the north Arkansas zinc field. The difference between the price of these ores, the selling base of which is 40 per cent metallic zinc, and the price of blende, the selling base of which is 60 per cent metallic zinc, is gradually growing smaller. On a basis of metallic content, the smithsonite and calamine should bring only two-thirds as much as blende, but recent market quotations have shown it to be bringing as high as slightly under seven-eighths as much and in some instances this year choice lots have brought as much as the lower-grade blende at Joplin.



REPRESENTATIVE DISPLAY OF NORTH ARKANSAS SMITHSONITE AND CALAMINE ORES

STARTING A NEW TUNNEL ON A SMITHSONITE OUTCROP ON RUSH CREEK

Nine-tenths or even more of all the developed zinc mines in the north Arkansas field are smithsonite or calamine mines, the bodies of "jack," or blende, being practically unexplored, and this condition will probably exist until the former ores are exhausted.

The development of the smithsonite and calamine instead of the blende was brought about by natural conditions. A miner is no different from the average human being. He follows the lines of the least resistance. Most of the orebodies lie in the upper ore-bearing stratas above water level, and are easily mined in practically dry ground by tunneling and drifting. Although some bodies of blende have been opened up at these higher levels, most of them have been encountered below the water level, and have to be mined by shafts and drifts which require pumping to be kept in a workable condition.

The smithsonite and calamine are distributed over a large area in the northern part of the state. Mining is actively carried on in Marion, Boone, Newton, Searcy, and Baxter counties. There are also commercial deposits of these ores in Sharp and Lawrence counties, which are worked spasmodically. The earliest mining done in the state for the ores mentioned has been in the two latter counties. In 1857 a zinc smelter was operated by the Independence Mining Co. at Calamine, in Sharp County. This company did a general mining and smelting business, but its operations were stopped by the Civil War, its machinery being confiscated or destroyed by the Confederate Army.

Large areas in the North Arkansas field are still unprospected, and places where development has made commercial bodies of ore available constitute but a small area of the field. Smithsonite outcrops are of common occurrence along the exposed ledges bordering the rivers, creeks, and hollows in many sections of the field. Only a few of the known outcrops have been investigated to determine whether commercial bodies of ore exist or not. From the number of commercial mines that have been developed during the last few years, and considering the character and number of the outcrops, it would seem that the field as a whole contains an unlimited quantity of these ores, the production being limited only by economical development and mining. The smithsonite is invariably found in greater or lesser abundance along the outcrops of beds that contain or did contain blende.

Discussing the origin of the smithsonite and calamine ores, John C. Branner, former State Geologist, says:

> It is evident in all cases that the smithsonite is formed by the alteration of zinc blende and its recrystallization in the form of smithsonite. Calamine, like smithsonite, is formed from blende, but is not of such common occurrence. It is especially abundant in the Zinc Camp, which lies around

the town of Zinc, in Boone County. The siliceous rocks there are much broken. At several places where the calamine is found the blande has been removed in solution from the compact chert gangue, and cavities thus left have been filled with calamine crystals. Like smithsonite, calamine is found in many instances in loose lumps in the surface clays, and wherever it has been found in hard rocks, the rocks bear unmistakable evidence of having been altered by the action of the surface waters.

The carbonate and calamine deposits are invariably found along faults, fractures and synclines. These afford convenient paths for underground waters, and waters percolating through them coming from bedded deposits of blende carrying zinc solution naturally deposit these values there.

An interesting feature in connection with the faults is that it sometimes happens that the ores have accumulated not in the faults themselves but close to them on one side or the other.

When the ores occur along the ancient underground watercourses guided by the folds, faults, or fractures, they can be located approximately, at least, by a study of the surface of the geological structure.

In drawing general conclusions regarding these ores, Mr. Branner states:

The position of the ores in the secondary deposits has been determined largely by those structural features that have guided the underground waters in their passage through the rocks.

In some cases the accumulations have taken place along synclinal troughs; in other cases, in fissures along fault lines, and in still others, in the breccias formed along ancient underground watercourses. The subterranean waterways have in many instances been closed by the deposition of these ores and the water forced into other channels. The smithsonite and calamine ores are produced by the alteration of blende mostly in place.

The rocks throughout the north Arkansas field are for the most part horizontal. To this rule there are a few important exceptions, and in these exceptions the bending or tilting of the beds is for the most part comparatively gentle. Faults, however, have performed a prominent part in the disturbance of the horizontal bedding and the continuity of the strata of the region. In some places these faults are of but local importance, though in other instances a single break may be traced almost continuously for thirty miles or more.

By far the greater part of smithsonite and calamine is found associated with gangue and must be milled to prepare it for the market. A small portion of the production comes from the ground in chunks, and with a little hand cleaning is ready for shipment.

Milling Practice Improved by Use of Tables

The milling plants used in the field are the regular Joplin type mills equipped with sludge tanks, or Dorr thickeners and tables. A few plants have been erected in which the jigs have been entirely eliminated, the concentrating being done entirely with tables. This type of plant has been found to be very successful. The first mills, erected in the field over twenty years ago, were not equipped with tables, the entire concentration process being done with jigs. Assays of the old tailings at these plants have run as high as 8 per cent metallic zinc and few have run under 5 per cent. With table equipment this loss has been reduced to a fraction.

Ores Desirable in Chemical Industry

The purity of the smithsonite and calamine produced in the north Arkansas field makes them especially desirable for many purposes. They contain no iron, lead, or other foreign matter detrimental to either their manufacture into chemicals or spelter. They produce the best spelter that can be made from virgin ores, for which they were used almost entirely until two years ago, when the chemical companies were attracted to them. In the chemical industry they are principally used in the manufacture of zinc oxide, lithophone, and zinc chloride.

In many of the mines, especially in those where the orebodies have been built up in ancient underground watercourses, rare specimens in the shape of stalactites have been found. Some specimens resemble old castles and spires with a shelly interior, and others show grille work in delicate patterns. In one mine fifty-one specimens were saved, each of a different texture or color. Owing to their range in color and texture, the new prospector in the field many times confuses some specimens with lime carbonate or crystalized silica. Native prospectors determine their value largely by their weight, the ore being much heavier than any other formation resembling it.

Select specimens of smithsonite run as high as 52 per cent. metallic zinc, and calamine 54 per cent. The average car of concentrates or hand-cobbed ore ready for the market runs from 40 to 44 per cent. Few run as high as 47 per cent, or as low as 36.

In the early history of the field these ores were not much sought, blende being the lure for the prospector. John C. Branner made the following statement at that time: "It should not be forgotten that some of the most important and best-paying zinc mines in the world have been mines of smithsonite." And in connection with the north Arkansas field, and its subsequent development, his statement has been well substantiated.

Japanese Aluminum Industry Dependent Upon Foreign Raw Materials

Although the aluminum industry is now well established in Japan, most of the forty-four manufacturers conduct business on only a small scale, chiefly for home consumption, says a recent article in the *World Salesman*. The variety of articles manufactured is comprehensive, including all kinds of cooking utensils, candlesticks, pipes, cigarette cases, alcohol lamps, army canteens, bottles, and various kinds of castings. Japan is entirely dependent upon the United States and England for raw material in connection with this industry, though at present, in co-operation with an American aluminum company, plans are under way for the erection of a plant in Fukui Prefecture, which, with the help of experienced American workmen, will later be able to supply the raw aluminum material needed. In 1918 imports of ingots from the United States amounted to 1,466,967 kin (kin = 1⅓ lb.), valued at 1,662,471 yen, and from England they reached 12,346 kin, valued at 13,652 yen.

Federated Malay States Gold Production

The quantity of gold placed upon the market by Federated Malay States producers was 18,309 oz. in 1918, an increase of 155 oz. over that of the previous year, according to *Commerce Reports*. The approximate value of the 1918 production was $345,157. The production of gold from the Raub mines, in Pahang, totaled 16,990 oz.

Mining Enterprise in 2020

A Concise Account of the Discovery, Examination, and Exploitation of a New Element Occurring In a Hitherto Unexplored Part of the Extreme Southern Tip of South America—Prospecting, Mining, and Reduction by Wireless Devices

By Jules Verne IV, Jr.*
Written for *Engineering and Mining Journal*

F. WALLINGCRUDE BLACKSTONE sat at his desk dribbling a small stone back and forth from hand to hand. He was evidently trying to make up his mind. If we could have looked more closely at the stone we would have noted that its black mass contained small cubes of a metallic-like mineral which glowed with a smouldering fluorescence. He had been turning over a series of reports from many professional mineralogists and chemists, the burden of which was to the effect that the metallic mineral was unlike anything that had ever been discovered. Its specific gravity was 5; it was distinctly brittle; it left a bright fluorescent streak, but it apparently had neither name nor place among the discovered minerals. One chemist who had made a more thorough investigation than others stated that the mineral was a new element and fell into Group IV, Period VII, of the Periodic Table of Elements.

The stone had been forwarded to F. Wallingcrude Blackstone by an aviator friend who, when investigating high-altitude conditions in the vicinity of the South Pole, had been compelled to land on a high plateau in almost the center of Terra del Fuego to make adjustments on his turbo-supercharger. As he was about to touch the ground he had noticed a large prominent mass of black rock, which glinted strangely in the soft rays of the setting sun. After making necessary repairs, he investigated the mass and found it to be of considerable extent. Scattered almost uniformly through every piece which he broke off were the strange crystals we have described. Knowing of the keen interest taken by F. Wallingcrude Blackstone in minerals and mines, he had sent a specimen, together with the latitude and longitude of the place, to him on returning to New York. An immediate investigation of the strange mineral had been made, with the results as already given.

F. Wallingcrude Blackstone placed the stone on his desk, moved a jeweled indicator to a number, and said: "J. Montmorency Findit?" Apparently from the air at his left a voice said: "Here, sir!" "Note these instructions and act on them immediately," said F. Wallingcrude. "Arrange with the International Electro Prospecting Company of Newark to have one of their latest Model D24, single-stage prospecting machines sent to your office at once. Leave tomorrow for latitude ——, longitude ——. There you will find a conspicuous mass of black rock showing a peculiar mineral. Ascertain the size of this deposit, the proportion of contained mineral, and such general conditions necessary for its exploitation as your judgment indicates. Have your report on my desk at 10 a. m. day after tomorrow. Good luck!"

J. Montmorency Findit leaned back in his chair, laid his pencil down, and picked up his half-consumed cigarette. Puffing away, he touched a dial indicator in his desk and said: "Is this the airage?" A voice answered at his elbow: "Right here, sir." "Observe these instructions," said J. Montmorency Findit. "Prepare two high altitude planes for immediate service. Expect party of four to leave at 8 a. m. tomorrow. Adjust latitude and longitude controls for latitude ——, longitude ——, South Hemisphere." J. Montmorency Findit then called up in turn the members of his party who were to accompany him and notified the Electro Prospecting Company of Newark. He then wandered over to his club and spent the rest of the day at a game of billiards, which, however, was not played in the ancient way by wooden cues but by an electric impulse and direction machine, which enabled a player to smoke comfortably while playing an exciting game with several opponents.

The next morning the party, consisting of J. Montmorency Findit, his assayer, K. Dore, and two assistants, climbed into the seats back of the respective pilots in the two machines, and the word was given to start. Without a sound the machines rose rapidly to an altitude of 40,000 ft., the passengers quickly adjusting the atmosphere within the closed fusilage. The assistants settled down to a two-handed game of cards, J. Montmorency Findit being busy with the final adjustments upon the prospecting machine. The pilots had little to do, for by means of the latitude and longitude control the two planes, at a fixed distance apart, went unerringly to the point selected. When they reached the locality they automatically spiraled down at 10 a. m. to the minute, within hands' reach of the black rock mass.

The Future Mode

J. Montmorency descended from his plane and lifted the prospecting machine down. He then lighted a cigarette, for in spite of the fact that he was one of the famous mining engineers of the time, he still adhered to the ancient habit of thinking through a haze of cigarette smoke. He handed two small metallic cylinders to the assistants and directed them to walk in a north-south direction at a distance 500 ft. apart, placing the little cylinders upon the ground at intervals of 200 ft. He then set up the prospecting machine, upon which were two dials, respectively marked "Quantity" and "Proportion." K. Dore took his position in front of the last named dial, J. Montmorency standing in front of the first. The machine was an automatic integrating device, which determined quantity and proportion with a single setting. After tuning the machine J. Montmorency gave the assistants the signal to start. At the end of an hour the index fingers upon the dials stopped. J. Montmorency touched a button to recall his assistants and took down the readings, which were 7,000,000,031 metric tons on the one and 5.378 per cent on the other. As soon as the assistants returned they all entered the machines and at 4 in the afternoon were at the airage in New York. J. Montmorency dismissed his assistants and hastened to his club.

The report which he submitted the next morning was on a slip of paper and simply reiterated the figures we

*The inspiration for this article is due to Mr. J. F. Kellock Brown, but he is not responsible for the vagaries of the execution, for the article has a composite authorship.

have already given. F. Wallingcrude Blackstone looked at the slip and said aloud: "An enormous quantity like that must have some use. I am going to put it up to Professor Relativity, and in the meantime I will proceed with the organization of the company." He sprang to the jeweled indicator, gave it a whirl and said: "Oh, Professor! Tune up with this office and J. Montmorency Findit. I want a conference." Thus with F. Wallingcrude Blackstone in New York on Broad Street and Professor Relativity at Bear Mountain, on the Hudson, and J. Montmorency Findit in Brooklyn, the three entered into an animated discussion, the outcome of which was that Professor Relativity was to enter into immediate research for a possible utilization of the new element and report the next morning.

Organization Preliminaries

J. Montmorency was to arrange a modern mining and reduction plant, which was to be shipped by high altitude aeroplanes within the week, and during the rest of the day he was to organize and finance a $100,000,000 company. J. Montmorency turned the company affair over to the Finance Foundation of America, and then got into wireless with the Emerald Ray Mining Machinery Company and the Airero Induction Reduction Company, and placed orders for a unit of 25,000 metric tons' capacity daily. He then arranged with the Wireless Power of America to set an extra switchboard panel in their power house to transmit 50,000 kw. daily to latitude ——, longitude ——, Terre del Fuego. With these essential details off his mind he departed for another game of cueless billiards at his club.

Professor Relativity got into communication with F. Wallingcrude Blackstone the next morning, and reported that the element had unique possibilities in that it appeared to be the unknown base out of which the individual elements were constructed. By a simple transmutation it could be converted into any metal. At the limitless possibilities, F. Wallingcrude gave a long low whistle which degenerated into a chuckle. "At last I have it," he muttered to himself. Professor Relativity continued with his report by saying: "Unfortunately I have to report that the transmutation will be very costly, prohibitive, in fact, for all metals with an atomic number between 30 and 80. I have made cost sheets for all the metals, and, comparing these with the quotations in the *Engineering and Mining Journal*, have arrived at the limits I mention. While this is disappointing, the range is such as to cover copper, lead, and zinc and a few other metals."

F. Wallingcrude slid a peculiar board from one side of his desk and touched a point on a intricate diagram thereon. Almost at once a voice was heard to say: "The latest statistical information as compiled by the *Engineering and Mining Journal* is to the effect that there is a considerable shortage in many of the base metals and that prices have been steadily advancing during the past seven decades. In fact, there is an impending shortage and little potential supply." With a satisfied smile the board was slid back to place and F. Wallingcrude turned to another set of reports.

Two weeks later F. Wallingcrude was dreaming away on other mighty projects when a voice out of the air said: "This is J. Montmorency Findit. I have to report that the plant has been installed and the first shipment will be made today. The Emerald Ray mining machine is eating into the deposit, disintegrating it into a fine powder of 60 mesh. The reduction plant receives this in a blast of air and makes a 99.8 per cent recovery. The whole plant is working sweetly and is automatic with the exception of five men, who are required to load concentrates into high altitude planes, of which a fleet has been organized. Professor Relativity has constructed an entirely automatic refining plant and is ready to receive the first shipment. Marketing of our product has already been arranged for by the Base Metal Exchange."

F. Wallingcrude Blackstone sat in deep thought for awhile, and then he made a memorandum to the effect that on the next day the directors of the new company and himself were to meet for the first time and that he would personally report the progress that had been made and which promised a huge success both financially and technically.

It was a happy group that gathered at a well-served table in the aërial gardens of a well-known New York hotel of the period. J. Wallingcrude Blackstone was at one end of the table, Professor Relativity at the other, and between were the directors and J. Montmorency Findit. At the last minute a cautious stockholder, who had dropped into J. Wallingcrude's office while he was in the midst of inviting the directors to the dinner and had been included in the invitations, dropped in and took his place. He was a meek-appearing person and scarcely filled his chair. In fact, his smooth-shaved chin just cleared the snowy white cloth.

We will not weary you with an account of the animated discussion that ensued at the completion of the meal, nor with the intricate explanations of the action of the new element by Professor Relativity, nor of the technical descriptions of the Emerald Ray mining machine, enthusiastically pictured by Findit, but it is worth recording that at the very end our meek little stockholder who had not uttered a word throughout the meeting, said:

"Professor Relativity, I would like to ask you a question. Could you have produced these base metals by the transmutations you have just described without the use of the new element?" "Oh, yes," said the professor. "We have long been in possession of the methods by which this can be done." "Well, why did the company go down and open up that mine then," said the inquisitive stockholder.

Impending Promotion Methods

The professor waved his hand as he turned to F. Wallingcrude nonchalantly, saying: "There are lots of things we can do, but we always rely upon men like F. Wallingcrude Blackstone to start them. The mine was only an accident. It served, however, a useful purpose in making possible the capitalization of the enterprise. If you will take the trouble to consult the Register of Mining History in the Bureau of Industry you will find that shortly after the Minerals Separation period, about a hundred years ago, there was established, as a principle of mining-company flotation, the rule that a mineral deposit must be developed and the quantity and grade of the orebody pretty conclusively determined before a company could be formed. Even our friend Wallingcrude, skilled though he is in financing large projects, could not have formed a company, in this instance, without filing an affidavit giving the critical facts of the case. Fortunately for us, the development of scientific prospecting apparatus enabled us to get these important data in an acceptable way. We can now shut down our mine but continue our oprations and maintain our enviable position in the metal markets."

Western Hearings of Minerals Separation Case by Federal Trade Commission

BY GILBERT H. MONTAGUE*
Written for *Engineering and Mining Journal*

THE vigorous prosecution of Minerals Separation, Ltd., for violation of the Clayton Act and the Federal Trade Commission Act, by the Federal Trade Commission, was resumed early in the summer and was continued with hearings in San Francisco, Salt Lake City, and Denver until the commission and counsel adjourned for the vacation season. Thirty-one witnesses were called by the commission's counsel, Hon. Claude R. Porter and Hon. Gaylord R. Hawkins. Among the witnesses were: Edward H. Nutter, chief engineer of Minerals Separation North American Corporation; Theodore J. Hoover, who was formerly with Minerals Separation, Ltd., and T. A. Rickard, editor of *Mining and Scientific Press*.

The Government's case was recorded with many interruptions, objections, exceptions, and arguments on the part of the Minerals Separation counsel, Alfred A. Cook, of New York. One such protest covered nine pages of the record, and was tersely characterized by the chief counsel of the commission as "camouflage." The strength of the Government's case is indicated by Mr. Cook's admission when he said, "This matter seems to be developing into a matter of considerable importance."

The royalty rates of Minerals Separation were under fire by the Government throughout the testimony of over a dozen witnesses. Counsel for Minerals Separation stated: "We have a right to deal with whomsoever we please, on such terms and conditions as we please, irrespective of the Clayton Act." One licensee, who testified that his relations with Minerals Separation had been pleasant, said, "The royalty is too high. . . . We regard it as entirely too high. . . It becomes a very burdensome charge."

Mr. Hoover, in giving his judgment on the subject, based on his extensive experience and knowledge, said, "A careful inspection of royalties charged by the flotation process, compared with the royalties charged elsewhere in metallurgical industry, convinces me they are excessive."

John V. Quigley, a Minerals Separation field man, testified, "I tried to get them to take up the proposition of securing a license with Minerals Separation company, and they told me that it would be practically impossible to pay royalty of two-fifths of a cent a pound at the present price."

A mine operator, who negotiated with Minerals Separation regarding a license, but refused when the terms were disclosed, said that "under the schedule of royalties which had theretofore been sent to him by Minerals Separation it would work out as a very great injustice to his company's particular conditions, inasmuch as it indicated a royalty of between four and five dollars per ton of ore. Such a royalty he said, was exorbitant beyond all question.

An official of a Minerals Separation licensee narrated in detail the story of "a highly dishonorable" attempt by Minerals Separation to increase the royalty rate from the agreed figure of 3½ or 4c. a ton to 6c. and later to 12c. To make its demand for a 25c. royalty effective, Minerals Separation stopped in transit necessary machinery which had been partially paid for by its client. "Mr. Nutter said that he regretted the situation had arisen, but that the London officials had refused to permit the 6c. agreement to be gone through with," said the witness. "We had already stood for an advance of 50 per cent approximately, in the royalty charge, and it was altogether unfair and improper to try and increase it 200 per cent, or up to 12c. . . . We considered it a gouge, a hold-up on the part of his company. . . . We replevined the machinery . . . refused to sign the agreement and finally they agreed to the 6c. license." Correspondence which fully substantiated the oral narrative of this attempted "hold-up" was offered in evidence.

The facts on which Minerals Separation based its charges of infringement against scores of mining companies were shown by the testimony to have been vague and indefinite. E. H. Nutter, chief engineer of Minerals Separation North American Corporation, testified: "I am not familiar with the interlocking of these different patents. . . . To tell the truth, I am not very familiar with them. . . I believe that our process patents cover, broadly, the commercial application of flotation, and where a commercial operation is going on, using flotation, that is presumptive evidence to my mind that they are infringing some one of our patents . . . the general theory being that they could not be using flotation in a commercial way without coming under some one of our patents."

Mr. Nutter told of visits to mills by his field men, and voiced the opinion that only infringers would refuse to permit the Minerals Separation representative's inspection of their plants. "They will say," said Mr. Nutter, "We are using flotation, perhaps, but we don't want you to go through! Well, that is a confession to our mind that they are infringing us there, if they don't want us to go through to see what they are doing."

"Every user of flotation not a Minerals Separation licensee is on our infringement list," said Mr. Nutter. Companies on this list were notified of their "infringement" by the Minerals Separation patent attorney, no mention being made by him as to how they were infringing or as to what specific patent was involved. Mr. Nutter first said, with regard to this infringement list of 250 or 300 names, "My opinion is that they are all infringers." Later he said: "I don't think there are that many actually operating the infringements of our patents. . . . I should think something less than one hundred, perhaps—perhaps more than that, but not nearly so many as we have on our preliminary list." From these admissions of the chief engineer of Minerals Separation it would appear that two-thirds of the notices of infringement sent out by their patent attorney were addressed to those who even Minerals Separation admits were not infringing.

In the light of this admission, Mr. Nutter's further testimony is of considerable interest. "In making the settlements," inquired the commission's counsel, "haven't you taken up with these infringers the ques-

*This summary gives the case from the point of view of the American Mining Congress, for which Mr. Montague is counsel.—EDITOR.

tion as to what constitutes infringement, and how they were infringing?"

"I don't recollect" replied Mr. Nutter, "that that has ever come up. I think it has always been taken for granted by both sides that they were infringers."

The commission's counsel brought out numerous instances in which alleged infringers, as a result of notice mailed by Minerals Separation patent attorney threatening a lawsuit, settled with Minerals Separation, although Mr. Nutter, the chief engineer of Minerals Separation, was not able to point out their infringement.

Of one operator Mr. Nutter said, "He was sinning against the law of using flotation illegally."

"How was he using flotation illegally?" asked the commission's counsel.

"I don't know," replied Mr. Nutter; "I don't recall making any investigation at all. I think his statement was the result of the letter which Mr. Henry D. Williams (Minerals Separation patent attorney) sent around generally to those on our list of infringers."

One mine operator, who testified that he had experimented with oil flotation, but had never treated any tonnage or used it on a commercial basis, produced a letter from Minerals Separation's patent attorney, in which the latter stated: "You are hereby notified of infringement of my clients' patents . . . you are thereby directed to send me a full statement of your infringing operations in accordance with the interrogatories inclosed herewith, in default whereof I am directed to commence suit against you for an injunction, profits, and damages, including a preliminary injunction at the commencement of the suit to immediately stop your infringing operations." Referring to this letter, Minerals Separation counsel said, "I think there are a great many similar to it."

Another operator told of a visit by a Minerals Separation field man, who, he said, "got into the subject of our infringing immediately." "Did he say you were infringing?" asked the commission's counsel. "Yes," was the reply. "Now, in what particular did he say you were infringing their patents?" asked the counsel. "Didn't go into particulars," said the operator. "Did he point out in any way whatever the manner in which you were infringing Minerals Separation patents?" continued the counsel. "No, merely by using flotation," replied the operator. Similar experiences were recounted by other operators.

"There are a number of the staff men," said Mr. Nutter, "who are sometimes, or have been in the past, field men, who are now chiefly engaged in litigation work in New York." This statement was confirmed by Chester B. Allen, secretary of North American Corporation, who added, "In the intervals when litigation is slack—a time that occurs very rarely—we send them out into the field."

A number of companies were segregated by Mr. Allen into the "litigation group." A letter from John Ballot, president of Minerals Separation North American Corporation, referred to "visits to important infringers, outside of the litigation group or combine."

In addition to the threats of lawsuits sent broadcast by its patent counsel, Minerals Separation suggested unpleasant eventualities through its field men. "I endeavored," testified one of the field men "to get them to come into the fold and take out a license with the Minerals Separation company, to avoid any disagreeable business that might follow up."

"What has deterred you from reopening your mill?" asked the commission's counsel of a mine operator on the stand. "Well, the price of copper, for one thing," was the answer, "and the fear of litigation." "Litigation by whom?" "By the Minerals Separation." To ascertain which of the two reasons given—the price of copper or the fear of Minerals Separation litigation—was the more cogent to the operator, the commission's counsel asked: "If you had not fear of litigation by the Minerals Separation company, and with the price of copper as it is now, would you reopen your mill or not?" "Very probably we would," he stated.

Another operator, who had paid Minerals Separation $35,000 in settlement of alleged infringement, was frank in giving his reason for so doing. "The fear of getting into a row with Minerals Separation was the only consideration in mind. . . . After talking the matter over with my counsel we both agreed that we could not get into a fight with Minerals Separation. It was not because we felt Minerals Separation was in the right—purely and simply because the cost of getting into a fight was wholly beyond what we could consider. It was purely a matter of expediency. . . . It seemed as though Minerals Separation were getting the best of it, but we felt perfectly sure they were not entitled to it."

Important and authoritative testimony was given by Theodore J. Hoover, now head of the School of Mines at Stanford University, but from 1906 to 1910 connected with Minerals Separation, and well known as the author of the first book published on flotation. Mr. Hoover visited Australia in 1907. "I found on my arrival," said Mr. Hoover, "four distinct flotation processes in operation. One known at that time as the Potter-Delprat; one known as the De Bavay process, Minerals Separation process is the third, and the Elmore vacuum process is the fourth." All these processes, stated Mr. Hoover, were being used on a large commercial and profitable scale. "During the year 1908 the Potter-Delprat process produced 65,000 tons of zinc concentrates," he said. "The De Bavay process produced 23,000 tons of zinc concentrates, and the Elmore process produced 50,000 tons." The total production of these processes was 138,000 tons, which was 11,000 tons more than the two Minerals Separation plants produced.

Regarding the present status of these operations, Mr. Hoover said, "the Potter-Delprat plant, at the time of the closing down by the recent strike of Broken Hill, was in good working order, working on as large a scale as it ever had in any of its period. The De Bavay plant had grown to be the largest plant in Australia. . . . I cannot say definitely with regard to the Elmore process."

The commission's counsel asked "whether or not each of these processes is capable of use in the competitive field generally?" "Certainly," responded Mr. Hoover, "It is not likely that any one or two or three or four of these processes would be equally adapted to the same ore."

"Do you know whether or not any of these processes that you have described have been acquired by Minerals Separation?" "Yes," Mr. Hoover replied, "I cannot fix the time, but some time, I should say, between 1911 and 1914, we were quite cognizant of a combination of the patents involved under the names of Potter-Delprat, De Bavay, and the long list of so-called Minerals Separation patents."

Mr. Hoover produced, and the commission's counsel

put in evidence, a treatise by H. L. Sulman and H. P. Picard, entitled "The Theory of Concentration Processes Involving Surface Tension," which was given to Mr. Hoover by Mr. Sulman in 1906 or 1907. The authors were at that time, and are still, consulting engineers of Minerals Separation, Ltd., and patentees of several patents now owned by Minerals Separation.

According to the chief engineer of Minerals Separation, the process of concentrating ores by means of flotation, wherein the elements are agitation, aëration, and froth formation by the use of soluble and certain other reagents, is what Minerals Separation consider their process. The statements of Mr. Sulman and Mr. Picard, two Minerals Separation engineers, whose connection with the company and with flotation matters antedates that of Mr. Nutter, form an interesting comparison, as they were not intended for publication.

Mr. Hoover pointed out statements in the treatise regarding the use of a thick coherent froth in the Potter-Delprat, the Froment process, the Cattermole-Sulman-Picard process and the Elmore vacuum process. He called attention to statements concerning the use of air or gas as the exclusive lifting force in all these processes. He referred to statements regarding the use of "a small quantity of oil, so minute as to form an infinitesimal film coating, which, to all intents and purposes, became a part and parcel of the particle in the mineral," in all of these different processes. These statements Mr. Hoover characterized as being different from the present statements of the inventors.

Mr. Hoover was asked whether his attention had been called at any time to any statements of the respondents in this case different than the statements that he pointed out to the commissioner as appearing in the treatise by Sulman and Picard? "Yes," he replied, "the first one that occurs to my mind was the statement made in this court two days ago, I think, by Mr. Nutter. . . . the general statement that anyone using the flotation process (without a license) was an infringer. . . . I think all the statements of counsel and witnesses for the Minerals Separation in the various lawsuits would be classified under that same heading, as being inconsistent with the statement of fact in the book."

Mr. Hoover told how, as a young engineer, he had agreed that after, as well as during, his connection with the company, he would maintain secrecy with regard to his work with Minerals Separation. "One of the chiefest of my own derelictions," said Mr. Hoover, "was the signing of this iniquitous contract. . . . The carrying out of that contract has been a constant burden, has been a handicap in my professional career of the most pronounced nature. It has, on occasions, caused me great mental distress, and great financial loss."

Mr. Hoover said this imposition of secrecy was carried out to the limit of human endurance and was only disregarded by him when he concluded that otherwise he became an accessory to whatever misconduct he conceived the Minerals Separation were engaged in. It was as a result of this decision that Mr. Hoover made public the treatise of Sulman & Picard, which had been withheld from the public by Minerals Separation.

Minerals Separation, according to Mr. Hoover, objected strongly to the publication of his book (on flotation), and submitted "rather ample suggestions." They also objected to the publication of articles prepared by him, both before and after his connection with the company.

"The progress of the art in this country," said Mr. Rickard, "has been retarded by the attempt to impose secrecy upon the experiments and the operations of those using the process by means, of course, of those license agreements and other methods, but more particularly by the effort to tie individual metallurgists to the chariot wheels of this patent-exploiting agency."

Thomas Varley, superintendent of the Salt Lake City experiment station of the U. S. Bureau of Mines, was asked: "From all your investigations, as an official of the U. S. Bureau of Mines, can you tell whether the effect of the attitude of Minerals Separation company and its license agreement has been to increase or retard the saving of mineral waste by the flotation process?" "Their attitude," responded Mr. Varley, "has been to retard the development of the flotation art."

Another metallurgist of the Bureau of Mines, Will H. Coghill, was asked: "Would you say, having in mind the license agreement that you say you have read, the attitude that you have described in the press on the part of Minerals Separation company—would you say as a student, an observer and an expert on flotation, that Minerals Separation company's efforts have been to retard the development of the art of flotation, or have they been to assist in its development?" "Tending more to retard than to accelerate," was the answer.

"I might add that it is our belief," said the chief engineer of North American Corporation, "that our technical knowledge of the use of flotation alone, if there were not any patent at all, is worth more than the royalty to our licensees—just our knowledge of the technique."

Testimony of licensees and others has already been quoted with regard to the royalty rates charged. It remains to report what was said by some licensees concerning the value of the respondents' technical knowledge of the flotation process.

"Were you satisfied," asked the prosecutor of one Minerals Separation licensee, "with the results that you were obtaining under their process?" "Oh, no," was the answer. "Mr. Nutter sent a representative at the time the plant was installed, and the results hardly came up to expectations, and since then we would send down ore to Mr. Nutter, and they would make experiments. . . . One of their suggestions, I think, was beneficial; but aside from that I don't think there was much that helped." After stating that a point was reached where Minerals Separation apparently could be of no further help to them, the witness told of consulting an outside metallurgist, acting on his suggestions, and raising their recovery 16 per cent above that attained with the assistance of Minerals Separation's technical knowledge.

A letter from Mr. Nutter to another licensee was quoted, in which Mr. Nutter said: "I think I should say from the tests we have so far made it can be assumed that from the ores amenable to flotation a little bit better than 90 per cent can be expected in a concentrate."

"After you started the mill," the commission's counsel asked an operator, "what recoveries did you make?" "We made very poor recoveries," was the reply. "In July, we made 54 per cent recovery; in August, 62 per cent; in September, 60 per cent." Minerals Separation was then asked for assistance, the operator stated. "We made some changes at his suggestion," he continued, "and it looked promising for a few days, but it did not last. . . . I wrote Mr.

Nutter very earnestly that we were in a very bad way, and I felt that they were largely responsible, and that they should accept the responsibility of getting us on our feet. . . . I was discouraged over their failure to help us, and in casting about for chances for relief I wrote to Mr. Will H. Coghill, of the Bureau of Mines. . . . The chief objection of Minerals Separation company was that we were not grinding our ore fine enough. . . . Mr. Coghill told us we were using improper oils and we were grinding our ore too fine." Following Mr. Coghill's instructions, the ore was ground coarse, and the oils were changed, stated the witness. "In October," he continued, "the per cent of recovery was 67; in November 80; in December 82.7; in January 78; in February 73.6; in March 74.1. I might say in regard to the decreasing recovery in the last two or three months that we were approaching the surface with a large stope, and found a great deal of oxidized material."

After this testimony, counsel for Minerals Separation stated, "I would just as leave concede that Mr. Coghill went there and that his operations were better than ours."

The Minerals Separation license agreement was again under fire by the Government. An operator who negotiated with Minerals Separation for a license, balked at the royalty and the license agreement. "The royalty," he said, "seemed prohibitive, and to give a warranty deed on the brains of our organization for any improvement we might discover seemed ridiculous."

Another operator refused to disclose his secret processes to Minerals Separation. "There were certain processes or steps in our work that I am not willing to advise anyone regarding; there were certain fixtures and various chemical treatments that we had discovered ourselves; I said, 'As to the various constituents we are using in addition to oil, that is where I draw the line,' because I thought that was our own private property that cost us a lot of money to find out."

Mr. Varley, of the Bureau of Mines, testified that one company had not installed the flotation process, due to rather complicated conditions in the metallurgical practice, that is in the art of flotation, and due to the fact that the contracts which were presented by Minerals Separation company were not attractive. Of another company he said, "My investigation showed that the reason for not installing the system was due to the cost, and the unattractive license presented by the Minerals Separation."

Another witness, who declined a license, said, "I told him (the Minerals Separation representative) I thought the royalties were excessive, and that I also very seriously objected to the clauses which provided that we had to release all inventions or improvements to the Minerals Separation company."

A manufacturer of flotation machinery told of one mine operator who stated that he would not purchase a machine as long as the Minerals Separation company offered such impossible contracts. "He would not put in a flotation machine," said the witness, "until the Minerals Separation company permitted people to operate under their contracts in such a form that they could make money without paying exorbitant rates, and without the all-around disagreeable methods of doing business with them."

"I have always objected," said another witness, "to some of the clauses of their contract—the clause requiring employees to sign contracts to report their improvements, etc., to the Minerals Separation."

"In regard to the use of Minerals Separation and Callow machines in conjunction," said Mr. Nutter in a letter to a prospective licensee, "I think it rather likely that Minerals Separation would not look with favor on this, as the Minerals Separation alone can be depended upon to give a maximum result."

"I instilled some doubt in his mind," reported a Minerals Separation field man regarding his interview with a prospective licensee, "that the Hyde machine which he was installing in one of his mills would do satisfactory work." Mr. Nutter supplemented this by saying, "I think possibly they (Minerals Separation field men) had rather a poor opinion of it (the Hyde machine) . . . I have an idea that there are two machines that Mr. Hyde has gotten up. . . . . One was a pretty close imitation of what we call our standard machine, and another was a pretty close imitation of the so-called Callow machine. . . . I think some engineer told me it was not much good."

A Minerals Separation licensee testified that their consulting engineers had recommended the installation of Janney flotation equipment, but, he said, "Mr. Nutter said at that time they were not encouraging the installation of the Janney machines, and it would be quite necessary for me to secure the written consent of the company to make the installation. . . . He doubted whether it would be granted; hardly thought it would. . . . In reply to my question as to what might happen, he thought our license might possibly be revoked if we went ahead and made this installation without the consent of the company." Minerals Separation machines were accordingly installed at the company's plant.

Negotiations were described between the Stimpson Equipment Co., which sells the Janney machine, and Minerals Separation, with a view to effecting an agreement for their sale to Minerals Separation licensees. The terms stipulated by Mr. Nutter were objected to by the Stimpson company. For the privilege of selling their patented machine to Minerals Separation licensees, Minerals Separation asked 25 per cent of the gross profits and the sole license for the machine. "The objections we raised to it," said the witness for the Stimpson company, "were that we thought 25 per cent of the gross profits was too much, that we did not see why we should have to let Minerals Separation become sole licensee of the Janney machines." No contract resulted from these negotiations.

The comparative test of the Janney and the Minerals Separation machines at the Ohio Copper Co.'s plant, results of which were circulated by Minerals Separation as demonstrating the superiority of their machine, was delved into by the prosecutor. The witness, who was general manager of the Ohio Copper Co. at the time of this test, testified that the Janney machine used was a cast-iron affair, bought for experimental purposes, and that at the time of the test with the Minerals Separation machine it was badly eaten out and corroded. The Minerals Separation machine, on the other hand, was new, and of their standard type of construction. "My conclusion," said the witness, "was that the Janney machine did slightly better metallurgical work than the other."

The hearings are to be resumed, it is understood, at the office of the Federal Trade Commission in Washington in the late fall.

Mining Engineers of Note

William Young Westervelt

IN THE ever-changing order of things today, it is refreshing to find consistency—consistency of purpose, of interest and of endeavor. After a quarter of a century the Ducktown Basin of Tennessee remains the dominating interest of William Young Westervelt.

Graduating from the Columbia School of Mines in 1894, Mr. Westervelt took his first job, that of chemist and surveyor, with the Ducktown Sulphur, Copper & Iron Co., Ltd. Later he became the company's engineer, then superintendent, and in 1898, when he entered consulting practice in New York City, he was retained as consulting engineer and was responsible for the development of the Ducktown company's mines. The same thoroughness which characterized his success in this enterprise has been evident in other undertakings. In 1905 Mr. Westervelt, as consulting engineer for the Anglo-American Copper Co. of London, directed and developed the Ray property to the point of successful sale to the present owners, the Ray Consolidated Copper Co. It is interesting to note in this connection that it was due to Mr. Westervelt's advice that the system of horizontal drifting in exploratory work was replaced by vertical drilling in that district, where the flat-lying orebodies lend themselves favorably to the latter method. In 1909, as consulting engineer to the Grasselli Chemical Co., Mr. Westervelt developed and organized the New Market zinc property at New Market, Tenn., and also valued for the first bond issue the Butte & Superior property at Butte, Mont. In 1910 he examined the copper mines of the New Lymni, Ltd., on the Island of Cyprus, in the Mediterranean Sea. As consulting engineer for the Wilkes-Barre Dredging Co. he organized the gold properties of that company in Folsum County, Cal., during 1914, and in 1916 he prepared a report on the pyrites resources of the world.

WILLIAM YOUNG WESTERVELT

It was the consideration of these signal accomplishments that decided the American Institute of Mining and Metallurgical Engineers and the Mining and Metallurgical Society of America in their designation of Mr. Westervelt as a member of the War Minerals Committee at Washington in 1917. As chairman of that committee he directed the preparation of the War Minerals Bill, the utility of which is generally known, and although the ending of the war terminated the necessity for passage of the bill and the further need for the committee, there remains no doubt as to the value of the work which was done by Mr. Westervelt and his associates.

Recently Mr. Westervelt organized the Copper Pyrites Corporation, of which he is president, in the Ducktown mining district of Tennessee. He is at present giving most of his attention to the development of the iron and sulphur resources of the Ducktown Basin, and it is safe to predict that the next few years will see great strides made in the treatment processes now being used in that district. In addition to his membership in the American Institute of Mining and Metallurgical Engineers and the Mining and Metallurgical Society of America, of which he is vice-president, Mr. Westervelt also is a member of the American Electrochemical Society and the American Mining Congress. He holds fellowships in the following: American Geographical Society, Royal Society of Arts (London), and the North British Academy of Arts. Although Mr. Westervelt's contributions to technical publications have not been numerous they make up in quality what they lack in quantity. His well-prepared chapter in Robert Peele's "Mining Engineers' Handbook," "Mine Examinations, Valuations and Reports," is exceptional in its clearness, and the examples given to illustrate various points leave no doubt as to the author's meaning and his complete familiarity with the subject. He has also written several valuable papers on shaft sinking and similar subjects.

Mr. Westervelt, during a recent interview, assured a representative of the *Engineering and Mining Journal* that he had met with no exciting adventures during his career, that his life had been devoid of "thrillers," and he had led the existence of an ordinary, typical mining engineer. Some of this may be true, but to the last statement we take exception. No "ordinary" engineer could fill the enviable record Mr. Westervelt has made. His familiarity with organization, thoroughness of execution, urbanity, and a keen interest in the affairs of engineering and engineers make William Young Westervelt an outstanding figure in his profession.

By The Way*

Tipped With Iron

Iron nails are acceptable in Soviet Russia as tips for courtesy or service, according to an Associated Press dispatch from Germany. Members of the German Economic Mission to Russia are said to have advised Herr Crispien to fill his pockets with nails on setting out on a journey through that country. One immediately thinks of all the little tips that could be taken from father Hindenburg's statue if it were still standing. But there is nothing new in the use of iron for currency. The ancient Greeks so used it, and the student doubtless remembers how one of them had to hitch up a yoke of oxen to carry $20 or so with him when he went traveling. If iron is so valuable in Russia, the junk man must be king, or would be, were it not for the Soviets. With equipment rapidly being reduced to junk from breakdowns and lack of spare parts, it seems as if a reel of baling wire would carry a traveler further than a pocketful of nails. Indeed, under the existing conditions it looks as if there might be several good opportunities in various plants in Soviet Russia for master mechanics having experience in making quick repairs solely with baling wire. Joplin papers please copy.

Possibilities of Tin

Henry Ford is said to have a "synthetic metal" that is to replace vanadium in construction of automobile chassis. According to reports, however, Mr. Ford refuses to confirm or deny the story. Is it possible that after all a synthetic process for making tin has been discovered? If it be true that tin can be successfully substituted for vanadium in making automobile parts, then the same metal can also be substituted for vanadium in making the countless other things for which vanadium steel is employed, all of which, if true, may keep vanadium producers awake nights. Mr. Ford has already invested in iron mines in northern Michigan. If our surmise about tin be true, we shall not be surprised at all if, by chance, we hear that Mr. Ford is seeking to acquire tin mines in the Black Hills of South Dakota, a locality that has already produced an infinitesimal part of the world's tin, with the production steadily becoming more and more infinitesimal as the district grows older. We had hopes a while back that South Dakota's tin output in 1920 would show an increase that would augur well for the future, but these hopes were dashed when a notorious non-producer almost produced but didn't. Still we have faith in Mr. Ford's productive genius, especially where tin is concerned. We are certain that if Mr. Ford undertakes to mine tin in the Black Hills or any other hills he will mine it, if he has to put it there first himself. If tin should come to be mined on a large scale in the Black Hills, and if Mr. Ford should invest in tin properties there, Hill City or some other mountain city there might eventually be chosen for the site of a great automobile plant, if there really is anything to this synthetic tin that we started to talk about. But we don't believe it.

A Metropolitan Gold Mine

Why journey from New York to see a gold mine, when all one has to do is step into the office of Glaus Consolidated, Inc., on Broadway, drop into an easy chair and by the aid of the magic carpet of the movies be transported to the Golden Chief mine, which is in "Yavapia" County, in the heart of the richest mining district in Arizona? "Here you can see the land surrounding the Golden Chief (to quote from the company's prospectus), including the ranch, orchards and the mine itself. See the ore dumps, the railroad, and supply depot at Turkey Creek. Then travel along to Humboldt, where the mammoth smelters are located. See how the ore is handled from the time it leaves the mine until it is loaded, in ingot form, into cars ready for shipment. It's an interesting, educational picture, which you will enjoy. It will do more than words can to vividly portray this eldorado to you." The company's property consists of 240 acres. To quote further:

> The ore is very favorable in having a very rich deposit of Silica and also having the formation of a granite schist with a quartz base. Golden Chief is being actively operated right now. In fact a 100-ft. tunnel has been installed and we are about to crosscut on the vein, and by diamond drilling will eventually come to our rich ore deposits.

There is no serpent in this Garden of Eden. The workers are happy and contented. Welfare work is unnecessary. Comfortable homes, a fruit orchard, truck gardens and a ranch, a half-mile away, all will help keep down the labor turnover. For the thirsty there is an abundant supply of good—yes, water, from Dripping Springs, another camp luxury, which the company's men are not denied. The company, indeed, has a gold mine right in its own office.

From Our Own Sermon Barrel

How hard it is for a rich man to enter Heaven! The acquisition of wealth is often but a stepping stone to irreligion. No sooner do some amass a few ducats than they stick up their noses at their household gods and all the other deities, and go straight to the devil. Nothing is sacred to them any longer. We had supposed that there was one law so sacred, so sacrosanct, that none knowingly would dare flout it, namely, the law of supply and demand, the law which economists, editors, and even plutocrats have always spoken of with bated breath, as though it had a name that might not be uttered. This is the law that must be allowed to work without interference, even though it kill in the act of working, just as the car of the Juggernaut crushes the devotees in worship before it as it passes on. What tears have been shed at its violation by the Food Control Act and other nefarious acts during the war! Yet recently one of those in high places, President Breitmeyer, of the Diamond Syndicate of London, has forsaken the faith. He states that diamonds will not decline in price, no matter what happens to other commodities. As far as diamonds are concerned, President Breitmeyer's syndicate has the world by the tail, for it controls 90 per cent of the diamond industry. Let the law of supply and demand act, we beseech you, Mr. Breitmeyer, even though diamonds are one of the necessities of life.

---

*Editorial Notes

This page is not to be taken seriously. If our attempts at occasional humor are not detected as such, we at least wish to disclaim all responsibility. Our chronicling in a recent issue of the new German scheme for extracting gold from sea water has brought us in an honest offer to raise money for subscriptions. We have thought of labeling each of our whimsical paragraphs "Joke," but have concluded that perhaps a general notice will serve.

CONSULTATION

Liquid-Oxygen Explosives

"The principle upon which liquid oxygen is employed as an explosive is not quite clear to me—is it the physical property of the material that is relied upon to act? Is the explosive used to any extent commercially in this country? Where can I get further information?"

The use of liquid oxygen as an explosive is not new, as twenty-three years ago experiments showed that this material could be used as a powerful explosive. The principles upon which the explosive nature of liquid oxygen depend are both chemical and physical, but mainly chemical. Liquid oxygen alone is not utilized but is mixed with some carbonaceous material and the powerfully explosive mixture ignited. The rapidity with which oxygen will unite with finely divided carbon or carbonaceous material when intimately mixed with it is sufficient to generate great explosive force. The more condensed the oxygen (a greater amount for the same volume), the more violent is the explosion. Thus liquid oxygen, being very condensed and intensely cold, is employed. Liquid air has also been used, but as its explosive power depends upon the oxygen content, it is not as efficient as liquid oxygen.

The great drawbacks to using liquid oxygen as an explosive are the necessity of having an installation of a plant to liquefy the air, and the fact that ignition of the charge must take place within a very few minutes after setting it. On the other hand, this type of explosive is less dangerous to handle than dynamite or black powder, though care must be taken not to be "burned" by the exceedingly cold liquid. Misfires are not dangerous, as the unexploded oxygen evaporates in a relatively short time. Other advantages are claimed for the use of liquid oxygen, such as lower costs per unit of material blasted and elimination of the storage danger common to other explosives. The advantages claimed for the use of liquid oxygen explosives appear attractive.

Liquid oxygen has not been used commercially in this country so far as we are aware, and any introduction will have to overcome the familiarity of the miner with the present-day practice of using dynamite and black powder. The U. S. Bureau of Mines experimented with the material and reported upon the development of this class of explosives during the stress of the war, and has issued a Technical Paper, 243, upon the subject.

Uses and Production of Selenium

"Will you kindly tell me where and how much selenium is obtained in the United States, and what its chief uses are?"

The production of selenium in the United States is almost entirely confined to the electrolytic copper refineries of the country, which recover the metal from the sludge as a byproduct. In 1919, according to the U. S. Geological Survey, 60,025 lb. of selenium, valued at $125,966, was recovered in this fashion, compared with 103,694 lb., valued at $206,540, in 1918, and 39,630 lb., valued at $70,000, in 1917, indicating a high'y variable production for the past three years.

The demand for the metal is slight. It is used chiefly in the glass industry, in photographic chemistry, and for medicinal purposes. The peculiar electrical property which selenium possesses of having a varying conductivity, according to the intensity of light to which it is subjected, has led to its application in electrical work. Under the influence of light its conductivity may be 500 times more than its "dark" conductivity. It has been recently reported that as the result of research work at the University of Wisconsin by Prof. Lenher another property of selenium has been discovered which is likely to increase the demand for the metal. The discovery was made that selenium oxychloride acts as a strong solvent on certain organic substances. The unsaturated hydrocarbons such as acetylene, benzine, and toluene, dissolve readily, whereas the paraffine hydrocarbons are unaffected (vaseline, paraffine wax, gasoline). Pure rubber, asphalt, bitumen, and the casein glue used in aëroplane construction dissolve easily in selenium oxychloride, and it can be used in coal analysis to extract the bituminous material in soft coal.

The present price of selenium is between $2 and $2.25 per lb., practically the same price as in 1918 and 1919.

The Market for Quartz

"I see an advertisement in *Engineering and Mining Journal* for quartz rock at from $5 to $17.50 per ton, according to size. Will you kindly advise me what this quartz is used for, and if there is a ready market for any or all quartz that I may be able to produce. I am working on a copper mine [North Carolina] that has considerable quartz, which I should like to place on the market if the price justifies my doing so."

The quartz quotations as given by *Engineering and Mining Journal* refer to various grades of the material as used for different purposes. The largest size, "fist to head," which designates that the pieces of quartz vary from the size of a fist to that of a head, is used as a filler in the acid towers employed in chemical manufacture; the larger sizes of quartz are also used as fluxes in copper smelting. Crushed and graded to various sizes, quartz is used in making sandpaper and sand belts, in sand-blast apparatus for "frosting" glass, and for numerous other purposes. The finely ground quartz may be used in filters, by dentists in cleansing the teeth, and in tooth powders.

The quartz that is mined in North Carolina is used chiefly in packing acid towers, although part of it finds application in the manufacture of acid-proof cements. It would thus appear that the best market for material mined in that state is its employment in the chemical manufacturing industry.

Method of Marketing South African Gold

In the Oct. 16 issue of *Engineering and Mining Journal* the last sentence of the article "Method of Marketing South African Gold," should have read " . . . about 117*s.* is now being received for the *fine* ounce"—a *standard* ounce is ½ a fine ounce. Of course, as pointed out in the first paragraph, the payment for gold is made in depreciated paper currency, in contrast to pre-war payments with currency on a par with gold.

HANDY KNOWLEDGE

Patching the Roofs of Copper Reverberatory Furnaces

BY GEORGE J. YOUNG
Written for *Engineering and Mining Journal*

Patching reverberatory roofs may involve the replacement of a comparatively short longitudinal length up to as great a length as 35 ft., dependent on local failure or the general weakening of an entire section of the reverberatory. Where a reverberatory is to be shut down, the construction, whether of an entire roof section or a part only, does not involve any features particularly different from those used in its initial construction. If the furnace is in use and the requirement is put up to the mason to construct the patch in the most expeditious manner possible, considerable opportunity is offered for skill in devising methods.

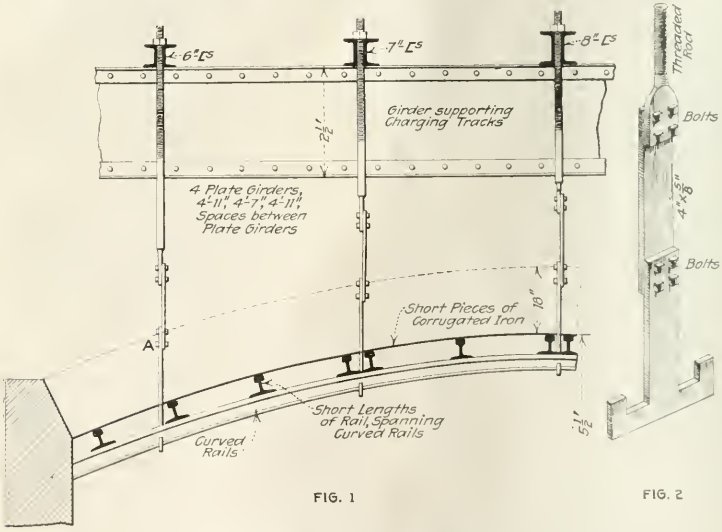


FIG. 1. METHOD OF SUPPORTING TEMPORARY BED FOR BRICKWORK
FIG. 2. SKETCH OF HANGER

One method is to fill the furnace space with calcine, flue dust, or crushed ore, after allowing a cooling interval sufficient to permit the workers to get at the furnace. This material is charged into the furnace through the opening made after breaking down the roof within the limits of the patch. It is rounded off to conform to the radius of the roof, making a center upon which the masons lay the arch. On completion, the filling is dragged out through side doors. It is evident that a considerable amount of labor and time is required. Another method requires a considerable time for cooling before work can begin. When the furnace has cooled sufficiently to permit the workmen to begin, a wooden arch centering is constructed, following the pattern used in the initial construction of the furnace. On this the roof is laid, and when completed the wooden centering is removed from the furnace through the bridge wall or side doors.

A third method in use by the Arizona Copper Co. at its smelter in Clifton, Ariz., has the merit of simplicity, reduces the time for cooling and the labor and time in constructing and removing arch centering, and effects a saving in material. The significant feature is a steel hanger, Fig. 2, which supports a light steel centering constructed of steel rails. The hanger consists of two parts, an upper threaded rod which is bolted to a ⅝ x 4-in. flat plate and a lower part which is bolted to the upper flat plate. On the lower part is a "tee," in which there are two receptacles for steel rails. The threaded rod is supported by a nut, which bears upon a pair of channel irons and enables the rods to be adjusted to the necessary height of the roof, as shown in Fig. 1.

The pairs of channels are supported on the track girders, which extend across the reverberatory roof at the charging end, the part of the reverberatory roof subjected to the greatest heat and most excessive corrosion. Five pairs of channels are used for the full width of the roof, the center pair being 8-in. channels, the two contiguous pairs being 7-in. and the outer pairs 6-in. Curved rails conforming to the radius of the roof are placed in the hangers and short lengths of rail across these. On the top of this centering, second-hand corrugated iron or tin plate is placed. A small amount of fine ore or flue dust is used to level up the inequalities of the surface, after which the centering is ready for the construction of the arch. On its completion the hangers are unbolted at "A," Fig. 1, and the steel centering is dropped. It is dragged out through the side doors, and the furnace is ready to resume operations.

In one case where a 35-ft. patch was necessary the reverberatory was shut down at 2 a.m. At 7:30 a.m. the repair gang went to work, and in 5½ hours the steel centering had been placed. Twenty hours was required for the mason work, using two masons and three helpers, and the steel was pulled by the furnace crew in two hours, making a total of 32½ hours for the completed job.

The method just described is in use at a number of smelters in the Southwest, and the novelty in this instance is its use for making larger patches than at other plants. The details were worked out by J. Owen Ambler, smelter superintendent for the Arizona Copper Co., Ltd., and his staff.

THE PETROLEUM INDUSTRY

Liquid Fuels—Wanted: A National Policy

Consideration Should Be Given to the Need for Securing Maximum Oil Production, Reduction of Consumption, or the Finding of New Sources, to the Obtaining Of Substitutes and to Adequate Distribution of Available Supplies

BY R. S. McBRIDE
Written for *Engineering and Mining Journal*

ONE day we read of the curtailment of Mexican oil supplies by a new revolution and the domination of the world petroleum markets by Great Britain. The next we are informed that the petroleum interests in Mexico are to be fully protected by the provisional government, and that Great Britain would not think of interfering with United States petroleum development or of attempting any of the unreasonable things which are charged. As a consequence, an uncertain state of mind has been developed with respect to the imminence of the liquid-fuel shortages which we know must ultimately confront this country. It is not worth while to speculate respecting the merit of these claims as to Great Britain, Mexico, Persia or any of the rest, for at best it would be speculation. It is worth while, however, to raise the more important question: What is going to be the United States policy with respect to the future of liquid fuels?

NEED OF A UNITED STATES FUEL POLICY

When the need of a national policy is suggested it is not meant that the Government should enter the petroleum business to direct or interfere. The industry must serve itself; but it must do this along national lines, and intelligently. Paternalism is not a successful stimulent; it is rather a prop for weak industries. Petroleum, or rather our liquid fuels, do not need such a cane or crutch. They need only a tonic for the nerves and then a vigorous prod from the rear to start things into action along the right line.

The needed national policy will consider three things:

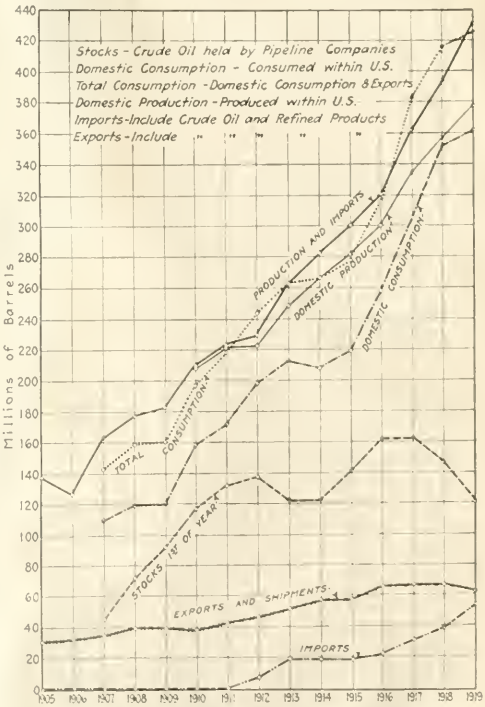
1. How can we secure the maximum petroleum production and delivery to markets, and what will this maximum be?

2. What substitutes or supplements in liquid fuel supply can be produced, and in what quantities?

3. How can the available supplies be best distributed among the various classes of users, when the total demand exceeds the available supply?

These three questions would each justify extended discussion, but for the present article they can be treated only briefly to show the need of further consideration on a broad basis.

One need not worry as to details or exact figures regarding petroleum resources or consumption of the next few years. It makes little difference, indeed, as to whose figures or interpretation of figures is used; there are at least three outstanding facts that are undisputed: (1) The United States still produces more than half of the oil marketed in the world. (2) At the same time, the United States uses about 80 per cent of the world's output. (3) The United States has approximately 10 to 15 per cent of the total known oil reserves of the world. These three facts are generally agreed upon, and almost any interpreter of them will agree that we are prodigal in this line as elsewhere and have rapidly built up so-called "essential" uses beyond our means of supply.

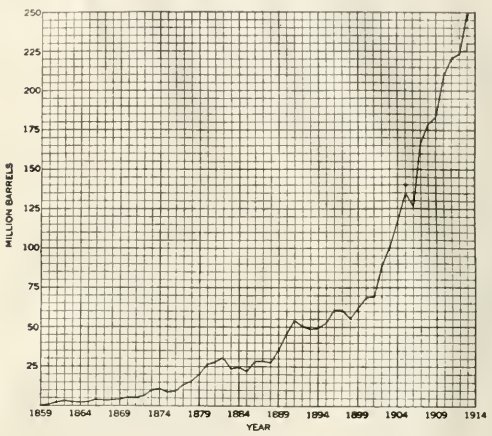


UNITED STATES PETROLEUM AND PRODUCTS
(Courtesy Bureau of Mines)

We can accept any of the several estimates of petroleum reserves, six, or eight, or ten billions of barrels, and then may use any particular system of estimating the rate at which consumption is going to increase, either gradually or by continually progressing steps, as in the past, and we have the same result. The best we can make of the situation when we set production and consumption figures side by side is to admit that with

petroleum alone we cannot maintain the present pace. David White, in a recent statement, summarizes the situation as follows:

The recoverable oil in this country, according to the conservative estimate, would probably be practically exhausted in seventeen years if the 1919 rate (nearly 380,000,000 bbl.)



ANNUAL PRODUCTION OF PETROLEUM IN THE UNITED STATES
(Courtesy Bureau of Mines)

of production could be maintained for so long, while a reserve of seven billion barrels, a moderately liberal estimate, would disappear in eighteen and one-half years.

Whether we agree exactly with this part of his statement or not, we cannot deny his later statement as follows:

The production of natural petroleum in the United States must pass its peak at an early date—probably within five years and possibly within three years—though the long sagging production curve may be carried out beyond the century. . . . The output of oil in 1919 could only with great difficulty be made to increase abreast of the increase of consumption in 1919, and possibly within three years and very probably within seven years, the production of this country would pass its climax, notwithstanding the growing deficiency as compared with the needs of the country.

Even the most sanguine, therefore, will have to agree that we are doomed either to reduce our liquid-fuel consumption or new sources must be sought. For the present article we go only this far in the discussion of the first question of national policy above mentioned.

Supplementary Supplies and Substitutes

The second question in national policy demands consideration of the substitutes and supplementary supplies of liquid fuel. Most discussions of this subject have given principal consideration to only one or two of the several possibilities. As a matter of fact, all means for supplementing existing liquid-fuel supplies are needed. Even taken together they are not enough adequately to satisfy the total of the liquid-fuel demands of the country.

The most obvious means of augmenting liquid-fuel supplies is, of course, increasing domestic production. An increasing import of foreign production, or, what is equivalent, a decreasing export, would work to the same end. The less obvious but equally effective method of increasing the efficiency of use, thereby decreasing demand, also requires consideration. These three considerations taken together afford the major means of supplementing the petroleum supply on which the United States must depend.

The question of substitutes is, however, quite a different one. Shale oil will in time become available in tremendous quantities in this country. It has afforded, therefore, a basis for most spectacular prophecy of new resources to substitute for petroleum. Alcohol and benzol from sources such as fermentation, coking of coal, and others offer promise on a smaller scale as substitutes for certain petroleum fractions, particularly gasoline. None of these suggestions, however, rival shale oil in available quantities nor general applicability of the liquids available.

Use of Coal, Byproduct Gas, and Electricity in Place of Petroleum

A third group of what may be termed petroleum substitutes is found in a field foreign to liquid fuels. Materials in this class are powdered coal, coal-oil mixtures, byproduct gas, and even electricity. These sources of heat, light, and power would, of course, readily lend themselves to many of the purposes for which petroleum is now applied. In any general discussion, therefore, the possibilities in these directions must be considered carefully.

An extended discussion might be developed of all these varieties of supplementary or substitute materials. For the present article, however, they cannot be considered in detail. As clearly pointed out, all materials and methods, taken together, are not enough to bring the present supply up to the total demand. For this reason, it is more profitable for the present to turn to the third national question as to how the available supplies can be used to best effect during such period of inadequacy.

Present Applications of Petroleum

It is not practicable to give any exact statement of the present uses of petroleum, but an excellent idea of the principal application is obtained from the Bureau of Mines figures of refinery output in this country during 1919. The important points in this summary are as follows:

Product	Output in Millions of Gallons
Gasoline	3,958
Kerosene	2,342
Gas and fuel oil	7,627
Lubricants	847
Miscellaneous	1,279
Total	16,053

The gasoline goes principally into automotive and other internal-engine uses. The kerosene is to some extent used for internal-combustion engines, but primarily is an illuminant. Lubricating oils have obvious application. The gas and fuel oils go into naval and marine-engine and power-plant applications, to the water-gas and oil-gas manufacturer, for a wide variety of industrial heating and steam raising, and to some extent to industrial chemical applications. The miscellaneous output is made up of specialized products which are applied in many fields, partly as fuels but also largely for other uses, such as inks, medicinal products, paints, road oils, and other minor uses.

A still more significant method of classifying the present distribution of petroleum was used by the U. S. Geological Survey in its study of the fuel and gas oil

requirements. This bureau summarizes some of the major demands in this field from official sources as follows:

	Barrels
Shipping Board—for merchant marine (1920)	40,000,000
Shipping Board—for merchant marine (1921)	60,000,000
Navy requirements (1918-19)	5,500,000
Navy requirements (1920-21)	8,000,000
Railroads (1918)	36,700,000
Gas manufacture	25,000,000
Other public utilities	11,000,000
Crude oil used on leases	5,700,000
Total accounted for (1920, approximately)	150,000,000

This tabulation is by no means a complete representation of fuel-oil demands, but it indicates the order of magnitude of the requirements of some of the principal users that have been conspicuously in the market during recent months. They, indeed, represent over 60 per cent of the United States fuel-oil requirements at present. The notable increase in the requirement of the merchant marine and Navy is a point that should be particularly considered in this connection.

Ranking of the Petroleum Users

Not all users of petroleum products are in competition with each other for their supply, because certain of the products are available only for a limited variety of uses. It is undoubtedly worth while, therefore, to consider the relative importance of the various demands for these materials. As a result, we can gain at least some measure of the economic justification of these applications and establish what might be termed an economic priority list for petroleum.

It is not intended to suggest that the Government should now establish any machinery for classifying petroleum uses or enforcing of priorities. The question may well be asked, therefore, as to what application is intended for any such preference list. Certainly, under our present scheme of regulation of industry, we cannot expect that a co-operation of petroleum producers will undertake to establish a distribution system giving priority to certain classes of users. Even if they wished to do so, the existing law forbidding such means for restraint of trade would prevent. On the other hand, that users will of their own volition comply with any schedule of priorities that may be advanced or suggested is beyond belief.

Despite these facts, there still remains an important function to be served by a system of classification of users of petroleum. This function is the direction of thought of the industry toward reasonable trade practices for the best interest of the industry, and the similar guidance of engineering plans by users of petroleum who must of necessity sooner or later be confronted with some limitations upon the purchase of liquid fuels. If we can establish even approximately what is to be, in the more or less immediate future, the order in which petroleum preference is granted, it will become a much simpler problem to determine where and in what manner essential liquid fuels are most advantageously to be applied.

News From The Oil Fields

Continental Mexican Brings in First Well in Chinampa Field

Several Companies in Tampico Region Pass Million Mark in September

From Our Special Correspondent

Another big gusher was brought in recently on the Continental Mexican Petroleum Co.'s Lot 95, Chinampa. It is estimated that the daily flow is in the neighborhood of 60,000 bbl. The oil was found at a depth of 2,083 ft. After closing the gate valve it was found that there was a leak between the 8¼-in. and the 10-in. casing which was flowing about 600 bbl. This was soon closed off tightly and no further trouble expected from it. This is the first well drilled in this field by the Continental Mexican Petroleum Co., as they have just recently commenced operations. They have a flow tank station at Palo Blanco, and their terminal and tank farm is opposite Tampico on the Panuco River.

The Compania Mexicana Petroleo, "El Aguila," lost their sixth 55,000-bbl. tank within the period of one month when their tank No. 116 was struck by lightning and destroyed. Much of the oil was saved by pumping it out of the tank but the estimated loss is $60,000.

Several of the companies passed the million barrel mark in September exports. Among the "top-notchers," are the Huasteca Petroleum Co., the Island Oil Co., and the Cortez Oil Corp.

Change in Mexican Petroleum Tax Considered

Petroleum companies have completed payment of their export taxes for July and August, the amount of revenue received by the treasury totaling more than 8,500,000 pesos. Announcement is made that more than 2,000,000 pesos paid to Gen. Pelaez and other revolutionary leaders would be applied to account as tax payments.

Consideration is being given complaints by oil companies relative to methods adopted for fixing the tax rate, and it is planned to change the system so that the average selling price for a period of six months will be taken as the basis, instead of prices for two months.

The Bolin Oil Co., of Casper, Wyo., has acquired leases on an extensive acreage near Round Butte, Col., 20 miles north of Fort Collins. Drilling will be started soon on the Grimes ranch in this leased area.

Controversy Over Oil Lands in Utah

From Our Special Correspondent

Interest in the oil fields of the San Rafael swell in Emery and Grand Counties, Utah, increases since the passage of the Federal Leasing Bill, which throws open large areas to development, and a controversy as to the ownership of certain sections has arisen between the state and Federal governments. The land in question comprises Sections 2, 16, 32, and 36 in each township in the San Rafael section, and the matter of ownership hinges on the question as to whether it was known to be mineral bearing at the time of cession to the state under the enabling act under which corresponding sections in each township in the state were granted to the state. Survey of the land in question was not undertaken until 1912, and a part of the area remains unsurveyed. The Government claims it was known to contain oil in commercial quantity at the time of the survey, and includes it in the naval reserve withdrawn from entry in 1912, and now offers it for lease for oil development. The state claims it as land known to be non-mineral in 1912, on grounds already set forth.

Date Set for Red River Boundary Case

Oil and Gas Leasers Given Time Extensions—Completions in Burkeburnett and West Columbia Fields

From Our Special Correspondent

The Supreme Court of the United States has set Dec. 13, 1920, for hearings in the Red River boundary case between Oklahoma and Texas. This case is of especial interest because of the valuable oil-producing area along the part of the boundary affected.

At the last special session of the Thirty-sixth Legislature Governor Hobby signed a bill extending the time in which holders of gas and oil leases on University lands may finish development work. Through an emergency clause the bill is in immediate effect. Lessees holding about 2,000,000 acres of University land in West Texas are affected by this bill, and $200,000 annually will be paid the University in rents.

Judgment was entered in the Fifty-third District Court of Travis County in favor of the State against eleven oil companies for violations of the regulations of the Railroad Commission. The fines were only $50 to $100 each, as it was shown that no wilful violation of the regulations was intended.

Stephens County oil production increased 5,000 bbl. per day for the week ended Oct. 9 over the production of the previous week.

A number of producing wells were completed in the Burkburnett district during the week ended Oct. 9, but all were within the known producing area. Northwest Burkburnett and the Texhoma section, south of the Breckenridge townsite, were the areas in which most of the wells were brought in.

The well of chief interest completed in the coastal fields during the week ended Oct. 9 is the Bassett Blakely No. B3 of the Gulf Production Co. at Blue Ridge, Fort Bend County. This well is reported to have made an initial production of 1,200 bbl. of oil daily from a depth between 2,800 and 2,900 ft. It finally proves Blue Ridge to be an oil field. Drilling has been carried on here for years, and nothing but indications were found until the Gulf Production Co. brought in its Nos. 1-B and 2-B, two small producers, during this year.

At West Columbia, the largest Gulf Coast producing field, the Humble Oil & Refining Co.'s. No. 1 Robertson was completed early in the week of Oct. 9 at 3,270 ft., making over 1,000 bbl. of oil. It sanded, and after bailing the flow increased until it was making 8,000 bbl. through a choker. This well is about 1,200 ft. north and west of the Abrams No. 1 well of the Texas Co. The Mary C. Masterson No. 1. well of the Gulf Production Co. was also completed during this week, flowing five hours at the rate of 10,000 bbl. daily, when it sanded. It is now being worked over. This well is also about 1,200 ft. north of the Abrams No. 1 well.

Operative Agreement Reached in Lander County, Wyo.

From Our Special Correspondent

The Producers & Refiners' Corporation and the Wind River Refining Co. recently signed an agreement whereby the former is to operate the eight Wind River wells in Lander County, belonging to the latter, pay all expenses, and divide the oil equally between the two companies. This agreement is in settlement of certain legal difficulties arising over sale of part of the Wind River property in the Lander Field to the Producers & Refiners' last December. It is stated that the Wind River Co. will reopen its refinery at Lander next spring, and operate it on its own and purchased oil to its full capacity of 1,000 bbl. daily.

The Twin Sisters Oil Co. recently filed articles of incorporation in the State of Wyoming. The capitalization is $3,000,000. The company will operate near Lander; the directors are: E. H. Fourt, J. F. Longenecker, and Charles Waters.

Well No. 4 of the Ohio Oil Co. on Sec. 34 of the Rock Creek field, recently completed, is making 250 bbl. daily from the first sand. It is expected this well will make a larger production when drilled deeper. Work has started on No. 1 well of Wilson & French on Sect. 24 of this field.

Western Illinois Oil Notes

From Our Special Correspondent

The Petro Oil & Gas Co. has moved in two drilling outfits to the Irvington district, in Washington County, near Centralia, where it will drill six or more test wells on a strong "structure" or anticline that has been favorably reported on by several geologists and mining engineers. Some oil has already been found in the No. 3 or "Stein" sand at 1,460 ft. and seepage occurs in neighboring coal shafts. It was through oil seepage in the coal shafts that led to the opening up of the Junction City, Sandoval and Centralia pools in the Nos. 3 and 4 sand. The Sandoval pool has been one of the most reliable pools in the state, the wells coming in with an average of 118 bbl. and are still making 5 to 12 bbl. when over ten years old. Some of the wells came in at 500 bbl. from the No. 4 sand, while the Carlyle pool, some 15 miles distant, produced 1,000 to 1,800 bbl. wells from the No. 3 sand.

The Centralia Oil Co. recently brought in a 20-bbl. well on the Langewisch farm and another well is now drilling at over 800 ft.

The value of the Illinois oil output this year is estimated at about $40,000,000,- which is the largest in the history of the state. As Illinois oil is now bringing $3.77 to $4 per bbl. at the well, this now old oil state is being given considerable attention by Mid-Continent oil men, many of whom got their start and made fortunes in Illinois 7 to 15 years ago when the oil sold for 60 to 70c., before the present extensive pipe lines were built.

Eastern Kentucky Leads in September Drilling

From Our Special Correspondent

In eastern Kentucky, Lee, Wolfe, Estill, and Powell Counties show the greatest part of the drilling during the month of September, with Magoffin, Johnson, Lawrence and Floyd showing an increasing amount of new work. Recently in Lee County, the Associated Producers' No. 7 on the Townsend lease made 20 bbl. The Security Producing and Refining Co. on the Estes lease got a 15-bbl. producer. In Powell, two strikes of 10 bbl. were made by the Ohio Oil Co., on the Brandenburg lease, and Ohio Fuel Oil Co., on the Smyth lease. In Wolfe, the Carter Oil Co. has a 10-bbl. well on the Honaker lease. A number of small pumpers were drilled in Lee, Estill, Powell and Wolfe Counties.

In the Johnson-Magoffin pool several 10 to 20 bbl. strikes have been made, while the Lawrence County field shows four new wells averaging 5 bbl. each.

Oil Activities in Arizona

From Our Special Correspondent

It is reported that gas is raising not only at the Adamana well near Holbrook, Ariz., but also at the well of the Holbrook Co., ten miles distant, and in the Black Canyon well, twenty miles to the northwest, indicating similar and encouraging conditions over a large area at the same depth, about 2,100 ft. The Adamana well is drilling steadily, with continuing gas pressure. The Holbrook Co. has received a supply of 8-inch casing that has been expected for a long time. The gas at the Black Canyon is said to have thrown water 12 ft. above the collar, though the water has been standing 400 ft. below the surface. The original Zuni well has been abandoned, with a string of tools left in it, and another has been started, 40 ft. distant. Work has been suspended for some time on the Hopi well. On complaint of a stockholder, President G. S. Mayfield and Secretary Thomas McCauley of the company have been summoned to appear November 5 before the State Corporation Commission at Phoenix to answer charges with regard to the use by them of moneys secured through the sale of stock.

Oil Excitement Starts in South Dakota District

From Our Special Correspondent

A standard oil rig has arrived and has been moved to the Crooked Oaks district in South Dakota, where Messrs. Norbeck and Nicholson will drill the first well in this new field. Twelve thousand acres have been leased by the above firm and the rig was brought in from Wyoming, where they already have several oil wells. A feeling of much excitement is in evidence throughout that part of Butte County and some of the larger oil concerns have geologists on the ground making investigations and taking leases.

ECHOES FROM THE FRATERNITY

SOCIETIES, ADDRESSES, AND REPORTS

A Producer's View on Copper

Abnormal Profits of Manufacturers of Brass and Copper Goods Retarding Consumption

"Large profits that copper manufacturers are demanding on their products are doing much to keep down domestic consumption," said an official quoted by *Wall Street Journal*. "Personally, I know of a number of instances where copper and brass were to be used until the manufacturer found out the high prices demanded for those products.

"Producers have been mining their ore and making it into copper with practically no profit. Manufacturers have not been willing as yet to reduce their profits.

"Producers are getting tired of this. The result is quite likely to be an entry of the copper producers into copper and brass manufacturing, making copper companies self-maintained enterprises similar to steel companies.

"Anaconda has pointed the way. At Great Falls, Mont., that company is already drawing copper into wire, and it would not be surprising to see it making brass before long. American Smelting & Refining Co. has been rolling copper into sheets for years.

"Copper-wire drawers tell me that many companies have all the work booked that they can do for months to come. Much of this copper-wire drawing is for foreign account. It would seem there is no real reason for wire-drawers to keep out of the market. I know that their old contracts for copper are almost exhausted.

"What copper needs is concerted action by producers. However, the laws prevent this. The largest companies are in the main producing about half what they did in 1918. Some companies, however, are still mining at from 70 to 85 per cent, or even nearer, their war rate. All companies that are mining at more than 40 per cent their 1918 rate should curtail.

"If any important producers should find themselves forced to curtail production drastically within the next few weeks, you can be perfectly sure that they will make plans for entering upon the manufacture of copper goods, thereby protecting themselves in the future from the short-sightedly rapacious middlemen of the copper industry, the manufacturers."

Franch Gold Shipped by Germany

Bits of French gold paid to Germany as indemnity in 1872 are in the shipment of gold which arrived Oct. 4 in the United States and came indirectly from Germany. That gold is a part of that which Germany paid to the United States Food Commission.

Tin Deposits of Mexico Are Widespread and Promising

The failure to realize any successful tin-mining operations in the United States under the war stimulus to the general mining industry, except one inconsiderable operation in South Dakota, renews interest in the possibilities for the tin mining in Mexico. The Mexican tin deposits have been long known. In fact, they were worked in pre-Cortez times, and there has been a continuous production on a small scale in various parts of the republic. At no time has the total output of the Mexican tin mines reached large proportions, and the industrial operations have been on a small scale, and mostly by the Mexicans.

About twenty-five years ago a Pittsburgh syndicate undertook the development of tin in Durango. The capital raised and expended was large, and the operations for the time were elaborate. This undertaking was unsuccessful, according to *The World's Markets*, partly because of the extravagance of the ideas of its backers and certain internal financial features, but chiefly, of course, by reasons of the fact that tin was not found in commercial quantities. This failure and the publicity it engendered in the United States had a great deal to do with the neglect of the Mexican tin resources by the aggressive North American capital for nearly a quarter of a century after. Perhaps, also, the fact that there was practically no successful tin mining in the United States influenced the trend of American interests in the Mexican tin deposits.

During the later years of the Porfirio Diaz era several serious and reasonably promising attempts to realize on these Mexican tin deposits were made. Notable among these were the operations in the western part of the State of Aguas Calientes, in the southern part of the State of Zacatecas and near San Luis Potosi. Other promising but less accessible deposits, on the border of Durango and Zacatecas and in the south of Mexico, were controlled with a view to later developments.

It is known that the limited explorations which had been done on some of the more promising of these Mexican tin deposits resulted in favorable reports by engineers from the United States, and serious operations were planned. It is expected that the resumption of mining in Mexico will result in a continuation of these operations and probably in the inauguration of new ones. Well posted authorities express the opinion that tin mining in Mexico will be a successful branch of the industry. Considering the reported wide-spread occurrence of tin ores, it is also to be expected that tin mining will not be confined to a single locality.

Vanadium From Oil and Super-Steel Discussed

J. Leonard Replogle, president of the Vanadium Corporation of America, when interrogated at the annual meeting of the company regarding rumors of the discovery of vanadium substitutes, as well as vanadium ore having been obtained from oil seepage, replied that the so-called super-steel discovered by Professor Arnold, of Sheffield, England, one of the processes referred to, actually calls for use of 100 per cent more vanadium than is now employed in making high-grade steel. The Arnold steel also used more molybdenum, another alloy of which the Vanadium Corporation owns large deposits in Colorado. Development of molybdenum could only benefit the Vanadium Corporation.

The head of the Vanadium Corporation also expressed no apprehension regarding competition from oil producers. He said that vanadium in minute quantities is found in iron ore, clay, and even in oil, but the cost of production made development of these sources of supply utterly out of the question. Only recently a cable from England stated that the oil company reported to be obtaining vanadium from seepage had given up its experiments.

It developed that E. E. Fernandini, who originally owned the Peruvian vanadium deposits of the Vanadium Corporation of America, and who is accounted the wealthiest man in Peru, was some time ago elected a director.

Iron and Steel Engineers Meet in New York City

The Association of Iron and Steel Electrical Engineers held its fourteenth annual convention, in the Hotel Pennsylvania, New York City. After registration and business sessions during the forenoon of the first day, the technical program began that afternoon with papers on practical education by B. A. Cornwell, and standardization by Walter Greenwood. Tuesday's papers dealt with power transmission, A. L. Freret discussing "Underground Transmission," while Tuesday afternoon was devoted to an interesting excursion. Wednesday's sessions considered the annual report of the electrical development committee and two papers, "Determination of Auxiliary Drives" by Gordon Fox, and the tonnage of the reversing electric mill, by K. A. Pauly. The annual banquet was held on that evening and greatly enlivened by the presence of many wives of members.

The addresses were continued on Thursday and the convention closed on Friday with an excursion after hearing the standardization report.

Zion National Park, Utah, Dedicated

The formal dedication of Zion National Park, Utah, to the American people was held at the Park, Stephen T. Mather, director of the National Park Service, presiding. Congress created the Zion Park, Nov. 19, 1919, making it the ninetieth member of the National Park system. The area has been reserved since 1909 and was first known as the Mukuntuweap and later as the Zion National Monument.

Utah's interest in the dedication of her greatest scenic exhibit as a national park for all the people is worthy of special note. Governor Simon Bamberger and U. S. Senators Reed Smoot and William H. King all made appropriate addresses and the Salt Lake Commercial Club arranged a special trade excursion to the dedication.

Zion National Park is in extreme southwestern Utah. It is reached by rail from both Salt Lake City and Los Angeles by the Salt Lake route to Lund, thence by motor stage a distance of a hundred miles. It is also reached by motor from either Salt Lake City or Los Angeles over the Arrowhead Trail.

The park contains 120 square miles. Zion Canyon is the most important scenic feature, bisecting the park from north to south. This canyon is 15 miles in length varying in width from 50 to 2,500 feet, with walls 800 to 2,000 feet high. A well known writer says, "This canyon, winding like a snake, abounding in enormous peaks and domes, and glowing like a Roman sash, is one of the most striking spectacles which even America has to offer." Because of its gorgeous coloring Zion Canyon has been called the "Rainbow of the Desert."

Although the newest of our national parks, Zion Park is only new in presentation as an attraction for our traveler and lover of the marvelous in nature. Historically the canyon is probably thousands of years old. Only this year ruined cliff dwellings of the pre-historic race have been discovered in almost inaccessible places in the canyon walls. The Mormon pioneers were the first Europeans to discover the region, entering in 1858. In 1861 Brigham Young visited the region and named the canyon Little Zion. Capt. Clarence E. Dutton, geologist and explorer, wrote, "No wonder the fierce Mormon zealot who named it was reminded of the Great Zion on which his fervent thoughts were bent, of houses not built with hands, eternal in the heavens." Major John W. Powell visited the region in 1870. Captain Dutton studied it several years later.

However, until the coming of the railroad and the motor road few persons had ever seen the region. Those who did had described it in such glowing terms that it was supposed their enthusiasm had run away with their veracity. Elevated to parkhood in the age of automobiles and plentiful gasoline, and of an enthusiatstic nation, Zion Park may come into its own.

International Lists of Papers Need Support

Royal Society Calls a Conference To Discuss the International Catalog

The Royal Society of London called a conference to be held in London to consider the future of the *International Catalogue of Scientific Literature*. Financial problems confront this great compilation of selected titles of current contributions to all branches of scientific knowledge, and it is uncertain what further steps are necessary for its continuance or modification. American representatives are in attendance to speak for the National Research Council, the Smithsonian Institution, and the National Academy of Sciences of the United States. Robert Mearns Yerkes and Shepherd Ivory Franz of Washington, D. C., represent the National Research Council; Leonard Eugene Dickson, professor of mathematics in the University of Chicago, the National Academy of Sciences; and Leonard C. Gunnell of Washington, the Smithsonian Institution.

The Metric System Neglected by Australia's Parliament

During the past summer a motion in favor of the establishment of a metric system of weights and measures came before the Australian House of Representatives, but was shelved after brief debate.

"Some of the arguments advanced against the metric system were as diverting as ever" states *Chemical Engineering & Mining Review* of Melbourne. "For instance one opponent used the fact that under a metric system one-sixty-fourth would have to be referred to as 0.015625; but he carefully refrained from mentioning the further fact, that if a metric system were in universal use no one would want to refer to one-sixty-fourth at all.

"Another representative advanced the ingenuous argument that under a metric system goods could not be packed for transport so conveniently as under a system which dealt in cubes. Sir Granville Ryrie met his argument very effectively by asking him how he would deal with a cube of galvanized iron sheets 10 ft. long."

The labor of learning the metric system is not as great as the labor required to learn the much more complicated systems of weights and measures now in use; and as for changes in machinery required, the metric system advocates have shown that a very small percentage of the existing mechanisms would have to be actually scrapped, but as the *Review* remarks, "if the new apparatus would give more efficient service, the sooner the old is scrapped the better. The chemist . . . uses metric weights and measures in his laboratory, and the old heterogeneous collection of pints, pounds, and inches in his everyday relations to commerce. How many chemists would be found to vote against the adoption of a metric system?"

American Manufacturers' Export Association Holds Annual Meeting

The fact that during the war exports of machinery and raw materials from the United States increased tremendously in value and that now the tendency is for a contraction of this trade led to a discussion of this topic at the annual meeting of the American Manufacturers Export Association on Oct. 14 at the Waldorf-Astoria. W. L. Saunders, of the Ingersoll-Rand Co., a mining engineer and president of the association, presided and presented the initial paper. He pointed out that although the value of the commodities exported during the past six years had increased greatly, comparative consideration of the actual tonnage or bulk exported showed but a much smaller upward trend. The strong competition from European and other quarters that might be expected, was another subject emphasized in his paper. Financial cooperation is all essential to make an attempt to capture "the great promise and opportunity of export trade now before the country."

James S. Alexander, President of the National Bank of Commerce, spoke from the standpoint of the banker, outlining the abnormal credit situation in the country, the necessity of conserving credit and the co-operation that the banks can render in the matter of export trade. He also stressed the European need of raw products rather than manufactures, which Europe is gradually becoming in a position to manufacture herself. His paper was replete with practical suggestions for the guidance of the exporter.

W. A. Harriman, President of the American Shipping and Commerce Corporation, discussed "The Big Shipping Problems of the United States," the keen competition of foreign shipping interests, and the serious lack of proper personnel in the American Merchant Marine.

Then followed an address by Dr. MacElwee, Director of the Bureau of Foreign and Domestic Commerce, divulging the Bureau's plans for the future. Other papers of more or less economic nature followed, of importance particularly to exporters.

An interesting feature of the exhibit was a display in a side room of paper clothing from Austria. It was the first the writer had seen; the texture of the cloth rather resembles that of our grass-carpets.

Mining Society of Pennsylvania State College Meets

The first fall meeting of the College Mining Society was held Oct. 1 in the furnace room of the Old Mining Building at Pennsylvania State College School of Mines, State College, Pa. There was a large attendance, and an agreeable, profitable program for the coming winter was outlined. The officers are H. H. Fraser, president; G. R. Sutton, vice-president; C. E. Bersinger, secretary-treasurer.

Book Reviews

Steam Shovel Mining. By Robert Marsh, Jr. Cloth, pp. 258, 9 x 5½. First Edition. McGraw-Hill Book Co. Inc., New York. Price, $3.50.

Much has been written concerning the use of power excavators in the civil engineering field, but of their application in mining comparatively little has appeared in print except in scattered form, and the attempt of Mr. Marsh to segregate this data on steam-shovel mining will be highly appreciated by those who are interested in this method of mine operation. The first chapter discusses the utility of the power shovel and describes the general types. This is followed by the considerations governing the selection of equipment, such as shovels, locomotives, cars, track, and drills. Chapter 3 deals with the general problems of steam-shovel excavation and pit layouts. Chapter 4 contains descriptions of the methods of drilling and blasting which are used in the different districts. The disposal of material, under which is included transportation and the building and maintenance of dumps, is covered in Chapter 5. Chapter 6 deals with the engineering work necessary in planning the development of a power-shovel mine, also outlining the mapping and estimation of the orebody and the manner of reaching certain conclusions which affect the ultimate removal of the overburden and ore. Chapters 7 and 8 contain, respectively, data on the cost of shovel work and general administration. The matter is well arranged, and the author has carefully analyzed the problems of steam-shovel mining, making comparisons and suggestions in a most helpful manner. D. E. A. C.

Aluminium. By G. Mortimer. Cloth; 5 x 7¼; pp. 152. Isaac Pitman & Sons, New York. Price, $1.

A text on the metallurgy and application of aluminum is a rare thing, but in this handy little volume, which is a companion text to similar books upon other metals and commodities, are described the essential features of the manufacture, manipulation, and marketing of the metal.

The metallurgy of aluminum, as practiced nowadays, is comparatively simple; in fact, to use the author's own words, "The electrolytic process [for aluminum manufacture] is one of those fatally simple ideas which look so attractive on paper, beautifully conceived, and straightforward enough to describe. In practice, owing to the essential delicacy of the series of operations and the difficulty of insuring a consistent level of purity in large consignments of materials, the production of pure metal from one year's end to another demands experience and able management. The progress of the metal from the preparation of pure alumina to the final casting into slab form for rolling is girt about with pitfalls and chequered with the failure of concerns which had not just that meed of experience essential to the success of this most intriguing of industrial processes."

Sketching the early history of the chemical discovery and isolation of the metal, the author describes the relatively recent large-scale electro-metallurgical development of the aluminum industry, concurrent with the introduction of cheap electric power, and the epoch-making invention of Charles Hall, of Oberlin, by which large-scale commercial production was made practicable. In 1854 aluminum was worth aout $112 per lb. Its present price is about 35c.

In illustrating the narrow limits of working in the electric furnace, it is shown that in the solid condition aluminum is lighter than the other materials in the bath, but heavier in the fused state, enabling it to sink to the bottom of the furnace. If it did not sink a disorganization of the whole process would ensue.

The alloys of aluminum, their treatment, and hints on working the metal receive extended consideration in the text, and the growing tendency to use aluminum in the electrical trade, and thereby displace copper, is stressed. The crux of the matter, "that one pound of aluminum will do the work of two pounds of copper and that it must show a saving, therefore, at anything under double the price of the red metal," emphasizes the competition between these two metals in the electrical field, and in high-tension transmission work especially.

The book is well illustrated with photographs and diagrams, and we cannot but echo the opinion of a prominent metallurgist who has perused the volume, that "It enables one quickly to grasp the big outstanding features of aluminum metallurgy and is highly stimulative of thought upon various branches of the industry."

It is to be noted that the spelling used is the British form, aluminium (not aluminum). F. E. W.

Recent Patents

1,351,091. Method of Obtaining Zirconium Oxide. Louis E. Barton, Niagara Falls, N. Y., assignor to the Titanium Alloy Manufacturing Co., New York, N. Y. Filed Sept. 24, 1919.

In obtaining zirconium oxide from a material containing an undesired substance, the steps which consist in melting said material with a carbonaceous reducing agent to production of zirconium cyanonitride; and subjecting the resulting product to the action of sulphate of an alkali metal.

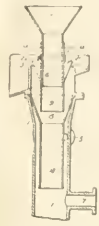
1,351,835. Reverberatory Furnace. Henry L. Charles, Butte, Mont. Filed Aug. 30, 1917.

The within described method of feeding ores into a reverberatory furnace consisting in dropping the same upon the hearth in such a manner as to pro-

vide piles or mounds at frequent intervals.

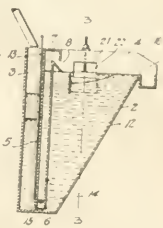
1,351,234. Separator for the Treatment of Coal, Clays, Ores, and the Like. John Marriott Draper, Bridgend, England. Filed Feb. 4, 1919.

A separator comprising an outer tube or receptacle, an inverted conical inner chamber contained within the upper part of said receptacle and from the apex of which a tube extends downward, a central feed fitted with a telescopic adjustable delivery tube to regulate the point of delivery in relation to the bottom or apex of the inverted conical chamber, a hydraulic connection for the admission of liquid to the outer tube or receptacle below the top of the inner chamber, and a circular or peripheral overflow ledge above the upper end of said chamber.



1,351,155. Ore-Flotation Apparatus. James B. Brown, Denver, Col. Filed Sept. 4, 1917.

A container divided into a feed chamber, a separating chamber provided with an overflow and a transfer conduit which adjacent its bottom communicates with each of the chambers for the reception of material, and which has an outlet adapted to deliver material in sheet-like form onto the liquid level in the separating chamber, determined by the overflow, and means for introducing a gas into the lower part of the transfer conduit.



1,352,075. Casing-Head. Henry S. McGarry and John D. Carr, Humble, Tex. Filed Mar. 28, 1919.

A device comprising a tubular member having an opening therethrough, provided to receive a pipe, said member being adapted to be screwed on the upper end of a well casing, and being provided with an annular recess in the upper end, a portion of the wall being formed with an upwardly inclined wall, and the covering adapted to fit into said recess and through which said pipe extends, said covering closing the openings through said tubular member.

MEN YOU SHOULD KNOW ABOUT

D. F. Hewett is making an examination of the Crimora mine in Virginia, for the U. S. Geological Survey.

E. F. Burchard has returned to his desk at Washington after an absence during most of the field season.

John Gross, of the U. S. Bureau of Mines, has been transferred from Fairbanks, Alaska, to the Rolla, Mo., station.

E. R. Mansfield has returned to Washington after completing an extensive examination of phosphate deposits in Idaho.

E. W. Shaw will sail from Buenos Aires on Nov. 1, for New York. Mr. Shaw has been working on oil geology in Bolivia.

W. Parsons Todd, vice-president of the Quincy Mining Co., is in the Michigan copper country on his regular inspection trip.

W. S. Murray, chief engineer of Super-Power Survey, addressed the Water Power League of America at Washington recently.

F. B. Laney has been placed in charge of the department of geology of the University of Idaho, at Moscow, to succeed D. C. Livingston.

Phillip Maverick has resigned as testing engineer with the Greene-Cananea Copper Co., at Cananea, and has gone to Tampico, Mexico.

Samuel W. Cohen, consulting mining engineer, of Montreal, sailed Oct. 6 for Europe, where he will spend two months on professional business.

S. M. Greenidge and Walker S. Clute have been appointed valuation engineers in the oil and gas section of the Bureau of Internal Revenue income tax unit.

George I. Adams, formerly on the geologic staff of the U. S. Geological Survey, was in Washington early in the month, having just returned from China.

David White, chief geologist of the U. S. Geological Survey, has completed an inspection trip through the oil and oil-shale regions in Utah and Colorado, and is now in Wyoming.

H. H. Armstead, president of Armstead Mines, Inc., and of Armstead United Cos., is in Talache, Bonner County, Idaho, inspecting one of the company's mines there.

Harry T. Hamilton, manager of the Moctezuma Copper Co., Nacozari, Sonora, Mexico, was a recent visitor to the Arizona Copper Co.'s Concentrator No. 6 at Morenci, Arizona.

Stephen L. Kapper, chief engineer, and Harold Yost, geologist, of the Phelps Dodge Corporation at Tyrone, N. M., attended the meeting of Phelps Dodge engineers recently at Nacozari, New Mexico.

Rienzi W. Macfarlane, assistant superintendent of the Arizona Copper Co., Ltd., Longfellow mining division, has returned to Morenci, Ariz., after a month's absence in Mexico.

William Russell, London manager of the Dorr Co., 101 Park Ave., New York City, is now studying the latest practices in metallurgical and chemical engineering fields in this country.

G. Perry Crawford has completed his work for the season in Spitzbergen and returned to London. Mr. Crawford will visit France, Switzerland and Italy before returning to the United States.

L.-A.-E. Sauvage, lately retired from L'Ecole Nationale Supérieure des Mines, Paris, writes that he still continues to lecture on machinery at the Conservatoire des Arts et Metiers. His present address is 292, rue St. Martin, Paris, 3me.

E. J. Donahue, for some time past the secretary-treasurer of Britannia Mining & Smelting Co., Ltd., has been promoted to be general manager vice J. W. D. Moodie, who recently retired. Mr. Donahue will be stationed at Britannia Beach, B. C.

N. C. Sheridan, mining engineer, of Wallace, Idaho, who has been in charge of operations for the Snake & Opportunity Mines Co., near Hillsboro, N. M., has returned to the Cœur d'Alene district as manager of the Midnight Mining Co., Mullan, Idaho.

Henry W. Crowther, after nearly five years' service, has resigned as manager of the Kingman Consolidated mines in Mohave County, Ariz., and has gone to Los Angeles, Cal. He has been succeeded by Will Halloran, former superintendent of the property.

A. J. Reef, formerly construction engineer at the Mammoth plant, Kennett, Cal., of the U. S. Smelting, Refining & Mining Co., and recently at the Salt Lake City office, has been transferred to the home office of the company at 55 Congress St., Boston, Mass.

H. L. Chamberlain, E. M., general efficiency engineer for the Quincy Mining Co., Hancock, Mich., has resigned. Mr. Chamberlain is a graduate of the Michigan College of Mines, class of 1903, and has been with the Quincy company for the last seven years.

F. G. Cottrell, Director of the Bureau of Mines, will leave Washington Nov. 8 for an absence of three weeks. He will visit the Bureau stations at Petrolia, Tex., and at Bartlesville, Okla. From Bartlesville he will proceed to Denver to attend the convention of the American Mining Congress.

J. A. Burgess, who resigned lately as manager of the United Eastern Mining Co., Oatman, Ariz., has opened an office in San Francisco, as a consulting engineer and geologist. He is making a geological examination of the Oatman district, preparatory to the hearing of the apex case of the United Eastern and Tom Reed companies.

Theodore Dengler, general manager of the Mohawk Mining Co. and of the Wolverine Copper Mining Co., has had the management of the Michigan Copper Mining Co., Ontonagon County, Michigan, added to his duties. Jesse Butler, who has been superintendent of this property since Mr. Brady's death, will continue to act in that capacity.

OBITUARY

Michael L. Foley, of the Foley O'Brien Mining Co., Toronto, died Oct. 9 in that city at the age of 51. Mr. Foley was for many years actively associated with mining and oil interests and was widely known in the mining districts of northern Ontario. Previous to his last illness he was manager of the Canadian Petroleum Co.

David A. Herron, for the past 15 years manager of the Tomboy Gold Mines Co.'s properties near Telluride, Col., died Sept. 24, in Denver, Col. Mr. Herron was born in Dehra, India, Dec. 24, 1860, but received his technical education in Pennsylvania and Illinois. For a time he practiced civil engineering, and later followed mining. He succeeded his brother John Herron as manager of the Tomboy properties, and was an eminently successful mining executive, devoting almost his entire time to his work. He was a kind, thoughtful man and was respected and loved by his employees. The banks and many of the business houses of Telluride closed during his funeral and for the balance of the day, in token of respect for the deceased and his family. He was buried in Telluride on Sept. 27.

SOCIETY MEETINGS ANNOUNCED

The American Society of Safety Engineers met at 29 W. 39th St., New York City on Oct. 22, in joint session with the New York section of the Illuminating Engineering Society. The program was devoted to papers that brought out the various ways by which good lighting arrangements promoted the safety of employees in various occupations. An informal dinner at Healy's preceded the meeting.

The Northwest Mining Convention will be held in Spokane, Wash., Feb. 28 to Mar. 5, 1921. In addition to the mineral exhibit the committee is planning for an educational and machinery exhibit. Members of the national bureaus, including the Geological Survey, the Bureau of Mines and the Forestry Service, will be invited to address the convention. Topics to be discussed will include the price fixing, importing, and exporting of gold, silver and other metals. Each of the several societies identified with the convention will have charge of a session.

THE MINING NEWS

The Mining News of ENGINEERING AND MINING JOURNAL is obtained exclusively from its own staff and correspondents, both in the United States and in foreign fields. If, under exceptional conditions, material emanating from other sources is published, due acknowledgment and credit will be accorded.

LEADING EVENTS

Joplin Zinc Producers Again Shut Down for Two Weeks

This To Be Followed by Drastic Curtailment for Rest of Year—Hope To Extend Movement

Zinc ore producers, representing over 90 per cent of the entire production of the Joplin - Miami district, voted on Oct. 15 to shut down for two weeks, this shutdown to be followed by drastic curtailment for the remainder of the year. Virtually all of the large producing companies are in the agreement, including the Eagle-Picher Lead Co., which it is understood, was willing to shut down for one month. It is estimated the shutdown will mean a decrease in production of at least 9,000 tons of ore and probably 9,500 or 10,000 tons.

A shutdown similar to this was tried last June and was quite successful. Organizations at the mines were regained almost intact and it is believed this will be the case this time. The companies, of course, will endeavor to give employment to as many of their men as possible in development or prospect work, or any other work not actual production. The men mostly are acquiescent to the shutdown, believing that it was either that or a cut in wages. Operators frankly state they do not believe they could fairly cut wages so long as the price of living remains what it is in this district.

An effort is being made to get the co-operation of large zinc producers in the Montana, Tennessee and Wisconsin fields in the shutdown movement. Many mines shut down on Oct. 15, and the remainder the following day.

Broken Hill Strike May Be Settled Soon

The prospects of an early resumption of work at Broken Hill and Port Pirie, New South Wales, Australia, are favorable. An independent tribunal was appointed to consider the matters in dispute, Mr. Justice Edmunds, of New South Wales, being appointed chairman. It is unofficially reported that the claims of the union for a reduction in the hours of work underground have been dismissed and that the judge's award provides for a 48-hour week for surface men and a 44-hour week underground. It is also reported that Justice Edmunds refuses to abolish the contract system. Increases will probably be given in the rates of pay but no information is yet available as to this.

WEEKLY RÉSUMÉ

Zinc producers of the Joplin-Miami district have shut down for two weeks, as a result of market conditions; this is to be followed by a policy of drastic curtailment during the balance of the year. In Colorado the carriers have undertaken to readjust freight rates on ores and concentrates within the state in response to appeals from shippers. In Utah, many companies are pushing the assessment work that must be done on claims in 1920. In Arizona on Oct. 11, fire destroyed part of the town of Lowell in the Warren district. The labor survey recently undertaken by the provincial government in northern Ontario has shown the mining camps to be in need of 2,000 men. Twenty-five million dollars worth of bonds, the balance of those authorized almost two years ago, has been issued by the Anaconda Copper Mining Co. Ore shipments sent to Ashland docks from the Gogebic Range in northern Michigan were recently interfered with for a few days by forest and brush fires along the C. & N-W. It is reported from Australia that the chances are good for a speedy settlement of the strike at Broken Hill and Port Pirie; also that various state mining ventures in Queensland have recently suffered setbacks.

From Washington it is stated that W. R. Crane has been appointed head of the new Bureau of Mines experiment station at Tuscaloosa, Ala.

Anaconda Issues Balance of Bonds Authorized Two Years Ago

A new issue of $25,000,000 of Anaconda Copper Mining Co. 7 per cent secured gold bonds, series B, is offered at 96¾ and interest, to yield about 7⅜ per cent, by a syndicate of which the National City Company and the Guaranty Trust Company of New York are the joint managers. The bonds are due in 1929 and close the issue of $50,000,000, $25,000,000 Series A of which were sold in January, 1919. The proceeds of this issue are to provide additional working capital. This issue completes the financing authorized nearly two years ago, when $50,000,000 in bonds was authorized and half of them sold at 6 per cent, paying in part for development of South American properties.

According to John D. Ryan, chairman of the board of directors, earnings of the company for the seven years ended Dec. 31, 1919, averaged more than $24,500,000 annually after paying interest and all taxes, but before depreciation charges. The average yearly earnings have been equal to nearly 50 per cent of the Series A and B bonds, which constitute the sole funded debt of this company. The bonds are secured by a pledge of stocks of constituent companies.

Denver Convention of American Mining Congress Next Month

Approaching Meeting of Great Importance to Metal Mining Industry, Particularly to Colorado

The 23rd annual convention of the American Mining Congress will be held in Denver, commencing Nov. 15. This will be an event of importance to the metal mining industry, and therefore to several of the western states besides Colorado. The convention will not be confined exclusively to the consideration of the metal mining industry. Nine general divisions of the convention's work will be considered as follows:

1. Present-day relations between employer and employee; improvement in efficiency; wages; hours; working conditions; and contracts.

2. Tariff pertaining to mine products; and uniformity of national and state mining laws.

3. A national conference on the standardization of mining machinery, labor and life-saving devices.

4. The existing excess profits tax law, which has proved unworkable, unfair, and destructive to business, will be considered in connection with the report on the subject by a committee now at work.

5. The problem of the decline of the national gold production, and steps to prevent the further depletion of the nation's monetary gold reserve will be considered.

6. War minerals will receive attention, and the relief of worthy claimants who, under the technicalities of the existing law, have been refused relief.

7. The petroleum industry and the development of the vast oil shale deposits of Colorado and other states will receive special attention.

8. There will be a conference of coal operators to consider many problems of vital importance to the industry nationally and locally; also a conference of users of oil flotation processes.

9. There will be a conference for educational and scientific purposes, under a special committee working with the permanent American Mining Congress committee on standardization.

A publicity committee has been organized in connection with the convention, consisting of Warren E. Boyer, of the Denver tourist bureau; Edward Foster, Colorado commissioner of immigration; Dowell Livesey, editor of the Denver *Commercial;* Alva A. Swain,

Pueblo Chieftain; and Thomas Tonge, of Denver, as chairman.

The convention is of special interest to Denver as a mining and mining machinery center. The metal mining industry of the whole country is confronted by adverse post-war conditions. Unsatisfactory labor supply, high price of all mining supplies, and increase in freight, smelting, and power charges conspire to increase the cost of production. In many cases the margin of profit has been wiped out, and mines will close down. Many properties have suspended development work, are curtailing their output, and reducing the number of men employed. It is generally understood that some gold mining companies are actually planning to shut down for an indefinite period as soon as present ore reserves have been reduced to a point where they will no longer return a profit under present conditions, and with this end in view the companies are letting their equipment run down, and are not making the customary replacements and renewals. Under these conditions it is difficult, if not impossible, to interest new capital in mining enterprises of a speculative nature. This condition is resulting in a migration from mining districts, thus reducing the local demand for farm produce and manufactured goods. This, in turn, adversely affects commercial centers like Denver, and reduces railroad business to and from mining districts. Moreover, the decreased taxable values in mining districts will mean that the other districts, such as farming and city communities, will have to supply the deficit. If agricultural interests were forced to carry a large part of the burden of such redistribution of taxation, little sympathy would be wasted on them by mining men, for during the past several years the agricultural interests in Colorado have exercised a predominating influence in legislative affairs, and have had little consideration for mining interests.

Overlapping Research Work Causes Dissatisfaction

The resignation of Dr. A. B. McCallum as chairman of the Canadian Advisory Council for Scientific and Industrial Research is stated to be due to dissatisfaction with the overlapping in research work and conflict between different organizations having similar objects. The Mines Branch and Geological Survey have their functions along lines of research which from time to time infringe upon the work of the Conservation Commissions or conflict with the plans of the Research Council. It is stated further that the Council has been subjected to the inconvenience of having to ask the Civil Service Commission for those it employed even for expert work. The Council moreover was greatly disappointed over the failure of the Government to approximate $500,000 for the establishment of a laboratory and bureau for research at Ottawa in accordance with the recommendation of a parliamentary committee.

New Developments in Don Luis District, Ariz., Important

About 80,000 Tons Shipped From Extension of Warren District Ore Zone—Sulphide at Depth

Recent developments have shown a very interesting extension of the ore zone of the Warren district, in Cochise County, Ariz., on the south side of the range. This ore area, the development of which has been independent of that of the main zone, is known as the Don Luis district. The probable connection with the main zone is through the Cole orebodies of the Calumet & Arizona Mining Co. However, insufficient work has been done to prove this.

Good orebodies have been developed by the Wolverine & Arizona, the White Tailed Deer mine of the Copper Queen, the Night Hawk Leasing Co., and the Boras Leasing Co. Small ore showings have also been encountered in the Wade Hampton mine of the Copper Queen and the L. S. & P. No. 3 workings of the C. & A. company.

The first work done in this area was from 1900 to 1902 on the White Tailed Deer claim on which copper and gold-silver ore outcropped. Subsequent to this early work, the White Tailed Deer group of claims was bought by the Copper Queen.

In 1902 the L. S. & P. Mining Co. acquired ground in this area, the ground being the southern extension of their South Bisbee Group of claims. In 1903 they sank the L. S. & P. shaft No. 3 on the Uncle Sam claim and did some drifting with indifferent results.

The Wolverine & Arizona Mining Co.'s group also extends into this area. This company in 1903 sank a shaft on the Broken Promise claim. Considerable development was done from this shaft both by drifting and by diamond drilling, but no ore was encountered, and work was discontinued in 1906.

The area lay dormant until 1910 when Mr. Lundvall, of Don Luis, obtained a lease on the White Tailed Deer mine. Work was done in a small way by him on the outcrop, and considerable silver and copper ore was shipped. In 1911 the White Tailed Deer shaft was sunk with the idea of prospecting for the extension of the ore outcropping. This ore dipped into the hill to the north. In 1912 a large orebody was encountered on the 150 level in the Sweepstakes claim. Shipments from this orebody continued on lease account until 1916, when operations were discontinued. In the latter part of the same year the Copper Queen company reopened the mine, developing considerable new ore and extensions The mine was shut down in 1918. Considerable ore is still in sight.

In 1912 Mark Dixon, of Don Luis, obtained a lease on the Wade Hampton mine. Stringers of silver bearing copper ore outcrop there, and were followed down. Considerable prospecting was done, but ore did not open up and work was discontinued in 1915. The ground was leased again in 1918 and some ore shipped as special silica ore to the Copper Queen smelter. The copper content was very low and the mine was again shut down in 1919.

In 1916 a lease was granted to Messrs. White and Verfurth by the Wolverine & Arizona Mining Co. on their Broken Promise claim. The shaft was started on an outcrop of iron and silica. Ore was entered at 240 ft. and some shipped. The company, on the discontinuance of the lease, developed this showing which proved to be a large orebody. Shipments have been continued intermittently to date and considerable ore is blocked out.

In 1917 the Boras claim of the Copper Queen was leased to the Boras Leasing Co., which was backed by local capital. Work was started on a stringer of copper ore outcropping on the claim. Operations were continued in a small way from an inclined shaft until the early part of 1919, when it was decided to sink a vertical shaft and prospect for the continuation of this stringer in depth. M. J. Elsing, formerly mine superintendent at Greene Cananea, was put in charge of operations. The shaft was sunk and toward the end of 1919 ore was encountered on the 400 level. This ore developed rapidly into a large high-grade compact orebody, from which steady shipments have been made and continue to date. This ore and all of the previous ore developed in the district was oxidized ore. In August, 1920, sulphide ore was encountered on the 600 level which has developed into a large orebody.

In 1917 the Night Hawk Leasing Co. was started by local capital to operate the Night Hawk claim, situated between the Boras and White Tailed Deer claims. Considerable work was done before ore was encountered. In 1919 a winze from the 450 level struck ore, which was subsequently developed on the 650 level, into a body of fair size from which steady shipments have been made. In September, 1920, a new orebody was encountered on the 650 level which is very promising. The work has been under the management of James McKenna, of Bisbee.

During the war a considerable tonnage of manganese ore was mined on the No. 4 claim of the Copper Queen. This ore outcropped and was worked by surface cut. Some of this type of ore was also mined on the Loyalty and Happy Home claims of the Copper Queen.

The encouraging results obtained by all operators in the Don Luis district is significant of the possibilities of outlying ground away from the main ore zone. This area has the advantage over other areas in that the ore appears to lie at shallow depths.

The total ore shipped to date is about 80,000 tons. The tenor of the ore is as good as that in the rest of the camp. As only a small part of the area has been prospected, the outlook is good here for a very valuable addition to the ore reserves of the Warren district.

Miami produced 4,549,140 lb. copper in September and 4,630,720 in August.

Readjusting Freight Rates in Colorado

But Those on Ore and Concentrates Shipped to Eastern Points Are Called Prohibitive

In compliance with the application of the Colorado Metal Mining Association for a readjustment of freight rates on ores and concentrates shipped from points of production in Colorado to destinations within the state, the carriers are now readjusting rates throughout the metal mining districts.

On Sept. 13, at a general conference of operators and traffic managers of Colorado roads, assurances were given that although no general order would be issued concerning the increased rate authorized by the Interstate Commerce Commission, readjustments would be made to meet conditions of each particular district. Operators were assured that if the shippers from each district would present their problems to their carriers, adjustments would be promptly made.

Readjustments have already been made in the San Juan, Leadville and Aspen districts and rapid progress is being made in fixing a rate satisfactory to shippers from various other districts. In most instances the rate in effect up to Aug. 26 has been restored on ores and concentrates carrying values less than $25 per ton, though in some instances, the lower rate is extended to a product of higher grade where it is shown that the rate was necessary to move the ore.

In the main, the adjustment of rates on intra-state shipments have been satisfactory, but operators declare that rates on ores and concentrates shipped to the zinc plants in Kansas, Oklahoma and other eastern points, under the increased schedule, are prohibitive and will result in a total cessation of shipments unless the former rates are restored. On Oct. 12, the Colorado Metal Mining Association made application to the Western Trunk Line Committee at Chicago, asking that it submit to the carriers a proposition looking to the restoration of the rates of Aug. 25. In the petition it was stated that:

"Increased production costs due largely to increased freight rates have resulted in an alarming decrease in production of zinc-bearing ore in this state, and the recent further increase threatens to effect an almost entire cessation of shipments of zinc ore and concentrates from Colorado common points to Kansas and Oklahoma smelters. In 1917 the production of zinc from Colorado ore amounted to 130,115,000 lb.; the production in 1919 decreased to 51,445,000 lb. At present there remain but three important shippers of these ores, and in the case of at least two of them, the increased rate wipes out the margin of profit and unless a readjustment of rates is made at an early day, these mines will cease production.

"The situation as to zinc ores in Colorado is such that outside of a very few exceptionally favored cases, the increased rate entirely absorbed the small margin of profit previously awarded mines which depended on shipping to eastern plants. Any further increase will terminate the existence of the few mines which are still shipping.

"The reason why increased freight rates are especially burdensome to Colorado zinc mines is that their product nearly always contains precious metals, lead and copper as well as zinc, and in order to recover them, after distilling off the zinc, the residue has to be shipped back to Colorado for smelting. Finally the crude bullion produced by smelting has to be shipped back to the eastern refineries. In this way the industry has to bear a triple freight charge and the effect of each increase is tripled, the final outcome being that most Colorado zinc producers can no longer compete with the Missouri and Oklahoma mines."

It is believed that an early date will be fixed for the hearing, and that the old rate, or possibly a lower one will be established.

Skip Wrecks Head Gear in Spite of Safety Devices

A serious overwinding accident occurred at "C" shaft of the East Norrie mine on the Gogebic Range in northern Michigan on Oct. 14, although no casualties occurred. With the empty skip a short distance below the collar and the loaded one on the first level the engineer made a mistake, reversed his engine and hoisted the empty skip at full speed. The hoist is driven through a reduction gear by an 875-hp. induction motor, has post brakes, and is fitted with two safety devices of recent design to prevent overwinding and overspeed, but these were improperly adjusted or were inadequate to prevent hoisting the skip up against the headsheave causing considerable damage.

The steelwork in the dump was wrecked, the crosshead torn from the skip and over to the first idler stand, and the body of the skip jammed just below the headsheave. It will require several days to repair the damage. Fortunately ore can be hoisted meanwhile at "D" shaft. The accident emphasizes the importance of frequent adjusting and testing of safety devices on hoists.

Forest Fires Hamper Shipping from Gogebic Range

During the last week shipments of ore from the Gogebic Range to the Ashland docks were greatly interfered with by brush and forest fires along the right-of-way of the C. & N-W. Ry. The Soo Line escaped the fires pretty well and many of the C. & N-W. trains were run over its tracks. However, many mines could not get enough cars even for the daily hoist let alone stockpile shipments. Many train crews were sent out to fight the fires and managed to prevent serious damage to the tracks. Heavy rains finally removed all further danger.

Utah Companies Getting Busy on Assessment Work

Little Chance of Exemption for 1920 Causes Work To Be Pushed—Chief Con. Active

Assessment work, allowed to lapse with government permission during the period of the war and subsequently owing to labor shortage and abnormal conditions, is being done in various Utah camps to hold unpatented ground for 1920. There is a good deal work of this kind going on in the Tintic district where some of the larger companies have been taking new ground, and where many new enterprises were undertaken following the coming in of a new producer in the Tintic Standard in the eastern end of the district. Much deep work is necessary in Tintic, where the ores are found largely some distance below the surface, and shaft sinking, although in its nature expensive, has been the best method of development.

The Chief Consolidated, which from its older ground is the largest producer of silver ores in the state, is this year doing its assessment work on its large holdings of newer territory, some of which is unpatented, by means of shaft work centrally located to benefit the group in question and of permanent value to it. It is now starting two new shafts, one to the northeast of the Central Standard, and another southwest of the Copper Leaf near the old Baltimore claims, which it acquired a number of years ago. A third shaft is projected for the extreme northern end of the Chief holdings. Last year this company spent over $25,000 in assessment work on its unpatented claims, although not obliged to by law to develop its holdings. Other companies are starting their assessment work. The East Crown Point is understood to be arranging a contract for the further sinking of its main shaft as assessment work. The Tintic Humboldt has put a small force on assessment work.

B. C. Operators Would Change Tax Act To Allow for Depletion

Representatives of the mine operators of British Columbia are anxious to induce the provincial government to amend the Taxation Act in order that allowance may be made for the depletion of ore reserves in mining property. As it now stands anything that is allowed comes as a concession from the minister of finance after an investigation. The opinion among mining men is that the principle of allowance for depletion of ore reserves should be recognized in arriving at the basis for the taxation of a producing mine. A delegation from mining companies interested in this Province recently met the Premier and members of the Executive to discuss this and other phases of the Taxation Act. They are confident that their arguments will have the effect of producing the desired amendments at the next session of the legislature.

Army Gas Mask and Dust Respirator Worthless in Mine Fire

Two Men So Equipped Killed in Recent Fire in Calaveras Copper Co.'s Mine in California

The following report of the recent fire in the mine of the Calaveras Copper Co., at Copperopolis, Cal., has been published in the California Metal and Mineral Producers' *Bulletin* to correct any erroneous impression that may have been received from the incorrect and garbled accounts published in the daily press:

"On Sept. 30 at 12:20 a.m. a fire was discovered in buildings near the collar of the Union shaft. As soon as possible all men were taken from the mine. The next morning about 9 a.m., an ex-soldier wearing his army mask started for the 1,200 level of the Discovery shaft, the main working shaft, to open an air valve. The mine at this time was filled with gas from the fire which had burned down the headframe at the Union shaft and the falling burning timbers had ignited the timbering in the shaft.

"This man did not return and two other men wearing the ordinary dust respirators started for the 1,200 level to recover the first man who had gone into the mine. Just what happened to these two men is uncertain, but one of them got back to the surface alive but suffering from the effects of gas.

"Mr. Kelsey, manager of the Argonaut mine, with three men and mine rescue apparatus arrived at the mine during the day but acting under instructions from the chief mining engineer of Industrial Accident Commission made no attempt to enter the mine until more trained men and apparatus were at hand.

"F. L. Lowell, deputy mining engineer of the Industrial Accident Commission, and Mr. Cooke, of the Bureau of Mines, left Berkeley on Thursday with the Bureau of Mines Rescue Truck No. 6 and had arrived within eight miles of Copperopolis at 4 a.m., Oct. 1, when the magneto drive shaft on the truck broke. The rescue apparatus from the truck was then taken to the mine in an automobile. B. O. Pickard, district engineer of the Bureau of Mines, and Mr. Gardner, in charge of Mine Rescue Car No. 1, of the Bureau of Mines, were at Reno when advised of the fire and arrived at Copperopolis on the morning of Oct. 1. Mine Rescue Car No. 1 was at Tonopah and arrived at Milton, the nearest railroad point to Copperopolis, at 2 p.m., Oct. 2.

"As soon as the mine rescue apparatus from the truck reached the camp preparations were made to train men in its use. The first descent into the mine was made on the afternoon of Oct. 1. Upon the arrival of the crew of Mine Rescue Car No. 1 rescue crews were organized and the bodies of the two men were recovered on the night of Oct. 2. Their bodies were found in the sump below the 1,200 level and apparently both men had been overcome by the gas and had fallen into the sump. Both men were killed either by gas or by falls, as their necks were broken and the bodies were otherwise bruised, but their lungs contained no water.

"*We wish to state in the most emphatic terms in the English language or in any other language that to wear an army gas mask when entering places containing gases from mine fires or from blasting is certain death to the man wearing the mask and as in the above case other men may lose their lives in trying to recover the first man.*

"*Do not allow an army mask to be brought onto your property for any purpose whatsoever.*

"*Dust respirators are good for dust only.*"

New Dredging Project To Be Undertaken in Guianas

Guiana Development Co. Plans To Instal Dredge and To Build Modern Camp on Upper Maroni

Perry Tiffany, president of the Liberty Company, and George A. Laird, general manager of the Guiana Development Co., with a party of ten engineers and operators, will sail for South America about Oct. 20 to begin active work on installation of dredging equipment on the Maroni River, between French and Dutch Guiana. The company intends extensive development work including the construction of docks, power plant, machine shops, and other buildings, as well as the building of a modern camp, to be equipped with ice and cold storage plant, water works and sewage system. A large part of the equipment has already been shipped to San Laurent, French Guiana.

No. 1 dredge, now being built by the Yuba Construction Co., of Marysville, Calif., will be shipped from San Francisco early in January by which time it is expected that barges for river transfer of equipment and a road passing around the Armira Falls will be ready for the transfer of equipment to the plant where operations will be started. While attempts have been made at various times to install equipment in the upper waters of the Maroni, the obstacles in the way of transportation have been too great for the successful culmination of the venture. The Guiana Development Co. is prepared to meet any emergency and is thoroughly equipped for marine and land transportation.

Reno Chamber of Commerce Establishes Bureau of Mining Information

Development of the little known minerals and metals of Nevada is contemplated by the Reno Chamber of Commerce through a recently established bureau of mining information. The bureau proposes to bring together buyers of these minerals and owners of deposits. Owners have been invited to send in descriptions of their properties to the bureau for listing.

First National Standardization Conference at Denver in November

The standardization committees of the American Mining Congress recently issued invitations to a National Standardization Conference, to be held in Denver, Col., in conjunction with the 23rd Annual Convention of the American Mining Congress, to be held Nov. 15 to 20, 1920. The purpose of the conference is to discuss improvement and standardization of mining practice, or mining methods, as applied to mining equipment and machinery, labor and labor saving devices, safety codes, costs, accounting, government and state co-operation with mining companies. The invitation is signed by Colonel Warren R. Roberts, of Chicago, Ill., chairman of the coal mines section, and Charles A. Mitke of Bisbee, Ariz., chairman of the metal mines section of the standardization committee; Horace F. Lunt, State Commissioner of Mines of Colorado, and Richard A. Parker, chairman of the mining bureau of the Denver Civic and Commercial Association.

The standardization committee of the American Mining Congress is divided into the coal and metal sections. Each section is composed of a general committee, and a number of subcommittees, the chairmen of which automatically become members of the general committee.

The metal mines section of the committee came into existence this spring with the appointment of a number of subcommittees, and others are planned. Seven subcommittees have already been appointed. They are:

The subcommittee on standardization of drilling machines and drill steel; on standardization of steam shovel equipment; on standardization of underground power shovels; on standardization of underground transportation; on standardization of fire-fighting equipment; on standardization of mine timbers; and on standardization of mine ventilating equipment.

The personnel of these subcommittees is representative of the large metal producers of the country, and efforts were directed toward the making of an impartial selection, in order that the standards finally adopted might be the result of the concentrated thought of the best talent in the industry.

As the committee members are very widely scattered, frequent meetings were considered an impossibility, and the work of the committees is therefore being carried on largely through correspondence. In order to collect material for a working basis, and to obtain an idea of the needs of the industry, a questionnaire embodying the main points proposed to be taken up by the various committees is sent to each committee member and to operators in districts not represented by committee members. Upon the return of this information, the chairman of the subcommittee compiles and tabulates the data thus obtained, sending

copies to each of his committee members, with a request that after carefully studying the same he will furnish the chairman with suggestions and comments. A further exchange of such suggestions is then made, which paves the way for a general discussion between the chairman and his committee members, and which, it is hoped, will ultimately result in the evolution of standards of value to the mining industry.

Lake Iron Ore Shipments Put At $57,000,000 Tons for Season

It has been estimated that about 57,000,000 tons of iron ore will be sent out from the Lake Superior district during the 1920 season. This will be several million tons short of requirements, due to the fact that the boats lost considerable time during the early part of the navigation season and it was close to mid-summer before the mines were able to ship steadily. The coal shortage also has had something to do with slowing up the shipments. However, the season's movement will be close to 10,000,000 tons ahead of 1919, but about 8,000,000 tons short of the biggest year. It is reported from Cleveland that some furnaces will be short of ore for the winter run and they are willing to contract now for more ore if they can get the vessels to haul the ore. It is almost impossible to make vessel contracts at present as many of the boats will soon enter the grain trade and the others will have all they can do to meet present requirements.

Some operators are already trying to figure what the iron ore price for 1921 will be in view of the fact that pig iron is a trifle weaker and steel is expected to take a drop. Ore is selling higher than ever before and it is not believed that the price can be maintained if pig and steel go down. The recent increase in rail and freight rates hit the mining companies hard as they must pay the transportation charges on ore to lower lake ports from the mines. Many a small operator would suffer if the price declined and wages and freight rates remained at the existing levels.

Mount Bischoff Tin Reserves Less

J. D. Millen, late general manager of the Mt. Bischoff Tin Mining Co., operating at Waratah, Tasmania, is now a senator in the Commonwealth Parliament. C. W. Gudgeon, the new mine manager, has issued an estimate of the ore reserves showing a considerable reduction in the tonnage estimated by Mr. Millen. Mr. Gudgeon estimates that there are 123,870 tons, averaging 0.35 per cent tin, in sight together with 266,000 tons of "probable" ore. This is equivalent approximately to three years output, but active development work is proceeding and the mine has been such a consistent producer for so many years that its supporters are optimistic as to the result. The output during the half year ended July 31 was 49,098 tons.

Ontario Mining Camps Short 2,000 Men

Labor Survey Completed by Government Finds Shovelers and Trammers Most Scarce

Following the inspection of the labor situation in Northern Ontario by the general superintendent of the employment service of Ontario, it was found that the actual shortage in Cobalt, Porcupine and Kirkland Lake amounts to 2,000 men. This figure applies only to the operating mines and does not take into account the smaller properties, nor the number of men required for new exploration work, which would be undertaken if labor were available. The mine managers have been trying to arrange to have foreign labor imported to fill this shortage. Although there is a certain amount of unemployment in the factory centers, it is generally found that this class of labor is not suitable for mining purposes. In Cobalt the average labor turnover is about 25 per cent a month, and it is impossible for the companies to do efficient work under these conditions. The shortage of shovellers and trammers is most acute and this class of labor was generally recruited from foreign countries previous to the war.

Fire Destroys Part of Lowell in Warren District, Ariz.

Fire on the night of Oct. 11 wiped out more than one-half of the town of Lowell, a suburb of Bisbee, sweeping everything on the north side of Main Street and up to the municipal market on Naco road. The damage is estimated at $750,000.

Claims of Returned Soldiers Opened for Re-staking, it Is Charged

Complaints have been made to the Ontario government that in many cases claims staked by returned soldiers have been thrown open for re-staking and taken up by other parties in disregard of an Order-in-Council issued Dec. 18, 1919, relieving such claims from forfeiture for non-performance of assessment work until Jan. 1, 1921. The Minister of Mines has issued instructions to mining recorders to protect the holders of such claims against forfeiture, but in the meantime the situation has been complicated by reason of the new holders having performed assessment work in good faith. What measure of relief will be adopted in such cases is as yet undecided.

Lectures for Prospectors

Instructions have been given the different government mining engineers of British Columbia to prepare to deliver a series of lectures on elementary geology and mineralogy at the different important centers of their several districts during the winter. This is being done at the suggestion of the Prospectors' Protective Association of British Columbia.

Tintic Standard Co. Erecting Ore Treatment Plant

The Tintic Standard Mining Co. is erecting an ore-treatment plant at Harold, Utah, 12 miles from their mine in the East Tintic district and on the Tintic branch of the D. & R. G. The process to be used will be the Holt-Dern, at present in use at Silver City, Utah. Only low-grade and highly siliceous ore will be treated at the plant. The high-grade and basic ores are to be shipped directly to the smelters. The unit under construction at present will consist of seven standard Holt-Dern roasters, each of an average daily capacity of 160 tons of charge. The crushing plant will be of sufficient capacity for two units of the size now being installed. It will consist of a gyratory, Symons disc crusher and two sets of 48 x 16-in. rolls. The leaching and solution tanks will be of concrete construction. A boarding house, machine shop, carpenter shop and warehouse will also be constructed. In addition to scrap iron precipitation erection of an electrolytic precipitation unit is planned after the plant is started. This will be about Dec. 1.

Recent Production Reports

The Rand's gold output in September was 682,000 oz. against 702,000 in August.

Butte & Superior produced 7,500,000 lb. zinc in concentrates and 138,000 oz. silver in September compared with 7,800,000 lb. zinc and 140,000 oz. silver in August.

Utah Copper produced 8,420,000 lb. copper in September compared with 8,820,000 in August.

Chino Copper's September output was 5,161,894 lb. copper compared with 4,000,148 in August.

Ray Consolidated's output in September was 4,502,000 lb. copper compared with 4,505,000 in August.

Nevada Consolidated's production in September was 4,650,000 lb. copper, the same as in August.

Granby Cons. M. S. & P. Co. produced 2,239,174 lb. copper in September compared with 2,471,200 in August.

Chile Copper produced 9,496,000 lb. copper in September compared with 10,640,000 in August.

Calumet & Hecla produced 7,278,215 lb. copper in September against 7,520,107 in August. Production by companies in September was: Ahmeek, 1,618,300; Allouez, 0; C. & H., 4,169,788; Centennial, 0; Isle Royale, 727,864; La Salle, 0; Osceola, 643,200; Superior, 46,893; and White Pine, 82,169.

Shipments of copper ore, matte, etc., to the United States from Alaska in September were 2,287 gross tons containing 1,635,677 lb. copper. Other metal shipments were: Palladium, 175 oz.; platinum, 19 oz.; gold ore and base bullion, $263,850; gold bullion, 36,592 oz., and silver ore and bullion, $13,687.

NEWS FROM WASHINGTON

By PAUL WOOTON
Special Correspondent

Cottrell's Successor a Topic of Discussion

Chemists Want a Chemist, Geologists a Geologist, and Oil Men a Petroleum Technologist

Country-wide interest is being evidenced in the type of man who is to succeed Dr. F. G. Cottrell as director of the U. S. Bureau of Mines. Chemists are taking exception to the assumption that the new director must be a metal-mining executive. They see no reason why a chemist, who is a good executive, should not be a perfectly proper director for a Bureau which is divided into branches of chemistry, petroleum, coal mining, metal mining and safety.

The geologists also have been heard from and they suggest that one of their profession may possess the necessary requisities for the directorship. Some oil men are of the opinion that, since their industry represents investments greater than those in any other branch of mining, a petroleum technologist should be considered, thereby insuring that the Bureau would expand its petroleum work, which is held to be entirely inadequate to the importance of that industry.

Crane Heads New Tuscaloosa Experiment Station

W. R. Crane, who has been chief engineer of the War Minerals Relief Commission, has been chosen to be superintendent of the new experiment station of the Bureau of Mines at Tuscaloosa, Ala. The work of the station is to be largely on coking and by-product problems, but two non-metals specialists will be assigned to the station. It is the hope of Bureau officials that eventually this station can be expanded to the point where coking and byproduct experimentation may be commensurate with the importance of those industries.

There is an insistent demand on the part of the industries interested in non-metallics that they have a station of their own in the center of the non-metals producing region. They are anxious that the work done by the two specialists at Tuscaloosa be regarded as temporary, pending the granting of the appropriation for another station which they fully expect to be devoted exclusively to non-metals work.

Bert W. Dyer New Federal Mine Inspector for Alaska

In the future the work of the Federal mine inspector for Alaska is to be on a somewhat different basis. The vacancy, which has existed in this position since the resignation several months ago of Sumner Smith, has been filled by the appointment of Bert W. Dyer, who has been in charge of one of the Bureau's mine rescue cars. He is a mining engineer and has had experience in both metal and coal mining.

In the past the headquarters of the Federal mine inspector have been at Juneau. Mr. Dyer's headquarters will be at the mining experiment station at Fairbanks. It is believed that his field work will tie in effectively with the work of the station. It is believed that the territorial mine inspector can take care of the metal mines without a great deal of assistance from the Federal inspector. This will give the Federal inspector a chance to devote more of his time to the coal mine areas.

Disabled Soldiers Studying Mining Engineering

Courses in mining engineering are being pursued by 104 disabled former service men under the vocational education statute. The total number taking engineering courses is 1,949. The work in mining engineering is divided among thirty-seven schools, of which two are in New England, nine in the east, four in the south, eight in the middle west and fourteen in the west.

Courses in oil engineering are being pursued at the University of Pittsburgh, University of Florida, Marietta College (Michigan), National Petroleum School (Chicago), University of Utah, California Polytechnic School, Occidental College (Los Angeles), and State School of Mines (Oklahoma). Eighteen ex-service men are enrolled at these schools. The work is under the auspices of the Federal Board for Vocational Education.

War Minerals Awards

Only two awards were recommended by the War Minerals Relief Commission during the week ended Oct. 9. Both were chrome cases. In one, Walker & Arnold made claim for $5,174.47 and were awarded $713.34. The other claim was that of C. D. McGonnigal. He asked to be reimbursed to the extent of $1,910.62, but the Commission awarded only $51.78.

In addition, re-allowances totaling $2,731.05 were recommended. In the claim of Fred A. Babcock, an additional $159.95 was allowed. A review of the claim of Gaylord & Landis, which had been disallowed, resulted in an award of $680.93. An additional $610 was allowed in the claim of the Hillside mine which already had been awarded $10,642.27. In the claim of E. C. Trask, the original award was $483.99. On review an additional $1,280.17 was allowed.

Operators Meet Bureau of Mines' Officials at St. Louis

Ways of Aiding Zinc and Lead Industries in Tributary Districts Discussed

That the Bureau of Mines can extend material assistance to the zinc and the lead industries in the region tributary to St. Louis was an opinion unanimously expressed at the conference in that city on Oct. 9, when Bureau officials met representatives of the operators.

It was agreed that the Bureau should confine itself to problems common to all mines, rather than undertake to be of any great amount of assistance in aiding individual companies. The problems of the district are divided into three classes—those of metallurgy, ore dressing and mining. The underground handling of ore is the principal mining problem common to all properties in the region. John Gross, one of the Bureau's ore-dressing engineers already is on the ground. A survey is to be made of milling operations. Work is to be begun at once on the Illinois ores containing fluorspar. This will be followed by a study of the ores in the Joplin district.

In the metallurgical studies efforts will not be confined to the improvement of the retort practice but will include efforts to develop new thermal metallurgy. Dorsey A. Lyon, the supervisor of the Bureau's experiment stations, is now casting about for the necessary personnel to organize the highly specialized work necessary in conducting the Rolla station.

Goodpaster-Salchaket Area Surveyed in Alaska

During the field season, just closed, in Alaska a geologic survey was made of the eastern extension of the rocks which in the Fairbanks district have proven so richly auriferous. The region in which the survey was made last summer is known as the Goodpaster-Salchaket area. Most of the general region east of Fairbanks already had been surveyed, but this area, which contains some 2,000 square miles, never had been covered. The work was done by P. S. Smith, of the Survey.

To Study Effect of Oxy-Acetylene

Increasing use of the oxy-acetylene torch in underground mining operations is bringing many inquiries to the Bureau of Mines as to the possible injurious effects which may result from this operation when carried on in confined places. It is known that some irritation to the eyes and lungs results from the use of these torches, even in the open air.

NEWS BY MINING DISTRICTS

Special London Letter

Excited Trading in Esperanza on News of Rich Strike—Passing Rio Tinto Dividend Causes No Surprise —Rand Stocks Prominent

BY W. A. DOMAN

London, Oct. 5—Relief to the otherwise stagnant condition of the mining market has been provided by excited dealings in Esperanza shares. The mine is managed in America, but the holding company is a London undertaking. At the last annual meeting of shareholders the chairman, R. J. Frecheville, referred to development work that was in progress, and his remarks led to high expectations as to the values that would be encountered in the Descubridora vein. These have proved to be of a very remarkable character, and the price of the shares jumped, by stages, from about 15s. to 52s. 6d. Jobbers were caught short, and some of them are reported to have cut very substantial losses. With business quiet in other departments dealers flocked to the Esperanza arena, and helped themselves more or less liberally. The interesting point in the mine at the moment appears to be the No. 5 level. In the north drift 10 ft. gave the extraordinary values of 64.84 oz. gold and 577 oz. silver; the previous 16 ft. assayed 40.5 oz. gold and 664 oz. silver. Of this very rich ore there is a length of 47 ft. Latest disclosures are not so high, though they are still of a remarkable character, 21 ft. showing the reef to be 25 in. wide, and containing 13 oz. gold and 397 oz. silver to the ton of 2,000 lb. In the south drift latest advices are to the effect that 15 ft. over 12 in. show 4 dwt. gold and 13 oz. silver. Apparently a fair sized bonanza has been struck, the point being emphasized by news that good values have been met with 150 ft. higher in the mine, but such values are not yet announced. The above figures might not of themselves warrant such an improvement in price as has taken place, but the Esperanza company possesses other important interests that are expected to turn out well.

To anyone who had followed events the non-declaration of an interim dividend by the Rio Tinto company did not come as a surprise. Apart from that in October, 1914, this is the sole occasion when the interim dividend on the ordinary shares has been passed. The Rio Tinto makes more out of its pyrites nowadays than out of copper, and the European market has ruled decidedly dull. The company has also felt the competition of America, where during the war greater quantities of pyrites were produced. Added to this there has been a strike of workmen which the management attribute to external influences. Other parties blame the company for not raising wages, because the whole district is dependent upon the mine, and it is a serious thing when 10,000 men cease operations. In order to avoid starvation thousands of miners have left the district. The shares are mainly held in France, and from Paris they have recently been turned out, with the result that the quotation is the somewhat nominal one of £30. Previously double this figure was nearer the mark.

As the premium on gold is being maintained at a high level, and as there are indications that the South African gold mining companies will declare enhanced dividends for the current half year, public attention is again being directed to this market. Many companies are making more out of the premium than out of working profit at standard price. The East Rand Proprietary Mines which, before a free market in its product was permitted, could see the end approaching, has taken on a new lease of life, and its profits are becoming very substantial. At the moment the shares are more or less of a gambling counter, but the position of the debenture holders is greatly improved.

CANADA

British Columbia

Labor Situation in Slocan Unchanged—Trail Smoke Nuisance Case Being Arbitrated

Nelson—The strike in the Slocan continues in effect, operators showing no dispostion to return to their former state of activity, even if the One Big Union organization should officially declare the strike ended. Operations are being maintained at the Silversmith Mines, at Sandon, with an O. B. U. crew. The Bosun, between New Denver and Silverton, is working with a force recruited from the diminished ranks of the International Union of Mine, Mill and Smelter Workers, and a start has been made in the direction of resuming operations at Noble Five and Rambler-Cariboo. Outside of these properties, and a number of leasing syndicates, the Florence at Ainsworth and the Blue Bell at Riondel, mining activity in the Slocan and Ainsworth mining divisions is at a very low ebb. There is no prospect of improvement this winter, unless the labor situation eases up. The lumber operators' demand for labor is lessening.

The California mine, near Nelson, continues development with a small crew, although milling operations have been temporarily suspended. The milling done this fall has been more in the nature of a test of a process worked out for concentration of ores of the California mine, the old Athabasca gold stamp mill being leased and practically rebuilt for that purpose.

Trail—Much interest is being shown in the outcome of the case involving claims for damages by ranchers near Trail against the Consolidated M. & S. Co., on account of alleged injury to fruit trees by smoke and fumes from the smelter at Trail. The case has gone to arbitration, with Judge Forin, of Nelson, as arbiter. Voluminous evidence is now being taken, but it is not anticipated that a decision will be reached until the end of the year.

Allenby—Canada Copper Co.'s 2,000-ton concentrator is ready to start. The power line was completed in September and at present the company is drying out the transformers. The ratio of concentration will be approximately 19 to 1.

Yukon Territory

Operations in Keno Hill Region

W. E. Cockfield, of the Canadian Geological Survey, who has been working in the Keno Hill, Mayo, and other adjacent sections of the Yukon during the summer, says that there is much activity in the Keno Hill region and that much development is being carried on by the Yukon Gold Co. The company expected to ship 3,000 tons of ore this winter. The ore assayed high grade silver-lead, running 200 oz. of silver and 50 to 60 per cent lead to the ton. The principal ore, he said, was galena, siderite, and manganese, occasionally carrying freibergite. The gold content was small, not exceeding, as a rule, $4 to the ton. On the upper Stewart River there were some stamp mills in operation but little placer mining was being done. A gold dredge had been in operation on Highett Creek during the summer. Mr. Cockfield has gone East.

Ontario

May Merge Orr Gold Mines With Kirkland Lake and Teck Hughes—No Oil at Paradis Bay

Gowganda—The Trethewey mine in Gowganda has shipped another ten tons of high-grade ore.

Elk Lake—The Cane property in the Elk Lake district has shipped 200 bags of ore, and has an additional quantity on hand. This ore, it is expected, will run approximately 400 oz. to the ton.

Cobalt—The annual report of the Hudson Bay mine shows a total income of $102,000 and expenses of $99,000, leaving a profit of $3,000 for the year.

There appears to be very little foundation for the recent report of oil at Paradis Bay, near Cobalt. An investigation by the Provincial Department shows that no oil exists, but that there is a possibility of there being gas.

Kirkland Lake—Since the recent reopening of the Orr Gold Mines in Kirkland, the orebody has been further extended, and has now been proven for a length of about 400 ft. and a width of 10 ft. The amalgamation of this property with the Kirkland Lake and Teck Hughes mines is being talked of.

ALASKA

The matter of using part of the mill equipment of the Alaska Gold Mines for the manufacture of wood pulp is under consideration by the company and certain outside interests. Nothing definite has developed to date, it is stated.

CALIFORNIA

Electro Metals Co. To Build Smelter at Trinidad

Quincy—The Seneca-Eureka mine in the Seneca district of Plumas County, about five miles from Lake Almanor, a gold property of some promise, is now being actively developed by its owner, C. D. Hazzard, of Quincy. The property covers an area about two miles long and one mile wide reaching from the North Fork of the Feather River to the top of the mountain. All claims are contiguous and the entire group is covered with good timber and has two streams of water on it that may be used for power purposes. The property contains five ledges, four of which show good values in free gold and the fifth carries considerable arsenical sulphides.

The Blue King group of claims, five miles northeast of the Walker mine, and which is now being operated by the Mason Valley Mines Co., has one of the widest mineralized zones on the surface to be found on the Plumas copper belt. There are three parallel veins, 150 ft. apart, with sufficient values between so that the mineralized zone is considered 300 ft. wide. The veins are 8 ft., 12 ft. and 20 ft. wide, respectively, and are traced by croppings for a length of 800 ft. There are seams of high-grade which run 6 per cent copper, though the average near the surface is not believed to be over 2 per cent. The ore, however, runs better in silver and gold than most of the ores of the belt.

Eureka—The old town of Trinidad, 30 miles north of Eureka, which was once one of the principal lumber shipping ports of the county, is getting on the map once more. An electric smelter for producing aluminum and the treatment of other metallic ores by electro-chemical processes is to be built. A deed conveying the whole property and rights and another instrument placing the property in the hands of trustees to operate and conduct it for a term of 25 years from July 31, 1920, have been filed with the County Recorder. The deed is from Frank and Carl Langford, of Eureka, and W. G. Devereaux, of San Francisco, to B. L. Thane, Roy H. Elliott, Frank R. Wehe and E. K. and F. Solinsky of San Francisco. The company will be known as the Electro Metals Co.

Downieville—Work on the 3,000-ft. tunnel to tap the channel in the Bella Union-Poor Boy ground will begin shortly. Most of the tunnel will have to be run through hard rock, and it is planned to instal power as early as possible next spring, but it will be several months before definite plans can be made.

NEVADA

Arrowhead's First Shipment Nets $57.40 Per Ton—Nevada Packard in Receiver's Hands

Arrowhead—The first shipment of 30 tons from the Arrowhead mine netted the company an average of $57.40 per ton. Mark Bradshaw is now consulting engineer.

Packard—The Nevada Packard mine is now in the hands of a receiver as a result of action taken by creditors to whom about $55,000 is owed. Captain Herman Davis, superintendent, has been named as receiver. The Packard has been shut down for some weeks owing to lack of power and this precipitated the action.

Eureka—Shipments for the first week in October were as follows: Eureka Holly, 13 cars of ore; Eureka-Croesus, 6; Eureka-Prince, 5; Cyanide mine, 3; Silver West slag dump, 3 cars of speiss; Richmond-Eureka Mining Co., 29 cars spiess.

Virginia City—The production of the Con. Virginia for the first week in October is given a gross value of $15,000. The north drift from the bottom of winze on 2,150 level was advaneed 41 ft. and is credited with yielding 134 tons of ore assaying $77.84 per ton.

Pioche—Ore shipments from the Pioche district for the week ended Oct. 7 were 50 per cent below normal owing to increased freight rates. A reduction of train service is already reported. Shippers were as follows: Prince Consolidated, 950 tons; Virginia Louise, 400; Bristol Silver Mines Co., 150; Black Metals Co., 110; Emerick Deerfoot Lease, 85; Combined Metals Co., 50, and S. T. Campbell Bristol, 50; total, 1,795.

ARIZONA

Shannon Working Yeager Canyon Property

Jerome—Shannon has resumed development of its Yeager Canyon property, near Jerome, intending to sink to depth and outline the copper deposit that has been cut above. In Cochise County ore is being shipped from the Gleeson mine to the Douglas furnaces of the Copper Queen. The Shannon directorate had been empowered to venture in Texas oil, backed by the money realized from the sale of its property in the Clifton-Metcalf district, but the officers have found nothing attractive and are turning back to their Arizona mines. Much of the cash realized has been securely placed in bonds.

Globe—A station has been cut on the 1,500 level of Iron Cap and extensive lateral development work will be started at that depth, as well as upon the 800 level, where there will be exploration to the westward. The new mill is reported working well, with a high percentage of recovery from 300 tons treated daily. A fire control system is being established underground, with doors that are closed by release of pneumatic pressure on the surface.

NEW MEXICO

Great Eagle Fluorspar Mine Sold—Amory Stevens Manganese Properties To Resume Shipments

Lordsburg—The Great Eagle fluorspar mine on the Gila River north of Lordsburg was sold Oct. 2 to Michigan capitalists represented by A. Ross, mining engineer. A considerable cash payment was made with balance to follow in a short time. The deal was consummated by D. L. Hill, president of the Bonney-Consolidated Copper Co. A mill will be erected at once, some of the machinery being contracted for by wire. A finished high-grade product will be turned out, suitable for acid and enamel purposes, the middlings being sold and shipped subsequently for metallurgical purposes.

The Co-operative Mining Co. has purchased all the equipment of the Radium Co. of America's property at White Signal. The new hoist has been installed and the main shaft will be sunk 200 ft. below the present level, which is 235 ft. A car of mine-run ore is shipped about every two weeks to the El Paso smelter.

Silver City—Judge M. W. Porterfield, who has been in charge of the Amory Stevens manganese properties on Boston Hill, has been in Chicago, Washington and Pittsburgh in an effort to have the old freight rates restored on this product, which is low grade, the advanee in freight rates having utterly killed the business. He reports that his efforts have been successful and shipments will start again just as soon as the old rates are officially restored. These properties had been shipping about 300 tons daily to the C. F. & I. at Pueblo.

COLORADO

New Plant for Treating Radium Ores Erected in Boulder

Ouray—Development at the Camp Bird in the east heading from the tunnel level has been unencouraging. Only short stretches of commercial ore have been opened, and these are in narrow widths. It is not believed that these ore showings will afford a sufficient daly tonnage for profitable milling. Therefore work in this part of the mine has been suspended for the present, and activities have been transferred to the west end workings from the tunnel level and reaching out under the past productive area in this end of the mine. The west heading is 614 ft. long, measuring from the tunnel intersection with the vein. For a distance the vein was pinched and indistinct, but widened to 4 or 5 ft. near the breast, having all the characteristics of the vein in overlying levels, except that it is lean in values, and no payable ore has been encountered. During April the heavy snowfall did some damage to buildings. The roof of one wing of the cyanide mill collapsed. During the quarter ended June 30, 1920, 881 ft. of development work was performed. The length of the east heading was 2,270 ft.

Boulder — The Tungsten Products Co. has expended about $7,000 in the erection of a chemical plant for treating radium ores. The plant is located in Boulder at the corner of Pearl and Third Streets. The ores which will be treated at this plant are being mined in the company's property at Gateway, Col., on the southwestern slope.

SOUTH DAKOTA

Bob Ingersoll Mine Sold, Also Swansea Lithia Property—Golden Summit Shuts Down—Cutting to Resume

Keystone—The Bob Ingersoll has been sold to Dennis Henault and associates. This property has produced considerable lithia ore, mica and beryl during past years and it is expected that under the new ownership the output will be greatly increased.

The Swansea lithia mine in the same district was also sold within the last few weeks and active work is to be started soon.

The Maywood Chemical Co. continue shipments of spodumene to their plant in New Jersey, the Etta mine supplying most of the material.

Hill City—Work at the Golden Summit mine, under lease and option to the First National Gold Mining Co., has been suspended owing to scarcity of labor and high costs of operation.

Deadwood—Preparations are under way to resume work at the Cutting property. New pumps capable of handling the large amount of water have been ordered and upon their arrival will be installed and the development work will be continued.

UTAH

Utah Apex To Add Flotation Unit—Homestake, at Park City, Being Reopened

Bingham Canyon—The Utah Apex is sinking its shaft to the 2,000-ft. level to reach the downward extension of the orebody on the 1,800 level. A flotation unit will be added to the mill, which will reduce costs on low-grade ores. A decision in the suit with the Utah Consolidated is expected before long from the United States District Court at Salt Lake City which has had the case under advisement for nearly a year.

Park City—The Homestake situated near the Glen-Allen and the Park-Utah in the southeastern part of the camp is being reopened after several years, owing to promising developments in neighboring properties. There is a 150-ft. shaft on the ground and a tunnel reaching the vein at a depth of 200 ft. The first work to be undertaken will be drifting on the vein. Samuel Paul is president and general manager and Robert Gorlinski, vice president.

The Ontario has resumed work on the 2,000-ft. level, the lowest level in the mine, after a months' intermission, owing to breaking a crank shaft on the compressor. A new pump has been installed on the 2,000 level which has been unwatered.

MONTANA

Silver Butte To Reopen Balaklava—Cascade M. & M. Co. Leases Property of Cascade Con.

The Silver Butte Mines Corporation has acquired through purchase and under a reorganization plan all of the Butte-Balaklava's $225,000 bond issue. Under the reorganization scheme Balaklava stockholders received 50 per cent of the bonds in cash and the balance in stock of the Silver Butte Mines at a par value of $1. Holders of Butte-Balaklava stock can exchange it share for share with Silver Butte Mines with 50c. added for each share exchanged. Considerable stock, it is stated, already has been exchanged. Arrangements are under way for the immediate reopening of the old Balaklava mine in the Butte district, which has not been operated since 1917. The Balaklava shaft is down to a depth of 1,600 ft. but is in need of repairs. From 20 to 30 leasing applications to work the Balaklava have been received. The Corbin property of the Silver Butte Mines embraces the Corbin King group of 26 acres, through which four known veins strike, three of which have been cut at a depth of 400 ft. by a two-compartment shaft, conditions being promising with respect to vein filling. Six carloads of ore already have been shipped from development operations, which averaged 21 oz. of silver and a 12 per cent copper. Unwatering and cleaning out will require about a month's time. Lumber was shipped to Corbin recently. An electric hoist, good for 1,000 ft. in depth, will be installed together with a compressor plant.

The stockholders of the Cascade Mines & Mills Co., operating in the Neihart district, have leased to the Cascade Consolidated Silver Mines Co. its property, including mines and mill, for three years. W. L. Creden, formerly of the Davis Daly, is in charge.

ARKANSAS

Arkansas Lime Co. Adopts New Methods To Overcome Labor Shortage

Ruddells—The Arkansas Lime Co. has almost eliminated hand labor from its quarry operations. A steam shovel replacing twenty-five men was recently installed. George Weigart, manager, states that a saving of $50 a day over the old method is being made. A churn drill has also been installed and jackhammers and other rock drills are now used only for breaking large boulders. The churn drill is now at work on a round of four holes at the south end of the quarry, the face being 250 ft. wide and 85 ft. high. The holes will be 75 ft. deep and are about 15 ft. behind the face. It is estimated that these four holes can be shot successfully with 1,200 lb. of dynamite breaking 10,000 tons of rock. This blast will be fired next month after which a round of fifteen 75-ft. holes will be drilled back of the whole face. It will take until spring to complete this work. It is estimated that 36,000 tons will be broken with this round. These methods have been adopted to overcome the labor shortage which has hampered operations for the last two years.

MICHIGAN

The Copper District

Superior's Shafts Closed—Quincy Not To Absorb Hancock

Calumet—Both shafts of the Superior Copper Co. are completely shut down, the rails having been removed from No. 2 shaft. The winze which was sunk from the 31st level at a point 1,400 ft. south of No. 1 shaft did not show up copper bearing ground of commercial quality.

The persistent rumor to the effect that the Hancock Consolidated Mining Co. was to be absorbed by the Quincy Mining Co. has been officially denied. The basis of this rumor has probably been the fact that they have been working together in building the concrete reservoir at the 53rd level of the Hancock mine.

JOPLIN-MIAMI DISTRICT

Oklahoma-Kansas-Missouri

Picher, Okla.—The Mogul Mining Co. is sinking to 230 ft. after operating for several months at the 217-ft. level. Heavy water has kept the company from sinking deeper heretofore, but now by joining with the St. Louis Smelting & Refining Co. the water problem is believed solved. The company expects to sink two shafts near the mill to a deeper level later on and to operate the mine double shift. A. E. Dunlap, Miami, is manager and J. B. Stringer, Carterville, Mo., superintendent.

The Vinegar Hill Zinc Co. has taken an option on the Texas mine and mill and has placed four drill rigs upon the ground for prospecting purposes. The mine is located southwest of Hockerville, Okla., in good territory, but the company has been handicapped with lack of money for operation.

ALABAMA

Helen Bess Mines Recovering from Recent Fire

Birmingham—The Helen Bess mines of the Birmingham Ore & Mining Co., after suffering a disastrous fire which burned its washing plant, machine shop and other buildings recently, is again getting out ore in limited quantities. The fire started, it is believed, from high voltage wires on the top of the washing plant. The loss is estimated at $150,000 with partial insurance. A tipple and other buildings needed for actual operation are being built and some ore is again being mined. Labor trouble was recently nipped in the bud at this plant and at first it was thought that the fire was incendiary origin. The company does a commercial ore business.

THE MARKET REPORT

Daily Prices of Metals

Oct.	Copper, N. Y. net refinery* Electrolytic	Tin		Lead		Zinc
		99 Per Cent	Straits	N. Y.	St. L.	St. L.
14	16.00	37.75	38.75@39.00	7.00@7.10	7.00@7.10	7.20
15	15.60	37.00	38.00@38.50	7.00	7.00@7.10	7.15
16	15.35	37.00	38.00@38.50	7.00@7.20	7.00@7.10	7.15
18	15.10	36.50	37.50@38.00	7.00@7.10	6.85@7.20	7.10@7.15
19	15.10	37.00	38.25@38.75	6.85@7.10	6.85@7.15	7.10@7.15
20	15.10	38.50	41.00@41.25	6.85@7.10	6.85@7.00	7.10

*These prices correspond to the following quotations for copper, "delivered": 16.15, 15.75, 15.50, 15.25, 15.25 and 15.25c.

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point, or as otherwise noted. All prices are in cents per pound. Copper is commonly sold "delivered," which means that the seller pays the freight from the refinery to the buyer's destination.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Oct.	Copper			Tin		Lead		Zinc	
	Standard		Electrolytic						
	Spot	3 M		Spot	3 M	Spot	3 M	Spot	3 M
14	93¼	91¼	106	249	254½	34½	34¼	40⅛	41⅛

20	92	88½	101	250	255½	35¾	35⅝	38¾	39¾

The above table gives the closing quotations on the London Metal Exchange. All prices in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Oct.	Sterling Exchange	Silver			Oct.	Sterling Exchange	Silver		
		New York, Domestic Origin	New York, Foreign Origin	London			New York, Domestic Origin	New York, Foreign Origin	London
14	349	99½	85⅝	55¼	18	342½	99½	79¼	52½
15	346	99½	82⅝	53⅝	19	340	99½	76¼	50½
16	345½	99½	81¼	53	20	342	99½	78⅛	51⅜

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

Metal Markets

New York, Oct. 20, 1920

Metal-marketing conditions are much the same as last week. The trend of prices is still downward, but has not been met by any startling response on the part of consumers. Some experienced dealers feel that prices may be near the bottom in the case of copper, zinc, and tin, and that the wisdom of buying will soon be apparent to consumers. The latter are, however, in many instances financially unable, or unwilling, to lay in stocks at any price, and are using the last pound of metal which they can clean up in odd corners. The large quantities of scrap metal which have been available have exerted a particularly depressing influence, especially in the case of copper. These stocks have existed in Europe as well as in this country, and so have affected the foreign trade.

Copper

This metal has declined particularly rapidly, about 2½c. in three weeks. The cheap prices at which copper is now being offered in an effort to stimulate sales have been mildly successful in some quarters, and the sales reported to us, principally for forward delivery, were the largest for several weeks. These sales were, however, not due to any particular consumer demand. Inquiries have been few and for small lots. Nobody seems to want immediate shipment.

Cancellation of orders and demoralized trade conditions have been felt more by producers during the last week than at any previous time. It is questionable whether 15c. copper will attract any great demand from consumers, but the metal can hardly go much lower without being bought up by speculative interests, who rightly feel that such cheap copper is as good to have on hand as cash.

Lead

Conforming to the market trend, the A. S. & R. price was reduced ½c. to 7.25c., New York, on Friday the 15th. The outside market is even below this figure. Lead is the only major metal selling for what is considered to be a fair price, but at 7c. producers are certainly not profiteering. Production continues below normal, and supplies for the current month have generally been marketed. On the other hand, there is no particular scarcity. The market is being allowed to drift along, and demand is just about equal to supply. Inquiries have not been numerous; battery and lead-pipe manufacturers particularly have kept out of the market, though the demand from the paint and cable companies continues good.

Imported lead is reported to have been offered during the last week at 6.70@7.10c. The London advance was a surprise to the trade. Importations will now hardly pay, and, as long as present conditions hold, the market has seen the last of European lead. Mexican production is also cut down, owing to the strike of the coal miners in Coahuila; the low price of silver also exerts an influence. There are, therefore, some bullish factors to offset general trade conditions, and lead producers may consider themselves fairly well off.

The market for forward delivery is absent, buyers demanding a discount from prompt, which sellers are not willing to give.

Zinc

Some metal has been sold, but at declining prices. Producers are losing money on zinc now marketed, and are generally unwilling to sell into speculative hands, even at five to ten points' premium over the prices which they obtain from actual consumers. Production is rapidly decreasing, and it is felt that this will automatically stop any further large decline. Reports state that many producers will shut down entirely for two weeks, and at least one large smelting interest has practically ceased operations.

Tin

The extremely low prices of tin, only 3 or 4c. higher than the average for any of the last ten years, has stimulated interest among consumers in the last three days. The market is still dull and weak, however. The interest is mostly

confined to December and January metal, and spot is neglected. Electrolytic has been in fair demand at the same price as Straits to ½c. under.

Straits tin for future delivery: Oct. 14th, 39.50@40.00c.; 15th, 39.00@39.50c.; 16th, 39.00@39.50c.; 18th, 38.50@39.00c.; 19th, 39.25@39.75c.; 20th, 41.00@41.25c.

Arrivals of tin in long tons: Oct. 11th, Australia, 150; 13th, Hongkong, 100; 14th, London, 25; 16th, Straits, 35; 18th, London, 125.

Silver

Since our last report the London market has declined daily to a low level of 50½d. on the 19th, but reacted to 51⅜d. on the 20th. On this latter date, rupee exchange rose somewhat, and purchases of silver for account of the Indian Bazaars were reported. The New York price has closely followed the London parity, and moderate buying for China account has continued, although the inquiry from this quarter has broadened at the present writing. The trend of the market is uncertain.

Mexican Dollars—Oct. 14th, 65¼; 15th, 62¾; 16th, 62; 18th, 60½; 19th, 58¼; 20th, 59⅜.

Gold

Gold in London on Oct. 14th, 117s. 6d.; 15th, 118s.; 18th, 118s. 10d.; 19th, 120s. 3d.; 20th, 120s. 3d.

Foreign Exchange

The British coal strike has weakened sterling, exerting an influence in two ways—first, by making coal shipments from the United States to Europe necessary, and second by decreasing British exports to this country.

On Tuesday, Oct. 19, francs were 6.435c.; lire, 3.79c.; and marks, 1.43c. Marks continue to ease off with the continued use of the currency-printing press in Germany. New York funds in Montreal, 10½ per cent premium.

Other Metals

Aluminum—For 50-ton lots: ingot, 99 per cent and purer, 33.1c.; 98@99 per cent, 32.90c. The market is dull and weak. Importers find it hard to make sales.

Antimony—Spot metal, 6½@7c. per lb. Cookson's "C" grade, 12½@13c. Chinese and Japanese brands, 6¾@7c. W. C. C. brand, 8½@9c. Chinese needle antimony, lump, firm at 6½@7c. per lb. Standard powdered needle antimony[1] (200 mesh), 10c. per lb. Market dull.

White antimony oxide, Chinese, guaranteed 99 per cent Sb_2O_3, wholesale lots, 10c.

Bismuth—$2.55 per lb., 500-lb. lots, and $2.57 per lb., 100-lb. lots.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady.

Cobalt—Metal, $6 per lb.; black oxide, $4.10 per lb.; sulphate, $1.60.

Iridium—Nominal, $400@$450 per oz.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb. for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]**Molybdenum** Metal in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.

Monel Metal—Shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$95@$100 per oz.

Platinum—Firm at $95@$105 per oz.

Quicksilver—Market quiet; $70 per 75-lb. flask. San Francisco wires $68@$70. Market weak.

Ruthenium—$200@$220 per troy oz.

[1]**Selenium**—Black powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]**Thallium Metal**—Ingot, 99 per cent pure, $20 per lb.

[1]**Tungsten Metal**—$35@$60 per kilogram, according to purity and gage.

Metallic Ores

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a maximum of 6 per cent silica, 75@85c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 70@75c.

Manganese Ore[1]—60@70c. per unit, seaport; chemical ore (MnO_2) $70@$80 per gross ton, lump; $80@$90 per net ton, powdered.

Molybdenum Ore—85 per cent MoS_2, 65@70c. per lb. of contained sulphide, New York.

[1]**Tantalum Ore**—Guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots.

[1]**Titanium Ores**—Ilmenite, 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $6 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $4.50@$5, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25@$1.50 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[1]**Zircon**—Washed, iron free, 5c. per lb.

[1]**Zirkite**—According to conditions, $80@$90 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

Zinc and Lead Ore Markets

Joplin, Mo., Oct. 16—Zinc blende, per ton, high, $51.30; basis 60 per cent zinc, premium, $41; Prime Western buying $40@$37.50, settling $50@$40; fines and slimes, $37.50@$35; calamine, basis 40 per cent zinc, $35@$30. Average settling prices: Blende, $45.11; calamine, $38.93; all zinc ores, $44.94.

Lead, high, $115.60; basis 80 per cent lead; buying, $65; settling, up to $112.50; average settling prices, all grades of lead, $92.19 per ton.

Shipments for the week: Blende, 12,698; calamine, 356; lead, 1,962 tons. Value, all ores the week, $767,690.

The last settlement of lead ore bought on $112.50 basis was made this week, but deliveries are still being made on $110 basis, with reported contracts extending deliveries to Dec. 1 on $110 basis.

The last deliveries on $50 basis for zinc were made this week, with considerable ore outstanding bought on $47.50@$42.50 basis.

The mines are closing down tonight for two weeks, or for an indefinite period, both statements have been issued from semi-reliable sources. There is a sold tonnage in bins around 40,000 tons, with 25,000 tons unsold. Closing the mines is deemed expedient to permit purchasers to load out the purchased ore. The restriction is believed will be as thorough as the midsummer closing. Followed by a proposed lighter restriction it is possible shipments may catch up with purchases by Dec. 1.

Platteville, Wis., Oct. 16 — Blende, basis 60 per cent zinc, $45 per ton for high grade. Lead ore, basis 80 per cent lead, $75 per ton. Shipments for the week: Blende, 1,078; calamine, 15 tons. Shipments for the year: Blende, 54,779; calamine, 2,474; lead, 4,398; sulphur ore, 1,284 tons. Shipped during the week to separating plants, 2,455 tons blende.

Non-Metallic Minerals

Asbestos—Crude, No. 1, $2,000@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax.

Barytes—Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $24@$30 in bags, carload lots; (off-color) $22@$26 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $23; ground (white), $45; ground (off color) $30@$32 per net ton, less than carload lots, f.o.b. New York. Crude, first grade, $10 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin)—Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines. Georgia; crude, $8@$12; ground, $15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$18 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $30@$35, car lots, f.o.b. Baltimore; ground, $17@$21, f.o.b. North Carolina points; $17@$21 per ton, No. 1 ground, f.o.b. New York State; $21@

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

$23 per ton, ground, f.o.b. Maine. Crude spar very scarce.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Graphite—The 90 per cent crucible grade is held in Alabama for 9c. per lb. and 85 per cent grade is practically unobtainable, prices being 7@9c. The higher lubricating grades sell for 11@40c., according to carbon content. In Ceylon, some of the largest producers have closed their mines until prices advance to meet increased production costs, and stocks at Colombo were lowered only 3,000 tons in the first five months of 1920.

Gravel—No analysis guarantee, f.o.b. Roseview, Ill., $25 per ton; gravel suitable for acid, chemical or enameling purposes, $60.

Gypsum—Plaster of Paris in carload lots sells for $4.25 per 250-lb. bbl., alongside dock, New York. Raw crushed rock, $3.50@$4.50; calcined stucco, $9; f.o.b. works, Illinois.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $75@$85 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—India block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20 @$1.40; No. 4, $2@$3; No. 3, $4.25@ $5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $3.50; No. 3, $5, No. 2, $6.50; No. 1, $8; A1, $10; extra large, $25, all f.o.b. New York; ground, $150 per ton, Philadelphia. Domestic, uncut, f.o.b. Franklin, N. C., as follows: Scrap, $45 @$50 per ton; punch, 10c. per lb.; circle, 15@25c.; 1½ x 2 in., 75c.; 2 x 2 in., $1.15; 2 x 3 in., $1.65; 3 x 3 in., $2.10; 3 x 4 in., $2.50; 3 x 5 in., $2.75; 3 x 6 in., $3.75; ground 165 mesh, $240 per ton; ground roofing mica, $60; mica washers, 75c.@$2 per lb.; 1¼-in. disks, No. 1, $1.60 per lb.; No. 2, $1.30.

[1]**Monazite** — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses. Tennessee production sold up months ahead.

Pumice Stone—Imported, lump, 4@ 50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish fines, per unit, 12c., c.i.f. Atlantic seaport; furnace size, 17c.; Spanish lump, 14@16c.; domestic fines, f.o.b. mines, Georgia, 12@14c. Market improving.

Quartz—(Acid tower) fist to head, $10; 1½ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines.

Sand (Glass)—Dry glass sand, $4 per net ton, f.o.b. cars Mapleton, Pa. Sand, f.o.b. Ottawa, Ill., is $3 per ton; $2.50 on annual contracts. Sand at Klondike. Gray Summit and Pacific, all in Missouri, is $2.50 on contract; some outside sales have been made at $4. St. Louis, open market, at $3.50; contract price on large quantities, $2.50; on small quantities, $3.

Sulphur—$18 per ton for domestic; $18@$20 for export, f.o.b. Texas and Louisiana mines. Market quiet.

Talc — Paper making, $12@$22 per ton; roofing grades, $9.50@$15; rubber grades, $12@$18, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $12@$15 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60 @$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered. 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $225 @$250 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15 to 18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 18½@19c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c., f.o.b. works.

Ferromanganese—For 76 to 80 per cent, prompt delivery, $170@$175 freight allowed; last half, $170; English, $170, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $82.50@$85, f.o.b. furnace.

Ferromolybdenum[1]—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2@$2.50 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $82.50@$85; 75 per cent, $150@$160.

Ferrotungsten[1]—Domestic, 70 to 80 per cent W, 80@90c. per lb. of contained tungsten, f.o.b. works. Foreign, 70c.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Ferro-uranium—35 to 50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium[1]—Basis 30 to 40 per cent, $6.50@$8 per lb. of V contained, f.o.b. works.

Metal Products

Copper Sheets — Current New York price, 26½c. per lb.; wire, 20c.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver — Unchanged at 38½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 25½c.; sheathing, 24½c.; rods, § to 3 in., 22½c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $160 per 1,000, f.o.b. Pittsburgh.

Chrome Cement—40@45 per cent Cr_2O_3, $55@$60 per net ton, and $65 in sacks, carload lots, f.o.b. eastern shipping points.

Fire Clay—First quality, 9-in. shapes, $55@$60 per 1,000, Pennsylvania, Ohio and Kentucky. Second quality, $45@ $50.

Magnesite Brick — 9-in. straights, $110 per net ton; 9-in. arches, wedges and keys, $121; soaps and splits, $134.

Silica Brick—9-in., per 1,000: Chicago district, $65@$70; Birmingham, Ala., $56@$61; Mount Union, Pa., $55 @$60.

Iron Trade Review

Pittsburgh, Oct. 19, 1920

Although some independents are disposed to lower their prices from time to time as they need business, others seem disposed to hold prices and curtail output, while predictions are made that production will be forcibly curtailed this winter by reappearance of transportation difficulties.

Pig Iron—Basic iron, which lagged in the advance because consumers were not covering ahead to the extent that obtained in foundry iron, is naturally leading in the decline, as there is occasional demand to induce sellers to name competitive prices. Although $45, Valley, as against the previous market of $48.50, was the lowest noted a week ago, since then a Pittsburgh district consumer has bought 1,500 tons from a middleman at $40 and has been quoted $42 by three producers. Some odd lots of foundry have been sold at last quotations. We quote: Bessemer, $48.50; basic, $42; foundry, $47, f.o.b. Valley furnaces, freight to Pittsburgh being $1.96.

Steel—Mills seem to be endeavoring to hold to $60 for billets and $65 for sheet bars, but on a 5,000-ton lot of billets $55 or less was done.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $16.50@$17; foundry, $18.

The Antimony Price Recession

As the United States Is Dependent Upon Foreign Supplies, a Price Drop Is of Little Domestic Consequence—Large Available Stocks and Pre-War Demand Indicate Maintenance of Low Quotations

THE antimony market is exceedingly dull, and supplies are fairly large; in fact, the purchase of surplus stocks of the metal from England, consisting of antimonial lead composition metal, or shrapnel material, is having a depressing effect upon the market. Prices are already below the pre-war figure of about 7½c., and in common with most other metals, a price tendency downward is recorded. However, the price of antimony gives little concern to the country at large, as there is no appreciable primary domestic production and the consumption is small.

Undeveloped natural antimony resources are available and were profitably worked during the war, when the price of antimony remained over 25c. per lb., but in normal times, or periods in which the price does not rule over 7 or 8c., the domestic prospects and mines can be worked only at prohibitive costs. From an economic standpoint this forced curtailment of domestic production is really an asset, as it leaves untouched a reserve that can readily be utilized in times of necessity when foreign supplies are unavailable.

Numerous Uses of Antimony, but a Small Demand

The relatively small but numerous pre-war uses of antimony, and the cheap foreign supplies, with their large resources, were greatly stimulated during the war by the consumption of antimony in shrapnel ammunition. But as this use has disappeared, the reversion to peace-time employment has again sharply limited the use of the metal.

Type metal, an alloy of antimony, lead, and tin, which has the property of expanding on solidification, is, from the standpoint of utility, the most important alloy of antimony. Britannia metal, an alloy of antimony, tin, copper and zinc, is used in cheap tableware; acid-resisting valves can be made from a lead-antimony alloy. Minor uses of antimony alloys are in battery plates, toys, brasses, and aluminum alloys.

The oxides of antimony are finding increasing application. The white oxide (Sb_2O_3) is used in the manufacture of opaque white enamel and sanitary ware, an application to which tin oxide is also put, and with which it must compete. The trioxide, Sb_2O_5, is used as a coloring agent in glass manufacture, it being more fusible than the tetraoxide. Antimony oxides and antimony sulphides are also used as paint pigments, and the coloring of rubber red is frequently accomplished with the aid of the sulphide. Safety matches, medicines, and ceramic industries consume minor amounts of antimony compounds.

Foreign Sources Important

China and Japan have been the chief supplying agencies of antimony in its various forms, but Mexico, France, and Bolivia are other countries with an important production that helps supply the world. China is by far the most important antimony-producing country, but its position was formerly minimized by the control which Great Britain had over the antimony-smelting industry. Brands of British antimony such as Cookson's and Halett's, made from foreign ores, enjoyed world-wide favor, and through well-developed antimony-smelting facilities in the British Isles, England was enabled practically to dominate the world's antimony market. Chinese, Mexican, Australian, and Continental ore was formerly smelted and refined in England, and the close co-operation of British trading interests exerted a strong influence in obtaining the raw material necessary for the furnaces and markets for the product. The war naturally changed this situation. Exports of Chinese ore and metal were in the hands of English and Continental firms, but this grip was broken by the war, and one result was the organization of the Wah Chang Trading Co. and the establishment of a direct selling agency in New York for the Chinese antimonial products. Through this step the Chinese metal has grown in favor and has become firmly established in the domestic market. The fact that China has large antimony reserves and adequate marketing facilities is assurance that the most important source for antimony for many years to come lies in the Far East.

Domestic Production Negligible

The great antimony-consuming countries of the world—that is, the United States, France, Germany, and Great Britain—are, with the exception of France, normally dependent upon foreign supplies of the metal. The producing countries are slight consumers.

The table gives the essential features of the domestic antimony industry for the war period. It is to be noted that domestic antimony production from ores jumped during the war, only to vanish in 1919. Under the present economic situation it would require a price of at least 20c. to make domestic antimony production profitable.

PRINCIPAL FEATURES OF THE UNITED STATES ANTIMONY INDUSTRY
(In Short Tons)

	U. S. Production From Ores	Antimony Content in Byproduct Antimonial Lead	Smelter Production From Foreign and Domestic Ores	—Imports— Ore	Metal, (Regulus)	—Exports— Matte, Regulus, Metal	Average Price, Cents

1919	....	1,943	.....	409	7,159	214	8 20

It is altogether likely, now that the prospect of stabler conditions in Mexico seems realized, that our southern neighbor may increase her antimony production. In 1912 and 1913, 3,296 and 2,345 long tons of crude metal and regulus were shipped to England, but none came to the United States. Both English and American capital are engaged in developing Mexican antimony resources, and the necessary smelting facilities are available locally. The most important mines are owned by Cookson's, of England.

The world's production of antimony easily responded to the war demands. Whereas pre-war production was about 20,000 metric tons per year, during the war a peak production (1916) of 75,000 metric tons was attained. The ability of the world to meet any extraordinary demand for antimony is clearly apparent from the war record.

Latest Rand Gold Production

During September, the gold production of the Rand, in South Africa, amounted to 682,173 oz., a decrease in output from the August figure, 702,083 oz. A table summarizing production since 1917 follows:

RAND GOLD OUTPUT 1917-1920
(Fine Ounces)

	1920	1919	1918	1917
January	670,503	676,059	714,182	782,634

INDUSTRIAL NEWS

Auger Rotator of New Design

In drilling soft, broken, or loose ground, it has been found that the ordinary compressed air hammer drill strikes too hard a blow for satisfactory progress. Its penetration is so great at each stroke that it is unable to throw the mud and cuttings from the hole, resulting in speedy clogging of the bit. To overcome this difficulty the so-called auger drill has been developed. In this type the stroke is relatively short and the blow light and rapid. At the same time the strength and speed of rotation have been increased, to provide for keeping the hole true and round, and to aid in ejecting the sludge. Solid spiral steel and a "fishtail" bit are often used with auger drills, the twisted steel serving as a conveyor for the cuttings.

An improved Sullivan Auger Rotator, recently placed in service, possesses certain distinctive features, which are securing added effectiveness in drilling work of the kind described above. The Sullivan "DR-37" Auger Rotator weighs 35½ lb., being shorter and lighter than other types.

The strength and rapidity of rotation have been materially increased. In all the Sullivan rotators the rotation is accomplished by means of straight and spiral flutes milled in the front portion of the piston bar, which are engaged by lugs on a removable bronze nut. The piston grooves also engage lugs on the interior of the encircling ratchet, which imparts the turning movement to the chuck, and thus to the steel. In the ordinary rotator the piston and steel are turned on the up or back stroke; but in the new model Sullivan auger the reverse is true, the steel being turned by a four-pawl ratchet on the forward stroke as the blow of the piston is delivered, thus rendering the rotation of the steel stronger and more positive.

The action of the standard rotator valve combines with the forward stroke rotation to keep vibration and jar on the operator down to a low factor. In this new model an automatic, pulsation-type lubricator has been embodied, thus furnishing the working parts of the tool with a sufficient quantity of oil at all times.

Increased drilling speed, effective cleaning of the drill hole, and smooth operation are factors noticed favorably by drillmen in using these tools. Holes up to ten feet in depth are drilled readily in iron-ore formations. The rate of progress is maintained with unusual evenness as the depth increases, instead of falling off, as is characteristic of older types. For occasional use in hard ore the "DR-37" is equipped to use hollow steel, and a push button in the lower valve-buffer turns the air down the steel for cleaning.

Trucking Ore on Big Cottonwood Canyon Grades

Five Packard trucks owned and operated by the Cardiff Mining & Milling Co., Salt Lake City, Utah, are handling an unusually "steep" job with great success. They are hauling lead ore from the lower ore bins of the Cardiff company three miles from Big Cottonwood Canyon, Salt Lake County, Utah, to Murray, Utah, a distance of fifteen miles.

The first four miles of the haul are comparatively level, as one of the views shows, but the remainder of the route has a total rise in elevation of approximately 1,700 ft. through a narrow and rugged canyon. Two of our photographs give a good idea of this portion of the way, and some indication of the grade overcome.

The trucks make the trip twice in a twelve-hour day. Part of the time they have been in operation twenty-four hours a day. On the down trip the average load for each of the trucks is from six to eight tons, an over-load of from 10 to 30 per cent. On the return trip each truck carries from 1,000 to 7,000 lb. of up-freight for the mine.

Bad roads made the haul even more difficult at first. This was solved by the use of shale obtained from the bottom of the canyon. After the shale was placed on the road, the trucks on their daily trips packed it down until the road became virtually a boulevard. This was

FIG. 1. PACKARD TRUCKS AND THE BIG COTTONWOOD CANYON GRADES THEY CONQUER, WINTER AND SUMMER

a material aid in reducing the operating expenses of the trucks.

The truck service is uninterrupted during the summer months and until the snow begins to fall, about Nov. 1. After the first season the trucks were replaced with teams for the winter months; but last winter the trucks managed to operate with the help of teams used in plowing the snow off the road.

Industrial Cost Association Interests Mining Men

The Industrial Cost Association, which met in New York City on Sept. 27, lists among its active members important mining and general industrial organizations. The purpose of the association is the standardization of accounting and cost practices and terminology, to promote the adoption of standard governing principles and active co-operation and interchange of experience between representatives of manufacturers; also to act as a clearing house in distributing all such information.

M. F. Simmons, of the General Electric Co., Schenectady, N. Y., is president of the association, C. H. Smith, of the Westinghouse Air Brake Co., is first vice-president, Roland H. Zinn, of the Tanners' Council, is second vice-president, and A. A. Alles, Jr., secretary of the Fawcus Machine Company, Pittsburgh, Pa., is secretary-treasurer, 2818 Smallman St., Pittsburgh, Pa.

Steel Foundrymen Organize To Perfect Higher Standards in Casting Practice

Announcement has been made of the appointment of R. A. Bull, of Pittsburgh, Pa., as consulting metallurgist for a number of prominent steel foundries grouped for the purpose of developing and perfecting higher standards in the production of steel castings. Mr. Bull will devote his entire time to preliminary research work immediately, and has resigned his position as vice-president of the Duquesne Steel Foundry Co. to secure the necessary freedom.

Among the companies undertaking the work noted are the Electric Steel Co., Chicago, Ill.; Fort Pitt Steel Castings Co., McKeesport, Pa.; Isaac G. Johnson Co., Spuyten Duyvel, N. Y.; Lebanon Steel Foundry Co., Lebanon, Pa.; Michigan Steel Castings Co., Detroit, Mich.; and Sivyer Steel Castings Co., Milwaukee, Wis.

Mr. Bull is a member of numerous technical associations and has frequently contributed to the technical press. Since 1911 he has been a director of the American Foundrymen's Association and during 1916 and 1917 served two terms as its president. His connection with the foundry industry covers a period of over twenty years, during which he has held important positions in foundries at St. Louis, Chicago, New York, and Pittsburgh.

TRADE CATALOGS

Elevator Controllers — The Cutler-Hammer Manufacturing Co., Milwaukee, Wis., has issued a new two-color booklet, "Elevator Controllers," of twenty-four pages, describing the new line of elevator control apparatus recently developed by that firm. This booklet, which is known as Publication 840, illustrates the new controllers and emphasizes their simplicity, quiet operation, and smooth acceleration. The last few pages are devoted to auxiliary apparatus.

New Jersey Concentrating Co., 66 York St., Jersey City, N. J., weighing, sampling, grinding ores, and custom concentrating, sends us an illustrated four-page folder designed to emphasize the completeness of the company's installation and the wide geographic range of its custom business with big and little producers of tungsten, chrome, manganese, zirconium, and other ores. (Telephone 4173 Montgomery.)

Chain Drives—The Link-Belt Co., 910 So. Michigan Ave., Chicago, Ill., announces as ready for distribution its publication No. 345 "Link-Belt Silent Chain Drives for Cement Mill Equipment." Officials of cement mills will find this an interesting and valuable book, and may procure a copy by writing to the above address or any of the company's branch offices.

The same company's publication No. 257 is a 78-page book on the use of roller chains for power transmission, and its tables will appeal as a handbook for the power transmission engineer. A copy will be sent on application.

The Taylor-Wharton Iron & Steel Co. has recently sent us a souvenir booklet which was issued in commemoration of the 125th anniversary of the making of iron and the 25th anniversary of the making of manganese steel at its plant at Highbridge, N. J. The edition is well illustrated with photographs of the officials, employees, plants, and manufactured products. A complete history of the development of the company, which was originally organized in 1742, and its accomplishments are given. On Oct. 13, 1917, a celebration was held at Highbridge, N. J., upon the occasion of the above anniversary. At this time notable addresses were made by Knox Taylor, president of the company, Prof. Henry M. Howe, John R. Hardin and others. It is a most creditable fact that the organization includes several men who have remained in the service of the company for many years.

Condensers—The Link-Belt Co., 910 South Michigan Ave., Chicago, Ill., recently published an attractive illustrated twenty-four-page book (No. 352), covering its traveling water screens. This publication will be sent to anyone interested in the effective and economical screening of condensing water

Copper and Cotton

THE spectacular slump in the price of copper during the last few weeks illustrates the close relation of the mining industry to other great industries, and its dependence upon general economic conditions. The copper slump was another of those almost perpendicular crashes which have taken place in quick succession—in cotton, sugar, wheat, and corn. It is like a row of dominoes: it is altogether a fine point as to which falls first, but that they fall in the end is inevitable. Some of the industries affected have taken the slump as an unexpected shock, with surprise and indignation. The cotton growers, for example, visited Washington and interviewed Secretary Houston, demanding that the Government "do something" to hold up the price of cotton. Similarly, the wheat growers charge somewhere conspiracy which has resulted in lowering the price of wheat below what is claimed to be the cost of growing; and they also demand that the Government "do something." But neither these plaintive cries for help nor the violence of the night riders of the South will have any effect on the great economic laws which are moving in the direction that has been foretold by every economist and financier since the war—and is as clear and as unavoidable as the law of gravity. As schoolboys we know that

"What goes up must come down
On the head or on the ground."

The blind ones are getting this drop "on the head"; but in these days of enlightenment it is probable that the majority of business has sidestepped it, and is letting it fall "on the ground."

There will doubtless be no pilgrimage to Washington of copper miners, beseeching the Government to "do something" to boost the price of copper. They have not had their fair share of the fat profits which the growers of cotton and wheat have had in the aftermath of fever-prosperity which succeeded the armistice, and against which it was understood that the temperature of the patient would fall below normal before health would supervene; but they are not likely to charge conspiracy, being, we believe, somewhat wiser, as a class, as to what is transpiring in the world than the planter of cotton or of corn.

This general process of deflation, of returning to normal values, of which these sudden slumps are symptoms, is what the common citizen has been praying for to come soon. As miners and otherwise just plain citizens, we have heard with secret joy (although not indecorously exhibited) of the cuts in the price of cotton, wheat, automobiles, and the rest. We see relief from the strain of exorbitant prices, and hope for the teacher, the Government employee, and all the group submerged by that H. C. L., which, if continued, would go far toward extinguishing culture and education, in the wild stampede for "grub." It depends, of course, upon whose ox is gored. We do not welcome it in copper or in zinc. But if we have to be operated on with the rest, the sooner it is over and we begin to be convalescent, the better: so bring on the anæsthetic!

We hope that in copper the operation is over. Certainly copper is selling at less than it costs to produce, a situation which can hardly be long drawn out. We hope—and believe—that we have touched bottom; but we have no precedent to guide us in hazarding a confident prediction, because the governing factors are such as have never before existed in the history of the world.

Choosing a Director for the Bureau of Mines

UNDER the above head *Chemical & Metallurgical Engineering* discusses in a leading editorial the problem of the forthcoming choice of the Bureau of Mines director. We quote from this editorial as follows:

"All will agree that the greatest care should be exercised in making the choice. The position calls for certain qualifications that are quite obvious. Primarily, we suggest that it seems appropriate that the director of the Bureau of Mines should be a mining engineer—one experienced in the theory and practice of mining, skilled in administration and organization, sympathetic with the related subjects of chemistry and metallurgy and having a broad view of the mining industry and its relation to the welfare of the country. In addition to these qualifications the incumbent should be in a position to make that sacrifice which a Government salary entails, and yet he must not be so secure in his independence as to have lost ambition and initiative."

Cheapening the Mining Engineer

THOUGH the training of disabled ex-service men by the Government is a praiseworthy action, such training for the higher professions should be conducted with due regard to the established educational standards. We are not sure that this is being done. We recently had a visit from a fine young chap, who was suffering from disability from wounds received while with a machine gun battalion in France. He had been offered by the Federal Board for Vocational Education the chance of being educated to a profession by means of a two-year course of instruction, and was hesitating between a course in oil engineering and one in salesmanship. It transpired that he had not had any education beyond the grade schools. Under the circumstances, we were unable to encourage him to go in for oil engineering (a large part of which is, or should be, geology), as it is impossible to turn out a competent mining or oil engineer or geologist from an unprepared youth in that period; and we advised him that, being imperfectly prepared, he would be at a disadvantage compared with

thoroughly trained men. Therefore, we counseled the choice of the salesmanship course.

Our Washington news chronicles the fact that free courses in mining engineering are being given to disabled ex-service men in thirty-seven schools in the United States. The range of schools is not reassuring. Can one enumerate thirty-seven American schools capable of turning out competent mining engineers? We make this query not as a denial, but asking for further information. We do know that in several schools mining engineering and mining geology have been compressed into one summer course. The desire to enlighten the people at large, along the University extension idea, has triumphed over the laudable caution and standards of the educator, and a flood of men have been loosed on the investing public who, with a little of that knowledge which is the most dangerous thing in the world, have masqueraded as engineers or geologists.

We call on the universities and higher schools to look to their principles and ideals. It is a matter of congratulation that the American Institute of Mining and Metallurgical Engineers has in the last few years established proper standards for membership; and the newly organized Society of Economic Geologists will do the same for the science of geological engineering.

Vacations for Wage Earners

MORE and more is the social condition of the working man being improved. Neither is this altogether a result of the labor shortage, as some scoffers have inferred, for the movement is one which has been going on for some years. On the other hand, it is not pure philanthropy, for contentment and happiness are recognized to result in more efficient performance of duty, and a reduction of the labor turnover redounds to the profit of the employer. In the mining industry, particularly, conditions are vastly better than a few years ago. One reason, it must be admitted, is that conditions, at least in some camps, were too unspeakable to continue, and another is that things had to be made more attractive than in similar employment in urban communities in order to hold men in out-of-the-way places.

A recent step in the right direction has been the granting of vacations with pay to those who work by the hour or day as well as to those who work on salary. So far we have heard of no mining companies taking this step, although it is likely that some have done so. The plan has recently been adopted by the Western Electric Co., as mentioned in our Sept. 11 issue. Other companies which have instituted a similar system are the Chain Belt Co., of Milwaukee; the Willys Overland Co., the Utica Drop Forge Co., the Studebaker Co., and the Ritter Dental Mfg. Co., of Rochester. In the case of the Western Electric Co. it is said that heretofore factory workers have not received paid vacations because of the fact that they received pay on an hourly basis, with extra rewards for overtime, whereas the salaried men got no rewards for overtime. In most cases, this would not be true, for the average overtime of the salaried worker is balanced by absence and tardiness for which no deduction is made.

Granting a paid vacation of two weeks of the year to wage earners who have worked steadily will help to eradicate class distinction and will tend to remove the idea that they do not belong to the privileged class. It will also in many cases make for greater efficiency. A man or a woman who has worked hard for a year needs a rest without the thought that it is costing him or her money in addition to what is spent. The plan will work best among the steady men, generally Americans, who will use the time to visit the home folks, to lay in a supply of wood, or to go on a hunting or fishing trip.

The Vagaries of Orebodies

WE HAVE HEARD of certain Utopias where successful mines are situated within the proximity of prosperous farms, where attractive topography is combined with agreeable climatic conditions, and other equally desirous surroundings furnish the mine manager with an abundance of the needs and pleasures of life. But such enviable combinations are few and far between, and fortunate indeed is he who can include mine, farm, and game preserve in the domain over which he rules.

We recall a visit some years ago to a section of one of the Western mining districts. The trip was made by buckboard, ten miles across the sagebrush, with the sun particularly active, and the dust shrouding the wagon in dense clouds. After an hour's going the foothills were reached, and the upward climb along the sides of the mountains offered a grateful relief from the monotony of the sage flat. Here was an ever-changing vista; the wooded slopes presented a pleasing picture, and the small valley-like depressions were covered with an abundance of vegetation.

The first stop was made at a small spring, which bubbled from the rock clear as crystal. In the party was an Eastern capitalist. This was his first visit to the West, and, although familiar with the financial features of mines and mining, his knowledge of "ground" required upholstering. After taking in his surroundings his first exclamation was, "What an elegant place for a mine!" Subsequently successful mining was done in that section, but several miles from the "elegant" location and in a country almost devoid of vegetation.

Ore deposits in their occurrence are no respecters of persons. They are where they are, and those seeking them for exploitation should be prepared to supply any deficiencies which might be needed to secure a product suitable for treatment. Whether those deficiencies be water, fuel, labor, or other requisites, the economical procuring of them forms a part of the engineer's task in opening and operating the mine.

Prospecting, although somewhat lax during the last few years, still continues in many corners of the globe, and is followed by exploration, and, if circumstances warrant, by development. That climatic conditions are severe and that other handicaps are present do not prevent the constant search for orebodies or the procuring of metals. This has been true and will remain so.

In the article "Desert Prospecting," which appears in this issue, Mr. Leroy A. Palmer points out many of the conditions that may be expected by those engaging in that branch of investigative work. There are undoubtedly drawbacks that discourage prospecting in the "desert provinces," although several decided advantages, such as the lack of vegetation and soil covering, are favorable factors in these localities. Neither the prospector nor the mining engineer can have everything.

One Reason Mining Languishes in Colorado

IT IS A FACT that mining is not as prosperous as it once was in Colorado. This is due to the exhaustion of some mines, the pressure of economic conditions, the relatively few discoveries in recent years, and the fact that mining activity seems to be recurrent in irregular cycles. In the aggregate, the amount of mining that goes along in a steady stream unnoticed is relatively large. The newly discovered district is the center of attraction; the steadily producing mine is apt to be overlooked. The backbone of the industry is, however, these steadily producing mines.

To maintain the volume of mining, new mines must necessarily be developed and brought to production to take the place of those which are approaching exhaustion. Fresh capital and intelligent and honest promotion are important factors in bringing prospects through the various stages to the producing mine. Nothing can do so much in giving a state or a mining locality a bad reputation as unwise or dishonest promotion. Legitimate enterprises suffer. Capital is made more difficult to secure, and the whole industry must endure the consequences, both directly and indirectly. A particularly vicious example of questionable promotion practices has come to our attention in a four-page advertisement of the Redcliff Mining & Milling Co., appearing in the Sept. 25, 1920, issue of the *Daily Mining and Financial Record*, of Denver. We quote two brief extracts:

> Your Fortune is in Reading this Advertisement.
>
> The biggest proposition ever offered to Womankind and Mankind in the History of the mining World.
>
> Stock is $1 per share and never again will you have the opportunity of buying it for any less after this association is completed. Your fortune is before you; your brains and your judgment is your action. The time is now—today—this minute. Be sure you read every word.

Whatever of merit there may be in this particular offering, it is our opinion, after reading the whole advertisement, that no intelligent human being would care to put his money into it. The extravagance of the claims, the inconsistencies of statement, the unrestrained use of ink and type are an insult to the community in which such an advertisement is circulated and a reflection upon the industry of a state which has occupied a unique position in the mining industry. It is time for those who have the interests of Colorado at heart to put the stamp of disapproval upon such practices. The publication of such matter constitutes one of the reasons why mining languishes in Colorado.

We note that there appears in the advertisement an extracted report written by Forbes Rickard under date of April 5, 1911, on the property in question. In the advertisement the report is erroneously signed Robert Rickard, instead of the correct signature, Forbes Rickard. We have ascertained that Mr. Rickard visited the property on his own behalf and out of kindness gave one of the interested parties, a miner, a copy of his report. It was used without his permission in the advertisement; nor did he give the parties permission to use his name as a reference, which is done in the latter part of the advertisement.

The report in question is conservative and in refreshing contrast to the rest of the advertisement. Written over nine years ago, it undoubtedly gave a fair estimate of the possibilities of the property in question, as they existed at that time, but its author could not foresee present economic conditions. Nevertheless, it serves as a warning to the person who has the patience to wade through the advertisement. Mr. Rickard is an innocent party to the whole affair, being drawn into it without his knowledge or consent.

The Divining Rod Again

THIS is the busy season for the bandit gold and the divining rod business in the Middle West. According to the *New York Sun*, a Kansas City dispatch reports great activity "near Indian Springs," in Kansas, the home of grasshoppers, cyclones, and W. J. Bryan. It seems that

"Fifty years ago a robber band fled thither from a daring, Wyandotte County robbery and buried its glittering pelf."

Pretty good as a starter to one of our bedtime story series:

Act 2 The Wiggler

Upon the scene there arrives one Bartels, with two others, in possession of a magic divining rod, a "gold indicator," which, however, appeared to the profane eyes of Miller, the owner of the farm whereon the treasure was located, as simply "the butt end of a buggy whip with a wire spring on the end." More necromancy. "It was explained that if the spring wiggled while the instrument was held over any spot it was useless to dig there, for no gold would be found; if it didn't wiggle, that was the place to delve for wealth. Therefore, the only requirement for finding gold apparently was an iron nerve and a steady hand on the part of the prospector.

"Taken to the top of a hill the spring wiggled frantically. In the ravine below, it refused to "indicate." The three men began to dig strenuously. At four feet they found an Indian arrow head. The dirt fairly flew. And then at sixteen feet they found—the skeleton of a horse."

That was all. The amateur miners did not get deeper. Like the green Leadville miner, their "hole had come to a point," and the limit of depth possible to engineering skill had been reached. "It was Saturday night, time was up, and the expedition returned disconsolate." What magic inhibition prevented them from working after this Saturday night, the story does not say; doubtless they were poor spirits who had to return to their ghostly vigils when the clock struck twelve. The terms of the contract which they had made with the owner refers to this mystery, among other interesting clauses:

"For the digging rights, $25. Only one hole to be dug One-half the treasure to go to Mrs. Miller. *No fair digging after Saturday.* Oil, gas, coal, or lead found incidentally to be Mrs. Miller's."

Oh, the rare optimism of this "incidentally"! Would that we were boys again, or owned a divining rod, $25, and three free days, and could dig for bandit gold, and, "incidentally," oil, gas, coal, and lead—yes, and diamonds and pearls. We should have put these into the contract.

This divining-rod business should be organized. A $25,000,000 corporation would not be too much, even though a start can be made with $25 and a buggy whip. We look to see the scattered industry united and properly equipped.

Desert Prospecting

Conditions Characteristic of the Arid Regions—Topographic Features Frequently Deceptive—Principles To Be Observed in Investigations of Dry Placers—The Occurrence of Water

By Leroy A. Palmer
Written for *Engineering and Mining Journal*

IN A RECENT ISSUE of *Engineering and Mining Journal*[1] I gave a description of an outfit which I had used with success for desert travel and made suggestions as to conduct in camp and on the trail. Those whose work is of such a nature that they are interested in an article of the kind mentioned may also find interest in a brief discussion of various geologic and topographic conditions which are characteristic in a large degree of the arid regions. The features which I purpose to discuss are not limited strictly to "the land of little rain," but I have found them best developed under its influences, so that they may fairly be considered to be characteristic of it.

Disintegration Through Temperature Changes

In the disintegration of the rocks of the desert provinces, physical agencies play a more active part than chemical, and attention has been directed to the lack of moisture, both as precipitation and in the air, the principal chemical reagent in the alteration of rock. A very important feature in disintegration, however, is the action of heat and cold.

As is well known, there is a considerable difference in temperature between day and night in the American desert. Desert nights are proverbially cool, and when one gets away from the valleys and into the mountains there are very few, even of those following the scorching days of summer, in which a blanket does not form a useful part of the bed clothing.

This diurnal range in temperature is fairly uniform throughout the year, the difference between night and day in winter being much the same as in summer. It is by no means unusual for the desert dweller to break the ice in the bucket to get water to wash on a winter's morning, shed his coat for greater comfort before noon, only to button it about him the more closely before the sun has dropped out of sight in the evening.

Because of the light soil cover, or the entire lack thereof, the rocks are more directly affected by temperature fluctuations than they would be if heavily mantled with soil and protected by forest growth. Rocks are poor conductors of heat, a fact which makes itself apparent to anyone who goes underground. Poor conductors expand and contract readily under the influence of heat and cold. A classic demonstration of this principle is the comparison between silver and mercury. The conductivity of mercury is 1.3 in a scale in which silver is standard at 100. The coefficient of cubic expansion of mercury is 0.0001001 to 0.0000318 for silver, or in the ratio of 3.15 to 1. In accordance with this principle, the alternate heating and cooling to which the rocks are subjected by the daily changes in temperature is accompanied by a considerable expansion and contraction. Though this action often results in a considerable "shelling off" of thin outer layers, it is natural that the heaving which accompanies such expanding and shrinking should take place along the joint and bedding planes, as being the lines of least resistance, thus tending to open them still wider. Such moisture as is precipitated on the rocks largely follows these openings, and in winter the frost working into them causes a heaving and a splitting along fairly regular lines. Some of the results of this action will be discussed later.

[1]Jan. 31, 1920.

Erosion by the Elements Active

Ordinarily disintegration and erosion are so closely associated that it is natural to think of one as essentially accompanied by the other, but in the desert they do not always work in conjunction with each other. In the later consideration of alluvial aprons we shall note that the disintegration of the rocks of mountains is frequently accompanied by the building up of their

FIG. 1. CANYON IN ALLUVIAL APRON

slopes instead of their denudation by the activities of erosive agencies, so that from the standpoint of volume there is little change in the mountain mass.

Water as an agent of erosion is active in the desert, as is evidenced by many a deep canyon with steep cut, almost perpendicular sides. This erosion is not the result of a slow wearing down of a perennial stream, but is rather the action of intermittent rushing torrents. The mean annual rainfall is low, but the higher slopes receive a considerable precipitation, one year with another, and this precipitation is likely to be concentrated in a few heavy storms instead of scattered through the year or through a long rainy season.

It is frequently the case in a mountain watershed that some one canyon or valley, often the trunk channel, has tributary to it a catchment area far out of proportion to its normal carrying capacity. The steep canyon sides, bare rocks, and exceedingly limited vegetation tend to a high percentage of run-off within a short time, so that when these torrential rains come, the precipitation over a large watershed is rapidly concentrated in a narrow canyon or small valley, and a raging torrent is formed where a few hours before was parched sand and blistering boulders.

A person who has not seen one of these desert floods can hardly conceive of their treachery and tremendous

force. It would almost seem that a jealous Providence sends them on occasions to warn Man of his insignificance and the instability of his works. As a tenderfoot I worked on the construction of the Los Angeles & Salt Lake R.R. while it was being built across the Nevada desert, and I could not understand the necessity of putting in bridges 200 ft. and more in length opposite insignificant looking side canyons whose channels did not give the appearance of ever having carried more than sufficient water to wet one's feet. I saw that same railroad after a flood—eighty miles of it wiped out of

FIG. 2. PSEUDO-FAULT

existence, ninety-pound steel twisted into loops, a whole freight train swept off the track and slammed against the side of a mountain—Man's deepest thought and highest skill set at naught by Nature's forces.

Wind is an active erosive agent in the desert. The arid regions are generally windy throughout the year. Were it not for the winds of summer they would scarcely be habitable during that season, and the winds of winter and spring are frequently of great severity, there being little in the way of trees or other vegetation to act as a protection for the surface. When the wind becomes violent it sweeps up quantities of sand and fine gravel and drives then with it in the terrific sandstorms for which the desert is noted and whose violence can scarcely be exaggerated.

These sand- and gravel-carrying winds exert an active erosive force, which is frequently manifested in the weird and picturesque forms into which the rocks are carved. The Old Woman Mountains, in the eastern part of the Mohave Desert, in California, get their name from one of these odd shapes, which resembles a woman carrying a child in her arms. The entire range presents a skyline of serrated peaks and castellated crags as a result of this æolian action.

Alluvial Aprons Have Appearance of Conglomerates

Among the most prominent features of desert geology, notable topographic features as well, are the alluvial aprons or outwash slopes of the mountains. These outwash slopes are found in a greater or less degree of development bordering practically all of the wider valleys. They extend from the low part of the valley in a uniform slope onto the flanks of the mountains which border it, and sometimes actually reach to the summits of the outlying peaks. Their composition exhibits the sorting of water and wind, the higher parts of the slope being composed of coarse rock fragments which grow finer as one descends, so that the foot of the slope in the low part of the valley is fine sand.

In a region of heavy rainfall, as the rocks disintegrate a considerable portion of the soil so formed is immediately washed from the slopes by the rains, finds its way into the watercourses and finally carried into the larger streams and removed from the region.

In the desert the result is different. As I have indicated, under conditions of aridity physical forces play a more active part in the disintegration of rocks than chemical forces, with the result that the pieces into which the rock is broken are coarser. Then there is not the rainfall to remove the broken pieces with the same rapidity as elsewhere. Hence they accumulate about the slopes, filling first the shallow gullies of moderate grade and then the steeper ones, continuing in this way and drifting with the high winds characteristic of the desert until they have built up a slope that is comparatively uniform.

The sand and gravel of these alluvial aprons assume a compact structure so as to make, or at least approach, a conglomerate. This is particularly so if calcium carbonate or some other cementing material is available in the rocks of the upper slopes, so that it may be taken into solution and form a binder for the unconsolidated material through which it percolates. In such cases the canyon streams, debouching from their narrower confines into the broader valleys, trench deeply into these outwash slopes, which stand well in their consolidated state, and the result is a canyon-like watercourse, frequently very narrow, with high, steep-cut walls, as shown in Fig. 1.

Deceptive Topography

In the discussion of the subject of disintegration it has been stated that, under certain conditions, rocks have a tendency to rupture along joint or bedding planes instead of yielding to a slow breaking down into soil. This leads to the development of topographic features which may readily receive an erroneous geologic interpretation if conclusions be drawn on casual

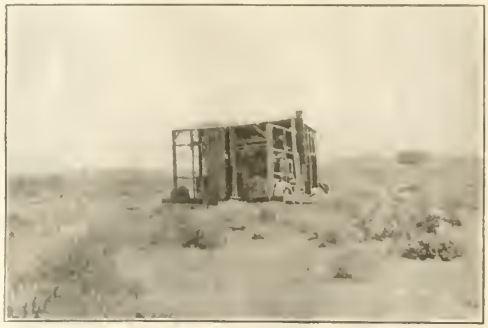

FIG. 3. DRY WASHING MILL, GRANITE MOUNTAINS

observation. Chief among these I would class certain forms which might be mistaken for faults and others which might appear to be the result of glacial action. These will be considered briefly, although the subject is one which is of interest from the academic rather than the economic standpoint.

The pseudo-faults, if I may be permitted to coin such a word, appear as bold escarpments which are the result of the action of such disintegrating forces as those mentioned, acting along joint or shrinkage planes so as to split the rocks along lines approximately vertical.

This is particularly noticeable in the cases of some lava flows coming under my observation which have assumed a columnar structure on cooling. These columns have been split off, whole ones at a time, by frost working along the planes of cooling, so that an abrupt cliff which might readily be mistaken for a fault scarp remains.

Another occurrence, which is of even less importance from the economic standpoint, is a form of topography which bears every resemblance to that resulting from glacial action. I have never found evidence of real glaciation in the desert, but in the Mohave Desert I have seen such topographic manifestations of nearly all of these phenomena as might well be called "text-book illustrations." But, like the escarpments, whose appearance is likely to convey an incorrect impression of faulting, these evidences of glaciation will not stand up under critical scanning.

Economic Features

Nearly all of the minerals that are found anywhere occur in the desert, but it is a region in which prospecting has been far more limited than in the better-watered localities. The reason for this is obvious. It is human nature to follow the line of least resistance, and where one man has the hardihood to face the desert a dozen men choose a country in which conditions are not so rigorous.

Certain minerals, notably of the salines, are characteristic of the arid regions and are found in but few other places in this country, but their origin and occurrence form by far too broad a subject to come within the scope of this article. A consideration of some of the desert forms of deposits common to other localities as well should be of interest.

Desert Prospecting Has Numerous Advantages

As has been indicated, prospecting in the desert is simplified by the fact that dense vegetation is wholly lacking and soil covering is not heavy, occurring usually in scattering patches of limited extent. As a consequence, the correlation of different formations and the tracing of veins is rendered easier than in a locality with heavy soil and luxurious vegetation. This is exemplified in many ways. For example, the relations between outcrops and prospect workings are more readily recognized.

Float does not migrate to the extent that it does in a country in which the mountainsides are traversed by numerous streams and rivulets, which may assist in carrying a piece a long distance from the point where it was broken. Consequently, outcrops may be sought generally within a reasonable distance of float, and topography forms a fairly reliable guide as to the relative positions of the two.

Dry Placers Require Special Consideration

One of the interesting forms of desert deposits is the dry placer, so called because it occurs under conditions that require working by some means other than the application of water in one of the methods usually prescribed for placer mining. These deposits are usually found under the same topographic conditions as placers in other localities, occurring in a gulch or canyon where the gold has been carried after erosion from veins or stringers on a mountainside and within the catchment area. I have found them, however, in quite unlooked-for places, one such occurrence being near Williams Well about twenty miles northerly from Barstow, Cal.

This deposit is in a flat of very gentle topography, so gentle, in fact, that in some places it is difficult to tell just where the low places are. The region is underlain by an intrusive granitic rock, and, being nearly flat, has accumulated a considerable covering of soil, especially in the gulches or such depressions as formerly existed, so that these have been filled to such an extent that it is not always easy to distinguish them from the points that were higher originally. The intrusive is traversed by quartz veins carrying considerable iron and associated with basic dikes. The gold is rough, which, in connection with the topography, indicates its near-by origin, as the flat is in reality a plateau, and drainage is away from it rather than to it. The gold has accumulated in the shallow depressions, and some pieces of fair size were found. It lies close to the surface and is associated with float hematite, which impregnates the soil, the size of hematite pieces being some criterion of the size and amount of gold found. An interesting feature that I noted in examining this deposit was that the gold was almost invariably discovered where a small yellow flower grew.

FIG. 4. COLTON WELL, PROVIDENCE MOUNTAINS

Of course the explanation is simple enough. The liberation of the gold from its inclosing matrix is accompanied by the disintegration of one of the associated rocks or minerals, which weathered to a soil favorable to the growth of this particular flower. In this case the mineral was probably the hematite, as it was found closely associated with both the gold and the flower.

Some time ago an attempt was made to work a wide shallow gulch on a large scale with the dry washing mill shown in Fig. 3, but the project failed for the same reason that many another mining venture has gone wrong. The promoters neglected to explore their ground carefully beforehand, and soon exhausted that portion that was amenable to handling by the process installed. As the illustration shows, the mill was on wheels, or rather rollers, so that it could be kept close to the excavating, performed with plow and scraper. It was moved by winding a cable from a deadman to a winch in the mill. This process of handling and treating returned a good profit during the limited time that it was in use.

The usual and generally accepted rule that placers grow richer as bedrock is approached does not necessarily hold true in the desert. It can readily be seen that the natural result for a deposit in the bed of a running stream in which the gravel is permeated with water and subjected to its continuous action would be that the gold, being heavier than the gravel, sinks and tends to concentrate on the bedrock, but this is not

the case with desert deposits. Such water action as they receive is intermittent and frequently in the form of sudden floods, which rise quickly and subside before the water really has time to sink through the stream gravels to bedrock. Consequently, its influence extends only to shallow depth, and the richest placer may be found within a few feet or even a few inches of the surface, whereas the bedrock is practically barren. This is particularly the case with deposits such as that found at Williams Well, where concentration does not occur in well-defined stream channels but in depressions in a comparatively level surface and near the lode in which the gold originated. In desert deposits, and notably those of the kind just mentioned, enrichment is not so much the result of the concentration of the valuable portion as of the removal of the valueless. To borrow a comparison from the gravity concentration of ores, I may liken the concentration of the gold in the bed of a running stream to that which takes place in a jig in which the heavy mineral settles against the action of a current of water, whereas the shallow desert placer is comparable to the vanner, in which the heavy mineral clings against a current that washes the lighter away.

Water Scarce but Usually Available

Water is by no means as scarce in the desert as popular conception assumes. There are occasional springs and tanks—both open and "stand" tanks—so that one who knows the country need not, as a rule, go very many miles for an amount sufficient for the needs of a prospecting party.

Water from underground sources is frequently available without much work. One who is simply passing through a country on a prospecting trip will not find it advisable to stop in one locality such time as might be necessary to develop a supply, but if he is establishing a small camp for prospecting development he can frequently satisfy his needs without going a great distance or expending too much labor. In most such cases location and development of water are not so much a matter of technical skill as applied common sense. As water locators, some desert animals, coyotes especially, are far ahead of the witch with the forked stick. I have seen more than one water hole developed where a coyote had shown the way. Seepages along joint planes or fractures frequently are followed with good results, or fracture zones may be found productive even if no water appears on the surface. Fig. 4 is a well used to water several hundred head of cattle and was made by sinking about fifteen feet on a fractured zone in granodiorite and then crosscutting a few feet to expose the zone to its full width.

Alluvial basins and canyon bottoms usually hold water in considerable quantity, and where they are crossed by ribs of rock the water is forced toward the surface. Under these conditions digging will usually develop water at no great depth, but care should be taken to locate the well such a distance above the barrier that rock will not be struck within the influence of evaporation from the soil, which is somewhere about eight to ten feet under average conditions. If this is not done, the result will be a dry hole, but if the limit of evaporation is passed with the hole still in alluvium, and within the influence of the rock barrier, a supply should be found at reasonable depth, the amount varying, of course, with the geological and other conditions affecting the location of the hole.

Importance of Rhodesian Chromite

For some years previous to the war, Rhodesia was the chief producer of chromite, though its output was almost equalled by New Caledonia, according to *The Ironmonger*, the combined yield of these two countries amounting to nearly 90 per cent of the world's production. During 1918, however, the Rhodesian output declined, owing principally to lack of ocean freight facilities and to competitive production in the United States, Canada, and India. Thus the total shipments in 1918 were only 37,875 tons, as against 59,321 tons in 1917 and 87,406 tons in 1916.

The total output of chromium ore in southern Rhodesia up to and including 1918 amounted to 581,558 short tons, valued at £1,718,241. This total value exceeds that of any other mineral produced in southern Rhodesia except gold. Chromite occurs at many localities in Rhodesia. Of these the best known are those of Selukwe, Makico, and Lomagundi, but productive mining has hitherto been confined to the Selukwe property, which has been worked since 1905. The deposits at Selukwe consist of numerous lenticular masses of chromium ore in a matrix of talc-schist and serpentine. The ore is won very cheaply by open-cut mining, and the cost of production is merely nominal, amounting only to a few shillings per ton. The ore as marketed contains from 42 to 51 per cent of chromic oxide, 8 to 15 per cent of magnesia, and 14½ to 16½ per cent of alumina. The best ore contains on the average about 50 per cent of chromic oxide. The material is sent by rail to Beira and shipped to Europe as crude ore. Shipment was suspended for a time after the outbreak of the war in August, 1914, but was resumed in December, and the output for 1914 showed a substantial reduction compared with 1913. The output rose again in 1915, 1916, and 1917, despite the fact that exportation was hindered by lack of shipping facilities.

The price per short ton realized for the ore during 1917 was £4 9s. 7d., an increase of 14s. 7d. per ton compared with the price during 1916. This increase in value stimulated prospecting, which resulted in the discovery of a large deposit in the Lomagundi district. Lack of shipping facilities, however, caused a serious fall in production during 1918, and the output for that year was confined entirely to the Selukwe mines.

Sand-Lime Brick Production Increased in 1919

The sand-lime brick produced in the United States in 1919, according to an estimate made by the U. S. Geological Survey, amounted to 145,000,000 brick, valued at $1,725,000, an increase of 47,000,000 brick and of $841,000 over 1918. The maximum output of sand-lime brick—227,344,000 brick—was made in 1916, but the maximum value was that of 1919.

The output of common brick was 142,755,000, valued at $1,688,000, an increase of 45,937,000 brick and of $822,000 compared with 1918. The rest of the output was face brick, which showed an increase of 664,000 brick and of $19,000 compared with 1918. The average price of common brick per thousand in 1919 was $11.82, compared with $8.94 in 1918, $7.54 in 1917, and $6.43 in 1916. The average price of face brick in 1919 per thousand was $16.48, compared with $11.35 in 1918, $9.36 in 1917, and $9.64 in 1916.

Present Value of Deferred Profits

In Which the Mining Engineer's Spouse Confounds the Stock Salesman and Points Out a Few Neglected But Important Considerations in the Sale of Mining Stock

By Mrs. Ernest Lee Waite*
Written for *Engineering and Mining Journal*

THE wife of a mining engineer is, *ex-officio*, a potential authority on deferred profits. Furthermore, present value is to her a matter more vital and urgent than it can possibly be to any other class of mining investor. Therefore no apology or further explanation is necessary for what may seem to be an instrusion upon a special field of technical finance or financial technicality.

Suppose that a representative of a reputable broker calls and submits an offer of shares of the "Pasado Mañana Silver Mines, Ltd." He is well trained in his business, and presents a masterly argument to show how this British corporation is controlled and managed by technical experts; and that the profits from treating the present ore reserves will produce dividends equivalent to 10 per cent per annum on the investment for fifteen years and an additional amount to provide a sinking fund, which, reinvested at 4 per cent, will replace the original investment at the end of the fifteen years.

"That sounds interesting," says Mrs. Engineer; "in effect, you offer me an extra profit of 6 per cent per annum for the entire period of fifteen years, above the conservative rate of 4 per cent per annum. But if I leave all my money in a savings bank or in good bonds, I can get 4 per cent interest and compound it semi-annually. Do you mean that if I buy these shares I can save the same amount of money and also have the extra 6 per cent per annum as pin money during the entire fifteen years?"

"Practically so," replies the salesman, who feels that the signing on the dotted line is but a matter of moments. "It is like this: It will take five years to equip the property with hoisting machinery and treatment plant. After that period of deferment the life of the present ore reserves is calculated as exactly ten years, during which time uniform dividends will be distributed at the end of each half year. As a matter of convenience the issue of Class A preference shares, with a par value of £10 each, has been determined as with a total par value exactly equal to the calculated total net profit available from the present ore reserves. During the ten years dividends are to be distributed, to the holders of this first issue of preference shares, at the rate of 10s. per share at the end of each second quarter. Putting this in terms of American money, for each dollar of nominal capital there will be distributed twenty payments of what you Yankees would call a 'jitney' each, eh? Quite so. Now, to determine the present value, at which figure we offer you the shares on account of your husband's profession, we employ the formula given on page 46 of this excellent book."[1]

"Oh, I see," murmurs the proposed investor; "I am quite familiar with that volume. It is excellent, as you say, in many ways. I often use it in calculating values when my husband and I are preparing his report. That is what we call the 'selling formula.' But when we are working things out in the interest of a possible buyer, we arrive at a present value by another route. In that case, it is desirable to allow compounding at the full remunerative rate during the deferred period. In fact, not only desirable but almost imperative; since the risk feature of the investment is compounded during the time that the mine is earning nothing. In ante-bellum days such a point might have been debatable; but now, with the disorganization of all the elements of costs and realization, the seller of a mine is indeed lucky to cash in at a present value calculated by almost any formula."

"But, madam, consider the speculative value of increased reserves that may be developed during both the deferred and the calculated operating period."

"That is a factor which I have not overlooked," is the calm response. "Such speculative value is one of the major elements that influence trading in mining shares. It is almost invariably discounted and rediscounted. In a private transaction in shares such as you offer, it might be called a trade discount to the profession; and therefore it has no place in the calculation of the price at which the shares are to be offered. Coming back to your formula: If we substitute the known interest and time factors as you have stated them, we have, for the present value of the £1 per year,

$$P = \frac{\frac{\left(1+\frac{.04}{2}\right)^{10\times 2}-1}{.04}}{1+.10\,\frac{\left(1+\frac{.04}{2}\right)^{(10+5)\times 2}-1}{.04}}$$

"The solving of this equation, to learn the supposed value of each £10 share, is a mere detail for some intelligent hireling. But the essence of it all is that the formula is devised to give the maximum plausible valuation. It is plausible when examined in a superficial way, but upon close analysis its falsity may be demonstrated. For instance, when the deferred period is taken as zero, the numerator and the denominator show common terms which may be factored so as to produce an equation identical with that of formula 9*a* on page 37 of this same excellent book; giving us

$$P = \frac{1}{\frac{.04}{\left(1+\frac{.04}{2}\right)^{10\times 2}-1}+.10}$$

as the value, at the beginning of the operating period, of the ten-year annuity of £1 per annum in semiannual instalments of 10s. each. I should like to ask you whether this will give the correct value per share at the date when the mine begins its era of actual earning."

The salesman notes the algebraic simplicity and feels

*Hope Cottage, 23 Bishopsgate Street (Without), London.†
†Address guaranteed—to be fictitious.—EDITOR.
[1]"The Valuation of Mineral Property," by T. A. O'Donahue; published by Crosby, Lockwood & Son, London, 1910.

that it is safe to reply affirmatively. Upon consulting a table of annuities he states that the value, presumably computed by an identical formula, would be £7 1s. 8d.; equivalent to $34.47½ at normal exchange. He also states that the present value, at the beginning of the deferred period, as calculated by the formula first given, works out as £4 16s. 1d., or £4.805, and equivalent to $23.38 at normal exchange; being less than half of the par value of £10, or $48.66½ at normal exchange.

"That is extremely enlightening," remarks the modern Portia, "but in getting your £4.805 you shed what you British might call the 'bloody insurance' on the accumulated interest credit during the deferred period. Following the same principle as shown on page 45 of this really useful book, we get these items that I am jotting down:

Principal	£4.805
Interest at the rate of 10 per cent on £4.805 equals £0.4805, and £0.4805 per annum for five years, compounded semiannually at 4 per cent per annum amounts to	2.631
The amount of the principal at the end of the deferred period is therefore	£7.436

You see, it is very simple for me to figure this out; as I use the factor 10.94972 for ten semiannual periods at 2 per cent, as given in the handy interest table on page 70 of the same book, multiplying it by £0.240½ as the interest credit for six months. I say interest *credit* because it is not interest actually paid out, but merely a promise. If the original invested capital requires the remunerative rate of interest in the way of additional profit bargained for as insurance on account of the element of risk, as explained on page 7 of the book, then is it fair to evade the maintenance of insurance on the accumulated interest credit? I say it is not. Just see the difference between the valuation with a deferred period of zero and the calculated amount of the principal at the end of a deferred period of five years. As the deferred period is increased, so the discrepancy becomes greater."

"Ah, yes, madam," replies the expert, "but that is readily explained by the fact that in each case the unit of original capital, upon which the remunerative rate is applied, is a different amount."

"Quite true," assents the other, "that is where part of the deception comes in. To correct it, for each class and kind of mining investment there would have to be a special sliding scale of remunerative rates, applying a different one for each variation in the deferred period. Further, the *actual* remunerative rate on the equity of accumulated principal keeps dwindling lower and lower as the operating period approaches.

"When you offer me an investment on the basis of netting me an extra 6 per cent per annum over and above what I can accumulate at a conservative 4 per cent rate, you certainly rouse my gambling spirit. Now, anybody with a gambler's instinct also has a desire to spend money. I *do* want the extra 6 per cent, but I want to spend it as I go. I should have to sell a little of the stock from time to time, or else put it up as collateral and pay current loan rates and submit to ordinary bank discount or worse. Am I right?"

"Bless my soul, my dear madam," is the earnest response; "I should advise you, by no means dispose of the shares at any early date. This is a most extraordinary mine, and it will be an easy matter to find parties who will accept the shares as security. In fact, our house will introduce you to a private banker who is most accommodating. Let me see, did you say 100 or 200 shares?"

"Ha! Ha! Mr. Broker-man, I did not say any amount; but here is what I am willing to do: I know all about your mine, as my husband tried to option it several years ago. We are quite satisfied as to the ore reserves, but the profit will of course depend upon future conditions in the Republic of Tortillas. The remunerative rate of 10 per cent and the sinking fund rate of 4 per cent are about right as dating from the end of the deferred period; but an accumulative rate of only 4 per cent during the deferred period is entirely out of harmony with banking customs for borrowers. You go back to your office and figure out the compound bank discount operation to show the proceeds of £7 1s. 8d. times 200, discounted semiannually for five years at the average bank rate during the past five years. Multiply your answer by the current sterling exchange rate to get the price in dollars. I will then fill out my check for that amount and instruct my bankers to deliver it to you in exchange for a certificate for 200 shares of the Pasado Mañana Silver Mines, Ltd. Good afternoon."

New Designations of Bureau of Mines Stations

The Bureau of Mines has renamed its mining experiment stations, designating them by their line of work or with reference to the district in which located. Hereafter the stations will be designated as follows:

Name	Location	Work
Petroleum	Bartlesville, Okla.	Oil.
Pacific	Berkeley, Cal.	Chemicals; magnesite; miscellaneous.
Ceramic	Columbus, Ohio	Ceramics.
Alaska	Fairbanks, Alaska	Development of resources of Alaska.
North Central	Minneapolis, Minn.	Utilization of low-grade iron ores.
Pittsburgh	Pittsburgh, Pa.	Mining, largely coal; electrometallurgy.
Rare and Precious Metals	Reno, Nev.	Rare and precious metals.
Northwestern	Seattle, Wash.	Ceramics; coal washing; electrometallurgy.
Inter-Mountain	Salt Lake City, Utah	Low-grade lead and zinc ores.
Southwestern	Tucson, Ariz.	Low-grade copper ores.
Central District	Urbana, Ill.	Coal.
Southern	Birmingham, Ala.	Iron and steel; coal; coke; byproducts; non-metallics.
Mississippi Valley	St. Louis, Mo.	Lead and zinc.

German Iron Mines in France Sold

The iron mines near Villerupt, in the north of the Briey basin, which belonged to the Rheinische Stahlwerke and the Krupp Works, have been bought through the intermediary of the Société Métallurgique de la Loire by the Steinfort Steelworks of Luxemburg, according to the *Mining Journal*. The Steinfort Steelworks, formerly the property of the German firm of Felten & Guilleaume, passed into the hands of the Société Métallurgique de la Loire some months ago. They have five blast furnaces, one open-hearth furnace, and electric steel works, and a steel and rolling mill, as well as a foundry, are to be built. A company has been formed with a capital of eight million francs for the exploitation of the iron mines, whose annual output before the war was from 600,000 to 700,000 tons.

The Mining and Metallurgical Industry of Norway

Brief Review of Resources and Past and Present Production — Iron Still the Most Important Metal, With Copper and Molybdenum of Secondary Interest — Development Dependent Upon Increased Application of Electric Power

By Matthew R. Blish
Scandinavian Representative of the Liberty National Bank of New York
Written for *Engineering and Mining Journal*

THREE distinct ore fields occur in Norway. One is in the southern part of the country, containing copper, iron, nickel, silver, zinc, and molybdenum. This field is an extension of the great ore belt of central Sweden, and, although much smaller in extent, contains somewhat the same character of ores. The second field is in the central northern part of the country around Trondhjem, and contains iron pyrites, copper, chrome, and zinc. The third large field is in the Far North, and here are found iron and copper. Table I shows the production of the various ores from 1896 to 1917. Limestone, upon which the electrochemical industry is based, is found in five different places, namely the Christiania field, the Bergen tract, the coast district in Romsdal amt, the Trondhjem field, and the deposits in Nordlands amt. Besides these, granite, labradorite, soapstone, slate, apatite, and feldspar occur.

Several Mines Hundreds of Years Old

Some of the mines of Norway have been worked for many generations. Probably the first attempt to extract minerals from the ground was made at the old iron mines in the southern part of the country, about the middle of the sixteenth century, at which time the production of charcoal iron began. Next in age come the silver mines at Kongsberg, which were opened in 1623 during the reign of King Christian IV. At one time these silver deposits were among the richest in Europe. The copper mine at Roros has been in uninterrupted operation since 1646, or about 275 years. Before the world's large mining centers came to be of such great importance, and our present rapid transportation, these mines were of far greater value to the economic life of Norway than they are at present.

The production of iron pyrites held first place for many years, and in fact it was not until 1915 that it was surpassed by iron ore. The ores in the southern and northern iron fields are of quite different characteristics, and each must be considered by itself. The southern ores contain about 54 per cent of iron, are non-magnetic, necessitating hand picking, and some deposits show a large content of titanium, which renders the ore unfit for reduction to iron. The phosphorus and sulphur content are low. These ore have been used for centuries by the old Norwegian iron works, which began at the end of the sixteenth century to smelt down the ore by the use of charcoal.

The production of pig iron continued intermittently through the years which followed, reaching a high point of 9,900 tons per year in 1845. About this time the lumber trade became a competitor of the iron works for the products of the forests, and the use of charcoal for smelting became too costly to allow the Norwegian pig iron to compete with the iron which was now beginning to be produced in other countries by the use of coke. The production of pig iron fell to 1,000 tons in 1880, and continuing this descent reached the figure of 400 tons in 1905, produced by only one plant near Tvestrand, whereas at the end of the eighteenth century there were no less than eighteen companies with twenty-two furnaces.

TABLE I. TABLE OF MINING OPERATIONS

Average Yearly Production in Metric Tons

	Silver Ore	Copper Ore	Nickel Ore	Iron Ore	Zinc Ore
1896	527	29,910	...	2,000	...
1901–05	868	38,134	4,512	51,452	948
1906–10	2,170	36,940	8,492	102,311	1,869
1912	4,027	60,018	30,697	408,092	40
1913	5,411	70,349	49,990	544,686	897
1914	7,372	57,951	48,529	652,273	243
1915	8,431	56,097	77,018	714,917	1,829
1916	7,515	28,670	79,903	417,899	1,017
1917	7,147	39,298	69,639	302,739	269

Average Yearly Production Value in 1,000 Krone

	Silver and Silver Ore	Copper Ore	Nickel Ore	Iron Ore	Zinc Ore	Other Ores
1896	400	1,136	...	14		101
1901–05	474	1,727	89	356	12	104
1906–10	517	1,897	127	1,045	45	87
1912	665	2,584	305	5,400	1	59 (a)
1913	630	2,844	497	7,350	19	37
1914	910	2,697	487	8,460	5	140
1915	1,040	7,844	1,010	11,800	64	1,142 (a)
1916	620	3,280	310	9,390	33	2,170 (b)
1917	980	4,905	2,250	8,380	10	4,971 (c)

(a) Of which 1,040 was molybdenite. (b) Of which 1,550 was molybdenite. (c) Of which 4,125 was molybdenite.

The total production up to 1905 was about 1¼ million tons. During the next five-year period the production of pig iron dropped off to almost nothing, averaging only fifty tons per year from 1906 to 1910. The years 1911 and 1912 saw some improvement, the production in the latter year being 300 tons. When, in 1913, the first electric furnace for smelting ore was put into operation, the production of pig iron by charcoal alone fell to practically nothing, and at present amounts to only a few tons per year.

TABLE II ELECTRIC PIG-IRON PRODUCTION

Years	1913	1914	1915	1916	1917
Tons	346	6,909	8,742	6,233	6,295

Production of electric pig iron from 1913 to 1917 may be seen in Table II. So far all electric iron has been produced from southern ores, but the electric smelting of northern ores is a possibility of the near future, if the plans of certain Christiania business men and engineers materialize.

Northern Iron Deposits Only Recently Developed

Whether or not the existence of iron in northern Norway was known prior to 1900, it was not until 1911 that the large deposits were opened. These ores are magnetic, contain only about 37 per cent of iron, and are higher in phosphorus and sulphur than the southern ores. On account of the low iron content, the practice of concentrating the ore is common, and it is also exported in the form of briquets. By far the largest part of Norway's iron wealth lies in the north. It has been estimated by Professor Vogt, of the Trondhjem

Technical High School, that the total iron-ore deposits amount to 150 to 175 million tons, containing about 100 million tons of iron. The Sydvaranger Iron Ore Co., whose mines are in Finmarken, near the Finnish border, contributed 600,000 of a total export of 715,000 tons in 1915, which was the record year in iron-ore production.

Although the exports of ore since 1911, when Sydvaranger began to produce, have been many times greater than before, the first ore was shipped abroad from the southern mines in the early 60's. The ratio of the ore exported to the ore mined has fluctuated greatly through the years, principally on account of a variation in the demand from foreign countries. These ratios are also an indication of the manner in which the iron and steel industry, owing to a lack of coal, has failed to take advantage of the iron resources which have been available. During the 60's about 30 per cent of the ore mined was exported; during the 70's about 50 per cent; during the 80's about 80 per cent; during the 90's about 30 per cent, during the period 1901 to 1905 about 94 per cent, and from 1906 to 1913 about 96 per cent. Exports from 1912 to 1919 inclusive are shown in Table III. Exports for 1920 are running at a rate of about 120,000 tons.

TABLE III EXPORTS OF IRON ORE AND BRIQUETS, TONS

	1912	1913	1914	1915	1916	1917	1918	1919
Iron ore..	230,123	373,071	311,443	164,506	187,805	150,960	61,443	25,680
Iron-ore briquets.	174,867	195,692	156,352	261,386	216,896	46,875	35,253	7,567

Application of Water Power Necessary

England and Germany have always bought most of Norway's iron ore. There is no indication that Norway's iron and steel industry will develop to any great extent until some substitute has been found for coke in the smelting process, or, in other words, until the almost unlimited waterpower of the country has been made available for this work. Sweden has carried this process to a much higher degree, but attempts to smelt Norwegian ore have so far not been attended with great success. As mentioned previously, a plan is now under way for the establishment of a company to reduce the ore from one of the Northern mines by an electric process. Its projectors are waiting, before proceeding, to get the backing of the Storting to a guarantee for a loan. At present the high price of coal and labor has caused the shut-down of most of the iron mines and smelters. No pig iron has been exported since October of last year.

Copper Industry Suffering From High Costs

The most important copper-bearing ore is chalcopyrite, containing, in one mine in the southern district, 24.5 per cent copper, but averaging for the entire country only about 5 per cent. Iron pyrites, which is mined principally for its sulphur content, contains about 1½ per cent copper. Some copper has also been extracted by a nickel-refining company from nickel ore. These three ores constitute the only sources of copper in Norway. Practically no copper ore is exported as such, and there are no imports of copper ore. Up to the present only a small percentage of this ore is smelted electrically, practically all being reduced by the use of coke. One company, the Sulitjelma Mine, is experimenting now on an electrical method.

As shown in Table V, the exports of copper fell off during the war, beginning with 1916, and in 1919 amounted to only 394 metric tons. The reason for this decrease in the last year is, of course, the slump in the copper market. Copper cannot be produced here with the high coal and labor costs and sold on the present market.

TABLE IV YEARLY AVERAGES OF COPPER PRODUCTION AND CONSUMPTION

Yearly Average in	Copper Production, Tons	Copper Consumption Tons
1891 = 1895	792	1,200
1896 = 1900	1,100	1,328
1901 = 1905	1,260	1,365
1906 = 1910	1,610	1,700
1911 = 1915	2,420	4,420

Table IV gives the production and consumption of copper for several years before the war. Production kept pace with consumption fairly well up to 1911. During the period 1911 to 1915, while production fell short of consumption by 2,000 tons, the exports averaged for this period about 2,100 tons. In other words, the copper production was sold to Sweden, Germany, and England, to be converted into finished copper and brass goods, and reimported into Norway. The demand for copper wire and other copper articles has increased about 3½ times over that before the war, and this demand has been covered in considerable part from the United States. The imports of copper and copper wares in 1913 amounted to about 2,000 tons, and in 1919 to about 7,000 tons. At present nearly all of the copper mines are closed down, and the electrical industry is buying its copper from foreign countries in a finished state ready for use.

The nickel-refining industry obtains practically all of its nickel ore from deposits in the southern field. At present the nickel ore is concentrated by three mining companies, and sold to the Christiansands Nickel Refining Works for refining into metallic nickel. Before the war some nickel-copper ore was imported also. None of the nickel ore is exported as such.

TABLE V. EXPORTS OF METALS FROM NORWAY

	1912	1913	1914	1915	1916	1917	1918	1919
Nickel	385	594	696	761	723	442	60	
Copper	1,551	2,644	2,558	2,691	1,430	1,900	1,254	394
Zinc (*a*)	8,914	10,538	16,517	22,617	28,150	18,395	3,390	3,950
Lead (*b*)	118	30	200		86	70	5	115
Aluminum (*c*)	1,140	2,177	2,942	2,883	4,488	7,601	6,835	3,120
Ferrosilicon	6,022	6,323	6,144	9,308	25,256	29,450	16,861	2,458
Ferrochrome (*d*)			2,796		2,875	3,550	(*e*)	(*e*)

(*a*) Refined mostly from foreign spelter. (*b*) Contains also old scrap lead (*c*) Refined entirely from foreign ore. (*d*) Produced partly from foreign ore (*e*) Figures unavailable.

Refining is carried on by an electrolytic process, invented and developed by the company's chief engineer, Victor Hybinette. The nickel content of the ore is 1 to 2 per cent. Table V shows the exports of nickel from 1912 to 1919. During the war a considerable part of these exports went to Germany. In 1918 the company suffered a loss from fire at its plant, and, owing to readjustments and the drop in the nickel market at the close of the war, no exports were made during 1919. Refining, however, is now proceeding satisfactorily, although no export has been made in 1920. No nickel is imported as such, but certain nickel wares come from abroad, principally from Sweden, Germany, and the United States. Owing to the comparatively small nickel deposits in Norway, it is doubtful whether export to the United States can ever profitably be carried on.

The zinc deposits in Norway are very small and are confined to the fields in the neighborhood of Christiania, Bergen, and in the Trondhjem amt. The average prewar production of zinc ore was only about 1,000 tons, containing approximately 30 per cent zinc, and many of the mines have been unproductive for the last five years.

A small amount of lead is found in certain of these ores. Practically no zinc ore is exported.

Table V shows that there was exported from Norway in war years a considerable quantity of refined zinc, which was, however, refined almost entirely from foreign spelter, mainly from Germany. The pre-war imports of spelter amounted to from 12,000 to 15,000 tons per year. Practically all of the zinc refined from this spelter was exported again, for the home consumption of zinc is small, probably not over 500 tons annually, which is used for galvanizing nails and similar purposes. Since the war most of the spelter has come from Australia. In 1919 the import amounted to 31,000 tons, and although the export of refined zinc did not show an increase in keeping with this large import, this may be explained by the fact that almost no spelter came into the country during 1918. Volatilization of the spelter by electric heating is the process of refining.

Practically the only interest which the Norwegian zinc industry has for the United States is the possibility of sending spelter or zinc ore to Norway for electrolytic refining, and the sale of the finished product on the European market. Although this is looking into the future, it may be considered as a possibility.

As previously stated, the silver deposits in Norway were at one time among the richest in Europe. During many years' operation they have been worked out to such an extent that the government is considering the introduction of a small proportion of nickel into its coins to conserve the remaining silver. This mining industry, of course, has no interest for the United States, except that it may be necessary for Norway to import some silver in years to come.

Previous to the war the ferro-alloy industry consisted of the production of ferrosilicon, which was being made in 1909 by three companies. This alloy is produced from quartz, and scrap iron or iron ore. It is the most widely used of all ferro-alloys at the present time, and as quartz is found in many places and in great abundance in Norway, it is natural that this alloy should be most extensively manufactured.

Next in importance and in quantity of manufacture is ferrochrome. The chrome deposits in Norway are found in the Trondhjem and Nordlands amts. Up to 1916, when 2,757 tons of chrome ore was mined, the production was small. In 1917 a total of 3,975 tons was taken from the earth. These ores contain from 14 to 38 per cent chrome oxide. The native ores were not, however, used to a great extent in Norway for the production of ferrochrome while it was possible to secure the rich African chrome ores. This was impossible during the latter part of the war, but now these ores are being used almost entirely.

Another important ferro-alloy is ferromolybdenum. The molybdenum occurrences in Norway are claimed to be among the most important in Europe, but so far they have been worked to only a small extent. They contain about 80 per cent molybdenite. Ferromolybdenum was used during the war by Germany, but has not so far been used extensively by England and the United States, where ferrotungsten is preferred. The invention of Dr. Arnold, of England, has caused considerable stir here, with the hope that his method of steel manufacture by the use of ferromolybdenum may prove so successful that the mining of molybdenum and the production of the ferro-alloy will be stimulated thereby. It will be years before this hope is realized, and in the meantime the use of ferromolybdenum is not extensive.

Other metals are found in Norway, such as wolfram and titanium, and at the beginning of the war, when the demand for ferro-alloys began to assume enormous proportions, experiments were conducted for the production of such ferro-alloys as ferromanganese, ferromangan silicon, ferronickel, ferrotitanium, and ferrowolfram. With the exception of ferronickel, a small amount of which was exported in 1913, statistics do not show exports of these other alloys. It is now planned to make ferromanganese from ores imported from the Caucasus. The ferro-alloy industry, under the stimulus of war demands, grew considerably, but it still depended mainly on ferrosilicon for its chief support. In 1917, the year of greatest export, the value of this alloy sold abroad was $4,250,000. Experts have stated that success in the ferro-alloy industry lies in the ability to adapt the production to suit the demands and the markets. The industry is based entirely upon the use of electric current, but a small amount of coal or coke for reduction purposes must always be used, and this must come from abroad.

Ferrochrome and ferrosilicon are the only two alloys exported at present, and they are going mainly to England. The United States has no inducement to buy Norwegian alloys now, because they can be obtained at home more cheaply. There is also a duty of 15 per cent on the import of such materials into the United States, and, in addition, the ferro-alloy industry, which was built up during the war, will probably be maintained for a few years at least, even though the production is expensive.

Copper Industry of Japan

Copper deposits are found over a large part of central Japan. The ores, which occur in Tertiary volcanics, consist of chalcopyrite and pyrite running 2½ to 3½ per cent copper, and are commonly concentrated before smelting. The gangue is usually quartzose. Lenticular deposits of cupriferous pyrite in Paleozoic schists and sediments occur on the west and the south side of Japan. These mines yield smelting ore carrying about 3½ to 4 per cent, but contain little silica. Pyritic smelting is extensively practiced. Over one-half the copper production comes from four chief mines: Ashio and Kosaka, of the Tertiary type; and Hitachi and Beshi, of the Paleozoic schist type.

The state reserves to itself the right of original ownership in all ores, including copper. The right to work them is granted to individuals or companies of Japanese nationality. Copper mining, smelting, and refining companies seem to be entirely Japanese in ownership and policy. The number of mines is considerable, but their ownership is concentrated in a few hands, and the smelting and refining industry is still more concentrated. Japanese producers sell their own copper, all foreign selling agencies being strictly Japanese. The mines in Japan are not generally worked as joint-stock enterprises, but are mostly family properties inherited by the present owners.

Because of labor conditions, abundant fuel near the mines, and free water transportation, Japanese copper production has increased rapidly in recent years. High prices and the adoption of modern methods of mining and smelting have been important contributing factors.[1]

The Mining of Paint

The Yellow Ocher Deposits of the Cartersville District, Georgia, Constitute an Important Source of the Pigment Necessary in Its Manufacture

By Marshall Haney
Written for *Engineering and Mining Journal*

In 1877 E. H. Woodward opened the first ocher mine near the town of Cartersville, Ga., the ore being hauled in wagons to this point, where it was prepared for market. A. P. Silva opened a mine in the same locality in 1878. In the process of drying the ocher he used a crude brick furnace about thirty feet long and four feet wide, with a sheet-iron bottom and a fire box near one end, and this crude device gave good satisfaction. The hauling of the crude ore to Cartersville for preparation was continued for many years. Messrs. Earle and Oram started the first systematic mining and preparation of the ore in 1891, using modern machinery. During the period between 1891 and 1900 many mines were opened and in operation, and the output for 1900 was valued at $73,000.

OCHER WASHER IN THE CARTERSVILLE DISTRICT

Location of the Cartersville District

The Cartersville district, which has produced a large proportion of the ocher mined in the United States, derives its name from the town of Cartersville, the county seat of Bartow County, and is about fifty miles northwest of Atlanta, Ga. The ore-bearing area includes about seventy square miles in the southeastern portion of Bartow County. This region is equally divided between the Paleozoic formation on the west and the older crystalline and metamorphic rocks of the Piedmont Plateau and Appalachian Mountains on the east. The separation line of these two groups of formations marks the position of the Cartersville fault, the most important structural feature of the region.

This district is a portion of the southern Appalachian region partly in the Appalachian Mountains and Piedmont Plateau provinces and partly in the valley province. The region has been subjected to intensive compression in a northwest-southeast direction. The formations (Paleozoic) to the west have been folded and faulted and those to the east have been mashed and squeezed. Another result is shown in the upward and westward thrust of the older rocks to the east on the younger rocks of the west, producing the Cartersville fault. At many points the rocks have been greatly altered by chemical and physical action.

Ocher Occurs in Shattered Quartzite

The most important formation is the Weisner quartzite, which shows evidence of great compression over the district, and this produced conditions favorable for the deposition of ocher. The ocher is confined entirely to the Weisner (Cambrian) quartzite and occurs in a continuous belt from near Emerson to Rowland Springs, a distance of nine miles. It is found in the shattered zone of the quartzite. No clue to the vertical extension of the ore is furnished by any of the extensive workings in the district, although it is generally believed that the ocher occurs at considerable depth.

There is little difference in the appearance of the ore in this district excepting for a slight variation in color. This varies from a dark to a light bright yellow, and is caused by the clay admixture with the ocher, which in turn depends on the character of the rock which the ocher replaces. The colors of ochers generally depend upon chemical composition. Prospectors are guided in locating the ore by fragments and masses of quartzite impregnated with ocher and of a yellow color, and in many places there is little or no showing at the surface and its presence is indicated by natural or artificial cuts and openings. An important surface indication which aids in tracing the ocher deposit is the presence of barite, which occurs in many places in the residual decay covering the quartzite.

The ocher deposits form along irregular branching veins which cut the rock in many directions, and at irregular intervals the veins narrow and widen and thin and thicken. For this reason the workings are very irregular, and in some places the chambers are ten or twelve feet in diameter and connected by an irregular narrow passage with another chamber of varying dimensions. Where the ocher bodies are inclosed by quartzite it is frequently necessary to blast, although this is not required where the ore is inclosed in clays.

The pure portion of the ocher bodies is soft and is easily mined with pick and shovel. Much of the mining is open-cut where the overburden is too thin for underground work. On the developed properties the method of mining consists of adits driven into the ridge, with shorter drifts and tunnels worked from the main ones

at suitable points. By so doing a number of levels, one above the other, have been worked. Timber is necessary to prevent caving, and the workings are extensive enough to use electric lights and tramways. The tram cars are hauled by mules or by means of cables.

The principal impurities of ocher are clay, sand, and manganese dioxide. The preparation for the market consists of washing, drying, pulverizing, and packing. After the ore has been mined it is carried on a tramway from the mines to a washer similar in construction to the washers used for washing manganese and brown iron ores. The fine portions of the ore remain suspended in the water covering the revolving shaft of the washer and are floated out by the water escaping through the openings near the top of the washer into a flume, which empties into a series of vats a short distance away, where the ocher settles. Most of the water is removed by decantation and the rest by evaporation.

FLUMES FOR CONVEYING ORE FROM WASHER TO DRYING VATS

Most of the treating plants handle from twenty-five to thirty tons per day. The vats are arranged in series and steam pipes are run at close intervals along the sides and bottom for steam heating. By this method only one or two days are required to dry the ore completely. The rack, air, and sun method requires about eighteen days to complete the drying. After the ore is dried it is pulverized and packed in barrels or bags of uniform size for shipment.

Activities of Ontario's Cobalt-Nickel Refineries

From Jan. 1 to July 1, 1920, according to the Ontario Department of Mines, 1,445 tons of ore, 581 tons of concentrates, and 1,185 tons of residues were treated in the southern Ontario refineries at Thorold, Deloro, and Welland, for a recovery of 1,477,490 oz. of silver, in addition to arsenic, metallic nickel, metallic cobalt, and compounds of these last-mentioned metals. The companies operating were the Coniagas Reduction Co., the Deloro Smelting & Refining Co., and Metals Chemical, Ltd., respectively. The last mentioned operated for the first three months of the year only, after which the plant was taken over by Ontario Smelters & Refiners, Ltd. Alterations in plant and process were made, which prevented production during the second quarter of the year. This new company also owns the plant at Chippawa formerly operated by the Standard Smelting & Refining Co. Copper sulphate was recovered from residues by one of the companies. It should be pointed out that the output of metallic nickel and nickel oxide from silver ores is small compared with that from nickel-copper refining. Only 203,713 lb. of metallic nickel and 15,384 lb. of oxide were marketed.

Talc Mining in South Africa

The mining of talc in South Africa appears to be a development of the war period, according to Trade Commissioner R. A. Lundquist, as little appears to have been done in this field prior to 1913. Even then early mining was for gold, with talc as a byproduct. The production for the past few years is as follows: 1913, 1 ton; 1915, 44 tons; 1916, 132 tons; 1917, 785 tons; 1918, 670 tons; and 1919, 757 tons. In addition to the above raw talc production, the mines themselves have turned out a considerable amount of manufactured talc goods, totaling 412 tons in 1917.

The more important districts in which talc is found are the Barberton district, the Krugersdorf district of the Transvaal, in Zululand, and in southern Rhodesia. The more important of the above is the Barberton district, though it is said that fine foliated talc is found in southern Rhodesia. The area over which talc is known in the Barberton district is about ten miles long and averages about a mile in width, and the deposit occurs in the form of nearly vertical bands up to fifteen feet in thickness. It is said that the talc reserves in the Barberton district are enormous and if properly developed should yield a large tonnage available for export.

At present there are only three producing talc mines in the Union. These are the Verdite mine, Jamestown, Barberton, Transvaal; the Scotia talc mines, Joe's Luck, Barberton, Transvaal; and the mines of R. R. Berrett, Greytown, Natal. The first two mines are the principal producers, and operate in the district between Jamestown and the Sheba Valley.

The Verdite mine and the Scotia talc mines each have a plant capable of dealing with 200 tons per month, though it is understood that recently the latter mine has developed its plant capacity to a point where it can turn out as much as 1,000 tons per month.

The talc is locally prepared according to the French system, using a disintegrator of the "cyclone" type, with a fan separator.

The local demand for talc is not great, and both the Verdite mine and the Scotia talc mines have large surplus outputs available for export. For crushed massive talc the present quotation is £6 5s. per ton of 2,000 lb., f.o.b. Delagoa Bay, for orders of not less than 200 tons. For uncrushed blue massive bulk talc the price quoted is £3 5s. per ton, f.o.b. Delagoa Bay, for orders of not less than 200 tons.

Not So Very Long Ago

Extracts From Early Mining Promotion "Literature" Often Have Familiar Sound —Sheepherder Discovers Bonanza by Well-Known Camp-Fire Process —Rocky Mountains And High Altitudes Best Places for Ore Deposits

By Kirby Thomas
Written for *Engineering and Mining Journal*

AN EARLY DAY keeper of the records who was attached to the Astor Library, now merged with the great New York Public Library, has left some interesting monuments to his zeal for history and to his industry. These are to be found in the form of a series of bulky indexed volumes which include many documents of human and business interest, together with a large number of mining reports and prospectuses of mining companies, which were thrust upon the dear public of a generation or more ago—even as today. These records are even now frequently consulted for the historical information that they suggest and for definite data otherwise difficult to obtain. In the light they throw on the different standards and ideas which have developed with the closer identification of engineering with mining they make curious reading. There is, however, a familiar note in some of the promotion reports, as will be observed from the extracts that follow.

This reservoir of the early history of mining, with its recital of names famous in the beginning of the industry but now almost forgotten, and its stories of hopes, which were mostly deferred, as we now know, seems worthy of being tapped for the interest, instruction, and amusement of the present-day seekers after the "golden fleece." Perhaps those so inclined may draw some self-comforting moral from these personal documents of those who have gone before, not so very long ago.

The Old Formula

Extracts and excerpts from these records are here given, with some necessarily brief comments and elucidations:

A pamphlet, apparently published about 1858, relates the story of the Mina de Tajo, a Mexican undertaking. On the front page is a quotation in large type from an alleged, but not specified, Spanish record, which declares that the mine "*es muy rica, riquisima—abandonada por las aguas*" (very rich, very very rich—abandoned on account of the water). Following this is the serious relation of an incident, familiar to those who read much about mines and mining. A lost sheepherder built a fire to keep off the mountain chill, and in the morning found in the ashes buttons of silver melted out of the hearth-stones, which, in this case, as in others which have gone before and followed after, were rich and docile silver ore. This incident is supposed to have happened about 1727.

Anthropologists may consider this recital a plagiarism of their musty notes of the early beginnings of happenings to the human race, and on the other hand some modern engineers, who have made bold to embody variations of this incident in their reports, may not admit priority. The herder made an open cut on the hillside, near the place where the ore came from; hence the name Tajo, meaning, in Spanish, a cut or trench. The history of the mine, supported by official records and human testimony, is consecutively detailed down to 1850, when, according to the record, one Boniface Rojas, "a noted scoundrel," got control of the mine and looted the rich ore reserves, which fact, perhaps a new idea at the time, is given as a good and sufficient reason why the company which inspired the prospectus was able to secure the property so advantageously. Ward's "History of Mexico" is quoted in substantiation, and, of course, also Alexander Humboldt.

The ore is reported to have had a value of from $56 to $1,500 a ton. On the expected basis of an output of "*630 cargas*" yearly, a profit of $914,000 annually was promised. One H. J. Van Ripper, "citizen of the United States and eighteen months resident of Rosario, and engineer of the mine," made formal affidavit that "the width and power of the vein in no place, to my knowledge, has been discovered." The principal backer of this undertaking seems to have been one Don Jose Gordon, whose name suggests hybridization. Presumably the mine referred to is the same as the Tajo mine of later-day fame, as it is described as being seventy miles from Mazatlan.

Best Silver Mines Found in High Altitudes

In 1865 J. P. Whitney, of Boston, issued a pamphlet entitled "The Silver Mining Regions of Colorado." In his opening paragraph he justifies himself by declaring that he has "the authority of the most eminent geologists and metallurgists for the assertion that the Rocky Mountains are the legitimate localities for true gold- and silver-bearing ores." Further, he says that there is "undisputed proof of the volcanic origin of the ores" and also that "true plutonic ores are in such profusion and in such inexhaustible quantity as to almost challenge one's belief." Continuing—"main lodes have been vomited forth from the mysterious depths of the earth, etc. . . . The mines are identical with those of Mexico, of which they are a continuance. . . . It is a well known and established fact that the best silver mines are invariably found in high altitudes."

In conclusion, the author asserts that he met a soldier near the mine, who had "a two-pound nugget of silver cut with difficulty from a ledge." He describes the first ingot of silver ever produced in Colorado. It was from the smelter of Lyon & Johnson and was made Aug. 26, 1865, from "Clear Creek district ores." Explaining the state of the metallurgical art of the day, he discusses the "Lyon smelting process," the "Crosby & Thompson method of desulphurization" the "Behr & Keith process" and the "Mason process." It is interesting to note that none of these names are today current in metallurgical circles.

Whitney's pamphlet ends with a very cheering picture concerning the attractiveness of investments in mining.

a sentiment which is not entirely foreign to the modern promotion literature.

The author of the prospectus of the DeLery Gold Mining Co., issued in 1866, was either an amateur or was over-conscientious. The opening paragraphs of this appeal set forth that "the business of mining the precious metals is confessedly one of great risks. All prudent men regard its allurements with suspicion. None but the bold will fearlessly venture money in a direct search for gold and silver. The history of Mexico and the Pacific Coast furnishes abundant proof that these apprehensions are well founded." After these alarums the writer proceeds to offer the "guaranteed stock" of the company, "capital $1,000,000, guaranteed stock $500,000."

It would be interesting to know how the stock was "guaranteed," but this information was not vouchsafed. The company was founded to operate the gold placers in the Seigneurie Rigaud Vaudreuil, on the Chaudiere River, in Quebec. It is blandly asserted that "merely initial exploration has revealed some forty miles of gold-bearing quartz ledges." Surely this fact should have been sufficient without the "guarantee." The company's office was at 72 Cedar St., New York.

Ores of Colorado and Mexico Identical

The Mineral Point Tunnel Co., 1878, seems to have been a sort of grandparent for the large progeny of similar undertakings which later disturbed the majestic scenery of the San Juan Mountains of Colorado. The sponsors "propose to call attention of the investors to only such facts as upon more extensive examination can be fully and satisfactorily maintained." Following this very reasonable premise is a quotation from "the great French mining engineer, Simoreis," to the effect that "the silver mines of Colorado give undisputed evidence of great natural wealth. The ores are true silver ores and the mines are identical with those of Mexico, of which they are a continuation."

This same convenient authority declares that "it is a well-known fact that the best silver mines are invariably found in high altitudes." Continuing, he says: "This property is located in the backbone of the silver-mining district, and it is the focal point at which centers and crosses great mother veins." The company had a capital of $1,000,000. The shares, par value $25, were offered at only $10.

Several pages are given to testimonials as to the character and ability of F. J. Pratt, who is apparently the chief figure in this early incident. The proposition is unqualifiedly endorsed by several governors, by half a dozen postmasters, by three mineral surveyors, and, of course, "an old and experienced miner" is quoted, and also "a prominent law firm from Lake City." E. Steinbach, "Dep. U. S. Min. Sur. and Mem. Amer. Inst. Min. Eng.," makes a fairly good report on the property, but spoils its verisimilitude by a fantastic map and section which shows all of the veins "focalizing" on the tunnel courses.

The "Corinna Silver Mining Co." of Bangor, Me., apologetically announced in 1880 that it "had not intended to issue any prospectus until the property had been thoroughly examined and reported upon by a mining expert." The company's property, it is interesting to know, was at Corinna, in Maine, and it was discovered by one Abel Adams, "who had some experience in California mining." The "main" shaft, 60 ft. deep, and two other shafts, 12 and 14 ft. deep respectively, are reported to have shown "rich antimonial silver ore, which resembles closely Nevada ores." It is stated that "in the vicinity of the vein are large quantities of gossan and melted rock, which are said to be an unfailing indication of a large body of ore below."

In a pamphlet, dated 1877, Ross Conway Stone makes a defence of the mining industry in this hardy fashion: "Gold and silver mining have stood the test of these disjointed times, and despite commercial crises continue to increase in strength. . . . It is fashionable to call gold and silver mining a gamble and ephemeral—the rule is to the contrary." He advises the "East" to secure "its own mines instead of *stocks*, manipulated by San Francisco magnates." These sentiments are reminiscent of the panic of '73 and recall the reputed methods of the Comstock financial operators of the time. Mr. Stone has not neglected to include a familiar list of "dividend" mines and of "bonanza" properties.

Many Endorsements for Red Elephant

The Red Elephant Mines Co., 1864, had the distinction of endorsement in reports made by "Prof. Rossiter W. Raymond, Prof. E. E. Berthoud, General Francis L. Vinton, E. Le Neve Foster, M. E., and W. A. Campbell, Esq. The company had a capital of $5,000,000, shares $10 par, office 30 Broad St., New York. Harvey Durand was president. In the prospectus it is claimed that the company owned the four most developed mines of the Clear Creek district, Colorado, namely the Free American, White, White Extension, and Boulder. It is also claimed that the average content of the ore was from 140 to 175 oz. of silver; further, that "there is every certainty of the orebodies not only going to depth but steadily improving with depth in quantity and quality" —a fine figment not yet extinct in mining literature. Mr. Foster says: "The proposition is one of the best in Clear Creek, and can be recommended to parties desiring to invest in mining operations."

Dr. Rossiter Raymond is quoted as follows: "The opinion I formed was highly favorable to the property. It has persistent fissures, carrying extensive shoots of exceptionally rich ore." It is to be noted that Dr. Raymond in this early day stood by his guns, so to speak, with reference to the spelling of "ore shoot"—possibly his genius may have originated the nice distinction between "shoot" and "chute."

The prospectus contains telegraphic reports (some enterprise at the time) from Charles S. Richardson and J. Alden Smith, both state geologists, strongly endorsing the property. The latter says: "The property is capable of producing from $50,000 to $75,000 per month, and of increased production when more ground is opened up." With such indorsements and reports a modern Boston promoter would certainly be able to bring about a serious stringency in the money market. The prospectus is further adorned by some lithographed pictures of scenery and maps in block colors.

The Sir Roderick Dhu Gold Mining Co., in the Black Hills, had some good neighbors, a fact which was not overlooked in the printed report of the superintendent, F. A. Babcock, made to John McGuiness, Esq., president, New York, in 1879. It is noted that the Homestake property was selling on the market on the basis of $4,000,000, and the Deadwood and the Father De Smet for more than $2,000,000 each. "Why should these be more valuable than the Sir Roderick Dhu, which has

abundance of ore and the requisite mill facilities for manipulating it?" Superintendent Babcock naïvely asks. He quotes Louis Janin's classic report on the Homestake as an inferential endorsement of his own mine. He estimates $6 ore and mining and milling costs of $2.35 a ton, and promises monthly earnings of $19,500, or 23 per cent annually on the capital of $2,000,000, "providing the company has sufficient working capital." He asserts that the mine is "capable of magnificent development." He points out the moral of the Comstock operations as an example of the fallacy of not developing mines ahead of the immediate requirement.

A Bird's Eye View of the Black Hills

The "Bird's Eye View of the Black Hills Gold Mining," edited by Harry L. Norton, and published in 1879, by the New York Mining Exchange, 60 Broadway, records that there were 5,000 mining locations in the Black Hills and fifty-two stamp mills (1,720 stamps). The stamps were from 550 to 800 lb. each. The output for 1878 is given as $6,000,000, and the total investment in mining is $2,500,000.

The Black Hills Placer Mining Co., 37 Wall St., New York, Major General Alexander Shaler, president, published "for private distribution," in 1879, a report by Marcus Walker, indorsed by John Rigby, "M. E.," in which a monthly profit of $100,000 is estimated, which was certainly modest, considering that the property was claimed to have "2,300,000,000 cu.yd., which by estimate will net more than $1 a yard."

The endorsers of the Columbia Silver Mining Co., 10 Pine St., New York, said to be mining at Austin, Nev., were certainly as eminent as one might desire. Professor Silliman, of Yale College, is quoted under date of 1866 as saying that these mines carry "the richest and best silver ore known." Professor Fisher, of Yale, is given as authority for the assertion that "these mines are far richer and more extensive than those of Mexico, or any others yet developed." Bishop Simpson, of the Methodist Church, is responsible for the statement that these mines "are richer the more they are worked, and no one has been able to estimate their depth or extent." The company had a capital of $3,000,000, shares par $100.

Rossiter W. Raymond was secretary and Chauncey M. Depew was president of the MacDonald Silver Mining Co., which in 1866 published a report by Aldeberg & Raymond, mining engineers, on the company's property in Lander County, Nev.

A prospectus of the Bassick mine, in Colorado, published in 1879, contains very complete reports by Henry Cummings, who was later famous in connection with the Hornsilver mine, in Utah, and by James D. Hague, "M.E.," and Professor John S. Newberry. Mr. Cummings congratulates the new owners of the Bassick, Messrs. Frank G. Brown, of New York, and Dennis Ryan, of Frisco, Utah, and ingenuously says, "You should be emulated in your method of employing the most skillful, experienced and reliable expert to examine the mines you purchase. . . . If all persons desirous of purchasing mines would pursue a like method and also adopt your policy of paying for a mine 50 per cent of the estimated value of the ore reserves that can be actually measured mining would be unattended by the hazard generally attributed to it."

It is to be hoped that the policy which Mr. Cummings approved will not be taken too seriously by the capitalists of today, otherwise mines are likely to go without buyers for some time. Mr. Cummings makes very scant observations on the nature and origin of the unusual ore occurrence at this mine, simply suggesting that the boulders fell into the chimney and stating that they were coated by solutions from below "which were so hot as to char remnants of wood found with the ore." He declares that "the character of the orebody is without parallel, and it is the largest telluride mine yet discovered." He estimates the ore reserve as 2,000,000 tons, value $58.40 a ton. Shipment to Denver cost $20 a ton freight, and 10 per cent of the gold and 15 per cent of the silver were deducted by the ore buyer for losses in treatment.

Mr. Cummings also figures in a very interesting publication made by the Hornsilver mine at Frisco, Utah, in 1879. In Mr. Cummings' report the public is assured that the "ore is associated with trachyte of volcanic origin." The ore reserves are calculated in detail, the results showing 527,000 tons, containing an average of 71.52 oz. of silver and 42.26 per cent lead. The net value of the reserve claimed is $27,976,552. The company had a capital of $10,000,000, in shares of $25 each. A separate report made in 1878 by William E. Hooker estimates the grade of the ore at $34.46 and the net ore reserve at $17,955,000. The prospectus includes some remarkable plates and drawings, made by the late Leo Rosenberg, of New York.

Alaska Gold's Operations

A publication more recent than the preceding, yet old enough to give some interesting cost data for comparison, is that of the Alaska Gold Mining Co., for 1897. The property had in operation 120 stamps (1,020 lb. each). The crushing result was 3.75 tons in twenty-four hours for each stamp. The costs per ton were: Milling, $0.3217; mining, $0.9532; chlorination, $0.2106; total, including general and overhead, $1.5602. The yield per ton was $2.1242. The total ore mined for the year was 158,000 tons.

The report notes that labor was plentiful. The roll included 105 whites and 33 Indians. The wage scale was as follows: Miners, $2.50 per day, labor, $2 per day, drillers, $2.50 per day, with bonus, including in each case board and lodging. The mill men were paid $90 a month and the hoisters and concentrators $65 to $75 a month, also with board and lodging. The Indians were paid $2 a day and "no board."

The international aspect of this company is indicated on the title page, which designates as the company's bankers "The Bank of California, San Francisco; Messrs. William Rothchild & Sons, London; London agents, the Exploration Co., Ltd.; Paris agents, Compagnie Française de Mines d'Or et d'Exploration." Honorable William Alvord was president and Captain Thomas Mein, consulting engineer.

These are a few selections from the archives. They may carry interesting recollections to some of the readers of *Engineering and Mining Journal* and afford a crude standard by which to measure the progress in the profession of mining engineering, and perhaps some philosophical minds may be able to deduce from these data whether or not the human race is progressing.

Selenium is recovered as a byproduct in the electrolytic copper refineries operated by the Raritan Copper Works, United States Metals Refining Co., Nichols Copper Co., and American Smelting and Refining Co. Practically none is imported.

Mining Engineers of Note

Philip North Moore

PHILIP NORTH MOORE carries his seventy-one years lightly, and younger men may well envy his buoyancy of spirit, his pleasantry of manner, and his keen enjoyment of his work. Graduating from the Columbia School of Mines in 1872, Mr. Moore spent the five years following on the state geological surveys of Michigan, Missouri, and Kentucky. He then entered into consulting practice in Leadville, Col., and later became treasurer and managing director of the Slate Creek Iron Co., in Kentucky. Since that time he has maintained his headquarters in St. Louis. Successively, he has been manager of the Courey Placer Mining Co. and the German Bar Mining Co., of Virginia City, Mont.; president of the Rose Run Iron Co., Kentucky; president of the Tecumseh Iron Co., Alabama, and of the Admiralty Zinc Co., of Oklahoma. From 1917 to 1919 he was a member of the Engineering Council, and from 1918 to 1919 a member of the engineering division of the National Research Council. Mr. Moore's standard in life has been to build a character rather than prominence, on quality rather than quantity. He was wont to observe that he had never reported on a mining property in which he was interested, and never managed a property in which he was not interested. It was the St. Louis conception of his character which led his friends to break away from the "state" ticket of the American Institute of Mining and Metallurgical Engineers, and nominate him as an independent and opposition candidate for the presidency of that body in 1917; and after a warm but good-natured campaign, out of which both sides got a lot of fun, he was elected. His administration was marked by a great deal of achievement and some unconventionality from Mr. Moore, who has a habit of stating the unvarnished truth as he sees it with the minimum of circumlocution, which may on occasion prove temporarily disconcerting. He does not lack the ability to express his thoughts, however, and this ability has been taken advantage of by pulling him forward often as spokesman for the American Institute of Mining Engineers and Engineering Council.

PHILIP NORTH MOORE

Mr. Moore's present job is as a member of the War Minerals Relief Commission, whose function it is to pass on claims under the War Minerals Relief Act, and allot to successful claimants their share in the $8,000,000 relief fund appropriated by Congress. There are now two engineer members of the commission, Mr. Moore and Mr. Pomeroy—the chairman of the commission being "Honest John" Shafroth, former Senator, and Governor of Colorado. It is a job where the engineer's knowledge and judgment is the main consideration, and from the way the work has been carried on we may extend the sobriquet of its chief to the other members, and say "Honest Phil" and "Honest Horace." We do not think any of the most disappointed ones among the claimants who have to be sent away empty handed would file objection to these designations, although some of them might remark that there are times when they are not looking for just that kind of rigid adherence to the rights of the Government and the public welfare. We will not go so far as to say that "Honest Phil" has it in mind that some of that $8,000,000 may be turned back into the public treasury. This would be a heresy that would be contrary to all instances of the doling out of Government pap. At any rate, the pressure will be to have the decisions of the commission, if negative, or if "Honest John," "Phil," and "Horace" have not seen their way clear to loosen up, contested ad infinitum in the Court of Claims.

We understand the commissioners are not in favor of the Court of Claims; but if they will consult the case of Jarndyce vs. Jarndyce, as recorded by Dickens, they will find the precedent of once a claimant, always a claimant. If it were not for that, one would be tempted to say that the mining industry had been darned lucky to get such understanding and sympathetic (*yet* conscientious) administrators as the War Minerals Relief Commission; and that anybody who would not abide by their decision was either a poor sport or the hungry attorneys were pulling his leg. It is a fact that a few claimants that were not entitled to anything have slipped in under technicalities, and received awards.

BY THE WAY

Majority Rule

"This moornin'," said Cap'n Dick, "I wuz talkin' to one o' they college chaps 'oo's learnin' practical minin' trammin' gob on tha h'eight 'underd level, an', dam-me, 'e's come forth with tha mos' h'interestin' discussion o' they Rooshian chaps 'oo call theirsel's Bullsheviki. 'Cordin' to w'ot 'e sez, this 'ere name, Bullsheviki, in Rooshian, means majority. Which reminds me o' poor h'ol' Nicky Trebilcock. One evenin', a nummer o' years h'ago, I sat 'longside Nicky at a meetin' to h'arrange for tha Miner's Union picnic. Nicky, 'e wuz 'ard o' 'earin', an' w'en Jim Penglaze h'asked for tha h'opinion o' tha majority as to w'ere tha picnic was to be 'eld, Nicky 'as to turn to me to h'ask w'ot Jimmy 'ad to say. Several h'others then come forth with suggestions for h'approval o' tha majority, an' all this time Nicky wuz cranin' o' 'is nuddick an' 'is 'and be'ind 'is ear. Sam Treloar, chairman 'o tha refreshment committee, h'announced that, majority bein' willin', 'e would 'ave a special keg o' beer for 'Arry Rowe's brass ban'. By this time Nicky 'ad growed h'excited, an' seemed turrible h'upset. Turnin' to me, 'e sez, 'They bloody h'Irish do seem to be 'avin' all tha h'influence raoun' 'ere lately. Never 'ave I 'eard tell o' this chap *Jarrity* afor', but, dam-me, 'e do seem to 'ave tha 'ell o' a lot to say about this 'ere picnic."

Consult a Physician

We love approval, but it does not interest us long; we are too profoundly aware of our excellencies. Adverse criticism, however, interests us at once: there is always the thrill of the anticipation that we may have unconsciously made an error, and a real pleasure in discovering the mistake or in revising mistaken policies or trends. We love and respect our highly critical friends, and they show the most genuine kindness in pointing out where we can improve. Once in awhile, however, we run across a kicker, who takes the trouble to write us or phone us and kick, without being quite sure what he is kicking about—at least without the mental power of getting down to anything specific. For such a case we can only infer domestic unhappiness or a disordered liver; yet we are too delicate to attempt to prescribe individually. Speaking in general and out of a vast experience, we do not know of any universal remedy for the former; for the latter, we recommend turning for relief to a physician, and not an editor.

The Early Miners

"One of the most marked and best characteristics of the old miners was their kindness," runs a passage in Hittel's "History of California." "An affecting incident illustrative of this occurred in 1848. It was at a little camp, the name of which is not given and perhaps is not important. The day was apparently a hot one and not very far advanced toward the cool of the evening, when a youth of sixteen came limping along, footsore, weary, hungry, and penniless. There were at least thirty sturdy and robust miners at work in the ravine; and it may be well believed they were cheerful, probably now and then joined in a chorus or laughed at a good joke. The lad, as he saw and heard them, sat down upon the bank and watched them in silence—his face telling the sad story of his fortunes. Though he said nothing, he was not unobserved. At length one of the miners, a stalwart fellow, pointing up to the poor boy on the bank, exclaimed to his companions, 'Boys, I'll work an hour for that chap, if you will.' All answered in the affirmative; and picks and shovels were plied with even more activity than before. At the end of an hour a hundred dollars' worth of gold dust was poured into the youth's handkerchief. As this was done, the miners, who had crowded around the grateful boy, made out a list of tools and necessaries and said to him, 'You go now and buy these things and come back. We'll have a good claim staked out for you. Then you've got to paddle for yourself.'"

Half and Half

When the railroad was built last fall to the Rosiclare and Fairview mines in the Elizabethtown fluorspar district of Illinois, both the companies wanted the station named after their own town. The railroad company did the best it could to please them and named the station Rosiview. It was located midway between the town and mines.

The Hydro-Electric Baptists

Dr. George Otis Smith, the director of the U. S. Geological Survey, recently addressed the men's society of one of the Presbyterian churches in Washington on the subject of the super-power survey. Dr. Smith is a Baptist. Dr. Charles Wood, the pastor of the church, at the conclusion of Dr. Smith's address, asked how it would be possible to electrify the men's society into greater activity and inquired of Dr. Smith how the Baptists did it. "They use water power," Dr. Smith replied.

Worthy Pupils

The *Denver Post* has a high regard for the Government's oil specialists. This is indicated by the following quotation from a recent issue of that newspaper:

> Two thousand members of the Independent Oil Men's Association are in Denver for the twelfth annual convention of that organization. Of those in attendance one thousand nine hundred and sixty-two are millionaires. The other thirty-eight are salaried employees of the Bureau of Mines who showed them where and how to make their millions.

We predict that a good part of these millionaires will forget all about it the very second that the tax collector comes snooping along.

Correspondence Solicited

The Bureau of Mines has received a request for information as to the process of making soap out of soapstone. Since the Bureau has no soapstone specialist at this time, Assistant Director Holbrook suggests that possibly some reader of this page may be able to supply the requested data. The first idea that occurs to us, although we admit that it may not be worth much, is that it would be appropriate, if nothing else, to begin by erecting a washing plant. This may help our readers to set their train of thought in motion. Replies received will be forwarded to Mr. Holbrook or printed on this page, as desired. We hope to get a lot of good suggestions, for it has steadily been getting more difficult to fill up this page ever since the Eighteenth Amendment went into effect.

CONSULTATION

Gold Mining Tax Exemption

"Under the existing revenue laws of the Treasury Department is a gold mine exempt from the excess-profits tax? An explanation of the working of the excess-profits tax as it relates to gold mining will be appreciated."

The Revenue Act of 1918 states in Sec. 304 (C), "In the case of any corporation engaged in the mining of gold, the portion of the net income derived from the mining of gold shall be exempt from the tax imposed by this title (Title III, War Profits and Excess-Profits Tax), and the tax on the remaining portion of the net income shall be the proportion of a tax computed without the benefit of this subdivision which such remaining portion of the net income bears to the entire net income."

The text of the section is sufficiently clear and warrants little additional explanation. The tax on the "remaining portion of the income" is based upon the proportion which the net income derived from other than gold-mining activities bears to the total net income, and as calculated upon the tax which would have been imposed had *all* profits been obtained from other than an exempted business.

The following illustration, which considers a corporation engaged in the mining of gold and other metals, is a representative instance and brings out the working of the law. It is assumed that a mining company engaged in the production of gold and other metals has a net income of $300,000, of which $100,000 is attributable to gold mining, on an invested capital of $1,000,000. Without going into the details of the derivation, suffice it to say, that the excess-profits tax which this corporation would have to pay if engaged in some other form of activity would amount to $63,400. However, the $100,000 income from gold mining entitles the company to a tax exemption on this sum. Hence the excess-profits tax imposed would be computed on the remaining portion of net income, or $200,000, and the tax thereon would be proportionate to the tax computed on the entire net income without the benefit of exemption. In other words, $200,000 : $300,000 :: x : $63,400, where x is the tax on the $200,000 of remaining income and $63,400 the normal excess-profits tax on a corporation engaged in an enterprise other than gold mining. The tax would therefore be $42,266.67.

In these trying days for the gold miner it may be "rubbing it in" to discuss such a matter as an excess-profits tax, yet the problem is one in which all metal mines are interested, not only those producing gold principally, but also the ones in which gold production is merely incidental to the recovery of some other metal, such as copper.

Tellurium Production

"Can you tell me how much tellurium was produced in this country during 1919?"

The *Engineering and Mining Journal* has not been able to compile figures on the annual production of tellurium, and it is to be noted that the U. S. Geological Survey has also failed to publish any such information, because only one producer, the Raritan Copper Works, reported production or sales of the metal to the Survey. The demand for tellurium is small.

Optical Fluorite

"Will you kindly inform me what are the specifications of fluorspar for optical uses and give me other information explaining the particular application for this material?"

Optical fluorite is a rare variety of the common mineral fluorspar, which, as its name implies, possesses physical properties which make it particularly desirable for certain kinds of optical work. Such fluorite must be clear, colorless, free from all defects, and contain pieces of suitable material at least one-fourth of an inch in diameter. Common defects found in specimens of optical fluorite consist of internal cracks, cleavage planes, bubbles, and the inclusion of foreign matter, such as particles of dirt or other minerals. By moistening the specimen with kerosene it is possible to detect the presence of faintly developed or incipient cleavage planes that might not otherwise be suspected as being present.

The chief demand for optical fluorite is from telescope and microscope manufacturers, who employ it in the manufacture of special lenses and prisms. The material is cut into the desired form and placed between glass lenses. The fluorite lens has the property of correcting the spherical and chromatic defects of the glass lenses, a characteristic which is due to the low refractive power, single refraction, and weak color dispersion of fluorite. It is reported that these "apochromatic lenses" represent the finest type of microscope objectives made, and that the value of a microscope is greatly increased by the use of such a lens.

According to the U. S. Geological Survey, little optical fluorite is produced in the United States, although certain localities are known to have been productive and have possibilities. In the United States, southern Illinois, in Switzerland, Meiringen, and in Japan, Obira, Bungo, are the world's important producing centers.

It is seldom that pieces of fluorspar are large and clear enough to be of use to the optical industry. Were it more abundant there is little doubt that a greater number of microscopes would be equipped with optical fluorite. Absolutely clear material is of the greatest value, but faint tints of green, yellow, and purple do not render the material useless for this purpose. Prices vary widely according to the particular quality of the specimens offered for sale. From $1 to $10 per lb. is usually paid. The U. S. Geological Survey estimates requirements at several hundred pounds of optical fluorite annually.

To those wishing to market this product, it is suggested that they communicate with the U. S. Bureau of Standards at Washington, D. C., or with one of the large optical companies.

HANDY KNOWLEDGE

Bucket-Dumping Device for Use on an Incline

BY J. B. HARPER

Written for *Engineering and Mining Journal*

A bucket-dumping cradle which was used in sinking a 50-deg. inclined winze on the property of the Jerome Verde Copper Co. and the manner of timbering at the winze station are shown in the accompanying sketch.

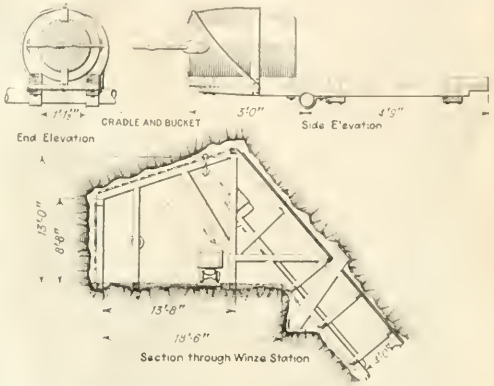
The cradle illustrated consists of two parallel 4 x 6-in. timbers spaced the same distance apart as the skids in the incline and fastened tightly to a piece of 4-in. pipe which rotates in hangers above the collar of the incline. A piece of strap iron arched across these timbers and bolted to them, together with hooks at top and bottom, forms a sort of basket into which the bucket is hoisted. The lower hook passes around the 4-in. pipe and is made slightly shorter to take the greater strain. The position of the cradle on the support is such that the

EMPTYING THE BUCKET INTO A CAR

lower end is heaviest and rests upon iron stirrups bolted to the end of the skids. These stirrups appear in the photograph, which shows the bucket in the dumping position.

A loaded bucket hoisted to the hooks at the end of the cradle overbalances it, and as the cable is slacked off the bucket tips forward and dumps instead of sliding back. As the slack cable is taken up the cradle resumes its normal position and the empty bucket slides back on the skids.

The dimensions of the cradle depend on the size of the bucket to be used. The bucket in the illustration is 2 ft. 9 in. long and 1 ft. 9 in. in diameter, having a capacity of nearly eight cubic feet. It is cylindrical



BUCKET-DUMPING CRADLE FOR USE ON INCLINE

except for the upper and lower edges, which are rounded over on a 3-in. radius to facilitate passage on the skids. This bucket appears to be the maximum size which can be handled by a No. 1-H "Little Tugger" hoist, and was designed for this purpose.

Loose ground made it desirable to cut the winze station as small as possible. The device illustrated requires little headroom. It has been in use for nearly a year, and has proved thoroughly satisfactory.

Determination of Low Percentages Of Lead

Alexander's Method Modified When Lead Is Under 5 Per Cent—Auxiliary Solution of Lead Acetate Employed

BY JOHN H. HASTINGS

Written for *Engineering and Mining Journal*

In using Alexander's methods for the determination of lead, it is somewhat difficult to distinguish an exact end point in titrating when the burette reading is between 10 and 20 c.c., more difficult when between 5 and 10 c.c., and almost impossible under 5 c.c., on account of the slowness of the reaction between the ammonium molybdate and lead solution. Several methods have been proposed as a substitute, but for simplicity and speed none equal the method commonly known as Alexander's.

A modification which I originated and have used for about two years involves the employment of an auxiliary solution of lead acetate, 1 c.c. of which contains 0.005 g. of lead. This solution is added to the lead solution just before titrating to bring the burette reading to 20 c.c. or more. The method is applicable to ores and metal-

lurgical products particularly. Lead may be determined down to 0.1 per cent when 5 g. of material carrying small amounts is taken. It is recommended for use when the lead is under 5 per cent. The method in detail is as follows:

One-half to 5 g. are weighed out into a 250-c.c. Pyrex beaker. If the sample be a sulphide, 10 to 25 c.c. of nitric acid is added; if it be oxidized, 5 to 10 c.c. of hydrochloric acid is used in addition, or else the sample is given a treatment with that amount of hydrochloric acid, with or without the addition of nitric acid after evaporation, depending on whether sulphides are present. If the lead is insoluble the regular treatment with hydrofluoric acid is used.

The lead is separated as a sulphate. The amount of soluble lead sulphate is determined as described in running the standard. This eliminates the necessity of using "lead" acid or alcohol. Any lime present is washed from the lead sulphate.

Fifteen to 20 c.c. of sulphuric acid is added to the solution, which is heated until the sulphuric acid is fuming well, then over a free flame until copious fumes of sulphuric anhydride are evolved. The solution is cooled and diluted with 100 c.c. of cold water. It is then brought to a boil and let stand until all iron sulphate is in solution. After cooling, it is filtered, and the precipitate washed four times with cold water. The precipitate and paper are dropped into a 250-c.c. beaker containing 15 c.c. of a saturated solution of ammonium acetate diluted to 100 c.c., with water. The ammonium acetate is then brought to a boil and boiled a few minutes to dissolve all lead sulphate. Twenty cubic centimeters of the lead acetate solution is then added and the solution titrated hot with a standard solution of ammonium molybdite, using tannic acid solution as an indicator. The end point is a pronounced change to a yellow color. The number of cubic centimeters required in standardizing the lead acetate solution is subtracted from the reading. The per cent of lead is calculated from the remainder.

The various solutions used in the analysis are made up as follows:

The ammonium molybdate solution contains 4.25 g. of the salt per liter of water.

The lead acetate solution contains 9.15 g. of the salt per liter of water, and is cleared by adding a few drops of acetic acid.

The tannic acid solution is a 0.1-per cent solution of tannic acid in water.

The ammonium molybdate solution is standardized by weighing in duplicate 0.1 g. of c.p. sheet lead, which has been thoroughly cleaned, and dissolving in 1 c.c. of nitric acid and 15 c.c. of water and running through as described in the method, except that no lead acetate solution is used.

The lead acetate is standardized by adding 20 c.c. to a 250-c.c. beaker containing 15 c.c. of a saturated solution of ammonium acetate, together with a filter paper and 100 c.c. of boiling water. It is then titrated as described in the method.

The amount of lead taken into solution by the dilute sulphuric acid and wash water is determined as follows: A standard sample of ore running about 5 per cent lead is run according to the method, using a 0.5-g. sample. It is also run using a 2-g. sample, but with no lead acetate solution. The difference in the percentage of lead in the ore shown by the two methods of determination is the amount due to the soluble lead. This figure must be added to each burette reading on the sample after subtracting the number of cubic centimeters of lead acetate used. The correction amounts to from 0.2 to 0.4 c.c. In the methods of standardizing no other blank needs to be considered.

Practice of Opening Kegs of Black Blasting Powder With Wooden Tools Condemned

By S. P. Howell*

The Bureau of Mines has repeatedly called attention to dangerous practices in the transportation and opening of kegs of black blasting powder. It has not been definitely established just how opening a keg with a wooden moil, wooden sprag, or a wooden mallet causes explosions, as it appears to be difficult to strike a spark with wood against metal, but it may be that in breaking the keg, the sharp points of the sheet iron would be driven inside of the keg; that two or more of these points may have been made; and that in rubbing over one another, these points or the edges of the strips may have caused a spark, or it may be that the strips or points may have been driven forcibly against the side of the keg and produced sparks, or it may be that the wooden tool was covered with a gritty substance, thus facilitating sparking, or it may be—and this has been demonstrated at the Explosives Experiment Station of the Bureau of Mines—that the fine particles of black blasting powder remaining in the angular groove of the chime received the impact from the wooden tool and this ignited the particles.

Evidence shows, however, that the method of opening kegs of black blasting powder with wooden tools by punching a hole through the top of the keg is an unsafe one. The usual 25-lb. black blasting powder kegs are provided with a bunghole and a cap for closing it, and in all cases the powder should be poured from the keg through this bunghole.

The excuses for not doing so are usually that the bunghole is so small (diameter of 1⅞ in.) that it requires too much time to get the powder out of the keg through this bunghole, or that the bunghole is so far from the chime (1½ in.) that all of the powder cannot be poured out of the keg. In view of the menace of other methods of opening the kegs, these excuses cannot be given serious consideration. A keg of FFF black blasting powder can be emptied through the bunghole in forty to fifty seconds, leaving less than 100 grams (about 3½ oz.) of explosive in the keg, and it is not difficult to get all but half an ounce of the powder out of the keg by shaking.

The Bureau of Mines therefore recommends that kegs of black blasting powder be not opened with any tool, whether of metal or wood, and that the keg be emptied only through the bunghole provided for the purpose.

Camouflaging a Worn Corrugated Iron Roof

Some old corrugated iron was used in the roof of a new mill in the Joplin district. Although the roof was tight enough for all practical purposes, the effect of the old nail holes was unpleasant. A few hours' work with some J-M elastic roof putty permanently stopped all the holes and gives the effect of a new roof. The same result can be effected by dropping large-headed roofing nails into the holes. Window dressing only, but it gives a visitor a much better opinion of the mill.

*Bureau of Mines, "Monthly Report of Investigations."

THE PETROLEUM INDUSTRY

A Suggested Schedule of Petroleum Priority

Influence of Price, Application, Demands, and Requirements of Liquid Fuels Are Factors Which Should Determine the Base for a Preferential List—Proposal Represents the Application of New Principle in Natural-Resource Thought

BY R. S. McBRIDE
Written for *Engineering and Mining Journal*

IN A PREVIOUS ARTICLE[1] the importance of thinking nationally of our petroleum problems has been pointed out, and the suggestion made that we must soon consider which of the various applications of petroleum will be given preference in supply. Continuing this discussion, it is desired to give here a suggested priority list. This, it is hoped, will at least serve as a stimulation of further discussion and for more thought on our basic economic problems of petroleum distribution. It is not expected that it will do much more than this, for the problems treated are still largely unsolved—perhaps, indeed, partly unsolvable, today.

During recent years we have had a variety of bases for determining priorities. Throughout the Great War priority commonly was granted to a specific individual or firm in order that a particular job on hand might be accomplished expeditiously. Then, too, we had priority classes for fuel, in which the character of the institution served or nature of the work to be done by the fuel user determined his position in the list, as, for example, the relatively high placing of public institutions, hospitals and like establishments, the intermediate ranking of public utilities, and the superior ranking of war industries over those termed "non-essential."

More recently, in the case of coal transportation, another class of priority has been granted by the Interstate Commerce Commission; that is, according to geographical subdivision. This was done that New England and the Northwest would not freeze or be threatened with idle industries during the coming winter season. However, none of these priority systems serves for the present purpose. What is needed is a scale by which we may judge the relative social service performed and thereby establish the economic justification for priority.

Photograph by courtesy of the Bureau of Mines

A FULLY DEVELOPED PETROLEUM AREA

The wells in this region, at Kern River District, California, are placed from 200 to 300 ft. apart. One of the large open reservoirs that are utilized for the temporary storage of oil is shown in the immediate foreground of the picture

It is realized that any effort to this end cannot expect to command general concurrence with every detail; in fact, there will perhaps be as many priority lists established as there are investigators in this field. However, there are certain principles to which practically all agree, and these justify careful consideration, in the hope that at least we may establish some basis to guide the industrial thought for the immediate future.

In the following discussion of such priority it is intended to take rather a middle ground between what can be our every-day practice this year and what might be termed an ideal future practice toward which to work. The suggestions of the following sections are a recommendation toward which it is believed we can immediately turn, with the expectation of realizing the relationships suggested within a few years. Still further development beyond that period will also be needed. However, it is impossible for anyone to say today just

[1] "Liquid Fuels—Wanted: a National Policy," *Engineering and Mining Journal*, Oct. 23, 1920.

how each of the several interests which must be regarded as competitive today will develop or to predetermine their proper rank for periods of the more distant future. This limited applicability over relatively few years should be carefully borne in mind, to avoid a misunderstanding of the rather high position given to some uses of petroleum that cannot be recognized as worthy of such preference permanently.

The Influence of Price in Determining Priority

In the final analysis, the laws of supply and demand, if unrestricted by artificial legislation, fix petroleum prices properly in reference to trade conditions. He who can still afford to pay the price thus fixed can expect to remain in the market as a successful purchaser. He who can least afford to pay the prices thus established will soonest be eliminated. This, perhaps, is the law of the jungle, but it is almost inevitable that it shall rule. A further consideration of some of the aspects of this principle, however, is worth while.

Liquid fuels are for most uses simply competitors of gas, coal, and electricity as sources of heat, light, and power. So long as liquid fuels afford to the purchaser an attraction superior to these other energy supplies, the purchaser will continue to use the liquid fuel if it be available. Price is, to be sure, only one of the elements in determination of the relative suitability of liquid and other fuel supplies. Convenience of use as compared with solid fuel, ease of storage as compared with gas, and other similar factors enter. However, in the last analysis the purchaser buys the one which gives him for the least expenditure of money and effort the desired operating result.

Under these circumstances, as soon as the petroleum becomes decidedly more expensive per unit of service rendered than coal, let us say for heating, the extensive use of liquid fuel for this purpose will promptly cease. It is likely that price will thus establish a sound basis for determining industrial priority, especially if unaffected by governmental restrictions. Indeed, one might say that such a priority list established by ability to pay the price will ultimately be identical with a list established solely on the basis of the economic justification for use of the liquid fuel. Nevertheless, it is worth while to examine these problems from a broader point of view. To this end, let us consider a dozen of the principal applications of petroleum.

A nearly unanimous opinion probably can be expected with respect to the first on the priority list; a general agreement that lubrication is the most important and most nearly irreplaceable application of all petroleum products. One is justified, therefore, in placing this requirement at the head of an economic priority list.

Next in order, one must probably place either illumination or the special chemical requirements for miscellaneous petroleum fractions. Of these two uses the former draws upon rather a different group of oils than the latter. It, therefore, makes little difference which is placed second and which is third on our list. Kerosene, as an illuminant for districts where city gas, electric current, or acetylene are not available for lighting, certainly serves a fundamental social function that is hard to provide for otherwise. Moreover, this use of kerosene calls for only a part of the illuminating oils which can be manufactured from the available petroleum resources that will be handled if demands in other lines are met. There seems some ground, therefore, for placing illumination as number two in the schedule.

Numerous chemical processes require the use of liquid fuels, but these do not draw very heavily upon our petroleum supplies. To the extent that neither gas nor solid fuel seems quite as well adapted to the processes in question, so far are we justified in giving distinct preference to this requirement.

Within the chemical industry there is also a highly specialized requirement of petroleum fractions or products, which are used not for fuels but rather for other purposes. Ink oils, medicinal oils, petrolatum, paint oils, and similar petroleum products are conspicuous examples. These demands represent applications that certainly justify encouragement. And fortunately this encouragement can be given without any particular burden upon other uses, as the quantities needed are small compared with other requirements.

Within the group of chemical applications there is, also, a peculiar class that is rather the result of the existence of products not readily adaptable to other uses. To the extent that these relatively inferior products can be efficiently applied in chemical industry, we should give great encouragement to such use. All of these so-called "chemical" uses are grouped together and placed as third in the economic priority schedule proposed.

The requirements of petroleum fractions for automotive fuels is peculiar in that the fraction commonly needed is not largely in demand for any other purpose. Gasoline is, in fact, almost synonymous with automotive fuel. Practically all gasoline can be given to automotive requirements, and this use placed as number four in a priority list, without giving rise to serious objection.

The only sense in which automotive requirements are in conflict with other demands for petroleum is that fuel-oil fractions are now being used to a considerable extent for the production of gasoline by cracking. In placing automotive requirements as number four, it is not intended to include with them this indirect production of gasoline; this rank of four is confined to the gasoline produced by the older methods of distillation.

It is well known that all the gasoline which can be made by present-day plant practice is quickly absorbed by the markets. The competition or priority with respect to gasoline, if such were undertaken, would, therefore, require a very different type of classification than that which we are now discussing. It would require, in fact, a discrimination between uses of greater and lesser economic justification. In other words, a contrast between essential, desirable, and purely luxury applications. To enter a discussion of that question is, for the present purposes, wholly unnecessary.

After recording the first four entries on a priority list a more difficult problem is met, for at this stage one must decide as between those who require substantially the same fractions of petroleum. There are eight groups of gas-oil and fuel-oil uses that must be so judged and ranked. These applications are: Gas manufacture, gasoline manufacture, internal-combustion (Diesel) engine use, navy fuel, merchant-marine fuel, locomotive fuel, steam power-plant fuel, and fuel for heating plants.

In this group gas manufacture is distinguished from others because it represents a distinct type of fuel-oil application. Other public-utility fuel users would also require special treatment were it not for the fact that their oil requirements fall within the scope of the other groups mentioned. For example, these other public-

utility uses are in Diesel engines, power plant, or heating plant; and for present purposes these need not be distinguished from similar demands by other users.

It is a general principle in our census of manufactures that a measure of industrial development is the increase in value added by manufacture. For this purpose, value of raw materials is compared with value of products and the difference taken by the census as of economic significance. Proceeding upon the same theory here, we can place gas manufacture and gasoline manufacture somewhat ahead of other demands for fuel oil. In these applications the oil is not consumed but rather is converted into a material available for application in a superior class.

If it were possible quickly to substitute coal-gas plants for existing oil-gas and carburetted water-gas installations, there would be no particular need to regard the city gas manufacturer as entitled to serious consideration for high place in a priority list for fuel oils. However, such quick change of gas-making process is not possible. The machinery and materials needed for installation of coal-gas or coke-oven plants cannot be made available for a considerable period. Neither can the funds required for so large a change in investment be secured by utility companies at present. Gas represents an essential of modern city life. For the present and for a considerable number of years to come, therefore, preference must be given to gas manufacture over other fuel-oil requirements *to such extent* as will permit uninterrupted adequate gas supply.

This situation may continue longer than at first seems likely, for natural-gas supplies are now continuously decreasing in quantity, and manufactured gas must inevitably ultimately replace them. Much new construction of coal-gas and coke-oven plants will doubtless, therefore, be directed to extension of gas-making facilities in such districts of the country as were formerly served to a large extent by natural gas. Municipal growth and extension of gas supply into suburban territory also tend to limit gas-works construction to only that which can be regarded as extension of present plants. Thus, for many years to come an important fuel-oil demand for water-gas making must be met.

Gasoline production from fuel-oil fractions, when it can be efficiently practiced, raises the petroleum production from a lesser to a greater usefulness. To the extent that equipment is available for this conversion to gasoline, preference will, doubtless, be given for such use by the petroleum refiners. This will be not only a matter of good business judgment on their part, but also, for the reason cited, an economically justifiable procedure. On the other hand Diesel-engine use is so much more efficient than most gasoline-engine use that there is no ground for encouraging conversion of fuel oil to gasoline for work which the Diesel engine can do. Therefore, as Diesel-engine demand develops, this new factor will enter to offset the present tendency toward cracking to make "gas."

Having disposed of gas making and gasoline manufacture, there remain for consideration only power and fuel uses. Because of the greater efficiency of petroleum use in internal-combustion engines, as contrasted with boilers of any type, we certainly must give preference to this use. As a matter of fact, this, for the immediate present, is not of large commercial significance, because the internal-combustion engine (limiting ourselves here to the non-automotive type) does not demand any large percentage of our fuel-oil supplies. Nevertheless, with increasing costs of liquid fuels, we may look forward to great increases in this more efficient method of fuel-oil utilization; and as these uses develop we probably shall continue to place them at this point in any priority schedule.

The remaining users of fuel oil burn the oil under a boiler or for direct heating purposes. Of these users the naval requirement unquestionably comes first. Following this, most persons would doubtless agree that the merchant-marine demand should be met before other use can be justified. That this merchant-marine demand is going to increase continuously in the next few years cannot be questioned. Not only are the estimates from our Shipping Board good evidence of this, but also there is extensive development of oil-fired shipping by the British. In fact, the "Olympic" and "Aquitania," two great Cunarders, only recently made their maiden voyages as oil-burning vessels.

After these marine uses, we can probably give the locomotive boiler next position. The large advantage of liquid fuel for such mobile power plants is well recognized. To the extent, therefore, that the locomotive cannot be electrified, we can justify oil burning in preference to the use of oil for stationary power or heating-boiler use. This preference is also supported by the critical state of the transportation demands of the country at the present. It is to be anticipated that this preference for locomotive use will not continue long except in certain limited portions of the country where liquid fuels are much more readily available than solid fuels. Oil for locomotives is rapidly becoming practically prohibitive in cost or wholly unavailable.

As a matter of fact, by the time we reach this stage it makes little difference to whom we give priority; for if the higher classes of use are satisfied, no oil is left to distribute. Nevertheless, one may as well continue to theorize through to the end, and discriminate between the steam-power plant and the heating plant. It appears that the former should be given preference over the latter, for a greater increase in efficiency is doubtless generally obtained in power production through oil firing as compared with solid-fuel firing, than can be found in contrasting liquid-fuel and solid-fuel use for heating puposes. Thus, we would place steam-power-plant use ahead of heating-plant application, the latter being the last of the twelve items in the schedule.

As a result of the discussion, one obtains a priority list for liquid fuels as follows:

	Character of Use	Kind of Oil Applied
1	Lubrication	Lubricants (fuel oil)
2	Illumination	Kerosene
3	Chemical byproducts	Miscellaneous
4	Automotive engines	Gasoline
5	Gas manufacture	Fuel oil
6	Gasoline manufacture	Fuel oil
7	Internal-combustion (Diesel) engines	Fuel oil
8	Navy	Fuel oil
9	Merchant marine	Fuel oil
10	Locomotive firing	Fuel oil
11	Steam-power plants	Fuel oil
12	Heating	Fuel oil

It is doubtful if this schedule will meet general acceptance, but it represents the application of a relatively new principle in national-resource thought, and, as such, it should be considered. In any event, whether one agrees with it or not, it represents a starting point for the consideration of a still more important engineering problem, namely: What attention must be given to petroleum substitutes, in order that all these industrial needs for liquid fuels may most effectively be met? This latter question, however, requires separate discussion.

NEWS FROM THE OIL FIELDS

Revision of Standard Petroleum Specifications

By R. S. McBRIDE

The conference on the revision of standard specifications for petroleum products held Oct. 18 in Washington was attended by representatives of all the Government departments interested, state oil inspectors, oil producing and refining interests, and automotive interests.

The specifications particularly under consideration were those for gasoline, kerosene, burning oils, fuel oils, and a wide variety of lubricants. In executive session the committee continued consideration of the proposals for the two days following the public conference and it is expected that the revision of the standards will be completed within a short time and revised standards published covering all of these materials. Nominally the specifications which it adopts relate only to Government purchases of petroleum but in practice a number of states are adopting the specifications, particularly those for gasoline.

Four states have already adopted the motor gasoline specifications of this federal committee and others give evidence that they are likely to do so. Some states are writing the specifications into the state law; others simply provide that the latest specification of the committee shall govern, or place the matter in the hands of a commissioner.

The advantage of state regulation in contrast with federal legislation seems to be wholly with the smaller refiners who like to have different standards which will permit disposal of their poorer products in states where less rigid requirements prevail. It was the consensus of opinion that where state laws do specify gasoline standards, the refiners, particularly the larger operators, are very careful as to the quality of material shipped into that state.

Oil-Land Leases in California

To date over 105 applications for the leases to oil lands under the Federal leasing law in California have been made. The total acreage under these applications is 31,840. A total of royalties amounting to over $6,775,000 has been paid to the Government by California lessees. Of this amount one-fifth, or $1,355,000, will be turned over to the State of California. At present the Federal Land Office is compiling maps showing unappropriated oil lands in areas of known favorable structure and formation. This information is available at the various offices of the Land Office in San Francisco, Visalia and Los Angeles.

Texas State Institutions Require 80,000 Bbl. of Oil Annually

From Our Special Correspondent

The State Board of Control has awarded contracts for supplying the various state institutions with oil. The Nortex Refining Co., of Eldorado, Kan., will supply the institutions of north Texas, and the Humble Oil & Refining Co. those of south Texas. In all, about 80,000 bbl. will be required for the year.

Stephens County is now the largest oil-producing county in Texas. Many new wells are being brought in, and it is probable that the present production of about 90,000 bbl. daily will be increased. South of Breckenridge, in this county, the I. A. Stocker No. 2 well, after being shot, settled down to a flow of 4,000 bbl. daily; the joint well of the Humble Oil & Refining Co. and the Templeman Oil Corp., in the Breckenridge district, was also shot, and its flow increased to 400 bbl. Other companies that have increased their Stephens County production lately are the Gulf Production Co., Fensland, Magnolium Petroleum, Mid-Kansas and Texas companies. Extensive work is now being pushed in the Eliasville district.

Burkburnett and Electra fields continue to furnish many new producing wells. The most important completion lately is the big gas well of the Camp Oil & Gas Co., south of Burkburnett, in the Texhoma district.

Three Sections Prospecting for Oil in Nevada

From Our Special Correspondent

Drilling for oil continues in three widely-separated areas in Nevada and a derrick is now being erected for active operations in still another. Individuals who are connected with the Red River Lumber Co. have acquired a big acreage near Sulphur, on the Western Pacific R.R., and will sink a test well. The Red River Lumber Co. is working a sulphur deposit near by, although it is said to have no connection as a company with the oil-drilling operations.

The well of the California Excelsior Oil Co., in Fishlake valley, 55 miles from Tonopah, is now down over 400 ft. and making progress at the rate of 25 ft. a day, according to K. Davis, a former Texas operator who is in charge of drilling operations. Mr. Davis states that there is a showing of oil in the well and that he is much encouraged.

The greatest activity is in the Fallon section. Six companies are actually drilling in the field and as permits under the new leasing act are now being received it is expected that still others will soon be busy.

September Oil Production in Wyoming Shows Increase

From Our Special Correspondent

During September forty-four wells were completed in Wyoming, twelve of them dry. The total oil production was 785 bbl. greater per day than during the preceding month. Over 400 wells were being drilled on the first of the month. In the Osage field one dry and five producing wells were completed during the month, the largest number for any field in the state. A recent completion is the V. M. Kirk well, which came in from below 1,500 ft. as a gusher. The Quinn Oil Co. is down over 1,400 ft., and in all about 20 rigs are set up in this field.

Well Near Fort Norman, Can., of Scientific Importance

From Our Special Correspondent

It has been recently announced that drilling operations of the Imperial Oil Co. on the Mackenzie River struck oil on Aug. 25 at a depth of 783 ft. The oil flowed out of a six-inch casing for thirty minutes, when the well was capped and shut in. Any estimate as to the amount of oil this well would produce is only a guess, as there was no receiving tankage available and an accurate test could not be made. The discovery is considered an important strike and scientifically of much value. From a commercial point of view, however, it is not of immediate value as it probably will be years before it can be made available in quantities for the use of the Canadian market on account of its remoteness from any refinery outlet.

Two New Gushers Added to Tampico Field

From Our Special Correspondent

Two more big gushers have been added to the list of Mexico's oil producers. The first was brought in by the Cias del Agwi, and the second by the Huasteca Petroleum Corporation. The Agwi well was brought in at a depth of a little over two thousand feet. The gusher is located on the bank of the Tancochin River on Lot 251, Amatlan. Its estimated flow is in the neighborhood of 30,000 bbl. daily. This company has three other big producers as this same lot. The second well, which was a test in the Zacamixtle country, is one of great importance. Several companies have dotted this territory with well locations, as the geological reports recommended this section highly. When salt water was struck in the International well two weeks ago and several other tests were down over 2,500 ft. things looked doubtful, in fact several of the rigs closed down temporarily.

ECHOES FROM THE FRATERNITY

SOCIETIES, ADDRESSES, AND REPORTS

Chinese Silver Mines of Six Hundred Years Ago Discovered

Much Silver Was Removed—Still More Accessible by Modern Methods—Obstacles to Successful Exploitation

"In the Kaying section of northern Kuantung," writes S. S. Beath, of Kaying Academy, in *Millard's Review of the Far East*, "there are several mines that have long been abandoned. Recently American mining interests have investigated to learn if they still contain ore of sufficient value to warrant further operations by modern methods.

"Geologically speaking, the mines here are in a limestone formation that was probably at one time intruded by molten rock, thus forming the pockets of ore that were mined. Silver and large quantities of galena were thus formed. The latter ore is still to be found near the surface of the earth. There are also large deposits of manganese, but the high cost of shipping has prevented its export.

"One of the most promising sections lay to the northeast of Kaying in a rather sparsely populated valley. A portion of this valley, perhaps a mile square, had been worked over carefully by the ancient miners and not less than a million tons of slag remains as the result of the smelting process. Most if not all the ore smelted was produced in a small contiguous area and treated at small charcoal smelters.

"The underground workings of these mines are well preserved, though they are probably 600 years old. Shafts chiseled out of the solid rock lead down at about 45 deg. to a series of horizontal passages, then a second series to a lower level, and so on, to a considerable depth. The work must have been dangerous and tedious, as these excavations are only large enough to admit one man. It is probable that the ore was carried out in baskets. No trace exists of any pumping system, though it is reasonable to suppose that crude bamboo pumps were employed to keep the water under control. Baskets and bamboo pumps are still used in Nankin.

"The American miners interested in this exploitation originally expected to find silver ore at relatively shallow depth, assuming that the native miners must have been soon hindered by mine water. The surprisingly extensive and deep native workings have led them to conclude that the best solution of their problem involves the exploitation of possible deeper ores by means of modern mining machinery.

"In the process of investigation a stone tablet was discovered in the vicinity that explained the reason for the closing of the mines. This tablet, dating from a dynasty in power 600 years ago, bears an edict from the magistrate at Kaying forbidding any further working of the mines. The edict responded to a petition by the local clans stating that the operations were interrupting the natural water courses, spoiling the fields, and that the water was being poisoned by the smelting process, resulting in many deaths.

"The same group of engineers are working on perhaps half a dozen other similar projects, many of which are promising. South of here there is an abandoned silver mine of the vein type that is said to be of tremendous size. The work was stopped, according to local tradition, because of 'feng shui' difficulties over a grave belonging to a prominent clan. The ancient miners followed the veins of ore under a large mountain, and when baffled by underground water they dug an immense underground channel that is said to be a considerable feat of engineering. Today local opposition to the 'foreign devils' prevents further exploitation of a most promising mine. Large quantities of unmined ore are almost certainly there. It seems to be the general opinion of these men that the Chinese miners with primitive tools showed great skill in making Mother Earth yield up her treasure.

"Many current reports seem to indicate that China is virgin territory as far as mining is concerned, like Siberia, but in this section at least most of the deposits of common minerals have been discovered and worked. This is true of surface mines, but little is known of the deeply covered mineral resources. The most promise seems to lie in the direction of reopening these ancient mines, and applying modern methods.

Obstacles to Western Development

"There are many difficulties and obstacles to be overcome in this type of work. Official channels are difficult to navigate, and official sanction once secured may fall on deaf ears when one has to deal with local officials and clans. Part of the opposition is due to a conservative attitude toward foreign enterprise, but the greater reason is the so-called 'feng shui' idea, which is well known to all residents in China. This conception, which forbids the disturbance of the vicinity of graves by digging, of course is a great hindrance to mining. There is, doubtless, much unmined silver and other ore in this section, but whether foreign interests will be able to mine it is, at least for the present, rather problematical. If the difficulties were technical, modern methods would make success reasonably certain, but the other difficulties I have mentioned are much harder to deal with successfully."

Prospectors in New Caledonia Propose, but Paris Disposes

A group of prospectors in New Caledonia (French) recently requested the Consul General of that colony to promulgate and enforce a law that should reserve the rights of discovery to the prospector concerned. The Consul General replied, according to *Le Bulletin du Commerce de la Nouvelle-Caledonie*, to the effect that he did not make the laws for France-in-the-Southern-Hemisphere ("la France australe") and that only certain gentlemen living at their antipodes, knowing nothing about Nouvelle-Caledonie and ignoring their existence for the most part, decided all Caledonian questions, and from them there was no appeal. Thus it is that they have inflicted on the mining world a law which both the colony and its prospectors must obey.

"Perhaps," says *Le Bulletin*, "if someone should try to make these gentlemen who manufacture the world's laws listen to reason, rights of discovery would be accorded—but it is doubtful. These mining laws are voted by indigenes or autochthones of Carpentras, Paris, Cognac, or Dragugnan, who do not know what a mine is and do not care. They vote 'for' or 'against' with serene indifference. They will vote a law that ruins a province if the author of the bill is their friend. It is possible that they would adopt a good law for Nouvelle-Caledonie if it were presented by a member of the majority. But that would not be their fault."

Aluminum-Bronze Coinage Chosen by France

In these columns for July 31 it was announced that France had decided to replace or supplement her silver small-change supply with metallic tokens or "counters" issued for the chambers of commerce in denominations of 2 fr., 1 fr., and 0.50 fr. *Journal du Four Electrique et des Industries Electrochimiques* has recently stated that after a number of tests France has decided to use the aluminum-bronze of Henri Ste.-Claire-Deville for these chamber of commerce counters. The greater hardness of this alloy will necessitate special machinery for the minting of this issue. Some years ago it was suggested that the French copper coins be replaced by others struck from this bronze.

Four hundred members of the American Society of Mechanical Engineers have organized a section on Materials Handling. This section will hold special meetings on particular subjects coming within the scope of its field.

MEN YOU SHOULD KNOW ABOUT

F. W. DeWolf, State Geologist of Illinois, was in Washington, D. C., last week.

Harold W. Stotesbury recently examined a mine in Hailey, Idaho, for the Tonopah Mining Co.

Philip S. Smith has returned to Washington after a summer of field work in Alaska for the U. S. Geological Survey.

W. C. Alden has returned to his desk in the U. S. Geological Survey after a study of the glacial deposits and Tertiary bench gravels in Montana.

D. F. Hewett has returned to Washington after examining the Crimora manganese mine, Augusta County, Va., for the U. S. Geological Survey.

L. C. Graton, consulting geologist, of Cambridge, Mass., left for Peru early in October. He expects to be absent from the United States for six months or longer.

Tom Hamilton, mining engineer, expected to leave Bolivia for Buenos Aires, Argentine Republic, on Aug. 17, and hoped to reach the latter city by Sept. 6.

George E. Collins, mining engineer of Denver, Col., was in New York recently on professional business. Mr. Collins expected to leave for Denver on Oct. 23.

E. L. Hawes, mining engineer with the Ingersoll-Rand Co., is going to the Johannesburg office of that company in the Union of South Africa, and not to South America.

George H. Garrey, consulting engineer and geologist of the Tonopah Belmont company, has returned to Tonopah, Nev., after spending several months in the East.

Dr. Willet G. Miller, provincial geologist for Ontario, and Thomas W. Gibson, Deputy Minister of Mines, are making an official visit to the mining districts of northern Ontario.

W. H. Knowles, field representative of American Mining Congress, was in Helena, Mont., early in October, in connection with the organization of a Montana chapter of the congress.

J. D. Millen, recently general manager of Mount Bischoff Tin, Tasmania, is now a senator in the Commonwealth Parliament. He was succeeded as general manager by C. W. Gudgeon.

Carl O. Lindberg, mining engineer, of Los Angeles, Cal., is in New York on his way to Bolivia, sailing early in November. He expects to return to the United States about Jan. 15, 1921.

William J. Loring was in Carson City, Nev., early in October in connection with the suit in the Federal court brought by David Taylor against the Nevada Humboldt Tungsten Mines Co.

George D. Van Arsdale, consulting chemist to Phelps Dodge Corporation, will move to Los Angeles, Cal., where he will open an office as consulting engineer in hydrometallurgy, flotation and similar fields.

C. W. Knight, assistant provincial geologist, Ontario Bureau of Mines, is in charge of the geological examination of the Bourkes area along the L. & N. O. Ry. His present addresss is Bourkes, Ont.

Paul Paine, consulting petroleum engineer, of Tulsa, Okla., and formerly with Gypsy Oil Co., is a special lecturer at Massachusetts Institute of Technology, where he is giving a course on oil and gas production.

Bulkeley Wells, of Denver, and George M. Taylor, of Colorado Springs, Col., have been appointed to the committee of Colorado Metal Mining Association to co-operate with those seeking to readjust relations with the management of Colorado School of Mines.

F. H. Curry, formerly with Inspiration Consolidated Copper Co., Miami, Ariz., sailed from New York City on Oct. 22 for Cape Town, South Africa, on his way to the Belgian Congo, where he will be mill superintendent for L'Union Minière du Haut-Katanga.

Elmer H. Finch and Max W. Ball, geologists formerly with the U. S. Geological Survey and now of the Matador subsidiary of Royal Dutch-Shell Oil Co., recently accompanied president W. Van Der Gracht of Roxanna Oil Co. (Cal.) to the oil fields of Grand County, Utah.

H. A. C. Jenison, of the U. S. Geological Survey, was looking over the Engels, Walker and other mines on the Plumas copper belt of California recently. Mr. Jenison visited the Calaveras Copper, Penn Mining and the Mammoth mines before he returned to Washington, D. C.

Bert W. Dyer, of U. S. Mine Rescue Car No. 5, Butte, Mont., graduate of University of Utah, and Assistant Mine Safety Engineer of Bureau of Mines since 1918, has been appointed Mine Inspector for Alaska. He will have headquarters at Fairbanks on the Tanana, and will work in co-operation with the Alaska Mining Experiment Station.

G. F. Loughlin, geologist in charge of the division of mineral resources, U. S. Geological Survey, was in Butte, Mont., recently on his way to the Pacific coast, and visited the geological department of the Leonard mine. He will visit the Survey offices at Salt Lake City, Denver, and San Francisco, before returning to Washington, D. C.

E. W. Shaw, geologist and mining engineer, formerly with the U. S. Geological Survey, who has been doing geologic mapping with a number of other geologists in Bolivia, was in Charagua on Aug. 16, and expects to return to the United States in December. His address until Oct. 1 was care of Bolivian-Argentine Exploration Corporation, Bartolome Mitre 478, Buenos Aires.

SOCIETY MEETINGS ANNOUNCED

The New York section of The Mining and Metallurgical Society of America met at the Columbia University Club, New York City, on Oct. 27 to hear an address by Van. H. Manning, research director of the American Petroleum Institute, who spoke on "The Petroleum Industry."

The Nevada Chapter of American Association of Engineers, which recently completed its organization, will announce its program at a meeting to be held Nov. 9, at the rooms of the Chamber of Commerce, Reno, Nev. The officers of the chapter are H. M. Loy, president; H. F. Holly, vice-president; L. V. Campbell, secretary.

The meeting of the Columbia Section of A. I. M. E., to be held at Kellogg, Idaho, has been postponed from Oct. 29 and 30 to Nov. 19 and 20. This change has been made in the hope that it will thus become possible for the president, Herbert Hoover, to attend the meeting, as he plans to do. Besides an address by Mr. Hoover, the program will offer papers by Rush J. White and Thomas L. Owens, assistant manager of Federal Mining & Smelting Co. L. W. Armstrong, of Spokane, Wash., is secretary of the section, and Rush J. White is chairman of the local committee of arrangements.

OBITUARY

Gustave de la Marre, chief engineer of Cie. des Mines de Roche-la-Molière & Firminy, and graduate of St.-Etienne in 1894, died in his forty-ninth year on Sept. 30, after a brief illness. M. de la Marre had been with the Firminy mines ever since his graduation, and passed from the rank of mining engineer to chief by successive steps. He had long filled the duties of the last position before being formally installed therein.

G. D. E. Mortimer, mining engineer, and president and general manager of Bolivian Mines Co., Inc., Casilla No. 12, La Paz, Bolivia, died in that city on May 4, last. Mr. Mortimer was a native of Clifton, Ohio, and was educated at the Episcopal Academy of Philadelphia, Pa., and Lehigh University. He showed great ability as a mining engineer, notably as organizer and administrator, being greatly helped by his sunny and lovable disposition. Before going to La Paz Mr. Mortimer had had charge of the Inca Oro at Sorata, Bolivia. Yet earlier he had been in charge of mining properties in California, Arizona, Nevada and Kerr Lake mine, Cobalt, Ontario. Letters may be addressed to his company at 1202 West End Trust Building, Philadelphia, or in care of Rev. S. D. McConnell, Easton, Md.

The Utah Consolidated—Utah-Apex Lawsuit

Court Decides in Favor of Utah-Apex Five Out of Six Cases Brought by Utah Consolidated Mining Co. To Stop Former From Mining Ore in Yampa Limestone — Plaintiff Failed To Prove Formation a Broad Lode

BY E. B. JENNINGS

[*The decision in the apex litigation between the Utah-Apex Mining Co. and the Utah Consolidated Mining Co., both operating in Bingham Canyon, Utah, was handed down by Judge Tillman H. Johnson, of the U. S. Circuit Court of Appeals, on Oct. 20 after the case had been under advisement by him since Jan. 31 last, when the arguments ended. Judge Johnson decided five of the six cases in favor of Utah-Apex in suits brought by Utah Consolidated to enjoin the Utah-Apex company from mining ore under Utah-Apex territory in the Yampa limestone. The court found against the Utah Consolidated because that company did not show by preponderance of evidence that the Yampa limestone was a broad lode. The decision in the Leadville case, brought by the Utah-Apex, holds that the barren Highland Boy limestone between the Highland Boy orebodies and the Leadville orebody breaks the continuity of the lode and that the Highland Boy limestone cannot be considered the lode.*

In the case brought by the Utah-Apex company holding that the Dana Leadville fissure is the apex by extralateral rights of orebodies being mined by the Highland Boy, the court held that the Utah-Apex did not prove by a preponderance of evidence that the Dana fissure above and the Leadville fissure below were one and the same fissure, and decided this case against the Utah-Apex.—EDITOR.]

THE lawsuits between the Utah Consolidated and Utah-Apex mining companies, which, after pending for nearly two years, finally came to trial in November, 1919, constituted one of the most important litigations in the West. The suits were tried before Judge Tillman H. Johnson, of the U. S. Circuit Court of Appeals, in Salt Lake City. By consent of the two companies the action of the Utah-Apex against the Utah Consolidated, which was known as the Leadville or Highland Boy case, was tried first. This occupied three weeks.

The second suit, known as the Yampa case, occupied a like time. In the Yampa case, the Utah Consolidated company asked for $3,000,000 for illegal extraction of ore from the Yampa limestone, which apexed on the Utah Consolidated property. In replying to this action the Utah-Apex Mining Co. filed suit for $1,750,000 for ore mined from the Dana or Leadville vein. Both suits developed into debates on the question of which was the lode, the flat-dipping limestone beds or the nearly vertical veins which cut them. In the Yampa case, the ore in question had been mined on the Petro vein, in or near its intersection with the Yampa limestone. In the Dana suit, the ore mined by the Utah Consolidated was in the Highland Boy limestone at its intersection with the Dana or Leadville vein. The Utah Consolidated company obtained surface rights from the Utah Metal & Tunnel Co. to gain a clear title to the apex rights of the Highland Boy limestone. There was some question as to the exact point of apexing of the Dana vein on the Charles A. Dana claim owned by the Utah-Apex, but this was cleared up by some surface work done by the Utah-Apex to prove this. This left the decision to be based entirely on the opinions of the expert geologists and engineers.

Work was started by both companies almost two years before the suits came to trial. Prominent attorneys and geologists from all over the country were retained by both companies. Among these were Judge Curtiss H. Lindley, of San Francisco; Judge John A. Marshall, of Salt Lake City; Dr. Waldemar Lindgren, Dr. A. C. Lawson, Albert Burch, and O. P. Peterson, who were retained by the Utah-Apex. The Utah Consolidated engaged John Grey, of Spokane, and A. C. Ellis, of Salt Lake City, as attorneys. Horace V. Winchell, former president of the A.I.M.E.; Dr. J. F. Kemp, Dr. C. K. Leith, Reno H. Sales, A. N. Winchell, Perry G. Harrison, and R. N. Hunt represented the geologic staff of the Utah Consolidated.

The models used in court by the Utah Consolidated were made by F. C. Calloway, and consisted of a wire reproduction in miniature of the surface and underground workings of both mines and a block model of the limestone beds of the Utah Consolidated and Utah-Apex properties. The maps used by the Utah Consolidated were constructed by the company's engineering staff. The Utah-Apex exhibits were nearly duplicates of those shown by the Utah Consolidated, the models having been made by E. C. Uren, of Nevada City, Cal., and the maps made under the direction of Frank Anderson, a mining engineer of Salt Lake City, and S. G. Emidio, of the Utah-Apex. The cost of all the exhibits was about $100,000.

DANA CASE OPENED

The testimony in the Leadville case was opened by Utah Consolidated, the defendant. R. N. Hunt explained in detail the conditions existing in and near the Leadville vein and the Highland Boy limestone, as shown by the geologic maps. Mr. Hunt did not attempt to elucidate the theory of the mineralization, but confined his testimony to actual conditions that he had observed. The direct and cross examination of Mr. Hunt occupied about three days.

A. N. Winchell described the rocks and ores of the district, of which he had made an exhaustive petrographic study. Mr. Winchell explained in detail the methods used in making a microscopic examination of rocks. He stated that he had found that the ore was to a large extent in the limestone formations and rarely in the interlying quartzites. Mr. Winchell had made a study of nearly eight hundred specimens taken from the formations of the district.

Prof. C. K. Leith described the deposition of ore in the limestone beddings. The presence of ore was due, he said, to several factors, namely, the proximity of the porphyry and the consequent alteration of the limestone, the porphyry dikes in the limestone, and the bending and thickening of the limestone lodes. The fact that a great part of the ore is along and parallel to the bedding showed that this bedding was the distinctive feature of the occurrence of the ore on the Utah Consolidated property. Mr. Leith stated that the fissures and beddings were closely related but that the porphyry intrusions were the mineralizing factors.

1. SURFACE PLANT OF UTAH-APEX MINING CO. AT BINGHAM CANYON, UTAH. 2. UTAH CONSOLIDATED MINING CO.'S SURFACE OUTCROPS OF DANA FISSURE. 5-6. A LINE DRAWN BETWEEN THESE POINTS WILL REPRESENT THE COURSE

Dr. J. F. Kemp discussed the possibility of correlating the Jordan and Commercial limes, which are the principal mineralized portions of the U. S. mine, with the Yampa and Highland Boy lime beds of the Utah Consolidated on the opposite side of the Utah Copper porphyry mass. He showed that this correlation was possible.

Horace V. Winchell explained that the mineralization of the lime beds was due to the solutions from the cooling porphyry masses, but that it was impossible to tell by what definite fissure or crack these solutions came up to the overlying lime beds. In defining a lode, Mr. Winchell said: "A lode or vein is mineralized rock or rocks which contain such indications of valuable minerals as to justify development with the expectation of finding ore. As soon as quartzite over a considerable distance becomes mineralized, then it becomes a lode. Just as soon as either the other rocks can produce and do produce ore, or contain indications which lead the experienced miner or prospector of judgment to develop it in the expectation of finding ore, then it becomes a lode." The Highland Boy and overlying limestones were so mineralized, and were claimed to be lodes.

Reno H. Sales, geologist of the Anaconda Copper Mining Co., defined the conditions in the stopes of the Highland Boy lime and in and near the Leadville fissure. He described the fissures passing through the stopes in the limestone but did not directly connect these fissures with the mineralization of the Highland Boy limestone. Mr. Sales completed the testimony for the Utah Consolidated in this case.

The first witness for the Utah-Apex, Frank Anderson, told of sampling the limestone and adjoining quartzite, the results of the sampling showing that in the places sampled the quartzite disclosed more mineralization than the limestone. In cross examination, Mr. Anderson stated that he had never heard of a broad limestone bed being sampled to prove it a lode.

J. A. Norden, assistant superintendent of the Utah-Apex company, described the upper levels of the Apex mine along the Parnell bedding and the Dana fissure. He stated that the greater part of the ore in these workings had been taken from the quartzite. These workings are several hundred feet above the ore in question in the Highland Boy limestone.

Colonel Ellsworth Dagget, of Salt Lake City, formerly mining engineer at the old Winnamuck mine, recalled that his experience in the early days in Bingham had been that the ore to a large extent was found in the fault fissures. He showed several specimens of ore taken from the mines in Bingham from the fault fissures.

Orrin P. Peterson, geologist for the Utah-Apex company, described the Dana fissure in the upper levels of the Apex mine. He said that the mineralizing solutions from the Dana fissure had gone out for several hundred feet into the limestones and quartzite, but, because the quartzites were more crushed than the limestones, the former were more susceptible to the solutions.

Albert Burch, of Berkeley, Cal., told of making an extensive examination of both mines. In making this examination he found that the country rock consisted of three types, namely limestone, quartzite, and porphyry. Within these three classes of country rock are two types of veins, the broad lode veins and the distinct fissure veins. In the Highland Boy lode the fissures are so close, Mr. Burch said, that it is impossible to distinguish between them. The tongues or dikes of porphyry running off into the country rock were very important in its mineralization and also in limiting the extent of the orebodies in the limestone. In regard to the Dana or Leadville vein, whose principal mineralization is lead ore, this lead ore could not have been deposited from the same vein as was the copper ore in the Highland Boy limestone, but was deposited through the Dana Leadville system of veins. This Dana Leadville vein passes up through the quartzites and limestones above.

FACE PLANT. 3. PLANT OF UTAH METAL & TUNNEL CO. 4. APPROXIMATE LOCATION OF CHARLES A. DANA CLAIM AND OF THE YAMPA LIMESTONE OUTCROP. 7. APPROXIMATE LOCATION OF HIGHLAND BOY LIMESTONE OUTCROP

Dr. A. C. Lawson, of the University of California, in his testimony described the several types of veins, lodes, and orebodies. A simple vein has two distinct and well-defined walls, whereas a lode may be made up of several veins close enough together to be mined at one operation. In correlating the Dana and Leadville fissures, Dr. Lawson showed the similarity of the two fissures, inasmuch as they had the same dip and strike, the same direction of movement, and the same type of mineralization. As there is no complete connection from the surface to the Highland Boy limestone on the Dana fissure, and as it is faulted by the base of the Yampa limestone, it is impossible to make a complete correlation. There was no doubt in Dr. Lawson's mind that the Leadville and the Dana were one and the same fissure.

Dr. Lindgren gave a long introductory talk on the geology of the Bingham district at the beginning of his testimony. He did not consider that the correlation of the Jordan and Commercial limes with the Yampa and Highland Boy had been conclusively proved. Dr. Lindgren limited the Highland Boy lode in the Highland Boy limestone by the foot wall and the Alice W. dike, a small porphyry dike extending along the strike of the bedding. Outside of these limits, the limestone was not mineralized until the Dana Leadville fissure was reached, this being several hundred feet to the west. He described the Dana Leadville vein and his reasons for considering it the same vein or system of veins from the surface to the 1,800 level of the Apex, which is the lowest level in either mine. He considered the Dana Leadville system to be of later origin than the Highland Boy lime, and thought that the two were in no way related. Dr. Lindgren's testimony ended the expert testimony of the first suit, and the Yampa case followed immediately.

Testimony in Yampa Case Heard

In the Yampa case it was necessary to introduce a new set of maps and models, which were explained in detail by Perry G. Harrison. In this suit it developed that the Utah-Apex had mined ore on the Petro fissure and the Yampa lime at their intersection. The Petro fissure was followed down from the surface through the Yampa lime and extends below this into the underlying quartzite. There are continuous stopes from above the 1,000-ft. level to the 1,500-ft. level along this fissure and in or near the Yampa lime. As the old Yampa mine, now a part of the Utah Consolidated, is to a great extent inaccessible, it was necessary to rely on old maps and information furnished by former employees of the Yampa Most of the ore taken from the Yampa mine and the Utah Consolidated's workings in the same bedding has been copper ore, whereas the ore mined on the Petro fissure in the lime has been lead ore.

Mr. Winchell's testimony for the Utah Consolidated consisted of his description of the Petro fissure from the upper levels to the lowest level of the Apex and its effect on the mineralization of the Yampa lime. In this case both companies used the same witnesses as before, and the testimony was practically the same, being a statement of geologic facts and theory of the mineralization.

A third suit was presented the last day of the trial by the Utah-Apex. This was the Dana extralateral case, which was to cover the extralateral rights of the Charles A. Dana claim. No testimony other than the presentation of a map showing the extralateral rights was given.

The Utah Consolidated is one of the oldest mines in the Bingham district, having been a producer for over twenty years. In size it is the second largest, furnishing employment to about 600 men. The company has extensive holdings in the district, including the old Yampa mine, which was recently purchased from the Tintic Mining & Development Co. Its workings are in a comparatively small area in the High-

land Boy and Yampa limestones. R. H. Channing, of New York, is president; Fred Cowans, general manager, and A. S. Winther, superintendent.

The Utah-Apex Mining Co. was erganized a short time after the Utah Consolidated, and ineludes the old Petro, York, and Phoenix mines. The workings of the Apex are in the lime beds and veins stratigraphically above and to the north of the Utah Consolidated, and the lower and recent workings go below the haulage level and follow the fissures from above into the Yampa limestone and intervening quartzites. Recent work which has been done connecting the two mines shows the proximity of the workings and difficulty of distinguishing between the property of each. R. E. Haffenreffer, Jr., of Boston, is president, and V. S. Rood is general manager. The Utah-Apex is the largest lead mine in the state, and employs about five hundred men.

Canada Copper's New Concentrator Placed in Operation

The new 2,000-ton concentrator of the Canada Copper Corporation at Allenby, B. C., was finally placed in operation on Oct. 18. The new primary crushing plant is said to be giving excellent service at full rated capacity. No other report of results has been received to date.

St. Louis Section of Institute Holds Autumn Meeting

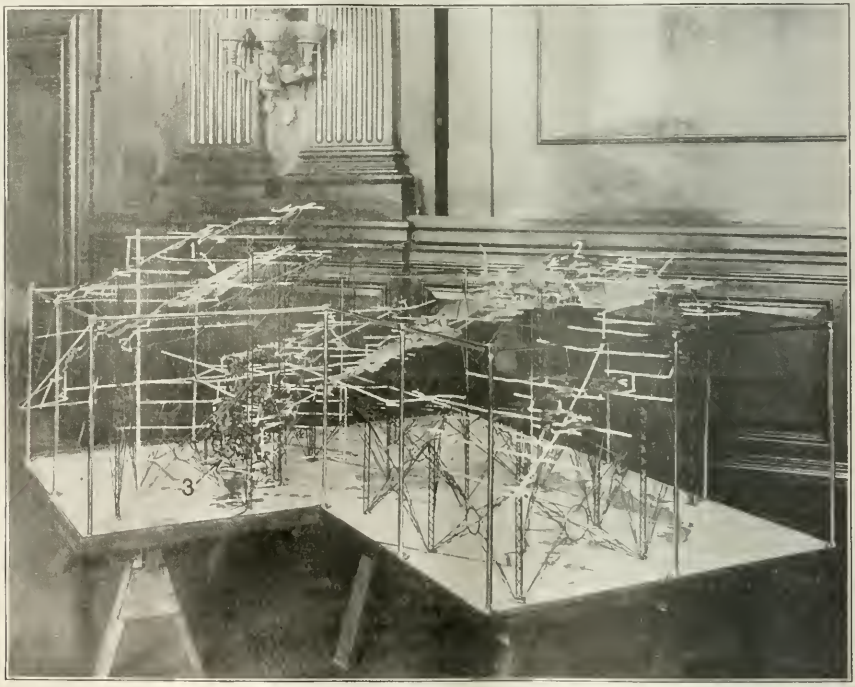
Visit Plants at Bonne Terre, Flat River and Fredericktown—Many Social Features

The St. Louis Section of the American Institute of Mining & Metallurgy held its Autumn meeting in the Lead Belt. The party left St. Louis on the evening of Oct. 15 and were entertained that evening at the Bonne Terre Club House with dancing and bridge whist. The morning of the following day was spent in visiting the mines and mills at Bonne Terre and Flat River of the St. Joe, Federal and National companies, with luncheon at Farmington. In the afternoon the entire party went by auto through the picturesque hills of the Ozarks, which were in their beautiful Autumn foliage, to Fredericktown, in Madison County, and inspected the mill and smelting works of the Missouri Cobalt Co., the only plant in Missouri that is producing copper, nickel, cobalt and some lead, the latter as a by-product, although the mine was originally worked for lead alone.

The local committee entertained the members in the evening with another dancing and bridge whist party, followed by refreshments.

The morning of the following day was spent at Iron Mountain, which is being reopened on a small scale, and a very enjoyable picnic luncheon was served on the "Elephant-Rocks," the huge granite boulders at the Graniteville quarries that have been formed by aerial erosion. One of these is a 20-ton rocking stone that some of the members tilted with ease. Beautiful, bright, warm weather favored the excursion until the conclusion of the trip to the granite boulders, when as the party was on the eve of breaking up to return home, a violent thunder storm arose that was reminiscent of April, rather than the late fall.

The energetic efforts of the local committee made the event a great success, which was enjoyed by over 200 members and guests, in which the local membership was well represented. Those chiefly responsible for the success of the meeting, in which the ladies participated as an innovation, were C. J. Adami, of the St. Joseph Lead Co.; H. G. Washburn, of the Federal Lead Co.; Messrs. Comyns & Thompson, of the National Lead Co., and T. J. Mateer, of the Missouri Cobalt Co.



WIRE MODEL (1 IN. = 50 FT.) EXHIBITED BY UTAH-APEX MINING CO. TO ILLUSTRATE PETRO-YAMPA CASE. MODEL MADE BY E. C. UREN, NEVADA CITY, CALIF.

But nine fatal accidents have occurred in Marquette County, Mich., during the last year, according to the report of the mine inspector, James H. Yelland. The fatality rate is 1.88 per 1,000 men employed. During the year 4,799 men were employed on the average in the industry, including quarries. This is the lowest fatality record made in the county.

Claim Increased Freight Rates on Bullion Absorbs Profit

Colorado Operators and Traffic Managers Seek Remedy for Interstate Shippers

During the recent investigations in Colorado into the matter of increased freight rates it developed that the increase on bullion shipped from western smelting points to refining plants on the Atlantic seaboard, places a heavy burden upon the mining industry. While mine operators do not directly pay this freight, the cost of moving the bullion is passed back to them by the smelters in increased charges and deductions. Operators claim that the increase, when apportioned back to each ton of ore produced, often absorbs the profit in mining it.

On Oct. 16, the Colorado Metal Mining Association filed with the Western Trunk Line Committee, an application for a hearing looking to a readjustment of bullion rates in effect between smelting points in Colorado and seaboard refining points. Mining organizations in the various western states were invited to join with the Colorado organization in asking for the hearing, since any readjustment of rates must necessarily include an entire revision of the bullion rates from all western smelting points.

The Colorado organization in support of their petition stated:

"Owing to the increased cost of operation, producers of lead and copper ores, except in the most favorable locations and conditions, have found it no longer profitable to mine them and the output has declined to an alarming degree. Conditions in Colorado are now such that unless relief is granted, the few remaining mines which make an appreciable production of these ores, must cease shipping.

"The following table shows the decline in production since the increased rates became effective early in 1918:

PRODUCTION IN POUNDS FROM COLORADO MINES

	1917	1918	1919
Lead	69,990,012	65,960,760	35,859,675
Copper	8,122,004	6,122,004	3,310,090

"It now seems probable that the 1920 output will show an even greater decline.

"The falling off in production was due to the increased cost of operation in which transportation charges are a large factor both directly and indirectly. Transportation charges are said to affect the producer not only directly in the movement of ore and bullion, but in still greater measure are reflected back in increased treatment charges, deductions and cost of supplies.

"Prior to the order of the Railroad Administration of May 25, 1918, the bullion rate from Colorado common points to the Atlantic seaboard was $7.60 per ton. Under Order No. 28 the rate, instead of taking a 25 per cent increase, as in the case of other commodities, was arbitrarily advanced $6.50 per ton. With the 33⅓ per cent increase recently ordered, the rate is now, including war tax $19.34 per ton, or an increase of 153 per cent over the pre-war rate.

"The first increase, figured on each ton of ore as mined, in many instances entirely absorbed the profit, and a large proportion of the mines were forced to close down. The last increase will still further curtail shipments, and instead of increasing the revenues of the carriers will result in just the opposite effect. The decline of the mining industry in Colorado has greatly reduced the revenues of railroads serving the mining districts and the distressing conditions are rapidly leading to the almost complete depopulation of communities which depend upon the mines."

WEEKLY RÉSUMÉ

The long awaited decision in the lawsuit between the Utah Apex and the Utah Consolidated mining companies was rendered on Oct. 29 in favor of Utah Apex. Advices from Wallace, Ida., state that the pending apex litigation between the Federal Mining & Smelting Co. and the Hecla Mining Co. has apparently been settled out of court. In British Columbia, the Canada Copper Corporation finally started its new concentrator at Allenby on Oct. 18. Mine operators of the Cobalt district, Ontario have adopted a flat wage scale in place of the bonus plan recently in effect. At Bisbee, Ariz., the Phelps Dodge Corporation has laid off part of the force engaged on the Sacramento Hill excavation work owing to the delay experienced in building the new concentrator. In the Grass Valley district, California, the power restrictions hampering the operations of the gold mining companies have been removed.

In Washington, the gold committee of the American Bankers' Association reported unfavorably on the McFadden gold bonus bill at the convention of the Association held during the week. O. C. Ralston, of the Bureau of Mines, who has recently returned from Alaska, states that the erection of a smelter there is not advisable.

Federal and Hecla Apparently Settle Apex Dispute

Both Companies Stop Work Intended To Demonstrate Possession of Apex

After a year of intensive preparation for a battle in the courts over apex rights involving the ownership of the bonanza orebody in what is commonly termed the "east" vein of the Hecla mine, the Federal Mining & Smelting Co. and the Hecla Mining Co. have apparently settled their differences out of court. So far as the public is concerned, there had been no intimation that a settlement was pending, and the orders issued by both companies on the same day to discontinue all work that was under way in preparation for the litigation came as a complete surprise. James F. McCarthy, manager of the Hecla, was in New York the day the order was issued, and Frederick Burbidge, manager of the Federal, was in Spokane.

Northwest Convention Date Set

The Northwest Mining Convention will be held in Spokane, Wash., February 28 to March 5, next year, according to a preliminary announcement.

Phelps-Dodge Corp. Cuts Down Sacramento Hill Force

Slow Delivery of Mill Construction Material Delays Completion—Market Conditions Also a Reason

The Copper Queen Branch of the Phelps Dodge Corporation announced on Oct. 16 that a number of men would be laid off from the Sacramento Hill steam shovel work on Nov. 1. The reason given is that owing to delay in receiving materials needed for mill construction the starting of the new concentrator will be delayed approximately six months or until July 1, 1920, so that the company can now lay off one-half of the Sacramento Hill force and be ready for ore production by the time the mill is completed. Present market conditions are also given as a further reason. About 350 men are effected.

Work of removing Sacramento Hill, in Bisbee, Ariz., was begun in April, 1917, with steam shovels, the object being to recover approximately 25,000,000 tons of low-grade copper ore that lay under the flank of the hill. This tonnage includes smelting, concentrating and leaching ore. The peak of the mountain was originally about 300 ft. above the gulch on the upper side. When the work is finished, in place of the hill, there will be two pits, roughly circular in outline, one about 1,500 ft. in diameter and 420 ft. deep and the other about 2,200 by 1,500 by 440 ft. deep. The total amount of material to be moved was about 40,000,000 solid cu.yd. in place, of which by volume slightly less than one-third was ore. It will require in all about sixteen years to complete the work.

To date, about 5,500,000 cu.yd. of material has been moved, which was nearly all waste, and has been hauled away and dumped about two miles from the pit. A concentrator is being built to handle 4,000 tons of ore per day and ore production will begin in 1921.

The hill is being worked off in horizontal benches 60, 45 or 30 ft. in height. About sixteen miles of railroad track were required to connect these benches with the waste dumps and the concentrator. The ground is drilled with churn drills and heavy compressed air drills, and blasted with dynamite to break it up and facilitate loading by the shovels. Seven steam shovels are used on the work, all standard machines, weighing about 110 tons, and having 3½-yd. dippers.

Cobalt Operators Drop Bonus for Flat Wage Scale

At a recent meeting of the Cobalt Mine Managers' Association it was decided to drop the bonus plan of wages, under which a bonus was paid depending on the price of silver, and adopt a flat scale. The wages will be unchanged, $5.25 for miners and others in proportion. Following the drop in the price of silver, wages were retained at the same level as when silver sold for $1.20 per ounce, and it was felt better to drop the bonus altogether and go on the flat wage basis.

Smelter Unnecessary in Alaska, Says O. C. Ralston

Tonnage Insufficient To Warrant Erection of Plant—Granby Accessible to Southeast Mines

Concentration or hydrometallurgy seems to be the logical recourse in handling the copper ores in Alaska, rather than attempting to smelt these ores within the territory. This is the opinion expressed by Oliver C. Ralston, of the Bureau of Mines, who with Alfred H. Brooks, of the Geological Survey, at the direction of the Secretary of the Interior, collaborated in an investigation of the metallurgical needs of the Alaskan copper ores. "In general, it is hard to see any justification for a smelter," said Mr. Ralston, "to be built by anyone in either the Prince William Sound or southeastern Alaskan districts. The impression seems to have prevailed that a copper smelter was needed in the Territory. Such demand arose for an investigation that a report on the subject was called for."

Mr. Ralston's report will discuss the various types of ore and the methods which seem to him to be best adapted for their treatment. There are several thousand copper prospects in Alaska which are not being worked. There is not enough tonnage available from the so-called independent operations to justify the erection of a smelter. Even if the output of the principal producers were added, the tonnage even then might not be sufficient to justify a smelter of sufficient size to be really economical.

Since the smelter of the Granby Consolidated Mining, Smelting & Power Co. at Anyox, B. C., is fairly accessible to the copper mines in southeastern Alaska, there apparently is no thought of an additional smelter in that region.

Mr. Ralston did not visit Broad Pass. While there are a number of very promising copper prospects in that region, no large amount of shipments can be expected for some time to come.

Cottrell May Continue as Head of Bureau of Mines

The latest development in the discussion of the Bureau of Mines' directorship is the suggestion that in view of the wide differences of opinion as to the type of man who should hold this position, Dr. F. G. Cottrell may withhold his proposed resignation and continue at the head of the bureau for an indefinite period.

At the close of business on Oct. 23, the total purchases of silver which have been made by the Bureau of the Mint under the Pittman Act was 20,091,231 fine ounces.

McFadden Gold Bill Reported On Unfavorably by Committee of American Bankers' Association

Measure Defended by Sponsor on Floor of Recent Convention in Washington—Report Referred to Economic Policy Commission for Further Study

A report unfavorable to the McFadden gold bill was made by the committee on gold of the American Bankers' Association at the convention of that organization in Washington last week. The report was signed by the three members of the committee; namely, George M. Reynolds, president of the Continental and Commercial National Bank, Chicago; A. Barton Hepburn, chairman of the board of the Chase National Bank, New York; and Lawrence E. Sands, president of the First National Bank of Pittsburgh. The report, however, was not adopted by the Association as a whole but was referred to the economic policy commission of the Association for further study. Waldo Newcomer, president of the National Exchange Bank of Baltimore, was chairman of that committee.

Representative McFadden, of Pennsylvania, the chairman of the Banking and Currency Committee of the House of Representatives, not only defended his bill on the floor of the convention to which he was a delegate, but made a detailed reply to the arguments of the committee on gold. Extracts from the report made by the committee on gold follow:

"A large body of other industries, whose costs have risen faster than their prices, have similarly suffered.

"Recognizing that no national emergency exists calling for special treatment of the gold mining industry, it is difficult to make a case for singling out the gold mining industry for special relief from the Government. That it has suffered is unfortunate, but it is one of the costs of the war. It is one among a large class of those which the war has injured.

"Gold mining, however, though suffering under present conditions, enjoys a peculiar advantage which few other industries enjoy. As a consequence of the fact that gold is the standard of value the price of gold in terms of gold money is necessarily fixed. The demand for gold, however, is always unlimited. The gold miner can always sell at a fixed price as much gold as he can possibly produce. He finds his costs rising in periods of boom and prosperity, and he suffers as a consequence. On the other hand, periods of adversity, depression and falling prices bring to the gold miner, as to no one else, increased profits. He has an unlimited market in the worst depression, and the more severe the depression the lower his costs of production tend to be. He is at present suffering in an intensified form from the upswing of prices and costs. He has in the past, however, enjoyed periods of prosperity when the rest of the community was suffering, and in the natural course of things he may look forward to the recurrence of similar situations.

"In reality the propaganda in favor of doing something for gold is exactly on a par with the propaganda in favor of doing something for silver, about which we heard so much a generation ago. It has no more stable foundation than did the silver propaganda. There is nothing to justify Government interference in behalf of this industry, or to justify a Government bounty upon the production of virgin gold. Per contra there is very much to be said against such action on the part of the Government.

ARGUMENTS AGAINST BONUS

"We may pass briefly over the difficulties of administration of such an act; the danger that frauds would be practiced upon the Government; the difficulty of distinguishing virgin from old gold melted down. Gold which differs from other gold merely in having a special history. . . . The temptation to manufacture history instead of mining gold would be very great.

"Again, the provisions in the McFadden Bill introducing the index number of commodity prices as a basis for fixing the rate of taxes on gold manufacture and of premium on gold mining constitute an opening wedge for the general introduction of the index number as a standard of value in the United States.

"The greatest objection of all, however, lies in the danger in which this measure would involve the gold standard itself. Nearly all of the European states are on a paper basis. Only a few of the smaller countries of Europe are even approximately maintaining the gold standard. The United States, par excellence, and Japan, as well, stand out conspicuously as nations maintaining the gold standard. All the world believes that our dollars are as good as gold. All the other nations of the world are struggling and hoping to get back to the gold standard. We enjoy a proud preëminence in this respect, and it should be zealously guarded and maintained.

"Offering to pay a premium for the production of gold in this country, in-

stead of strengthening our position would weaken it. . . . Great Britain, with far greater difficulties than we are facing, has resolutely refused to do anything of the sort in reply to the petition of her South African gold miners. . . . Action of the kind proposed by the United States would be a red flag to the commercial world. The passage of the McFadden Bill, instead of strengthening confidence in the position of the United States would weaken it. . . . Increased gold production in a period of low prices and low costs makes it easier for prices to rise again, while diminished gold production in periods of high prices and high costs tends to reduce prices and costs again."

In answering the arguments advanced in the committee report Representative McFadden said:

"Since the consumers of gold in the industrial arts and trades are receiving their metal at the pre-war price no reason can be assigned why they should not pay an increased cost alike with all other industries which have been forced to pay the increased cost for their raw materials.

"As compared to 1914 the purchasing power of the dollar in terms of all commodities in 1919 was 47 cents. The gold producers' ounce in 1914 had a purchasing power of $20.67, whereas during 1919 the same ounce could purchase in terms of all commodities but $9.70. Since the price of gold has been arbitrarily fixed by statute at $20.67 an ounce the gold producer is in the same position as a person who received the same income in 1919 as in 1914 and finds that a $2,000 income has shrunken in purchasing power to $970. This is the principal reason for the decline in the gold production from $101,000,000 in 1915 to less than $60,000,000 this year. Were it not for the fact that the Government has arbitarily fixed the price of gold, in which event the law of supply and demand does not operate, it would not be necessary to consider compensating the gold producer for a part of the decline in the purchasing power of the dollar which has taken place the last four years. The premium to be paid to the gold producer, based upon the new ounce of production, cannot be construed as a bonus or subsidy for the above reason. Most of the wage increases that have been allowed by various industries and the increases in transportation rates, car fares, and for municipal gas and electric services throughout the country have been based upon the increase in commodity prices or the decline in the purchasing power of the dollar. The products of all other industries except that of the gold mining industry have been automatically increased in price during this period, so that the cost of production is fully covered, together with a profit, by which alone future production of such commodities may be assured. . . .

"Particularly in view of the fact that Congress has fixed the price of gold, it seems that Congress has now the power to stimulate the production of gold by creating the machinery whereby the consumer of gold in the industrial arts may pay more nearly the cost of production for his raw material, thereby enabling the producer of new gold to increase his output to meet the industrial requirements of the arts and trades, and protect the monetary gold reserve from further industrial depletion. The Government should legislate to stimulate the domestic gold supply and thus relieve the strain and send into the currents of industry the invigoration of this new gold. . . .

"The Committee's objection to the bill, based upon the possibility of fraud arising from the difficulty of distinguishing between virgin and old gold, is more serious in theory than it will prove in practice. With the co-operation of the Bureau of the Mint, the Bureau of Mines, and the Geological Survey, all of which organizations have field representatives in the gold mining districts, any successful fraud on the Government could only be on a very small and negligible scale. The affividavit of production specified in the bill and the penalty provided insures the Government protection against fraud.

"The British gold producer has been aided by the exchange premium. This bill offers a domestic solution for our own gold problem."

How Shall Government Dispose of Broken Hill Concentrates, If Strike Ends?—Esperanza Disappoints

BY W. A. DOMAN

London, Oct. 12—Now that there is a probability of a resumption of mining operations at Broken Hill a question of importance in connection with zinc concentrates arises. Before the war the output of lead and zinc concentrates of the bulk of the Barrier mines was controlled by what was termed the German metal octopus, concerning which much was heard on your side during the war. To provide itself with spelter the British Government was compelled to make ruinous contracts with American firms. Mr. Hughes, the Premier of the Australian Commonwealth, decided to cut the German connection absolutely, and even abrogated contracts. For a long time he endeavored to induce the British Government to support him in his action and met with little success. After considerable correspondence, however, the Australian producers made an arrangement with the Imperial authorities by which the latter determined to thwart any renewal of the Zinc Convention, and to prevent the Germans from again depriving this country of essential metals. A contract was entered into to purchase a moderate supply of zinc concentrates at a high price. Later this was thought to be unworkable, and by a modified agreement the government contracted to purchase a much larger quantity, 300,000 tons per year, at a lower price for ten years after the war. The price has never been divulged and considerable speculation has existed as to what it may be. For the first five years it is to be a flat rate, and for the second period it will be determined by market conditions, with the previous flat rate as a minimum. As the Broken Hill mines have not produced for about seventeen months in consequence of the miners' strike, the Government has not bought any considerable quantity of concentrates. The object of the arrangement was to encourage the smelting of concentrates in this country, and financial assistance was given by the government to at least one important undertaking at Swansea Vale. For various reasons, partly technical and partly labor, no real industry has been established, and the Swansea Vale works have come to a standstill. In fact it is credibly reported that only one smelting works is now in operation, as the costs are on such a scale as to preclude profitable results being obtained. This is a great blow to certain metal interests in the country who had expected to employ large amounts of capital remuneratively. But quite apart from supplying concentrates to smelters here at reasonable rates the British Government has undertaken to guarantee a certain quantity to French and Belgian smelters, which before the war were largely dependent upon German goodwill, even if they were not in fact dominated by the metal ring. The question now is, how will the British Government dispose of the large tonnage of concentrates which it has contracted to purchase.

Esperanza shares after their skyrocketting as a result of the phenomenal gold and silver values in the Descubridora vein at the No. 5 level have received a nasty shock. This rich vein, though no sensible person could have expected it to persist with such high metallic content, has temporarily cut out and the price has tumbled about 20s. per share from the highest touched. As a borehole has proved the existence of the reef about 150 ft. from

the present face there is still the probability of good, profitable values being found again. Shares of neighboring mines, especially the Mexico Mines of El Oro, through which the Descubridora vein is expected to pass, also experienced the effect of the disappointment though the manager of the Mexico Mines announces some very high gold and silver values. But "Hope springs eternal," and in the Asquithian phrase holders of Mexican shares are prepared to "wait and see."

Twelve months ago the Falcon Mines of Rhodesia had a large stock of copper on hand, and also had borrowed something like £144,000 to finance it. Now a rumor is in circulation that the unsold metal has been disposed of and that the indebtedness has been repaid.

Special Australian Letter

Gold Producers' Association Distributes Premium — Broken Hill Prop. Outlines Plans in Report

From Our Special Correspondent

Melbourne, Sept. 20 — Broken Hill South Ltd., New South Wales, received £127,733 during the year ended June 30 from realization on the products of former periods, all active operations being in abeyance throughout the year on account of the strike. Sundry revenue items, such as dividend and interest, yielded a further £36,578. Maintenance and cessation expenses totalled £98,645, and after meeting administration and taxation costs, and allowing £19,637 for depreciation, a net profit of £13,599 remained. The surplus of liquid assets, as on June 30, was £488,907, as against £617,149 at the commencement of the term. Ore reserves were estimated at 3,500,000 tons.

The Gold Producers' Association, Ltd., which attends to the marketing of gold for Australian producers, paid premiums totaling £1,365,506 to its shareholders, up to June 30, 1920. The latest distribution, which covered the balance of premiums earned in the first half of 1920, amounted to £300,857, and was divided among the several states as follows: Western Australia $220,860; Victoria, £45,668; Queensland, £21,913; New South Wales, £7,474; Tasmania, £3.258; South Australia, £1,159; Papua, £523.

Owing to strikes and consequent shortage of coal, the Wallaroo & Moonta company's mines and smelting works were closed down for five out of the twelve months ended June 30, 1919. From Wallaroo mines 64 336 tons of material was mined, the yield therefrom being equal to 2,044 tons refined copper. From Moonta mines the tonnage mined was 8,340 tons, assaying 2.51 per cent copper. The cementation plant at Moonta produced 650 tons of precipitate, containing 71.8 per cent copper. Experiments have proved that Moonta ore can be successfully concentrated by mixing it with Wallaroo vein matter. The smelters treated during the year 21,203 tons of Wallaroo ore, 1,410 tons from Moonta, 684 tons purchased, and 434 tons of precipitate from the cementation works. The total product was 2,302 tons refined copper, and 301 oz. gold. The acid plant was in commission twenty-four weeks, and produced 2,430 tons sulphuric acid. An important change is being made at the smelters, in the erection of a large reverberatory furnace with a hearth area of about 2,000 sq.ft. Pulverized coal will be used for firing, and a pulverizing plant is to be installed, the first consignment of machinery for this having arrived from America. The year's work resulted in a loss of £38,914. Liquid assets at June 30 exceeded liabilities by £267,200.

Extensions of plant at the Newcastle iron and steel works, which it will take two years to complete, and the establishment of new industries are outlined in the annual report of the Broken Hill Proprietary Co., Ltd. One statement of especial importance is that, with the large number of coke ovens in operation, distilling about 270,000 tons of coal a year, it is desirable to save all the byproducts, and a fully qualified man has been engaged to take charge of the coke oven department and erect a by-product plant.

CANADA

British Columbia

Dolly Varden Planning for Winter Work

Stewart—The Algunican Development Co. has decided that further development of the George Group situated on the south side of Bear River shall be postponed to next season.

Good progress has been made in opening up the property of the Indian Mines, Ltd., situated on the west side of Cascade Creek, between the Salmon River glacier and Cascade Creek. Development consists of three open cuts on the outcrops and two tunnels.

Alice Arm—For several weeks there have been about 200 men employed at the Dolly Varden mine. During the summer large shipments of ore have been made, development and construction work also being carried on. It is understood that about 65 men will be kept on the payroll for development during the closed season.

Nelson—Spokane capital, which became interested in the Revenue group, on the South Fork of Kaslo Creek, early in the summer, has carried on extensive surface development with a view to putting the property in shape to be worked underground during the winter. Accommodations for over twenty men have been provided, and if the heavy snowfall does not come too early, and interfere with the getting in of supplies during the late fall, work along the lines originally planned will likely be carried out.

The Cork-Province Mines, Ltd., owning extensive mineral holdings and a mill and camps on the South Fork of Kaslo Creek, has leased the camps and the saw mill to the Howland & Waltz logging syndicate, of Minneapolis. The syndicate will use the camps during a part of the winter, but the lease contains a proviso to the effect that the mining company may resume occupancy upon a month's notice.

Indications are that tonnage handled at Consolidated M. & S. smelter at Trail for 1920 will be well in excess of that handled during 1919. By the middle of October the tonnage for 1920 had already surpassed that of 1919, being 267,768 tons. The tonnage of the Sullivan mine in 1919 was considerably smaller because of labor troubles and strikes. Of the 1920 tonnage, about 155,000 tons came from mines operated by the Consolidated M. & S. Co.

The Keystone Development Co., in which Winnipeg capital is chiefly interested, has maintained development of the Charleston group, near Whitewater, during the past summer and fall with encouraging results, according to reports, particularly as to work on the Keystone claim. The property carries values in silver-lead, and is located on veins paralleling the Whitewater lode, which has been one of the best producing areas of the Slocan.

Ontario

Engineer Reports on Associated Goldfields as Result of Criticism

Gowganda—At the Castle property of the Trethewey mine, the Office vein has been crosscut on the 75-ft. level and shows several inches of high-grade ore.

Cobalt—The Coniagas has stopped the re-treatment of old slimes until next summer. Some minor mechanical troubles developed, and this, coupled with the low price of silver, has caused the management to anticipate suspension of the season's operations by a few weeks.

During September eleven Cobalt companies shipped 1,607 tons of ore and concentrates, of which 93 per cent went to Canadian smelters and 7 per cent to American smelters.

Kirkland Lake—The Kirkland Lake Gold is treating 125 tons a day and expects to bring the mill capacity up to 175 tons. Drifting has been started on the 900-ft. level, the deepest in the camp. Labor shortage is impeding development, as is also the case with the Teck-Hughes, where sufficient men cannot be obtained to put on an extra shift.

The Wright-Hargraves mill is waiting delivery of thirteen motors which will delay the starting of the mill until after Jan. 1. The main vein has been developed for a length of 400 ft. and a width of over 20 ft., on the 400-ft. level. The north vein is 6 ft. wide, and carries good values.

The scarcity of labor and the high cost of materials has caused the Ontario Kirkland to delay work on its mill. It was planned to build the foundation this fall, but this has also been postponed.

The Hunton has decided to increase its capital from $1,500,000 to $2,500,000 in order to have sufficient treasury stock to finance development. The main shaft is to be sunk to 400 ft.

It is officially announced that the Kirkland Lake Proprietary (1919, Ltd.) has completed the taking over of the assets of the English Tough Oakes Gold Mines, the old Kirkland Lake Pro-

prietary Co., the English Aladdin Cobalt, and the Sudbury Syndicate. A notice sent out to the stockholders of the Ontario Tough Oakes states that arrangements are now under way for the acquisition by the new company of the assets of the Ontario Tough Oakes, the Burnside and the Syndicate Gold Mines.

A recent report on the Associated Gold Fields of Larder Lake again brings this company into the limelight. The report was the result of action taken by several of the large shareholders who were not satisfied with the statements made by the management. The control of the company is in the hands of Dr. McKay, a dentist, whose knowledge of gold, prior to his connection with this company, appears to have been limited. At the annual meeting, held some time ago, he stated that the ore ran over $11 a ton, and that the company had reserves aggregating $159,000,000.

The complete text of the report has not been published. Apparently it accepts the assay results of the company's engineers, and the conclusions are almost entirely based on the results of diamond drilling. It is said that experience has shown that in the gold district of Northern Ontario, diamond drilling is not a safe guide for the estimation of values and that numerous instances could be quoted in support of this, but results at the Dome may be considered as typical. This may be said to be the first engineer's report to have been made on this property, which has succeeded in obtaining so much of the public's money and which has aroused such a storm of criticism.

MEXICO

Boston Syndicate Buys Iron Property in Durango—Explosives Embargo Removed

City of Mexico—The Secretary of finance in a recent interview expressed considerable indignation because a number of banks in the City of Mexico have refused to receive on deposit the new silver coins in quantities beyond twenty pesos, alleging that the coins are under weight and not legal tender. They claim also that the Government has been working overtime in the mint because the exchange of the new silver peso and half dollar for gold coin is "good business." Secretary Alvarado denies that the government is making an excessive issue of silver and says that there is still a great scarcity of change in the interior.

Advices from Durango City state that the large iron property near there, locally known as Cerro del Mercado, has been sold to a Boston syndicate. The Cerro del Mercado, which is almost within the city limits, is a remarkable single deposit. It is 3,600 ft. long and 1,100 ft. wide, covering ninety acres. The hill is 640 ft. high and is estimated to contain above the base 200,000,000 tons of ore of unusual purity, free from sulphur and phosphorus and running about 63 per cent iron. An option was secured by Japanese capitalists some time ago, but owing to international objections, it was cancelled.

The war department has withdrawn the restrictions regarding the importation of explosives into mining camps, which restrictions together with red tape formed one of the main drawbacks to active mining operations in many parts of the country under the late Carranza regime. General Calles, minister of war, during his recent trip through Chihuahua and Sonora made a careful investigation of complaints regarding these obstacles and upon his return issued an order permitting the free importation of explosives of all kinds. The fact that Mexico is absolutely at peace with herself is best proven by the withdrawal by the government of all the small garrisons which were formerly maintained not only in country villages, but in the principal mining camps, and the lifting of the embargo on explosives.

The fact that Mexico passed the United States, her nearest competitor in silver output in 1919, and resumed her position at the head of the silver producing countries of the world caused the Minister of Commerce and Industry to state that the silver production this year in Mexico would be over $200,000,000. The minister bases his statements on reports already in for more than half the year and the fact that more mining concerns will open in the next three months than were actually in operation during the past three stormy years. The recent drop of silver again has in nowise affected operations as it is generally assumed that the metal will strike a normal gait above 90c. and remain there.

The finance department is preparing to enforce the provisions of the last presidential decree which requires that all receipts for taxes paid on mining property must be in order by Nov. 1. The government apparently intends to be severe with those who have made no attempt to set themselves straight, either intentionally or from neglect. Companies that have not complied by Nov. 1 will be listed and a complete record turned over to the Department of Commerce and Industry with instructions to cancel the titles at once and to open the properties for redenouncement.

MICHIGAN

The Copper District

Osceola's September Output Drops—Michigan To Suspend—Isle Royale Purchases Tamarack Hoist

Houghton—The production of the old branch of the Osceola Consolidated Mining Co. decreased to 4,700 tons in September. This was owing to the fact that the branch operated but one shift.

The Victoria Copper Mining Co. is producing about 125,000 lb. of copper with 100 men, which is considerably less than half its normal quota. The management is now reaping the advantage of the Taylor hydraulic air compressor which it installed on the west branch of the Ontonagon River about fifteen years ago. This equipment furnishes all the motive power needed, even in the stamp mill. With coal around $10 per ton this surely is a distinct advantage.

The Michigan Copper Mining Co. have decided to suspend mining operations temporarily. This decision has been reached because of the high prices of supplies and decreased labor supply. The property is in good condition as regards equipment and copper content of the openings on the Butler lode, which is from 30 to 80 ft. wide. Even with the small labor force Michigan has been producing from 100,000 to 200,000 lb. of copper per month for the last six months.

The Mayflower-Old Colony is passing through some well mineralized ground in the south drift about 200 ft. from the shaft. The indications are that it has passed through the disturbed zone and is about to enter the more regular vein formation.

The auxiliary hoisting engine at the old Tamarack No. 3 shaft has been purchased by the Isle Royale Copper Co. and is being installed at its No. 5 shaft. This is a 32 x 72-in. duplex hoist with an 18-ft. drum built by the Nordberg Manufacturing Co., of Milwaukee.

Gogebic Range

Production Stops at Davis Mine—"G" Pabst Coal Handling Equipment Being Installed

Ironwood—The new change house at "A" shaft of the Norrie mine is now in use. It is similar to the one at "E" Aurora, single story, 40 x 138 ft., and of fireproof construction. The coal and ash handling equipment at "G" Pabst power house is being erected. The coal will be loaded by locomotive cranes fitted with grab buckets, which will dump into a large hopper car from which it will be loaded into small cars and hauled to the crushing plant, from which point it will be taken by conveyors to the feed hoppers over the stokers. The ashes will be drawn off into cars, run outside the building, and dumped into a skip, which will hoist them up and dump into a large bin over the railroad tracks. The coal dock has a capacity of 35,000 tons but has not yet been filled. Last week several fires have developed in the coal piles and are causing trouble; even at "A" Aurora where the piles are very small there have been fires.

The Davis mine has temporarily ceased to produce, the small amount of ore which was left on the upper levels having now been worked out, and development work on the bottom levels has not yet reached the ore which is expected to be encountered coming over from the Newport mine as the footwall carries it northward. The fire which occured in the Davis shaft 18 months ago delayed this development at least six months and brought on the present condition. The work on the pump house on the 26th level is progressing well. A mucking machine is being used to get out the rock.

JOPLIN-MIAMI DISTRICT

Oklahoma-Kansas-Missouri

Lucky O. K. Gives Up Option on Acme Mines

Hockerville, Okla.—The Lucky O. K. Mining Co., after a 30-day investigation, gave up its option on the mines of the Acme Mining Co., southeast of Picher. P. W. George, manager for the Lucky O. K., which is a subsidiary of the Federal Mining & Smelting Co., states, however, that the option was given up more because continued low zinc ore prices and falling lead ore prices do not encourage as much additional operational activity as the taking on of the Acme mines would mean for his company. However, the Lucky O. K. has recently taken an option on the Lucky Jenny and Choctaw Chief mines, which are located in Hockerville, a short distance south of the Farmington mine. The Farmington was taken over by the Lucky O. K. some months ago, and, after a thorough drilling campaign, was opened up and has been made a profitable property. Under its original management it had been considered a failure. The success of the Lucky O. K. management is due to deeper operations. The company has placed a drill right in the middle of the main street in the little town of Hockerville.

A short distance south of the Choctaw Chief mine the Hawkins Mining Co. continues developing its recently discovered lead mine. While slowly sinking its discovery shaft, the company is making an average of about five tons of lead per day, with only two men in the ground and a total force of six men. In the meantime it has been sinking a field shaft about 350 ft. to the north, but the manager is now considering the advisability of sinking still a third shaft in between these two and erecting a concentrator at this shaft. He has a mill at Sunnyside ready for moving. The first 100 tons of lead from his mine he sold at $115 per ton, and the next 100 at $100. He declines to sell at the new low prices and will hold for a time at least.

The Right Good Mining Co. is erecting a concentrator on a 40-acre lease of the Kropp land, about one-half a mile south of Hockerville. Drill prospecting is being carried on while the mill is being erected, but there is a shaft into ore at a depth of only 154 ft. W. T. Dunlop, Clay Center, Kan., is manager of the company, which was unsuccessful in developing a good mine in the Lincolnville camp.

Tar River, Okla.—Auburn Mining Co. has purchased the Cliff mill at Joplin, and is moving it to a 40-acre lease southwest of Tar River, where the mine already has been well developed by Douthat Mining Co. The latter company got in litigation and the property was recently sold by order of the court, the Auburn Co. getting it on a bid of $40,000. The principals of this company include several of those formerly interested in Douthat. Abel Green, formerly manager of the Adams-Hicks, is manager.

Miami, Okla.—Al Standefer has been appointed receiver of the Pottorff-Smith mine, three miles south of Baxter Springs. H. Logan had claimed a one-half undivided interest in the property and protested the appointment of a receiver, and asked for a court order directing partition of the property. This was denied.

Blue Mound, Kan.—The Blue Mound Mining Co. has recently opened up promising lead ground on a lease a quarter of a mile east of its mill and at the foot of the blue mound which marks this entire section. The ore is found almost in solid soapstone, the dirt as it comes from the shaft containing scarcely any grit. For this reason the company is considering the installation of some kind of log washer equipment such as is used in the Batesville, Ark., manganese field for ore cleaning. If this is done it will be an innovation for zinc mining. The Blue Mound Co. has temporarily abandoned development at the shaft it equipped last winter and which is still east of the lead strike, but plans to reopen it when the price of ore becomes more satisfactory.

The Euterpe Mining Co., located in Kansas, northeast of Hockerville, Okla., has started up its new mill and reports exceptionally good dirt. It has had difficulty in getting coal for operations, however.

The Empire Development Co. is temporarily down while it carries on some prospect development work on its lease, just to the northeast of the Euterpe.

Webb City, Mo.—A very fair strike of coal has been made by the Home Coal Co. on the Connor land, south of Carterville, in a district that for a long time was a rich zinc and lead field. The strike was made at a depth of only 17 ft. from the surface, where a vein 7 ft. thick has been proved up. Three skilled coal miners have been engaged to bring the coal to the surface, where it is commanding a price of $6, undelivered, or $7 delivered to Carterville and $7.25 delivered to Webb City. George J. Kusterer, formerly manager of the Onamena Zinc Co., is manager.

MISSOURI

Southeast Missouri Lead District

Lee Mine, Near Vineland, Being Opened —Beulah Closed Down for Winter— Shulte Under Option to Picher Lead

Anaconda—The Picher Lead Co. is developing its recently acquired Fisher mine near Anaconda, in Franklin County, where some small, rich lenses of solid galena were discovered by the former owners. Churn drills have been brought in to test the lower ground and some encouraging lead is said to have been found at about 400 ft. This will be checked up with diamond drills. The rich galena lenses were found at 40 ft., as is customary in this district, or at very shallow depths.

Annapolis—The Annapolis Lead Co. has sunk its shaft over 200 ft. at Annapolis, in Iron County, and expect to bottom it next month, when the erection of the mill will be started. A large body of disseminated lead ore has been proved up on this property with the diamond drill.

Fredericktown—The Shulte property at Fredericktown, in Madison County, has been taken under option by the Picher Lead Co., which will do further drilling before finishing the shaft started by the late Harry Cantwell. Considerable nickel and cobalt occur, besides lead. The tract is only two miles from the mine of the Missouri Cobalt Co.

Vineland—The old Lee mine, near Vineland, in Jefferson County, is being re-opened by Desoto and Joplin people. This property produced considerable shallow lead from gash and pipe veins many years ago, but has been full of water for over twenty years.

The Sherry Lead Co. is about to start drilling for disseminated lead east of Vineland, near the old Valle mines, where a heavy fault has more or less mineralized the country.

Kelcey—The Beulah mine, at Kelcey, in Franklin County, has closed down for the winter, on account of the pyrite shipments freezing in the cars. This mine has produced considerable pyrite, of the marcasite form, and has recently been put in good shape for a large tonnage that at present is going to the Chicago market. The ore runs from 40 to 44 per cent in sulphur and is very desirable for acid making, as it is free burning. The property is owned by East St. Louis parties.

COLORADO

Valley View L. & M. Co.'s Mill in Operation

Matterhorn—The new 100-ton mill of the Valley View Leasing & Mining Co. is in operation. It is equipped with a gyratory crusher, ball mills, tables and flotation.

Leadville—Work was recently resumed on the Emma and Mabel placer, in the East Tennessee section of the Leadville district, which has been idle since last June on account of surface water which necessitated a close-down. Lessees of the property expect to carry out extensive development work in an attempt to locate the source of free gold which has been found in the placer fields of the East Tennessee section. A shaft 50 ft. deep was sunk through the quartzite on the property a year ago and a 90-ft. drift run through a varied formation. It is expected that but little work will be required to bring the breast of the drift into the contact under the parting quartzite, and it is here, the lessees believe, that the gold veins should be found.

Although the East Tennessee section has never produced any large mines, mining men are of the opinion that it will ultimately prove a good producer. The Jenny June and Lucy L. claims, comprising a portion of the Emma and Mabel placer, have both produced gold ore, which has been taken from small

veins in the lime formation. The free gold found in the placer fields of the district is sharp-edged and shows no signs of being washed for a very great distance. This fact has lead mining men to the conclusion that somewhere in the district the mother lode will be found.

Cripple Creek—An ore shoot opened recently on the 13th level of the Modoc mine is developing into an important deposit. The shoot has been opened for a length of 120 ft. and has an average width of over 30 ft. The ore extends up to the 11th level. About 50 per cent of the stope now being worked is shipping ore. New hoisting equipment is being installed, and development will proceed on the 14th and 15th levels. The new hoist will be operated by a 250-hp. Westinghouse motor, and will be designed to operate two double-deck cages from a depth of 2,000 ft. The new installation will cost about $25,000.

Idaho Springs—The Little Mattie mine has been taken over by the Commonwealth Silver Mines, Inc., J. F. Cleveland, president, and is being unwatered, preparatory to a campaign of active development work. The mine is opened by about 5 miles of underground workings, including a 900-ft. shaft. Equipment includes a 60-ton concentration and flotation mill.

Alice—The Roosevelt Mining Co. will build a tram about three-quarters of a mile long, from the Reynolds mine to the mill, and install a new air compressor. The 15-stamp mill is being remodeled.

Breckenridge—During July and August the Wellington Mines Co. operated at a loss, but in September it distributed a dividend of $100,000. Total dividends to date amount to $2,050,000. During 1919 the company suffered from unsettled market and labor conditions and high cost of production. However, systematic development work was carried on. New equipment has been installed recently, including a new compressor. The company proposes to resume sinking the old Oro shaft as soon as miners are available. J. W. Oldham is president and R. M. Henderson manager.

NEVADA

Nevada Con.'s Giant Blast Breaks Huge Tonnage—Pioche Shipments Falling

Ely—It is estimated that 200,000 tons of rock were moved when twelve tons of powder, placed in eight holes drilled in the hill in the center of the pit at Copper Flat, where exploded recently. It was one of the biggest blasts ever set off by the Nevada Con. and the location of the holes was carefully planned by engineers of the company. The school at Ruth was adjourned in order that the pupils might witness the sight, but from the spectacular point of view it was somewhat disappointing to those who expected to see the whole hill go up in the air. However, it was entirely satisfactory to the engineers.

Dayton—The big steel dredge of the Gold Canyon Dredging Co., the initial performance of which was witnessed by over 1,200 persons on Sept. 5, is working smoothly and several cleanups have already been made.

Pioche—Mining activity is waning in the Pioche district, owing, it is said, to the apathetic attitude of the officials of the Salt Lake Route towards the effect of the recently increased freight rates. Ore shipments from the district showed an increase over last week's total, but were considerably below the average. The Prince Consolidated produced a larger tonnage but the smaller properties showed a decided decrease. Shipments were: Prince Consolidated, 1,510 tons; Virginia Louise, 515 tons; Bristol Silver Mines, 150 tons; Black Metals, 100 tons; Combined Metals, 55 tons; Currency Lease, 40 tons; and Zero Lease, 40 tons.

CALIFORNIA

Power Restrictions Removed in Grass Valley District—Ruby Copper Instals Mill

Quincy—The Ruby Copper Co., in the Plumas copper belt, has installed a mill and is making an average of 1,000 lb. of concentrates per 10-hour day. The mill at present is losing much of the bullion.

The Reinmiller Copper Co. has practically completed the road from the main Susanville road to the mine and the men will soon be put on mine development. Recently the grading crew opened up a promising blind quartz vein.

Johnsville—The old Plumas-Eureka, which is one of the historic gold mines of Plumas County, is about to be taken over by the Guggenheim interests, according to local reports. The Plumas-Eureka was located in 1850 and has produced several million dollars. The most of the free-milling gold ore averaged between $6 and $8 per ton, but occasional bodies of very rich ore were also found. Colonel Proskey, of Reno, at one time owned the property.

Doyle—The Plinco Consolidated group of 23 claims, located about 15 miles east of the Walker mine, has been taken over by John F. Cowan, of Salt Lake City, according to a recent announcement. High-grade copper ore has been opened up on three levels and is said to be 25 ft. wide in some places on the 200-ft. level.

Grass Valley—The Pennsylvania plant of the Empire Mines will be opened as a result of the order issued to remove power restrictions. The effect of the new order will be to make available all power needed to restore the operating schedules of the mines in the Grass Valley district.

ARIZONA

Bisbee—The work of reopening the Irish Mag shaft is practically completed. The work was started in April, 1920, by the Irish Mag Leasing Co. under the management of M. J. Elsing. This company is operating on a lease of the Irish Mag claim from the Calumet & Arizona Mining Co. Three hundred and sixty feet of the shaft was completely caved.

IDAHO

Coeur d'Alene District
Big Creek Again Operating After Shutdown

The Big Creek Mining Company is again in operation after an enforced suspension due to an order from the court forbidding the company to contaminate the water of Big Creek by discharging water from the mill into the stream, this being the source of domestic water supply for the town of Kellogg. The company constructed a flume which diverts the water to a point far removed from the creek The mill is now running full time on a large accumulation of low grade ore on the dump. Men are being put on in the mine as fast as they can be secured, and in addition to the usual mining operations, a raise will be driven from the lower tunnel to the level 550 ft. above. The management announces that it is expected to be on a dividend paying basis by spring.

Crosscutting from the bottom of the 400-ft. shaft at the Chicago-Boston has advanced about 50 ft. and it is expected that the vein will be reached in about 200 ft. This work is being done by the Interstate-Callahan, which controls the Chicago-Boston.

WASHINGTON

Mining at Republic Suffering Because of Gold Situation

Index—Development during the summer at the Kromona mine in the Sultan Basin district has been encouraging. The copper vein has an extended natural exposure and a crosscut recently completed shows that it maintains its values over a good width. Winter rains and snows have stopped work until next summer. The Florence Rae mine, in the same district, has been bonded by a syndicate which is planning active mining operations.

Republic—Operations in the Republic camp are dormant, more so than for years. This is owing to the present gold situation which will not permit shipment of gold ores of medium grade. The mines of the district are working below the 500-ft. level and increased costs and freight rates are discouraging extensive shipments of ore. The revival of the district appears to be contingent upon the solution of metallurgical problems, the gold ore having so far proved refractory.

The Quilp mine is supplying siliceous ore to the Trail smelter where it is used as a flux. This ore is being drawn from stopes above the 700-ft. level. It is probable that when these stopes are exhausted the Surprise shaft will be sunk 200 ft. further.

The Last Chance and Lone Pine-Surprise properties are involved in apex litigation and neither is producing at present.

THE MARKET REPORT

Daily Prices of Metals

Oct	Copper N. Y. net refinery* Electrolytic	Tin 99 Per Cent	Tin Straits	Lead N. Y	Lead St. L.	Zinc St. L.

26	14.85	39.00	40.50@40.75	6.75@7.00	6.60@6.90	6.95
27	14.85	39.50	40.75@41.00	6.75@7.00	6 60@6.90	6.95

*These prices correspond to the following quotations for copper, "delivered": 15.25, 15.25, 15.00@15.25, 15.00, 15.00, and 15.00c.

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point, or as otherwise noted. All prices are in cents per pound. Copper is commonly sold "delivered," which means that the seller pays the freight from the refinery to the buyer's destination.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Oct.	Copper Standard Spot	Copper Standard 3 M	Copper Electrolytic	Tin Spot	Tin 3 M	Lead Spot	Lead 3 M	Zinc Spot	Zinc 3 M
21	91	89½	101	251½	256½	36⅛	35⅞	38¾	39⅞
22	89¾	88⅝	100	248	254¾	36	35¾	39	40
23									
25	91½	90	100	251½	257¼	36⅛	35⅞	39½	40½
26	89¼	88¼	100	258½	263¼	36½	35⅞	39¾	40¾
27	88¼	87¾	100	261¾	265¾	36⅜	35¾	39	40

The above table gives the closing quotations on the London Metal Exchange. All prices in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Oct.	Sterling Exchange	Silver New York, Domestic Origin	Silver New York, Foreign Origin	Silver London	Oct.	Sterling Exchange	Silver New York, Domestic Origin	Silver New York, Foreign Origin	Silver London
21	343½	99½	81⅞	53¼	25	347	99½	80⅞	52½
22	343½	99½	80½	52⅝	26	346½	99⅛	80⅜	52⅛
23	345¼	99½	80	52⅛	27	347	99½	80⅜	52⅛

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

Metal Markets

New York, Oct. 27, 1920

Price recessions have continued during the last week but to a diminished degree. Both producers and consumers are beginning to consider that present prices are at or near the bottom and it is unlikely that any further marked declines such as have taken place during the last few weeks will occur. Metal for forward delivery is beginning to command a slight premium as a general rule, for the spot demand is totally lacking. With present general conditions and a declining tendency in price levels, it is, however, almost too much to expect any marked increase in metal prices. The approaching election seems to have been overshadowed by other conditions and has probably exerted little influence on the market. Those who look for increased buying after Nov. 2 may, therefore, be disappointed.

Copper

The market seems to have reached a stable basis at 15c., delivered, after the recent rapid decline from the 18@19c. level. Large producers are now selling about on a parity with the outside market. Rumors have been circulated about large lots of copper having been sold both at 15c. delivered and slightly under this price, but after careful investigation, both among producers and consumers, we are unable to confirm any of these transactions. There is no doubt that several sales of rather large volume were made on the quiet during the recent recession, producers slashing prices to make sales without wishing to make the facts known. So far as we know, business at the current level is of small volume, buyers not wishing to carry large stocks on their inventories at the end of the year. Some sales of somewhat larger volume are being booked for January delivery.

Lead

The A. S. & R. official price continues at 7¼c., New York, and some producing interests are quoting this price without, however, making any sales. The market is gradually becoming more restricted, and unless it improves, producers are apt to find at the end of next month that some of their November metal is unsold. The number of cancellations and requests for postponed deliveries is increasing. Another striking feature is the fact that consumers are offering spot metal for resale, a particularly depressing influence. At current prices, London lead cannot be laid down here for less than 7⅛@7⅜c., so that trouble from importations is hardly expected.

Chemical lead is scarce and a slight premium is being demanded for this variety in the St. Louis district, where 6.90c. has been asked for the last two or three days. Mexican lead is offered at ¼c. under this figure in St. Louis, owing to its having been thrown into that market by a cancelled contract.

Zinc

This metal has exhibited a further gradual decline, and yesterday the 7c. level was passed, sales taking place at 6.95c. Not all producers were willing to sell at this figure but apparently little or no business could be induced at any higher quotation. Consumers are simply not buying. The curtailed production should tend to help the market as it did last summer, and also, with black sheets in better supply, the galvanizing business should improve. Stocks of zinc are, however, larger than producers would like to have them. Metal for forward delivery commands 5 to 10 points premium.

Tin

One producer says the principal feature of the tin market just now is a demand for futures at the prices quoted for spot. There are large supplies of spot Straits now in New York, and consumers are not interested. Recent forced sales caused by buyers of unknown reputation declining to accept deliveries have had a depressing influence. The market is very irregular. Some electrolytic has been moving at around 39c. One consumer was offering electrolytic for resale yesterday at 39¾c.

Straits tin for future delivery: Oct. 21st, 40.00 @ 40.75c.; 22d, 39.75 @

40.00c.; 23d, 40.00@40.50c.; 25th, 40.50 @41.00c.; 26th, 41.25@41.75c.; 27th, 42.25@42.75c.

Arrivals of tin in long tons: Oct. 20th, Rotterdam, 10; 21st, London, 50.

Silver

From October 21 to 27 the London price has fluctuated between 53¼ and 52⅝ pence. London reports buying for Indian bazaar and China account as responsible for the upward movements; and further sales of melted coin from the Continent and a certain amount of speculative selling are the factors causing the decline.

During this same period the improvement in sterling exchange has been sufficient to increase the London parity by over one cent, but the fall in the London quotation has more than offset this.

The New York price continues to follow closely the London parity, as buying for China account in this market is not strong enough to cause any appreciable advance over the London rate.

Exports of bar silver from San Francisco for the month of September amounted to 5,958,000 ounces, and from New York to England for the period October 1st to 20th to 185,600 ounces.

Mexican Dollars—Oct. 21st, 52; 22d, 61⅛; 23d, 60⅞; 25th, 60⅞; 26th, 60⅞; 27th, 60⅞.

Gold

Gold in London on Oct. 21st, 119s. 3d.; 22d, 119s. 6d.; 25th, 118s. 2d.; 26th, 118s. 2d.; 27th, 117s. 9d.

Foreign Exchange

With brighter prospects of settling the labor troubles in England, sterling has tended to strengthen during the last few days. Other exchanges have generally been quiet with narrow movements. On Tuesday, Oct. 26, francs were 6.35c.; lire, 3.74c.; and marks, 1.43c. New York funds in Montreal, 10½ per cent premium.

Other Metals

Aluminum—For 50-ton lots: ingot, 99 per cent and purer, 33.1c.; 98@99 per cent, 32.90c.

Antimony—Spot metal, 6⅛@6⅜c. per lb. Cookson's "C" grade, 12½@13c. Chinese and Japanese brands, 6⅜@6⅜c. W. C. C. brand, 8¼c. Chinese needle antimony, lump, firm at 6@6¼c. per lb. Standard powdered needle antimony[1] (200 mesh), 10c. per lb. Market dull.

White antimony oxide, Chinese, guaranteed 99 per cent Sb_2O_3, wholesale lots, 10c.

Bismuth—$2.55 per lb., 500-lb. lots, and $2.57 per lb., 100-lb. lots.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady.

Cobalt—Metal, $6 per lb.; black oxide, $4.10 per lb.; sulphate, $1.60.

Iridium—Nominal, $400@$450 per oz.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb. for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]**Molybdenum Metal** in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.

Monel Metal—Shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$85 per oz. Dull.

Platinum—Firm at $95@$105 per oz.

Quicksilver—Market quiet; $60 per 75-lb. flask. San Francisco wires $62.50@$65. Market steady.

Ruthenium—$200@$220 per troy oz.

[1]**Selenium**—Black powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]**Thallium Metal**—Ingot, 99 per cent pure, $20 per lb.

[1]**Tungsten Metal**—$35@$60 per kilogram, according to purity and gage.

Metallic Ores

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a maximum of 6 per cent silica, 75@85c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 70@75c.

Manganese Ore[1]—60@70c. per unit, seaport; chemical ore (MnO_2) $70@$80 per gross ton, lump; $80@$90 per net ton, powdered.

Molybdenum Ore—85 per cent MoS_2, 65@70c. per lb. of contained sulphide, New York.

[1]**Tantalum Ore**—Guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots.

[1]**Titanium Ores**—Ilmenite, 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $6 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $4.50@ $5, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25@$1.50 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[1]**Zircon**—Washed, iron free, 5c. per lb.

[1]**Zirkite**—According to conditions, $80 @$90 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

Zinc and Lead Ore Markets

Joplin, Mo., Oct. 23—Zinc blende, per ton, high, $51.10; basis 60 per cent zinc, premium, $41; Prime Western, settling basis, $50@$40; buying basis, $40; fines and slimes, $37.50@$35; calamine, 40 per cent zinc, $35. Average settling prices: Blende, $45.14; calamine, $38.48; all zinc ores, $45.01.

Lead, high, $111.85; settling basis 80 per cent grades, $110@$65; buying basis, $65; average settling price, all grades of lead, $98.69 per ton.

Shipments for the week: Blende, 13,135; calamine, 263; lead, 1,906 tons. Value, all ores the week, $773,990.

The second mine close-down of the year became effective this week. Sellers claim the production is lessened 90 to 95 per cent and buyers concede a possible 80 per cent. The first week ends with the production restricted approximately as in July. At that time a part of the mines resumed operation the middle of the second week. There is to be another week and possibly will extend over Election Day. The mines operating are generally selling on the market, but ore held by those down is not offered. It is estimated that there is an unsold tonnage of 20,000 to 25,000. The purchase this week was 3,250 tons, approximately the production. Seven regular buyers were out of the market this week. The car situation tightened at the week-end.

Platteville, Wis., Oct. 23—Blende, basis 60 per cent zinc, $45@$45.50 per ton base for high grade. Lead ore, no sales. Reported shipments for the week: Blende, 1,117; sulphur ore, 58 tons. Shipments for the year: Blende, 55,896; calamine, 2,474; lead, 4,398; sulphur ore, 1,342 tons. Shipped during the week to separating plants, 2,308 tons blende.

Non-Metallic Minerals

Asbestos—Crude, No. 1, $2,000@ $3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@ $75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax.

Barytes—Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $24@$30 in bags, carload lots; (off-color) $22@$26 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $23; ground (white), $45; ground (off color) $30@$32 per net ton, less than carload lots, f.o.b. New York. Crude, first grade, $10 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin)—Crude, $9@ $12; washed, $12@$15; powdered, $18@ $22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground, $15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@ $30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$14 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $27@$30, car lots, f.o.b. Baltimore; ground, $17@$21, f.o.b. North Carolina points; $17@$21 per ton, No. 1 ground, f.o.b. New York State; $21@ $23 per ton, ground, f.o.b. Maine. Crude spar very scarce.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M. In Canada 85 per cent calcium fluoride sells for $20 per ton f.o.b. Madoc; output limited. Canadian price generally $18 (Canadian currency) per ton, f.o.b. mines; market inactive.

Graphite—The 90 per cent crucible grade is held in Alabama for 9c. per lb. and 85 per cent grade is practically unobtainable, prices being 7@9c. The higher lubricating grades sell for 11@40c., according to carbon content.

Gravel—No analysis guarantee, f.o.b. Roseview, Ill., $25 per ton; gravel suitable for acid, chemical or enameling purposes, $60.

Gypsum—Plaster of Paris in carload lots sells for $4.25 per 250-lb. bbl., alongside dock, New York. Raw crushed rock, $3.50@$4.50; calcined stucco, $9; f.o.b. works, Illinois.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. In Chicago district, $57.70; Atlantic seaboard, $61@$63.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—India block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20 @$1.40; No. 4, $2@$3; No. 3, $4.25@ $5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $3.50; No. 3, $5, No. 2, $6.50; No. 1, $8; A1, $10; extra large, $25, all f.o.b. New York; ground, $150 per ton, Philadelphia. Domestic, uncut, f.o.b. Franklin, N. C., as follows: Scrap, $45 @$50 per ton; punch, 10c. per lb.; circle, 15@25c.; 1½ x 2 in., 75c.; 2 x 2 in., $1.15; 2 x 3 in., $1.65; 3 x 3 in., $2.10; 3 x 4 in., $2.50; 3 x 5 in., $2.75; 3 x 6 in., $3.75; ground 165 mesh, $240 per ton; ground roofing mica, $60; mica washers, 75c.@$2 per lb.; 1¼-in. disks, No. 1, $1.60 per lb.; No. 2, $1.30. The foregoing domestic prices obtain also in the Chicago district.

[1]Monazite — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. Finely ground Tennessee rock sells for $8.50 per net ton for 13 per cent phosphorus content, agricultural application; for acid-making, 14 per cent, $9; both prices f.o.b. Centerville, Tenn.

Pumice Stone—Imported, lump, 4@ 50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish fines, per unit, 12c., c.i.f. Atlantic seaport; furnace size, 17c.; Spanish lump, 14@16c.; domestic fines, f.o.b. mines, Georgia, 12@14c. Market improving.

Quartz—(Acid tower) fist to head, $10; 1¼ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines.

Sand (Glass)—Dry glass sand, $4 per net ton, f.o.b. cars Mapleton, Pa. Sand, f.o.b. Ottawa, Ill., is $3 per ton; $2.50 on annual contracts. Sand at Klondike, Gray Summit and Pacific, all in Missouri, is $2.50 on contract; some outside sales have been made at $4. St. Louis, open market, at $3.50; contract price on large quantities, $2.50; on small quantities, $3.

Sulphur—$18 per ton for domestic; $18@$20 for export, f.o.b. Texas and Louisiana mines. Market quiet.

Talc — Paper making, $12@$22 per ton; roofing grades, $9.50@$15; rubber grades, $12@$18, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $12@$15 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60 @$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $225 @$250 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15 to 18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 18½@19c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c., f.o.b. works.

Ferromanganese—For 76 to 80 per cent, prompt delivery, $170@$175 freight allowed; last half, $170; English, $170, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $82.50@$85, f.o.b. furnace.

Ferromolybdenum[1]—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2@$2.50 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $82.50@$85; 75 per cent, $150@$160.

Ferrotungsten[1]—Domestic, 70 to 80 per cent W, 80@90c. per lb. of contained tungsten, f.o.b. works. Foreign, 70c.

Ferro-uranium—35 to 50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium[1]—Basis 30 to 40 per cent, $6.50@$8 per lb. of V contained, f.o.b. works.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Metal Products

Copper Sheets — Current New York price, 25½c. per lb.; wire, 19c.

Lead Sheets—Full lead sheets, 10½c.; cut lead sheets, 10¾c. in quantity, mill lots.

Nickel Silver—Unchanged at 36½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 23½c.; sheathing, 23½c.; rods, ⅝ to 3 in., 20½c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $160 per 1,000, f.o.b. Pittsburgh.

Chrome Cement—40@45 per cent Cr_2O_3, $55@$60 per net ton, and $65 in sacks, carload lots, f.o.b. eastern shipping points.

Fire Brick—First quality, 9-in. shapes, $55@$60 per 1,000, Pennsylvania, Ohio and Kentucky. Second quality, $45@ $50.

Magnesite Brick — 9-in. straights, $110 per net ton; 9-in. arches, wedges and keys, $121; soaps and splits, $134.

Silica Brick—9-in., per 1,000: Chicago district, $65@$70; Birmingham, Ala., $56@$61; Mount Union, Pa., $55 @$60.

Iron Trade Review

Pittsburgh, Oct. 26, 1920

Throughout the steel trade it has been admitted of late that prices of independents will decline to the Steel Corporation level. This leaves two interesting questions, how it will be until the decline is completed, and whether the Corporation prices then will be what they are now. As to the first question, some of the independents have fairly well-filled order books, despite recent cancellations, and are indisposed to reduce their quotations until they have shipped as much as possible on existing contracts.

Pig Iron—On an inquiry for a small lot of foundry iron for Pittsburgh delivery several Valley furnaces showed that they would shade $45, furnace, but the order went to another district at a lower delivered price. We quote foundry at $45, Valley, against $47 formerly quoted. Some in the trade insist that basic iron is quotable at $40, Valley, on the basis of some small sales, the former quotation having been $42, and we quote basic at $40@$42. On offerings of bessemer, not taken, we quote that grade at $47, Valley, instead of $48.50 formerly quoted. Freight to Pittsburgh is $1.96.

Semi-finished Steel—No transactions are reported, and we quote the market nominal at $55@$60 for billets and $65 for sheet bars.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $16.50@$17; foundry, $18

The Decline in Copper

Cheap Metal Will Cause Decrease in Production and a Natural Readjustment to Existing Economic Conditions—Producers Are in the Same Position as Those in Other Industries—Production Above Pre-war Rate

COPPER has yielded to the long strain under which it has been laboring. Month after month—in fact, ever since last winter's heavy buying—there has been anxious anticipation of a buying movement, which, unfortunately, has not matured. Glancing over the average prices of electrolytic copper for the first nine months of the year, it is surprising to note the small fluctuation in the price of the metal. The lowest average price in June, 18.065c., and the highest in January, 18.918c., show a difference of only .853c. This stability of copper prices emphasizes the comparative dullness of the market for practically the entire period. Contrasted with a similar period of 1919, we have a range from a low in March of 14.856c. to a high in August of 22.319c., indicating by this wide variation the intense speculative trading that occurred last year, when large quantities of American copper were purchased by the Japanese only to ruin the market subsequently in this country.

AVERAGE PRICES NEW YORK ELECTROLYTIC COPPER, 1919-1920

	1919	1920		1919	1920
January	(a)	18.918	August	22.319	18.345
February	16.763	18.509	September	21.755	18.144

(a) No market.

In the middle of September copper was sold at about 18.50c., delivered. The price then gradually declined, but sharply of late, so that copper can now be obtained for 15.00c., delivered—a decline of 3½c. in a little over a month. The copper companies are producing copper to sell, and not to hold, and the consequent lowering of their price to make a market accounts for the sharp decline. The policy of most producers has been to hold their output from the market at the absurdly low prices for the metal, with the thought that not only was there a great and potential demand for copper all over the world but that domestic production was going on at an unprecedented rate and a buying movement would start of its own accord—at any rate, they felt that a further concession in price would not result in increased purchases.

Finally the financial strain of carrying so much unsold copper became acute. Certain producers no longer found themselves able to follow the policy they had mapped out, and gossip had it that they underbid their competitors in order to sell their copper. During the period of market dullness the largest business recorded was by the smaller producers, and always at prices below that of the major operators. This trade inequality has begun to disappear; practically all the large copper interests are participating in the market and are furnishing keen competition to those interests which formerly consummated the greater share of business. As a result, the price of copper reflects the keener competition for trade among the copper sellers.

At 15.00c. copper is decidedly below a pre-war price basis (the average price of New York electrolytic for the years 1906-1913 inclusive was 15.274c.), and is undoubtedly below the cost of production of all but the lowest-cost producers. The cost of producing copper as given by representative copper companies in their annual reports for last year follows:

Utah Copper (open-cut porphyry)	12.366c
Copper Range (deep lake mine)	a 15.02
Inspiration (deep mine porphyry)	a 13.412
Ray Consolidated (deep mine porphyry)	b 14.94
Nevada Consolidated (porphyry)	b 16.14
Tennessee Copper (lode)	c 18.72
Calumet & Hecla (deep lake mine)	19.77
Chino (porphyry)	b 15.49
Shattuck Arizona (lode)	22.20
Chile Copper (porphyry)	18.35

(a) Exclusive of depreciation and depletion charges.
(b) Exclusive of Federal taxes.
(c) Exclusive of New York charges

The list is selected from both large and small producers, porphyry and lode copper mines, and although the method of cost accounting in many cases is different, the table furnishes an indication of what 15c. copper means to the industry.

Of course business moves in cycles. There are periods of depressions and periods of prosperity. Losses must be taken with the gains. The copper industry is passing through one of these depressed periods, after having experienced a period of unprecedented prosperity when copper prices ruled abnormally high. That is the one comforting feature of the situation, and were it not for the financial surpluses which most copper companies accumulated during the war, the industry would indeed be in dire straits. But there is a limit to which these financial reservoirs can be drained, and for many months they have been called upon to tide the companies over the present trying period.

If copper cannot be produced at a profit—15c. copper does not represent a profit—mines will shut down. Production is already being curtailed. A preliminary estimate of copper production for September places it at 103,000,000 lb., which is a decided decrease from the preceding month's figure of 116,000,000 lb. and the smallest output of the year. There is one striking feature of the activity of the copper mines during the post-war period: although they have not operated to *capacity* they have been operating above the pre-war rate of production. The following table is intended to illustrate this point. From 1909 to 1913 smelter production in the United States averaged 1,149,000,000 lb. In 1919 production was about 1,210,000,000, but in 1920 a preliminary estimate, should production continue at the present rate, is 1,350,000,000 lb. This is about 18 per cent above the pre-war average given, and would indicate that there is much room for healthy contraction in the copper supply.

COPPER PRODUCTION AND PRICES, 1906-1920

	Smelter Production in Pounds	Average Price Electrolytic N. Y.		Smelter Production in Pounds	Average Price Electrolytic N. Y.
1906	917,000,000	19.27c	1914	1,093,000,000	13.602
1907	879,000,000	20.004	1915	1,424,000,000	17.275
1908	948,000,000	13.208	1916	1,943,000,000	27.202
1909	1,105,000,000	12.982	1917	1,923,000,000	27.180
1910	1,086,000,000	12.738	1918	1,938,000,000	24.628
1911	1,084,000,000	12.376	1919	1,210,000,000	18.691
1912	1,241,000,000	16.341	1920	a1,350,000,000	
1913	1,229,000,000	15.269			

aEstimated

How great a curtailment of production may take place it is hazardous to predict, but that producers are becoming tired of the present state of affairs and are determined to force an issue seems clear. Europe is in no position to purchase the copper it needs under the present foreign-exchange situation, and is content to utilize the large amounts of scrap material still available on the Continent. This attitude alone of our greatest copper customer should be sufficient to compel the industry to contract its output, and, coupled with the smaller domestic demand, would seem to insure it.

Despite the serious predicament of the copper producers, no one doubts for a moment that the industry will emerge successfully from its ordeal, and that after economic laws have again become balanced, a period of unexampled prosperity may confidently be expected. The market is seeking out its bottom with a determination to reach a level from which confidence on the part of the consumer in a stable market will be restored. To do this it is necessary for the market to not only reach the bottom but also to get under it so that prices will be raised or the market supported. This state of affairs is progressing at the present time, and low levels for the year are being recorded.

The McFadden Gold Bonus Bill

THE statement of Congressman Louis T. McFadden, chairman of the Banking and Currency Committee of the House of Representatives, presented before the recent Forty-sixth Annual Convention of the American Banking Association in Washington, is printed in abstract on another page. We commend it as a sound and thoughtful discussion of fundamental monetary economics.

Concerning the advisability of a bonus to gold miners, as proposed by Mr. McFadden, the bankers are by no means in agreement—there are two mutually dissenting parties, as there are outside the banking world. Mr. McFadden's argument is directed against the report of a certain Gold Committee appointed by the American Banking Association, which rendered an adverse report on the bill; but this committee is held by the sponsors of the bill to represent a minority, and it is certain that some important banking interests remain so much in favor of the bill that they have included a statement of their support in their newspaper advertisements.

Now, the proposition, if it is to stand, and if it should stand, must be shown to be desirable, first and last, on the basis of national welfare. While we of the mining profession naturally have our own industry very much at heart, it would be not only unfair but suicidal if we should advocate any measure which, though it would rescue the gold-mining industry from disaster, would depress the prosperity of the rest of the country and delay the natural healing processes which supervene on the wounds of war. It is on this broad basis of national welfare and no other that the measure is presented, and on which we support it.

Those bankers who oppose the bill are misled in some cases, it appears, by some elementary knowledge of economics, proving anew that a little knowledge is a dangerous thing. Mr. McFadden, for example, combats the statement of the Gold Committee that "Increased gold production in a period of low prices and low costs makes it easier for prices to rise again, while diminished gold production in periods of high prices and costs tends to reduce prices and costs again."

Here, in a way, is a true and fundamental statement; and yet it is absolutely inapplicable in the present case. It is evident that with gold, or silver, or anything else, as a medium of exchange, the greater the supply of the standard, the cheaper it will become, and the less it will purchase; in other words, the prices of other commodities will rise in terms of gold or silver, as the case may be. This was illustrated by the discovery of the great Valenciana silver mine, in Mexico, in the sixteenth century: the flood of silver caused a rise of commodity prices throughout the civilized world. The absolute inapplicability of this law to the present world monetary conditions lies in the fact that our basis of exchange is now not gold and silver, but so-called money which is mostly paper with a minimum and quite insufficient security of gold and silver. Therefore, it is now and long will be the case that the monetary control of prices (there are, of course, other factors) follows the law that commodity prices will tend to increase as the ratio of paper to metal (gold) increases: that they will rise with inflation and diminish with deflation. Deflation means a diminished ratio of paper to gold; and there are two ways of accomplishing it—one by decreasing the amount of paper, the other by increasing the amount of gold. The latter is what the McFadden bill proposes to do.

A more astonishing economic view, urged by a great financier against the McFadden bill, was that it was inadvisable to increase the gold reserve, as that would mean more credit based upon the increased gold, and so further inflation! It is difficult to argue concerning this warped point of view, as it assumes the fundamental depravity of American bankers—which may or may not be true. Certainly, the financier who uttered this objection should know better than we; but, if so, the remedial castigation should be applied to our banking system. On this theory the way to induce deflation would be by reducing the gold reserve, and complete deflation would be accomplished with its disappearance.

Though we are not threatened with any situation so extreme as the condition of complete disappearance, apparently viewed with equanimity by our great banker, we are face to face with a shrinking gold reserve, which we can hardly escape. We can hardly expect stable return of prosperity till Europe again becomes a buyer as largely as of old. The present situation in copper is typical of this. Now, Europe cannot buy before her exchange depreciation is remedied—until then she has nothing to offer us. The slowing down of her purchases, however, increases the amount of her exports as compared with her imports, and, as regards us, this means that her balance of trade with us is being gradually adjusted, which means eventually a movement of our gold to Europe to adjust balances; and this is a tendency which will be healthy for the world. Against this the fact is that more gold is now going into the arts in this country—principally jewelry—than we are producing—so that our outstanding paper currency will tend to have a shrinking basis of metal security.

Our whole endeavor should be to build up the world's metal security underlying its paper notes. The McFadden bill could wisely be adopted in this country, and copied in all other gold-producing countries. It serves the double purpose of tending to increase the production of gold, and decrease the economic waste of it by turning it into purposes of adornment. The tax of ap-

proximately 50 per cent which the jewelers would have to pay is a moderate one. Considering the general problem of taxation for revenue, together with the McFadden problem of taxation for increase of gold reserve, we would be inclined to recommend a 500 per cent tax on gold and jewelry, of which 50 per cent would be turned over to the miners as a bonus, and the remainder into the Treasury to help meet the general expenses of government. We think that the McFadden proposition might well be modified so as to exempt from taxation gold employed for useful purposes, as in dentistry; this would further insure the retaining of the commodity standard of gold value as on the old fixed basis, and would, in addition, refute the charge of a change in the gold standard. But the hoarding of gold, especially in times of great financial stringency, is looked upon with disfavor by bankers; indeed, if the reader will ask for a single $20 gold piece from his bank, he will probably detect some disfavor or suspicion on the part of the banker; and it is nothing less than hoarding to suspend it around one's neck or across one's chest, or locked up in one's strong box as jewelry. Hoarding of this sort of silver and gold (as ornaments) in India has long made that country a veritable sink of the metals; and at the present time more than the total production of gold of the country is thus hoarded in this country, as jewelry. Will not the bankers view this also with the appropriate alarm?

The Government Employee And His Discoveries

RECENTLY a meeting was held at the Chemists' Club in New York, under the auspices of the American Institute of Chemical Engineers, the New York Section of the American Chemical and American Electrochemical Societies, and the American Section of the Society of Chemical Industry, to hear Dr. Cottrell, Director of the Bureau of Mines, and Dr. Alsberg, Director of the Bureau of Chemistry, present their plan for solving the problem of discoveries or inventions by Government investigators. This plan is embodied in Senate bill 3,223, which has been passed by the Senate, and will go to conference in December. Briefly, it provides that inventors who are Government employees may be assigned to the Federal Trade Commission (subject to the acceptance by that commission), which may license such inventions, and collect fees and royalties therefor, out of which fees and royalties a certain per cent shall be set aside to remunerate the inventor.

The submission of the plan in New York met with the most plain and hearty disapproval of the important and representative meeting of chemists to which it was submitted, and the meeting and the proposal are discussed in a long and able editorial in *Chemical & Metallurgical Engineering* for Oct. 27, which aligns itself against the project.

We are inclined to join in the general reaction of dissent from the proposed plan. Though the problem of retaining able scientists in the Government pay is doubtless an important one, we do not think this is the solution, for this preventive remedy, we judge, is far worse than the disease. The effect, in our opinion, would be to subsidize scientists while they were working out inventions by which they hoped eventually to profit financially.

There is no use minimizing the spur and the bias given by the prospect of monetary reward, and if the Government should adopt this system we could not blame the employee for shaping his efforts in that direction. He would be in an enviable position—nothing to lose for the time spent in his researches, for the Government would support him comfortably and indefinitely, and everything to gain. We can imagine what a horde of hungry inventors, who have had experience in being on the losing side of the gamble, would apply for Government jobs!

Neither is the proposal to still further expand the powers and functions of the Federal Trade Commission likely to prove popular. This organization has already been accused of socialistic ideals, and the plan in question certainly trends in the direction of intensifying that paternal nursing by the Government which is called state socialism. The industries apprehend it as such, if we may judge from the very definite antagonistic attitude of the meeting to which we have referred. We believe that the plan is a dangerous and unsound one, and hope for the rejection of the bill by Congress.

The Newer Branches of Engineering

JUST why it is we do not know, but engineering seems to be getting more popular. Perhaps it is the free advertising which Herbert Hoover has given the profession, or possibly the Federated American Engineering Societies is having some influence. But, anyway, an engineer is no longer considered one who runs an engine, just as a chemist is no longer merely a soda-water clerk.

The latest is Real Estate Engineering, or, as the pioneers in the profession call it, Property Management Engineering. This is the heading of an advertisement occupying the entire last page of the *New York Tribune* of Oct. 26. The advertisement goes on to say that engineers are scientists who know the facts about materials with which they work and who must not merely guess. They must also have the ability to put their knowledge to practical use. That is just the way the officials of the company running this ad. feel about the handling of real estate. Hence the title. They admit that the question as to what Property Management Engineering means has been asked them many times, and we do not wonder.

Julian Street, in his interesting little satire on the modern advertising man, just published under the title "Sunbeams, Inc.," follows the career of Mr. H. Bell Brown from newspaper reporter through his "'induction' into the profession of advertising engineering. It would seem that he was cut out for it. Either he learned with a speed hardly short of miraculous, or else advertising engineering may be mastered in a much shorter space of time than engineering in the commoner branches. Had he, for example, become an automobile engineer, a constructing engineer, or a civil engineer, instead of an advertising engineer, and progressed as rapidly, he would have been building motor cars, skyscrapers, steel bridges, or railroads within a year."

We are glad to see engineering becoming so popular, but we hope that the new-coming class will not totally supplant the old. No doubt Soup Engineering and Baked Bean Engineering will soon be featured in the advertising pages of our popular magazines. At present,

as is well known from the advertisements, our beans are baked by chemists, who analyze each bean as it goes into the can. Why wouldn't a good engineer be fitted to superintend the ovens, or, as they might be termed, roasting furnaces? Or even—but this is too much to expect—a good cook?

The Wrong Kind of Immigrants

EMISSARIES from Soviet Russia with well-lined pockets are reported on good authority to be coming to this country. The immigration from former Russian territory, is, at least, becoming heavy, and it would not be at all surprising if agitators were slipping in despite the vigilance of the Federal authorities. The trouble in Italy, the seizure of many large factories, is, of course, Russian inspired, even if not actually financed, as alleged, by Soviet funds. The recent miners' strike in Britain probably has some foundation in Russian agitation.

We in America cannot watch too closely the character of immigrants which we are welcoming to solve our labor problems. Mining districts have been in the past a particularly fertile field for inspired discontent among foreign laborers, and it is unlikely that agitators will overlook them again should definite plans be made to stir up trouble. To secure the best efficiency, mining officials and others whose position gives them an insight into labor conditions should co-operate to the fullest possible extent with the Federal authorities. It is not enough these days to keep an eye on suspicious foreigners: they should be reported to the U. S. Commissioner of Immigration at Washington, that their history may be traced so far as is possible. In this way known trouble makers of national rather than local reputation may be more readily apprehended.

Communism in Russia seems to have been a very profitable undertaking for the group who are making misery for the rest of Russia, and it is to be expected that they will use money liberally to widen their field.

Scientists and the Divining Rod

IN ANOTHER COLUMN will be found an account of the discussion at a meeting of the Royal Society of Victoria, in Australia, of the divining rod as a water finder. It is interesting reading. The general feeling of the meeting on the subject was the one we have before editorially expressed, that the divining rod, though often used in good faith, "was a subject for investigation on the part of the psychologist rather than the geologist." A number of experiments were cited indicating the cheerful and conscientious blundering around of divining-rod operators. Sometimes they struck water, sometimes not—exactly as if they had shot an arrow into the air and dug for water where it fell.

We recommend the study of the phenomena of the divining rod to a mixed committee of geologists and psychologists. A great deal of interesting data on the human mechanism would be the result; and the subject is well worthy of scientific investigation. Solid citizens —exceptionally solid and square-set on their feet—are credulous of this, as of all other wonders beyond their ken. They live by faith, for they really understand little of what is going on in this world.

We once watched an honest divining-rod operator who walked over a field, and his rod bent over with irresistible force when he passed over a certain kind of soil which he said he had assayed, and which ran $5 a ton in gold (his apparatus, we should have said, was "set" for gold, by slipping a gold bar into each of the handles). We noted with amusement the massive gold watch and chain which lay across the operator's breast, and the massive gold rings on his fingers, all of which fine gold did not affect the instrument that was convulsed by the supposedly $5 a ton dirt beneath his feet! Yet this evidence made no impression upon a lawyer and a banker who were present.

Therefore, to be complete, the study of the psychology of the divining rod should be extended to that of some of those who believe in it; and this would lead further on to the study of the similar firm basis of their other beliefs, and to the psychology of solid citizens as a whole. These are the types of men we observe going around the streets these days with their winter overcoats on, although for some days (as we write) the temperature has been above 80 deg. midday; but is it not after October the first, which is the one incontrovertible fact that these gentlemen grasp? They are of the solid supporters of society, who know quite firmly whether they are Republicans or Democrats, Baptists or Presbyterians: and what is right and what is wrong in general.

The Chemical Wizard

PROF. F. W. CLARKE, chief chemist of the U. S. Geological Survey, whose great work "The Data of Geochemistry" has gone through several editions and revisions, is now engaged in making a study of the chemical composition of waters. He finds the mineral contents of waters from different rivers and lakes to vary widely, and to correspond in the proportion of the elements which they contain to the chemical characteristics of the rocks which underlie the drainage basins, and from which the mineral elements have been derived by solution. So close is this that when a notable exception was found in one instance, and the mineral elements of a certain stream were found not to correspond to those of the rock terrains over which its drainage flowed, according to the map, Dr. Clarke investigated with great interest this apparent exception to the rule. He found that the map was wrong and showed the stream in a wrong location; and the corrected location showed the usual chemical correspondence between stream and rock.

On Making a Correction

THE total depravity of inanimate things is illustrated anew in the accidental misplacing of the tables and a transposition of headings on page 809 of *Engineering and Mining Journal* of this volume, in the article on "Mineral Resources of the Belgian Congo," in the Oct. 23 issue. Also the gold content per cubic meter of the Moto mine, in the same article, should have read 2.32 grams instead of 3.32 grams. The *Journal* wishes to make due acknowledgment to Mr. Sydney H. Ball for directing our attention to the matter.

Through a typographical error, on page 815 of the *Engineering and Mining Journal* of Oct. 23, Mr. Gilbert H. Montague was made to say in his article on the western hearings of the Minerals Separation case, "To make its demand for a 25-c. royalty effective, Minerals Separation . . . " This should have read, "To make its demand for a 12-c. royalty effective."

WHAT OTHERS THINK

Advantages of Alignment Charts

Permit me to refer to an article published in your issue of July 17, 1920, page 108, entitled "Charts for Computing Blast-Furnace Performances." This article discusses only the construction of the charts. The author evidently does not employ the alignment charts invented by M. D'Ocagne in 1884, which have advantages over rectangular co-ordinate charts for the plotting of equations with three variables.

I have at hand a catalogue issued by the Robins Belt Co., called "Handbook of Conveyor Practice." This shows, as a recent innovation, some charts used in substitution of many tables. This practice is valuable and ought to be followed by all manufacturers when presenting their products to the public; they need to give useful, definite data, which, if presented in tabular form, might occupy many pages of their catalogs, but when charted are in a very condensed and useful form. However, they should undoubtedly choose the system best suited to their needs.

In this system each variable is represented by one scale and the values which satisfy an equation of three

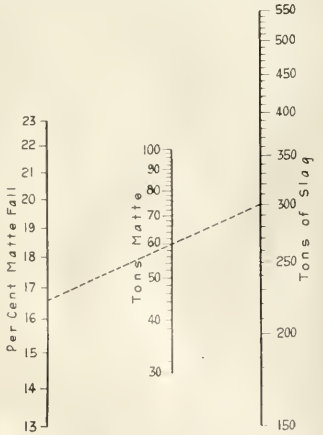

CHART FOR DETERMINING PERCENTAGE OF MATTE FALL

variables are always in a straight line. If one of the variables is the unknown quantity, it is only necessary to connect with a straight line the values of the other two variables and the prolongation of this line will intersect, in the scale, the corresponding value, which will solve the equation connecting the three variables. In practice, the straight line can be drawn with a lead pencil or indicated with a tightly drawn thread or by the edge of a rule or triangle.

To me the rectangular co-ordinate charts possess no other interest except historical; their construction is laborious, especially when curves must be drawn; the visual interpolation required to determine the approximate value of a variable is more difficult than on a scale, and the general aspect of the chart is confusing and similar to a cobweb.

I present for the consideration of your readers two charts of alignment scales which solve the same problems worked out by Mr. Ficket in order to show the greater simplicity obtained. For their construction the following data should be furnished: (a) The formula

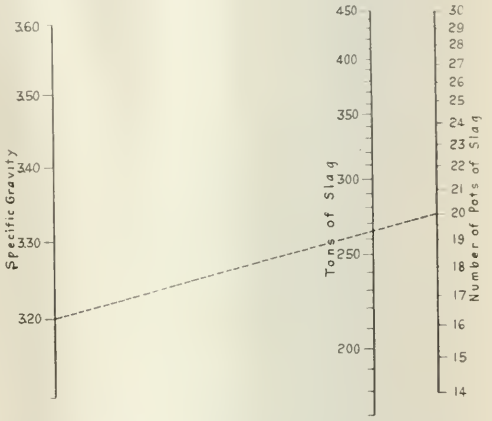

CHART FOR COMPUTING WEIGHT OF BLAST FURNACE AND REVERBERATORY SLAG

which connects the variables of the problem. (b) The limits within which the variables will be used. (c) The degree of accuracy which it is desired to obtain.

Turbo vs. Reciprocating Compressors

In Mr. Bancroft Gore's article entitled "A New High-Speed Turbo Compressor," appearing on page 717 of your Oct. 9 issue, he makes the statement, "Although the turbo blower, for capacities considerably in excess of these requirements, has generally supplanted cumbersome steam-driven reciprocating units, considerable difficulty was found in placing the order for the machine shown herewith." The capacity he refers to for his requirements is 4,000 cu.ft. per minute. I believe this statement is misleading.

I know of only four copper-smelting plants in the West in which a steam-driven turbo compressor has been installed for supplying air to copper converters. These compressors are rated at from 20,000 to 30,000 cu.ft. per minute, and deliver air at a pressure of from 11 to 16 lb. per square inch. At three of these plants the turbo compressors were shut down after operating only a short time, on account of their high steam consumption. At the other plant waste-heat steam is used for driving the turbo compressor, and the waste-heat steam is in competition with low-cost hydro-electric

power; however, the turbo compressor is operated only during the summer months, when there is no excess of waste-heat steam.

In two of the plants new reciprocating steam blowing engines have been installed since the turbos were installed, so that the latter may be kept shut down except for emergencies.

It appears from Mr. Gore's graph that his compressor, when working at its rated capacity of 4,000 cu.ft. per minute at 15 lb. pressure, requires about 4,600 lb. of steam per hour at 150 lb. gage and 100 deg. F. superheat and with a vacuum of 4 in. absolute and barometer reading 28.1 in. This is equivalent to 1.92 lb. of steam per 100 cu.ft. of air delivered, or, at 30 in. barometer, it would be about 1.94 lb. of steam. Under these air and steam conditions I would expect a good reciprocating engine equipment of this capacity to deliver 100 cu.ft. of air from 1.25 lb. of steam. A larger reciprocating unit would do better. Also, larger turbo compressors, when working at their rated capacity and with high vacuum, will more nearly approach the performance of reciprocating blowing engines. However, the economy of a turbo falls off rapidly at loads less than its rated capacity, whereas a reciprocating blowing engine maintains its economy fairly uniformly over a wide range in capacity.

The turbo compressor has advantages, as pointed out by Mr. Gore; however, for furnishing air for copper converter plants, where the amount required usually varies widely, and when the cost of generating steam is of consequence, it will often be found that these advantages are not of sufficient importance to be worthy of great financial consideration. A. G. McGREGOR.

Warren, Ariz.

The Cave Creek District, Arizona

I have just finished reading an article on the Cave Creek District, north of Phoenix, by Mr. Lewis in the *Engineering and Mining Journal* of Oct. 9. I made an examination of the Red Rover mine for the owner, Frank A. Gillispe, in September, 1920, going into the geology of this deposit in great detail, and I believe that Mr. Lewis is mistaken in his analysis. I will quote from our report.

"*Geology:* The Red Rover mine is situated in an area of sedimentary rocks which have been intruded by a dark greenish diabase and is overlain in part by a thick flow of rhyolite.

"To the south of the Bridal Chamber on the opposite side of the gulch is a granitic schist which has a strike of N 40 deg. E and dips 52 deg. to the north. Upon this granitic schist lies a series of sedimentary rocks. In order from the granitic schist upward and to the north they are red to brown sandy slate showing much jasper, a sandy slate, a white crystalline limestone, a sandy slate, a white crystalline limestone, a variegated brownish limestone, a sandy slate, arkostic sandstone, slates, a conglomerate and a highly metamorphosed slate. Under ground part of these same sedimentary rocks are found, and in addition there is a large area of a dark greenish diabase which has been introduced.

"In the vicinity of the vertical shaft the sedimentary rocks are covered by a rhyolithic flow which forms in a half moon to the south of the shaft. The surrounding mountains are capped with a heavy basaltic flow.

"The granitic schist has the appearance of having been faulted against the sedimentary rocks. The sediments show the effect of great pressure which has produced a schistosity in all of the sediments which has an almost vertical dip and strikes to the northeast. The sedimentary rocks have all been very much metamorphosed by the compressive force.

"*Orebodies:* The principal orebodies occur in a fissure which follows very closely a stratum of crushed variegated limestone. With the exception of a short distance near the west end of the ore drift south of the shaft on the 500-ft. level, the hanging wall of the ore is the bedding plane of a fine-grained sandy slate which overlies the variegated limestone, and the foot wall of the ore is a white crystalline limestone. In the vicinity of the ore the crushed variegated limestone is completely silicified. On the surface the diabase is seen in contact with the ore to the west of the inclined shaft."

The orebodies are some distance from the granitic schists and have no connection with them.

Boxite or Boozite

As an early contributor to *Engineering and Mining Journal*, in fact as long ago as 1883, I feel that I want to enter a protest against the use of its columns as a means for disseminating the principles of the proper use of language.

In the issue of Oct. 2 your correspondent, and with the well-chosen pseudonym (for we all know how light of weight is aluminum), takes a whack at the philologists by interrogating their authority. Unfortunately, he apparently does not know that bauxite, or beauxite, is not, I believe, found at Bozeman, Mont., although corundum is, nearby: that this hydroxide derives its name, not from Bozeman, Mont., but from the original locality, Baux, near the old Roman town of Arles, southern France, and that most, if not all, of the authorities (and I do not add an inclosed interrogation) agree that the mineral be pronounced as is the name of the French locality, with the added *lithos* or ite. I never could understand how box could come out of baux or beaux.

He then adds: "But who ever heard it called that? Why, even professors of mineralogy," etc. Well, I have very generally heard it pronounced correctly. To be sure, I have also heard boxite, but by a very few persons who are not supposed to know better, and hence were excusable. However, my preceptors of years ago pronounced it as indicated by Murray, the Standard, the Imperial, et al., wherein I appear to have been more fortunate than Al. U. Minum. And it was never my misfortune to have my teachers make lapses in English like e. g. "Ain't it fine?" but I am told that there are some guilty ones even today. But Al. U. Minum does not in his communication venture to tell us how he pronounces bauxite.

I refer your correspondent to my article in the New York *Sun* of Nov. 23, 1919, and if he really is in search of some "choice bits" of deviation from the straight and narrow path of good English, to the Cleveland daily papers. JOHN EYERMAN.

[The derivation of the word bauxite has been familiar to us since our earliest infancy, and we are perfect in French, as in all other languages; yet in America we (ourselves) pronounce it "boxite." We like to make ourselves intelligible, and the Anglicization of the pronunciation of words of foreign origin is an established linguistic principle. The discussion is closed.—EDITOR.]

Trailing Out of Murphy, Idaho

MURPHY, IDAHO, IS THE SHIPPING POINT FOR THE DEMING MINES CO.

The property of the Deming Mines Co. consists of thirty-eight claims and is situated about forty miles southwest of Murphy, Owyhee County. The ore is sulphide and carries gold and silver. Considerable new development has been done. The equipment, in addition to a hoisting and compressor plant, consists of a 100-ton mill provided with ball mill, six-cell Janney flotation machine, Senn tables, Oliver filter, roasting furnace and cyanide plant. The property is temporarily shut down pending re-financing.

Recovery of Silver From Manganese-Silver Ores

Chloridizing Roasting Followed by Cyaniding Offers Considerable Promise on Material Which Cannot Be Treated by Less Costly Processes—Volatilization and Recovery By the Cottrell Process Also Being Developed

By Jay A. Carpenter
Consulting Metallurgical Engineer, Los Angeles, Cal.
Written for *Engineering and Mining Journal*

IN PRESENTING a method of treating certain refractory manganese-silver ores by chloridizing roasting followed by cyaniding, it is necessary to state that it is simply the combination of two well-known metallurgical processes that in the last two decades have had the disadvantage of high loss of silver by volatilization and too high an operating cost with silver at low prices. With the steady development of roasting furnaces and pyrometers, with the use of crude oil and powdered coal as fuels, with the invention of the Cottrell system, and, lastly, with the marked increase in the price of silver, this method may now be applicable to silver properties with refractory ore that at present lie dormant.

Rapid development has taken place in the treatment of silver ores since the days of Hofmann, Stetefeldt, Brückner, and Russell. In the 60's and 70's the chloridizing roast, followed by the hyposulphite leach or amalgamation, was the accepted method of silver recovery from ores of too low grade to smelt. With the drop in the price of silver this low extraction method became impracticable. Starting with the new century came the application and intensive development of the cyanide process to the treatment of both oxidized and sulphide silver ores. This process, alone or in conjunction with table concentration, treats successfully nearly all silver ores that carry little of the interfering base metals.

Economic Limit of Flotation

In the last five years the flotation process has solved successfully the problem of treating base silver ores in which the silver occurs in the form of a sulphide along with copper, zinc, or lead sulphides. Just as the ambitious cyanider of fifteen years ago found to his sorrow that cyaniding had its limits when applied to manganese silver ores, so the flotation expert of today is learning that flotation has its economic limit when applied, with sulphidizing, to treat oxidized silver ores. Low extraction and erratic results will probably limit this combination to sulphide ores with a very small oxidized content.

The combination of the cyanide process with a reducing process successfully solved the treatment of Nipissing low-grade silver ore, in which the silver was combined with arsenic and antimony in refractory sulphides. There still remains to be successfully demonstrated, however, a practical way to treat the refractory manganese silver ores and the oxidized ores of silver combined with copper, lead, and zinc.

Two Available Methods for Treating Manganese Silver Ores

Two proposed methods of treating the manganese ores are about to be tried out in operating plants. The older one is that of giving the ore a preliminary wet treatment with SO_2 gas, to reduce the refractory oxidized silver compounds. This method should prove successful where the SO_2 can be made cheaply and where it would not be destroyed by carbonates in the ore. The other method is that of giving the ore a reducing roast before cyaniding, and can be applied to ores containing carbonates. The success of this process will depend on the type of the roasting furnace, and the operating care given the roast, as silver oxidizes very readily to compounds insoluble in cyanide. It will probably solve the treatment problem of certain manganese silver ores, but not all, as many of these ores are benefited but little by a reducing roast and a few are made more refractory. Skilled metallurgists worked on the treatment of oxidized silver ores combined with copper, lead, or zinc without success, and it was only because of a rapid rise in the price of metals that the practical metallurgist ventured to try roasting as an aid to the problem.

The Chloridizing Roast

As the silver is locked up in an insoluble form by an oxidizing roast, it was natural that the line of attack lay in a chloridizing roast. The process of preliminary chloridizing roasting as applied to oxidized lead ores, before brine or acid leaching, was carried out in plants in Utah with small volatilization loss and with fair success, owing to cheap salt and fuel. However, with strictly silver ores there was still the drawback of the loss of the metal by volatilization of the chlorides. In the silver plants of the 60's this loss usually amounted to from 10 to 25 per cent of the silver content. It is true that early in the first decade of the present century came the idea of driving off all the metals as chlorides and catching them in specially constructed dust chambers, but one such commercial plant proved a failure.

The Importance of the Cottrell Process

The development of F. G. Cottrell's remarkable and simple method of collecting dust and fume revived this process. Volatilization, which was the difficulty in the chloridizing roast in the 60's, is now relied upon to recover all of the silver, copper, and lead as volatile chlorides, giving the roasted ore as a tailing product. The Western Precipitation Co., of Los Angeles, controlling the Cottrell patent, is doing a great deal of experimental work with special reference to gold- and silver-bearing copper carbonate ores in a limestone gangue. The U. S. Bureau of Mines, at its Salt Lake station, has done and is doing much valuable work on the application of the process, especially to lead ores.

Small-scale tests have demonstrated that over 90 per cent of the gold, silver, copper, and lead in oxidized ores can be recovered as a chloride fume by this method. The fuel and chemical consumption and other details of treatment in these tests have been such as to give hopes that the process can be made commercially

successful on low-grade ores where fuel and salt can be delivered at a reasonable cost for freight charges. The process is fortunate in that the mechanical details of chloridizing roasting and recovery of the fume by the Cottrell system and its reduction by fusion appear to offer no serious difficulties. The scope of the process depends principally upon the oil consumption per ton of ore, not only to chloridize the ore but also to maintain the necessary temperature at which the large stream of heated air gradually picks up and carries off the chlorides from the roasting furnace to the collectors.

Application of Chloride Volatilization Process

The vapor pressure of silver chloride is probably considerably less than either that of gold, lead, or copper, and this accounts for its slower recovery by this method. Hofmann, in his "General Metallurgy," states that silver chloride alone is non-volatile at red heat, but is carried along with the more easily volatilized chlorides. From this it would seem that the chloride volatilization process opens a new field for the treatment of oxidized copper and lead ores carrying silver and occurring in a limestone gangue, but that it is not well adapted to the treatment of ores containing silver only. However, its development is rapidly increasing available knowledge of chloridizing roasting and the recovery of volatilized chlorides, and suggests the possibility of treating refractory silver ores containing no copper by a chloridizing roast at just high enough a temperature to chloridize the silver, and recovering the volatilized silver by the Cottrell system and the major portion by leaching the roasted ore with a weak cyanide solution.

A CREW OF TONOPAH CYANIDERS

From Hofmann's "Hydrometallurgy of Silver" I condense the following information:

Chloridizing roasting was usually applied to complex sulphide ores, although in some cases ores free from sulphides were successfully roasted. The object of the roast was first to oxidize the sulphides, then chloridize the metals, and then, if followed by amalgamation, to drive off the base-metal chlorides by volatilization. In the first part of the roast the sulphides burned, forming sulphates, which then reacted with the sodium chloride to give chlorine and metallic chlorides. The iron chlorides did not volatilize, but gradually oxidized, releasing chlorine for the chlorination of the other metals. The copper, lead and zinc chlorides volatilized readily, whereas the silver chloride did not, the quantity volatilizing depending on the amount of the other metal chlorides volatilizing and upon how high the heat was carried. Arsenic and antimony volatilized rapidly as the oxides before chlorine was released, and the balance went off as chlorides. If the ore contained gold, a considerable portion of it was lost as a volatile chloride, and the balance left as metallic gold, making amalgamation necessary.

The action of quartz in the ore was indifferent until at high temperature it decomposed salt, giving chlorine and sodium silicate. Clay, slate, and gypsum were inert. Lime rock acted unfavorably, as it decomposed metallic sulphates and chlorides to give calcium sulphate and chloride, thus consuming much salt and preventing the complete chlorination of the silver.

In general, the ore was crushed coarse in order to leach after roasting. To it was added about 5 per cent salt, and it was roasted with wood as the fuel in various types of furnaces, including the Brückner, Stetefeldt, and Howell-White. The metallurgists varied the degree of heat, length, and time of roast, the amount of air used, the time of adding, and the amount of salt, all according to the composition of the ore and their ideas of the process.

The roast took several hours, the dusting losses were heavy, and the volatilization loss of silver high. The consumption of fuel was low on heavy sulphide ores but high on oxidized ores unless a Stetefeldt furnace was used to bring the ore in direct contact with the flame. However, Hofmann states from his own experience that if he used a thick bed of ore, lots of air, and a low heat, the fuel consumption could be kept low and that the loss of silver by volatilization could be reduced to as low as from 2 to 5 per cent.

When the difficulties of maintaining an even heat with wood as a fuel are considered, and the unreliable method of judging temperature by the color of the furnace, the difficulties under which these metallurgists worked to find and maintain the best conditions readily can be appreciated. After sampling, in great anticipation, a couple of tailing piles of roasted silver ore in Nevada, I have come to the conclusion that they succeeded very well in removing the silver from the ore.

I do not know how much of the silver went up the roaster stack, but they were aware of this loss and worked hard to prevent it. In contrast to this is the fact that nearly all of the work in the present century on the chloridizing roast has been to get the silver to go up the stack. The pioneer in the work is Stuart Croasdale, of Colorado, who, in 1903, carried out successful experiments and patented the process. In 1906 a large plant, based upon the experimental work, was erected at Mayer, Ariz. Cement kilns were used for roasting and specially designed dust chambers to recover the fume. As is usual with a new process, much was written about the plant and what it would do. Later, the work of Christianson and Holt in chloridizing lead ores, and the invention of the Cottrell collectors, stimulated new interest in the process, and in 1917 the Bureau of Mines station at Salt Lake City, under O. C. Ralston, published the results of a great deal of experimental work.

Speaking of the volatilization of silver, Ralston states that in a reverberatory furnace treating an oxidized lead ore, with one hour's treatment at 900 deg. C., all the lead and copper are volatilized, leaving 10 to 20 per cent of the silver. The zinc volatilization varied greatly, being from 5 to 75 per cent. Concerning sulphur, he states that over 2 to 3 per cent in the ore gives lower silver volatilization recovery. His conclusion was that oxidized lead-silver ores can be chlorinated at 600 deg. C. and then successfully leached, or at 900 deg. C., and the metals recovered as a fume.

However, a working plant based on this experimental work was erected by a mining company at Eureka, Utah, the history of which is similar to that of the Mayer plant of eleven years before.

Recent Work on the Volatilization Process

The Bureau of Mines is still working on the problem, having recently made a working test at the Yellow Pine mill at Goodsprings, Nev., on the volatilization of silver and lead from a zinc carbonate concentrate. Another working plant under the direction of Robert H. Bradford is about to start up at Salmon, Idaho, to treat a copper ore. A subsidiary of the Western Precipitation Co. has a small plant at Humboldt, Ariz.

With so many working on the process, and with the failures of the past as a guide, there is a good chance for success, for the problem is mainly that of reducing the fuel and chemical consumption. The Bureau of Mines did not publish the percentage of recovery of the volatilized metals, but with ample collector capacity it is stated that from 95 to over 99 per cent are recovered.

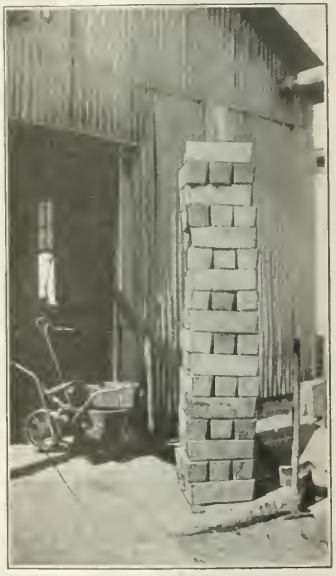
From a chemical standpoint present-day chemists have not added much to the improvement of the chloridizing roast, the principal improvements being mechanical. The best chemical improvement is the addition of calcium chloride along with the sodium chloride, a change which undoubtedly speeds up the chlorination, with a consequent saving of fuel. To melt down the fume, producing calcium chloride as a slag, is also an advantage. The present-day investigators have found, contrary to the old idea, that zinc is very slow to volatilize, and that limestone in the ore is generally beneficial to chlorination. Although the mixing of ores to prevent sintering has been given some attention, nothing has been published about it, or about the design and control of the furnace, or other ways greatly to increase or reduce the temperature of chlorination and the speed of volatilization, all of which are now the weak points of the process. The Cottrell system, by not only recovering the volatilized metals but also the volatilized sodium and calcium chlorides, has come to the rescue of the chlorination roast of silver ores.

Benefit of Fine Grinding

The silver metallurgist who knows the ease with which a silver chloride is cyanided is naturally inclined to believe that with a refractory manganese-silver ore containing no copper it is unnecessary to attempt to drive off the silver as a chloride when it can be recovered as a metal cheaply by a well-tried process.

The silver of a raw silver chloride ore goes into solution in a weak cyanide solution very rapidly, and the time and percentage recovery are usually dependent upon fine grinding. A minimum of agitation and aëration is required. Sodium cyanide dissolves more than its own weight of silver, adding harmless sodium chloride to the solution. On precipitation with zinc, the double zinc cyanide formed under reducing conditions is an excellent solvent for silver chloride under oxidizing conditions in the agitators. At a mill that I operated, treating a silver chloride ore, the actual consumption of cyanide was less than the theoretical amount of new cyanide required to dissolve the known weight of silver. This, taking in consideration also the mechanical loss of free cyanide from the plant, indicated that the same cyanide molecule must have been combined several times in rotation with silver, then zinc, then silver, and so on. On recent experiments with a raw silver chloride ore containing zinc carbonate, solution used for the sixth time showed as low a cyanide consumption and as high an extraction on the ore as when used the first time. The reason is that the solution remains free from soluble sulphides, sulphocyanides, and the like. Such ores are usually well oxidized, which aids the solution in remaining fresh and active.

Freshly precipitated silver chloride is apparently as quickly soluble in cyanide solution as salt in water, as one notices when titrating a cyanide solution containing sodium chloride in solution with the standard silver nitrate solution. As long as there is a trace of cyanide, the cloud of silver chloride formed by the rapid addition of the nitrate disappears almost instantly. Titrating with Aero cyanide shows the same action.



A TOWER OF SILVER

It is thus easy to understand how quickly the freshly formed silver chloride from a chloridizing roast of a silver ore goes into solution in a cyanide solution. With such a roasted ore I have obtained with a 0.75-lb. NaCN solution an extraction of 50 per cent in one minute, 75 per cent in five minutes, and the maximum extraction in one hour. Zinc in the roasted ore will do no harm, because, if it forms any double zinc cyanide with the free cyanide in the solution, this compound still remains an active solvent for the silver chloride. With the sulphur removed from the ore by the roast, and the iron thoroughly oxidized, the contact of the ore with the solution tends to oxidize instead of reduce it, thus promoting extraction.

Comparing this with the loss of cyanide and lack of dissolving efficiency of cyanide solutions working on silver sulphide ores so well discussed in E. M. Hamilton's "Manual of Cyanidation," one can appreciate the simplicity and cheapness in cyaniding a silver ore that has been given a chloridizing roast. From a mechan-

ical standpoint the roasted ore is coarse enough to leach readily. The wider one's acquaintance becomes with the cost and difficulties of the modern all-sliming mill, the more he will appreciate this brief statement.

The question arises as to what effect the continuous accumulation of soluble chlorides in the cyanide solutions would have on the extraction or precipitation. The answer, without detailed operating experience, would be that ocean water has been used as the source of supply for cyanide plants. The American Cyanamid Co. states also that Aero brand cyanide contains 43 per cent of soluble sodium and calcium chlorides and that it is used in one mill at the rate of 278 lb. per ton of ore on 3,000-oz. silver ore, with the barren solutions retained in the circuit, and "no fouling occurs." However, if the soluble chlorides should give trouble, or their recovery would be of economic value, they could be leached off as a strong brine before cyaniding, to be used in whole or part as a solvent in the Cottrell system and then to dampen the ore going to the roaster, and thus furnish chlorides for the roast.

Short Treatment at 900 Deg. C. Gives Good Results

From my test work on several oxidized refractory silver ores I have drawn a few general conclusions as follows: A temperature of about 900 deg. C. is necessary to get a high chlorination of the silver. The time of roasting at this higher temperature is short, being only thirty to forty-five minutes. Sulphide ores do not give better results on silver chlorination at lower temperature than oxidized ores, which is contrary to Hofmann's results from practical experience, but agrees with Croasdale's idea of the efficiency of the action of silica in freeing chlorine from salt, and of the Bureau of Mines' statement of the efficiency of volatilized sodium chloride as a chloridizer. With an oxidized ore the presence of carbonates appears to be beneficial, probably from the fact that they retain the chlorine down in the ore bed as chlorides, releasing it slowly with rising temperatures. Hofmann, in his "General Metallurgy," states that lead, zinc, and iron carbonates decompose when the temperature reaches 400 deg. C., manganese and magnesium at 600 deg. C., whereas calcium requires 900 deg. C. However, I believe the reaction between limestone and salt starts considerably below this temperature, as an ore with considerable limestone in it showed no contained carbonates after roasting at less than 900 deg. C.

Calcium and magnesium chlorides appear to react and volatilize faster and at a lower temperature than sodium chloride. I cannot, however, agree with Haria R. Layng that they are so much superior to sodium chloride as chloridizing and volatilizing agents. In fact, on oxidized silver ores I have been unable to make a high volatilization recovery of the silver with either of these chlorides or with sodium chloride, with a temperature of over 1,000 deg. C. for one hour, with rabbling and a fairly strong current of air.

The Treatment of Mined Gold and Silver Ores

Gold volatilizes more quickly than silver, and on a certain refractory oxidized silver ore carrying 0.5 oz. gold and 10 oz. silver which was chlorinated several times at 900 deg. C. for forty-five minutes, approximately 40 to 50 per cent of the gold volatilized, whereas the silver showed no measurable loss. This was rather exceptional, as with another ore containing no gold but the same amount of silver, and chlorinated under the same conditions, approximately 10 per cent of the silver volatilized. The total percentage of silver chlorinated under similar roasting conditions apparently varies rather directly with the silver content, for with a 40-oz. ore the tailings after cyaniding showed an extraction of 95 per cent, whereas with a 5-oz. ore it was only 80 per cent. However, the cost of the chloridizing roast limits it to 10-oz. ore or better.

From a manipulation standpoint it is easy to determine when the salt melts, when the sulphides burn, when the chlorides start to come off, and when the chlorine is about exhausted. When a stream of warm air is directed over the roast the volume of fume is increased many times, but there is little difference in the total percentage chlorinated, although considerable difference in the amount volatilized. However, contact with air is necessary, as roasts without rabbling gave poor results. On roasts similar except in the use of calcium chloride instead of sodium chloride, the chlorine fumes started at a lower temperature and were much heavier, but diminished to a small volume in very much less time. This proved the value of a mixture to maintain uniform chlorination with the minimum amount of chlorides. Refractory manganese-silver ores contain silica and iron oxides, and usually calcite or limestone. Care must therefore be taken, if the temperature is raised to 1,000 deg. C. to drive off the chlorides, that the ore does not sinter and thus lock up the silver compounds, preventing chlorination as well as volatilization. Steady rabbling of the ore, and fluxing it to change its composition, will aid somewhat. These observations on the roast are given in detail to aid anyone who wishes to experiment. In my work I use for preliminary experiments 400-g. portions of ore, using as the roasting dish a 6 x 12-in. muffle cut away at the top, and making the roast in a large muffle furnace with auxiliary gas burners, air hoses, and complementary appliances.

Only Coarse Crushing Necessary

In the practical application of the process of chlorinating and cyaniding refractory manganese-silver ores, the ore would be crushed to only 4 or 20 mesh. In out-of-the-way places with wood as a fuel it would be roasted in charges in Brückner furnaces. Where fuel oil or coal can be obtained, the choice would lie with a continuous rotary kiln, or a furnace with horizontal hearths if it would stand the heat. The Cottrell collectors can be placed in the stack flues, or individual units used, or they may be built of wood, as at certain cement plants. The size of the installation is remarkably small, and the amount of power required surprisingly low. A simple leaching plant would cyanide the roasted ore, and the same refining furnace would treat both the zinc precipitate and the silver chloride, giving silver bullion as the final product.

The reduction in cost of the simple crushing and leaching plant over that of an all-slime plant should go far toward balancing the cost of the roasting furnace. The economy in power and labor should balance to a large extent the extra cost of supplies, which would be largely for fuel and salt. Where these can be delivered at the reduction plant without high freight charges, it may be possible to treat refractory silver ores that can otherwise be treated only by smelting.

The amount of oil necessary to bring a ton of ore to 1,000 deg. C. and keep it there a sufficient time to

volatilize the metals is variously estimated at from 15 to 25 gal. To heat the ore to 900 deg. C. for a shorter time, for chlorination only, would require considerably less. The amount of new salt required for volatilization is estimated from 50 to 180 lb. per ton, with probably less for chlorination only.

The volatilization process has not yet been demonstrated in working plants, but there is, in my opinion, a wide field of refractory ores to which it is adapted. On the other hand, the combination of chloridizing and cyaniding as outlined in this article can be considered as established, and the only new feature is its combination with the Cottrell system. It is limited to silver ores that cannot be treated by less costly processes.

For students of these processes I append a list of books and published articles. Unfortunately, the list of authors does not contain the names of many metallurgists now working on chloridizing and volatilizing precious-metal ores. A discussion of their work would be of benefit to all:

South African Diamond Mines Prosperous In 1919

The diamond-mining industry, which, next to gold mining, is the most important of the mining industries in South Africa, enjoyed a particularly prosperous year in 1919, according to *Commerce Reports*. The output was increased from 2,543,735 carats in 1918 to 2,592,099 carats in 1919, a gain of 48,364 carats, and the value increased from $33,876,008 in 1918 to $54,688,647 in 1919, or nearly $21,000,000. Exports of diamonds during 1919 amounted to 2,752,303 carats, valued at $56,192,346, as compared with 2,571,646 carats, valued at $34,372,298, exported in 1918. In the pre-war year 1913, however, the exports of diamonds amounted to 5,503,861 carats, valued at $58,478,419.

The diamond market throughout the whole year was in a buoyant state. Prices advanced materially, owing primarily to the limitation of sales to market requirements, a policy which has been consistently pursued by the principal diamond producers in South Africa. A comprehensive agreement was reached by the three largest producers of diamonds in South Africa and the principal group of producers in the Southwest Africa Protectorate, whereby their entire output will be purchased by the London Diamond Syndicate, and placed upon the world's market through this one channel only.

Movements of Metals and Ores in August

Imports and exports of the more important metals and ores, as reported by the Department of Commerce for August, 1919, and the figures for August, 1920, as finally revised, are as follows:

IMPORTS, AUGUST, 1919 AND 1920
(In Pounds, Unless Otherwise Stated)

	Aug., 1919	Aug., 1920
Antimony ore, contents	78,400	146,284
Antimony matte, regulus or metal	741,550	2,570,743
Copper:		
Ore, contents	4,172,049	5,752,146
Concentrates, contents	3,262,921	5,287,911
Matte, regulus, etc., contents	1,648,708	130,588
Imported from (in part)		
Canada	2,670,936	3,831,447
Mexico	3,204,371	2,134,787
Cuba	2,143,507	4,123,917
Chile	169,385	203,252
Peru	54,633	405,361
Unrefined, black, blister, etc	15,954,604	17,971,202
Refined, in bars, plates, etc	1,429,343	
Old, etc., for remanufacture	439,915	1,894,317
Composition metal, copper chief value	98,400	324,717
Lead:		
Ore, contents	860,654	1,500,484
Bullion, contents	4,959,021	5,139,435
Imported from (in part):		
Canada	300,765	745,597
Mexico	5,508,058	5,873,237
Pigs, bars and old	1,120,089	7,403,826
Manganese ore, long tons	8,240	99,601
Imported from (in part):		
Brazil, long tons	3,600	88,776
British India, long tons		4,900
Tungsten ore, long tons	553	131
Pyrites, long tons	30,705	48,832
Imported from (in part):		
Spain, long tons	21,275	19,201
Canada, long tons	9,430	16,940
Tin ore, long tons	33	5,385
Tin bars, blocks, pigs, etc	9,872,459	11,195,937
Imported from (in part):		
United Kingdom	5,901,348	2,039,044
Straits Settlements	2,746,253	5,969,928
Dutch East Indies		220,459
Hongkong		2,387,847
Australia	224,000	181,440
Zinc:		
Ore, contents	1,606,497	2,083,429
Imported from:		
Canada	195,646	366,162
Mexico	1,402,151	1,717,267
Blocks or pigs, and old	11,545	1,826

EXPORTS OF COPPER, LEAD, AND ZINC
(In Pounds)

Copper:		
Ore, contents	None	None
Concentrates, contents	10,500	None
Unrefined, black, blister, etc	1,176,390	61,437
Refined, in ingots, bars, etc	47,385 901	39,050,235
Exported to (in part):		
Belgium		2,978,454
France	8,901,736	14,633,149
Germany		4,808,472
Italy	4,490,261	112,285
Netherlands		2,327,411
United Kingdom	11,358,619	6,828,152
Japan	15,095,000	
Sweden		2,889,617
Composition metal, copper chief value	1,226	11,417
Old and scrap	20,223	123,907
Pipes and tubes	295,856	653,994
Plates and sheets	591,784	3,901,891
Wire, except insulated	3,203,901	2,056,285
Lead:		
Pigs, bars, etc.:		
Produced from domestic ore	1,657,083	188,057
Produced from foreign ore	7,498,822	509,504
Exported to (in part):		
Denmark		112,000
Canada	230,023	17,074
Brazil	258,719	134,400
China	224,305	6,092
Zinc:		
Dross		82,100

Norwegian Nickel Industry Curtailing.

It is reported by the *Mining Journal*, London, that 200 out of 1,250 workmen employed by the Evje Nickel Ore Mines, in Norway, have been discharged, owing to the costs of production making it almost impossible for the company to compete with foreign rivals.

Stuck Steel

Methods That May Be Used To Eliminate One of the Annoyances That Beset the Drill Runner — Several Causes Contribute to the Handicap of Stuck Steel, Which Is Incidental to Operations in All Mining Districts

By D. E. Dunn
Written for *Engineering and Mining Journal*

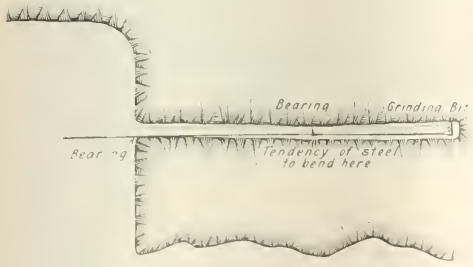
EVERY mining district has the most difficult drilling in the world. If you don't believe this, ask the drill runners about the conditions in their district. In the Michigan copper country the amygdaloid is bad and conglomerate is worse. In the Lake Superior iron district the soft hematite is sticky and the cherty iron carbonate wears the bit gage. Butte rock is hard and "fitchery"; Joplin ground is full of "vugs," and the pebbles falling behind the drill bits stick the steel—and so it goes.

One of the principal troubles that cause difficult drilling is stuck steel. Drill steel becomes stuck for the following reasons:

1. Improper alignment of drill steel and hole.
2. Incorrect type of bit.
3. Incorrectly formed bits.
4. Feeding too much or too little water.
5. Weak drill rotative power.
6. Worn or broken shanks.
7. Worn or broken drill parts.
8. Drilling into a seam or in "fitchery" ground.
9. Pebbles falling behind bit or mud collar forming behind bit.

A common cause of stuck steel is the improper alignment of the drill steel with the hole. When this occurs the drill steel will bear on at least two points in the drill hole, there is a tendency for the steel to bend, increasing with the divergence from true alignment, and a severe grinding on the reaming surfaces of the bit. All of this will cause difficult rotation and will, in many cases, stop rotation entirely.

This condition is due to poor operating. The steel must be brought nearly into line to have it enter the hole. The experienced drill runner can line up the

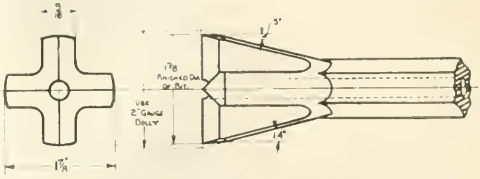


STEEL AND HOLE OUT OF ALIGNMENT

drill laterally "with his eye." He will do this after entering the steel and cranking it nearly to the cutting face, and tighten his "tee-bolt nut." He will then open the throttle (inlet) valve a little, and let the drill find its own vertical line, helping it a little by raising up on the crank end, and finally tightening the clamp bolt nut. If the hole is very much out of line time can often be saved by abandoning it entirely and starting a new one.

The choice of the proper type of bit is important in helping to eliminate stuck steel. For example, a narrow rapid-cutting chisel bit would bury itself in some soft limestones. Six-point bits are usually in disfavor because of their slow drilling and small clearance space for the cuttings.

The cutting edge has the greatest diameter on a single taper bit. This cutting edge wears rapidly, and soon the diameter is less than at another point farther back on the bit. Then the hole cut by the cutting edge is too small to admit the rest of the bit and a reaming action takes place which will soon stall the rotation and



11 AND 5 TAPER 4 POINT CROSS STRAIGHT FACE WET BIT

stick the steel. To overcome this many and varied designs of bits have been made, some of which were extremely complicated, and if they had any advantage underground, the time taken by the blacksmith to make them and resharpen them more than outweighed this advantage.

The bit that has been found most successful for rapid cutting, long-wearing gage, and ease of making and resharpening is the 14 deg. and 5 deg. double-taper cross or four point. This double-taper bit when properly made has a reaming surface whose diameter is the same as the diameter of the cutting edge and which backs up the latter with a good stock of metal, increasing the life of the gage. It also acts as a guiding surface, preventing the steel from running off into seams or fissures. The use of this type will, in the majority of cases, remedy any trouble caused by wear of gage.

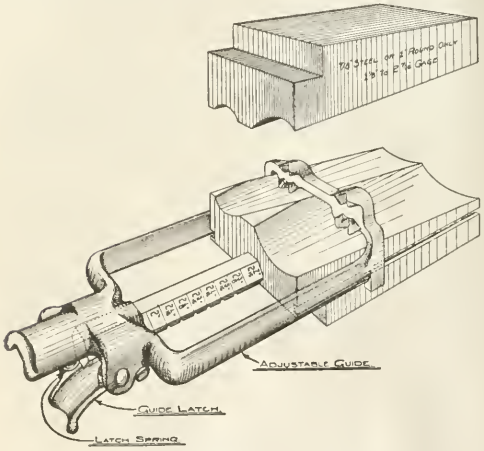
It has already been said that the bit should be properly made. That leads to consideration of the methods of making and sharpening drill steel and their bearing upon stuck steel. Primarily, there are two methods of sharpening drill steel, by hand and by machine. The latter method is by far the more rapid, accurate, and satisfactory, and should be used wherever three or more drills are in operation. However, even machine-made bits are sometimes faulty. This is usually due to careless blacksmithing, because the machines are extremely simple and rugged and, should they get out of adjustment, it is a relatively easy matter to put them into proper condition again.

The manufacturers of drill-steel sharpeners are continually making the machines more nearly fool-proof. One of the latest improvements for assuring better bits is the use of double-bored gaging blocks with an ad-

justable latch guide. The wide range of these blocks permits the operator to gage accurately an entire normal run of steel on the one set of blocks, and these adjustments for the various gages require only the pressure of a finger on the adjustable latch guide.

An interesting but less common cause of stuck steel is the feeding of too much or too little water through the hollow drill steel. When too little water is fed a mud collar frequently forms behind the drill steel, which makes it difficult to extract the latter. Sometimes when drilling into rock bearing metallic ore, and too much water is fed, a mineral separation takes place. The gangue is sludged off, and the drill pounds away ineffectively on the metallic residue, finally becoming stuck. Sometimes dry drills are run in abrasive ground. The steel soon heats up, and the temper is rapidly burned out of the bit. This condition may be remedied by using a water feed or a wet drill.

Sometimes the shank portion of hexagon steel becomes so worn that it permits the steel to slip in the rotative sleeve, or the lug on round steel becomes worn



DOUBLE BORED GAGING BLOCKS

or broken off, with the same result. The drill steel will then be hammered into the ground without rotating and will soon become stuck. The only remedy for this is to keep the shanks in proper condition. The same results are obtained when use is made of worn or broken drill parts, principally worn pawls, chuck and bushings, and broken pawl springs and rifle bars. The only remedy for this fault is to replace the worn or broken parts.

The rotation of some drills may be too weak for the rock conditions. This, however, is exceptional, because rock-drill manufacturers have strengthened the rotative power of the drills up to a practical limit. Frequently, drill trouble is attributed to weak rotation when that is far from being the true cause.

Unequal cutting may easily take place when drilling into a seam or in fitchery ground, and this throws the steel out of line and sticks it. Drilling into brecciated ground sometimes causes pebbles or small bits of rock to fall behind the bit, and these wedge against the steel and the drill hole, stopping rotation. In some limestones and other calcareous formations the water mixing with the cuttings will form a mud collar back of the bit.

In all of these instances mentioned it becomes a question of loosening and removing the stuck steel. There is one popular method of performing this operation that should *not* be followed, and that is to pound away on the drill steel with a 16-lb. double jack. This manner

HAMMERING DRILL STEEL BREAKS THE STEEL AND THE DRILL

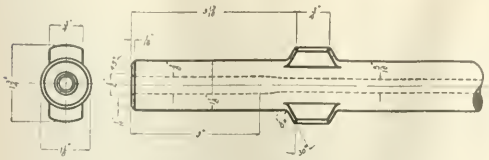
of loosening the steel is common, but usually the only real results obtained by it are bent steel, broken drill parts, strong back, and increased vocabulary. Usually the steel itself stays stuck. However, there is another method of loosening the stuck steel that is practiced

LUBRICATING GIVES THE ROTATING PART CHANCE TO WORK AND FREE THE STEEL

effectively in many camps. Here is how it is worked by Bert Chadwick, mine foreman of the Black Hawk Lead & Zinc Co. at Picher, Okla.

Upon employing a new man he shows him his working place, tells him what he wants done, and then retires to the background to wait for the new man to get into

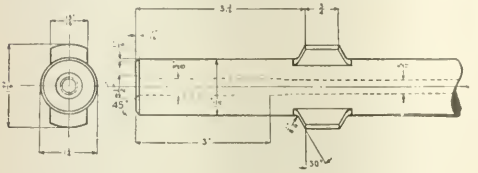
trouble. This the new man usually does, as the rocks are very oppressive and small pebbles continually fall behind the drill bits. Usually in a short time the steel will get stuck in the hole, the drill man begins to sweat, pounds the steel with a sledge, and gets no results. About this time Chadwick steps up, saying "Let me try it." He takes the oil can, fills the back and front cylinder oil pockets with oil, opens the throttle, and 99 per cent of the time the steel backs out of the hole



ONE AND ONE-EIGHTH-INCH LUG SHANK

without any further trouble. The blow slightly loosens the drill steel and the properly lubricated rotative parts take care of the rest.

Rock-drill lubrication is not given sufficient thought, yet it is one of the most important items in drill operation. Representatives of the large oil companies and of the large rock-drill manufacturers are waging a continual campaign of education along these lines. Their greatest foes are ignorance, thoughtlessness, and neg-



ONE AND ONE-FOURTH-INCH LUG SHANK

ligence. However, the increased ease of operation and the greater speed of drilling of properly lubricated drills should convince the operator that this matter ought to be properly considered. The increased footage and the decreased cost for drill repair parts should convince the mine manager.

There are proper and improper lubricants for rock drills as for any other machinery. With every drill

JACKHAMMER SHANK

shipped is sent an "oil tag," which designates the best lubricants for that drill. These tags embody information that has meant exhaustive and costly testing on the part of the drill manufacturers. The information is valuable, and should be recognized as such. However, sad to say, a great number of operators still think that axle grease is good enough, others think cylinder oil will do, and others don't think. Representatives of either oil companies or the rock-drill manufacturers are always pleased to consult with the representatives of the mine management and to give them the benefit of expert knowledge and long and varied experience.

Italy's Mining Industry During the War

The following table by Consul General D. F. Wilber gives the amounts, in tons, of the principal products of the mining, quarrying, and also of the metallurgical industries in Italy produced during the four years of the war as compared with the production in 1913:

Products	1913	1915	1916	1917	1918
Iron ore and manganiferous iron	603,116	679,970	946,604	998,632	694,677
Manganese ores	1,662	12,557	18,147	24,582	31,896
Copper ores	89,847	74,470	88,475	86,842	82,302
Lead ores	44,654	41,590	39,460	39,076	37,583
Zinc ores	158,278	80,622	94,043	79,453	67,116
Iron and copper pyrites	317,334	369,320	410,290	500,782	482,060
Mercury (metal)	1,004	985	1,093	1,071	1,038
Sulphur and sulphur mineral, ground	406,406	380,240	287,965	230,074	253,390
Coal and lignite	701,079	953,082	1,305,840	1,722,157	2,171,397
Petroleum	6,572	6,105	7,035	5,668	4,907
Pig iron	426,754	377,510	467,005	471,188	313,576
Iron and steel	933,500	1,009,240	1,269,486	1,331,641	992,523
Copper	2,091	940	860	1,248	1,114
Lead	21,674	21,812	24,362	16,237	18,332
Zinc			258	367	1,188
Antimony	76	548	660	535	367
Aluminum	874	904	1,226	1,740	1,715
Marble	509,342	246,883	200,700	134,233	87,483

The production of iron and steel increased considerably during the war, but fell off again in 1918. The production of aluminum about doubled and that of zinc, none of which was produced in 1913, reached 1,188 tons in 1918.

There was a great decrease in the production of marble, which was 509,342 tons in 1913 and only 87,483 tons in 1918.

The following table shows the number of mining companies in Italy and total amount of capital invested in them, from 1912 to June 30, 1919, inclusive:

Year	No. of Companies	Capital, Lire	Year	No. of Companies	Capital, Lire
1912	39	129,622,490	1916	49	164,865,775
1913	41	131,289,390	1917	56	235,486,950
1914	46	145,655,815	1918	75	283,596,950
1915	48	153,541,615	1919 (to June 30)	82	336,806,950

Whereas from 1912 to 1916 the total capital of the mining companies in Italy increased only from 129,600,000 to 164,800,000 lire, and their number was increased by 10, from January, 1917, to June, 1919, the number of companies increased from 49 to 82 and the capital investment from 164,800,000 to 336,800,000 lire.

The Italian mining industry is most highly developed in Sicily (the Province of Caltanissetta), in Tuscany (the provinces of Florence, Arezzo, and Grosseto), and in Sardinia (the provinces of Cagliari, Sessari, and Iglesias). It is also developed in Lombardy, particularly in the provinces of Bergamo and of Brescia, and in Piedmont, in the province of Turin.

Mica in India

The two principal mica-producing regions in India are the Hazaribagh district, in the Province of Behar and Orissa, Bengal, and the Nellore district, Madras Presidency. There is every reason, says D. A. Hall,* to expect that India will retain its position as the most important mica-producing country. The great number of deposits offer almost every grade of muscovite required in the trade. The industry is well established, and labor conditions are extremely favorable for the production of a commodity requiring such a large amount of hand labor before being ready for market. It is true, however, that the richest and most accessible deposits have been mined out, and scientific methods must be applied to mining if production is to retain its former place.

Experiences of a Custom Assayer

Intentional Salting Easier To Detect Than Accidental Preliminary Examination of Samples Important

By E. C. D. Marriage
Pioche, Nev.
Written for *Engineering and Mining Journal*

FIFTEEN years' continuous operation of a custom assay office in Nevada has demonstrated to me the importance of exercising the utmost care in the preliminary examination and preparation of samples submitted for assay. Errors will creep in despite of all efforts to avoid them; and it is by the successful elimination of these errors that business is built up and the necessary confidence of the community secured and held. Often, in such custom assay offices too little importance is attached to this work. Samples are tagged as received, and turned over to an assistant. A quartz sample, possibly brought in by a prospector from a new district, is passed through the crushing plant following a rich sample, with the result, sometimes, that the really barren quartz is found to contain several ounces of silver to the ton, and the prospector undertakes a long trip back to his discovery, only to find, on checking, that a mistake has been made. Thus time and money are wasted, owing to the negligence of the assayer in whom the prospector places his trust.

A few years ago several samples of gold quartz were brought into my office by a local mining promoter, which I was requested to assay for gold. The promoter explained to me that they were low in grade but represented a big tonnage and asked that I save them for future checking and for possible mill tests. As I was busy weighing my day's pulps, I turned the samples over to my assistant for preparation after quickly examining the character of the quartz in the top of the sacks, which bore out the promoter's description, being hard, glassy, and apparently very low in grade. Later in the day the promoter returned for the results. As I watched the cupels which were finishing in the muffle I could see very plainly that the results were going to be surprisingly high. Subsequent weighing indicated gold values of which the lowest was $300 per ton and the highest over $2,000. The promoter was dumfounded. He assured me of his extreme care in sampling and watching the samples when taken and evidently felt that my work was at fault. I suggested an examination of the quarterings, and together we quickly picked out a number of small pieces of apparently rich ore. Resampling, which necessitated over one hundred miles of night traveling, in which I myself assisted, gave the true results of from $2 to $16 gold per ton, but the loss of confidence resulted in killing the prospective deal.

The exact method employed by the salter in tampering with the samples and inserting the rich ore was never discovered, though his identity was known to me. He had previously requested me to melt a quantity of rich telluride ore from Colorado, the resultant gold being of a beautiful greenish color which compared exactly with the big button obtained when I assayed the saltings found on examining the original samples.

Later in the same year an owner of a group of mining claims who was endeavoring to sell his property locally made an abortive attempt to raise the grade of the prospective purchaser's sample right before my eyes. Knowing that I was alone in the assay office, and that I was in possession of the samples, he came into my office just as I was about to finish pulping them. Engaging me in conversation about some work he intended to give me, he followed me into the bucking room. Just as we entered, my telephone bell rang. Excusing myself, I started toward the front office. On second thoughts, however, I turned quickly at the door, and re-entered the bucking room, catching my friend right in the act of adding a quantity of rich argentiferous galena to one of the pulps in which he was interested. Caught red-handed, he tried to bribe me to increase the assays, and, failing in that to buy my silence. Subsequent assay of the quarterings which I had kept showed very low values. The whole matter was dropped, and my friend henceforth pursued his mining career in other fields.

In my opinion it is much easier to detect intentional salting than that which sometimes takes place in a day's run. In instances of the latter kind, a sample that apparently should assay a trace is found sometimes to contain fair values, and all the ordinary sources of possible error are traced down without the mystery being solved.

For a number of years I had been assaying for a company developing a big silver deposit, and although rich spots occurred quite frequently in the deposit, the average of the whole was proving disappointing as a milling proposition. One day a number of pulps were brought to my office by the superintendent of this company with the request for very careful assaying in duplicate for silver only. My results when submitted checked very poorly with the returns on duplicate pulps made by a traveling assayer who had recently settled in the district, mine being considerably lower. This man claimed to be employed by an Eastern exploration company which was considering an option on the property. As usual, the higher assays were trusted, and I temporarily lost considerable work.

Soon after this I ran across a number of samples of barren-looking material from the same district, the owner of the property having obtained results from the same traveling chemist showing an average of over 10 oz. in silver per ton, and he told me that he had already located a whole mountain and considered his fortune made. Needless to say, the samples ran a trace, and I suggested the only possible solution, salted flux, unless my traveling competitor was just naturally optimistic of the district's resources. The next day the latter called on me and requested me to assay his fluxes. The litharge carried a pleasing amount of silver and the mystery was solved.

In a custom office, in assaying widely varying samples of ore, too much care cannot be taken in examining the original sample as submitted for assay. The preservation of the original quarterings is a great aid in running errors to ground, thus protecting one's customers and establishing and maintaining the confidence of the mining community.

Platinum in Colombia

Foreign Capital To Realize Future Possibilities of Industry — Output of Choco Region Increasing — That of Urals Passed Its Peak Before War — Ordinary Methods of Production Employed

By J. Ovalle
Written for *Engineering and Mining Journal*

THE United States of Colombia is the second largest producer of platinum in the world, being outranked only by Russia. At present, Colombia produces an average of 30,000 troy oz. of platinum per year. Her exports of the metal to the United States during the war period are shown in the following table, which also reveals the total imports into the United States:

IMPORTS OF PLATINUM FROM COLOMBIA TO UNITED STATES DURING WAR

Year	Imports From Colombia, Oz.	Value	Total U. S. Imports, Oz
1915	13,601	$417,938 00	40,538
1916	25,588	1,473,553 00	89,656
1917	21,278	1,536,422 00	30,170
1919	5,246,522 00	....	....

The value of platinum exported by Colombia in 1918 through the port of Cartagena alone amounted to $1,325,481, and the quantity exported in 1919 was over 30,000 troy oz. The decrease in imports in 1917 was due to the protracted dry season in the Quibdo district.

The significance of the table printed above becomes apparent when the fact is borne in mind that in the three years preceding the war the imports into the United States of platinum in bars, unpolished, and in other forms averaged between 100,000 and 120,000 oz. per year, and of that quantity Colombia supplied only 10 per cent, that is to say, an average of from 10,000 to 12,000 oz yearly.

The production of the metal in Colombia has been greatly stimulated by the high prices prevailing during the war. Before the war the price in New York averaged about $45 per oz., as compared with $20 per oz. for gold in the same period. In 1917, platinum was quoted at over $100 per oz. in New York. The demand for war purposes tended to push the market price even higher, until the United States Government found it expedient in 1918 to fix the price at $105 per oz. But with the signing of the armistice the market experienced an unfavorable reaction. In 1919, the price came down considerably, but soon thereafter the demand was stabilized and the market resumed its former strength, so that in August of this year the metal was quoted in the Choco district at $110, and this price is substantially in effect at the present time. Despite the unsettled situation prevailing in 1919, Colombia managed to increase the amount of platinum exported to the United States.

Platinum is found in the Choco region, near the western frontier of Colombia, at an altitude of from 1,500 to 5,000 ft. The platinum region extends all along the Atrato River and its headwaters and along the Cauca Valley as far south as the Ecuadorean border; but the richer districts are found at the headwaters of the Atrato and along the San Juan and Condoto rivers. Most of the Colombian supply, however, comes from the Quibdo (Atrato) district.

The Condoto River district, which is a great producer of the platinum, is of alluvial formation. On account of the broken nature of the ground and the dense jungle, no accurate estimate has been made of the possible future production or of the extent of the platinum-bearing ground. In this district platinum predominates, the amount of gold found with it being about 4 per cent of the combined metals. In the Quibdo deposits gold predominates, the platinum content being only from 15 to 10 per cent of the combined metals.

Another producing section embraced in the Choco and Quibdo district, and of growing importance, is near the headwaters of the Quito River. It is being actively worked now.

The Atrato River is about 300 miles long, two-thirds of its course being navigable by steamers. It empties into the Gulf of Uraba (or Darien) through fifteen mouths, two of which are navigable by small sea-going vessels and eight by canoes. This river drains 24,000 square miles and during floods discharges 175,000 cu. ft. per second, a larger discharge, in comparison with the area drained, than any other river in the world. This voluminous discharge is due to the heavy rainfall common to this section of the country. The bars at the river mouth are covered by only 5 or 6 ft. of water, but the channel for about 100 miles inland has a depth of from 40 to 70 ft., and a width ranging from 750 to 1,000 ft. At Quibdo, 220 miles inland, the river has a depth of from 8 to 20 ft., with a width of 850 ft. The Atrato is navigable by steamers as far as the confluence of the San Pablo and Certigui rivers, a distance of about thirty miles above Quibdo.

The San Juan River has a length of 245 miles, but owing to a great number of navigable affluents, the system affords 300 miles of navigable waters. Navigation, however, is greatly hindered by bars at the mouth of the river, which are covered by only 6 or 7 ft. of water. The main river, which empties into the Pacific Ocean through seven mouths, is navigable for 140 miles by small steamers. Its width varies from 300 to 1,200 ft. Its discharge is 50,000 cu.ft. of water per second, a larger discharge than that of any other South American river flowing into the Pacific.

It has been a tradition that platinum was discovered in what is today known as Colombia in 1735 by a Spaniard named Antonio Ulloa. His report was the first news in Europe of the existence of such metal. In the old days, long after Ulloa's discovery, platinum was separated from gold and thrown away as being of no value in the Choco region. Large quantities of this platinum dust have been recovered. Recently one owner extracted seventeen pounds of platinum from the foundation of an old building in the Quibdo district.

Platinum in Colombia is generally gathered from the bottom of rivers and, as a rule, is found with gold, the proportion varying according to locality. Both metals are dug from the sand and substratum of small streams,

a work mostly done by Indians and negroes on their own initative. This method of recovering platinum is now being improved by the introduction of steam dredges. The platinum so collected is exported by way of Cartagena and Barranquilla, Colombia's chief seaports.

Foreign capital is gradually taking cognizance of the vast possibilities involved in the future of the industry and, accordingly, is entering the field in Colombia. The most important undertaking up to the present is that of the Anglo-Colombian Development Co., a subsidiary of the Consolidated Gold Fields interests, and certain American interests known under the corporate name of Compañia Minera Choco-Pacifico.

URAL AND CHOCO (COLUMBIAN) FIELDS COMPARED

In reviewing the platinum situation in 1918, the chairman of the British Gold & Platinum Corporation said, in part, with regard to the two main platinum fields in the world:

"Some time previous to the war, 90 per cent of the world's output of platinum was produced in Russia, later falling off, which was very marked even before the war, being due to the exhaustion of the best known areas in the Urals. We find that in 1911 the Russian production was 300,000 troy oz. In 1912 it had diminished to 185,381 oz., in 1913 to 173,642 oz., and in 1914 to 156,775 oz. In 1915, the Russian output fell to 107,774 oz., and in 1916 to 78,674 oz., but no doubt the decline since 1914 has been as much due to the dislocation caused by the war as to the exhaustion of the deposits, However, due attention must be paid to the fact that Mr. de Hautpick, an authority of the Russian Imperial Government, some years ago predicted the exhaustion of the Urals within a period of thirty or forty years, and it is a fact that gravels which were left as unpayable in former years have now been treated, the increase in the price of the metal having made the treatment of these gravels profitable.

"In the case of the Choco district of Colombia we have a virgin ground, with steadily increasing instead of diminishing production of platinum, the output having been 12,000 oz. in 1911, 15,000 oz. in 1912, 15,000 in 1913, 17,500 in 1914, 18,000 in 1915, and 25,000 in 1916, and I understand that in 1917 it went up to some 50,000 troy oz., showing a gradual increase since 1911, which has now reached 300 per cent, and this, be it remembered, eliminating the production of one dredge with very crude appliances indeed.

"Careful survey and prospecting carried out by British and American engineers have proved the existence of platinum and gold in payable quantities over many square mile of (Colombian) territory. The deposits of the Choco district are such as to be well suited for treatment by means of dredging and hydrauliclicking. When I was out there I was much impressed with the natural facilities for such mining. But the Colombian fields are really only in their infancy."

Tungsten in Eastern Asia

The increase of output of tungsten from eastern Asia has been marvelous. In 1913 it amounted to 2,497 tons, and in 1918, to 20,228 tons—more than 56 per cent of the world's production. As elsewhere, production must decrease until the accumulated stocks in the reducing centers are used; then production will again proceed.

The alluvial deposits of China are by no means exhausted, the veins are scarcely touched, the tungsten-bearing area is large and only partly prospected, and such prospecting as has been done has been almost wholly for placers. Labor is cheap, and a large future output is sure. More liberal ideas of trade and government are slowly taking root in China, and ultimately educated Chinese or trained foreigners will work the deposits. The output for a long time will be large, though it may never again be as large as it was in 1918.

So far as can be learned, the easily worked placers and the upper parts of the veins in Burma are becoming exhausted rather rapidly, and recourse must therefore be had more and more to the mining of those parts of the veins below water level and in harder rock, and this will probably mean a diminution rather than an increase in output. Siam seemingly should give an increased production, as the mines are comparatively new, and there still should be opportunity for discoveries. The Federated Malay States and the Unfederated States (Johore, Kedah and Trengganu) should produce at least as much in the immediate future as in the past—given the demand and an equal price.*

Iron Ore Discoveries in Russia

According to Swedish reports, enormous deposits of magnetic iron ore exist near the town of Kursk, on the borders of the Ukraine. This discovery is the result of twenty-four years of systematic surveys carried out by Dr. Ernst Leyst, formerly professor of geology at Moscow University, who died in 1918, but whose papers were rescued and brought to Sweden, where they were examined by Dr. Valfried Petersson, professor of mineralogy at the School of Mines, and by Mr. Nathorst, mining engineer to the Swedish Iron and Steel Association. It is stated that these experts have come to the conclusion that magnetic deviations of unprecedented intensity and extent established by Professor Leyst can be explained only on the assumption that they arise from enormous deposits of iron ore, running in two parallel lines in the direction north-west south-east, and situated at a distance of thirty-seven miles from each other. Both lines have a length of about fifty-seven miles and consist of a series or orebodies, but it is impossible solely on the basis of Professor Leyst's magnetic charts to estimate accurately the extent, quantity, or quality of the beds.

British Columbia Fluorite Shipments

The volume of fluorite shipments from the Rock Candy mill, in Lynch Creek, in the Similkameen district of Canada, is increasing rapidly, according to Consul Norton F. Brand, and the Kettle Valley Ry. has established a twice-a-week service to handle the business. About 100 tons of fluorite is mined daily. It runs about 25 per cent waste, so that the resulting concentrates amount to about 75 tons per day.

Shipments of fluorite concentrates are now being made to eastern Canadian steel plants as well as to those at Gary, Ind., which latter have received the bulk of the concentrates up to the present. An examination of the exports to the United States since Jan. 1, 1920, indicates the rapid expansion which the fluorite industry has enjoyed. During the months of January, February, March, and April the exports amounted to 64, 196½, 251½ and 416½ tons, with values of $835, $2,255, $3,270, and $5,772, respectively, making a total of 918½ tons, valued at $12,132.

*F. L. Hess in "Political and Commercial Geology," McGraw-Hill Book Co., 1920.

Men Prominent in Mining

James Finch Callbreath

IT HAS long been conceded that the virile spirit of the West is catching. It is not necessary that one be born within the confines of that vast domain, to be hailed as a "Westerner," for it is a generous country, democratic in its impulses, and proud to own those men and women who claim it by adoption. The West is by no means half hearted in its expression of good will to those who have aided in the work of making great those institutions in which it has an entirely justifiable pride and satisfaction. On the evening of Nov. 20, 1919, hundreds of mining men assembled at St. Louis started an ovation that has seldom been equaled in the history of industrial conventions—an ovation that began with appreciative applause and ended in an outburst of spontaneous cheering. This tribute was paid to James F. Callbreath, secretary of the American Mining Congress, in recognition of fifteen years of unbroken service in behalf of that organization. The American Mining Congress stands today as a monument to the persistence, diligence and whole-heartedness with which Mr. Callbreath initiated and carried out his plan for a great national mining organization. James Finch Callbreath was born at White Lake, Sullivan County, N. Y., in 1858. He received his early education in the public schools, and was graduated from the University of Denver with the degree of LL. B. During the early period of his life, which was spent in Sullivan County, he devoted his efforts largely to newspaper work, and was for many years editor and publisher of the *Sullivan County Republican*. From 1887 to 1890 he was chairman of the Sullivan County Republican Committee and took an active interest in political affairs.

JAMES FINCH CALLBREATH

Mr. Callbreath was among those who believed in the opportunities of the West. Establishing himself in Denver, he became editor and publisher of the *Mining Reporter*, which he conducted for a number of years before that publication was merged into *Mining Science*. From 1895 to 1906 he practiced law in Denver and again became active in political affairs, finding himself a member of the Denver Charter Convention in 1903 and elected to the Denver City Council in 1904, with which body he served conspicuously as an exponent of civic improvements. He was also elected president of the Denver Chamber of Commerce in 1903. During these years he became interested in a number of mining operations. The American Mining Congress then had its headquarters at Denver. It was an ambitious organization, but mostly ambition. No one seemed to have sufficient time to execute its mission, and interment seemed imminent. In 1904, at the Portland, Ore., session of the organization, Mr. Callbreath was persuaded to step into the breach, with the understanding that he was not to be called upon for more than half of his time. As secretary, the office which he still holds and which has always been the chief executive and active position, he not only caught the spirit of the co-operative movement but quickly visualized the great opportunities of the future. Agitation was then developing for representation of the mining industry at Washington. Mr. Callbreath was the logical leader, and he quickly developed a program of activity that has since occupied his entire attention. He spent many months at Washington in an effort which eventually resulted in the creation of the United States Bureau of Mines, with the late Dr. Joseph Austin Holmes as its director.

The success of the American Mining Congress and the worth of Mr. Callbreath's straight-line methods became recognized. He has, since 1907, devoted himself exclusively to the furtherance of the interests of the mining industry and the upbuilding of the organization. It is no longer a one-man, one-room institution. It is a great national chamber, with a continuous record of signal accomplishments, embracing seven distinct divisions, representing practically every branch of the minerals industry, with a trained specialist in charge of each department. Its offices occupy 4,000 sq.ft. in the Munsey Building, Washington.

The history of the mining industry is replete with individual accomplishments of national value, but perhaps no one servant of the mining interests has covered such a representative field as the Secretary of the American Mining Congress—James F. Callbreath.

By The Way

The Aërial Tramway Improved

The psychological moment has been seized by the Davino Aërial Apparatus Co., of Los Angeles, to put their aërial transportation device before the mining public. Shippers in many localities have been confronted with a serious problem since freight rates went up on Aug. 26. In some cases the old rate has been restored but many operators are still facing the dilemma of having to shut down or else ship at a loss. At this crisis the Davino company appears on the scene. This company, according to an advertisement in a southwestern contemporary, manufactures, or will do so if it receives an order, a whale-shaped propeller-driven airship that is depicted in an illustration as speeding from mountain peak to mountain peak suspending from an overhead aërial tramway, resembling a series of miniature Brooklyn Bridges. No money is needed—an interest in the mine will suffice. The company states:

> We offer to anyone who can show us a mine worth operating the installation of our lines at our own expense for an interest in the mine. We can construct small light capacity lines, single rail or double rail, to handle any mine capacity regardless of the nature of the country, and our machines will climb steep grades impossible by other types of transportation at high speeds. We will guarantee our service and if you are interested, and have a mine, especially one that is held up on account of transportation, here is your chance.
>
> Send in a map, mark your mine; if you have some neighbor miners interest them so we can link a group of mines on one line. If you can send us a sample of your ore, or asbestos, or whatever your product is (we will return upon your request), have it accompany a letter giving the value of each mine, an approximate value of ore per ton or product per ton, and your offer of an interest in the mine for our transportation, or for handling the raw material to the finished product at our expense.
>
> Gentlemen, our machines may seem odd, especially the use of the propeller in connection with mining work, but we do not care about anyone's opinion. We furnish the money and our machines do what we claim.

The value of this new mode of transportation has already been demonstrated in the amusement world, according to the company. The chances are that it will continue to furnish amusement on being introduced in the mining world. Whatever the outcome, however, the company cares for no one's opinion, as it proclaims.

Wet Competition

An amusing experience was related by one of the early adventurers on the Yuba River in California, who chose an easier way of making a living than by standing all day in the water washing gravel, according to Hittel's History of California. He said that he had managed with great toil and at great expense to get a large cask of whisky to some rich diggings on that river where he broached and commenced retailing it at immense profit. On the next day, however, he noticed that his custom fell off; and, on investigation, he found that another Yankee had also rolled up a cask of whisky and was underselling him higher up the river. As a counter operation, he moved still higher up stream by a circuitous route and reopened; but it was not long before his competitor again supplanted him; and from that time on the two rivals continued running opposition and cutting each other until finally, growing wiser, they formed a combination with the intention of keeping prices up to the highest notch and jointly reaping the profits. But almost as soon as the new concern was started a canvas house went up next door, on which was written, in large letters, "Liquor Store," and the backbone of the monopoly was thereby effectually broken.

Illustrated

The latest report of the Broken Hill Proprietary Co., of Australia, closes with a half-dozen interesting photographs taken about the company's Newcastle steel works. One of these shows H. R. H. the Prince of Wales, K. G., upon the occasion of his visit to the plant last June. Another is a view of the blooming mill. Reports of this sort are far more readable when illustrated in this fashion. The extra cost is negligible.

The Optimist in Mining

Bonanzas are not altogether things of the past in the United States. A prospectus has recently come to hand of a company claiming to hold property in the Black Hills of South Dakota, the manager of which "conservatively estimates" the "probable ore tonnage" at 1,000,000 tons of mica, 2,000,000 tons of 3 per cent tungsten ore, 25,000,000 tons of feldspar, and 5,000,000 tons of 2 per cent tin ore, the gross value of all of which is put at $381,000,000. This company is the American Minerals Co., which claims that it is operating at Keystone, S. D., under a declaration of trust dated Aug. 24, 1920. The manager, C. T. Cabrera, says that he feels justified in stating that this estimate is less than one-sixth of the actual tonnage on the company's properties. He does not state, however, whether the balance is tin or tungsten ore, mica or feldspar. Net earnings during the next twelve months, based on single shift operation of the mines and on the operation of the "two mills now under construction," are estimated as follows: Mica, $1,449,420; tungsten, $51,000; feldspar and lithia ores, $50,000; and tin and tungsten, $800,000. The manager says of tin, "The market is steady and regular, running around 60c. per pound with very little variation, and the supply produced seldom equals the demand." Mr. Cabrera is to be complimented for the restraint he places on his imagination and for his conservative statements. One can only wonder what he might have said if he had been feeling real optimistic.

In Memory of the Pilgrims

The new Pilgrim half dollar is now to be obtained, though it may hardly be said to be in circulation. Attractive in design, it shows the figure of a Pilgrim Father on the face. On the back is depicted the Mayflower under full sail. We paid the National Shawmut Bank of Boston a dollar for our copy of this half dollar, and, although we do not quite understand the nature of the transaction, we believe we got our money's worth.

A Recommendation

It is against the general policy of this chronicle of mining engineering progress to recommend one good product in preference to another. However, we cannot refrain, after careful investigation, from recommending the Marcy[1] to millmen. Even so, we must admit that the odds favor Harding.

[1] The latest Arrow collar.

CONSULTATION

Ground Mica

"We herewith take the liberty of asking you whether you are in position to give us the address of any person who has a knowledge of the right way of making mica powder for wallpaper manufacturers?

"We have here in Sweden some mica mines, and from them we can produce hundreds of tons of mica powder. We have made some trials to grind mica but not with a good result."

Both Government and private agencies have found it difficult to obtain information regarding the details of the various processes for grinding mica. Operations are frequently shrouded in needless secrecy, and the processes zealously guarded. However, sufficient information has been published or given out otherwise to make known the general details of the various methods.

A. L. Hall has classified the methods of pulverizing mica into (1) disintegration by heating, (2) abrasion with millstones or metal burrs, and (3) baking at intense heat, followed by pulverization by a blast of steam. As millstones require water to wash out the ground material, and drying is difficult, they are not frequently used as a pulverizing medium. The most modern method, baking and steam-blast pulverizing, has not been widely used. Reliance has mainly been placed upon a mechanical grinding machine or pulverizer in the form of a metal cylinder lined with corrugated cast steel and containing a revolving shaft to which are attached disintegrators or metal heaters. When the shaft is rotated at a high speed (3,000 r.p.m.) and pieces of mica are introduced into the cylinder a pulverized product is made which can be either drawn from the cylinder by an exhaust blower or removed by falling through a screen. A precaution to be observed in using such a machine is that not too much material is fed into the cylinder, as the pieces expand greatly on being ground, and any excess of material may choke the machine.

The ground material is carefully screened, customarily on a set of vibrating screens. Products of 8, 10, 24, 40, 60, 80, 120, 160, and 200 mesh may be made. Separation by means of air currents and gravity has also been used, but how successful such installations have been we do not know. There is a plant at Denver, Col., which employs the pneumatic system of separation, resorting to a special air-tube mechanism, which causes the velocity of the ground material to be so retarded that the material settles in various bins according to its fineness.

In constructing any plant to grind mica provision should be made for the manufacture of ground-mica products other than those for use in the wallpaper industry. This will insure a wider market range through a diversified product. Ground mica has a variety of useful purposes. Thus, it is employed in the manufacture of some lubricants, fancy paints, tiles, and concretes. Rust-preventing paint can be made from a mixture of ground mica and aluminum. Owing to its heat-resisting qualities, ground mica is also used in pipe and boiler coverings and in fireproof paints. The rubber-tire industry uses ground mica as both a tire ingredient and a powder for inner tubes. Some roofing preparations consume quantities of ground mica. In India it is reported to be used even in medicines.

Electrolytic Zinc References

Our company has a complex zinkiferous ore carrying the zinc as sphalerite, copper as tetrahedrite, and good silver values with the tetrahedrite. We are desirous of making a complex concentrate and then treating same by alectrolytic process to eliminate the zinc. We desire to erect a plant to handle only from 7 to 10 tons of concentrates per day. How and where can we get reliable information relative to the electrolytic process and cost data of a small plant?

The following papers treat the subject of electrolytic zinc production in more or less extended fashion, and give up-to-date information on the subject:

"Electrolytic Zinc." By C. A. Hansen, *Transactions* American Institute of Mining and Metallurgical Engineers, vol. 60, pp. 206-242.

"Electrolytic Zinc Extraction at Trail, B. C." By E. H. Hamilton, *Transactions* American Electrochemical Society, 1917, Vol. 32, p. 217.

"The Future of Electrolytic Zinc." By Thomas French, *Transactions* American Electrochemical Society, 1917, Vol. 32, p. 321.

"Some Economic Factors in the Production of Electrolytic Zinc." By R. G. Hall, *Transactions* American Institute of Mining and Metallurgical Engineers, 1918, Vol. 57, p. 709.

"Electrolytic Zinc Plant of the Judge Mining and Smelting Co." By L. W. Chapman, *Chemical and Metallurgical Engineering*, issue of March 24, 1920.

"Electrolytic Zinc Plant of the Consolidated Mining and Smelting Co. of Canada, Ltd." By L. W. Chapman, *Chemical & Metallurgical Engineering*, Aug. 11, 1920.

Chrysotile, Crocidolite, and Amosite

"I am somewhat confused by the difference between several varieties of asbestos, such as a chrysotile, crocidolite, and the rarer form amosite. Will you kindly endeavor to make clear in your "Consultation" page the distinction between these several types?"

The three varieties of asbestos, chrysotile, crocidolite, and amosite, are all commercial forms. Chrysotile is a form of serpentine asbestos, whereas the other two are forms of amphibole asbestos. Chrysotile in Canada occurs in serpentine derived from the alteration of peridotite, and in Arizona from the alteration of limestone. Rhodesia and the Transvaal contain important deposits of chrysotile asbestos of excellent white quality, but which may shade to a pale green.

Crocidolite is a variety that is peculiar to the South African deposits and occurs in the Asbestos Mountains of West Griqualand in cross-fiber veins inclosed in thinly bedded shaly rocks. It is remarkable for its blue color and high peroxide of iron content. Lavender-blue crocidolite is also reported in the area.

Amosite, the third variety of asbestos, is a grayish white monoclinic iron amphibole, which is produced in the Lydenburg and Pietersburg district of the Transvaal. Indications point to large African resources.

THE PETROLEUM INDUSTRY

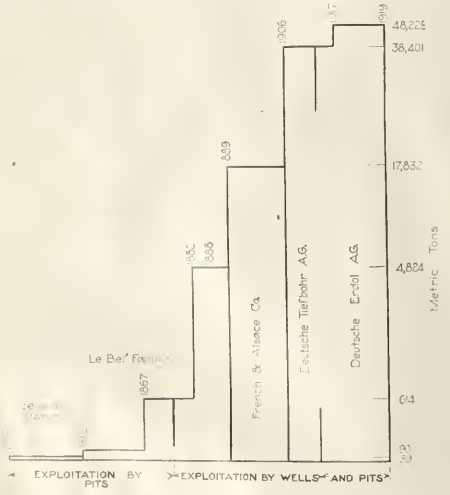
Petroleum Industry in Alsace

BY ANDRÉ SURNY-DE BONNIER

Written for *Engineering and Mining Journal*

In the fifteenth century (1498), an oily matter was discovered[1] in a water well on the spot known today under the name of Pechelbronn, and was used for medicinal purposes. The exploitation of the petroleum began at the end of the eighteenth century, and the accompanying diagram shows the development of the field, which covers about 44,000 hectares. Its length varies between twenty and twenty-seven miles and it is about ten miles wide. Different kinds of oil are found in the various oily sand beds; for instance, from 170 to 200 ft. deep a sort of asphalt is found, and from 230 to 300 ft. there is a heavy oil, and the lighter oils occur at greater depths.

The first exploitations were made by shallow pits, and the sand was washed with hot water to obtain the greasy matter. This method was practiced up to 1875, and was then replaced by underground galleries, from which the petroleum, after being collected, was pumped. Later the plan of drilling by means of the Fauvelle system with water injection was tried with success, and



PETROLEUM PRODUCTION IN ALSACE

today about forty installations of drilling apparatus are in use. About one hundred wells are drilled every year, from 1,000 to 1,200 ft. in depth.

Following the remarkable experiments that Paul de Chambrier made in 1897 to show how large was the quantity of oil left in the sand bed when exploitation was made exclusively by drilling operations, it was decided to not only continue the exploitation by well but to exploit also by means of underground galleries, where the petroleum could collect. It is estimated that from six cubic meters of oil in the ground only one meter can be pumped. To recuperate part of the oil left in the ground and to increase the production during the war, the Germans dug several pits. Three are today in operation, with 3,400 meters of galleries.

The pumping operations are expensive and slow. The average quantity given by wells, of the 500 producing wells of the region, is only 240 liters daily. On the other hand, the time during which petroleum can be pumped is usually long, from fifteen to twenty years. The total production of the field is 50,000 metric tons yearly. This corresponds to 1/1000 of the world production and to one-eighth of the total pre-war importation of oil in France.

The recovery of the Alsace oil field is consequently a great help to France. It is not only a material gain, but makes her, in case of necessity, independent for some of the oil products. The occasion is also propitious for organizing on French soil a practical school of petroleum technology, and for teaching her sons how to take advantage of the hidden treasure contained in her soil and in that of her colonies.

[1]Paul de Chambrier (general-director of the Pechelbronn mines), "History of Pechelbronn, 1498-1918." Attinger Bros., Paris and Neuchatel, 1919.

Prospecting for Petroleum In Queensland

SPECIAL CORRESPONDENCE

Prospecting for petroleum in Queensland has been in progress for a number of years, and early in September, 1919, there was a development which may be pronounced at least encouraging. The locality where the boring has taken place is at Roma, on the Western Railway, 318 miles west of Brisbane, and at an elevation 979 ft. above sea level.

Operations in the search for oil at this place have been attended with many vicissitudes and delays, but the belief is strong among experts and others that the oil is there, although whether in commercial quantity of course nobody can say. An artesian well sunk in 1899 was being deepened in 1900, when at 3,683 ft. natural gas to the extent of about 40,000 cu.ft. per diem was obtained. This gas was allowed to go to waste for over four years, after which, when the quantity was 70,000 cu.ft. a day, a gasometer was built, the township was reticulated and the town lighted; but the gas had been turned on only ten days when the supply so diminished that the lighting scheme had to be abandoned. In 1907 a mineral-oil prospecting company began the sinking of a bore close by, and at a depth of 3,702 ft., in October, 1908, struck a heavy flow of gas, which some people alleged smelled of petroleum, but which was immediately ignited from the boiler fire, and was not extinguished till the following December. In an attempt to sink the bore below the gas zone the tools got jammed in soft "running" strata, and in March, 1910, the bore was abandoned.

After a lot of investigation and obtaining expert advice from abroad the government took the matter in hand, engaged a petroleum engineer from California, and started another bore. This was begun in January, 1916, and carried on by the expert until about the middle of 1918, when, his term having expired, he returned to America, leaving an assistant borer, who had also been secured from the United States, in charge. The depth reached was then 3,230 ft. By May, 1919, the bore was down to 3,705 ft. (about the depth of the gas zone proved in the previous bore), when a weld in the stem broke, leaving the bit and two feet of the stem in the hole. All attempts to remove the tools failed, and the second American borer left for home. In August, 1919, however, while a man engaged in Australia was employed in removing some of the casing with a view, if possible, of boring past the obstruction, a heavy flow of gas, evidently released by the work in hand, was encountered. There had previously been indications in the bailings from depths ranging from 3,610 ft. to 3,700 ft. of gas of a petroleum nature, and the strong flow now struck unmistakably bears evidence of containing oil. When the last mail left officials were engaged in measuring the flow and analyzing the gas.

Recently a license has been taken out to prospect for oil at Goodna, seventeen miles from Brisbane, and the company formed for the purpose has already begun boring operations there.

Petroleum Situation in Rumania

Rumania possesses an area of 20,000 hectares (1 hectare = 2.47 acres) recognized as oil bearing, of which only 2,500 hectares are being worked, according to Consul Edwin C. Kemp in *Commerce Reports*. The total of possible oil-bearing land is estimated at 100,000 to 150,000 hectares. These lands are located in the Carpathians, the principal centers being Prahova, Bacau, Buzeu, and Dambovitza; 90 per cent of the output comes from the Prahova district. The bulk of the production is refined and the residue is used in Rumania for fuel purposes, for which there is an increasing demand.

In 1916 the wells and refineries were destroyed before the invasion of the enemy, who immediately began repairs, and obtained a production of 450,000 metric tons in 1917 and 1,214,000 in 1918, the greater part being used for military purposes. When the enemy withdrew, the re-establishment of the industry was undertaken, but the production in 1919 amounted to only 920,000 tons, and reports for the first six months of 1920 show about 463,000 tons. This decrease in production was due partly to a strike in the oil fields from July 10 to Aug. 20, 1919, but more to the lack of materials for drilling and refining and to lack of storage space.

The decreasing value of the leu and the lack of transportation made it difficult to obtain materials needed for the repair and maintenance of the refineries and wells. This lack of transportation, which included the unrepaired pipe lines, also made it difficult to utilize the storage facilities at the ports and necessitated stopping the flow of a number of wells. Especially is this true of two of the largest producing companies of the Moreni district not in the "Birex" export organization, which had a certain outlet via the Danube to adjoining countries. In 1919 drilling fell to 10,000 meters, as compared to 80,000 to 100,000 meters in a normal year. It has been estimated that material to a value of 1,000,000,000 lei per year will have to be imported for five years to bring the annual production up to 2,000,000 metric tons.

Bureau of Mines To Advise on Petroleum Losses

Engineers, chemists and automobile men throughout the country have been working toward the development of some liquid fuel as a substitute for gasoline to meet the increasing demands. The Bureau of Mines states that the entirely preventive losses in the evaporation of gasoline from crude petroleum from the time the petroleum leaves the wells until it arrives at the refineries reaches a total of more than 300,000,000 gal. each year, or sufficient to keep 1,200,000 automobiles in commission for a year if each car uses 250 gal. of gasoline.

These are merely the preventive losses from evaporation alone and do not take into consideration other losses, many of which in part may be avoided. The total loss from evaporation amounts to more than 600,000,000 gal. of gasoline for the country, according to the investigations of the Bureau, which has calculated that one-half of this, or 300,000,000 gal. of gasoline, may be saved. The Bureau will soon issue careful directions to the oil men as to how this situation may be remedied.

Soviet Russia's Oil Supply

Professor Johan Lomonosov, who, with Krassin, arrived in Stockholm from Reval on July 23, has been appointed by the soviet government as its representative in Sweden to superintend the delivery of the locomotives now on order on Russian account.

In this connection a most important consideration for Russia is that of fuel. Lomonosov has during the past few months been staying in the coal and oil districts of south Russia and the Caucasus, and on that point he is extremely optimistic. There are stored, 500,000,000 poods (1 pood = 16 kg.) of oil, which is being transported as quickly as tonnage is available.

Bureau of Mines Warns Against Fraudulent Representation

A number of instances have recently been brought to the attention of the Bureau of Mines in which reports of analysis made by the Bureau have been used for advertising purposes. General statements made by the Bureau have been used to advertise trade-marked or proprietary preparations. For example, one company submitted a sample of motor fuel to the Bureau of Mines during the war to see if it would be satisfactory as an aviation fuel. Recently, this same company has been advertising a motor fuel under a trade name as having been "thoroughly tested by the Government Bureau of Mines in Washington, D. C., successfully fulfilling every claim made for it by the inventor." On investigation it has been found that the fuel which is being advertised is different in character from the fuel originally submitted for test.

The Bureau wishes to emphasize that analyses and tests are made only when it is a matter of public interest to do so, and no authority has been or will be given to use this information for advertising purposes.

NEWS FROM THE OIL FIELDS

New 100,000-Bbl. Well in Amatlan Field

From Our Special Correspondent

One of the largest wells in the Amatlan field was brought in recently when the Freeport & Mexican Oil Co. struck oil in its well No. 3 on Lot 251 Amatlan. A conservative estimate of the daily production is estimated at 100,000 bbl. The pay was encountered at a depth of slightly over two thousand feet. This well is offset by a well owned by the Cia El Aguila which is producing about 50,000 bbl.

Thompson's well on Lot 114 Chinampa has been drilled in at the depth of 1,986 ft. It is producing about 40,000 bbl. daily. This is the shallowest well in the Chinampa field and seems to be on the summit of the oil dome which underlies this famous lot. A pipe line has already been laid and is being connected to the well.

The Transcontinental Co's well No. 3 on Lot 134 Chinampa has been successfully closed in, after flowing wild for over two weeks. When the broken valve was taken off the casing the well shot the oil over the crown block of the derrick. The well has been flowing 40,000 bbl. since it came in.

Johnson County Prominent Among Kentucky Fields

From Our Special Correspondent

Johnson County, Ky., is rapidly assuming first place in the new fields, as Warren gradually takes its place among those of proven territory. A 15-bbl. well has been found in the corporate limits of Paintsville, the county seat, making it the first Kentucky town to enjoy this distinction. A good well was brought in on the Davis farm, one mile away. The Virginia-Kentucky Oil Co. owns this well, and has also brought in two on the Rice farm, said to be 20-bbl. producers.

A gusher estimated at 500 bbl. daily production was brought in by the Georgia Petroleum Co. on the Lloyd Crowe lease, in Warren County, recently. It came in flowing a stream the size of the casing, over the mast. The depth was 370 ft. The well on the Pete Foster lease is now on the pump, and making 15 bbl. The Stoll Oil Co. is laying a new pipe line in Warren County from wells in the Woodburn vicinity to Rock Quarry loading station.

The Whittaker Oil Co. brought in No. 2 on the Nicoll lease near Bowling Green, good for 75 bbl. Another 75-bbl. well is No. 2 on the Gonce lease, nine miles south of Bowling Green. What may prove a new shallow pool has been found along the Barren River, where a flowing well was brought in on the John Campbell farm. No. 2 on the Whittaker farm was brought in at 478 ft. and showed 204 bbls. in a 24-hour test.

In Lawrence County, a 25 bbl. well has been drilled on the Meredith-Kelley lease. In Powell County, a 1,500-ton shale plant is being built. The Twin Lakes Petroleum Co. reports a 25-bbl. well in Simpson County, near Temperance. Phelps and associates will begin drilling four wells on the Gibson lease in Allen County.

Officials of the High Gravity Oil Co., under indictment for conspiracy to defraud investors, were exonerated in Federal District Court here when the jury was given peremptory instructions to dismiss the case. Sixty-two persons from all parts of the United States were present, claiming to have been defrauded. They besought the District Attorney to "find some other way," but there was none. Principal defendants were William F. Sheridan and two sons, William F., Jr., and Redmon F. Sheridan.

Mining and Metallurgical Society Discusses Petroleum

At a meeting of the Mining and Metallurgical Society on Oct. 27, Van. H. Manning addressed the members upon the petroleum situation at home and abroad, saying in part:

"One of the unfortunate results of the war has been a departure from a friendly spirit of competition in business between some of the nations of the world. A nationalistic tendency has developed. We must expect as a natural result of the war an awakened sense of self-protection. All nations may well give serious consideration to the question of their future supply of raw products, but this must not be at the price of sacrificing principles in international trade which are the very substance of world progress in peace. It is, moreover, not a far-sighted policy to conserve within the confines of any nation the materials which are now essential to civilization and the world's progressive welfare."

After pointing out the actual condition of petroleum as revealed by the latest statistics, Mr. Manning discussed the attitude of the United States toward foreign restrictions, and the attitude of those nations controlling foreign sources of supply.

As confirmed by the subsequent remarks of Dr. Ledoux and Mr. Ralph Arnold, Great Britain and France are keenly desirous of obtaining the participation of Americans, or the United States Government, in their ownership and production of future petroleum supplies, so that there is no reason to exect any great difficulty in arriving at an *entente cordial*.

In closing his remarks, Mr. Manning suggested a plan of action, saying:

"Our diplomats are doing all that is humanly possible to untangle this intricate problem and your help is needed. No greater or more lasting and far-reaching service can be rendered than making possible and effecting the securing by or for American citizens a participation in the development of the world's resources of petroleum. This may be accomplished under the following plan:

1. To make a careful study of the oil resources of the world and the laws and regulations governing these resources.
2. Congress should enact a general reciprocity measure covering all trade relations with foreign countries.
3. To encourage our nationals to acquire and develop and market oil in foreign countries:
   (a) By an assured adequate protection of our citizens engaged in securing and developing foreign oil fields.
   (b) By co-operative action on the part of the industry under Federal charter or otherwise that will permit the industry more effectively to perform its function in seeking out and acquiring oil territory in foreign countries, developing the same and distributing the petroleum produced therefrom.

"When these things have been accomplished, our State Department should begin negotiations to develop an oil entente for all nations. If there could be brought about an association of international relationship between these oil-producing countries working in harmony to furnish the world with power and light, a repetition of a World War would be impossible."

Possibilities for Third Oil Field in Arkansas

From Our Special Correspondent

The Arkansas Natural Gas Co. has had a show of oil at 2,232 ft. in its well in Sec. 1-15-15 Calhoun County, Ark. Casing is being set for a test. If this well develops commercial production it will be the third field in Southern Arkansas, the two already known being the Hunter, near Stephens, Onachita County, and the Constantin, near El Dorado, Union County.

Utah Oil Notes

From Our Special Correspondent

The experimental plant of the Western Oil Shale Co. at Vernal is reported to be doing satisfactory work and the operators are considering enlarging its capacity. The Galloupe process is being used.

The Ohio Oil Co. has been granted an oil leasing permit on lands near Caineville, Wayne County, and is expected to begin work as soon as oil-drilling apparatus and tools have arrived. This company will also start drilling in Garfield County near Circle Cliffs. The company expects to expend considerable money to ascertain the value of the ground it has under lease.

Technical Papers

Mineral Statistics — The Imperial Mineral Resources Bureau is issuing pamphlets containing a statistical review of various minerals during the period from 1913 to 1919. These pamphlets are somewhat like the sections of Mineral Resources published annually by the U. S. Geological Survey. Those so far issued are: "Nitrates," 28 pages, price 9d.; "Arsenic," 19 pages, price 6d.; "Felspar," 16 pages, price 6d.; "Magnesite," 42 pages, price 1s. 3d.; "Borates," 24 pages, price 9d.; "Fuller's Earth," 15 pages, price 6d.; Monazite, 15 pages, price 6d.; and "Chrome Ore and Chromium," 29 pages, price 1s. A bibliography of the important publications on each subject during the last six years is a good feature of each book. They may be obtained from H. M. Stationery Office, Imperial House, Kingsway, London, W. C. 2.

Southwestern Arizona—The future of mining in southwestern Arizona (pp. 5) is discussed by J. C. Anderson in the August number of the *Mining and Oil Bulletin* (Los Angeles, Cal., 25c.). The last two or three years have witnessed a gradual resumption of activity in the district around Tucson and to the southwest.

Kaolin—The Division of Geology of the Department of Conservation, State of Indiana, (Indianapolis Ind.), has published a cloth-bound book of 131 pages entitled "Kaolin of Indiana," which may be obtained for 50c. The geology and development of the deposits in the southern part of the state are described. The principal uses of Indiana kaolin have been in the ceramic industry and in the manufacture of aluminum sulphate.

Ontario Natural Gas—A report on the natural gas situation in Ontario has been published as Part V of the Twenty-ninth Annual Report of the Ontario Department of Mines. (Toronto, Ont., free.) A serious and general shortage of natural gas exists in that province.

South African Iron Ore—A brief description of the occurrences of iron ore and fuel suitable for smelting, in South Africa, occupies fourteen pages in the July *South African Journal of Industries* published by the Government Printer, Box 373, Pretoria, price 6d.

Misfires—"Misfires in Metal Mining" is the title of the U. S. Bureau of Mines *Reports of Investigations*, Series No. 2,156 (three pages), obtainable on request to the Bureau at Washington. Eleven recommendations are given for reducing the number of missed holes to a minimum.

Graphite—The U. S. Tariff Commission, Washington, D. C., has published a very complete little booklet of twenty-eight pages entitled "Information Concerning Graphite." It may be obtained on request. Information is given on the domestic and foreign production, various grades, milling methods, costs, etc., and a list of domestic producers in 1917 is appended.

Oil From Shale—David T. Day has an article in the September *Review of Reviews* in which he discusses the petroleum shortage and points out the development of oil shale as the logical remedy.

Porcupine Goldfield—*The Mining Magazine* for September (Salisbury House, London Wall, London, E. C. 2.; price 1s. 6d.) contains an excellent eleven-page article on the Porcupine goldfield in Ontario. This is considered the most promising gold district in the world. The Hollinger mine is surpassed by only one or two mines in present output and by none in prospects. Mining, milling, and economics are discussed.

Wyoming Oil—Bulletin 716-C of the U. S. Geological Survey (pp. 18) describes geological conditions in the Mule Creek oil field, Wyo.

Tennessee Minerals — The twenty-fifth annual report of the Mining Department of Tennessee, Nashville, Tenn., (free), is at hand. Though mostly devoted to coal, short chapters are included describing the activities among the state producers of barytes, bauxite, cement, clay, copper, gold, silver, iron, gas, mineral paint, oil, lime, phosphate, quartz, sand and gravel, stone, zinc and lead.

Iron Ore in Montana—Bulletin 715-F of the U. S. Geological Survey (pp. 8) describes iron-ore deposits near Stanford, Mont.

Cinnabar—U. S. Geological Survey Bulletin 715-E (pp. 11) is devoted to the geology of the Yellow Pine cinnabar-mining district in Idaho.

Hydrotalcite—The U. S. National Museum, Washington, D. C., has issued an eight-page pamphlet on the chemical composition of hydrotalcite, pyroaurite, stichtite, and brugnatellite. It may be obtained upon request.

Molybdenite—A two-page description of the Standard Molybdenite mine and mill at Everton, Victoria, is to be found in the September issue of the *Chemical Engineering and Mining Review* (Melbourne; price 11d., post free).

Recent Patents

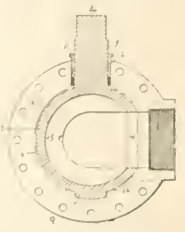
Rock Crusher. No. 1,354,855. John G. Simpson, Knoxville, Tenn.

Mining Drill. No. 1,354,944. Carl Biernat, Glasford, Ill.

Overflow Separating Device. No. 1,355,070. Charles Allen, El Paso, Texas. A form of the Allen cone.

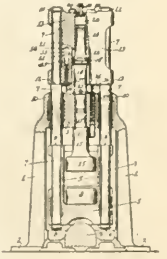
1,352,423. Casing Head. Paul Arbon, Tulsa, Okla. Filed April 21, 1919.

A casing head for gas and oil wells having in combination a shell consisting of sections adapted to be detachably secured together, each section having a nozzle and a semicircular projection forming one-half of a third nozzle and each section having one-half of bearings for trunnions, said bearings being arranged with their axes at right angles to the axes of the respective nozzles, and a rotatable valve having a diametrical passage therethrough and a passage or opening extending at right angles from the diametrical passage and having trunnions with their axes at right angles to the axes of said passages or openings, one of the trunnions extending outside of the shell.



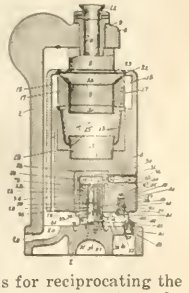
1,353,096. Stamp Mill. James W. Vanmeter, San Francisco, Cal. Filed June 30, 1919.

A stamp mill comprising a fixed frame; a mortar mounted on the frame for reciprocative movement; a stamp fixedly mounted in the frame and over which the reciprocative mortar plays to crush the ore by impact against said stamp; a cylinder connected with the mortar; a piston fitted in said cylinder fixed against reciprocative movement; fluid controlling connections to reciprocate said cylinder on said fixed piston; and means carried by the cylinder and actuated by contact with the fixed frame for operating said fluid controlling connections.



1,353,097. Stamp Mill. James W. Vanmeter, San Francisco, Cal. Filed Nov. 5, 1919.

An ore stamp mill comprising a frame; guides fitted to the frame; a mortar fitted upon said guides for reciprocative movement, and adapted by the removal of one of said guides to be turned outwardly from the frame upon the other of said guides as an axis; a fixed stamp carried by the frame; and means for reciprocating the mortar to crush the ore against the stamp.



ECHOES FROM THE FRATERNITY

McFadden on the Gold Report

Other Points in His Analysis Presented Before the Annual Convention of the American Bankers' Association

(Condensed from Authorized Text)

[*The unfavorable report on the McFadden gold bill, by the committee of the American Bankers' Association, was abstracted on p. 880 of this journal for Oct. 30, and a very brief statement of Mr. McFadden's answer thereto was also given. The following paragraphs present additional points made by him in that reply.*]

In addition to paying the exchange discount, the French Government has imposed a sumptuary tax for the use of gold in the future fabrication of articles (other than money) by law of June 25, 1920, and a further tax on fine gold contained in articles of manufacture since 1873.

The Gold Committee refers to the excise tax proposed as interfering with the free flow of gold into the arts. The excise is to be paid only on the sale of the manufactured article, and not on the bullion, which the manufacturers will receive from the Mint as they always have at the fixed price of $20.67 per ounce. In this way a free gold market is maintained, and there is no interference with the free flow of gold either into the arts or from the arts into the Mint.

The committee's statement: "Increased gold production in a period of low prices and low costs makes it easier for prices to rise again, while diminished gold in periods of high prices and high costs tends to reduce prices and costs again." This is not borne out by the facts. The gold production of the world has declined from $469,000,000 in 1915 to $350,000,000 in 1919, a reduction of 25 per cent in the last four years, and yet prices throughout the world have risen enormously. *The degree of inflation is measured by the ratio of the gold reserve to the volume of the circulating media*, and it must be apparent that *an increase in the gold reserve without an increase in the circulating media would reduce the degree of inflation.* It must also be evident that the effect on prices of the supply of gold in active circulation is relatively small compared with that of the credit currency based on gold which is not "free," but locked up by the Treasury and Reserve Banks and used indirectly as the basis for a larger volume of currency. If this gold were really free and circulating, it could not be so used. The true remedy for inflation is to return the gold to circulation.

The committee has stated that a loss of $22,000,000 occasioned by the increased industrial consumption of gold over the production of new gold is a very small item to the monetary gold stock of the nation. The gold dollar in the vaults of the Federal Reserve Banks may serve as the basis of deposit liabilities of $2.50, and these deposits to the credit of a member bank may in turn serve to enable credit extension by that bank of, say, $19 to $35. With reserves close to the legal minimum, therefore, every million dollars of gold lost to the monetary gold reserve means forced credit contraction of at least twenty millions. The $80,000,000 withdrawn for industrial consumption during 1919 would be equivalent to a contraction in our credit structure of $1,600,000,000. Several of our banks recently pointed out the marked improvement in the money market resulting from the small amounts of gold which have come in from Europe. Is there *some magic difference* between gold imported from Europe and that produced in the United States? These small importations of gold ease our money market but hurt French and British exchange.

In 1915 the United States produced 21.5 per cent of the total world's gold output, and the British Empire 63.7 per cent. In the United States no assistance has been rendered the gold-mining industry. The gold producers of all British possessions receive the benefit of an exchange premium since July, 1919. This year the contribution of the United States to the gold production of the world will probably be not more than 12 per cent, about half of that which it contributed in 1915, while the stimulating effect of the exchange premium will probably increase the quota which the British Empire will contribute to 75 per cent. Whereas in 1915 the British Empire produced three times as much gold as the United States, in 1920 Britain will have produced six times as much. Are we to continue to ignore the problem of gold production in the United States, thus permitting the British Empire to gain an unquestioned supremacy?

Scientists Discuss the Divining Rod at the Victorian Royal Society

The layman's interest in the divining rod is perennial. It was expressed by Dr. Griffith Taylor, who was responsible for a discussion before the Royal Society of Victoria recently published in the *Queensland Government Mining Journal.*

Dr. Taylor described his investigations of experiments in water-divining at Canberra, whose site lies at the lower end of a valley of a small stream. On either side the valley is a ridge 900 ft. high. At a spot on one side indicated by the diviner a 50-ft. well collected 400 to 800 gal. per day. At a point on the other side the diviner also "divined" an underground stream, but the well driven there proved an absolute duffer. An ordinary hole put down in the middle of the valley by one of the Government engineers drew a plentiful supply for the whole neighborhood. Dr. Taylor doubted only the good sense of the water diviner; ordinary intelligence would have recognized that the valley in a district having an annual rainfall of twenty inches was ideal country for underground water.

Dr. Taylor had the actual divining rod used and demonstrated the way in which the diviner held it. That, in the hands of the diviner, it had "dipped" was beyond question. The rod had creaked in the hands of the big burly miner who held it. His idea was that the divining rod was a subject for investigation on the part of the psychologist rather than the geologist.

In conclusion, Dr. Taylor recalled the famous tests at Guildford, England, in which six diviners failed to discover water, even when standing over: (1) a well-known spring; (2) a sewer; and (3) a small reservoir from which the water was running beneath their feet.

In the discussion Dr. Gilruth and Mr. Carey told of a clergyman in Auckland, New Zealand, who used no rod but asked that no one address him, walked with short steps and held his arms rigid until suddenly affected by some force, when he would act as if he had grasped the terminals of a battery. At this spot he would instruct his client to dig. On two Government dairy farms he had found water twice on three tries.

Mr. Kenyon, of the State Rivers Department, was the only member who admitted that any scientific principle was involved. He pointed out that underground water exists (a) in sheets —sometimes narrowed to channels—not far below the surface, and (b) at greater depth as "artesian" water. Where (a) occurs the atmosphere on still, warm days is so disturbed that a surveyor cannot read his staff at any distance.

It is in this kind of country that the diviner flourishes, and Mr. Kenyon suggested that the atmospheric conditions might possibly affect the supersensitive kind of person who used the divining rod. In country where there was no under-surface water the diviner met failure. In Italy the farmers sought well sites by means of balanced poles or earthenware vessels on which the water condensed overnight. This seemed to give some scientific principle on which to base divining.

The general opinion of the meeting was with Dr. Taylor, that 99 per cent of the diviner's art was related to psychology, and 1 per cent to science—the geologists denying even the 1 per cent, and the "pure" scientist scorning both.

MEN YOU SHOULD KNOW ABOUT

J. O. Lewis is resigning his position as petroleum technologist, U. S. Bureau of Mines, to enter private employment.

W. J. Uren, general manager of the Seneca Mining Co., Calumet, Mich., is on a visit to New York City.

Harris & Ewing Photo

A. W. AMBROSE

A. W. Ambrose, who will become chief petroleum technologist of the Bureau of Mines on Nov. 15, was born at Lockeford, Cal., in 1889, where his early education was obtained. His high school course at Lodi, Cal., was followed by a course in the College of Mining of Leland Stanford, Jr., University, from which he was graduated in 1913.

After leaving college, Mr. Ambrose spent three years in the California oil fields. His work had largely to do with the study of the relation of geology to drilling and production. Later, he spent a year in private employment in the Louisiana and Texas oil fields. He joined the staff of the Bureau of Mines in 1917, and for two years served in Washington as assistant to the chief petroleum technologist. On June 1, 1919, he was sent to the Bartlesville, Okla., station as petroleum engineer. On Feb. 1, 1920, he was made superintendent of that station. He has been summoned from that position to take charge of the Bureau's petroleum work.

C. W. Purington, mining engineer, returned to Hakodate, Japan, from the Sakhalin and Okhotsk districts on Sept. 30.

John G. Flynn, recently with the Miami Copper Co., Miami, Ariz., has resigned to accept a position as mine superintendent with the El Oro Mining & Railroad Co., El Oro, Mexico, Mexico.

Fred Searls, Jr., who was in Reno, Nev., Oct. 23, left for his San Francisco office the same evening.

George O. Bradley, of the engineering firm of Bradley, Bruff & Labarthe, is seriously ill at the Lane hospital, San Francisco, Cal.

Hewitt O. Fearn, mining engineer, of Oyster Bay, N. Y., is now at Anyox, B. C., after a summer spent in prospecting in the Northwest.

Frank G. Stevens, mining engineer, who has been connected for some years with northern Ontario mining enterprises, is moving to Tepic, Mexico.

A. J. McNab, general manager of the Mason Valley Mines Co., left Reno, Nev., for his New York office on Oct. 21, after a visit to the company's properties in Nevada.

Jesse C. Scobey, mining engineer, has resigned his position as assistant to the president of La Luz & Los Angeles Mining Co., of Delaware, but will remain in New York City.

Dr. Ragnar Liden, of Stockholm, Sweden, geologist of the Swedish government railroad, is making a study of the clay occurring in the Cobalt district, Ontario, in connection with railway construction.

Robert Mond, general manager of the Mond Nickel Co., at Clydach, Wales, recently visited the company's properties in Ontario. He will take a holiday of several months in Canada and the United States, visit the Pacific coast, and later sail from New York City.

P. K. Lucke, consulting mining engineer, of Mexico City, D. F., Mexico, left that city for Europe about Oct. 19, and expected to return to Mexico at the end of December. While abroad, his address is care of Institution of Mining & Metallurgy, 1, Finsbury Circus, London, E. C. 2.

COL. C. S. BINCKLEY

Col. George Sydney Binckley, who has been on the editorial staff of *Ingeniera Internacional* since November, 1919, resigned his position on Nov. 1, 1920, to resume private practice as consulting civil and hydraulic engineer in Los Angeles, Cal. Col. Binckley commanded the 519th Engineers at home and for a year in France with the American Expeditionary Forces. He plans to resume certain scientific investigations interrupted by our entry into the Great War in 1917.

William Dunn, for some time with the Dome Mines Co., is now at the Simon Silver-Lead mine at Mina, Nev., in charge of the construction of the new mill.

SOCIETIES

The American Petroleum Institute will hold its annual meeting on Nov. 17, 18, and 19, 1920, in Washington, D. C. The headquarters and the sessions will be at the New Willard Hotel, 14th St. and Pennsylvania Ave., N.W.

American Engineering Council of Federated American Engineering Societies will hold its initial meeting on Nov. 18, 19, and 20, at the New Willard Hotel, Washington, D. C. The full program of this important meeting was published Sept. 25 on p. 633 of this journal.

The Mining & Metallurgical Society of America will give a dinner to E. A. Cappelen Smith at the Hotel Commodore on Nov. 10, at 7 p.m. The occasion is the presentation to Mr. Smith of the society's gold medal for distinguished service in the art of hydrometallurgy. Members of the society, the ladies of their families, and their guests are specially invited to attend. Reservations ($5 per plate) are made with C. A. Rose, 120 Broadway, New York City.

OBITUARY

George M. Richards, mining engineer, of 28 West 46th St., New York City, died at New Brunswick, Canada, on Oct. 12. He was buried at Woodlawn Cemetery, New York, N. Y., on the 17th.

Richard Lamb, consulting engineer, of 90 West St., New York City, died in hospital on Oct. 18 after a short illness, at the age of 61. He was a native of Norfolk, Va., a graduate of Brown University, and a member of several engineering societies, notably of the American Road Builders' Association. He was an authority on highway engineering and the engineer of a number of notable works. In the mining field Mr. Lamb took the leading part in opening the Virginia Copper Co. mine at High Hill, Halifax County, Va., erected its plant, and designed a plant for the electrical extraction of copper from ore. Mr. Lamb also designed an electric testing plant on the Erie Canal. He was buried at Brooklyn on Oct. 20.

THE MINING NEWS

The Mining News of ENGINEERING AND MINING JOURNAL is obtained exclusively from its own staff and correspondents, both in the United States and in foreign fields. If, under exceptional conditions, material emanating from other sources is published, due acknowledgment and credit will be accorded.

WEEKLY RÉSUMÉ

It is reported that Henry Ford will open the Imperial iron mine on the Marquette Range in northern Michigan that he recently acquired by purchasing the holdings of the Michigan Iron & Land Co. Minnesota and Wisconsin iron country men are said to be interested in the newly organized Milton Development Co. that has been formed to develop certain iron ore lands discovered in Columbia County, Ore. Control of the old Ohio & Colorado smelter at Salida, Col., has been obtained by Everly M. Davis, of New York, who, it is said, intends to reopen and operate this plant on local ores. On the Comstock Lode in Nevada the management of the North End Mines has announced that beginning Jan. 1 wages will be cut to $5 per day, which will permit operation of the mines of the company, all of which excepting the Con. Virginia are at present shut down.

In Canada, the employees of the Asbestos Corporation in Quebec have struck for higher wages and recognition of their union. Power shortage continues to hamper operations in Cobalt. La Rose's head frame and shaft house were recently burned at this Ontario camp. In British Columbia, Granby Consolidated is reported to have dropped its option on the Estall copper property.

Henry Ford To Operate Imperial Mine on Marquette Range

Property Included in Holdings Recently Acquired—1,000,000 Tons Blocked Out—Shut Down Since 1911

Henry Ford is to open the Imperial mine at Michigamme, Mich., on the Marquette Range, which recently came into his possession when he purchased the large holdings of the Michigan Iron & Land Co. Mr. Ford looked over the property a few days ago with his mining engineer and metallurgist and a decision was made to commence mining at once. The Imperial was first opened in 1882 and was closed down last in 1911. It was formerly operated by the Cleveland-Cliffs Iron Co., the latter concern surrendering its lease on April 1, 1919. The mine is well equipped with a steel head frame, engine and boiler houses, shops, change house and coal dock. The workings are quite shallow, being only 200 ft. in depth, and it will require but a short time to unwater them. The state tax commission estimates 1,000,000 tons of ore developed, but it is certain that much more than this exists on the property. The ore is a limonite, carrying from 50 to 52 per cent iron, low in sulphur and high in phosphorus. The moisture is very high. This is Henry Ford's first entrance into the iron mining business, but he has other mineral lands which might hold iron ore, and his work will be watched with interest by the mining men of the Lake Superior district. At present there are no active mines in the Michigamme field.

Governors of Zacatecas and Durango Define Attitude Toward Mining Industry

"Durango Perfectly Safe," Says Castro; Favors Erection of New Smelters—Governor Moreno for Taxation of Mines in Proportion to Output

SPECIAL CORRESPONDENCE

Jesus Augustín Castro, governor of the state of Durango, Mexico, and Donato Moreno, governor of Zacatecas, were recently interviewed by the correspondent of *Engineering and Mining Journal*. Both executives freely discussed the mining situation within their respective states and told of the steps contemplated to aid this important industry.

The state of Durango is perfectly safe today, in Governor Castro's opinion. "Any delay in resuming the operation of mines is not justified," he said. Upon being asked if he was disposed to use his influence to facilitate railroad transportation of machinery and supplies to mining camps he replied:

"I have so decided and have already taken up the matter. I have called the attention of the Federal Government to the resumption of traffic between the state of Durango and the United States via the old International Railroad, thus getting through communication from here to San Antonio, if necessary, without the long and tiresome detour by Saltillo and Monterrey."

Governor Castro said that his policy will be to facilitate the installation of as many smelters in the state as may be necessary to permit the miners to sell their products under non-prohibitive terms. He was asked if he thought it well to call upon foreign investors, in view of the national lack of capital for large mining ventures, with the understanding that all investments made in the country shall be subject to the laws of Mexico. He replied:

"I believe that an active propaganda should be started in order to evidence the unlimited mineral resources of the state of Durango, practically undeveloped up to the present time. My idea is to establish a statistical mining department in the state, to work either alone or in conjunction with the industry department of Mexico City; mining and geological explorations will be thus conducted all over the state, the results to be published for the sake of information to all mining investors.

"The government of the state of Durango is entirely disposed to grant all necessary protection and facilities for mining exploration and exploitation within the statutory provisions."

Asked as to the construction of railroads to mining camps, Governor Castro said: "The government of the state should never hesitate to co-operate in the reorganization of all railroad schemes already existing or that may be proposed in the future."

In regard to mining taxes in Durango, he said:

"I have no definite plan as regards the tax on mineral extraction; but referring to taxation, in general, my idea is to try a better distribution of the burden among the tax payers, so as to be able to diminish the taxes to a just amount."

The question was asked the Governor whether he favored the organization of a Chamber of Mines within the state. He replied:

"As I understand that a mining chamber would have for its object to promote, safeguard and harmonize all mining interests, it would thus co-operate with the Government, and, of course, I should support it."

VIEWS OF THE GOVERNOR OF ZACATECAS

"Zacatecas is one of the richest mining states in the Republic," said Governor Moreno, "developed for years only in its northern part. Operations were conducted on a large scale at a time when old treatment processes were still in use; the low silver price made possible the extraction only of high-grade ores, and as these were not found in depth, operations had to be shut down. Lack of transportation facilities and high freight rates also contributed to the suspension of work in the mines; but now that mining and treatment processes have improved some plans have been outlined for the resumption of operations in properties where enormous tonnage of low-grade ores is found. Under this scheme old dumps could be worked and treated. Following this general plan, operations have already been started in Fresnillo, Ojocaliente, Zacatecas, Sombrerete, Pinos, Nieves and Mazapil."

As to encouraging mining operations, Governor Moreno said:

"First, I will grant the mining companies the maximum facilities falling within the jurisdiction of the state, and at the same time I will take up with the Federal Government all matters

bringing a benefit to the mining industry. This would be easy to accomplish in view of the political solidarity already existing between the states and the Federal Government. Furthermore, I am discussing right now with the Geological Institute of Mexico City and with the Department of Industry and Commerce, the creation of a permanent Geological Survey Commission in the state, which will supply both the mining companies already operating and prospective mining investors with important information at no cost; this commission will start working on the exploration of southern Zacatecas.

"Few of the mining companies in Zacatecas are working now but they are all of importance. The country has just entered upon a period of peace indispensable for the prosperity of the Republic. Some well known mining investors in the state are feeling enthusiastic about the situation, and this Government has reasons to hope that within a year mining operation will reach their maximum activity."

As to mine taxation Governor Moreno said:

"This government, not only in regard to taxes on mineral extraction, but also to taxation in general, intends to follow a scheme of proportionate rates; in this manner the small and large producers will bear taxes in just proportion to their output, and the exploring outfits would not have to pay any taxes until they enter into a stage of production."

Governor Moreno is disposed to facilitate the study, location and construction of mining railroads. He said:

"Necessary influence will be exercised with the federal government for such a purpose; something about it has already been discussed by the representatives of Zacatecas in Congress, who support our projects and who are assisted by the attorneys for the state in Mexico City. Both in regard to this matter and to mining operations, this government intends to give fair assistance to all concerned with a view to securing the general prosperity of the state and nothing else."

The Governor was further asked what was the program of the Government as to the matter of assisting mining, principally in cases where operations are paralysed owing to internal difficulties of the corporations. He replied:

"If I understand this question, I might say that, referring to shut downs caused by troubles between capital and labor, this government has just enacted provisions creating the labor department with representatives in all the mining camps of the state. This department will conduct an intense propaganda against the nefarious activity of agitators, and at the same time will attempt to harmonize the tendencies of all parties following a program outlined by this government. So far, we have been successful, and I am sure that mining operations will not be hindered by conflicts between labor and capital; due to the importance of this matter it has deserved our preferred attention."

The government of Zacatecas is disposed to use all its influence so that the railroad companies would grant all necessary transportation facilities to the miners in the state. "This matter is of such a capital importance," said Governor Moreno, "that it has already been taken up with the President of the Republic; also the President-elect, Mr. Alvaro Obregón, knows about it, and I presume that all effort is being made in order to supply the National Railroads with necessary rolling stock, the lack of which is causing a crisis in the country and has been a decisive factor in the increasing high cost of living.

"The state government will encourage the organization of a mining chamber in Zacatecas," said Governor Moreno. "The organization of chambers, either of commerce, of agriculture or mining is considered by us as of essential significance, provided they accomplish their end; namely, the regulation of production, of imports and exports, the supply of working capital and implements, and even the regulation of minimum salaries in all centers of production."

Mexican Coal Strike Threatens To Close Large Companies

Eight Thousand Men Involved—Neither Side Giving Way—Arbitration Refused—No Violence

The particular cloud now on the mining horizon in Mexico is the labor muddle in the coal fields of the north. The strike for an increase of from 100 to 300 per cent in wages, recognition of the unions and a dozen other demands has reached an acute stage and the pumps and fans in several of the more important mines have been stopped and the properties are filling with water. Efforts on the part of the government to induce the men to return to work pending the appointment of an arbitration board have been fruitless. Neither side appears disposed to give ground. About 8,000 men are concerned in the strike and as they have no funds a great deal of suffering is already reported. The government has undertaken to supply the men and their families with the necessities of life. The trouble seems to have been started by professional agitators outside the coal fields, mostly foreigners, soviets and I. W. W. representatives from the United States. Dodgers are being circulated urging the men to seize the properties and work them on their own account. Unless a settlement is reached there will necessarily be a general closing of all mining and industrial plants in the north, as well as railway transportation, as they depend almost exclusively on the native coal output. Minerales y Metales and the American Smelting & Refining Co. have notified the government that they will not be able to keep their smelters and mines operating longer than a week unless they get coal. No violence of importance has been reported, and the fields are in charge of Federal troops.

ARMY AIRPLANE ARRIVING AT NOME, ALASKA, AFTER TRANS-CONTINENTAL FLIGHT

E. & M. J. Receives First Letter Brought by Airplane From Alaska

The accompanying photograph of the army airplane finishing its great transcontinental flight at Nome, Alaska, on Aug. 23, was brought to New York by the same airplane on its return flight in a letter mailed to the *Engineering and Mining Journal* by Donald E. Campbell, mining engineer of Nome. The letter to the *Journal* is therefore the first to have been brought by airplane from Alaska to New York. It left Nome Aug. 25 and owing to various delays on the homeward trip did not reach New York until recently. With it came two copies of the *Daily Telegraph Bulletin*, published at Nome.

Cie du Boleo, Baja California, produced 440,720 lb. copper in September.

Asbestos Corporation's Employees in Quebec Called Out

Recognition of Union and Wage Increase Demanded—Business Conditions Changing

The asbestos industry in Quebec is experiencing a period of intensity which has been absent during the prolonged period of rising prices and labor inactivity. The culminating issue has apparently been projected when by reason of contracting business conditions the companies have been unable to meet the ever increasing demands of labor. An embryo managers' association had been formed to meet like emergencies, but evidently the original instinct characteristic of the operators in the camp prevailed and a single operator has been allowed to bear the onus of the combined attack of the labor forces. On Oct. 11 a strike was declared by the National Union against the two mines of the Asbestos Corporation, demanding recognition of their union and a wage increase of 12½ per cent. The corporation pointed out their inability to comply with the request, but in spite of their representation and the efforts of the Labor Delegate from Ottawa, the strike was declared against the corporation alone, although all the other members of the Managers' Association were working under precisely similar conditions. No issue is at stake, save the unrest inherent in labor due to the recent abnormal wage earnings, and the Federal Conciliation Board will, undoubtedly, ultimately straighten out the present tangle.

Business conditions in the camp are feeling a reaction from the buoyancy experienced during the past three years. The European markets have been looked upon as the absorber of our increased production but the continued inability of foreign countries to adjust their most basic industries increases the probability of these expected markets being deferred for some time to come; in the meantime, however, the present avenues of consumption are fully capable of maintaining the industry on a sound basis of production. For the present year shipments have been steady and should make a substantial increase over last year's total of 135,000 short tons of asbestos.

The Weiser interests are contemplating the erection of a 350-ton mill on their "Reed Mine" property. H. R. Lynn has been engaged to build the plant. The Bennett-Martin Mines at Vimy Ridge, Coleraine, are pushing the construction of the six-mile siding connecting their mines with Coleraine Station on the Q. C. Ry.

Herr Becker of the firm Becker & Haag, Berlin, Germany, importers of raw asbestos, made his initial visit since the termination of the war. Thomas Lloyd, for the past seven years with Bell Asbestos Mines, has resigned to accept a position as superintendent of the B. C. mines of the Asbestos Corporation, Limited, in the Black Lake district.

Oregon Iron Lands Taken Over by Milton Development Co.

Two Deposits Found in Columbia County—Minnesota and Wisconsin Men Interested

Two deposits of iron ore are reported to have been found in Columbia County, Ore., six miles apart on properties controlled by C. A. Finley and others, of Portland. J. L. Washburn, president of the Northern National Bank, of Duluth, and John Z. Williams, a Duluth attorney, have become interested in these, together with Henry Turrish, of Eau Claire, Wis., interests who own and operate a logging railroad and conduct logging operations in that district. The Milton Development Co. has been incorporated with a capital stock of $200,000 for the purpose of taking over the holdings of the interests headed by J. L. Washburn and Henry Turrish and to determine the extent of the formations through development work. Investigations of the deposits have been made during the last year by J. W. Flannery, of Cleveland, Ohio, and A. M. Martin, of Chicago, who, it is claimed, are satisfied that the deposits are of considerable extent. The ore is claimed to be in blanket formation and richer in brown hematite than the average Minnesota deposits were at the same stage of their development. They have been shown to run from 52 to 59 per cent in iron and, although somewhat high in phosphorus, contain a small amount of manganese. The explorations were confined mainly to a point three miles north of Bunker Hill and at one place it was reported that the orebody was found to be 60 ft. thick and of an undetermined length and breath.

North End Mines on Comstock To Reduce Wages Jan. 1

The wage scale now in effect at the North End Mines in Virginia City, Nev., will be reduced to $5 per day on Jan. 1, 1921, according to an announcement made by Alex Wise, superintendent. When the miners went on "vacation" Sept. 5, following a demand for $6 a day, the North End Mines were the only ones to accede. In notifying the men that the advance was to be withdrawn Mr. Wise said:

"The old wage scale in vogue at the North End Mines prior to Sept. 5 must be put into effect as soon as possible in order that other properties under my management, other than the Con. Virginia, may be placed in operation again, which under the present scale is not possible; also that other properties along the lode may be able to resume work.

"In view of the general conditions throughout the country showing a downward trend of all commodities entering into the cost of living, I believe the new wage scale to be put into effect will work a hardship on no one, and create at least four or five times the present opportunity for employment along the Comstock lode."

Queensland State Mining Ventures Suffering Checks

Proposal To Erect Iron and Steel Works at Bowen, Costing £3,000,000, Gets a Setback

From Our Special Correspondent

Brisbane, Sept. 6—The State enterprises of the present Queensland (Labor) Government, as far as they relate to mining, are suffering some checks, and the failure of the Premier to get a loan from the British capitalists, intended largely to prosecute these enterprises, is to result in a general election, which is expected to take place in October. The biggest thing that has received a setback is the proposal to erect State Iron & Steel Works at the northern port of Bowen, at a cost of something approaching £3,000,000. A good deal of money has been already spent in preparing for this venture, and at the present time the government are testing a large deposit of iron ore on the northwest coast of western Australia, over which they hold an option (that cost £3,000) to purchase at £30,000. As this option will expire in October, and as it is doubtful whether the Queensland iron ores alone are good enough or extensive enough to warrant the carrying out of the big works, the government must be in a quandary as to just what they can do.

The State Battery at Bamford, in the far north, that was established to assist in the mining of the rare metals, is now closed down owing to the fall that has taken place in the price of molybdenite and wolfram. As the battery is now equipped for the treatment of tin also, and as the market value of this metal is keeping up, the suspension is not likely to last long.

The Chillagoe State Smelters, which together with the Chillagoe and Ethridge Railways and some mines, were purchased by the Government from the Chillagoe Co., have shown a small profit for six months' work, but a much better showing would have been made had it not been for an insufficient supply of ore to keep the works going at their full capacity. This was really the trouble when the Chillagoe Co. closed down several years ago, but there is no doubt the mining industry of the district suffered much while the works were lying idle.

As far as the Government's coal prospecting or coal mining ventures are concerned, they are looking promising. There is no question they have a splendid coal area on the Bowen field, 60 miles inland from Bowen, and the colliery will be ready for a large output as soon as the railroad being built from the port reaches the field. This coal will be a great benefit to the northern parts of Queensland, and is of course also intended for the iron and steel works if they are ever built. Some 300 miles further south, at the Styx River on the coastal railway, the Government has proved by means of boring and a shaft some of the best coal in Australia, and are selling enough to pay the cost of prospecting.

The shaft got into very faulty country, but further prospecting has disclosed a more settled locality, where profitable operations are now likely to be carried on. On the Dawson River, inland from Rockhampton and Mount Morgan, the first coal mined proved, on trial, to be unsatisfactory, but a 7-ft. seam of exceptionally good quality has now been struck. This field is connected by rail with both Rockhampton and Mount Morgan; from the former place it is inland about 60 miles.

On the whole, the coal mining industry of Queensland has of late been showing signs of expansion. Last year's output was nearly 1,000,000 tons, and that for the first half of the present year was greater than that for the like period of 1919. The value at the pit's mouth ranges from 12s. 6.6d. per ton in the south to 17s. 8d. in the north.

New Railroad To Be Constructed to Guanaceví, Durango

Contract With State Also Provides for Erection of Smelter

Officials of the state government of Durango, Mexico, recently signed a contract with Smith Bros. for the construction of a railway from Santa Catarina Tepehaunes to the mining camp of Guanaceví, and the erection of a smelter in the latter camp, at a total cost of $20,000,000. The government guarantees 6 per cent interest on bonds to be issued for this work, for a period of twenty years. Surveys are to be completed within ninety days and the entire work must be finished, according to contract, within two years. Immediately upon signing the contract the representatives of Smith Bros. left for the City of Mexico to secure the approval of the Federal congress and President.

Delinquent Mining Claims in Ontario Declared Forfeit

In a recent issue of the *Ontario Gazette* was published a list of 1,900 mining claims which reverted to the crown because of the non-payment of the acre tax under the Mining Act of Ontario. Under the Mining Act a tax of 5c. per acre per year is levied against all mining property in an unorganized district. Through oversight, or possibly in part, on account of negligence in the Mines Department, a large number of companies and claim owners had neglected this tax, and the special order-in-council throwing the claims open for re-staking came as a big surprise.

Included among the properties thrown open was the Teck-Hughes in Kirkland Lake, on which over $1,000,000 has been spent, and which has a 100-ton mill. There was a big scramble to restake this property, together with other properties which were believed to be valuable, but fortunately, at the last moment, a number of the more important properties were withdrawn by the government from re-staking.

Will Reopen Salida Smelter To Treat Colorado Ores

Everly M. Davis, of New York, Secures Control of Plant—Another Project To Ease Smelting Situation

Confirmation of the conclusion of the negotiations by which the old Ohio & Colorado smelter at Salida, Col., has passed into the control of new interests, represented by Everly M. Davis, of New York, a prominent mining operator, identified with the financing and development of the Rawley mine at Bonanza, Saguache County, has just been received at Salida. The smelter, which is equipped with a lead stack, after being owned by various interests, passed to the control of the American Metal Co. and was operated by it for several years. Owing to the reported shortage of the available supply of suitable ore, the smelter was closed down about two years ago and was subsequently sold at auction to Morse Brothers, of Denver, for the purpose of wrecking and dismantling to secure the equipment and material for sale as second-hand material. Plans were made for dismantling the plant when Mr. Davis appeared and made contracts with Morse Brothers, which it is understood will shortly result in the full resumption of operations. As an accessory to the project, it is proposed to build a seven-mile aerial tram from the Bonanza mine to Shirely station on the narrow-gage branch of the Denver & Rio Grande Ry., near Mears Junction, about twelve miles from Salida. The Rawley mine has positively developed, according to the company's report, 89,843 tons, averaging 8.89 oz. of silver, 2.35 per cent copper, 8.98 per cent lead, and 189,810 tons, averaging 10.9 oz. silver, 3.25 per cent copper, 0.3 per cent lead. The probable ore is estimated at an additional amount in excess of 560,000 tons. The company has been carrying on an extensive development for a number of years, the total footage amounting to 13,843 ft. Various plans to realize on this work have been delayed by financial conditions and the excessive cost of equipment and of operation. It is proposed to use the ore of the Rawley mine as a basis for the supply for the smelter and also to provide capacity to take care of additional Colorado ore which has been going to other Colorado smelters or to Salt Lake City. A considerable tonnage of low-grade ore is known to be available, which was not profitable to ship to other points than Salida. The increase in freight rates has further limited the shipment of ore from Leadville, in the San Juan district, and will result in increasing the supply for the Salida plant. This is considered the most important transaction affecting mining which has taken place this year.

Another project to ameliorate the smelting situation in Colorado and to meet the present conditions is being developed in connection with a power project on the Gunnison River above Lake City, in Hinsdale County. Denver and New York interests have secured an option from the Reynolds-Stearns Co. on the water power rights on the South Fork and propose to establish at Lake Cristobal a plant which will provide from 8,000 to 10,000 minimum horsepower. The estimated installation cost is about $125 a horsepower, which would permit of the surplus power being utilized for electrical smelting of the zinc-lead ores of Hinsdale County at a cost which, it is expected, will be much less than the prevailing smelting rates plus the present freight rates. This power and smelting project is being developed by L. F. Hulen, a Denver capitalist, who was identified with the western Nebraska potash developments during the war, and who recently has taken an option on the Golden Fleece mine, at Lake City, and has spent a large amount of money in exploration work and development thereon. Investigations of the methods of electrical smelting are now being made, and the consideration of the situation as regards actual and prospective ore supply. The general plan contemplates participation by mine-owning interests, which matter is now being worked out. If electrical smelting is found practical in this locality it is likely that other similar development in the San Juan district and elsewhere in Colorado will be undertaken.

Drilling Contest Held at Baxter Springs, Kan.

A. Abbott and A. E. Mitchell, representing the Hunt Mining Co., captured the championship of the Tri-state district for drilling in an annual contest staged at Baxter Springs, Kan., on Oct. 20. Using a Denver Turbro drill they drilled through a concrete block 6 ft. in thickness in 4 minutes, 26½ seconds, this time including the set-up and knock-down of their machine. They won a prize of $100 and the temporary ownership of a $75 loving cup.

Harold Miles and Fred Vickery, representing the Premier Mining Co., were second and only one second behind the winners, and there was some questioning of the judges' decision as to whether the winning team had completed the knocking down of their tripod when time was called. Miles and Vickery were the winners a year ago.

The contest was well attended, especially so on account of the shutdown of mines which made it possible for almost all the miners to be on hand.

Northwest Mining Association Elects

The Northwest Mining Association elected as its new board of trustees: Frank A. Ross, Frank C. Bailey, F. M. Smith, G. B. Dennis, Oscar Cain, Lehigh Nicholas and W. H. Linney. A communication urging support of efforts being made to obtain a readjustment of freight rates on bullion was received from the Colorado Metal Mining Association. The secretary was instructed to reply that the Northwest Association would give all possible aid.

Special Utah Power Contracts Declared Void

Order of State Public Utilities Commission Effective from Oct. 22—Companies To Appeal to Federal Courts

Special contracts between large users of power in Utah and the Utah Power & Light Co. that were entered into several years ago, in fact before the creation of the Utah public utilities commission, have been declared by the commission to be void, and such users of power placed by the commission, beginning noon, Oct. 22, on the standard rates prevailing in general. The commission has for some time been going into the matter of rates, and has held hearings at which companies protesting against increased rates and the abrogation of contracts have been appearing to plead their cases. These companies have been taking the position that the commission has no jurisdiction, and that contracts, lawful when made, should under the state and Federal constitution be held inviolable against interference by legal authority. Protesting companies have indicated that the matter will be taken to the Federal courts. A large number of mining companies are naturally effected by the ruling of the commission. The Utah Copper is the largest single user of power in the state, in some years having taken more than fifty per cent. of the power generated by the Utah Power & Light Co.

To Hold Flotation Conference at Denver

At the Twenty-third Annual Convention of the American Mining Congress to be held in Denver, Nov. 15-19, 1920, the committee on flotation will make a report covering the activities of the American Mining Congress and the Federal Trade Commission during the past twelve months, in the inquiry now being made relative to the contests between Minerals Separation, Ltd., and the users of flotation. The committee will include: George E. Collins, mining engineer, Denver, Col.; Philip Argall, metallurgist, Denver, Col.; T. A. Rickard, editor of the *Mining and Scientific Press*, San Francisco, Cal.; E. E. Paxton, president of the Engels Copper Co., San Francisco, Cal.; R. M. Henderson, president of the Wellington Mines Co., Breckenridge, Col.; J. M. Callow, president of the General Engineering Co., Salt Lake City, Utah; and G. W. Lambourne, president of the Daly-West Mining Co., Salt Lake City, Utah.

Good Weather Facilitates Lake Superior Ore Shipments

Iron ore shipments from the Lake Superior districts during 1920 will total 58,000,000 tons, according to estimates given by *Iron Trade Review*. Shipments to Nov. 1 were approximately 52,953,000 tons, and with the continuation of favorable weather conditions it is expected that an additional 5,000,000 tons will be shipped during November.

Prospective slackening of furnace operations has dissipated the fears which several of the operators expressed regarding the possibilities of their being able to make adequate deliveries. Ore contracts will not be filled, but the demand is less urgent. While two leading furnace interests in the East had but a few weeks' supply on hand a month ago and then were seriously concerned, especially in regard to the lack of cars to haul ore from the Minnesota open-pit mines to the docks, general improvement in shipping facilities, coupled with the present outlook in the pig iron market, is responsible for a more assuring attitude.

Power Shortage at Cobalt, Ont., Causing Mines to Curtail

Owing to a shortage of hydro-electric power, due to an exceptionally dry season, most of the Cobalt mines are curtailing their operations to some extent. So far this is mostly in the cessation of re-treatment of sands and work which could be cut off without interfering with production to any extent. Unless conditions materially improve, however, further reduction in power consumption will be necessary. So far this year there has only been 19 in. of rainfall compared with 35 in. for the corresponding period of the previous year, and the water in all the lakes and rivers is lower than has ever been known before.

The shortage of power applies equally to Kirkland Lake and Porcupine and the operators in the Sudbury district are also suffering.

Baja California Vanadium Deposits To Be Developed

The Baja California Vanadium Co. has been recently organized to develop and operate certain calcium vanadate deposits of Lower California. These deposits are situated five kilometers from tide water at Angeles Bay on the Gulf of California. They consist of large lenses of gypsum and calcium vanadate in a reddish shale.

Picked specimens of the calcium vanadate analyze from 40 per cent to 45 per cent vanadium pentoxide. The general tenor of the material in the lenses is a little over 5 per cent vanadium pentoxide. The lenses vary considerably in size. The principal one is 900 m. long and 450 m. wide. The deposit has not been explored to any extent vertically. The deepest shaft is but 25 ft. deep. Practically all work has been done in open pit thus far. In addition the enclosing shales contain up to 2 per cent vanadium pentoxide. The red shales cover a large area.

Tests for metallurgical adaptability have been conducted in the rare element laboratory of Will Baughman, of Los Angeles. The ore does not contain phosphorus, arsenic or other detrimental element and lends itself readily to extraction methods.

The deposit was discovered last spring by Leland Devine, who with A. I. Meyers succeeded in interesting backers for the project, and if present plans mature the company will commence operations this winter.

Bounty on Canadian Iron Ores Again Asked

The Canadian Tariff Commission at a sitting in Fort William recently received memorials from the Fort William and Port Arthur Board of Trade favoring the payment of a government bounty for fifteen years on all Canadian iron ores mined and marketed. The Port Arthur Board of Trade asked for a bounty of 50c. per ton but the Fort William petitioners thought that anything less than $1 per ton would be of little use in inducing proprietors of iron mines to develop their properties. It was agreed by all that the bounty should be paid to the producer of the iron ores and not to the smelters, as the latter system had been tried and proved a failure.

At the sittings of the commission at Sault Ste. Marie, Ont., on Oct. 18, the Board of Trade of that city asked for a bounty of $1 per ton on iron ore produced in Canada for fifteen years. President W. C. Franz of the Algoma Steel Corporation expressed the opinion that considerable development would take place if such a bounty were given to the miners. He thought that further prospecting of the iron ranges would bring to light other deposits of merchantable iron ore, which could go directly to the blast furnaces without previous treatment.

Indian Office for Miami, Okla.

Cato Sells, Indian Commissioner, has announced the establishment of an Indian office at Miami, Okla., to supplement the office that has been maintained for a number of years at Wyandotte, Okla. Mr. Sells states that it is impossible to carry on the work of the district at the Wyandotte office with the efficiency desired, owing to the vast amount of added work that has come about through the discovery of zinc and lead on the lands of the Quapaws, near Picher, Okla.

Blue Sky Law Proposed

A brief on blue sky legislation has been prepared by the mining bureau of the Spokane (Wash.) Chamber of Commerce, of which F. W. Smith, smelter director of the Bunker Hill & Sullivan Mining & Concentrating Co., is chairman. Although opposing the state blue sky legislation contained in the Frawley bill, the brief advocates the enactment of a Federal law providing that full information shall be filed in the originating state of the corporation and at Washington, D. C.; also it provides for the automatic opening of all states to a promotion when it has been passed on by Federal authorities at Washington.

To Expand Co-operative Work of Bureau of Mines

Investigations Conducted for State Institutions and Private Companies Yielding Good Results

Owing to the favorable results following the co-operative agreements entered into by the U. S. Bureau of Mines with state institutions and private companies it is intended to encourage this kind of work. In fact, a very important development along those lines is expected. At present the Bureau's appropriation is supplemented by more than a half million dollars annually. It is believed that this amount can be greatly increased to the advantage of private industry and to the public. An example of the co-operative agreement with private companies is that with the Northwest Magnesite Co. The purpose of the co-operation in this case is to conduct an investigation as to the best method of producing high-grade caustic-burned magnesia. The work is to include a study of the calcination of magnesite from the property of the Northwest Magnesite Co. with a view to determining the most favorable conditions as to time and temperature of calcination for the production of caustic magnesia yielding the best hydrochloride cement; a similar study of magnesite from various California and other properties; and a study of the various methods for judging the quality of caustic magnesia for the production of oxy-chloride cement.

The advantages to the public of the investigation would be that if domestic magnesite is found suitable as a plastic flooring material it will make the United States independent of foreign supplies, particularly from Greece, Mexico and Venezuela. It will tend to cause the development of this natural resource on a larger scale and may lead to the larger use and conservation of magnesium chloride, which is an essential ingredient in making plastic flooring cement. Magnesium chloride is produced in connection with the manufacture of salt by solar evaporation, but now goes entirely to waste.

The advantages to the Bureau are that it will increase its first-hand knowledge of the quality and the possibilities of domestic magnesite. It will give the Bureau certain fundamental but little known data. It will bring the Bureau in touch with an important group of mining men on the Pacific coast and is likely to convince them that the Bureau of Mines is able to attack practical problems and to assist in their solution. Since the Federal Government does more construction work than does any other single agency in the United States, it has a very direct interest in this cement which is being adapted so successfully to the construction of floors.

Typical of the co-operative agreements with state institutions is that with the University of Idaho and the Idaho Bureau of Mines and Geology. The purpose of the co-operation in this case is to disseminate further information with a view to improving conditions in mining, metallurgical and other industries, safeguarding life among employees, and preventing unnecessary waste of resources.

Due to their complexity, the treatment of ores from the Cœur d'Alene district has long presented a metallurgical problem. The Bureau of Mines has recognized the importance of devising ways and means for recovering a larger percentage of the values from those ores. Through co-operation with the state institutions and with the operators of the Cœur d'Alene district, the Bureau has been able to carry on an investigation which would have been impossible otherwise, owing to lack of funds. Through the co-operation with the University of Idaho, the Bureau of Mines has had the advantage of office room, laboratories, milling machines and other facilities, gratis. This co-operation has been in progress for nearly four years and has opened the way for much more extensive work.

At present the Bureau of Mines has in effect co-operative agreements in which the outside agencies contribute a total of $512,800. These agreements are with the following agencies: Sewalls Point Coal Exchange, Trent Process Corporation, Miami Copper Co., Monongahela Valley Traction Co., Panhandle Oil Co., American Society of Heating and Ventilating Engineers, Southern Pacific R.R., Sinclair Refining Co., Puget Sound Traction, Light & Power Co., Pope-Shenon Mining Co., Ocotillo Products Co., Northwest Magnesite Co., National Tube Co., The Koppers Co., Erie City Iron Works, Mid-West Refining Co., Welsbach Co., Vanadium Corporation of America, Chamber of Commerce of Bartlesville, Okla.; War Department, Bureau of Standards, Carnegie Institute of Technology, Colorado School of Mines, Primos Chemical Co., Salt Lake City and University of Utah, Illinois Geological Survey, University of Illinois, University of Arizona, University of Washington, University of Idaho, Idaho Bureau of Mines and Geology, University of Minnesota, Cornell University, Colorado School of Mines, Ohio State University, New York-New Jersey State Bridge and Tunnel Commission, State of New York, Industrial Commission of Utah, State of New Jersey, Pennsylvania Geological Survey, Oregon Bureau of Mines and Geology, State of Oklahoma, State of Colorado.

Survey's Copper Specialist Back from Western Trip

H. A. C. Jenison Reports Labor Problems To Be Serious in Various Copper Mining Districts

H. A. C. Jenison, the copper specialist of the U. S. Geological Survey, has returned from a visit to several of the copper-producing areas in the West. In addition to the depression due to the poor copper market, Mr. Jenison finds that copper mining in the West is struggling against a very serious labor problem. Even with the high wage scale now in effect the mines are finding it impossible to compete with Eastern industries. The greatest difficulty is being experienced in securing skilled operators. The increase in freight rates has added materially to the difficulties of the Western copper producers, Mr. Jenison says. He reports that plans are now well advanced looking to the shipment of concentrates and metal to the Pacific coast for transshipment through the Panama Canal to the eastern seaboard; in fact, shipments have already been made by the Granby and Anaconda copper companies.

Standardization Committee Will Meet in New York

With the idea of evolving something more definite in the matter of standardization of mine practice and equipment, the American Engineering Standards Committee is planning a meeting in New York Nov. 11. It is expected to formulate a report which can be presented at the convention of the American Mining Congress in Denver. The American Institute of Mining and Metallurgical Engineers, the American Mining Congress, the Mining and Metallurgical Society of America, the National Safety Council and the Bureau of Mines have been asked to name two representatives to form a sub-committee to assist in the work.

War Mineral Awards

Awards in war minerals relief claims made during the week ended Oct. 23 have been announced as follows (the name of the claimant, the mineral, the amount recommended, and its percentage relationship to the amount claimed, are shown): Benjamin F. Steacy, chrome, $640.12, 32 per cent; Carolina Chrome Co., chrome, $5,376.46, 25 per cent; A. H. Jarman, chrome, $70,288.45, 51 per cent; United States Manganese Co., manganese, $21,157.64, 15 per cent. In the claim of John Crisle, which had been disallowed, an award of $469 was recommended. This was 93 per cent of the amount claimed.

Special London Letter

Coal Strike Affecting All Industry—Tin Mines of Cornwall in Bad Straits

London, Oct. 19 — Virtually the sole topic of conversation in all circles is the coal strike, which began on Saturday. The very threat that the miners would "down tools" had an unsettling effect upon industry, and now that the strike is an actual fact works of all descriptions are closing down, throwing thousands of men and women out of employment, holding up shipping and causing the cancellation of orders in all directions. As the miners refuse to increase production, and the profit on export coal about which they are squabbling is rapidly vanishing, the economic position is becoming decidedly serious. One reflex influence of this intolerable attitude is to be seen in the Cornish tin mining industry. Never having been able to lay in stocks of coal owing to lack of financial ability and insufficient transport, the mining companies will shortly be compelled to face the question of ceasing operations. Some of the tin mines are very wet, and in the event of the fuel supplies becoming exhausted, and the workings flooded, the condition of the properties will be parlous. Seeing that they may be prevented from getting production away from the mines, and further that they may have to finance it for a considerable period, the smelters are refusing to purchase. This naturally is a great disadvantage to the companies, especially in view of the persistent fall in the price of the metal.

Not so very long ago tin was selling at £350 a ton; it is now only £238 5s. There seems to be a daily drop, and no means of stopping the dry rot. The explanation partakes of a dual character. Just when it was hoped and believed that the demand for the metal would expand and the price advance, some 2,000 tons were dumped upon the market from the East. This came as a distinct surprise, for the statisticians had previously held the opinion that they knew the exact quantity in port, afloat and abroad. To a certain extent this affected the problem of stabilizing the price, for it was surmised that other secret stores existed. Now that factories and engineering works are fast closing down the demand for tin has fallen away very considerably. In the event of any of the older Cornish mines being abandoned on account of the expense of dewatering, attention will be directed to reopening the silver lead mines which were worked about sixty or seventy years ago in Cornwall and Devon. Although there were about sixty such properties operations were not on a large scale. The idea would be to ascertain whether the lodes persist laterally and in depth, and if so whether the metal content could be profitably extracted in present conditions.

With the public really standing out of the markets, business is at a very low ebb. And yet funds are less scarce, because being unemployed in industry they are available for Stock Exchange purposes, or other financial operations. One or two mining companies are taking advantage of this state of affairs to arrange an issue of capital. Terms suggested are rather high, but as in the ordinary way there would be difficulty in obtaining money, they are cheerfully complied with.

CANADA

British-Columbia

Granby's Option on Ecstall Property Dropped—To Protect Against Worthless Stock

Anyox—The Ecstall copper property, for several years bonded by the Granby Con. M. S. & P. Co., which did much drilling and other development, has returned to the original owner, the company's option having been allowed to lapse. The general manager of the company is quoted as saying that the property no doubt would be worked eventually but not for the copper. Sulphur and iron are found in the ore but its copper content is not as high as in the product of the Hidden Creek Mines.

Victoria—The protection of the guileless public against the designing salesman of worthless mining stock is the subject of a recent pronouncement by the British Columbia Minister of Mines. He says: "The Minister of Mines has been given wide powers (under the Mineral Survey and Development Act), as any statement in regard to any company made by him is absolutely privileged. This is a policy intended primarily, and, in fact, solely for the protection of the investing public. The Resident Mining Engineers, being in the field and in close touch with actual mining operations and development, are in a position to know whether statements made by stock mining companies for the inducement of the sale of shares are accurate, or if they do not can readily confirm such statements. British Columbia in the past has been afflicted with too many flotations designed to 'mine the public.' The Department of Mines is determined that the issuance of worthless mining stock shall cease. Hence the legislation by which the government mining engineers are charged with the responsibility of assisting the Minister in seeing that the statements made by mining companies in prospectus or any documents issued for stock selling purposes are strictly in accordance with the facts. In the last few years there has been occasion more than once to apply the terms of the act with results of value to the public and the same policy will be continued, it being the intention that all money invested in mining shall be spent in legitimate mining development."

Ontario

McKinley Darragh To Shut Down Savage Mine for Winter—La Rose Shaft House Burns

Cobalt — The McKinley-Darragh Mines of Cobalt has decided to shut down the Savage mine for the winter on account of the shortage of power and labor. The retreatment of old tailings has also been stopped.

Fire completely destroyed the head frame and shaft house of the main La Rose shaft, which was one of the historical landmarks of the camp. The vein on which the shaft was sunk was the original discovery of the district, and the shaft house was the first one erected in the camp.

Crown Reserve has taken an option on the North Cobalt mine, which it will unwater in order to make an examination.

The Coniagas and the Mining Corporation have stopped the retreating of old tailings for this season, and the Dominion Reduction Co. will stop early in November.

Kirkland Lake—The Ontario Kirkland has issued a statement that they expect to have a 100-ton mill in operation by September, 1921. Construction work will not be started until spring.

Porcupine—Labor conditions in Porcupine are expected to improve through the importation of men by the Hollinger and Dome from Europe. These two properties are able to absorb about 1,000 men, but it is not expected that they would be able to obtain this number before a considerable time. The men coming from Europe will have a very beneficial effect on the labor situation.

It is understood that 200,000 shares of the Vipond-North Thompson stock is to be taken up at 30c. a share. This money will finance the company and permit of its being reopened.

At the North Davidson annual meeting the president stated that three diamond drill holes gave an average of $25 per ton over very big widths.

COLUMBIA

Amalfi—E. A. Probst, manager of La Viborita Mining Co. in Amalfi, Department of Antioquia, inspected the mine El Comstock Antioqueño early in September. This property is in charge of Gustavo White, of Amalfi, who states that the company is working but one of the three veins on the property and has in sight 1,200,000 tons of $10 ore. There is 1,200 tons on the dumps. A mill is needed with proper financing.

MEXICO

New Cyanide Plant Built by Melchor, Ocampo y Anexas—Silver's Decline Gives Concern

Durango—The mining agency here has just given out some interesting figures. In 1918, twenty-eight new mining denouncements were made in the state. In 1919, thirty-nine denouncements were made and this year ninety-one denouncements have already been filed, with the probability that the total number will pass the one hundred mark considerably before the end of the year. At the same time over 1,000 pertenencias have been allowed to lapse because the owners refuse to pay back taxes of several years. It is probably the intention in many cases to redenounce many of the properties, in isolated parts, thus escaping the taxes altogether.

Twenty-eight denouncements were recently made in the name of, or by agents of General Francisco Villa. One of these properties, it is reported, is very rich and the General has already refused a large sum offered by American capitalists.

The Melchor Ocampo y Anexas Co. in the Tejamen district has just constructed a new cyanide plant with the capacity of 100 tons daily.

City of Mexico—The rapid and continued decline of silver naturally threatens to throw the principal mining industry out of wear. Most of the important companies are holding their bullion, hoping that the fall is purely temporary and the smaller concerns are fighting from hand to mouth buoyed up by the same expectations. Silver cannot be mined profitably in Mexico under 80c. an ounce and if the price of the white metal continues down permanently, or for any great length of time there will, of course, be a general shutting down and a mining panic. The National Chamber of Commerce and Industry has already called upon the secretary of the treasury for relief in the shape of reductions in the mineral export tax and also a lessening of the general mining taxation. The secretary has the matter under examination, but, it is understood, is inclined to believe that the decline is only a flurry and that an advance can be expected at any time. At this date the actual working situation remains about the same. That is, the new work which has been inaugurated has not been suspended, nor is there any indication of any let up in the general output at this time.

ARIZONA

Hardshell Company To Resume Development Soon

Patagonia—A promising shoot of high-grade sulphide ore has been opened during the last few months in the Hardshell mine above the 325-ft. level. Several carloads have been shipped to the smelter and the returns range from $50 to $75 a ton in silver and lead. Interesting features of this orebody are that it is surrounded by carbonate ore in a leached and oxidized zone not far above present water level, and its lateral and bottom limits have not been determined by existing development. The orebody is being developed and mined by lessees Gardiner & Young, whose lease expires on Dec. 23, 1920, after which date the ground will be operated on company account. The company plans to resume development operations through its 435-ft. shaft in the near future. A crosscut will be driven to cut the Hardshell vein, and a drift will be advanced to connect with the bottom of the old inclined shaft. The company is in the market for fuel oil and equipment to unwater the shaft. The company's Bender properties have been leased and manganese-silver ore is being developed. The Hardshell properties are under the management of Howard K. Welch.

Tombstone — The Mellgren Group, consisting of 55 claims in the western part of the district have been purchased by a New York company, of which F. W. Clark is president. Enough work has been done on these claims in the past years to show a large amount of silver ore of milling grade. It is planned to erect a 250-ton mill. This company which is incorporated as the Tombstone Silver Fields, has also taken over the Old Guard mine and the Merrimac group and will start development work at once. All work is under the supervision of Frank Cavanaugh, an engineer of New York.

The Solstice Mining & Milling Co., composed of local business men, have purchased four claims in the State of Maine district, three and one-half miles south of Tombstone. A three-drill I.-R. compressor, a 30-hp. gasoline engine and gasoline hoist are on the ground ready for installation, a two-compartment shaft has been started and will be sunk 500 ft. before drifting is started. The company intends to erect a small mill to concentrate a large amount of 10-oz. silver ore on the dump. W. T. Boyd is president and M. M. Bludworth secretary. Both are Tombstone business men.

Two hundred names were drawn Oct. 27 for jurymen in the famous Bisbee deportation case which is scheduled to start Nov. 8.

NEW MEXICO

Hecla Divide Bringing in Machinery at Pinos Altos—Wentworth & Goodrich Add to Fluorspar Holdings

Lordsburg—Wentworth & Goodrich, of Battle Creek, Mich., who recently took over the Great Eagle fluorspar property north of Lordsburg, are reported to have taken over a fluorspar prospect in the Franklin Mountains about 25 miles north of El Paso. Development work will be conducted under the general supervision of Alfred Roos, mining engineer.

Pinos Altos—The Hecla Divide Mining Co. that recently took over the Langston mine, five miles north of town, have been doing considerable substantial road work preparatory to bringing in machinery and supplies.

CALIFORNIA

Yuba Gold Resumes Normal Dredging —Soulsby Mines Co. Incorporated

Hammonton—The lifting of power restrictions has permitted the resumption of normal gold-dredging operations on the Yuba River.

Kennett — The Mammoth is now working steadily with night and day shifts as a result of the lifting of the power ban.

Sonora—Articles of incorporation of the Soulsby Mines Co. have been filed in the county clerk's office in Sonora, which will be the principal place of business. D. Miller and D. Coleman, of San Francisco; W. H. Bourke, of Oakland; J. O. Gillice, of Berkeley, and Eric Sergerstrom, of Sonora, are directors. The capital stock is $500,000 with shares at $1 each, and the company is incorporated under the laws of California. J. O. Gillice, former superintendent, will be in charge.

Downieville—L. A. Thatcher, of San Francisco, who has purchased the machinery at the Gold Point mine here, is shipping it to his holdings in other parts of California.

Grass Valley—The Idaho-Maryland Co. has a 15-stamp mill ready to operate, although no ore has been taken from the mine and the lower workings are still filled with water. The stamps formerly used at the Union Hill plant have been installed at the Idaho-Maryland. The company has painted all buildings in the group surrounding the shaft a dark green and has improved its office building.

NEVADA

Ely District Quiet—Cyanide Mill Planned for Nivloc Mine—Operations at Tonopah

Silver Peak — The Nivloc Northern Mines Corp. has completed plans for installing a 100-ton cyanide mill at the Nivloc mine near Silver Peak. The plans call for the extension of the electric power line eight miles to the mill. A large tonnage of ore that is said to run over $10 in silver and gold is blocked out in the mine.

Winnemucca—The Silver State Chemical Co. has bought ground on which it plans to erect a plant of 35 tons daily capacity to treat silver-lead-zinc ores.

Simon—The U. S. Smelting & Refining Co. is reported to have advanced the funds for the new mill which the Simon Silver-Lead company is erecting, and also to have contracted for both the lead and zinc concentrates to be produced by the mill. Development work at the mine has recently been confined to the 7th level, which is 565 ft. deep.

Goldfield—The concrete collar at the shaft of the Goldfield Deep Mines company has been set, a wooden headframe erected and the 75-hp. hoist put in place. This will be used to the 800-ft. point, when an 80-ft. steel headframe and a 250-hp. hoist will be installed, the foundations having been prepared.

Tonopah—Recent shipments of bullion indicate a gross production from the mines of the Tonopah district for October of about $500,000. The last shipments reported, which represent the cleanup for the first half of October, were Tonopah Belmont $89,100, West End $46,000, and Tonopah Extension $49,000.

Divide—In the Tonopah Divide mine the crosscuts on the 800 and 1,000 levels are being driven ahead rapidly in a southeasterly direction. Developments on the upper levels have proven the ore shoot to have a rake to the southeast so these crosscuts are being driven toward the projected position of the ore shoot and not to cut the vein at the nearest point. Regular development work was performed on the upper levels with no important changes reported.

Important work for the entire western portion of the Divide district is being done through the Kernick Divide shaft from the 900 level. Financial aid has been arranged with the Revert Divide, Western Divide, Annex Divide and Hasbrouck sufficient to perform at least 3,000 ft. of crosscutting.

Active work is being prosecuted at the Alto, Hercules, Silver and many other properties throughout the Divide district.

Ely—The Ely district is quiet, only a small tonnage of copper ore being handled at the Nevada Consolidated mill at McGill, which is running at half capacity. The rich copper ore opened up recently at the Ruth mine has added new interest to the area adjacent to the strike and among other companies that plan to do increased work is Ely Calumet company, controlled by Al. D. Myers.

The lead mines at Ward, near Ely, will discontinue shipping to the Salt Lake Valley smelters pending adjustment of the freight rates which having been increased twice during the last three years are now prohibitive. A small force of men will be retained on development.

The milling plant at Taylor is now running exclusively on dump ores from the mines, the principal value being silver with some gold.

Pioche—Ore shipments from the Pioche district for the week ended Oct. 21 totaled 2,710 tons and came from the following shippers: Prince Consolidated, 1,925 tons; Virginia Louise, 505 tons; Combined Metals, 150 tons; Bristol Silver Mines, 90 tons; and Columbia Trust Co., 40 tons.

COLORADO

Vanadium Strike Near Telluride—Thermit Corp. Buys Vanadium—Uranium Property

Denver—The demand for zinc oxide has fallen off, and the zinc oxide plants at Leadville and Canon City are experiencing some difficulty in marketing their product. The light demand is chiefly due to the fact that it is used in the manufacture of automobile tires, which in turn are in poor demand on account of the falling off in the automobile business. Thus the slackening up of automobile manufacture has indirectly affected the price of zinc ores. Unless the price of zinc advances in the near future many of the small zinc ore producers in the Western states may have to discontinue operations, especially in view of the increase in freight rates. In the Leadville and Aspen districts the freight rates have not been advanced, and the zinc ores will move as formerly to the Leadville and Canon City oxide plants provided these plants can market their product.

Telluride—The discovery of vanadium-bearing rock in the white cliffs about one-half mile north of the city has created some local excitement and several new claims are being located. The Colorado Vanadium Corporation is interested in several of the new claims.

Mesa County—The Kunkle group of vanadium and uranium claims, at the head of Kirks Canon, in the Gateway district, has recently been sold to the Thermit Corporation, of New York, which will operate the properties for the vanadium ore, which is the principal product of the deposits.

UTAH

Increased Power Rates Expected To Work Hardship—Iowa Copper Elects

Salt Lake City—It is feared that the increased power rates stipulated by the Utah Public Utilities Commission for all users of power supplied by the Utah Power & Light Co., even for those holding especial contracts entered into some time ago, in fact before the creation of the commission as a body, will work hardship to the mining industry, already struggling under adverse conditions. In this regard, the Judge Mining & Smelting Co. on Oct. 23, the date on which the new rates became effective, closed its electrolytic zinc plant, giving as reason the low price of zinc and increased mining and refining costs. As already stated in these columns, the interests affected by the new ruling of the commission are planning to bring the question before the courts for adjudication.

Park City—Iowa Coper held its annual meeting Oct. 19, electing L. R. Perry president; D. G. Scott vice-president and manager; R. T. Kimball, secretary and treasurer; D. L. King and John Carson additional directors.

MONTANA

The Philipsburg Manganese Co. Shuts Down—Flohart Silver Resumes

Butte—Barnes King's North Mocassin mine will be closed so far as company operations are concerned because of a dwindling ore supply of the grade sufficient to afford a profit with gold mining costs at their present high level The mine will be turned over to lessees. This is the second property to be closed by the Barnes-King, the Piegan-Gloster having suspended about sixty days ago.

Philipsburg—Mines of the Philipsburg Manganese Co. have been closed, rendering about 500 men idle. According to officials the suspension is only temporary. The Philipsburg company chiefly has been producing manganese ore, with some silver, the former ore being shipped to Pacific Coast concerns, principally for battery use.

Neihart District—Mining operations have been resumed by the Flohart Silver Mines. Ore bins are being prepared for storing second-class milling ore. Ore is being mined in No. 1 tunnel and a shipment will be made soon.

MINNESOTA

Cuyuna Range

Feigh Suspends Shipping for Season—Shipment From Ironton Mine Also Stopped Temporarily

Ironton—Owing to inability to secure railroad cars the Cuyuna-Duluth Iron Co. has been forced to suspend shipments from its Ironton mine temporarily. The ore hoisted is being stocked and the operators expect to load it out before close of navigation. Shipments are behind schedule.

The Feigh mine, operated by M. A. Hanna & Co., has shipped 32,000 tons from stockpile and suspended shipping for the season. The underground force has been laid off temporarily to allow moving the boilers and hoisting equipment to new quarters in a concrete engine and boiler house which is now nearly completed. The property will probably be unable to resume mining operations for several weeks. The Feigh has over 50,000 tons of ore still in stock, which will hold over to next season.

MICHIGAN

Seneca Shaft Concreted to 5th Level

Calumet—Concreting of the shaft of the Seneca Mining Co. is completed to the bottom of 5th level. The crosscut will be driven to the vein and drifting started as soon as the forms can be removed within a week or ten days.

The 4th level south drift has reached the boundary and the north drift is 725 ft. from the shaft. The management continues to ship small quantities of rock (ore) to the Baltic stamp mill. At the Gratiot shaft of the Seneca drifting continues on the 13th level and the south drift will reach the limit of the property or Mohawk Mining Company's boundary in about two weeks. The 5th level crosscut has just cut the lode.

Menominee Range

Iron Mountain—The Oliver Iron Mining Co. has found it necessary to start up its auxiliary steam plants at the Aragon and Chapin mines, the water supply in the Menominee River being insufficient to develop enough current to keep the company's mines in operation. There are steam turbines at both the Aragon and the Chapin. Many of the other mining companies in the Michigan field are experiencing the same troubles, the streams and lakes being lower now than for many years.

THE MARKET REPORT

Daily Prices of Metals

Oct.	Copper, N. Y. net refinery* Electrolytic	Tin 99 Per Cent	Tin Straits	Lead N. Y	Lead St. L	Zinc St. L
28	14 85	39. 50	40.00@40.50	6 75@7.00	6 60@6.85	6.90

2	....	....	....	....	....	....
3	14.60@14.85	38.50	39.25@39.75	6.75@7.00	6.55@6.80	6.80@6.85

*These prices correspond to the following quotations for copper, "delivered": 15.00, 15.00, 15.00, 14.90@15.00 and 14.75@15.00c.

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point, or as otherwise noted. All prices are in cents per pound. Copper is commonly sold "delivered," which means that the seller pays the freight from the refinery to the buyer's destination.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Oct.	Copper Standard Spot	Copper Standard 3 M	Copper Electrolytic	Tin Spot	Tin 3 M	Lead Spot	Lead 3 M	Zinc Spot	Zinc 3 M
28	89	88½	97	265½	267	36½	35⅞	38¾	39⅛

30	343	99½	80	52½	3	343½	99½	82⅛	53¼

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

Metal Markets

New York, Nov. 3, 1920

The feeling in the market has been better during the last week, with the increased stability of prices. Copper, tin, and zinc are relatively so cheap that further declines are not expected, and lead seems to be firm at present prices, even with a weak demand. The chief interest during the week, of course, centered in the election. The result, however, being almost exactly as expected, is hardly likely to cause market changes of importance. The unanimity of opinion, as expressed by the voters, that the Republican party should now assume control, is considered a better omen for settled conditions than if the election had been close.

Copper

There is no doubt that 15c. copper has stimulated buying, and we are reliably informed that large tonnages have been marketed at current levels. Some of the reports, however, are exaggerated. Demand for modest quantities has been rather widespread, and producers generally consider that business has been fairly satisfactory. Metal for delivery early in the year, principally January and February, is desired by most inquirers, and some outside agencies are reported to have cut under the 15c. price slightly on prompt deliveries. A report is also current that some sales of forward metal were made today at 14¾c., delivered, to tempt the largest possible amount of buying. No general tendency further downward has yet manifested itself, however, and the feeling among both buyers and sellers is that no mistake will be made in contracting for the next few months' supplies at present prices.

An interesting feature of the copper market is the auction sales which have taken place on the Metal Exchange during the last month. These sales have in general been made by agencies whose sales contracts for metal at high prices have been cancelled. They resort to an auction sale to establish their actual loss, with the idea of later carrying the matter to the courts. In some instances also the seller has been the buyer.

Lead

No change has been made in the A. S. & R. official New York price of 7¼c. for metal sold on contract. This continues to be above the market, which is dull but steady, at practically the same prices which obtained for last week. German and French lead continues to come in, but is not a factor in the market, for it was sold into consuming hands some time ago. The weak demand is a result of reduced current requirements on the part of consumers, and the lack of ability to finance stocks for future use, rather than to a feeling that the price is likely to fall.

Chemical lead of good quality continues at a premium of about ¼c. over the price asked for the desilverized product. Few inquiries are reported, however.

The London price has receded gradually during the week, but remains above New York parity.

Zinc

The zinc market continues featureless. The tendency continues downward, but only a slight total loss for the week is noted. Sales have been small and many producers continue out of the

Monthly Average Prices for October

Copper:	
New York Electrolytic	15.934
London Standard	93.327
London Electrolytic	104.905
Lead:	
New York	7.070
St. Louis	7.018
London	35.238
Silver:

Antimony	6.723
Quicksilver	67.200

market at current levels. Production promises to decrease, and the Republican victory, with the accompanying possibility of a tariff increase, should tend to arrest further recession.

Tin

The consuming demand has improved slightly, but the traders still are the major factor in a narrow market. Metal for forward delivery is selling at such a premium that if the necessary financial arrangements can be made it will pay one to buy spot metal and assume the carrying charges.

Straits tin for future delivery: Oct. 28th, 42@42.75c.; 29th, 42@42.50c.; 30th, 41.75@42c.; Nov. 1st, 41.75@42c.; 3d, 41.25@41.75c.

Arrivals of tin in long tons: Oct. 27th, London, 50; 29th, Straits, 925; China, 175. Total for October, 2,900.

Silver

Since our last report the silver market has remained fairly steady until today, when a sharp advance to 53⅜d. occurred in London, with a consequent rise in the New York rate. Buying on the part of Indian bazaars is reported as responsible for the improvement. Fundamental conditions remain unchanged, with China the only possible substantial buyer, although Indian exchanges will have an effect upon the course of the market.

Mexican Dollars—Oct. 28th, 60½; 29th, 60⅞; 30th, 60⅞; Nov. 1st, 61¼; 3d, 62½.

Gold

Gold in London: Oct. 28th, 117s. 11d.; 29th, 118s. 1d.; Nov. 1st, 119s. 2d.; 2d, 119s. 2d.; 3d, 119s. 2d.

Foreign Exchange

The European exchange market was dull during the last week. Italian exchange reached the lowest figure it has ever known. German marks continue to recede, as is to be expected. Today, francs are quoted at 6.25c; lire, 3.62c.; and marks, 1.26c. New York funds in Montreal, 9¾ per cent premium.

Other Metals

Aluminum—For 50-ton lots: ingot, 99 per cent and purer, 33.1c.; 98@99 per cent, 32.90c.

Antimony — Chinese and Japanese brands, 6¾@6¾c.; W. C. C. brand, 8c. per lb. Cookson's "C" grade, 12½@13c. Chinese needle antimony, lump, nominal at 6@6½c. per lb. Standard powdered needle antimony[1] (200 mesh), 9c. per lb. Market dull.

White antimony oxide, Chinese, guaranteed 99 per cent Sb_2O_3, wholesale lots, 9½c.

Bismuth—$2.55 per lb., 500-lb. lots, and $2.57 per lb., 100-lb. lots.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady.

Cobalt—Metal, $6 per lb.; black oxide, $4.10 per lb.; sulphate, $1.60.

Iridium—Nominal, $400@$450 per oz.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb. for 100 lb. lots and over, f.o.b. Niagara Falls.

[1]**Molybdenum Metal** in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.

Monel Metal—Shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$85 per oz. Dull.

Platinum—Firm at $95@$100 per oz.

Quicksilver—Market quiet; $60 per 75-lb. flask. San Francisco wires $60@$62.50. Market steady.

Ruthenium—$200@$220 per troy oz.

[1]**Selenium**—Black powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]**Thallium Metal**—Ingot, 99 per cent pure, $20 per lb.

[1]**Tungsten Metal**—$35@$60 per kilogram, according to purity and gage.

Metallic Ores

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a maximum of 6 per cent silica, 75@85c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 70@75c.

Manganese Ore[1]—60@70c. per unit, seaport; chemical ore (MnO_2) $70@$80 per gross ton, lump; $80@$90 per net ton, powdered.

Molybdenum Ore—85 per cent MoS_2, 65@70c. per lb. of contained sulphide. New York.

[1]**Tantalum Ore**—Guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots.

[1]**Titanium Ores**—Ilmenite, 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $6 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $5@$5.50, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$2 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[1]**Zircon**—Washed, iron free, 5c. per lb.

[1]**Zirkite**—According to conditions, $80@$90 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

Zinc and Lead Ore Markets

Joplin, Mo., Oct. 30—Zinc blende per ton, high $48.10; basis 60 per cent zinc, premium, $41; Prime Western, $40; fines and slimes, $37.50@$35; calamine, basis 40 per cent zinc, $35. Average settling prices: Blende, $44.30; calamine, $38.34; all zinc ores, $44.14.

Lead, high, $104.85; basis 80 per cent lead, $65; average settling prices, all grades of lead, $82.47 per ton.

Settlements were made for zinc as high as $45 basis and for lead $100 basis.

Shipments for the week: Blende, 10,462; calamine, 286; lead, 1,708 tons. Value, all ores the week, $572,900.

Shipments for ten months: Blende, 491,363; calamine, 8,836; lead, 76,858 tons. Value, all ores ten months, $31,795,670.

All the mines in the closing movement held the full two weeks, with a number that will remain closed until after the election. It is estimated the two restriction movements this year reduced the production around 36,000 tons. There is rumor of another losing movement of one or two weeks at the year-end. The shipment this year already exceeds last year over 15,000 tons of zinc and 15,000 tons of lead.

Platteville, Wis., Oct. 30—Blende, basis 60 per cent zinc, $45 base for high grade. Lead ore, no sales reported. Shipments for the week: Blende, 1,175; calamine, 30; lead, 30 tons. Shipments for the year: Blende, 57,071; calamine, 2,504; lead, 4,428; sulphur ore, 1,342 tons. Shipped during the week to separating plants, 2,019 tons blende.

Non-Metallic Minerals

Asbestos—Crude, No. 1, $2,000@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax.

Barytes—Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $24@$30 in bags, carload lots; (off-color) $22@$26 in bags, carload lots; all f.o.b Kings Creek, S. C. Crude, 88 to 94 per cent, $23; ground (white), $45; ground (off color) $30@$32 per net ton, less than carload lots, f.o.b. New York. Crude, first grade, $10 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin)—Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground, $15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$14 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $27@$30, car lots, f.o.b. Baltimore; ground, $17@$21, f.o.b. North Carolina points; $17@$21 per ton, No. 1 ground, f.o.b. New York State; $21@$23 per ton, ground, f.o.b. Maine. Crude spar very scarce.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chem-

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

ical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M. In Canada 85 per cent calcium fluoride sells for 320 per ton f.o.b. Madoc; output limited. Canadian price generally $18 (Canadian currency) per ton, f.o.b. mines; market inactive.

Graphite—The 90 per cent crucible grade is held in Alabama for 9c. per lb. and 85 per cent grade is practically unobtainable, prices being 7@9c. The higher lubricating grades sell for 11@40c., according to carbon content.

Gravel—No analysis guarantee, f.o.b. Roseview, Ill., $25 per ton; gravel suitable for acid, chemical or enameling purposes, $60.

Gypsum—Plaster of Paris in carload lots sells for $4.25 per 250-lb. bbl., alongside dock, New York. Raw crushed rock, $3.50@$4.50; calcined stucco, $9; f.o.b. works, Illinois.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. In Chicago district, $57.70; Atlantic seaboard, $61@$63.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—India block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20 @$1.40; No. 4, $2@$3; No. 3, $4.25@ $5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $3.50; No. 3, $5, No. 2, $6.50; No. 1, $8; A1, $10; extra large, $25, all f.o.b. New York; ground, $150 per ton, Philadelphia. Domestic, uncut, f.o.b. Franklin, N. C., as follows: Scrap, $45 @$50 per ton; punch, 10c. per lb.; circle, 15@25c.; 1½ x 2 in., 75c.; 2 x 2 in., $1.15; 2 x 3 in., $1.65; 3 x 3 in., $2.10; 3 x 4 in., $2.50; 3 x 5 in., $2.75; 3 x 6 in., $3.75; ground 165 mesh, $240 per ton; ground roofing mica, $60; mica washers, 75c.@$2 per lb.; 1½-in. disks, No. 1, $1.60 per lb.; No. 2, $1.30. The foregoing domestic prices obtain also in the Chicago district.

[1]Monazite — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. Finely ground Tennessee rock sells for $8.50 per net ton for 13 per cent phosphorus content, agricultural application; for acid-making, 14 per cent, $9; both prices f.o.b. Centerville, Tenn.

Pumice Stone—Imported, lump, 4@ 50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish fines, per unit, 12c., c.i.f. Atlantic seaport; furnace size, 17c.; Spanish lump, 14@16c.; domestic fines, f.o.b. mines, Georgia, 12@14c. Market improving.

Quartz—(Acid tower) fist to head, $10; 1¼ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines.

Sand (Glass)—Dry glass sand, $4 per net ton, f.o.b. cars Mapleton, Pa. Sand, f.o.b. Ottawa, Ill., is $3 per ton; $2.50 on annual contracts. Sand at Klondike, Gray Summit and Pacific, all in Missouri, is $2.50 on contract; some outside sales have been made at $4. St. Louis, open market, at $3.50; contract price on large quantities, $2.50; on small quantities, $3.

Sulphur—$18 per ton for domestic; $18@$20 for export, f.o.b. Texas and Louisiana mines. Market quiet.

Talc — Paper making, $12@$22 per ton; roofing grades, $9.50@$15; rubber grades, $12@$18, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $12@$15 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60 @$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 13@14c. per lb.; sulphide, powdered, 16@18c. per lb.,

Nitrate—Soda, $3.25 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $225 @$250 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15 to 18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 18½@19c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c., f.o.b. works.

Ferromanganese—Domestic 76 to 80 per cent, $170@$175, freight allowed; $170, f.o.b. seaboard bases; English, $165, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $75@$80, f.o.b. furnace.

Ferromolybdenum[1]—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2.25@$2.50 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b works, $60@$65; 50 per cent, $76@$80; 75 per cent $150@$160.

Ferrotungsten[1]—Domestic, 70 to 80 per cent W, 75@90c. per lb. of contained tungsten, f.o.b. works. Foreign, 70c.

Ferro-uranium—35 to 50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium[1]—Basis 30 to 40 per cent, $6.50@$8 per lb. of V contained, f.o.b. works.

Metal Products

Copper Sheets — Current New York price, 25½c. per lb.; wire, 19c.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Lead Sheets—Full lead sheets, 10½c.; cut lead sheets, 10½c. in quantity, mill lots.

Nickel Silver—Unchanged at 36½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 23½c.; sheathing, 23½c.; rods, ⅝ to 3 in., 20½c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $160 per 1,000, f.o.b. Pittsburgh.

Chrome Cement—40@45 per cent Cr_2O_3, $55@$60 per net ton, and $65 in sacks, carload lots, f.o.b. eastern shipping points.

Fire Brick—First quality, 9-in. shapes, $55@$60 per 1,000, Pennsylvania, Ohio and Kentucky. Second quality, $45@ $50.

Magnesite Brick — 9-in. straights, $110 per net ton; 9-in. arches, wedges and keys, $121; soaps and splits, $134.

Silica Brick—9-in., per 1,000: Chicago district, $65@$70; Birmingham, Ala., $56@$61; Mount Union, Pa., $55 @$60.

Iron Trade Review

Pittsburgh, Nov. 2, 1920

The volume of business in steel products obtainable, even by cutting prices, continues limited. The Steel Corporation continues to operate as fully as physical conditions permit, the corporation being still short of coke at some points. Steel production on the whole is at fully 10 per cent less rate than in August or September.

The 2.35c. price on merchant bars, made recently by one independent, has been withdrawn, and quotations usually do not run below 3c. Plates continue to sag, and the common quotation of 3c. is shaded on particularly desirable business. Black sheets are down to a range of 6.25c. to 6.50c.

The American Sheet & Tin Plate Co. will probably not open its order books for the first half of next year until December, as it will carry over about three months of rolling. Its prices will probably be Industrial Board prices, as heretofore.

Pig Iron—Bessemer has been offered at $45, Valley, $2 under the former quotation. Foundry remains at $45 and basic at $40, Valley. Further declines are expected as inquiries develop, predictions being that the market will eventually find a stable level at between $30 and $35.

Semi-finished Steel—Prices remain nominal at $55@$60 for billets and $65 for sheet bars. Steel Corporation prices, as recently advanced $5, are $43.50 for billets and $47 for sheet bars.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $16.50@$17; foundry, $18.

COMPANY REPORTS

Oriental Consolidated Mining Co. Shows a Small Profit

Gold: Korea

The result of the operations of the Oriental Consolidated Mining Co., an American enterprise operating in Korea, for the year ending June 30, 1920, is summarized in the following table.

The tonnage and value of the ore milled were lower than during the previous year (250,868 tons, of a value of $1,464,830.70 was produced in 1918-1919) whereas operating costs were increased, so that net profit compares unfavorably with that of last year. Owing to a drought in Northern Korea during the summer and fall of 1919 and the spring of 1920, a heavy advance in the cost of foodstuffs, wages, and transportation occurred, and the use of hydro-electric power was curtailed, and steam used instead, adding further to the high expense of operating.

A salient feature of the operations was the inability of the company to take advantage of the high premium on gold in China, because the Japanese government prohibits the export of gold.

The production of the active mines which furnished ore for the mills during the year was as follows:

Name of Mine	Tonnage	Total Value of Ore	Value per Ton
Tabowie	128,405	$822,139.40	$6 40
Taracol	97,647	460,990.93	4 72
Chintui	4,811	23,012 66	4 78
Tongkni	2,460	50,893 48	20 69
Total	233,323	$1,357,036.47	$5 82

A total of 25,541 feet of development work was performed. Profit and loss account for the year ending June 30, 1920, follows:

DEBIT

	Cost per Ton	
To mining costs	$2.10	$490,002 08
Milling costs	.66	154,442 74
Concentrates expenses	.25	58,801 34½
Transportation of ore	.01	1,660.19½
General expenses	.65	152,060.64½
Total operating and general expenses	$3 67	$856,967 00½
Depreciation	1 07	250,000 00
Depletion 5 per cent of output	.24	56,610 08
Total debits	$4 98	$1,163,577 08½
Profits for year to balance sheet	.11	25,052 30½
	$5 09	$1,188,629 39

CREDIT

	Cost per Ton	
By bullion from mills	$2 44	$569,198 68
Concentrates	2.41	563,002 96
Store profit	.962	16
Interest and other receipts	.24	55,465 59
	$5.09	$1,188,629.39

The profit for the fiscal year amounted to $25,052.30½ after deducting depreciation and depletion charges. Dividends were paid during the year in July, 1919 ($107,347.50), and March, 1920 ($214,695), out of an accumulated profit to June 30, 1920, of $859,001.80. A United States income tax of $16,266.03 was also paid. Surplus profit on June 30, 1920, amounted to $520,693.27.

The company has $4,293,900 in capital stock outstanding, of a par value of $10 for each share.

OPERATING RESULTS OF THE ORIENTAL CONSOLIDATED MINING CO.

	1919–1920	1918–1919
Total receipts for the year were	$1,188,629 39 or $5 09 per ton	$1,282,085 80½ or $5.11 per ton
Total operating costs for the year were	856,967 00½ or 3 67 per ton	842,978 38½ or 3 36 per ton
Total operating profits before reserves	$331,662 38½ or $1 42 per ton	$439,107 42 or $1.75 per ton
Reserves for depreciation	$250,000.00	
Depletion	56,610.08	
	306,610 08 or 1 31 per ton	310,266 51 or 1.24 per ton
Net profits after deductions for reserves	$25,052 30½ or $0 11 per ton	$128,840 91 or $0.51 per ton

Broken Hill South, Ltd., Reports No Production During 1919

Zinc, Lead: New South Wales

Productive operations of the Broken Hill South, Ltd., were entirely suspended during the fiscal year ending June 30, 1920, according to a statement of the company, due to the continued strike of underground employees and the destruction by incendiarism of a large portion of the plant. The company is interested in the operations of the Electrolytic Zinc Co. of Australasia Proprictary, Ltd., to the extent of 120,000 fully paid £1 shares. It is estimated in the report that by the end of September, 1920, the output of refined zinc of this company will be raised from 15 to 25 tons per day. Additional units under consideration assure a further increase to 50 and 100 tons per day.

British Australian Lead Manufacturers' Proprietary, Ltd., is another company in the operations of which Broken Hill South is interested. The company has been established for the purpose of manufacturing white lead, paints, and lead products.

October Mining Dividends

The following is a partial list of dividends paid by mining companies during October, 1920:

U.S. Mining and Metallurgical Companies	Situation	Per Share	Totals
Am. Smelt. Sec., pf. A	U. S.	$1.50 Q	$255,000
Am. Smelt. Sec., pf. B	U. S.	1 25 Q	39,855
Caledonia Mining Co., la	Idaho	0 01 Q	26,050
Daly-West Mining	Utah	0 25 Q	62,500
Electric Point, I	Wash.	0 15 Q	119,062
Eagle-Picher Lead	Okla.—Mo.	1.50 Q	15,000
Inspiration Consolidated, e	Ariz.	1.00 Q	1,181,967
Phelps Dodge	U. S.	2 50 Q	1,125,000
Portland Gold Mining	Col.	0 015 Q	45,000
Tonopah-Belmont, s. g	Nev.	0 05 Q	75,000
Tonopah Extension, g. s	Nev.	0 05 Q	64,140
Tonopah Mining, g. s	Nev.	0 05 Q	50,000
United Eastern Mining, g	Ariz.	0.15	204,455
U. S. Smelting, Refining and Min	U. S.—Mex.	1.50 Q	526,673
U. S. Smelting, Refining & Min., pfd	U. S.—Mex.	0 875 Q	425,555
Vanadium Corporation Amer	Col.—Peru	1.50 Q	560,001
Canadian, Mexican, Central and South American Companies			
Alvarado Mining & Mill, g. s	Mexico	$0.50 Q	$17,500.00
Asbestos Corp., Can., Ltd	Can.	1.50 Q	45,000.00
Asbestos Corp., Can., Ltd., pfd	Can.	1 75 Q	70,000.00
Con. Mining & Smelting, Canada	B. C.	0 625 Q	263,342.50
Dome Mines, S	Ont.	0 25 Q	100,000.00
Hollinger Consol. Gold	Ont.	0 05 BM	246,000.00
Howe Sound, e	B. C.—Mex.	0 05 Q	99,208.00
Kerr Lake Mines	Ont.	0 125 K	75,000.00
Lake Shore Mines, g	Ont.	0 02 K	40,000.00
McKinley-Darragh-Savage, Ltd., s	Ont.	0 05 Q	67,431.00
N. Y. & Honduras, Rosario, s. g	C. A.	0 50 QX	100,000.00
Nipissing Mines, s	Ont.	0 50 QX	600,000.00

Q, quarterly; X, includes extra; BM, bi-monthly; K, occasional.

Calumet & Hecla Mining, Osceola Consolidated, and Wolverine Copper mining companies all found the metal market too low to justify declaring dividends. Caledonia Mining Co., previously paying monthly dividends, has now changed to quarterly; its last payment was 1c. in July. Daly-West Mining paid on Oct. 1 the quarterly dividend announced in our table for September; Electric Point reflects its prosperity by distributing an extra dividend of 12c. Tonopah-Belmont Development and Tonopah Mining companies both resumed dividends, and Kerr Lake Mines on Oct. 15 broke a silence that had lasted since its capital distribution of September, 1919.

INDUSTRIAL NEWS

New Type of Air Drill Perfected

Said To Be Simple in Construction and Light of Weight

The development of pneumatic mining and quarrying tools has been so rapid, and their performance latterly so efficient, that it is but natural they should now be regarded as having reached such a state of perfection that radical changes or improvements are, generally speaking, no longer expected.

And yet, notwithstanding this popular notion, The Denver Rock Drill Manufacturing Co., which has for quite a number of years been in the forefront of rock drill progress, has recently developed a new type of light mining and quarrying drill which, it is claimed, marks an advance in the progress of air drill manufaeture.

This new type of drill is built in three models, known respectively as Models NA-90, NRW-93 and NRD-95; the first named being a "dry" auger drill, specially designed for work in coal, iron and other soft formations; the second, a combination "wet" and "dry" rock drill efficiently serviceable in all kinds of rock and under all conditions, either above or below ground; and the last named, a "dry" rock drill particularly adapted to work in wet shafts or where out-of-door conditions prevail.

All three drills are quite light, can be easily carried about, and each requires but one man to operate it. They are built throughout of the very best steels compounded and with the utmost precision. While most Waugh drills are of the valveless type, the "Nineties" are equipped with an entirely new type of spool valve, having a positive efficient action. The rotation mechanism is of exceptionally strong design in which stresses in both teeth and pawls are reduced to a minimum. Lubrication is effected by pulsations of air which gradually feed the oil from a reservoir at the side of the cylinder into all parts of the machine.

Motor Trucks and Future Plans

Leo L. Robinson, chief of the Transportation Section of the Council of National Defense, contributes to *The Commercial Car Journal*, where he says, in part: "Records of the Highways Transport Committee of the Council of National Defense not only furnish concrete evidence of the number and character of transportation crises which may develop, but suggest methods for remedying many of them. These methods suggest first the greater utilization of the highway and its twin agency, the motor truck, as potential mediums for emergency service, as well as for that day-to-day performance upon which plans for the future may be built."

Advertising in the Vernacular Brought Trade

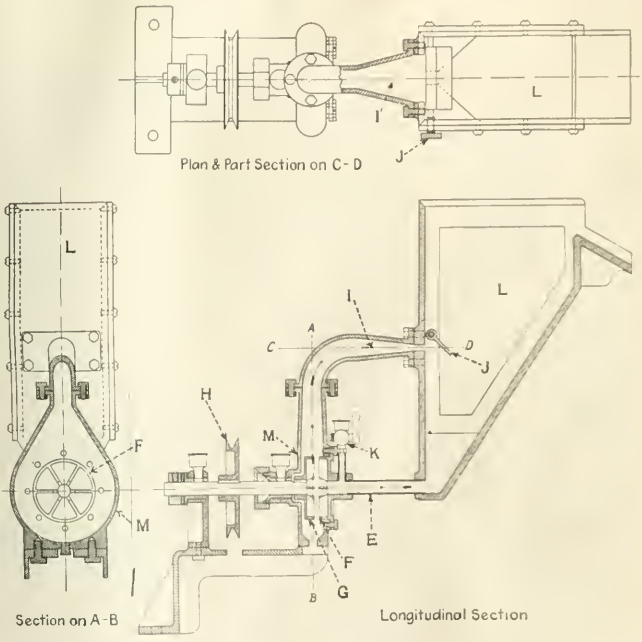
Major H. A. Chisholm, Canadian Trade Commissioner in Havana, Cuba, reports that previous to this year Cuba bought her building plaster from the United States. Firms in New Brunswick and Nova Scotia shipped crude gypsum to the United States. It was there manufactured into building plaster and shipped to Cuba, but now Nova Scotia and New Brunswick firms are shipping building plaster direct to Cuba. One Nova Scotia company recently received an order for 60,000 barrels of building plaster from Cuba. This latter firm advertised extensively in Spanish. The Canadian government trade commissioner in Cuba has interested himself in an endeavor to divert this trade into Canadian channels.

Water Screens.—The Link-Belt Company, 910 South Michigan Avenue, Chicago, recently published an illustrated twenty-four page book covering its traveling water screens.

Colburn Flotation Machine Gives Agitation at Low Pressure

The Colburn vacuum flotation process comprises a flotation machine of the multi-cell type through which the pulp flows from cell to cell. The pulp is first received in a compartment connected with the vacuum inlet of the first agitator, and this discharges against a baffle in the spitzkasten of the first compartment. The froth rises to the surface, where it overflows over a baffle to the concentrates launder. The portion of the pulp which settles to the bottom of the spitzkasten chamber is drawn into the second agitator and discharged into the next spitzkasten, and so on throughout the series. Discharge level is maintained by a baffle at the end of the machine and by openings between the cells.

The agitator consists of two plates, one stationary and the other rapidly rotated. The interior construction of the plates is identical, except that the stationary plate is provided with an inlet at the center. The interior of each plate is provided with twelve radial baffles, which are alternately long and short as shown in Fig. 2. The plates are adjustable, and the width of the



Drawing of Laboratory Cell

I Discharge
L Spitzkasten
J Adjustable Baffle

FIG. 1. SECTIONS OF THE COLBURN LABORATORY FLOTATION MACHINE

peripheral discharge is approximately $\frac{3}{32}$ in. The inlet to the stationary plate is of smaller diameter than the outlet of the agitator. The outlet of the agitator is flattened so as to discharge a thin, sheet-like stream against the baffle in the spitzkasten. The sectional view of the laboratory machine, shown in Fig. 1, makes this clear.

Connected with the suction inlets are vertical pipes which terminate in small valves placed well above the pulp level in the machine. By regulating the opening of these valves, any desired vacuum within somewhat less than $\frac{1}{4}$ to $\frac{1}{2}$ the maximum can be obtained. The rotating plate is speeded to between 1,200 and 1,300 r.p.m. in the 50-ton commercial machine. A 10-hp. motor is used on this machine, but actual figures on power consumption are not available. Pulp flow is due to the regular flow of pulp through the machine and is induced or accelerated by the action of the agitator. It is evident from the construction of the plates and the high speed of rotation that there is intense agitation under a low vacuum in the chamber between the plates. The regulation of the amount of vacuum is readily accomplished and enables the size of the bubbles and the degree of flotation to be adjusted with greater precision than hitherto.

It appears that the machine has considerable promise in the field of differential flotation as well as in the flotation of certain ores which have yielded only indifferent results when experimentally tested by flotation under other conditions. Several machines have been installed, and at present a single unit is being placed in the mill of the Leadville Mines Co., Washoe County, Nev. The results of these installations should be of considerable interest to those interested in flotation.

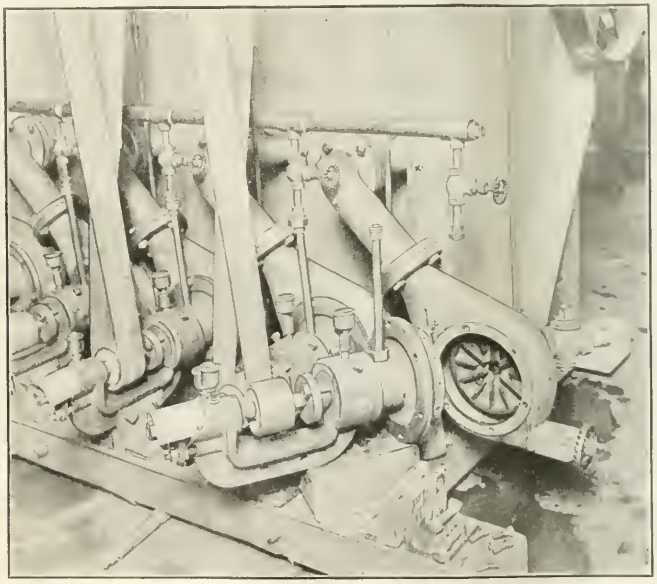

FIG. 2. GENERAL VIEW OF COLBURN VACUUM FLOTATION MACHINE

The Armstead Snow Motors Co., Talache, Idaho, of which H. H. Armstead is president and H. W. Sanders is secretary, anounces that it has effected co-operation with the Premier Motors factory, Indianapolis, Ind., for the construction, in quantity, of snow motors (an automobile which functions on any depth of snow). This machine was thoroughly tested out last winter on the road between Klockmann and Porthill, Idaho, by hauling concentrates from the Idaho-Continental mine. Mining and mechanical engineers, who have seen the car operate, say that Major Armstead has solved the winter transportation problem; and the manufacture of snow motors at the Premier factory, Indianapolis, will be one of the growing new industries of the United States. Next year the Armstead Snow Motors Co. expects to manufacture also in Canada and Russia.

The Chicago Chapter of the American Welding Society has issued a pamphlet "Keep the Guess Work Out of Welding." Copies of this booklet may be had by addressing the secretary of The American Welding Society, 608 South Dearborn St., Chicago, Ill.

The executive committee of this society (New York) has recommended forming a New York Section to operate separately from the parent organization.

TRADE CATALOGS

Screens—The W. S. Tyler Co., of Cleveland, Ohio has issued an attractive catalogue descriptive of the Hummer inclined screen. Unlike any other screen, the vibration is produced by electro-magnets and is applied directly to a drumhead tension screening surface. The intensity of vibration can be regulated easily by turning a small hand wheel at the top of the vibrator. The mechanism is placed on top of the screen, out of the way of the falling material. Screens of this type will no doubt find extended application, as they represent a marked advance over the old and slower methods of mechanical vibration.

Conveyors—Portable Machinery Co., Passaic, N. J., has issued a twenty-four-page catalog entitled "Portable Conveyors." This is complete with illustrations showing the various uses of the scoop conveyor and other portable conveyors manufactured by the company, and describes the labor, time-, and money-saving features of the machine in storing, reclaiming, loading, and unloading material, such as coal, coke, ashes, sand, gravel, crushed stone, fertilizer, cement, and chemicals. Copies will be sent free on request.

Ventilating; Heating—Buffalo Forge Co., Buffalo, N. Y., has published a very useful illustrated catalog of 115 pages, well arranged, on its fan system of heating and ventilating. Much space is devoted to the principles and the methods of check and control of air conditioning. Part III, or but eighteen pages of the whole, is devoted to the apparatus in particular. The numerous tables, graphs, and formulas of this catalog, No. 700, make it one of the most helpful issued on the subject.

Wood Pipe—Continental Pipe Mfg. Co., Seattle, Wash., recently issued Bulletin No. 16, "Continental Creo-Wood Flume," which describes the several features of that product. It is stated that this type of flume will carry more water for a given diameter than any other, preserves its semicircular shape, permits of reasonably sharp curvature, will not crack, disintegrate, or rust, and will not expand in hot weather nor contract in cold. Several installations are illustrated.

Sectional Buildings—The Steel Fabricating Corporation, Harvey, Ill., is distributing a large illustrated folder showing the many uses for sectional steel buildings and their economy. The illustrations suggest many ways in which these handy and easily moved structures could serve the mining and quarrying industries, a subject specially interesting to the corporation's free advisory service. A catalog will be sent any applicant who submits particulars of his needs.

Combinations in Restraint of Trade

IT IS REPORTED that the farm organizations may call on the farmers of the country to hold up crops in order to sustain the market; and representatives of organized labor have advised the farmer organizations that they would support them in the fight for higher prices.

The miners, representing the other great basic industry of the country, mining, will watch the farmers curiously to see how they fare. The operation of the law against combination in restraint of trade has never been enforced against the greatest combination of all, organized labor, on account of a popular and possibly sound prejudice. That there is one law for the rich and another for the poor, as the agitators say, is true; but it is the supposedly poor who are favored by the discrimination. Also, the socialists' plea in their platform that the "burdens of taxation should be borne by the rich," is true at present, should the gentlemen pause to observe. Income taxes, inheritance taxes, excess profits taxes, all prune the plutocrat.

Millions of wage earners whose annual earnings have been between two thousand dollars and five thousand dollars never dream of paying an income tax; and no attempt is made at collection. On the other hand, we knew a retired mining engineer who complained that taxation cut his income in half; and we heard of another case (for we do not move in such circles) where a man was trimmed out of 85 per cent of his income, in a lucky year. Another pathetic instance was of a man who had nothing and who made half a million in speculation one year and lost it the next. Also, the next year he had to pay his income tax on the year before, and as the tax amounted to a snug little fortune, and not only his cash but his banking credit was exhausted, he was somewhat embarrassed.

This inequality between the supposedly rich and the supposedly poor—which, however, often means taxing the white-collared class who earn less and exempting the horny-handed class, including the makers of watch fobs and perfumery, who earn more—is one which all classes look upon with tolerance: the wage-earning class, of course, do not complain of it, and the other class are either confident of their ability to hand it on to the ultimate consumer or they are good sports. They realize the right of the crowd to pelt them with whatever is handy while they try to climb the pole; if they cannot stand the gaff, let them join the crowd and give the next man a chance to try.

But we question whether the farmers who are thinking to combine in restraint of trade are poor men—we suspect that they belong to the wealthy or capitalistic class. Certainly they are not wage earners. Therefore, with the dual consideration of law and sentiment—how far can they go? As miners, we should like to know. Take the gold-mining industry, for example. We believe it will be admitted that at present all gold miners fall into the class of poor men. Can they—may they—combine to withhold their produce until relieving legislation shall be passed? They are told that would be unpatriotic, but a poor gold miner of our acquaintance wants to know why it should be more unpatriotic than a farmer withholding his wheat, or a labor-unionist his productive work. Will the labor unions support the miners if they combine in restraint of trade, in a fight for higher prices?

The World's Petroleum Problem

THE world situation regarding petroleum is set forth clearly and comprehensively in a recent article in the *Saturday Evening Post* by Mark L. Requa, formerly oil administrator in Washington. He quotes the communication of the Department of State to the Senate on May 17, 1920, concerning the restrictions by foreign countries, especially Great Britain and France, on alien development and ownership, including that by Americans. Concerning this discrimination, the State Department note says: "In the absence of prohibiting treaty provisions, this form of discrimination would seem to be justifiable from the viewpoint of international law, *however impolitic it might be as regards reciprocity and international comity.*" Concerning this, Mr. Requa remarks: "It would seem the part of wisdom that the United States negotiate at once treaty provisions giving our nationals the same freedom that foreign nationals enjoy in America."

Mr. Requa further quotes at length the agreement between the two governments of Great Britain and France, signed at San Remo in April by Sir John Cadman and M. Phillippe Berthelot. "This agreement," the document runs concerning itself, "is based on the principles of a cordial collaboration and reciprocity in the countries where the petroleum interests of the countries can be amalgamated to advantage. The present memorandum refers to states or countries as follows: Rumania, Asia Minor, territories of the former Russian Empire, Galicia, the French colonies, and the colonies of the British Crown." This agreement is, in effect, a pooling of interests regarding present and future requisitions of petroleum. In regard to Russia, for example, Article 6 states that "*the two governments will give their joint support* to their respective nationals in their common efforts, with a view to obtain petroleum concessions and facilities for export, and to assure the delivery of petroleum supplies." Mesopotamia is parceled out between England and France. In the British Crown colonies, French nationals are accorded rights of exploration and exploitation similar "to those accorded to British subjects in the French colonies." American citizens have not these rights, whereas the citizens of France and the "subjects" of Great Britain

enjoy the same rights in American territory as do our own citizens.

Mr. Requa remarks that a careful reading of this agreement "should convince any but the most skeptical that if United States oil companies are to make any headway whatever in the acquisition of foreign sources of supply they must have the same enthusiastic government support and co-operation as that extended to foreign nationals by their respective governments." He discusses the problem for America dispassionately and fairly, pointing out the necessity which Great Britain is under for engaging in a campaign for petroleum resources, and that the only sound policy for the United States Government is actively to conduct its own campaign. He points out that the World War really resulted from the struggle for raw materials, such as the iron of Alsace-Lorraine, and the petroleum and other resources of the Near East; and makes the searching statement that "the sea and air will not be free to all nations for purposes of international commerce unless the sources of petroleum and the petroleum products themselves are made available to all on equal terms and without discrimination."

Mr. Requa concludes that "Adjustment should and can be made by international agreement. No one expects the petroleum companies themselves to arrive unaided at any such understanding. That is impossible. But a properly formulated international agreement, negotiated by governments, defining the rights and limitations under which the different nationals may operate, is not only possible, but necessary, if we are to maintain lasting peace. And that agreement must be founded on a very simple principle: equal justice to all concerned."

This situation as treated by the former oil administrator has been ventilated thoroughly in these columns —in fact, we believe that it was first published there. Subsequently the new British Ambassador, Sir Auckland Geddes, informed the American people that the report was unfounded, and circulated by those desiring to disturb the good relation between the two countries; and the bulk of the American press fatuously quoted Sir Auckland and approved. Also, the remedy proposed by Mr. Requa is the one that has been suggested by us editorially—an amicable understanding among the nations which need the world's petroleum as to how the available supplies are to be rationed.

Recently there has been much friction between England and France over their petroleum agreement, the French believing they have been given altogether the worst of the deal.

No more important problem awaits diplomatic and legislative attention on our part, in order to protect ourselves and insure the future peace and prosperity of the world, than the matter to which attention is here directed; and action on it should be one of the first evidences of a new domestic and foreign policy.

The Future of Mining In South America

THERE can be little doubt on the part of the student of economic geology that the mining industry of South America is destined to increase in scope and importance. The same great mineral belt which covers our Western States sweeps down uninterruptedly through Mexico and Central America, and is represented in South America from Panama to Cape Horn; and there are also the important mining districts of the eastern part of the continent, corresponding roughly, perhaps, with our important mining districts east of the Rockies. But with all her mineral wealth, South America, taking it altogether, is deficient in the one mainspring of industry—coal—so that even the immense iron deposits of Brazil remain a problem as to utilization.

We in this country are already seeing the dawn of the gradual forsaking of coal and petroleum for power purposes, wherever possible, for electrical power—preferably hydro-electric power. The Super-Power Survey, which is being made under the guidance of the U. S. Geological Survey, has as its object the establishment of a connecting network of power lines from Boston to Washington, with the object of maximum development and efficiency of existing electric power possibilities.

Something of this same thought has been communicated to South America, where it is, of course, especially necessary. In another column we abstract some information gathered by the Guaranty Trust Co. of New York concerning this movement. The report is mentioned that an international power plant, with a capacity of 150,000 hp., will be erected jointly by the governments of Argentina, Uruguay, and Brazil, at the falls of the Iguazu, in Brazil. An electric smelting plant and steel mill, the first of its kind in South America, will, it is reported, be built in the Province of Sao Paulo. In Bolivia, an initial expenditure of $10,000,000 for power plants is planned. The plans of the Guggenheim Brothers for the development of their tin mines in Bolivia include the building of a hydro-electric plant, and possibly an electric smelter. In Peru, also, electrical development is not only spreading throughout public utilities and extending itself to the railroads, but is being employed at the mines. The Cerro de Pasco mines, as well as the Vanadium Corporation of America, are constructing hydro-electric plants.

Altogether, we are evidently on the verge of a new era for South America, when the development of her vast hydro-electric power will permit the exploitation of her mines on a scale never before possible, by providing not only the power for the working of the mines but the neressary transportation facilities.

The Utah Consolidated-Utah Apex Lawsuit

IT IS A DELICATE MATTER to take sides in a dispute, however amicable, between friends, especially when one's knowledge of the question in dispute is limited and perhaps inadequate: yet we cannot forbear registering our approval, according to our lights, of the decision of Judge Johnson in the great Utah Consolidated-Utah Apex lawsuit. The sums at stake run up into the millions, and the best legal and geological talent was secured on both sides. The sole point at issue, according to our correspondent, was as to whether certain limestone formations, known as the Highland Boy and the Yampa, which were ore-bearing formations, were the lodes in the legal sense, or whether the almost vertical veins which cut them at nearly right angles were the lodes. Orebodies were shown by the evidence to have occurred frequently at the junction of the vertical veins with the limestone. The cropping or "apex" of the limestone formations was in Utah Consolidated ground: the cropping of the vertical vein-fissures in that

of the Utah Apex. To which party belonged the ore at the junction?

This would appear to be a classic example of the absurdities of geological and legal interpretation and definition which arise from the desire to twist the apex law to one's own protection or profit. To prove that black is white has long been considered the function of the legal brotherhood; and now the geologists take up the task of proving that the country rock is the vein. We note two encouraging circumstances, however: First, from the report of the testimony, the distinguished geologists who were retained by the country-rock advocates seem to have limited their testimony very conscientiously to the facts: and the second that the learned judge proved able to distinguish black from white after the geologists and the attorneys were through with the argument. Possibly the latter encouraging circumstance resulted from the former.

We do, however, file our objections to the definition of a lode proposed by Mr. Horace V. Winchell on behalf of the country-rock advocates: namely, that "a lode or vein is mineralized rock or rocks which contain such indications of valuable minerals as to justify development with the expectation of finding ore. As soon as quartzite over a considerable distance becomes mineralized, then it becomes a lode. Just as soon as either of the other rocks can produce and do produce ore, or contain indications which lead the experienced miner or prospector of judgment to develop it with the expectation of finding ore, then it becomes a lode."

We have all seen or heard of broad lodes: but this definition would establish the record for breadth. As the quartzites which lie between the limestone in Bingham Canyon also are ore-bearing, as was shown by abundant testimony at the trial, they are also lodes; and there is no country rock "whatever" in the district. And as there is no country rock, there are no walls to the different lodes, and, therefore, all the formations become, technically, geologically, and legally, one vast lode. The Bingham Canyon lode, we take it, therefore, is limited above by the pure air of Utah, in depth by the volcanic fires, on the north by the international boundary, on the south by Palm Beach, on the west by the sunset and on the east by Wall Street; and its apex passes into a problem of the fourth dimension.

An early explorer in Alaska traveled on the theory that there was one continuous lode from Alaska to Cape Horn; and the mineral discoveries which he made in Alaska proved to him the truth of his theory. There is a simplicity in this conception which reminds one of the "One Big Union"; at any rate, it would make mine reports easier for the mining engineer.

How To Pronounce Bauxite

THE diverting discussion as to the proper pronunciation of bauxite has run itself out in our open forum, the "What Others Think" department, with the result that there remain, as before, two opposing parties, more deeply confirmed in their previous views than ever. We hardily closed the discussion by remarking that as for us we pronounced the word *boxite* (probably nearer *bawxite*, for the orthography has doubtless a subtle influence in tempting us to prolong the vowel), following custom and intelligibility, and we justified our choice on the principle of the Anglicization of foreign words. We are tempted, therefore, to publish the opinion which we have just received from P. B. McDonald, assistant professor of technical English in New York University, confirming our judgment:

"Answering the query of Mr. Minum in your issue of Oct. 2, about bauxite, I would say that in my opinion the pronunciation has become Anglicized. Originally, the French pronunciation was boze-ite, as the dictionaries still give, but the usage of geologists and miners has made it much like box-ite. This is entirely legitimate. In a similar way, Pa-ree has become Par-is, and Roma has become Rome. We pronounce the plural of beau and chateau as though an 's' were added; the French, I believe, ordinarily pronounce the plural like the singular. To say boze-ite might suggest booze-ite, which Nevadans might confuse with hootch-ite."

We resent, however, the fling at the Nevadans. Nevadans, like Kentuckians, are judges of fine distinctions.

So then, boys, it's all settled. All together, one, two, three, now! *Bawxite! Bawxite!*

The Price of Basic Commodities

EACH month the National Bank of Commerce publishes a list of the wholesale prices of representative commodities, comparing present figures with those before and during the war. From the latest issue of its publication, "Commerce Monthly," we extract the following information:

Commodity:	Price July, 1914	Price High 1914-1920	Price October, 1920	Present Per Cent of Pre-War Price
Beef cattle, cents per lb	9 10	16 80	14 70	161
Anthracite stove coal, dollars per ton	3 80	8 00	8 00	211
Bituminous coal, dollars per ton	1 30	11 00	9 00	692
Corn, dollars per bushel	0 70½	1 94	0 95	135
Cotton, cents per lb	13 31	41 50	20 25	152
Calfskins, cents per lb	20	90	18	90
Hogs, cents per lb	8 90	22 1	14 9	167
Crude petroleum, dollars per bbl	0 75	3 50	3 50	466
Para rubber, cents per lb	68½	86	24½	36
Silk, dollars per lb	3 26	21 57	8 03	246
Wheat, dollars per bushel	0 89	3 30	2 22½	253
Wool, dollars per lb	0 68	2 35	1 30	191
Copper, cents per lb	13 5	32 0	16 25	120
Lead, cents per lb	3 9	10 75	7 60	195
Zinc, cents per lb	4 85	21 00	7 30	150
Iron, dollars per ton	13.00	53.00	46.00	354

This table of course represents prices which were current last month, and some changes have occurred since then, but it is no less interesting. On the whole, it would appear that metal producers as a class are suffering no more than other producers of basic supplies.

There is no general relation between present prices and those obtaining before the war. Some commodities, such as bituminous coal, petroleum, iron, wheat and sugar, are still altogether too high, and production has evidently not caught up with demand. Fuel seems to be especially scarce. On the other hand, leather and rubber are cheaper than before the war. Copper is now relatively cheap, and is not likely to drop much farther, and, of course, gold has remained unchanged in price. If prices are to readjust themselves on the old comparative basis, it would appear that iron and lead are due for a considerable fall.

American silver producers, of course, are provided for during the next three of four years unless the Pittman Act is repealed. Zinc producers, it would seem, can hardly expect higher prices for their product, but can look for lowered costs through decreased prices for fuel, labor, and other commodities which they require.

Gold Mining in the Southern States

Recent Development of Mines in That Section Hindered by Absence of Mining Code, Lack of Mining Experience, and Failure to Recognize Limitations—Under Efficient Direction Some Properties Should Be Successfully Operated

By H. A. Megraw
Written for *Engineering and Mining Journal*

THE Southern States contain a vast amount of mineral wealth, much of which is being developed. This is no new fact to most of those familiar with the country. Iron, copper, zinc, lead, and other important minerals are being produced profitably, and the list is constantly widening. Few, however, know that the first authentic record of the presence of gold in that part of North America now included in the territory of the United States was on June 4, 1513, when Ponce de Leon, aboard one of his vessels off the coast of Florida, was told that a cacique, not far away, contained some gold. In 1516 and 1519, Diego Miruelo y Pineda found gold while cruising along the west coast of Florida. In 1527 Panfilo de Narxaez reported the presence of gold, and in 1539 Hernando de Soto found it in what is now the State of Georgia. Not many know that the first experienced miners in California came from Georgia, and that after them came the more highly skilled men from Cornwall. These facts make it evident that deposits of gold really have existed in the Southern States. Also, they, as a matter of fact, still exist.

Mining has not taken a more prominent place among the industries of the South, for several reasons. The early settlers, first of all, were not from a class accustomed to mining, and it probably did not occur to them to look for minerals. Gold does not and never did exist largely in the South in the form of highly concentrated, bonanza deposits. The ores were of comparatively low grade, particularly so considering that in that period extraction methods were primitive, laborious, and costly. Therefore the search for metal was not likely to be as assiduously prosecuted by a people so unfamiliar with the art as it might have been had the deposits been rich in virgin gold and easily accessible.

Furthermore, among the people of the South agricultural principles were well known. The land, exceedingly rich and tractable, made large profits easily obtainable through the practice of a familiar art. What need, then, to dig for gold when its equivalent might be obtained in an easier way?

Indian Tribes Resented Exploration

The native Indian tribes put many difficulties in the way of mining, as they had a strongly rooted reluctance to speak of it to foreigners and fiercely opposed all excursions of Europeans into their domains. And as mines occur in the roughest country, search for them placed the explorers in a position to be easily assailed. Consequently the practice received no encouragement.

The spirit of mining lay dormant for many years, until, in about 1799, John Reed found the famous Reed nugget at Meadow Creek, in North Carolina. This nugget weighed about 17 lb., and so slight was the current knowledge of minerals that it served several years as a door stop, prized only for its beauty as a stone. It was not until 1802 that Reed took his nugget to a jeweler at Fayetteville, who told him it was gold and induced him to part with it for $3.50. Many other nuggets were found subsequently, and mining began in the South. From 1804 to 1807 North Carolina provided all the gold produced in the United States, and all of it came from surface washings and shallow placer operations.

Vein mining began probably about 1825, in Montgomery County, N. C., a locality that has since produced much of the gold output of that state. Production was

DAHLONEGA CONSOLIDATED CHLORINATION PLANT, DAHLONEGA, GA. AN EXAMPLE OF OVER-INVESTMENT IN A SURFACE PLANT

begun all over the Southern territory, from Maryland to Georgia, particularly in the Dahlonega district of Georgia, which became one of the most profitable in the South. Here the discovery of gold in 1829 was followed by much excitement. The mineral lands were claimed by the state and were disposed of by lottery.

West Drained South of Miners in '49

Mining in general prospered for the next twenty years throughout the southeastern region. In 1849 the California excitement occurred, and, owing to the numerous and rich deposits that were soon discovered in the West, and because most of the skilled miners left the East for the more profitable fields of the West, mining in the South dwindled, and has ever since been followed in only a spasmodic and unstable manner.

The beginning of the Civil War put a stop to the small amount of serious mining work done up to that time. Only a little mining has been done since then, and much of that has been so colored with reckless speculation and downright chicanery, mostly instituted by adventurers from other parts of the country, that it has been impossible to distinguish the good from the bad. In recent years, however, mining upon a substantial basis has been

instituted in several parts of the South, and some success has been attained; enough, at any rate, to show that profits are possible.

The traveler through the Southern States who has knowledge of mining will find much to attract his attention and provide food for thought, but such a traveler must leave the beaten track of the tourist and delve into the backwoods where the old indications still remain He will, at times, be surprised to encounter a small sandy area in a clay district, and will be at a loss to account for it until investigation shows that a mine and mill once existed there, and that the sand is the only remaining sign of a milling operation. He will find in another place a miniature canyon carved in a hillside, and, his attention arrested by the glimmer of white quartz, he will note that this is the outcrop of a vein that was worked from the surface and that, having reached the ground-water level, its operators found that the character of the ore had changed and that they had to deal with a pyritic rock from which they could not extract the gold, although it still existed in undiminished quantity. Indications of mines and mining abound, and with the knowledge of what has been done it is impossible to believe that the advances of modern times have not made available these sources of mineral wealth that have been so long burdened with a world of misunderstanding.

Extent of Southern Gold Deposits

The gold belt of the Southern States begins in Maryland and runs southwest through parts of Virginia, the Carolinas, Georgia and Alabama. It is of varying width and richness, but its character is much the same throughout. The area is one of crystalline schists, and the ores occur in veins of quartz and quartzite cutting regions of metamorphosed slates.

The most important and extensive gold-bearing area is the great zone of metamorphic schists and slates extending from southern Virginia, through central North Carolina, and into South Carolina. In this area have been located some of the famous producers, among which may be mentioned the Union, Gold Hill, Russell, Hoover Hill, Fentress and also the only large silver mine of the section, the Silver Hill, in Davidson County, N. C., which was in operation before the discovery of the Comstock lode. In recent times some important properties have came into the producing class in this area, notably the Coggins, Iola, Haile, and some others. In Georgia and Alabama other producers have been opened, and throughout the whole geological formation there is possibility of profitable mining.

It would be a futile and useless task to list the mines of the South or to attempt a detailed description of the rocks in which they occur. The geological bureaus of the various states have admirably accomplished this work, and anyone sufficiently interested may readily obtain information from this source. To those who care to study the subject, however, a word of warning should be given. It will be found that in many cases the cessation of former mining operations came about through lack of available metallurgical processes by means of which to treat the pyritic ores economically. There should be no loss of courage through the acknowledgment of this fact. Modern developments in geology and engineering are sufficient to lead to the reopening of orebodies that may have been lost, and modern metallurgy can confidently promise simple and economical methods of gold extraction, even from the most rebellious ores.

Three principal factors have opposed the successful carrying out of extensive gold-mining enterprises in recent years. None of them presents insuperable obstacles, but no success can be attained without recognizing them and adopting methods to overcome them. The first of these factors is the law. The mining code does not exist in the South, where the landowner is also master of whatever is within or beneath it. This discourages prospecting. No one will search for mineral deposits, because, even if he finds them, he has no commercial interest in his discovery except what may be granted through the generosity of the landowner. Prospectors are not prone to depend upon that feeling. The work is of a kind that entails hardships and privations, so that the one who does it is entitled to a proportionately great reward when success crowns his efforts. Such an expectation is entirely without basis in the South, and consequently there is no systematic search for minerals.

The second factor is the lack of acquaintance with mining principles and methods by the general population. The average inhabitant of the South is not familar with mining, and indications that might mean much to one having such knowledge would be quite without effect upon him. When a people have for generations followed specific industrial pursuits, a part of the knowledge concerning them that they possess becomes in a degree hereditary. Add to this the additional familiarity absorbed unconsciously through environment, and a race is produced equipped to attack, with assurance of success, the problems encountered. The people of the South are not so armed. And this fact presents an obstacle to be overcome.

The third factor in opposition is the failure to recognize the limitations of a developed property, a failure which is the common fault of the Southern miner and the Western man who operates in the East. The local operator is likely to run his business on a penurious basis, failing to recognize the just claim of a good deposit to first-class equipment. Also, the local man is likely to be imposed upon by the manufacturer of freak machinery of the sort conceived in a fevered imagination, manufactured solely to sell and bought only by those not conversant either with the industry in general or the needs of a particular property.

Western operators, on the other hand, accustomed to large and continuous orebodies, often make the mistake of overestimating the resources of a Southern mine. A common error is to cut short development and spend large sums on surface equipment. Not a few Southern gold mines have been saddled with surface plants costing from $100,000 to $300,000, a burden that usually precludes financial success. It is rare, indeed, that such equipment has paid for itself.

Veins Discontinuous and Not High Grade

Southern gold-bearing veins are usually narrow, of low or medium grade, and are not of even value over great distances. Either in strike or in depth the ore-body is likely to be cut off abruptly, and the precious-metal content may change constantly. The limitations both as regards extent and grade must be recognized and dealt with in a reasonable manner; if not, there is little hope of profit; but if due regard is accorded to them a substantial return is reasonably assured.

As has been said, all three of the obstacles to mining

in the South may be overcome. The first one, based on the state of the law, must be overcome by the property owners themselves. Each person who has, or believes he has, upon his property a gold-bearing deposit should explore it thoroughly before attempting to interest anyone else in its possibilities. A simple and reasonable way to perform this preliminary development is to open a series of pits upon the vein outcrops where they appear at the surface. If a man will dig such a series of pits about 20 ft. deep, spaced at intervals of about 200 ft. between his boundary lines, he will have done valuable work in leading to a correct appreciation of his property by obtaining a good idea of its continuity and making possible a correct sampling of the rock. Unless a vein has commercially valuable ore and reasonable continuity, it is worth nothing. If the developments show both of these requirements, it is time to enlist the services of an engineer, who will be able to direct further development and also to provide the owner with a good survey.

The only dependable estimate of the gold content of an ore is based on determinations made in the laboratory by a qualified chemist. These, although correct in themselves, are of no value, however, unless they represent a fair average of the orebody under investigation. Careful sampling is a prime requisite, and so much training is required to do it properly that, for the unskilled man, an attempt at it is merely a waste of time and money. The landower can, however, by panning, ascertain superficially what a sample of his ore contains. Almost every one understands the mechanical operation of panning, and if the operator will be careful to compare each result with the showing given by an assayed ore, taking the same amount of rock to pan each time, he will be able to get some idea of how the rock is running. But it cannot be too strongly urged upon the operator that sampling must be done so as to obtain a fair average of the vein sampled, or the work is worthless, or, worse, misleading.

Landowners Favored by Law

If every proprietor would carry out this operation upon his mineral deposit, then utilizing the services of an expert, he would place himself in a position to turn the legal obstacle to mining into a positive asset. This is because the absence of the mining law dispenses with all claims of doubtful ownership such as depend upon the apex laws. With this advantage the owner is himself the final court of estimate. He knows the value of his property and can sell it at a price he knows to be fair, or he can with equal justice offer it as fully appraised, to be balanced with capital invested by others. At this time the mining industry has passed far beyond the stage of wild speculation, and by intelligent people who understand the advances made in geology, mining, and metallurgy, it is recognized as an industry plainly based upon mathematically estimable factors that can be forecast with an uncommon degree of certainty.

By no means, however, is it to be forgotten that mining has one essential characteristic that distinguishes it from all other industrial projects. This is the fact that every pound of ore taken from a mine reduces its total content by just that amount, and every dollar removed from it reduces its total value by just one dollar. In other industries raw material may be produced *ad libitum* through labor, but no amount of labor will produce an ore deposit.

By removing the difficulty that depends upon the absence of mining law, the greater part of the second one, unfamiliarity with mining methods, will also be counteracted. A proper acquaintance with the true value of a mineral deposit does not come as naturally and intuitively as it does in some parts of the West, but is to be gained through application and thorough study of a clearly defined problem. The greatest difficulty, therefore, will come from inability to recognize the signs of mineral deposits. This faculty can be acquired by study and practice, and the mineral industry of the South will improve immensely when the general public begins to understand its principles.

Available Publications Should Be Studied

Probably the best way to get a preliminary idea of the character of any particular part of the country is to study the publications of the U. S. Geological Survey and of the geological department of the state in which the land is situated. Most of the Southern States maintain geological departments, either as a state bureau or as part of the state university system. The publications of such departments are to be relied upon, and may impart extensive and valuable information to serve as a basis for prospecting.

Southern mining companies have been inflicted with an unreasonable amount of incompetent management. Direction and administration have often been in the hands of some man of local importance, often the original owner of the land upon which the deposit occurs, and in spite of his earnest and honest endeavors he is foredoomed to failure through his lack of knowledge of the requirements. In other instances men are taken from totally different walks of life, apparently upon the presumption that anybody can manage a mine.

Another kind of management, equally bad, is typified by the Western man who comes to the South to take charge of a property. He is accustomed to mining, in a broad sense, but fails to estimate properly the value of the ore deposit. He is accustomed to continuity of value, and it does not occur to him that conditions will be different here. He is likely to place too much dependence upon widely separated samples, a course that will never do with the Southern deposits. Nor must it be presumed that the vein value will increase with depth. That is a myth that has been found generally not to be true anywhere, and it is particularly untrue in the South. Here most of the gold-bearing veins will cease to be profitable at depths varying from 300 to 600 ft.

In mining work in the South it is always best to secure the services of a competent engineer, one familiar with the Southern ore deposits; at any rate this should be done in the formative stages of mine development. The money spent for his services will usually be an ultimate saving, and an infinitely better investment than the purchase of machinery of doubtful value through a cheap but inefficient manager.

In conclusion, it may truthfully be said that some of the gold deposits of the South may be of value. They can be made, by wise and careful direction, to render substantial profits to their owners; but management must be skilful and certain, and the allowable investment must be carefully considered. There is no room for mistakes.

The Gold Miners of South Africa

In April, 1920, a total of 225,457 men were employed in the gold-mining industry of South Africa. Of these, 24,068 were white and 201,389 colored or native laborers.

Mexico's Industrial Progress Since Diaz

Nearly All Railroad Construction Now Under Way Planned Under Carranza — Oil Exports Tripled in Seven Years — Metal Output During Revolutionary Period Indicative of Mining Activities

By JOHN E. KELLY

Written for *Engineering and Mining Journal*

INDUSTRIAL progress in Mexico since the time of Diaz has of necessity been interrupted and below normal, but despite the enormous destruction of property during the revolution, Mexico today is on a firmer foundation than she was on Nov. 20, 1910. The government of President Diaz and the strangle hold of the great landowners on the real estate of the nation were artificial, and the former could last only during the lifetime of its founder. It was bound to end in revolution, and the longer that revolution was delayed, the greater the loss of life and property that must inevitably ensue. The debacle threw the component elements that make up Mexico into a tangled heap, and it has taken ten years to settle them down upon a firm foundation once more. But, now settled, and the abuses of the Diaz and Huerta tyrannies abolished, Mexico faces the future with a brighter outlook than ever before.

Resumption of Industrial Activities

The industrial progress of a country is to be measured in relation to the stability of its government and the facility of communication. Progress in no wise remarkable now would have seemed miraculous to the inhabitants of the isolated villages of the Thirteen Colonies, confronted with Indian wars and impassable roads. That there was any progress at all during the years of the Carranza-Villa-Zapata dissensions, with the attendant paralysis of credit and communications, is evidence of the determination and courage of the native and foreign operators. The rise of Tampico to the position of the premier oil center of the world would have been an achievement of the first magnitude in the most peaceful country.

As an example of the progress of Mexican industry during the revolution may be cited the case of the City of Leon, Guanajuato, the scene of the battle that dealt the final blow to the Huerta regime. This city of 85,000 inhabitants is noted for its exports of shoes, shawls, and leather. In 1909, that is, under the Diaz regime, the total value of exports in the articles listed above amounted to 10,000,000 pesos. In 1919 the sum had risen to 23,000,000 pesos, and for the first nine months of 1920, a total of 20,000,000 pesos' worth of manufactured articles have been produced. This is a showing of which a city untroubled by political disturbances might well be proud.

The Railroad Situation

The railroads of Mexico experienced severe treatment during the revolutionary epoch, but, on the other hand, many miles of new track were laid, and other railways projected and contracts for their construction awarded. Apart from the delays caused by the constant burning of bridges by bandits, and the deterioration of roadbed and rolling stock for want of repairs, owing in part to lack of funds and, later, during the Great War, to the embargo on steel beams and parts, several roads were obliged to suspend operations completely, or at least to run bi-monthly. These included the Mexico Northwestern Ry., the operation of which was rendered exceedingly difficult because of the destruction of the Cumbre tunnel, several branches of the Mexican Ry., and all of the roads within the territory controlled by Zapata and Chavez Garcia.

Credit must be given the Carranza government for its attempt to restore the railways to their former condition, and even to construct needed additions. Nearly all the construction now under way was planned under Carranza, and the important Durango-Mazatlan and Sierra Mojada-Cuatro Cienegas projects were under construction when that government ceased to function. Colonel Paulino Fontes, promoted to be Director-General of the National Lines from his former post as Director of the Mexican Ry., bought over $2,000,000 worth of rolling stock, including forty locomotives, during the last few months of his administration.

The Mexican Ry. has been returned to its owners, the National Lines are either to be returned to, or bought from, the American stockholders, and the Tehuantepec railway is to be acquired by the Mexican government and double-tracked.

New Construction

New railroads, under construction or soon to be, include the following: The extension of the Southern Pacific of Mexico from Tepic to Guadalajara; the completion of the links of the Kansas City, Mexico & Orient from Creel to Estacion Fuerte, and from Falomir to Presidio, Tex., making this road upon completion the shortest route to the Orient, via the port of Topolabampo. A concession has lately been granted for a line that will join Tampico and Matamoros, where it will have connection with the Gulf Coast lines. An electric interurban is to traverse the oil fields between Tampico and Tuxpam; the valuable hardwood forests of Quintana Roo are to be tapped by a new line; the completion of the Durango-Mazatlan line is being rushed, and it is hoped to run the first train by the first of the year. A line starting at Casas Grandes, Chihuahua, will connect with the Nacozari line, giving, in connection with the K. C. M. & O. and the Durango-Mazatlan route, three railroads across the divide and opening up very rich regions. Mexicali will be connected with San Felipe Bay, below the mouth of the Colorado River; Toluca and Zitacuaro will have rail connection; and a new road will be run from the city of Zacatecas to the prosperous towns of Jerez, Villanueva, and Tultenango. In addition, the great bridge on the Pan-American railway at the Guatemalan boundary is under construction. When completed, there will be physical rail connection between northernmost Canada and Nicaragua, and, with only a few miles missing, to the Panama Canal.

More than any other section, Yucatan has suffered from the revolutionary epoch, not so much from the revolution itself as from the ambitious schemes of one of its leaders, and industrial progress may be considered to have practically ceased since 1914. Cut off from easy communication with the rest of the republic, and depending for its prosperity on the sisal harvest, Yucatan has been temporarily ruined through the attempt to implant a new social order modeled somewhat after the first French Revolution; the control of the sisal sales by the formation of the Comision Reguladora del Mercado de Henequen, and the practical monopoly of other commerce by the Compañia de Fomento del Sureste. These companies were permitted to issue bonds in payment of their purchases from the producers, and when, through mismanagement, they both failed, bankruptcy became universal throughout the peninsula. The Comision Reguladora was founded to regulate the price of sisal in favor of producers, as the name indicates, but the arbitrary attitude it assumed toward foreign purchasers, and the lack of a sound financial foundation, doomed it to failure. As the sisal producers were bound to deliver their fibre to the Reguladora and to accept its bonds in payment therefor until such time as the fibre should have been sold, the failure of the enterprise found them with the bonds on their hands, and dragged them down along with it. The Mexican government is now attempting to relieve matters, and has taken over the fleet of steamers owned by the Reguladora in exchange for the government's redemption of the Reguladora's paper.

Yucatan has not only been the victim of bankruptcy, but of the high cost of labor. The leader of the revolution who founded the Reguladora preached the doctrine of Bolshevism and the supremacy of the manual laborer. Socialism has never enjoyed any considerable hold upon the rest of the Mexican people, who are strongly individualistic, but in Yucatan the experiment has been tried—with disastrous results. The *socialistas* forced the scale of wages beyond all reason, a porter demanding a peso for carrying a trunk two blocks, and other labor asking from six to ten pesos for work that paid two to three pesos on the mainland.

The result might have been foreseen. The market was dull, the planters could not redeem their paper, labor was out of sight, and there followed bankruptcy, starvation, and emigration. The socialists found that a supremacy that permitted them to starve was of no value, and thousands have emigrated to the mainland, where the capitalist may rule, but pays.

Mining During the Revolutionary Period
