A new free spirit emanates from every corner, and the population is looking forward for a prosperous and peaceful future. The purely economic conflict with Japan, which occurred in Vladivostok, Habarowsk, and Nicolaewsk, is only one of those natural results of the past turmoil and intrigues of the various political cliques. It will be solved in the immediate future with satisfaction to both parties, and there is no foundation whatsoever for the rumor of a war between Japan and Russia. Such a war would be harmful for both. In the same way, it would not benefit Japan to hold Vladivostok for any length of time, as her retention of that port would mean a commercial boycott of both countries and guerilla warfare for generations to come. This is fully understood by both governments, and they are working now to settle the matter soon. In fact, the Japanese authorities have not interfered with the local administration of Vladivostok, which is in the hands of the Russian institutions.

Traffic Service Reorganized

The Siberian Railway has begun to increase operation and has reorganized the passenger and freight traffic. Regular express trains have begun to run from Vladivostok to Irkutsk, Tomsk, and Moscow. The big rivers are being used during the summer months to take care of the freight accumulated all over the country. This summer will see everything fully re-established, so that a year from now Siberia will have trade and industry in a normal state, at least as it was before the war.

Siberia, having been an agricultural and mining country, has suffered less from the ravages of the revolution than any other parts of Russia, except in the towns and around the railway. The farmers have accumulated enormous quantities of hides, bristles, wool, and grain that could be kept, and have increased their herds of sheep, cattle, horses, and camels. Hunters have not hunted much during the last five years, so the forests are full of wild animals. The people have had plenty to eat, have had fuel and lived retired from the exciting events of the outside world. The mines are unexploited, though the miners have worked here and there is a primitive way, as in the coal mines, and in the gold and platinum mines, which are under the control of the government. The Kuznetzk Mills, the big Lena Gold Mining Co., and various other mills in the Ural section have continued to work with reduced capacity. The Nerchinks Gold and Platinum Mines are abandoned, as here the machinery was ruined by the miners.

Report of Finance-Economic Council

I have received a copy of the official report of the meeting of the Finance-Economic Council (Finanso-Eknomichesky Soviet) at Vladivostok, on March 24, on which occasion Mr. Leonoff, the director of the Industrial Department of Siberia, gave an account of the situation. Leonoff, in his report, emphasized the importance of an immediate reorganization and increase of the river and railway traffic and the building of a railway from the harbor of Alexandrowsk, at the Island of Sakhalin, to the interior mining and lumber regions. The next step of importance, according to his view, lay in the establishment of a special mining reconstruction bureau and the opening of mines that belonged to the government and the companies controlled by foreign interests. The report emphasized the fact that all claims should be investigated by the new government, and justice done to everybody.

The local co-operative societies had already started the establishment of tanneries, canneries, soap factories, and flour mills. When Siberia is organized its dairy products can control the markets of the world, as the butter produced in the Omsk, Semipalatinsk and Tobolsk regions only, would be twice as muh as that of the United States. Siberia will have always the advantage of cheap labor and hay, as alfalfa here grows wild. Leonoff insisted that the zemstvos should liberally help the co-operative societies and farmers' unions in the establishment of big dairies for butter, cheese, casein, and milk sugar, on the one hand, and modern slaughter houses on the other. While the population in Petrograd and Moscow was dying of starvation, the herds of Siberia increased, as there was no market in which to sell the meat.

As the vast territory of Siberia, which stretches from the frozen arctics to the semi-tropics, has forests, mines, plains and riches that represent enormous values, and as the debts incurred by the past régime are comparatively nothing, this part of Russia will recover immediately from the turmoil. The Siberian population has a more practical spirit and greater active energy than that of European Russia; therefore it plays a great rôle in political life. To quote Mr. Leonoff:

"We need in Siberia now most of all foreign industrial co-operation: machinery for exploiting the mines;

We publish this article without subscribing to the views therein. Frank A. Vanderlip, recently returned from the Orient, has this to say regarding Siberia: "In Siberia there is literally no government. There is no money there that is readily acceptable, although there is plenty of paper currency; no banking; nothing necessary for law and order. The Japanese say they have 40,000 troops in Siberia making an attempt to maintain order. They originally went there with the Allies, but the latter and the United States have no policy in regard to Siberia and gradually withdrew their forces. The Japanese went back alone." See editorial, p. 249. —Editor.

machinery for the building of iron, steel, copper, and other plants. We need machinery for paper mills, canneries, tanneries, shoe factories, textile mills and sawmills. We have all kinds of raw material. Our Altai coal region is the richest in the world, and there the iron, copper, and manganese ores adjoin the anthracite fields. We have unlimited markets in China and Central Asia. We have the cheapest labor. Our own Russia will consume for a generation to come everything that we can manufacture.

Foreign Capital Invited

"The industrial policy of Siberia is co-operation between labor, the intellectual leadership, and the government. In order to pursue the evolutionary course, we will propose to foreign capitalists to come and take charge of our mines and mills and bring their machines and engineers. We give the labor and the raw materials. At many places we can give mines and mills which were operated by the past régime or its favorites; and, finally, we take responsibility and guarantee the profits. All we want is co-operation and just treatment of everybody. But we will not tolerate criminal exploitation as used to be, or corruption and all the methods of an autocratic government. More important than anything else, we will guarantee that there will be no strikes or destruction of any property, and see that always a fair profit is made by everybody.

"Therefore our proposal to foreign capital is this: Bring us your machines and engineers, and we will give the rest. Should the foreigners not like the agreed profit, we pledge ourselves to repay the value of the machines and other expenditures. We realize that a perfect state of co-operative industry cannot be established immediately, as some communists think in European Russia, and we admit that there should not be a hostile capital and labor, and the government should not be hostile. Our principle is harmony between these three factors in commerce and industry. We fully admit that the intellectual and talented mind should control physical force, but that control should not consist in economic but in purely moral power.

Local Government System

"The Siberian zemstvo government has concluded peace with the soviet government of European Russia, and is in many ways like the latter. The difference between a Russian soviet and Siberian zemstvo is merely in details and in certain forms of administration. The Siberian zemstvo is practically the same institution as in the state government of the United States, only with the difference that the provincial zemstvo of Siberia is far more independent from the central government than is an American state from the Federal Government.

"Besides, the Siberian provincial zemstvo consists of the county zemstvo only in certain major matters, but not as much as a state controls a county in America. Finally, there is the *mir* of the local district, or the *volost*, which, again, has its individual governing body for the immediate locality. Matters of land and forest concessions, in many cases even of mines and mills, depend not upon the central, provincial, or county zemstvo, but upon the peasant community, the *mir*. The zemstvo and soviet system of government is therefore the most free government imaginable and the possibility of rule by politicians is excluded. Though independent locally, zemstvos and soviets are united morally, and a concession granted a foreign capital by a local zemstvo is traditionally not objectionable to the provincial or the central zemstvo.

"Therefore dealings regarding concessions have to be conducted with each local administration; yet these all have their executive secretaries in a town like Vladivostok or Irkutsk, where the preliminary negotiations can be carried on till the final sanction has been granted. Also, the present government honors all the concessions and rights that were sold or granted to any company in the past by a municipal or local government. All that Siberia objects to is the method and way the Czar's régime granted such concessions, which were without any exception fraudulent, and contradictory to the local interests.

Function of General Government

"It is only matters pertaining to national questions, as the general financial policy, the declaration of war, making of peace, negotiations with the foreign countries, postal, railway, telegraph, shipping and other services, that are decided by a federal board, elected for one session only from all the provinces of the republic. Therefore dealings in matters pertaining to a mining, industrial, or trade question in Siberia are to be concluded with the Siberian local governments only.

"The Siberian zemstvo government is at this particular moment most favorably inclined to the manufacturers, engineers, and business men of the United States, and will be greatly pleased to grant to those the most favorable privileges and concessions and give preference over those of any other country except China. The American troops and their leaders in Siberia won the love and confidence of the whole Siberian population, and the American engineers left the warmest memories among the population wherever they came in touch with the people. Siberia is grateful to those who are her sincere friends; therefore what our local governments might even not accord to our own promoters, they are happy to grant to the Americans. We are a hospitable people."

This semi-official statement of an important functionary of the new government is a sufficient proof of the opportunity that an American business man or manufacturer can expect now in Siberia. Though there will not be a chance to heap billions in Siberian enterprise, as it will be under the control of the government, there will be a fine opportunity and an enormous field for new activity. One thing is sure: industrial enterprises will not be subject to taxes and bribes, blackmails of politicians and bureaucrats, but all transactions will be open for everybody.

Siberia Seeking Democracy

Democracy, the power of the people—that is the tocsin of new Siberia. Never before in the history of the nation has Siberia been shaken so strongly in its fundamentals as at present. Probably in no country in the world was the government so misrepresentative of the people as was the old government of the Czar.

It is the Siberian people and their qualities that eventually will show forth in their new institutions, just as the character of the Saxon has asserted itself in English institutions, and as it was the character of the first American settlers that molded the United States into what it is. For what the Siberian peasant is today, that, quickened and refined by education and by the stir of larger interests, will the Siberian population be tomorrow.

More than three hundred years ago Russia began to exile here the political offenders and the followers of new religious sects. Later the Department of Justice exiled here all the common criminals, with the exception of petty thieves and burglars. Those exiles became farmers, hunters, or miners, and they usually organized their individual colonies. Then emigration was encouraged, and young couples who found the village too limited for their energy wandered out to Siberia. Therefore it is the village more than the city that is the backbone of all the life and peculiarities; therefore it is the village and not the city that will give the best ideas of Siberia. Out of a thirty million population, only one million or a little more are living in the cities. It is through Vladivostok and Irkutsk or Omsk and Tomsk that the outside world thus far has seen Siberia—a class too highly colored by foreign influences to afford a fair view of a people whose life from time immemorial has been one with the open fields.

The first thing that strikes one on seeing the Siberian rural life is its strong similarity to the American colonies in the West. Like the American settler, the Siberian by his nature is an individualist. He is willing to take his chances in a general mix-up and yet remain an individual socially. Though the American colonist always envied the patrician until he himself settled in a town, a Siberian moujik loves nature and land and comes always back to his village. The European farmers sold their land to the nobility, but the Siberian peasant community never recognized any nobles.

Characteristics of the People

The average Siberian is exceedingly hospitable, generous, simple, religious, and highly emotional. Emotionalism has been, to a great extent, the cause of many Siberian social-political troubles in the past, for a moujik would sacrifice his last property for a cause, an idea, or a venture, regardless of results. You will not find a better-hearted man in the world than a Siberian moujik or Cossack. With all his illiteracy, his lack of education, he is a born artist, a man for whom the æsthetic ends of life are everything. For that reason you will find big municipal theaters, music halls, museums, and schools of drama and dancing in all the Siberian towns. You will find all the impulsiveness of a child-like nature. In all the communal life a Siberian peasant has remained always a strong practicer of co-operative methods.

The "Artel"

Despite the early start which the other nations had over Russia in industrial development, there has quietly grown up in Siberian towns an institution which shows a deep philosophy in the national character. This institution, which is known as the *Artel*, had its origin in the traditions of the village. Though still in a most primitive state, the ancient Russian farmers perceived a truth which the western nations are only now beginning to realize: that it is better to co-operate than to compete. And so, instead of working their fields, selling their products, and purchasing their supplies individually, they acted in groups and divided the profits. Despite the allurements of the "civilization" of the city, the Siberian peasants have continued their barbarous practice of co-operation.

The co-operative tendency is so widespread, both in the rural districts and in the cities—it has taken hold of the people's imagination so strongly—that they cannot conceive any big success in a large commercial or industrial enterprise unless it is based upon co-operative principles. The number of Siberian co-operative societies has increased so fast, and they are so powerful, that they compose the controlling financial force. The co-operative societies form a nation-wide trust. Everybody earns money and is satisfied with the system. This is proof that the Siberian, peasant and workman are instinctively democratic.

The Gentle Dinosaur

Written for *Engineering and Mining Journal*

If some of our readers have difficulty in visualizing the fact that sedimentary or stratified rocks have accumulated slowly as actual layers of sand, gravel, and mud, the footprint of the monster shown in the photograph may bring the conception home to them. This is one of two prints showing through the shale of a 26-ft. coal bed at the Castle Gate mine of the Utah Fuel Co. This airy creature trod the slimy mud (which is now

FOOTPRINT OF GIANT DINOSAUR IN ROOF OF COAL MINE

The photograph was taken by A. C. Watts, chief engineer of the mines of the Utah Fuel Co.

shale) in the swamps where the vegetable layers had previously accumulated to form what is now coal. Note how the mud "squashed" away from his foot—quite as if it had not happened a matter of thirty million years ago, more or less. The gentleman evidently was a three-toed dinosaur, or "terrible lizard," as the derivation of the name indicates. With a paw measuring two feet in each direction (the size of this track), he was really quite a terrible lizard.

The Production of Refractory Brick in the United States may be roughly divided as follows: Silica brick, 18 per cent; fireclay brick, including bauxite brick, 80 per cent; and magnesite and chrome brick, 2 per cent.

Smelting in Namtú, Burma

Trying Conditions During the War — Shortage of Labor, and Supplies Unobtainable — Plague, Cholera, and Influenza Epidemics — Details of Treatment of Lead-Zinc-Silver Ore in Smelter and Refinery

By Arthur W. Jenks*
Written for *Engineering and Mining Journal*

THE lead-silver plant of the Burma Mines, Ltd., up to the spring of 1919, when I left Burma, had experienced many difficulties caused by the war in that region, so remote from manufacturing centers. The plant was not up-to-date, and, during the war, extensive construction to remedy that state of affairs could not be entertained. Early in the war, the activities of German agents in Bangkok were successful in organizing an expedition against Burma. This expedition was promptly met by the British near the frontier, and numerous trials and sundry executions in Mandalay were the sequel. But at one time the matter looked serious in Namtú, and the best possible military measures were taken to repel the expected attack. The Europeans were organized into a company of volunteers; frequent and regular military drills were carried on; and the military organization then started was continued throughout the war. In fact, this local company, furnished with arms by the Indian government, was all the protection that could be provided, as no outside troops could be spared for isolated places like Namtú. As a matter of fact, no fighting occurred, but the time consumed by these protective measures, and the anxiety, were not conducive to the smooth running of a plant.

Up to the time of the entry of the United States into the war, there was much feeling among the British subjects against America. Later, this feeling was lessened; fortunately so, because, in the staff, composed as it was of Americans, English, and Australians, nationalistic antagonisms were developing.

As the war progressed, the Indian government was obliged to become more and more stringent in its regulations to compel the conservation of supplies. Coke suitable for retorts soon could not be obtained, and fuel oil from the Burmese field was substituted. Good belting and belt lacing were very scarce; repair parts for telephones and motors were unobtainable; and coal brought from Calcutta soared in price, and, besides, was difficult to obtain. The government listed the stocks of iron and of other supplies in all forms, in the hands of firms and corporations in India, and put its veto on the purchase of many articles. Yet, owing to the fact that the Burma Mines, Ltd., were listed in "Class A" of the manufacturing establishments, that being the classification given to the essential industries, preferential treatment was obtained. The fate of establishments with lower classification can be inferred. The

*Formerly smelter manager, Burma Mines, Ltd.

shortage of supplies was such as to preclude serious construction work at the plant, and even many most necessary repairs and replacements, such as ventilating hoods at the blast furnaces, were not effected, owing to lack of available material.

In 1918, the price of food began to rise, and the coolies were complaining of the cost of living. Wages in the smelter, by bonuses and otherwise, had to be raised somewhat, and the ordinary roustabout coolie received a rupee (32c.) per day on day wages, about twice what the same coolie would have received in Bengal. On contract the coolies were making from 1¼ to 1½ rupees at the beginning of 1919.

A calamity not directly connected with the war, but which in connection with the war difficulties badly upset regular operation at the mine and smelter for many weeks, was a succession of epidemics. The first, that of bubonic plague, was not so serious; a vigorous campaign against rats, vaccination of Europeans and of many Asiatics, and other sanitary measures checked it. But in August, 1918, cholera appeared, and, almost immediately, the influenza. The European staff were largely withdrawn from their usual vocations and used to form a defensive quarantine cordon around Namtú. Only one case of cholera developed among the Europeans, and by injection of saline solution the victim's life was saved. However, there were a number of deaths among the natives in Namtú. Outside the cordon, along the narrow-gage railway connecting Namtú with Namyáo on the meter-gage Burma railway, the deaths were numerous.

The bodies were cremated, when they could be found; the natives often would not report illness to the doctors, or even deaths. But by far the larger number of fatalities was caused by pneumonia resulting from influenza; the scarcity of doctors was such that it was impossible, for a time, to give proper attention to the large number who were ill. The company maintained in Namtú an excellent medical and sanitary staff, but the work at that time was entirely beyond their capacity. Many physicians had left Burma for the seat of war, and, though the company endeavored to secure more medical assistance, it was impossible to do so. The total number of deaths in and near Namtú was about 200, which was a good record in comparison with most places in India. In the whole of India, the deaths from the 1918 epidemic of influenza were estimated at from five to six million.

The effects of the epidemic of cholera and influenza upon the ignorant and superstitious laborers can be imagined. Only 40 per cent of the men at the smelter and refinery remained, 60 per cent being either victims of the epidemic or frightened away. The worst of the shortage was over by the end of November, but even in mid-winter of 1919, when the supply of coolies from the Chinese Province of Yunnán should have been good, the number of men was insufficient in Namtú, and the wood choppers, of whom there formerly were several thousand, had almost entirely failed to appear.

LEAD SMELTER AND REFINERY, LOOKING SOUTHWEST

Wood Fuel Not as Economical as High-Priced Oil

Until the year 1918, the supply of wood fuel, cut from the surrounding government forest reserves, had been sufficient to supply the roasters, the lead refinery, and the boilers furnishing power for the blowers of the blast-furnace department; but the increasing distance of the timbered areas from Namtú, the higher rates at which

it was necessary for the company's forestry department to let the wood-cutting contracts, the large amount of handling required in the plant, then, finally, the demoralization of the labor market by cholera and influenza, necessitated a sudden and complete change, at the close of 1918, from wood fuel to oil throughout the plant. Despite the high cost of fuel oil at that time, 81 rupees per ton, the change was economical as compared with the wood fuel.

The wood choppers persistently split the wood too fine, and added small limbs, with the object of increasing the cordage; but laborers were too few in the forest in the first half of 1918, and almost entirely absent in the last half, and no output commensurate with the needs of the works was possible. If sound fuel of proper size had been available, very possibly wood fuel might have been as economical as the high-priced Burmese oil; but owing to the scarcity of fuel for many months, old, partly decayed wood, a fuel giving no heat, and many small sticks, were shipped to the works; and this procedure necessitated the opening of the fire-doors with excessive frequency. The great amount of such wood fuel required, and the large amount of iron ore coming from Namyáo, strained the transporting capacity of the company's railway to the utmost, and fuel shortages were frequent. In consequence of the decreased rolling stock available on the Burma railways, threatened famines of oil supply, and of coke, often occurred; though it must be admitted that usually the coke and oil arrived before a serious shut-down was imperative.

Hindus Will Work in Rain, But Yunnánese Will Not

The rainy season is from May to October, continuing somewhat into November. This is the season of labor shortage, because the Chinese generally return to their homes in Yunnán province to work their farms. Besides, the Yunnánese do not enjoy working in the rain, even when, as in our case, they were furnished with rain coats. The same remarks apply to the Mainthas, a border tribe whose territory is partly in Burma and partly in China. The Yunnánese and Mainthas are usually excellent laborers, intelligent and cheerful. Their faces are expressive, and in that respect they differ widely from the Chinese seen on the Pacific Coast. They are very fond of meat, whereas the thin Hindu on whom one must depend mainly in the rainy season for any outdoor labor, eats little animal food.

The Hindu will work in the rain, but is inferior to the Chinese as a laborer, this difference being largely due to the fact that, on the same wages, the Chinese spend more for food than the Hindus. Early in December, the rains having ceased and the weather having become fine, the coolies normally poured into Namtú from the north, and there was labor enough until the beginning of the next rainy season. But large numbers of laborers were sent from India into Mesopotamia during the war, and this fact rendered it difficult to maintain in Namtú the needed quota of men in the various departments. As the sale of opium was permitted in the vicinity of Namtú, and as it was prohibited in Yunnán, confirmed opium smokers remained on the Indian side of the boundary. Such men naturally are nearly useless as laborers, and were only employed in case of dire need.

Though in 1916 and 1917 the shortages of labor in Namtú were not as frequent as in Mexico, they were often prolonged and led to many shut-downs of the furnaces, and delays in repair and construction work; but in 1918, the labor situation became excessively bad. As a result, the men, in the fall of 1918 and on into the following winter, were mainly new to the work, and were the despair of the European foremen. The furnace men often would come for a few shifts and then disappear; it would be necessary to begin again and replace them by absolutely green men. A bonus based on the production, or tonnage per month, and another based on the number of shifts worked in the month, helped considerably, but it was impossible to effect large economies of labor until three new shifts, mainly composed of raw material, had been trained.

Crushing Plant Unsatisfactory

The crushing plant for sulphide ore and iron ore gave much trouble and was not efficient. There were several causes. It was difficult, and sometimes impossible, to crush the iron ore from the Manpwe deposit, because it contained so much clay; there were mechanical difficulties; and it was impossible under the conditions at that time to secure competent men in charge of that plant. The Mong Tat deposit, which was being developed, yielded a hard ore high in iron, and gave no trouble in crushing and screening to ¾-in. mesh. The lead-silver ore itself, from the Bawdwin mine, crushed readily, except when it came from a stockpile, or when it had been wet much in transit by rains.

The roasting was done in six Godfreys running at the rate of 40 tons per 24 hours, and bringing the sulphur down to 11 per cent. They were used as pre-roasters, followed by sintering pots. One Dwight-Lloyd was finished in the fall of 1918, after much delay, and received its charge also from the Godfreys. The calcine from the pots ran between 4 and 5 per cent sulphur; from the Dwight-Lloyd, running at the rate of 90 tons per 24 hours, the sinter averaged 3½ per cent sulphur in material running 16 to 18 per cent zinc.

Dwight-Lloyd Machine Efficient

The selected Bawdwin ore sent to the crushing plant was running 40 per cent lead with 37 ounces of silver per long ton, 22 per cent zinc, over one-half of 1 per cent of copper, and a similar amount of nickel. At the crushing plant, the mixture for the Godfreys was made, and consisted of 25 per cent crushed iron ore and 75 per cent crushed lead ore. Material so high in zinc had not, as far as I was aware, been treated on the Dwight-Lloyd machine, and I naturally felt considerable anxiety until the machine had been tested on our mixture and found efficient. Additional testing and adjustment were necessary to improve costs and methods of operation, and were being carried out.

Our coke was shipped to Rangoon from Calcutta. It contained 22 to 24 per cent ash, and was not as dense as it should have been to obtain proper reduction in the blast furnaces. Usually 14 per cent was used on the charge. Better coke was being made in India, but it was all used by the iron and steel companies on war work. The two blast furnaces ordinarily used put through 180 tons of charge each per 24 hours. A third and smaller furnace had a capacity of 100 tons, and was principally used for the smelting of refinery residues. Of course the iron flux was largely contained in the sinter itself, but there was no arrangement whereby

the iron ore and limestone added direct to the charge at the blast furnaces could be crushed mechanically.

The blast-furnace slags up to the fall of 1918 had run 15 to 16 per cent ZnO. At that time, a small amount of matte was being made, and occasionally a speiss with 25 to 30 per cent nickel. To increase lead fall in the charge and the lead output of the plant, higher zincs were attempted, and were being run successfully, the average for January, 1919, being nearly 26 per cent ZnO, if the zinc is considered to be an oxide in such a slag. But there is manifest impropriety in so doing, as such slags contain 4 to 5 per cent of sulphur. An average slag of that character with a specific gravity of 4.1 ran approximately: Pb, 4 per cent; ZnO, 26 per cent; FeO, 39 per cent; SiO_2, 18 per cent, and CaO, 4 per cent.

The alumina was not determined daily, but was running about 5 per cent. The slag also contained much of the copper and nickel occurring in the ore, because there was no separation of matte. The limestone required for such a zincky slag was much less than had been required previously, and as against the increased *percentage* of FeO in the slag must be placed the lessened quantity of slag produced as compared with the slag formerly used, with 15 to 16 per cent of ZnO. The slags ran well, the tuyères were bright, but there was a decided tendency to form a zincky accretion on the bottom and sides of the crucible.

Dwight-Lloyd Sinter Improved Blast-Furnace Tonnage

The ores sent to Namtú from the mines were entirely sulphides, requiring roasting. The Burma Corporation began its operations on the slags, low in zinc but high in lead, produced in the ancient small Chinese furnaces; but of this material little remained. Consequently, the quantity of ore smelted was limited by the roasting capacity of the plant. Additional Dwight-Lloyds have since been provided. The use of Dwight-Lloyd sinter at the blast furnaces increased the tonnage put through; also, as was to be expected, the lower the sulphur in the roast was, both from the Dwight-Lloyd and from the pots, the better the furnace ran on these high zinc charges. Slag with 4 per cent lead, with 1½ to 2 oz. of silver, with appreciable percentages of copper and nickel and 20 per cent of zinc, can hardly be considered a waste product. In emergencies it can be made to produce lead and silver for the refinery with great rapidity.

As roasting capacity was limited, it was not practicable to utilize any of the Godfreys in the pre-roasting of blast-furnace matte. It was also impossible to export concentrated copper matte, because of the shortage of ships. These facts militated against the normal practice of working up the copper products of the blast furnaces and reverberatory residue furnace as quickly as possible. Baghouses or a Cottrell plant were needed at the refinery and blast furnaces, but during the war it was not found practicable to obtain the materials.

Refinery Had No Kettle Plant

As the necessary kettle plant for dressing and cleaning the blast furnace lead had not been provided, the bullion was run into rakes of molds at the lead well, weighed, and sent direct to the refinery. There it was charged into a reverberatory drossing furnace, the heavy copper-nickel skimming being withdrawn at a low heat. The composition of this was variable, but the following may be taken as fairly representative: Silver, 40 oz. per ton; lead, 62 per cent; copper, 10 per cent; antimony, 2 per cent; arsenic, 4 per cent, and nickel, 5 per cent.

This material was charged into the residue furnace, with the antimonial skimmings from the softening furnace, a small amount of ore from the mine, and the usual coal or coke dust as a reducing agent. The resulting copper matte ran low in nickel, but a speiss was formed abundantly, running 35 per cent nickel, this material being stored for possible future treatment. The speiss often gave trouble in the residue furnace, freezing around the lead tap.

The zinc used for desilverizing came largely from Japan and was of good quality. For example: Silver, 1.2 oz. per ton; lead, 1.21 per cent; copper, trace; zinc, 98.68 per cent; arsenic, trace; antimony, none, and iron, 0.05 per cent.

The percentage of zinc actually consumed was reasonable, but the cost of the spelter delivered in Namtú rose to nearly 1,000 rupees per ton, and the effect on refinery costs can be imagined.

The pressure for the double-cylinder Howard press at the kettles was deficient, and the mechanical arrangements for handling it were slow. These defects were remedied gradually, but the mechanical department was handicapped in many ways by the war conditions. The lead in the desilverizing kettle ran 100 to 150 oz., and when, occasionally, the high pressure was obtained, the assay of the crusts rose to 3,500 or 4,000 oz. per ton.

Wood a Satisfactory Fuel

Scotch coke, followed in 1917 by fuel oil, was used at the retorts; otherwise wood fuel was formerly used throughout the refinery and gave good results. With selected fuel, this was true even of the cupels. But the increasing cost and scarcity of wood fuel, as already explained, combined to cause the change to oil fuel throughout the refinery, which decreased the fuel expenditures. Besides, the Chinese workmen quickly became accustomed to the use of oil, and regulated the heat better than was possible when using the variable wood fuel delivered in 1918.

The Bawdwin ore contains no gold; or, more strictly speaking, there is one ounce of gold to twenty thousand ounces of silver. Consequently, no parting was done. The silver bars as sent to the mint ran about 998 fine, the principal impurity being copper.

A three months' average analysis of refined lead produced in 1917 gave 99.982 per cent lead. The bars of lead as sent to the Indian government weighed 115 lb.; but much heavier bars were molded for the Chinese market, as the import duty on lead in China is reckoned per bar, and not by weight. The Burma Mines Co. furnished the Indian government with all the refined lead it required during the war, 1,500 tons per month. The excess of the monthly production, 300 to 400 tons, went to China and to the local trade. The refined silver was sent to the Indian mint.

Deposits of Inter-Bedded Magnesite and dolomite beds, with small amounts of slate and promising deposits of talc, occur in South Manchuria, according to a bulletin issued by the Guaranty Trust Co. Though the Japanese have secured large areas of the deposits, considerable areas are under the control of the Chinese.

Mining Engineers of Note

W. H. Shockley

REGARDLESS of the merits or demerits of simplified spelling, W. H. Shockley can be credited with having the courage of his convictions in his advocacy of the movement, and, although disliking the notoriety which his views have brought, he is convinced that the measure is a necessary step toward a needed reform. Few American engineers can include in their list of experiences the numerous and extensive travels which have fallen to the lot of Mr. Shockley, and it is probable that his championship of spelling reform is due, in part at least, to his contact with the complexities of many languages. William Hillman Shockley was born in 1855, at New Bedford, Mass. His father was a whaling captain and his mother had been a school teacher. His maternal grandfather was Jethro Hillman, a builder of whaling ships, famous for their durability, and his paternal grandfather was a ship carpenter, a farmer of rocky soil, and the father of fourteen children. Mr. Shockley married May Bradford, an engineer (formerly a U. S. Deputy Mineral Surveyor) and artist, and they have one son. Following his graduation from the Massachusetts Institute of Technology in 1875, Mr. Shockley went to Florida as a surveyor, and later to California. From 1880 to 1893 he was employed at the Mount Diablo mine, Candelaria, Nev., as assayer, surveyor, bookkeeper, and finally as general manager. During this period he built a dry-crushing silver mill that was said to have held the record for capacity at that time. He operated a small gold mine at Grass Valley, Cal., for a few months in 1893, and the two years following studied languages, literature, art, and music in New York and Europe.

W. H. SHOCKLEY

Late in 1896 Mr. Shockley was sent to China by Bewick & Moreing as mining engineer for an expedition headed by William Pritchard Morgan, ex-Member of Parliament, with the aim of obtaining concessions, making loans, and establishing a mining administration. A nearly completed British loan of £16,000,000 was thwarted by Russia's threat to send troops into Mongolia. In 1898 he took over the Shansi concession of the Peking Syndicate. On this journey, Mr. Shockley religiously followed Agent Luzzatti's instructions to "be kind to Chinese," but, despite this kindness, two years later a reward was offered for his head by the Shansi officials.

During 1899 Mr. Shockley spent eight months searching for petroleum and visited the noted "fire-wells" of Shansi, long extinct and now mere seepages of dark oil. During his stay in China he made a collection of porcelains and embroideries, which are now loaned to the Stamford Museum. After leaving China in 1899, he "globe-trotted" through India, took a side trip to Egypt, and in 1900 went to Vladivostok, where an iron tramp steamer was placed under his charge. In this, with a gang of Russian and Korean workmen, Mr. Shockley and some American assistants explored the Siberian coast opposite Cape Nome. No gold was found, but considerable coal was seen. Mr. Shockley had a semi-mutiny among the men, but was able to complete the work planned and examined copper deposits at Petropavlosk, Kamchatka, and gold placers near Gejiga, at the head of the Okhotsk Sea. During 1901 Mr. Shockley examined gold mines scattered over western Australia and in 1902 surveyed a concession in Korea. In 1903 he reported on quicksilver mines in Texas and a gold mine in Peru, where, instead of the tens of millions of dollars reported by the vendors, Mr. Shockley found only a few rich spots of ore guarded by myriads of bats. Later he examined a large property in the Urals, comprising iron mines and furnaces, copper mines and smelter, gold placers and dredges, a chemical manufactory and a fleet of steamers plying on more than 2,000 miles of rivers. The wealthy Russian family owning this domain had invested $10,000,000, and never received a dividend.

Mr. Shockley investigated a concession in the eastern Sudan bordering on the Red Sea and Abyssinia during the early months of 1905, and later in the same year prospected gold and platinum claims which he, in company with a Russian engineer, had located in the northern Urals. Platinum was found on the property, but its occurrence was not in payable quantity. In 1913 Mr. Shockley returned to California, where he now resides.

BY THE WAY

Who Put the Ass in Assay?

Our Bolshevist editor, who never can be tamed, contributes the following comment on Roswheel's letter in our What Others Think department. We disclaim all responsibility:

"Although it is true that the dictionaries all accent the last syllable of the word 'assay,' even when used as a substantive, it is nevertheless true that the first syllable is universally stressed in this country. This in itself constitutes the best of authority, for usage makes language, of which the dictionaries are but the tardy recorders. By gradual change of the spoken language, Old French developed from Latin, and modern French from Old French. It is not the task of spoken language to keep back with the dictionary; but for the dictionary to keep up with modern diction. Moreover, when the same two-syllable word is used both as a substantive and a verb, it is the modern spirit of the language to stress the first syllable when used as a noun, and the last syllable when used as a verb. My dictionary (said the Bolshevist editor) states that 'assay' and 'essay' are substantially the same word, but the meaning of the two forms has drifted somewhat apart. Yet the dictionary stresses the first syllable of 'essay,' used as a noun, and the last syllable of 'assay,' as Roswheel points out. Wherefore (said the Bolshevist editor)? The trouble is (he said) that the dictionaries are not quite up to date.

"Anyhow (he said) I claim that 'Ain't,' to which Roswheel appeals as a horrible example of bad habit, is a perfectly good English word. It is the abbreviation for 'am not.' The proper conjugation of this form is: 'I am not or I ain't; you are not, or you aren't; he is not or he isn't; we, you, they are not or we, you or they aren't.' Can you make a better shortened form for 'am not'? It is in accordance with all the rules of euphony and elision given by the best of grammarians (said he). It has been a good form, hallowed by usage and correct in origin, since before the lexicographers were born, but they had nobody to explain it to them and couldn't find it in the Latin dictionary." (We have given the Bolshevist editor his time. He would have broken out into a defense of spelling "rhyme" as "rime," or some other fool thing, next).

Early Mining in California

"A roving and reckless miner, known as Bill, who had been washing gold on the Middle Fork of the American River, had occasion in 1849 to visit Coloma," says Hittel's "History of California." "There he managed to purchase for eight dollars a bottle of French brandy, which had been laid by for medicinal purposes. Upon drawing the cork, he insisted on the persons from whom he had bought it assisting him in emptying the bottle. Upon their refusing several times, he dashed it violently against a tree and broke it in a thousand pieces. On another occasion in the course of his spree, while paying for something, he dropped a small lump of gold, worth some three dollars, which a bystander picked up and offered to him. Bill, without taking it but looking at the man with a comical mixture of amazement and ill-humor, exclaimed, "Well, stranger, you are a curiosity. I guess you haven't been in the diggings long. You had better keep that lump for a sample." About the same time Bill, finding a congenial spirit in a man from Philadelphia, whence he himself hailed, induced him to join in purchasing a barrel of ale at $3 per bottle and a case of sardines at half an ounce per box. They then, armed respectively with a bottle under each arm, a glass in one hand and a box of sardines in the other, went about almost forcing everybody they met to eat and drink; and finally they settled down by the side of what was left of their refreshments for a general evening entertainment, to which everybody was invited and welcome. Scenes like the above were of frequent occurrence. But sometimes the dissipation wound up with a quarrel or a fight and sometimes bloodshed. Practical joking of the roughest character was also occasionally indulged in. An instance is related of a party of roistering mountain blades getting very full one evening in 1849, when one of them, unperceived, emptied a can of alcohol over the head of another who was somewhat of a bully, and, seizing a candle, set it ablaze. In an instant, "Man on fire! Man on fire! Put him out! Put him out!" was shouted on all sides; and put him out his companions did with a vengeance—many of them embracing the opportunity, in extinguishing the fire, of paying off old scores and effectually curing the bully of any further propensity to indulge in bluster.

No Use for Witchsticks

The State Commissioner of Corporations of California does not believe in so-called "witchstick" methods of locating oil or minerals. "I have no time for or patience with these age-old superstitions," he recently stated, "and, while the men who advocate them may be entirely honest in their belief, yet the fact remains that these methods are questionable and, I believe, entirely unreliable. Permits to sell the stock of corporations are not issued by the Commissioner of Corporations based upon any such representation.

"I have formed no definite opinion concerning the accuracy or value of the so-called 'Vibratile Motion Instrument' which, I understand, is being used to determine the presence of oil and minerals, and any representation made to the effect that this method of locating oil has my approval is absolutely incorrect."

Catacomb vs. Honeycomb

The following description of a Nevada mining property is credited to a Missouri engineer by the paper which published it:

———— ———— should be called the Catacomb Mines of Nevada, for man, with all of the ingenuity that gave rise to the term, could never equal Nature's results there. It is, in fact, a great repository that promises to keep many workers busy for a great length of time, as they uncover and remove the precious metals now known to have been cached by the caprice of forces that combined to create what we call a phenomenon because we do not understand them.

That Missouri engineer was thinking of "honeycomb" when he wrote "catacomb." The latter is about as good a name for a promising mining proposition as "cemetery" would be. Many a mine or prospect is indeed a cemetery of lost hopes. The claims could well have been located with tombstones at the corners, as happened a few years ago in Nevada when a rich strike was made in a certain graveyard. But this condition should never be reflected in the name.

CONSULTATION

Manganese Battery Ore

"Being a subscriber of your journal I am taking the liberty of writing you for some information on manganese dioxide. We are producers and shippers of high-grade metallic manganese ore. This class of ore we have no trouble in disposing of but we have a good grade of pyrolusite that runs about seventy-nine in dioxide which we have been unable to find a market for as a dioxide. A complete analysis of the ore follows:

Moisture	1 20	Calcium carbonate	3 15
Silica	9 00	Calcium fluoride	5 40
Iron oxide	0 43	Magnesium carbonate	1.00
Manganese dioxide	78 73	Gold, silver, phosphorus	
Aluminum oxide	0 92	trace; platinum, none	
		Nickel, copper, cobalt,	none

"You can see it is a suitable ore both for battery and dye purposes. While it is a little high in silica we can get it down to about 6 per cent by sorting. It contains no copper, small iron, no other metals.

"I would appreciate it very much if you would give me some information as to who could use this ore and about what price it should bring"

Manganese ore for use in dry cells or batteries is customarily supplied by brokers to the manufacturers in lots ranging from 5 to 100 tons under guaranteed specifications. There is no general and definite schedule existing in the market for manganese ore suitable for battery purposes as there is in the manganese for use in the steel industry. There are not many known deposits of manganese ore in the United States that are capable of meeting the rigid requirements of battery manganese (less than 1 per cent of iron and not more than traces of nickel, copper and cobalt) and furnishing a steady output—one that will not vary too much in grade. The analysis you present indicates a suitable battery grade or ore. Prices we are quoting for this sort of material vary between $75 and $90 per ton at New York, depending upon the analysis.

The value of an ore for battery use depends upon its content of manganese dioxide rather than upon its metallic manganese content, although naturally the compound is directly dependent upon the metallic manganese. Formerly Russian manganese ore from the Caucasus region was imported, as its richness and unusual purity made it admirably suitable for battery purposes. Analyses ran from 85 to 90 per cent and higher in manganese dioxide and usually contained considerably less than 1 per cent of iron. The analysis shown contains a lower percentage of manganese, but as considerable ore during the war containing but 70 per cent manganese dioxide was used, as the Caucasian ore was unavailable, the analysis is relatively high in that particular. The market for domestic battery ore depends upon the possibility of obtaining richer ore from other sources. The readily available Russian ore, its excellent quality and general superiority over American supplies made competition by United States producers practically impossible before the war. It was only after the Caucasian supplies had been shut off that attempts were made to experiment with domestic "battery" ore to determine the suitability of the various manganese minerals and to define the impurity limits. Battery users have found that by manipulation, results from domestic ores and foreign ores other than Caucasion closely approximate the results from the Russian ore.

Experimental work has shown that minute quantities of copper, nickel, and cobalt are harmful and that fourtenths of 1 per cent of these impurities render the ore unfit for battery purposes. It has also been found that 2 to 3 per cent of iron oxide does not necessarily harm the efficiency of a dry cell. Frequently, however, a 1 per cent limit is arbitrarily set.

The physical properties of manganese battery ore are also important and the ore should be somewhat porous to be most efficiently used in the dry cell. A hard but porous ore has been found to give better results than a hard dense ore, in spite of a higher oxygen content in the latter. Coarsely ground ore gives longer life to the cell than finely ground material. Screen analysis, hardness and density are all important in determining the qualities of a manganese ore.

We would suggest as possible interested buyers dealers who are practically all located in the East, or the manufacturers of dry cells. Consumption of manganese ore in glass and battery manufacture is estimated at 25,000 tons per year.

Relative Output of Electrolytic Zinc

"How does the production of electrolytic zinc compare with the total amount produced in the United States, and where is the largest electrolytic zinc plant?"

In 1919 there was produced 27,056 short tons of electrolytic zinc out of a total domestic production of primary zinc, amounting to 456,743 tons, or roughly 5.75 per cent. In 1918 the production of electrolytic zinc was larger, 39,669 tons, or 7.65 per cent of the total production of 517,927 tons. The following table gives comparative results compiled from U. S. Geological Survey statistics since 1914:

	Electrolytic Zinc	Total Primary Zinc	Ratio in Per Cent
1914	[illegible]	353,049	[illegible]
1915	252	489,519	0 05
1916	12,916	668,343	1 94
1917	26,910	669,575	4 10
1918	39,669	517,927	7 65
1919	27,056	465,743	5 75

The largest electrolytic zinc plant is at Anaconda, Mont., operated by the Anaconda Copper Mining Co., and with a capacity of 150 tons of zinc daily.

Increasing Production of Zinc Dust

"Has the domestic production of zinc dust increased in the past few years?"

The production of zinc dust in the United States

	Tons		Tons
1910	69	1915	1,755
1911	254	1916	2,709
1912	492	1917	5,915
1913	423	1918	6,995
1914	1,004	1919	6,598

shows a gradual increase from 1910 to 1919, with a slight decrease last year, and is given in the table.

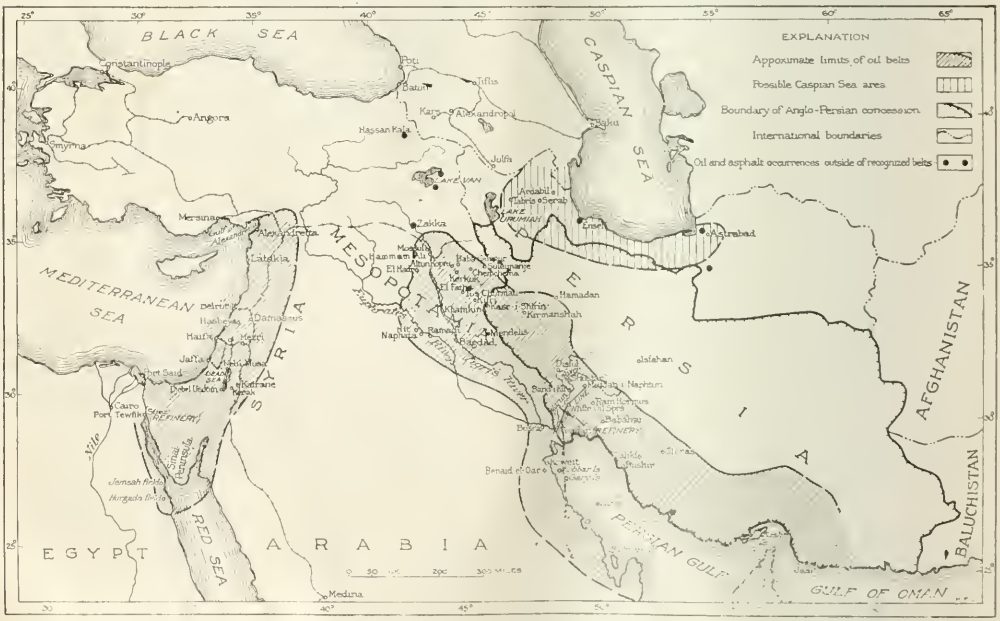
THE PETROLEUM INDUSTRY

Petroleum in Persia and the Near East

Area Comprises What Is Probably the Richest and Most Extensive Oil-Bearing Region of the Globe— Geological Characteristics and Commercial Possibilites—Potentialities of Development Indicated by Recent Changes of Political Control

BY EDMUND M. SPIEKER*
Written for *Engineering and Mining Journal*

IN A RECENT publication[1] of great interest to American oil executives a detailed summary of the occurrence and development of oil in Persia and in the former Turkish territories of the Near East is presented. The work might be characterized as a business man's paper, as it emphasizes, in particular, political and legal matters, the business history of oil concession-seeking, prospecting, and development. In addition, it summarizes in a fairly complete manner the available geologic and other technical data. It is the most comprehensive summary concerning petroleum in these regions yet published, and it is obviously of great value to an oil enterpriser planning a campaign of investigation and seeking a basis for intelligent first action. The author is a scientific assistant in the Hamburg Colonial Institute, and the work is doubtless a byproduct of German imperial ambitions and activities in these Asiatic territories during the period antedating the beginning of the war.



OIL REGIONS OF THE NEAR EAST

The importance of the region as a source of future oil production appears to be of first rank. Within ten years British operations in a single field in Persia have developed an annual capacity of over 30,000,000 bbl. of crude oil, and the scope of territories with similar geologic conditions and surface indications is so great that it seems more than likely that similar exploitation elsewhere in the Near East region could be multiplied many-fold.

With nothing more than normal commercial competition to meet, and under a fair "open-door" policy, these

*Published by permission of the Director of the U. S. Geological Survey.

[1]Schweer, Walther, "Die Turkisch-Persischen Erdolvorkommen. Hbh. Harmburgischen Kolonialinstitats Bd. XL., 1919": (Large 8 vo., 249 pp., with maps and illustrations.)

fields would doubtless be very inviting to American oil interests. At present all of the Turkish territories described are included in the so-called "mandatory area" of the peace-treaty settlement, and are the subject of great diplomatic and political activities, especially by the British, aimed mainly at control of the oil resources.

The interesting surface occurrences of oil in Persia and the Near East, mention of which is woven into the literature and primitive religion of remote periods in the history of these areas, are fully described, the data having been gathered from many sources. These facts, coupled with what little is known of the geology of the region, form the basis for the many optimistic forecasts of the oil possibilities of the area.

A remarkable belt of seepages lies along the entire southwest coast and frontier of Persia, extending in a general northwest-southeast direction into Mesopotamia. It is about 1,200 miles long, and appears to be the longest single stretch of territory, with more or less continuous surface indications of oil, yet found on the globe. In addition to the seepages of this Persian-Mesopotamian belt, scattered showings are known in all of the major divisions of the former Turkish areas, the most important of which are those in Palestine, Syria, and Arabia.

Mesopotamian Occurrences

The northwestern limit of the Persian-Mesopotamian oil belt appears to lie about twenty miles north of Mossul, on the Tigris. A seepage for which an exact locality description is lacking, appears to be the northernmost indication along the belt. To the south of Mossul, at the town of Hamman Ali, there are seepages at hot sulphur springs, some of which are used as curative baths. Oil and asphalt rise continually to the surface of the salt-sulphur water in a small pit at one of the springs. About 80 km. southwest of Hamman Ali, at El Hadr, is another seepage at which the natives collect the oil in pits.

A series of much richer occurrences extends to the south of Hamman Ali, in a zone which is called the Gajara field. This region, which is of great extent, contains many seepages which, having long been active, have built up asphalt deposits several meters thick. In this field the locality at the narrows of the Tigris, near El Fatha, where thick beds of bitumen outcrop in the steep river banks and indications of petroleum are plentiful, is especially worthy of note. Here a soft white limestone is the source of many streams of petroleum and asphalt which trickle down the banks into the river. These occurrences promise to be of much importance, particularly as they are on the line of the Bagdad railway.

To the north of the caravan road from Mossul to Bagdad, at a point about five miles northwest of Kerkuk, are occurrences in which the oil seeps from gypsum beds, running out over the road; and at Baba Gurgur, north of Kerkuk, there is a gas spring. Ten other seepages, the odor of whose petroleum is noticeable at a considerable distance, have been found in the bed of a small stream to the north of Kerkuk. Here the natives have dug pits about twelve feet deep, from which they obtain from eight to ten gallons of petroleum a day. The oil is carried by camels to Kerkuk. Other seepages, of which less is known, exist at Guil, to the east of Kerkuk, and south of Chemchema.

At Tus Churmati, about 20 km. south-southwest of Kerkuk, are several productive oil springs, which have been exploited in primitive fashion by the natives. The source of the oil at this locality is a series of marls, gypsum beds, and highly saliferous red sandstones dipping from five to thirty degrees to the northeast. Other oil springs are in the vicinity of Kifri, about 150 km. northwest of Bagdad, where beds of gypsum yield quantities of salt, sulphur and petroleum.

Farther to the south, about half-way between Mendeli and Khanikin, and on a series of hills approximately 200 m. above the Naphat River valley, an oil-bearing clay-shale is worked by the natives, several dug wells furnishing daily about 100 gal. of petroleum. The oil seeps out on the surface of salt water springs at the faulted crest of an anticline, and flows down the valley-sides to the river, making the water unpotable for a long distance down-stream.

Ancient Asphalt Deposits of Euphrates

On the Euphrates the most important occurrence is at Hit, between Wadi Mohamedi and Kubeisa. The asphalt deposits at this place were known and much used by the ancients, and are today, with the exception of the famous localities in Trinidad and Venezuela, the most remarkable known. The crude working methods of the natives yield about 2,500 tons of asphaltic oil yearly, and those who have visited the place say confidently that the amount could, with little difficulty, be greatly increased.

The oil-bearing formations, which form a series of gypsum beds in layers up to two meters thick, intercalated with sandy clays, are similar in geological association to the beds at Mendeli and Tus Churmati, and have been pronounced of Eocene age. The oil flows freely in numerous springs and at scattered points in valley bottoms about Hit, gathering on the surface of the water, and hardening on exposure to the air to form a brittle substance of the consistency of hard pitch. This is collected by hand as it forms on the water and is used by the natives for many purposes. The oil is highly inflammable. Other seepages of oil and asphalt occur along the Euphrates at Nasrieh, Ramadi, and Naphata.

Near the Turko-Persian boundry, on the pilgrim road from Mesopotamia to the Persian interior, are seepages of oil near the town of Kasr-i-Shirin. The uncertainty of the course of the international boundary at this point makes it impossible to say with certainty whether the individual occurrences are in Turkey or Persia. The oil seeps from a sandstone exposed in a small creek valley on the axis of an anticline in the Tertiary strata which form the hills in the vicinity of Kasr-i-Shirin, and is accompanied by salt water and some ozokerite. In 1901 D'Arcy drilled to a depth of nearly 3,000 ft., with discouraging results, but later attempts are said to have met with more success.

Occurrences in Persia

The principal oil belt in Persia is a continuation of the Mesopotamia area. Extending in a northwest-southeast direction along the western frontier and the Persian Gulf, seepages and other indications of oil occur in well-distributed succession from the region north of Shustar to the southeastern corner of the country, comprising an area about 1,000 miles long and 100 miles wide. Actual production is confined as yet to comparatively small areas, but the success of operations in those areas

which have been drilled, and the similarity of conditions in the remaining parts of the region, promise much for Persia in the matter of oil production.

The topography of most of the Persian oil belt is rough and mountainous. There are only a few regions of low relief in the southeastern part of the zone, along the coast of the Persian Gulf. The northern part of the main belt, which includes the Maidan-i-Naphtun field, is the most important developed oil region in the Near East. Outside of this fairly well-defined belt, there are scattered occurrences of oil in northern Persia, and it is believed that there may be another belt of similar importance along the south shore of the Caspian Sea.

Petroleum Springs Yield White Oil

In the mountains near Shustar, which is one of the largest cities in west Persia, are four petroleum springs which yield a clear white oil that is sufficiently light for use in lamps without refining. The rocks of the vicinity are red sandstone, soft limestone, gray marls, gypsiferous marls, and black marly shale, from which last the oil seeps. The general strike of the rocks is reported to be N. 45° W., and the structure at the seepages is apparently anticlinal. About twenty-five years ago attempts were made here to obtain oil by drilling, and although large quantities of gas were found, there was no resulting oil production.

About 115 miles from Shustar, at Haf Sheid, are seepages which yield small amounts of oil for native use. The source is a bed of light yellow loam, rich in sulphur and gypsum, and the daily production of three of the springs is 90 liters. Other occurrences have been found to the north of Disful, on the Kir-ab plain. The oil springs are in a deserted spot surrounded by the high Bakhtiari Mountains, and are worked by the inhabitants of the region, the production of the year 1850 being approximately 20,000 kg. Strata of sandstone, marl, and gypsum in disturbed position form the surrounding region.

The Rich Maidan-i-Naphtun Field

To the east of Shustar lies the producing field of Maidan-i-Naphtun, where the Anglo-Persian Oil Co. has enjoyed great success since 1908, in which year D'Arcy drilled the first well. The oil-producing region is situated in the foothills of the Bakhtiari Mountains, a wild and barren spot which in summer is intensely hot. Evidences of oil are to be found on every hand for great distances about, and following the unsuccessful attempt in the district of Kasr-i-Shirin and in the southern part of the Anglo-Persian concession, D'Arcy moved the drilling equipment to Maidan-i-Naphtun. His initial success there has been followed by further drilling, the succeeding wells all flowing under strong pressure, and after ten years or more of phenomenal production showing no signs of exhaustion. Several geologic surveys of the region have been made, and the information amassed to date is sufficient to indicate tremendous reserves of petroleum, which definitely establish the position of Persia as one of the world's leading producers of crude oil.

From the Maidan-i-Naphtun field the oil is conveyed by two pipe lines, one six inches and the other ten inches in diameter, to the refinery at Abadan, an island at the head of the Persian Gulf. Upon the completion of pumping stations now building or projected the line will have a capacity of 22,000,000 bbl. a year. The refinery, which had an initial capacity of about 1,750,000 bbl., has been enlarged, and is now able to treat much of the company's production. The oil is reported to be of high grade, containing a very large proportion of gasoline and kerosene of high quality, excellent lubricating oils, fuel oils of good quality, and a good percentage of paraffin.

Karun Valley Wells of Anglo-Persian Company

South of Maidan-i-Naphtun, in the Karun valley, are other evidences of petroleum. Near Band-i-Kir are seepages which have long been used by the natives, and at White Oil Springs, 54 km. southeast of Maidan-i-Naphtun, are producing wells of the Anglo-Persian Co., which are connected with the refinery at Abadan by the pipe line above mentioned. There are no surface indications of oil at this point.

About 250 km. southeast of Shustar, in the general vicinity of Ram Hormus and Shardin, are occurrences of petroleum which have been described by several travelers. Seepages about 16 km. southeast of Ram Hormus afford a local supply of petroleum and a thick oil, which is used as a varnish; and at Shardin are beds of hard bitumen up to thirty inches thick. Shallow wells drilled at Shardin have yielded a good quantity of oil, and a deep well drilled there in 1908 is said to have flowed under appreciable pressure.

A series of occurrences from Babahan, at the upper end of the Persian Gulf, to the vicinity of Jask, on the Gulf of Oman, give ample evidence of the continuation of the Karun oil belt along the Persian coast and in the southern interior. Near Babahan is a locality at which bituminous material oozes out of the rock, and at a point south of the road between Babahan and Isfahan are deposits of asphalt and bitumen.

The most productive occurrences of southern Persia are at Daliki, a stopping place on the road from Bushir to Shiras, 80 km. from the coast. Here oil flows in large quantities from a bed of limestone, and travelers report that in hot weather the air is almost saturated with the vapor of naphtha. The springs are worked on a small scale for native use, and attempts at more extended operations have not thus far met with success. The yield of all these springs has been noticed to increase materially immediately after earthquakes.

Oil Springs of Kishm

On the Island of Kishm, west of the narrows separating the Persian Gulf from the Gulf of Oman, are springs in which the oil issues from a sandstone which is said to be of Lower Miocene age, but which does not seem to be the original source of the oil. Drilling carried on here by the Mining Rights Corporation achieved little success, and later attempts are said also to have proved fruitless. On the mainland opposite the island are small occurrences at Latihun and Chamaevallah, and other indications of smaller importance have been reported from localities in the same general region.

In middle and north Persia are many localities which give evidence of petroleum. There are strong suggestions of an oil zone extending for 600 miles along the south coast of the Caspian Sea, from the Elbrus Mountains, at Ardabil, to Shah-Kuh-i-balae, 40 km. south of Astrabad, and on the east coast seepages are known to exist. However, the geological features of the region are too little known to admit of more than a supposition.

The petroleum zone of Kasr-i-Shirin appears to be continued through the Province of Kermanshah as far as Hamadan and perhaps farther. Oil springs have been reported in this region, and De Morgan states that oil is brought to market at places in the province, but here the evidence is likewise too meager to permit of definite statement. Drilling in the Province of Kermanshah has disclosed the presence of gas, but no oil is mentioned.

Arabian Occurrences

On the Arabian side of the Persian Gulf occurrences of oil are known to exist at Basra, where the presence of bituminous matter has been known since ancient times; and on Bahrein Island, where a deposit of asphalt very much like that of Trinidad was discovered in 1902. Indications of petroleum are said to be present also near Koweit, at Benaid el Oar. Travelers sailing along the gulf have reported the presence of oil on the water in the vicinity of Farsi Island, and a similar occurrence is said to be noted between Kubbar (Khubla) and Garu islands. Arabian sailors say that such occurrences are frequently noted in many parts of the gulf.

Further data concerning the indications of petroleum in Arabia are not available, and indeed so little is known of the country, as far as the geology is concerned, that it is not possible to suggest anything concerning its promise as a future source of oil beyond the obvious inference that the indications so far known easily justify further carefully directed investigations.

Syria and Palestine

Occurrences of asphalt and bituminous limestones, as well as showings of petroleum, are distributed throughout Syria and Palestine. Many of the deposits in Palestine were important sources of oil and asphalt in ancient times, and at the present time some of the more favorably located occurrences are being exploited profitably for both local and foreign trade.

On the east coast of the Gulf of Alexandretta, at the upper end of the Syrian coast, several small brooks flowing from Alma Mountain show traces of oil, and in the vicinity of the city of Alexandretta some drilling was done in the 90's, although apparently with no success. Farther down the coast, in the neighborhood of Latakia (Laodicea, Ladikije) are beds of asphalt and bituminous limestone, which are mined at several small villages, the most important of which is Kefrie.

In the Beirut province, 56 km. south-southeast of the city of Beirut, are deposits of asphalt at the town of Hasbeya, in the upper Jordan valley on the west slope of the Hermona Mountains. Here occur beds of pure asphalt as thick as 4 m., and much greater thickness of limestone containing 10 per cent of bitumen, from the rubble of which the asphalt is extracted either by solution in benzine or by mechanical concentration of the crushed rock. The yearly production of the locality is said to be between four and five hundred tons of asphalt, which could be increased by better methods.

There is a very rich deposit of bituminous limestone in the valley of the Jarmu, a stream flowing into the Jordan to the south of the Lake of Genesareth, at which place drilling just before the outbreak of the recent war is said to have disclosed petroleum at a depth of 400 m. Outcrops of asphaltic limestone have been noted at Mrani, about eight miles from Mezrib, at Ain-el-Tineh, north of Damascus, and at Sunuhre. Seepages of petroleum are found between Katrane and Kerak.

The region about the Dead Sea has been known since ancient times for its deposits of asphalt, and at present the natives exploit the better occurrences by rather crude methods, though, despite the good quality of the asphalt, and its consequent high market value, the trade in it is not actively carried on, and production is small. The asphalt, which is apparently the residual product of partial evaporation of petroleum, occurs in Cretaceous limestones and sandstones, in Pleistocene formations, and in the Dead Sea itself as floating lumps, which, having been separated from deposits along the shore and on the sea bottom, are brought ashore by the natives for local consumption.

Asphalt Masses Recovered From Sea

On the southern coast of the Dead Sea, southwest of Masada and near Djebel Usdom, is an asphalt conglomerate which contains 18 per cent pure asphalt. Not far distant from the asphalt outcrop are several oil seepages. On the northeast coast, in the lower course of the Wadi Muhamvat, the upper Cretaceous dolomites are veined with asphalt, and are of rather high bituminous content. On the east coast are seepages of a viscous, barely fluid asphalt at Ain-el-Hommar, where the asphalt gathers until the mass breaks off and falls into the Dead Sea. In the Juda desert, at Nebi Musa, on the northwest shore, are bituminous limestones which have been reported to contain 25 per cent of asphalt, and which are burned by the natives to make lime for plaster.

At many other places in the Dead Sea region the Cretaceous limestones and sandstones are charged with bituminous material. The occurrences of greatest importance to the natives, however, are the masses which rise occasionally to the surface of the sea and under the influence of the wind and waves drift to the shore. It has been noted that after earthquakes unusually large masses make their appearance. Following the shock of 1834 there appeared a mass from which the Arabs obtained twenty tons of pure asphalt, and after the earthquake of 1837 another mass, from which fifteen tons were obtained, rose to the surface. Smaller masses, which appear at the surface from time to time, are gathered by the native Arabs and sold at the market in Jerusalem.

Prospecting and Exploitation of the Oil Fields

Legal Considerations

The apportionment of mineral land concessions in Turkey and Persia has always been purely a political and diplomatic procedure, involving negotiations between diplomats and capitalists, and in consequence the matter of national interest has figured prominently even when the mineral rights have been sought by private individuals.

A source of much difficulty in the settlement of territorial rights has long been present in the form of the Turko-Persian boundary disputes. The uncertainty of the location of the national frontier, particularly in oil-bearing regions, has led to questions of concession tenure and caused considerable trouble, particularly to English companies whose oil fields are in disputed territory.

Since the Turko-Persian War of 1823 a long series of attempts at reaching a decision concerning the boundary has failed, despite the activity of numerous commissions and deputations of both interested and foreign powers.

Co-operation between England and Russia brought about an understanding between Turkey and Persia in 1913, the result of which was the erection of 223 boundary monuments, but the matter is not yet entirely settled.

The most important points on the boundary are the Karun region, the Kasr-i-Shirin district, and the Urmia region. In the Karun region the English interests have protected their holdings by reaching a friendly agreement with the Sheik of Mohammerah, but the boundary in the Kasr-i-Shirin district has been the source of conflict between Turkish and Persian troops, and as, through Turkish invasions in 1913, the region about Tschiasurk then became Turkish territory, the question of boundary regulation at this point in particular has become an important political problem.

Other difficulties in the exercise of concession rights have been found in the application of the land laws of Turkey and Persia. The Turkish law in particular was very complex and difficult to apply. Divisions of land into classes which were hard to define, and mining conditions which were not easy to follow, made prospective development a rather unsure undertaking, and it is to be hoped that the distribution of authority over Turkish territory resulting from the war will bring about a simplification of the law.

Persia has no definite mining law. According to the Persian constitution of 1906 the granting of concessions was put within the power of Parliament, but an exception was made if the interests of the Persian government or people make advisable a special arrangement, and in such cases the consent of the Parliament was not necessary. However, these conditions have no practical interest at present, as under existing conditions they are no longer in force.

Petroleum Concessions in South Persia

The weakness of the Persian government and the strength of Russian-English competition were important features of the history of concession granting in Persia during the nineteenth century. The advance of loans, and even military protection by stronger powers whose subjects were interested in developing natural resources, brought the Persian government nearer and nearer to complete dependence on outside assistance, until at present the production of mineral commodities, particularly of petroleum, is almost entirely in the hands of foreign interests.

The first grant of importance, the Reuter concession of 1872, was the cause of much international strife. The result of a strong political movement on the part of the English, it embodied sole rights to practically every branch of commerce, including not only natural resources of all kinds, but also building and manufacture, banking, railway building and operation, and general financial activity. It failed, as did many other attempts on the part of outside interests, to establish business in Persia between 1872 and 1888.

Failure of Persian Bank Mining Rights Corporation

After the opening of the Karun River to shipping in 1888, the number of concessions increased greatly. The Persian Bank Mining Rights Corporation, Ltd., in 1890 gained the privilege of exploiting undiscovered mineral land, but after spending its capital in fruitless exploration the company failed in 1894, and the French lost an opportunity to gain mineral rights of considerable value, chiefly through the counter-activity of the Russians and the English, in 1898. The history of English control of the oil industry in southern Persia begins with the granting to W. K. D'Arcy, in 1901, the rights of the Persian Bank Mining Rights Corporation. The detailed conditions of this agreement were not published beyond the statement that 16 per cent of the net earnings of the company were to go to the Persian government.

In 1909 the Anglo Persian Oil Co. was formed to take over the D'Arcy concession. (See summary for details.) An important feature of this grant was the promise of full protection to the enterprise from attack by hostile natives, and a guarantee of reimbursement for loss by damage to any of the property of the company. In a country as wild as the Persian interior this is a provision of great value. In 1914 the British government entered the company, obtaining important representation on the directorate, and later arrangements made the government the dominating interest.

TABLE I. SUMMARY OF CONCESSIONS AND CORPORATIONS IN SOUTH PERSIA SINCE 1901

Date Granted and Term	Owner	Character, Rights, and Locality	Remarks
901-60 years	W. K. D'Arcy	Monopoly for the exploitation, sale, and export of petroleum and its products in all of Persia excepting the five northern provinces.	1. All unimproved lands offered free of cost and taxes. 2. Exemption from import or export duties. 3. Sixteen per cent of net earnings to be paid to the state. 4. After 60 years properties and improvements revert to the state.
1903	First Exploitation Co.	Established for development of the D'Arcy concession. First operation in the Karun River region. Later limited to an area of one square mile in the Maidan-i-Naphtun field.	Founded by D'Arcy with the aid of the Burma Oil Co.
1905	Concessions Syndicate, Ltd., Glasgow.	Established for the development of the D'Arcy concess on.	Mainly owned by Burma Oil Co.
1906–110 years	Persische National Bank	Prospecting and development of meta's from vacant and state-owned lands.	Presumably a German corporation.
1909	Anglo-Persian Oil Co., Ltd., London.	Formed to take over the D'Arcy concessions and most of the stock of the First Exploitation Co., and the Concessions Syndicate.	Control of directorate by British Government
1909	Bakhtiara Oil Co	Subsidiary of Anglo-Persian.	
1915	Tanker Co	Subsidiary of Anglo-Persian.	

Russian Concessions in North Persia

Before the war Russian political and economic influence in northern Persia was so great that no other powers considered the territory in their search for mineral land, but recent developments have made the tenure of monopolies there a matter of doubt, and the strength of any national interests will naturally depend on the outcome of the diplomatic negotiations now in progress.

The history of Russian attempt at monopolization of the mineral resources of Persia begins with the plans for railroad and highway construction made in 1874 and 1882. Both of these plans failed, but later arrangements, details of which are set forth in the following table, afforded Russian capital the opportunity to com-

plete for itself a thorough grasp on the natural resources of the northern provinces of Persia, and from the date of the first successful enterprise of Mr. Sapekhdar in 1896 the record of Russian activity is one of success. With the granting of the concessions of 1916 (see summary) the monopolization of the petroleum resources of Persia was made complete.

Concessions in Mesopotamia

European capitalists began to take active interest in Turkish mineral resources in the middle of the nineteenth century. The Crimean War, which brought Turkey into the group of larger European powers, was followed by a period of business activity in the East, during which banks were established by the English and French, and the first attempts at extensive exploitation of the oil occurrences were made. Most of the early schemes for the development of Turkish oil territory failed, and, indeed, during the entire latter half of the nineteenth century no important progress was made toward the discovery and utilization of the petroleum resources.

Between the years 1854 and 1875 a swarm of speculators entered Turkey, the absence of sound business principle in their dealings being a drawback to development, and the panic of 1875, with its attendant political unrest, made it unprofitable for foreign interests to concern themselves with Turkish prospects for a number of years. During this time several unsuccessful attempts were made by the Turks themselves to produce oil.

In the time of Abdul Hamid further political turmoil held back development and increased Turkey's dependence on outside powers. The result of these disturbances was an increase in the keenness of competition among foreign powers in their efforts to gain political control in Turkey.

In the period just preceding the recent war several companies are said to have been formed, but nothing has been heard of activity on the part of any one of them. The shortage of fuel and illuminating oil in Mesopotamia during the war brought about an attempt to increase local production, but such efforts as were made did not achieve much success.

American Interests' Activities

American interests began to try to gain a foothold in Turkey in 1910, when the "Chester Project," believed to have been sponsored privately by the Standard Oil Co., was involved in a long series of negotiations concerning the construction of a railway and the exploitation of the mineral resources, chiefly oil, on either side of the right of way; but the concession asked was not granted. French capitalists, too, became interested in Turkish oil land at about this time.

The progress of advance made by German capital toward obtaining oil rights in Turkey, which began in 1903, is not entirely clear. In 1905 the Deutsche Bank sent a commission to Mesopotamia to study the oil lands, the substance of whose report was that the occurrences appeared to be local in extent; and that there was not sufficient evidence of continuous oil-bearing horizons to warrant the large expenditure involved in drilling in so distant and inaccessible a place. They considered that it might be worth while to drill at Gajara. The most prominent members of this commission were Dr. Kissling, of Berne; Dr. Backing, of Strassburg; and Dr. Cesare Porro, of Rome. As a result of the unfavorable report of the commission the Deutsche Bank allowed the concession rights of 1903 to lapse.

TABLE II. SUMMARY OF RUSSIAN CONCESSIONS IN NORTH PERSIA SINCE 1896

Year Granted and Term	Owner	Character and Locality	Remarks
1896–99 years	Mr. Sapekhdar.	Development of oil resources in Tunekaoun, Rujur, and Kalale-stag.	
1902–75 years	Russian Discount and Loan Bank.	For the construction of a road from Julfa via Tabriz to Kasuin and for exploitation of petroleum and coal 63 9 km. on both sides.	Twenty per cent of the returns to be paid to the Persian government.
1915–99 years, beginning one year after the end of the world war.	A.M. Khoshtaria.	Purchases Sapekhdar concession for 50,000 rubles, and acquires exclusive prospecting, development, and export rights for petroleum, gas, asphalt, and ozokerite on all other state and private lands for 70 years.	Sixteen per cent of return to be paid to the Persian government, and 6,000 rubles for the salaries of Persian commissioner Advance of 100,000 rubles to the state. Royalty of one kopeck per pood. Owner has right to dispose of the concession and to form subsidiary corporations Free importation of all materials and free use of state lands.
1916	Russian Persian Oil Production & Trading Co., Repento.	Acquires Khoshtaria concession.	All preliminary investigations to be completed not later than one year after the end of the world war.

TABLE III. SUMMARY OF CONCESSIONS IN MESOPOTAMIA

Year Granted and Term	Owner	Locality and Terms	Remarks
1903–99 years	Société Imperiale ottomane du Chemin de fer de Bagdad.	Concession to build railroad from Konia to Basra with branch lines. Mining rights in territory 20 km. on either side of railroad. The company to receive 350,000 francs yearly from the Turkish government to defray expenses.	Concess on for exploitation of oil fields not settled. Commission to study [illegible] appointed 1905. Rights transferred in 1912 to [illegible] Petroleum Co., in which the [illegible] as part owner, was given [illegible] of £20,000.
1910	Ottoman-American Development Co. "Chester Project" Dr. B. M. Glasgow, representative for J. G. White & Co., New York.	Negotiations entered into concerning construction of railroad from the Black Sea to Mossul and exploitation of mineral resources 20 km. on either side of line.	Concession not granted.
1914	Turkish Petroleum Co., London	Development of oil fields in Vilayet M[illegible]	Acquired rights of concession of 1903 Originally 50 per cent British, 25 per cent German and 25 per cent Dutch.

Importance of Near East Fields to England

The economic importance of the Mesopotamian oil fields to the English, due to their proximity to the holdings of the Anglo-Persian company in Persia, is clear; and it is interesting to note that the boundary disputes, which threatened constantly to change the political control of some of the oil fields, caused the English little anxiety, as their interests were protected by the Anglo-

Persian concession as long as the territory remained under Persian control, and an agreement with the Turkish Grand Vizier Hakki Pasha (?) gave them promise of concessions in Mesopotamia which would guarantee the safety of their holdings in the event that the Turks gained the territory.

Concessions in Asia Minor, Syria, and Palestine

The isolated petroliferous occurrences of Turkey have also been the object of negotiations concerning concessions. In 1889 a company was formed in Basel, Switzerland, with a capital of 5,000,000 francs, for the purpose of exploiting oil springs at Dschebel Musa, near Antioch, and others on the Gulf of Alexandretta, but after three years of prospecting the company failed. During the years 1892-1895 the Vereinigten Deutsche Petroleumwerke drilled at Alexandretta, with no success.

The occurrences in Vilayet Erserum have been sought by several groups of capitalists. They are said to have been granted to a Turk in 1906, and later several international financiers supposedly obtained the concession. In 1914 the Standard Oil Co. sent men to prospect the locality.

TABLE IV. SUMMARY OF CONCESSIONS IN ASIA MINOR, SYRIA, AND PALESTINE SINCE 1906

Year Granted and Term	Owner	Locality and Terms	Remarks
1906	General Zeki Pasha	Oil concessions in Vilayet Erserum.	
1907	Company for construction of Hedja Ry.	Oil rights at Heraclea.	
1909–99 years	Société minière syrienne Haiffa	Oil and asphalt rights in Vilayet Damascus	Took over older concessions.
1912–99 years	Syrian Exploration Co., Ltd., London.	Took over rights of Société minière syrienne, including 60,000 acres of oil land in Vilayet Damascus.	Royalty of 10 per cent, including annual rents of 10,000 francs. Under direction of Dr. G Schumacher, Haiffa.
1913	British Ottoman Oil Syndicate, London	Negotiates with E. A. Abravanel for purchase of a concession in the village Ayghim Veran, Boyobad district.	
1913	Prince Jussuf Pasha Kamel	Development of petroleum and asphalt in the Beirut province.	
1914	Standard Oil Co., New York	Examined concessions in Vilayet Erserum.	
1915	Latakia Oil Co	Asphalt and oil production at Latakia	Purchase of older concessions.
1916	Standard Oil Co., New York	Prospecting for oil and asphalt in the Dead Sea region	Acquired seven oil concessions southwest of the Dead Sea from local owners, as well as the sulphur, bitumen, and phosphate deposits of the surrounding region.

Many attempts have been made to mine on a large scale the asphalt deposits at Latakia, but difficulties of transportation and handling the material prevented the success of the undertakings. The summary given herewith gives the essential details known of other concessions granted and operations carried out at Beirut and in the Vilayet Damascus.

In 1914 the Standard Oil Co. sent a corps of geologists, engineers, and laborers to explore the Dead Sea region, and the party had just completed organization in the field for carrying out the work when the outbreak of the war put an end to its activity.

Concessions on the Red Sea

Many English companies are producing oil in the territory fronting the Red Sea. For a long time the operations were carried out by a large number of small companies, which later led to the formation in 1911 and 1912 of three larger companies, the Fersan Islands Oil Co., the Anglo-Egyptian Oilfields, Ltd., and the Eastern Petroleum Co. The Anglo-Egyptian Oilfields, which is a branch of the Shell Trust, controls the fields at Jemsah and Hurgada, whose annual production reached 128,998 tons in 1917, and owns the refinery at Suez, which is connected with Port Tewfik by four pipe lines and has a monthly capacity of 15,000 tons. As the production of the Red Sea fields never has quite equaled the capacity of the refinery, the company has accepted crude from other fields so that it might utilize the full resources of the plant, and in the earlier days of the Anglo-Persian activity in Persia, part of the Maidan-i-Naphtun oil was treated at Suez.

The Eastern Petroleum Co., which is an outgrowth of the Sinai Petroleum Syndicate, owns three concessions on the Gulf of Suez. The Fersan Islands Oil Co. was formed in 1912 to work oil lands on the Fersan Islands, at the south end of the Red Sea.

Brief Notes on the Geology of the Oil Belt

The geological characteristics of the regions mentioned in this report are known only in incomplete details. With the exception of the region surrounding the Maidan-i-Naphtun field, which has been studied by the geologists of the Anglo-Persian Co., geologic knowledge of the Persian oil territories, being almost entirely the result of hurried examinations, is fragmentary; and even less is known of the other regions in the Near East. Over most of these countries the only regions which have been brought to the attention of the outside world as possible oil fields are those in which seepages or other showings of petroleum exist. The vast areas in which development might be successfully guided by detailed geologic information have not been touched, and a comparison of the sum total of geologic exploration here with that of any of the great producing fields of today shows at once the tremendous opportunity offered by the practically unknown territories of southwest Asia.

In the Mesopotamian-Persian belt the oil occurrences are situated in the low hills skirting the main mountain ranges, in a zone about 1,200 miles long, parallel to the general direction of the Persian Gulf. The mountains, which in places attain elevations well above 16,000 ft., are formed mainly of older rocks overlain by Cretaceous and Tertiary sediments, and the slope from the mountain wall to the valley of the Tigris and Euphrates, on which most of the oil seepages have been found, is formed mainly of Tertiary beds.

In Mesopotamia, Maidland has distinguished four anticlines, all parallel to the general trend of the belt. The largest extends from a point northwest of Mendeli to the Tigris and thence northward to Hammam Ali. A second extends from Khanikin to Altun-Kopru; a third lies parallel to the Kara Dagh, and the fourth extends to the northwest from Suleimanje. The surface formations of this region are all Tertiary, and are apparently chiefly Miocene in age.

In the Maidan-i-Naphtun field the chief petroliferous beds are members of the Fars series, of Miocene age. A portion of the Tertiary section of this region is as follows:

Bakhtiara series, Pliocene, 15,000 ft.	Upper.	massive conglomerates.
	Lower:	clays, sandstones, shales, conglomerates.
Fars series, Miocene, 7,200 ft.	Upper (arenaceous):	clays, shales intercalated red and brown sandstone.
	Middle (transition):	clays, shales, intercalated gypsiferous limestone and sandstone.
	Lower (gypseous):	massive gypsiferous shale, clay, and intercalated limestone. *Main oil zone.*

The oil occurs chiefly in detrital vesicular limestones of the Lower Fars series. There are seepages from the Middle Fars at places, but the only locality at which it has been tested by drilling is at White Oil Springs, where a show of white, naturally refined oil was encountered. The Upper Fars is in general considered unpetroliferous.

The structure at Maidan-i-Naphtun is anticlinal, with many minor modifications and faults. There is also an anticline at White Oil Springs.

Along the coast of the Persian Gulf, in the southeastern extension of the Mesopotamian-Persian oil belt, most of the seepages issue from the Nummulitic series of the Eocene and Oligocene, with a few occurrences in the Fars. As a whole, the region does not appear as promising as does the Bakhtiari country, but in the absence of detailed knowledge no intelligent prediction can be made. The presence there of members of the oil-bearing series, together with surface showings and a series of anticlinal structures along the south coast, will undoubtedly offer sufficient encouragement to warrant thorough investigation within the next few years.

On the Island of Kishm, at the narrows separating the Persian Gulf from the Gulf of Oman, there is a series of gentle domes lying along an axis whose strike is E. N. E.-W. S. W., and extending the length of the island. The Upper Fars beds form most of the island, but there are outcrops of the Hormuz (Upper Cretaceous) series, and of the Tersai (Pliocene) series.

Conflict of Geological Opinion

The geology of the north Persian area, the possible belt along the southern shore of the Caspian Sea, is not only imperfectly known, but there is a difference of opinion among the men who have thus far reported on it. In the region between the Caspian Sea and Lake Urumiah the formations are apparently chiefly Tertiary in age, with some areas of Carboniferous rocks. At Ardabil, extensive shell beds are found resting on Pliocene sediments similar to those at Baku. The structure is apparently complicated, with much folding and faulting. To the east of Tabris are Mesozoic formations, with deposit of rock salt and gypsum, and about Serab carboniferous shales are found.

To the south of Serab is a long anticline, along which oil and gas are said to escape at places. The question as to whether this general region is geologically a continuation of the rich Baku field has given rise to disagreement among the geologists who have visited it. Tiehe thinks it is not to be connected directly with the Baku area, and others apparently believe that it is. Beyond the fact that locally, at least, a similarity to the Baku geology has been reported, not enough is known of the region to justify definite statement of conditions.

In the Dead Sea region the asphalt, which is undoubtedly the product of the evaporation and oxidation of petroleum, occurs in Cretaceous dolomites and to some extent in Pleistocene deposits. On the Red Sea a Miocene series which has been correlated with that of the Mesopotamia region is present. Oil is produced from the horizons on the Egyptian side, but so far more is known on the Arabian coast of the sea.

TABLE V. SUMMARY OF CONCESSIONS AND CORPORATIONS ON THE RED SEA SINCE 1907

Year	Owner	Conditions, Locality, Capitalization
1907	Anglo-Saxon Petroleum Co., Ltd., London	Total capitalization to 1914, £18,000,000. Subsidiary of Shell-Royal Dutch combination.
1907	Egyptian Oil Trust	Took over shares of Cairo Syndicate and later in part absorbed by Anglo-Egyptian Oilfields.
1909	Eastern Petroleum Co.	Oil concessions on the Jubal Islands. One concession on the Gulf of Suez sold to the Suez Oil Co.
1910	Suez Oil Co., London	Formed to buy twenty-five square miles of oil land on the Gulf of Suez near Anglo-Egyptian properties from the Eastern Petroleum Co., the Jemsah Syndicate, and the Isthmian Oil Co. Also obtained four concessions at Jemsah from the Egyptian Government.
1910	Red Sea Oilfields	In part absorbed by Anglo-Egyptian Co.
1910	Sinai Petroleum Syndicate, London	Purchased from the Cairo Syndicate twenty-five square mines of prospective oil lands on the Gulf of Suez.
1911	Anglo Egyptian Oilfields, London	Absorbed many minor companies. Egyptian government represented on directorate and owns shares. Properties at Memsah, Hurghada, and on Gulf of Suez.
1911	Asiatic Petroleum Co. (Egypt), London	Selling organization of Anglo-Egyptian.
1912	Fersan Islands Oil Co., Ltd., London	Purchased from the Turkish government concessions on the Fersan Islands, at the south end of the Red Sea.

Pipe-Line Construction in Poland

Work is proceeding on the construction of an oil pipe line from Drohobycz to Danzig, 621 miles in length, according to *Kurjer Warszawski*. Some time ago a pipe line was constructed from Baku to Batum, a distance of 683 miles. This pipe line has as object the pumping of petroleum directly from its sources to the Polish littoral and its exportation thence in foreign bottoms, supplying on its way the different Polish towns.

Oil and Coal in Costa Rica

The Sinclair Oil Co. has spent about $50,000 in drilling for oil in the Pacific slope area of Costa Rica, but the results have not been encouraging. The company still holds a government concession, but has allowed some of its private land contracts to lapse. There are indications of oil also on the Gulf of Mexico slope, and though options have been taken there, no work has been done to explore in this part of the country.

In the gulf slope region, coal has been discovered, and efforts are being made to interest American capital in its exploration. It is claimed to be a bituminous lignite and to be fairly high in carbon, with a high volatile content and no sulphur. As practically no coal is used in Costa Rica, owing to the climate and the great abundance of cheap electricity, the market will have to be found outside, either at Panama or in Cuba.

NEWS FROM THE OIL FIELDS

July Production in Coastal Fields Shows Gain

Other Districts Increase—Wildcat Wells in Eastland County, Tex., Heavy Gassers

From Our Special Correspondent

The coastal fields made a large increase in production during the last week in July. No. 1 Abrams well of the Texas Co., at West Columbia, Brazoria County, the big gusher, has increased its flow to 26,000 bbl. of oil daily. This is being made, too, with the drill stem and bit in the hole. It is impossible to set screen against the tremendous pressure, and some concern is being felt lest the sand coming up with the oil cuts out the casing before the top pressure subsides enough to permit removing the drill stem and setting an oil string and screen. Another big well in this field is the most easterly of the Humble Oil & Refining Co., flowing 10,000 bbl. daily.

An important completion at Hull, Liberty County, is the No. 14 Phoenix of the Gulf Production Co., which came in at 2,600 ft., making 4,000 bbl. of oil a day.

In Stephens County the production has also fallen off a little. New wells are being brought in frequently in the Breckenridge town site field, and apparently this district will develop into a larger producer than at present. In the Caddo field of this county the American Oil Engineering Co. has worked over its Standard No. 2 well, securing an initial production of 2,000 bbl., and which it is believed will stabilize at about 2,300 ft. A pipe line was completed last year, making 4,600 bbl. a day, and subsequently went dead.

Two wildcat wells of great interest were completed in Eastland County recently. One, the Terry Jacobs well of the Rising Star Production Co., is two and one-half miles northwest of Rising Star. This well is making a small production by flowing by heads from a depth of 2,460 ft. It is also gassing heavily. Storage capacity is being built before testing the well out further. The other wildcat well is the Prewett of the Pittsburgh Western Oil Co., half way between Carbon and Sipe Springs. It is making a small flow by heads from about 2,300 ft. A pipe line is being built.

The Texas Pacific Coal & Oil Co. has brought in a big gas well, the Riebe well, eight miles north of Strawn, Palo Pinto County. This well is said to be making thirty to forty million cu.ft. of gas daily from a depth of 3,700 ft. The Garner well, also a big gas producer, southeast of Strawn, is also owned by this company. It is believed that the district may develop into a large gas producer.

Oil Placer Claims Take Precedence Over Homesteads

From Our Special Correspondent

Homesteaders who have recently been filing on oil-shale lands in Garfield County, Col., are facing the loss of their homesteads if those who have previously filed placer claims avail themselves of their rights under the law. It appears that considerable land north of the valley of the Grand River in Garfield County have been designated as oil-shale lands, and are to a large extent covered with oil-shale locations. These lands are also being entered under the homestead law, resulting in conflicting claims between homesteaders and placer claimants.

As to the rights of the respective claimants in a situation such as this the Commissioner of the General Land Office at Washington has advised the local field division of the U. S. Land Office that the placer law as to oil shale is repealed by the leasing act of Feb. 25, 1920, since which date no further placer claims may be initiated for oil-shale lands. However, as to oil-shale placers located prior to the leasing act, if same were lawful, complete, and perfected by discovery prior to the act, the land being vacant and open to location at the time the location was made, such claims would operate to segregate the land. The claimant of such a claim would doubtless prevail in a contest against a conflicting subsequent agricultural claimant. In such a case the placer claimant should proceed to protect any interests he may have, as the land department has no record of mining locations in the absence of an application for patent. In case the land is covered by a mineral application for patent no other application should be allowed, but if the agricultural entryman is prior in time to the placer locator such location would be ineffectual unless the agricultural claim was an entry under the grazing act, which reserves all minerals subject to appropriation under the existing mineral laws.

High Prices Stimulate Formation of New Companies in California

The high price of crude oil has led many interests in California to form new companies during the last few weeks. The majority of the companies plan to develop the southern sections of the state, having in view the country about Orange, San Diego, and the Imperial Valley. Much work in the southern fields has been held up from lack of materials. The Shell Co. plans spending several hundred thousand dollars in the development of the new oil field in the Buttonwillow district, thirty miles west and a little north of Bakersfield.

Large Gas Well in Barren County —Other Kentucky Fields

From Our Special Correspondent

A gas well said to be the largest ever found in Kentucky, and estimated at a production of 50,000,000 cu.ft. of gas daily, was brought in on the B. L. Smith farm, in Barren County, last Wednesday by Merry Brothers. Oil men of Louisville who have discussed the report seem inclined to accept it as an accurate estimate.

Stockholders of the Old Dominion Oil Co. during a recent meeting voted for the consolidation of the company with the Superior Oil Corp. to form a new syndicate belonging to the Atlantic Refining Co. The deal has been pending since May 3, and has been reported "closed" and "off" several times. The meeting today ended negotiations. The price was announced as $5,923,007.25. The company owns extensive holdings in Lee and Estill counties.

In Warren County three fair-sized wells were brought in on the T. G. Sledge, Bailey, and Potter leases. These wells will produce between 300 and 500 bbl. daily, it is estimated. No. 3 on the Sledge lease was brought in last week, estimated as 25 to 30 bbl. The Houston Coal & Coke Co. shot a well on the farm owned by William Davenport's heirs, estimated at 30 bbl. per day. Haskell & Kerstatter, owners of the Perkins lease, shot No. 2 last week.

Calcasieu Parish, La., Active

From Our Special Correspondent

At Edgerly, Calcasieu Parish, La., the old No. 29 Bright-Penn well of the Gulf Refining Co., which was worked over and brought in July 27, making 15,000 bbl. of oil a day, has been reduced to 1,000 bbl. daily by the encroachment of water. This well when first completed several months ago made only 75 bbl. of oil daily, but deeper drilling recently induced the larger flow.

In this same field the White Oil Corporation and Mrs. L. H. McMullen, of Dallas, Tex., have begun drilling on the 950-acre lease of the Union Sulphur Co. south of the present field.

At Vinton, Calcasieu Parish, the largest completion recently was the No. 7 Gray well of the Rescue Oil Co., pumping 500 to 600 bbl. daily. The chief operating companies in this field are the Gulf Refining Co., Texas Co., Gum Cove Oil Co., Rescue Oil Co., and the Vinton Petroleum Co.

Several rigs have begun drilling in the vicinity of Buffalo Gap, in the Black Hills section of South Dakota. The possibilities of oil drilling in the central part of the state will be tested before fall, as the contracts for drilling rigs have been let for a test well a short distance from Fort Pierre.

ECHOES FROM THE FRATERNITY

SOCIETIES, ADDRESSES, AND REPORTS

"China—Future Mecca for Engineers"

Many Problems Await Honest Engineering Heads—Native Talent Offers Adequate Help—People Favor America

Under the above title Roy A. White writes entertainingly in *The Transit*, published annually by the College of Applied Science of the University of Iowa. "China," he writes, "today offers perhaps the greatest opportunity for the engineer of any country on the globe. A nation of four and one-third million square miles of territory, with over four hundred millions of thrifty, hard-working people. They have only some six thousand miles of railway, very few factories, and scarcely any of the modern improvements that we, in this country, deem necessary to everyday life. . . . With an area a third greater than that of the United States China has approximately one fortieth of our railway mileage; and in terms of per-capita per mile, while we have one mile of railway for every four hundred inhabitants, China can claim only one mile for every seventy thousand of its people."

Mongolia is comparable in area to our great West, and though it covers one and one-third million square miles it has not a single mile of railroad. Sze-Chuan (how many of our readers ever heard the name before?) an enormous inland province of seventy million people, also has not one mile of railroad; and in this province wheat brought 10c. a bushel during the war when it was selling for $2.50 a bushel at Shanghai!

Nevertheless, in 1918, China had 5,790 miles of railroads.

"Of this mileage 3,793 miles were classified as 'Chinese Government Railways,' 1,847 miles as 'Concessional Railways,' and, besides, there were about 150 miles of private lines in operation. There were also 330 miles under construction, and if one were to take into account all the lines contracted for the figures would reach the 100,000-mile mark with little difficulty. One who is not familiar with local conditions may reasonably ask, 'Why don't the Chinese build their own railways?' Owing to the lessons of the past the Chinese have learned not to put up money for corporation uses, for, more often than not, these funds find their way into the pockets of the officials, and the railroad, or whatever the project may be, never sees more than the first stages of construction."

Railway investments in China have been remunerative; in 1917 a net surplus for all roads of over $21,000,000 having been shown from operating revenues of nearly $64,000,000. Railways prove profitable in the beginning, being built into thickly populated districts.

"Most of the roads," Mr. White observes, "have foreign executive and engineering staffs; for instance the Peking-Han-kau line, having been built with Belgian capital, employs only Belgians on the staff, aside from the Chinese. There being no American railroad in operation, aside from a thirty-mile section noted elsewhere, there is no demand at present for American engineers. But it is hoped our financial interests will soon begin investing in that field, and then there should be a considerable demand for engineers' services. At the present time the ground is being laid for what may develop into enormous works in a multitude of fields: mining, railways, manufacturing, irrigation, forestry, and other lines."

The author points out that the Chinese in the past have accomplished great engineering feats. The canal system is thousands of miles in extent, and was begun 4,100 years ago. The Emperor Yang Ti started the Grand Canal from Shantung Province to the Yangtze River, hundreds of miles distant. During the last few centuries the canal became silted up but is now being reopened by American dredges, as a result of the researches of the American Red Cross into the causes of floods and famines.

"Another enormous engineering task which the Chinese accomplished was the building of the Great Wall. This wall has become known as one of the wonders of the world. It was built by various emperors, extending over several scores of years, and was constructed for the purpose of keeping in check the invasions of the tribes to the north and west.

"The wall starts at Shan-hai-kuan on the seacoast, two hundred miles east of Peking, and winds, in a circuitous route, westward about 2,000 miles to the northwestern corner of Kan-su, adjoining Mongolia on the north. There are many spurs to the main wall as well."

The writer observes that this great wall was built with great engineering genius, and that the lime and brick are wonderfully well preserved. He closes his article with a notable philosophic reflection:

"To the foreign well-wishers of China, who, on the one hand, see scattered all over the land such evidences of the constructive skill of that once powerful race, and on the other hand the present helpless state of affairs, a country with its customs and other taxes collected and administered by foreign powers, with its postal system and railways under the control of and built by other nations, it is a pitiful sight and one worth studying by the leaders of those countries that are all-powerful in this day and age, lest in some future generation they too shall have suffered a like fate. Had China's rulers and officials always been as efficient as her engineers, builders and workmen, we would not see the largest country in the world today the least able of any power to protect itself from grasping neighbors."

Minerals Separation Claims and Methods Explained to Utah Mining Men

George L. Nye and Gilbert H. Montague, attorneys for the American Mining Congress, who attended the Minerals Separation hearings in New York, San Francisco and Salt Lake City, were the guests of local mining men and operators at a smoker given in their honor at the Alta Club of Salt Lake City, Utah, recently. Mr. Nye and Mr. Montague gave an interesting review of the general flotation situation in connection with the methods of the Minerals Separation corporation. The point of attack is the system whereby the corporation, by claiming the right through its contracts to all improvements on the patents made by licensees, seeks to perpetuate its monopoly,—claiming also all rights to machinery inventions and to information gained in flotation operations. The company seeks an entire monopoly of flotation in as much as when over one per cent of oil is used claim is made under another patent. No objection is made to the payment of fair royalty, although the rates asked by the company are often excessive, and should be lowered. The Minerals Separation company has very complete lists of users of flotation processes, and classification is made according to whether the users are successful and in good condition for the exaction of royalty. Classification is made by states and districts, and according to what courts the hearings will come before in case the company claims infringement. An elaborate spy system is maintained so as to keep track of the operations of users of flotation processes and their methods.

Board of Regents Can License

The Attorney General of the State of New York has ruled that the Board of Regents has the right to license the prospective members of the examining board under the new registration law and then appoint them to the board of examiners. The Board of Regents had contended otherwise.

Book Reviews

The Examination of Mines in China. By E. M. di Villa. Cloth, 6x8, pp. 108. Printed by the North China *Daily Mail*, Tientsin, China.

The remoteness of China from the haunts of most mining engineers, the totally different language and customs of that country compared to those with which Americans and Europeans are familiar, and the absence of any organized geological survey, combine to make China comparatively unknown to most of us. If suddenly called to go there to examine some property many difficulties would be met. This excellent little book has been written to make it easier for those interested in mining in China to write a comprehensive report and to understand the information which a report should convey. Books of a like nature describing conditions in some other foreign countries would be a welcome addition to technical literature.

Simplicity characterizes the text. Much information is given which should be read by young engineers whose only interest in China consists in trying to persuade Charley Sing to return their laundry by Saturday night. Several pages are devoted to the basic principles of mine examination and the preparation of a report, information which applies as well to work in this country as in China. A part of the book, also of general though somewhat elementary interest, discusses ore formations and the important igneous and derivative rocks, with references to Chinese examples.

The last half of the book gives brief descriptions of the various mineral industries, separate sections being given to coal, iron, antimony, tin, zinc, gold, platinum, silver, mercury, copper, mica and oil. Representative mining costs and some valuable Chinese conversion tables occupy the last few pages.

Those who are familiar with "Mineral Enterprise in China," written by William F. Collins, and published two years ago, will find Mr. di Villa's book quite unlike the other, in that Chinese political history and conditions as affecting the mining industry receive but scant attention. We understand the edition is limited, but the author tells us he shall be pleased to send a copy to any engineer interested in China.

E. H. R.

Technical Papers

Asbestos—The Department of Mines of Tasmania has issued a thirty-one-page bulletin on "Asbestos in the Beaconsfield District." Unsuccessful operations were conducted in the Beaconsfield asbestos district, Devon County, Tasmania, from 1899 to 1901. A revival of the industry in 1916 led to active exploitation of the best deposits known, but after two years' activity the pockety nature of the deposits, and greatly increased cost of operation, led to a cessation of mining for a second time. The purpose of the inquiry outlined in this bulletin was to determine the continuity of the deposits, and the possibility of so modifying methods as to develop continuous successful operation.

The fibrous serpentine of the area consists of picrolite, a coarse splintery variety, and chrysotile, which is the commercial fiber. Although a maximum fiber length of 4 in. has been noted, the bulk of the fiber runs from $\frac{1}{8}$ to $\frac{3}{4}$ in. A discussion of the origin of the deposits is followed by a description of the mining properties. An unusual feature is the presence of certain places of abundant fibrous magnetite. The low-grade character of the deposits may be inferred from the fact that the marketable fiber in the more important deposits constitutes only 1 per cent of the rock quarried, whereas in Canada it averages between 5 and 6 per cent. The description is comprehensive, the deductions are reasonable, and in general the publication is a valuable addition to the literature of asbestos.

Manganese—U. S. Bureau of Mines Bulletin No. 173, 209 pages, (price 30c. from the Superintendent of Documents, Washington, D. C.) is possibly the most complete and authoritative book on the subject of manganese which has been published. The eleven chapters are devoted to general information; uses of manganese other than in steel making; problems involved in the concentration and utilization of domestic low-grade ores; preparation of ore; leaching of ores with sulphur dioxide; the Jones process for concentrating ores; cost of producing ferromanganese ores; production of manganese alloys in the blast furnace; importance of allocating low-ash coke to the manganese-alloy furnaces; electric smelting; and the use of manganese alloys in open-hearth steel practice. The bulletin represents the results of work done in the course of war minerals investigations and the chapters enumerated above have already been issued separately in mimeographed form. About 95 per cent of the manganese consumed in this country is used in the steel industry. The manganese deposits of the United States are, with few exceptions, irregular, pockety, and uncertain.

Mine Warnings—Technical Paper 244 of the Bureau of Mines. (price 10c. from the Superintendent of Documents, Washington, D. C.) describes experiments on the use of stenches as a warning in mines. Several substances have been used, the most favorable being butyl mercaptan, but there is no commercial source of this substance at present. However, a manufacturer is experimenting with a view to producing it. Ethyl mercaptan, butyric acid and amyl acetate are also satisfactory. These substances are injected into the compressed air line and soon permeate every part of the mine workings. In cases of fire, the unusual smell serves as a warning to the miners to come to the surface. Suitable ventilation must of course be provided to clear the mine air after using such warnings.

Recent Patents

1,347,200. Treatment of Zinc Solutions Preparatory to the Recovery of Zinc by Electrodeposition. David Avery and Rowland T. D. Williams, assignors to Electrolytic Zinc Co. of Australasia Proprietary, Ltd., Melbourne, Victoria, Australia. Filed July 25, 1918.

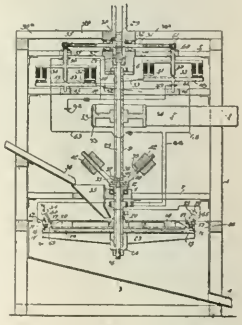
In the treatment of zinc solutions containing cobalt preparatory to recovery of zinc by electrodeposition the method of removing cobalt which comprises precipitating the cobalt by means of zinc dust in the presence of arsenic.

1,346,819. Flotation Process. Rudolf Gahl, Denver, Col., assignor, by mesne assignments, to Pneumatic Process Flotation Co., New York, N. Y. Filed Dec. 10, 1918.

A process of concentrating ores by flotation which consists in introducing additional sand substantially free from slimes into the normal pulp and subjecting the mixture to froth flotation.

1,344,519. Centrifugal Ore Separator. John Ainsworth Rice, San Francisco, Cal. Filed June 25, 1919.

In a machine for separating materials differing in specific gravity, a separating element mounted for rotation and comprising an upper member having a central inlet opening, a lower



ring-like member, a peripheral discharge opening being formed between said members, and a table between the members, and of less diameter than the members, said table extending over the opening of the ring-like member and forming with said members an annular peripheral chamber.

MEN YOU SHOULD KNOW ABOUT

Sidney Paige is engaged in an underground study of the origin of the ores of the Homestake mine.

E. O. Ulrich has just completed a study of the correlations involving Devonian and Carboniferous formations.

Kirby Thomas has returned to New York after an examination of salt and gypsum deposits in Tennessee and Virginia.

Will W. Boyer has been appointed a mineral geographer to serve with the land classification board of the U. S. Geological Survey.

F. C. Schrader, who made the original reconnaissance of the Jarbidge, Nev., district for the U. S. Geological Survey, is again in that field making an examination.

Walter L. Remick, recently assistant metallurgist with the U. S. Metals Refining Co., is now test engineer with the Research Corporation, 31 West 43d St., New York City.

D. F. Hewett has been transferred temporarily from the U. S. Geological Survey to the Bureau of Mines in order that he may make his report on Cuban War Minerals Relief claims.

Stephen Birch, president, and **W. P. Hamilton**, director of the Kennecott Copper Corporation, Alaska, are expected in New York this week. They have just finished an inspection of the Alaskan properties.

Marden W. Hayward, mining engineer, recently returned from a six-months' trip into Peru, Bolivia, and Chile, where he was making examinations for the American Metal Co., Ltd. Mr. Hayward's future address will be 263 South Clarkson St., Denver, Col.

J. C. Brumblay, Nevada representative of U. S. Smelting & Refining Co., returned to Reno July 30 from an extended trip into Inyo County, Cal. Mr. Brumblay has now left Reno for Salt Lake City, Utah, where he will take general charge of the field work for the Midvale plant.

H. W. Bell has been appointed to succeed **R. E. Collom** as head of the U. S. Bureau of Mines demonstration work in the oil and gas fields of Texas and Louisiana. Mr. Bell's headquarters will be at Dallas, Tex. He has spent the last three and one-half years as deputy supervisor with the California State Mining Bureau in the California oil fields, being last located at Santa Maria. Mr. Collom, who has temporarily been in charge of the Dallas office for the last six months, is resuming his work in the San Francisco office of the Bureau of Mines in the investigation of oil field problems.

Charles G. Yale is still in charge of the San Francisco office of the U. S. Geological Survey, where James M. Hill is now associated with him. Mr. Hill will assist Mr. Yale in statistical work for certain periods of the year and the rest of the time will act as geologist under orders of chief geologist of the Survey. It will be his duty in that connection to attend to certain geological work in Pacific Coast States, including Arizona and Nevada, to save time by prompt investigations of matters as they come up in the San Francisco office.

H. C. WANG

H. C. Wang, vice-president of the Chinese-American Industrial Corporation, Ltd., has come to this country in the interests of his company and of his native land. The corporation, which is made up of Chinese and American business men, has among its officers some of the most prominent and influential men of North China and its object is to develop direct trade relations with American manufacturers. It would also secure American co-operation in developing China's natural, industrial and manufacturing resources.

Mr. Wang is a graduate of Pekin University and a man of wide accomplishments. He was professor of mathematics at Imperial Tientsin University for five years before resigning to enter business. For four years he was in the Chinese Government Customs Service, and his services during the Tientsin flood of 1916 won him a government decoration. He was also counsellor of the Tientsin Chamber of Commerce, and for 13 years president of the Y. M. C. A. in that city.

Mr. Wang, who is probably the first native merchant of North China to come to this country, is also a gentleman of some property. He is owner of a tannery, of the Yung An gold mine, and secretary of the Kailan Mining Administration, which is the largest coal mining company in China, producing 14,000 tons daily and employing 20,000 men.

Alexander Anderson, mining engineer of Edinburgh, and representative of interests in China and Sumatra, is in the United States for a few months on a tour of inspection to study certain mining problems. He expects to visit some of the principal mining districts here, particularly the oil fields. Mr. Anderson has had an extended mining experience in Mexico and other countries.

OBITUARY

Arthur J. Ellis, a geologist of the U. S. Geological Survey, died in Washington on July 22, after undergoing an operation for appendicitis.

A. J. Sullivan, formerly general superintendent of the Chisholm district of the Oliver Iron Mining Co., died on July 7 following an illness of five years. Mr. Sullivan was born at Eagle Harbor, Mich., in 1866, and spent the earlier years of his life following mining on the Michigan ranges. In 1893 he went to Virginia, Minn., to work at the Auburn mine, and was later transferred to the Fayal and Genoa mines, being made superintendent of the latter in 1900. His authority was gradually extended, until in 1909 he was made general superintendent of the Chisholm district, which position he held up to 1915, when he was forced to give up active work by the nervous disorder which finally caused his death.

SOCIETY MEETINGS ANNOUNCED

Thirteenth Annual Conference on Taxation will be held on Sept. 6-10, 1920, at Salt Lake City, Utah, under the auspices of the National Tax Association. Among the many interesting papers promised, four bearing on the taxation of mines are scheduled for the morning session of Friday, Sept. 10. Among the speakers on that day are Governor Boyle of Nevada, Prof. William Peterson, of Utah Agricultural College, and R. C. Allen, vice-president of Lake Superior Iron Ore Association. Inquiries concerning the meeting and accommodations should be addressed to W. N. Beatty, care of Utah Power & Light Co., Salt Lake City, or to A. E. Holcomb, Secretary, 195 Broadway, New York City.

Lake Superior Meeting of A. I. M. E., the 122d meeting of the Institute, will be held Aug. 20 to Sept. 3, next, the party leaving Buffalo on the "Tionesta" and picking up other members en route. They will reach Houghton, Mich., Aug. 23 for a two-day stay. Parties will leave Aug. 24 for Ishpeming and Vulcan, and all reassemble at Minneapolis, Minn., Aug. 25. The Mesabi Range will be visited on Aug. 27, and Duluth reached in the afternoon of Aug. 28.

THE MINING NEWS

LEADING EVENTS

Number of Abandoned Claims in Mexico Large

Inability To Pay Taxes Under Old Policy and Great Accumulation of Fines the Reason

Mining agents of the Mexican government have been instructed when requested by mine owners to receive taxes one year in advance instead of quarterly only, as hitherto. Further, in the event of any district being in a disturbed condition owing to banditry taxes may be paid in Mexico City upon a proper showing.

According to the last report of the Department of Commerce and Industry there were 51,087 mining claims denounced in Mexico, covering an area of 442,225 hectares (2.47 acres in a hectare). Of this number more than three-fourths have been practically abandoned because of the refusal or inability to pay taxes and the enormous accumulation of fines. The recent presidential decree will probably result in a considerable portion of the owners reviving their claims.

The Department of Commerce and Industry of Mexico has just given out the following statement as to mines actually being worked at the present time in the Republic:

State	No. of Mines	No. of Companies
Durango	412	21
Guerrero	37	4
Guanajuato	97	48
Hidalgo	455	24
Jalisco	81	25
Mexico	110	21
Michoacan	146	42
Nayarit	42	5
Nuevo Leon	376	11
Oaxaca	8	3
Puebla	100	6
Queretaro	20	8
San Luis Potosi	244	18
Sinaloa	116	17
Sonora	316	23
Tamaulipas	28	6
Zacatecas	154	30
Lower California	12	2
Aguascalientes	71	5
Coahuila	206	25
Chihuahua	187	20
Total	3,138	365

A. S. & R. Considering Amarillo, Tex., as Possible Site for Smelter

The American Smelting & Refining Co. is studying conditions at Amarillo, Tex., with the idea of possibly locating a new smelter there. Nothing definite has been decided. The proximity of an abundant supply of gas for fuel at Amarillo is an important factor in the considerations.

WEEKLY RÉSUMÉ

Contempt proceedings, renewed by Minerals Separation against Miami Copper, were again dismissed on July 29 in the Federal court at Wilmington, Del. It is also reported that Nevada Consolidated has admitted infringing on the Minerals Separation flotation patents. A second orebody has been cut at depth in the Stewart mine at Butte by the Anaconda Copper Mining Co., causing a revison of ideas as to the probable life of the camp. In the Joplin-Miami district the United Zinc Smelting Corporation has obtained leases on 2,000 acres of land near Waco, Mo. The coal situation is reported to be easier on the iron ranges of Michigan and Minnesota, though car shortage in the East is still holding up shipments. Suit has been brought against the Inland Steel Co. for wasteful mining methods used by it at the Thompson mine, which it leases. Captain McDougall's suit against the Oliver Iron Mining Co. for patent infringement has been set for Sept. 20.

In Washington the phosphate and sodium land leasing regulations have been approved. Secretary Payne is back from Alaska and planning for the territory's development.

McDougall Suit Against Oliver Iron Co. Set for Sept. 20

The opening of the suit of Captain Alexander McDougall against the Oliver Iron Mining Co. to obtain large damages for alleged infringement of patents in concentrator construction, is set for Sept. 20 in the Federal court in Duluth. McDougall alleges that ideas that he had worked out and patented were used in the construction of the large washing plant at Coleraine, on the Mesabi Range.

Arguments in Utah Power Case Nearing Close

Arguments are being closed in the hearing before the Utah Public Utilities Commission in regard to an increase in power rates which the Utah Power & Light Co. is seeking to impose on some companies having especial contracts. The Utah Copper Co. has just ended its oral argument, in which it maintained that the rates charged under special contract brought adequate returns even under existing conditions of higher costs, etc, and that the valuation of the power company at $42,000,000 was excessive.

The power company argued that the power contracts, having been agreed upon before the creation of the commission, were subject to revision upon the date when the commission was empowered to act. It was also claimed that few of the contracts were made upon rates which today were paying adequate compensation. Other metal mining companies protesting have still to make their oral arguments.

Contempt Proceedings Against Miami Again Dismissed

Court Handles Minerals Separation Application in Record Time—Nevada Con. Admits Infringing

Minerals Separation again appeared before the U. S. District Court in Wilmington, Del., on July 26, with a renewed application for leave to file a supplemental bill charging Miami with renewed acts of infringement. Three days later Judge Morris rendered his decision, in which he denied the application, stating that he found nothing in Minerals Separation's arguments to justify him in a conclusion different from that of his recent opinion (*Engineering and Mining Journal*, July 24, p. 179,) upon the previous application in contempt proceedings which he had dismissed.

The rendering of an opinion on July 13, the hearing of another application on July 26, and the rendering of an opinion denying this latter application on July 29, all within practically a fortnight, is a remarkable record in a case that has been looked upon as of interminable length. Judge Morris' opinion, which is largely a quotation from his previous one, is, in full, as follows:

"This case is again before the court upon an application of the plaintiff for leave to file a supplemental bill charging the defendant with new acts of infringement since its discontinuance of the three processes heretofore adjudged to be infringements (244 Fed. 752).

"When considering the application heretofore made by the plaintiff that the defendant be adjudged guilty of contempt and/or that a further injunction be issued specifically enjoining and restraining the defendant from using the processes therein set forth I arrived at and stated the conclusion that 'in view of the nature of the new processes used by the defendant as charged by the petition, the questions raised thereby, and the decision of the Circuit Court of Appeals in this case (244 Fed. 752), I am of the opinion that the plaintiff must obtain the relief to which it is entitled, if any, touching the new processes, either through the proceedings now being had before the master and the decree to be entered thereon, or by a new bill, and not otherwise. Which of these procedures is the proper one under all circumstances or whether both must be resorted to, one as to some of the processes and the other as to the remaining processes, need not now be determined.'" The words 'new bill' were therein used to indicate a new original bill. I have considered the argument made in support of plaintiff's present application

and find nothing therein justifying a conclusion different from that at which I arrived when considering the petition hereinbefore mentioned. The present application must, therefore, be denied."

NEVADA CONSOLIDATED ADMITS INFRINGEMENT

The Nevada Consolidated Copper Co. has admitted openly that it has infringed that patent of the Minerals Separation North American Corporation governing the use of oil in flotation in amounts less than 1 per cent on the ore. This admission was made before Judge Hale in the U. S. District Court in Portland during discussion of a motion requesting further answers to interrogatories in connection with the infringement suit of the Minerals Separation against the mining company. The period of infringement extended from September, 1914, to August, 1917, when flotation was used in Janney machines.

The suit of Minerals Separation against the Magma Copper Co. has also proceeded another step, although the latter's motion for a bill of particulars has been denied. In this instance Judge Hale said: "It appears. . . . an attempt to force from the complainant a statement of what his endeavor is to be upon certain material allegations in the bill. . . ."

The litigation with the Magma company, as with Nevada Consolidated in the same court, has to do with two patents, one for the use of less than 1 per cent of oil and the other covering soluble frothing agents. As matters now stand each defendant must file answer to the Minerals Separation's bills of complaint before Oct. 1.

Butte & Superior Accounting Hearing Late This Fall

Hearing of the accounting to be made by the Butte & Superior Mining Co. as the outcome of its litigation with Minerals Separation is not expected to take place until late this fall, according to counsel for the latter company. It is said that it will require at least two months more for the Minerals Separation engineers to digest a ten-volume report made to the Federal court by the Butte & Superior, setting forth its side of the accounting. The defendant company asserts that if it is liable at all the damages should not exceed $451,000. The plaintiff claims damages amounting to as high as $18,000,000, asking for all the profits made by the Butte & Superior through the employment of the flotation process.

Atmospheric Nitrogen Co., formed late last year by Solvay Process Co. and General Chemical Co., with authorized capital stock of $5,000,000, has begun erection of the first unit of a plant at Syracuse, N. Y., for the fixation of atmospheric nitrogen. Buildings and equipment of this unit will be completed in about a year and will cost more than $2,000,000.

Would Remove Colorado School of Mines from Politics

Recent Ousting of Mines Experiment Station Last Straw—Prominent Men of State Disgusted

For several months prominent mining men of the State of Colorado have been smarting under the growing criticism of conditions at the Colorado School of Mines. This well-known institution has received more than its share of unenviable notoriety recently on account of the unfortunate and ill-advised action of the present administration in severing relations with the U. S. Bureau of Mines, and thus depriving the school of Federal recognition and co-operation. What practically amounts to the ejection of the Rare Metals Station of the Bureau of Mines on the pretext that the building occupied by the bureau was needed by the school, is the last straw so far as mining and metallurgical men of the state are concerned. Influential mine operators, and others who have the best interests of the Golden school at heart, are determined to devise some means to remove the institution from the control of an incompetent and irresponsible board of trustees that has committed one blunder after another in school administration.

One of the plans under consideration aims to place the School of Mines under an educational board, and probably under the management of the board of regents of the State University. In this event the school would remain at Golden, and in addition to its present functions would assume the research work now conducted by the State Geological Survey. Its work would be coordinated with that of the State University, and considerable duplication of engineering courses would be avoided. Further, an effort would be made to re-establish co-operation with the U. S. Bureau of Mines, by securing for Golden one of the new branches of the bureau, two of which are to be organized in the near future. Friends of the school realize that in order to accomplish this purpose, they must first place the school under a competent and dignified administration, and make it independent of the baneful political influences that have been such a handicap to its advancement for many years.

New Diesel-Driven Iron-Ore Carrier Completed

Cubore, a Diesel-driven ship of 11,500 deadweight tons, is about to make her maiden voyage to Cuba. Built by the Bethlehem Shipbuilding Co. for the Bethlehem Steel Corporation, she represents what is said to be the greatest advance in American marine engineering. She is propelled by a two-cycle, American designed and built, oil engine of 3,200 hp. This ship, which is 496 ft. long, 57 ft. wide and 37 ft. deep, will carry iron ore from the company's mines in Cuba consigned to steel plants in the United States.

Opening of 79 Mine in Arizona Noteworthy

Continental Commission Co.'s Efforts Achieving Interesting Results—Future Considered Promising

The first six months spent in opening up a prospect rarely show a balance on the profit side of the ledger. Mines that have paid from "grass roots" are dreamed of by prospectors but they are not often found. The record of the 79 mine in Gila County, Ariz., though lacking the spectacular features which surrounded some of the famous gold and silver boom camps, is none the less interesting.

The 79 group, consisting of 23 claims, is located in Gila County, near the Pinal County line, in the southern extremity of the Mescal Mountains. The nearest railroad point is Burns, a siding on the Arizona Eastern, about five miles distant by road. The concentrator of the Ray Consolidated Copper Co. and the Hayden plant of the American Smelting & Refining Co., in the deep valley below, seem but a stone's throw from the highest point on the wagon road leading to the mine.

The early history of the 79 mine is not unlike that of thousands of other prospects. It was originally located in 1879, hence the name. For years the principal owner was Mike O'Brien, who had a few associates. O'Brien, a typical prospector of the old school, lived on the property in a tunnel. Having placed on his interest in the property a definite cash value and having formulated hard and fast rules for a sale, the stage setting being his tunnel home, to which capitalists must come with the full purchase price in gold coin, O'Brien never saw the fulfillment of his plans. He was murdered about three years ago, presumably by Mexicans, who believed he had large sums of money with him or hidden in his tunnel.

The administrators of the O'Brien estate gave a bond and lease on the property in December, 1919, to the Continental Commission Co., of which Lee Reagan is president and Miss Alice McFaddin secretary and treasurer. At the time there was no road to the property. Everything was packed in on burros, but a start was made. A five-mile wagon road has been built, over a mile of it being solid rock work. In the meantime the company shipped 31 cars of ore, packing it all on burros to the end of the wagon road, then in wagons to the railroad. The ore, which was shipped to El Paso, returned an average of $1,126 per car after deducting the freight and treatment charges. The company's achievement during its first six months is certainly worthy of mention.

Rising slowly for nearly two miles over long hogbacks of rounded contour composed chiefly of Gila conglomerate the road reaches the older sedimentaries forming the higher parts of the Mescal Range. The mountain sides become more precipitous and the grades steeper. The underlying rock is chiefly

limestone, dipping gently to the east and southeast. The mine is 1,600 ft. above the Gila River at an elevation of 3,600 ft. above sea level in a very rugged section. Here the limestone forms steep-sided canyons, broken now and then by low scarps, which mark a bed harder than its neighbors. The limestone is a hard, compact variety, gray in color and generally magnesian. In places it is more yellowish, a characteristic which is conspicuous on some slopes when viewed from a distance. The thickness of the individual beds rarely exceeds two feet. The limestone is assumed to be the Martin limestone of Devonian age.

Within the limits of the property the only intrusive rock observed was a medium grained porphyritic to granitoid rock occurring as dikes of considerable width and great lateral extent. The rock is probably a monzonite or quartz-diorite.

The orebodies, which have a strike of N 15-20 deg. E and a dip to the south of from 35 to 50 deg., occur in the limestone. The principal outcrop, which is dark red, is very conspicuous, covering a whole hillside owing to the fact that the vein is exposed along its dip. The vein system consists of three parallel veins separated by more or less barren ground. The two outer veins are slightly over 4 ft. in thickness and the middle vein is about 28 in. thick. The ground between the veins varies in thickness from 2 to 4 ft., for the most part barren, though sometimes mineralized to a certain extent. Future development of the property may determine the extent of this mineralization and make it possible to mine with profit some portions of this intermediate ground.

The ore is lead carbonate occurring chiefly as "sand carbonates," though many large pockets of long, slender, white cerrusite crystals have been found. There are rare nodules of galena and occasional bits of copper sulphides or carbonates. The ore carries some gold and silver. The ratio of silver to lead appears to be about one ounce of silver to each 4 per cent of lead. Ore carrying copper either in the form of sulphides or carbonates is uniformly higher in silver.

Small deposits of molybdenum and vanadium also occur on the property. Of these the molybdenum deposit has received most attention because it has afforded the greater quantity of lead, as large boulders of galena occur with the wulfenite. The vanadium occurs almost wholly as descloizite and is of undetermined extent.

The development done by the Continental Commission Co. totals approximately 2,000 ft. Practically all of the material removed by this work has been ore. The company's engineer estimates that they have blocked out nearly 45,000 tons of ore. The completion of the work now mapped out will in all probability prove up as much more.

The immediate plans of the company provide for loading bins at the mine to facilitate handling the ore there, the substitution of auto trucks for wagons, and the installation of some of the more necessary mining equipment. The ore taken out by the development work proposed will probably pay the greater part, if not all, of the operating expenses for some time to come. The management is commendably cautious, proceeding on sound lines, resolved to prospect the property thoroughly before indulging in large expenditures for surface improvements and equipment. The development of the property will be watched with interest for it is confidently expected that the present efforts will produce a mine of considerable importance.

United Zinc Adding to Holdings in Joplin-Miami District

Quietly and without ostentation the United Zinc Smelting Corporation, the firm with which Charles M. Schwab is associated, has secured something in excess of 2,000 acres of leases on lands immediately east of Waco, Mo., and now has drills at work prospecting the tracts. The company also has numerous leases south of Galena, Kan., and also south of Baxter Springs, Kan., and is now preparing to put drills on these lands. The United Zinc company already owns the Manhattan mine and mill in the Picher field, and the Media and Electrical mills and mines in the old Webb City camp as well as the Coyote and Airdale mills and mines in the sheet ground section of the Joplin camp. It is conceded that should any good strikes be made on the tracts now being drilled the company would move some of its mills in the Joplin or Webb City camps to the site. The leases have been obtained and the drilling is being carried on under the management of George Moore, an ore buyer of Joplin and representative of the Victory Metal Co. in this field.

Simon Silver-Lead Mines Preparing Plans for Mill

An official report states that a mill is being designed to treat ores of the Simon Silver-Lead Mines Co. A process has been evolved by Minerals Separation which has been proved practicable by both laboratory and mill test. It is stated that two concentrates will be produced; No. 1 containing 39 oz. silver, 67.6 per cent lead, 9.6 per cent zinc, 2.8 per cent iron, and 2 per cent insoluble, and worth $125.82 per ton; and No. 2 containing 8.2 oz. silver, 3.2 per cent lead, 46.8 per cent zinc, 9 per cent iron, and 2.6 per cent insoluble, and worth $39.34 per ton. The extraction is given as 93.9 per cent of the silver, 93.7 per cent lead, and 71.3 per cent zinc. That the mine has a future is indicated by the fact that the annual report of the company states ore reserves to be 400,000 tons with an estimated profit per ton of $7.20 on Dec. 31, 1919. Favorable reports are made on developments from the 700 level which will add to reserves.

Early Hopes of Iron Operators Dashed by Car Situation

Tonnage from Lake Superior Ranges Dropping Behind Last Year's—Coal Arriving More Freely

The car situation in the East is still delaying shipments from the iron mines of the Lake Superior district and the tonnage for the season may prove to be less than that in 1919, which was below the average of the last five years, unless the ore can be moved from the lower-lake docks to the furnaces with greater rapidity. The Iron River district of the Menominee Range has sent out about three-fourths of the ore contracted for delivery in 1920. There are large stocks of ore at the mines on the Marquette Range. The Gogebic Range mines will not move the tonnage looked for earlier in the year.

The chief difficulty in the East is to keep the cars moving from docks to furnaces, and there is a shortage of rolling stock to handle the business. Some boats are compelled to tie up for a week at Lake Erie ports to await unloading. No time is lost in the mining district, there being plenty of cars, and the boats are loaded without delay. Many of the lake vessels will enter the grain trade in the fall and will not be available for carrying iron ore.

Iron ore shipments from the head of the lakes are 440,000 tons behind 1919 as of Aug. 1, the figures for this year being 21,423,110 as compared with 21,862,626 at the same date last year. The entire loss in shipments is found in the falling off by the Duluth Missabe & Northern docks at Duluth, which are now 2,820,000 tons behind last year's record. All other docks have improved the 1919 record. Below are the detailed figures:

Dock	Shipments to Aug. 1, 1919	Shipments to Aug. 1, 1920
D. M. & N., Duluth	9,821,136	7,000,222
D. & I. R., Two Harbors	3,616,110	4,121,853
G. N., Superior	4,596,179	5,726,362
Soo, Superior	649,087	647,900
N. P., Superior	235,269	320,665
C. & N. W., Ashland	2,489,673	3,066,976
Soo, Ashland	455,172	539,132
Total	21,862,626	21,423,110

The coal situation, which was fast becoming critical, has been taken in hand and if the program now under way is carried to completion the Northwest will not suffer for coal during the coming winter. Below are comparative figures of coal receipts on the Duluth-Superior waterfront as issued by Col. F. A. Pope, chief of the United States Engineers office for Duluth-Superior harbor:

	Anthracite	Bituminous
Received to Aug. 1, 1919	692,048	4,648,221
Received to Aug. 1, 1920	662,662	1,682,918
Decrease	29,386	2,965,303

Receipts will have to be maintained at an average rate of 53,521 tons per day from Aug. 1 to Nov. 30 to place on dock a reserve equivalent to that of 1919. The Federal orders regarding coal movement to the Northwest have helped relieve the anxiety of operators.

Anaconda Cuts Second Orebody at Depth in Stewart Mine

New Discovery Held To Have Important Bearing on Future of Butte District

Another new orebody has been cut by the Anaconda Mining Co. at 3,860 ft. depth in the Stewart mine in Butte in the course of shaft sinking. The other deposit recently discovered was found at a depth of 3,740 ft. and showed about 6 ft. of high-grade ore. The second shoot has a width of 10 ft., all high-grade, the ore being a heavy bornite with an admixture of "yellow" copper, and samples, it is said, ran as high as 47 per cent copper and 6 oz. of silver. Thus far this is the greatest depth at which ore has been found in Butte. The disclosure of ore at this depth has resulted in much elation in Anaconda circles, and is regarded as one of the most important the company has had in a number of years.

Inland Steel Sued for Wasteful Mining Methods

Thomas Keating, of Minneapolis, fee owner with George H. Crosby, of Duluth, of the Thompson mine at Ironton, has filed suit in the district court at Brainerd, Minn., against the Inland Steel Co. for $380,000 for alleged failure to mine ore properly from the Thompson mine under the terms of the lease. Keating owns three-quarters of the fee and George Crosby own the remaining one-quarter. The lease was surrendered by the steel company on Oct. 10, 1919. Keating alleges that more than 400,000 tons of ore was mined and removed as low-grade ore, which was not treated as provided in the lease. Some if it is alleged to have been wasted by placing sand and other material upon it after it had been dumped. The royalties asked for on the alleged wasted ore are $120,000. The complaint also alleges unskillful mining and pit work, for which damages in the sum of $250,000 are asked, and for alleged removal of mine supports, tramways, etc., from the property a further sum of $10,000 is asked.

Freight Rate Lowered on Lead

Lower rates on pig lead and bullion in carload lots from points in Idaho and Washington to Chicago and intermediate points have been ordered by the Interstate Commerce Commission, according to reports received at Spokane, Wash. The current rate is $13.10 a ton and the new rate will be $11.50, a difference of $1.60 a ton. The change will become effective about Oct. 1. It affects about half of the lead shipped from Idaho and Washington smelters. The total annual shipments from these states is estimated at 75,000 tons. Up to the time of the hearing, the rate to New York and other seaboard points was the same from Idaho and Washington as from Montana, Utah and Arizona, but to Chicago and intermediate points the rate was lower from Montana, Utah and Arizona than from Idaho and Washington. The blanket rate to New York placed all shippers on the same competitive basis, but the differential to Chicago and intermediate points forced Idaho and Washington producers to pay $1.60 a ton more than their competitors in Montana, Utah and Arizona.

Scandinavian Labor Situation at Crisis

There is every appearance that the mediation of Herr Kvarnzelius in the conflict between the miners and allied unions and the Luossava-Kirunavara Aktiebolag and the Grängesberg-Oxesund Trafikaktiebolag will shortly result in the resumption of work generally, according to advices from abroad. *Svenska Dagbladet* believes that if his decision, which has not been publicly divulged, is accepted by both parties, and there is every sign that it will be, work will be resumed in August. In Norway the result of the state compulsory arbitration has been all in the favor of the men. Alluding to it, in an interview by *Morgenbladet*, Director Paus said: "There can be only one opinion as to the result. It was in the men's favor. During the negotiations they asked for an increase of 50 öre per hour, and upheld that claim in the court of judgment, but they never were of the opinion that they would actually get it. Experience in negotiations during a conflict goes to show that a considerably larger increase in wages is always claimed above what they will accept in order that the margin can be reduced during the negotiations. Judgment being in their favor it will involve the greatest difficulties in the iron and metal industries. I do not think it at all improbable that many of these industries will have to shut down. It has already been shown that we are behind in competition with foreign undertakings."

Searles Lake Lessees Desire County Taxes Reduced

Appeal for reduction or elimination of county taxes on government leases to mineral rights in the Searles Lake region of California was recently urged before the board of supervisors, sitting as the board of equalization, by the independents who are attempting to promote plants alongside of the Trona, Borosolvay and West-End companies, all of which are operating on patented land and are therefore not involved.

Joining in the appeal for elimination of taxes, or a nominal tax, are the Merrill Chemical Co., the Nevada Chemical Co., Eagle Chemical Co., George B. Burnham, Willard W. Butler, Robert B. Phillips and W. W. Chapin. They have leased from the government on a royalty basis approximately 15,000 acres of land in Searles Lake, and Assessor E. J. Gilbert has assessed the possessory interest at $420,320. The taxes would be $10,965.

Civil Service Examinations

Those interested in the following examinations should apply to the Civil Service Commission, Wash., D. C., for form 1,312, stating the title of the examination desired.

Mining draftsman, $1,200, Sept. 8. An open competitive examination for both sexes. Examinations will be held at various points throughout the country. A vacancy in the Pittsburgh station of the U. S. Bureau of Mines may be filled from the results.

Curator, $2,400; assistant curator, $1,800; both sexes. Open competitive examination, Aug. 10, 1920. Vacancies in the division of mineral technology, National Museum, Washington, D. C., and positions requiring similar qualifications may be filled from the results. Not required to report at any place for examination.

Statistical draftsman, $1,500; both sexes. An open competitive examination, Aug. 3, 1920. A vacancy in the Bureau of War Risk Insurance at $1,500, and vacancies requiring similar qualifications, may be filled from the results. Not required to report at any place for examination.

Recent Production Reports

Phelps-Dodge Corporation produced 8,357,000 lb. copper in July against 7,552,000 in June.

Anaconda's July output was 11,700,000 lb. copper against 12,700,000 in June.

Miami produced 4,549,298 lb. copper in July compared with 4,400,000 in June.

Old Dominion's production in July was 2,640,000 lb. against 2,999,000 in June.

Chile Copper produced 7,500,000 lb. copper in June compared with 10,300,000 in May. The decrease was caused by shortage of fuel oil.

Shattuck Arizona produced in July 166,938 lb. copper, 919,886 lb. lead, 45,495 oz. silver and 505 oz. gold. Its copper output in June was 198,327 lb.

Anaconda produced 11,700,000 lb. copper in July and 12,700,000 in June.

Oriental Consolidated, Unsan, Chosen, obtained $66,000 from its July clean-up against $80,000 in June.

Inspiration Consolidated produced 6,500,000 lb. copper in July, against 7,300,000 in June.

Calumet & Arizona's July output was 3,528,000 lb. copper, compared with 3,812,000 lb. in June.

New Cornelia produced 3,522,000 lb. copper in July, as against 3,564,000 in June.

Cerro de Pasco produced 3,652,000 lb. copper in July, against 3,944,000 in June.

Backus y Johnston produced 1,458,000 lb. copper in July.

U. V. Extension produced 3,304,878 lb. copper in July, against 2,828,020 in June.

Arizona Copper produced 3,000,000 lb. copper last month unchanged from the month before.

Reno Station Must Limit Its Experimental Work

Would Otherwise Duplicate Research Being Conducted at Other Points, Says Dorsey Lyon

Some disappointment has been expressed in Nevada because the experiment station which is to be located at Reno is to confine its work to rare and precious metals. The complaint is made that the station should include research on other metals found in Nevada, as well as oil shale. This has led Dorsey A. Lyon, supervisor of stations for the Bureau of Mines, to state:

"It will be impracticable for each station to attempt to give attention to all the problems which might occur in the district in which it is located. For example, the station at Salt Lake City confines itself practically entirely to problems connected with the extraction of lead and zinc from low-grade and complex ores. There may be many problems in Nevada which are more important to the state than are those relating to rare and precious metals, but if the station at Reno should take up work on problems relating to oxidized ores of lead-silver, for instance, it would bring about a duplication of work already being done at Salt Lake City. As a matter of fact the principal work in oxidized lead-zinc-silver ores is being done in co-operation with the Yellow Pine Mining Co. at Goodsprings, Nev.

"With regard to the research on low-grade copper ores, the bureau's station at Tucson is giving its attention to such problems and, in connection with that work, has taken into consideration the possibility of treating the low-grade copper ore deposits said to exist at Mina. In fact, one of the bureau's engineers has made at least two trips to the district in order to investigate the possibility of treating Mina ores by processes developed at Tucson.

"As for oil shales, the bureau already has taken up research and investigation work at its station at Salt Lake City and is carrying on special work in co-operation with the State of Colorado at Boulder. It would be impossible to attempt to deal with all the problems met with in the mining and metallurgical industries of Nevada at the experiment station at Reno. The results of experimental work, while done outside of Nevada, are applicable to problems of that state as well. With the bureau's limited appropriations and the necessity of having specialists for each line of work it is important that the Reno station devote practically its entire time and attention to the problems arising in the mining and treatment of rare and precious metals."

Dr. Smith Breaks All Records As Survey Director

Dr. George Otis Smith, the director of the U. S. Geological Survey, has held that position longer than any of his predecessors. On August 13 he equaled the term of service of J. W. Powell. Major Powell was director of the Survey for thirteen years, three months and twelve days, and on August 13 Dr. Smith put behind him exactly the same period of service as director.

During the 41 years since the Survey was created it has had but four directors. Due to the fact that the first director, Clarence King, took the position simply with the idea of organizing the new bureau and was in office only one year the Survey, practically speaking, has been under the direction of only three men since it really began to function. That time has been almost equally divided between Major Powell, C. D. Walcott and Dr. Smith. It is a generally held opinion that the long tenure of office of the directors of the Geological Survey has been an important factor in the effectiveness of the bureau's work.

Phosphate and Sodium Land Leasing Regulations Issued

The General Land Office has issued regulations concerning phosphate and sodium leases and prospecting permits. The phosphate regulations provide that applicants for phosphate leases must file application in the Land Office of the district in which the land is situated; that the district office shall advertise the same for thirty days and forward to the General Land Office. The minimum royalty is 2 per cent of the gross value of output and the rental of 25c. an acre will be charged the first year, 50c. an acre from the second through the fifth years, and $1 an acre thereafter. Leases will be given for not more than 2,560 acres.

The sodium regulations provide for filing applications in the local office to cover not more than 2,560 acres; for issuing permits for two-year leases on a royalty and rental basis, the royalty to be not less than 12½ per cent of the value of production and the rental to be 50c. an acre for the first year and $1 for each year thereafter.

No particular forms of application are required.

Plan New Mine Rescue Truck

By far the best appointed mine rescue truck ever made is to be manufactured for the U. S. Bureau of Mines. The lessons of many years of experience with this type of equipment will be embodied in the new vehicle.

Payne Back from Alaskan Trip

Must Reduce Present High Costs There, He Says—Would Lighten Load Due to Conservation

Alaska's industrial progress is going to be stimulated if it lies within the power of the influence of the Secretary of the Interior. Secretary Payne is just back from his Alaska trip and, in a special interview with the correspondent of the *Engineering and Mining Journal*, declares that he is going to do all in his power to lighten the burden which was placed on Alaska's shoulders during the Pinchot wave of conservation. He is going to make it the first duty of a live committee to study ways and means for stimulating Alaskan activities.

Judge Payne realizes that one of the most helpful things that could happen to Alaska would be a greater incentive to mine gold. While he understands that time must be the most important factor in restoring gold to its normal buying power he believes that there is a great deal of gold in Alaska which can be mined under present conditions if capital and labor are made available and transportation improved, and other steps taken to reduce some of the unnecessarily high costs now hampering all mining operations in Alaska.

The principal purpose of the visit of Secretary Payne and Secretary Daniels to Alaska at this time was to look into the matter of the production of coal from Alaskan mines. Secretary Payne authorized the construction of a washing plant at the Eska mine, which is on the line of the Alaska railroad. The product of this mine is now being used as railroad fuel, but the coal can be greatly improved by washing. It is intended to mine this coal in quantities sufficient to meet the commercial requirements of the territory tributary to the Alaska railroad.

The Chickaloon mine, which is at the terminus of the Matanuska branch of the railroad, produces a grade of coal equal to that of Pocahontas, Judge Payne says. The vein is 16 ft. wide. There are 400,000 tons of coal which have been blocked out. There are a 600-ft. shaft and five levels on the property. Just at the present time it is not possible to forecast definitely what the future of the mine will be, as the vein is known to be faulted. It is believed, however, that it will be picked up again and its development continued. The Navy has $1,000,000 to spend in an effort to develop Alaskan coal.

Further in the interior the extensive lignite fields are expected by Judge Payne to have a decided bearing on industrial development. He also calls

attention to the fact that there are promising anthracite veins in Alaska as well.

The Secretary thinks that other industries in Alaska are going to be stabilized by the development of its agriculture. He was very much impressed with the high productivity of the soil and the large output per acre which can be had in a much shorter season than in the principal agricultural districts in the United States.

Judge Payne is very much impressed with the favorable indications of the occurrence of oil in Alaska. At his request A. H. Brooks, of the U. S. Geological Survey, is looking into the petroleum situation, with a view to making recommendations as to steps which may be helpful in encouraging prospecting for oil. Considerable prospecting is being done even under present conditions, according to reports that have been received.

Awards were recommended during the week ended July 31 by the War Minerals Relief Commission, as follows (the name of the claimant, the mineral, the amount recommended, its percentage relationship to the amount claimed are shown): Fred A. Babcock, manganese, $225.17, 10 per cent; Eleanore E. Hoeft, chrome, $5,138.30, 39 per cent; O. C. Irwin, chrome, $4,146.27, 12 per cent; Auburn Chrome Mines, chrome, $5,970.56, 30 per cent; Holbrook & McGuire, chrome, $5,905.18, 37 per cent. To date, the average percentage of the amounts claimed, which have been recommended for payment, is 30.34 per cent.

NEWS BY MINING DISTRICTS

MEXICO

Political Conditions Improved in General But Economic Conditions Still Bad

Durango

With the opening of the American Smelting & Refining Co.'s smelter at Asarco, Durango, at the beginning of this year a new impetus was given to the mining industry in this state and adjacent territory, which has been practically dead since 1912 on account of disturbed conditions and failure of transportation facilities.

Political conditions in the states of Durango, Zacatecas and Coahuila have improved materially during the last three months and there is a feeling of optimism noticeable that the improvement is permanent and further advances toward a normal condition can be expected. This is the feeling in spite of sporadic labor strikes, which have generally been adjusted satisfactorily to all concerned.

Only one or two operators were able to continue work during the worst period of disturbed political conditions, but in 1919 several others renewed operations on account of the high prices of silver, and during the present year still more have commenced work, and with the growing confidence there is something like a general rush at the present time to start development work and begin shipments from the mines already in paying orebodies.

One of the companies that is making rapid progress toward renewed operation of its mines at Tejamen, Durango, is the Cia. Minera Eureka, Melchor Ocampo y Anexas, S. A., where Theodore E. Dickel, the new mine superintendent, is installing a 100-ton mill, using table concentration and regrinding to be followed by flotation. The ores run from half a kilo to one kilo silver and some lead. It is expected that the plant will be in operation by Oct. 1. The company has about 40,000 tons on the dump and 3,000 tons of old sands to be worked up before treating newly extracted ore.

The Santa Cruz Mining Co., whose mines are located in the Otaez district, but with offices in Durango, is preparing to put in a mill to take the place of its old one, which is too small to handle the new production. This company has been notable for the quantity of high-grade ores shipped, which has been its principal production, but it is now intended to work up the accumulated dumps, which run from one to five kilos of silver per ton.

An increasing number of companies are resuming operations in the Guanaceví district, and with the encouragement given by the Government officials that a railroad will be built into that camp in the near future the prices of mining properties have stiffened considerably and many new denouncements have been made of properties previously passed over.

The three mills now operating in Guanaceví are still running on the old dumps, the mines not having been unwatered since they were forced to close down a number of years ago. The Soto Mines Co. has completed its new mill and concentrating plant and has commenced shipments.

In western Durango the Bacis Gold & Silver Mining Co. is again producing bullion and concentrates, since reopening January 1. The Ventanas mines are again working on a small scale. The Mexican Candelaria and the San Luis Mining Co., both near San Dimas, in western Durango, did not stop work during the disturbances of the last eight years.

Many of the smaller companies have resumed operations or are preparing to do so at once. L. C. Phillips has recently reached Durango on his way to start development work for the Cia. Minera Occidental, whose property is in the Canelas district.

Sonora

North Tigre Leasing Co. Ships First Concentrates

Agua Prieta—Ore shipments through the Douglas-Agua Prieta port for July greatly exceeded those for June. One hundred and ninety-five cars of ore and concentrates with a tonnage of 7,822 crossed from Agua Prieta in June, against 218 cars with a tonnage of 8,715 which crossed in July.

The estimated value of June shipments was $1,138,000, and July shipments were valued at $2,145,500. Figures for July follow:

Origin	Cars	Tons
Nacozari	179	7,160
El Tigre	22	810
Estrella	10	450
Nuevo Potosi	1	45
Palacio de Hierro	1	43
Promontorio	1	42
Belen	1	41
San Ygnacio	1	39
San Pablo	1	42
San Luis	1	43
Total	218	8,715

Total customs collections, including $528 head tax, amounted to $3,295.55.

The first car of concentrates from the North Tigre Leasing Co. is now en route to Douglas, Ariz. The company has recently put into operation a 50-ton flotation mill. The mill was built under the direction of Frank Holmes, who is manager of the property, the stock of which is held mostly in Douglas and Bisbee.

Chihuahua

Minerales y Metales To Increase Shipments

Santa Eulalia—The Cia. de Minerales y Metales is shipping to its Torreon smelter and is arranging transport to increase its shipments. The San Toy aerial tramway is being repaired and will convey all the company's ore from various leases to the standard-gage railroad which connects with the Mexican Central. The ore from the company's San Antonio Chico lease will be taken to the San Toy aerial tram in four-wheel-drive motor trucks.

The A. S. & R. Co. has installed an electric hoist and compressor at its San Antonio Grande lease, which is in the east camp and is now being managed by E. B. Butts. It is going to build an aerial tramway to transport the ore from this mine to the Velardeña-Mina Vieja tramway.

The striking miners of the A. S. & R. Co. have returned to work and shipments are again normal.

The improvements on the Chihuahua Mining Co.'s railroad are nearing completion. A switch from "Three Mile" is in operation to the smelter and the company is shipping directly there without rehandling the ore as before.

The Buena Tierra Mining Co. has installed a 1,378-cu. ft. compressor and is overhauling its main hoist.

Don Juan Rivera has installed a hoist on his Santa Rita lease.

Dr. J. M. Smith is shipping from his lease on the Coronel. A. H. Davison has examined the Central.

Guerrero

Many Claims Jumped in Recent Years

There is practically nothing doing in the state in the way of work or development. This section was pretty badly mauled during the various revolutions and uprisings since 1910 and the few important properties, such as Campo Morado, have been worked at and butchered by local bandits for their own account. Campo Morado, which has been under option for several years, waiting the dawn of peace, to an English syndicate, is still nominally in the hands of local patriots, though it is probable that the central government will take expeditious methods shortly to return the property to its owners.

During the last few years, when mines were almost entirely abandoned in this state, large numbers of properties were "denounced" or, properly speaking, "jumped." The absence of the local mining authorities and the fact that mining agencies belonging to the government were closed, created a confusion that made lawlessness quite possible. The present government has set its face against these methods, however, and under recent decrees all such irregularly acquired properties have been ordered vacated and the titles of the original owners sustained, even in the absence of the payment of taxes and other legal requirements. That is, sufficient time will be allowed all mine owners, absentees as well, to put their house in order, if they choose to do so.

The Department of Public Works has revived the concession for a railway from Toluca to the Pacific coast which will put into productivity a number of important old-time producers, among them the Inguarán copper properties belonging to the Rothschilds, which are now idle for lack of transportation. The department has also approved a plan for opening the Balsas River to navigation for about 150 miles above its mouth, thus connecting up a large area of smaller mining properties and an immense mineralized zone now practically unprospected. Preliminary work on the latter proposition has already begun.

San Luis Potosi

The Cia. Metalurgica Mexicana, owned and operated by the Towne interests, is operating only a few furnaces for copper and lead, owing to lack of transportation and scarcity of fuel oil caused by the recent strike in the oil fields.

There has been no general revival of work throughout the state although some few options have been extended to foreign concerns. Politically the state is quiet and free from brigandage, but economic conditions are very bad.

Jalisco

Larger Companies Again Shipping—Prospectors Active

Jalisco is one of the first states to recuperate after the revolution and, in fact, for some time most of the larger mines have resumed work and are shipping ores and bullion. The mineralized part of the state is being actively prospected by natives as well as foreigners and a large number of new denouncements were filed during July. Shipping facilities have been improved throughout the state and it is expected that work will be resumed this month on the Southern Pacific line from Nogales to Guadalajara. The new government is exceedingly anxious to have the road completed both as an economic and as a military measure.

Michoacán

Mining Dead and Transportation Paralyzed

Michoacán may be considered dead in the mining calendar. The transportation facilities have been completely paralyzed and no immediate effort is being made to improve the situation. There are still numerous small groups of bandits in the mountains with the result that no attempt is being made to revive work at any of the mines, except a few scattered properties near the Pacific coast and the Balsas River.

Aguascalientes

The A. S. & R. is operating only one or two copper furnaces and no lead furnaces. The recent strike resulted in an average increase of forty per cent in wages at the smelter and a reduction in the force. The company still refuses to recognize the unions, an attitude which is sustained by most of the large mining concerns of the country as well as the iron and steel foundries, oil operators and manufacturers in general.

There is some slight activity in locating new properties in the state, one recent location being a tin prospect.

Mexico

El Oro—All four of the principal mining companies in this district, namely, Dos Estrellas, El Oro Mining & Ry. Co., Esperanza Mining Co., and Mexico Mines of El Oro, Ltd., are practically in full operation.

CHINA

Rich silver mines are reported to have been discovered in China in the Province of Kirin, between Tienpaoshan and the River Tumen. The construction of a light railway for the conveyance of the ores is proposed.

CHOSEN

Unsan — Water shortage caused by lack of rain continues to cause curtailment of operations. All mills and equipment on the concessions were driven by steam power in June. Wood is also scarce. The mine air is bad owing to lack of power for proper ventilation. The June cleanup of about $80,000 was purposely low, as low-grade ore was treated, because the recovery always falls off in summer.

NEVADA

Rochester Combined Property Ordered Sold

Rochester—All the real and personal property of the Rochester Combined Mines Co., including a 350-ton mill that never treated a pound of ore, were advertised for sale on Aug. 7 to satisfy a judgment for $200,000 secured by William Adams and Nelson L. Bruck, trustees for creditors. At one time it was intended to take the Combined into the consolidation known as the Rochester Silver Corporation, but the deal was not consummated.

Divide—In the Tonopah Divide mine development on the 1st, 3rd and 5th levels, together with shaft sinking, totaled 120 ft. The shaft is now 915 ft. deep and it is intended to sink to 1,000 ft. On the 1st, or 165, level drifting on the new ore showing continues to prove ore of milling grade. On the 5th level the southeast drift was extended 35 ft. with ore of good grade showing across a width of 3 ft.

UTAH

Tintic Standard Using Scraper for Underground Loading—Judge M. & S. To Have New Office

Eureka—Ore shipments from the Tintic district for the week ended July 30 amounted to 146 cars.

The Tintic Standard is reported to be using a scraper similar to a road scraper on one of its levels for loading ore, and in this way meeting the present shortage of muckers. A small hoist has been installed and connected with the scraper by a steel cable, which both loads the scraper and hauls it up an inclined slide to the cars. Two men are required at the scraper, two loads from which are sufficient to fill one mine car. Space is, of course, necessary for this method of handling ore. In the present instance the stope is in dry siliceous silver ore on the 1,100 level. It is opened about 100 ft. west of the No. 2 shaft and has been found, as far as development has gone, to be 40 to 50 ft. wide, with ore continuing in all directions. Vertically the ore has been proved to continue to the 1,400 level. July shipments from the property are expected to amount to about 100 cars.

Park City—The Judge Mining & Smelting Co. is planning the construction of a new and modern office building to take the place of the one at present in use in Empire Canyon.

MONTANA

Neihart—Directors of Cascade Silver Mines have voted a note issue of $100,000, to bear 8 per cent and to be offered to stockholders at par. The issue is made to take care of merchandise accounts, it is explained, so that the company will not be forced to operate its mines until the I. W. W. strike, started June 1, is broken. The mines speedily can be reopened, it is stated, and the ore in sight will average $20 per ton.

CALIFORNIA

Unwatering Argonaut Rapidly—Deeper Development Planned at Kate Hardy —Juniper Still in High Grade

Jackson—New pumps have been added to the powerful plant of the Argonaut and dewatering is proceeding rapidly. It is thought that the use of compressed air caused the freezing of sections of the pumps, but this condition has now been almost eliminated.

Forest — Sinking of a double-compartment shaft from the main tunnel of the Kate Hardy mine is proceeding rapidly, the shaft following a rich ore shoot. It is planned to sink several hundred feet and to drift on the vein at several points. The property is well equipped, and the work now planned will be the first deep work ever done at the mine.

Susanville—The Juniper mine continues to show high-grade ore. The vein is said to be comparable with the bonanza ledge worked in the Juniper by the pioneers.

Bishop Creek—With $80,000 available for re-modeling its mill, the Wilshire Bishop Creek company has torn out all the old flotation machines and has installed two rougher and one cleaner machines. It is expected to have the mill handling 150 tons daily by Sept. 1.

ARIZONA

Sinking of Junction Shaft at Bisbee Started

Bisbee—Actual work of sinking the Junction shaft has been started. All preliminary work has been completed and the hoist placed on the 1,800 level. The shaft will be sunk from this level to the 2,300 level. The new ventilating shaft near the Briggs shaft had 300 ft. more to go on Aug. 1. It is expected that the shaft will be completed before the last of next month.

During July the Boras Leasing Co. shipper 1,250 tons of copper ore to the Copper Queen smelter at Douglas. The grade of the ore is about 8 per cent copper. In July the company paid its second monthly dividend of 10c. per share. The shaft has been completed to the 600 level and connection made with the stopes on this level.

The Night Hawk Leasing Co. during July shipped 15 cars of ore. Development continues on the 750 level.

Tombstone—Dr. H. H. Hugart and associates have opened the old Winters mine on the south edge of the town and have a car of good silver ore ready to ship. There is said to be considerable ore worth milling and construction of a mill is planned.

Jerome—At the U. V. Extension the 1,600 level crosscut recently cut 5 per cent copper ore. Ore has not yet been reached by development on the 1,700 level. Development on the 1,500 level has proved the ore to run 5.9 per cent copper and to have an area about two-thirds of that on the 1,400 level.

Chloride—The Dardanelles Mining Co. has installed its new pump and is pushing the sinking of the shaft to the 200 level.

NEW MEXICO

Peerless Mine Unwatered by Walnut Creek Co.

Lordsburg—Ore shipments from this district for August consisted of 95 carloads of an approximate value of $73,000.

The Co-operative Mining Co. received $2,500.41 for 37 tons of silver ore recently shipped to the El Paso smelter.

Silver City—The Walnut Creek Mining Co. has succeeded in unwatering the old Peerless mine that has not been worked for 40 years. Exploration work will begin at once. Jack Stark is superintendent.

Some very high grade silver ore has been struck in the old workings of the Telegraph mine, now being explored by W. P. Dorsey, son of the original locator.

Separ—A. J. Stockbridge has completed the erection of a Gibson pony mill at the Young Bounds ranch. This is intended to handle the free milling gold ores from the Rocky Trail property, a mile and a half east. Should this test apparatus prove satisfactory larger equipment will be installed.

MICHIGAN

Marquette Range

Shipping Graphite from Taylor Dump at L'Anse—Season Good in Cascade District

L'Anse—A shipment of 500 tons of graphite ore has been made from the Taylor mine dump to the Detroit Graphite Co.'s factory. It will be used in paint manufacture. Other shipments are to follow. The mine has been idle for years, but considerable graphite was left in stock at the property.

Palmer—Development work only is under way at the Isabella. Only ore taken out in drifting and raising is being hoisted. The results have been satisfactory. The Maitland, Richmond and Empire continue to be steady shippers. The Maitland will have the best record in its history. There seems to be a good market for low-grade siliceous ores of the Cascade district this season.

Menominee Range

Youngs Mine Now Shipping—Riverton Shaft Almost Completed

Stambaugh—The new Riverton shaft is now down 1,200 ft. with 50 ft. to go. The underground pump station is in commission. A laboratory and engine house are under construction.

Iron River—Shipments have started from the Youngs mine, recently purchased by the Florence Iron Mining Co. from the Youngs Mining Co. No time was lost in getting ready for mining after the deal was closed and shipments are averaging 150 tons daily. Considerable new machinery, including a new electric compressor, has been installed. Eventually, all of the mine machinery will be driven electrically. The power line is to be extended from the Fogarty to the Youngs.

MINNESOTA

Vermilion Range

Vermilion—Pickands, Mather & Co., one of the largest independent operators on the Mesabi Range, has organized the Vermilion Mining Co. and taken over the lease of the Zenith mine at Ely, Minn., one of the finest properties on the Vermilion Range. The Zenith was operated by the Oliver Iron Mining Co. from its opening until 1919, at which time the lease expired and the property reverted to its owners, T. F. Cole, R. B. Whiteside and associates, who have operated it themselves for the past year through the Zenith Iron Mining Co. The mine has shipped 5,620,000 tons and is credited on the Minnesota Tax Commission's records with a reserve of 2,100,000 tons. Kenneth Duncan, superintendent of the mine under the Zenith Iron Co., will remain in charge for the Vermilion Mining Co.

JOPLIN-MIAMI DISTRICT

Missouri-Kansas-Oklahoma

Iowa Mining Co. Erecting Mill—New Baker-Howell Concentrator Planned

Baxter Springs, Kan. — The Iowa Mining Co. is erecting a concentrator on a 40-acre lease on Gilmore land, two miles south of Baxter. In part the plant is being made over from the Oak Orchard Custom mill, until recently located north of Joplin. Gas engines will be used to furnish power, and the capacity will be about 150 tons per shift. The plant is to be ready about Sept. 15. Mining will be carried on at a depth of 145-ft., where several drifts have been run. About 800 tons of ore is on the dump. A. F. Place, of Leon, Ia., is president, and Fred R. Hobart, of Joplin, secretary and manager. Development has been under way for two years, there having been much water to handle until pumping by the Chanute Spelter Co., about two miles northwest, reduced it to about 400 gal. per min.

The Baker-Howell Co. is preparing to erect a concentrator at its property just across the state line in Oklahoma, two miles southwest of Baxter. The mine has been operated for some time as a hand jig plant, but recent development work is thought to warrant the erection of a mill.

Quapaw, Okla.—The West Virginia Mining Co. has resumed operations.

THE MARKET REPORT

Daily Prices of Metals in New York

Aug.	Copper	Tin		Lead		Zinc
	Electrolytic	99 Per Cent	Straits	N. Y.	St. L.	St. L.
5	18.35@18.60	45.00	49.25@49.50	8.65	8.25@9.00	7.55@7.65
6	18.35@18.60	44.75	49.50@49.75	8.65	8.25@9.00	7.60@7.70
7	18.35@18.75	44.75	49.00@49.50	8.65	8.25@9.00	7.65@7.75
9	18.35@18.75	44.50	48.50@49.00	8.65	8.25@9.00	7.70@7.80
10	18.35@18.75	44.00	48.00@48.25	8.65	8.25@9.00	7.75
11	18.35@18.75	43.75	47.75@48.00	8.65	8.25@9.00	7.75

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point. All prices are in cents per pound.

Copper is commonly sold on terms "delivered," which means that the seller pays the freight from refinery to buyer's destination. The delivery cost varies, and it would be confusing to figure net prices on individual transactions. Consequently, an average deduction is made from the "delivered" price. At present the average cost of delivery from New York refineries is 0.15c. per lb., and that deduction is made to arrive at the New York price. When copper is sold f.o.b. or f.a.s. New York, of course no deduction is made.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. We quote New York price at 35c. per 100 lb. above St. Louis. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Aug.	Copper			Tin		Lead		Zinc	
	Standard		Electro-lytic						
	Spot	3 M		Spot	3 M	Spot	3 M	Spot	3 M
5	94	96	111	283½	289	37½	37¾	42½	44
6	94½	96¾	111	283½	288	37¼	37¼	42¼	43¾
7	. . .	....	.	....	....	...	..	...	
9	93¾	95¾	111	279½	285½	36¾	36¾	42½	43¾
10	93½	95½	111	279½	286½	36½	36¾	42¼	43¾
11	93½	95½	112	276½	283½	36½	36½	42¼	43¾

The above table gives the closing quotations on the London Metal Exchange. All prices are in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Aug.	Sterling Exchange	Silver			Aug	Sterling Exchange	Silver		
		New York, Domestic Origin	New York, Foreign Origin	London			New York, Domestic Origin	New York, Foreign Origin	London
5	358½	99⅓	94½	58¼	9	361½	99¼	96	59⅝
6	362	99½	95½	59⅜	10	361½	99¼	95½	59⅜
7	366	99½	95	59⅝	11	364½	99¼	94⅝	58¾

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States. This quotation is retroactive to May 13.

Metal Markets

New York, Aug. 11, 1920

Continued inactivity characterized the metal markets during the last week, tin and zinc being particularly neglected. Sales of copper picked up somewhat, and lead remains firm and scarce.

Copper

Fair buying but no concerted activity have marked the week. Domestic consumption continues good, and is probably about twice what it was before the war. United States production is slightly more than the pre-war figure. The stocks of metal, which may be around 400,000,000 lb., and the difficulty which European nations have in buying our copper, prevent the price from rising to a figure which would give a reasonable profit to producers.

Some of the smaller traders are trying to ease the increased freight rates on to consumers by quoting f.o.b. refinery, whereas, before, they quoted the same price delivered.

Spot and August delivery could be obtained during the week at 18½@18⅜c., f.o.b. refinery, September at 18¼@18.60c.; and later deliveries, nominal at 18½@18¾c.

Lead

Large consumers, particularly white-lead, storage-battery, and cable manufacturers, are very actively in the market for September lead, of which there is a pronounced scarcity. Production is not as great as producers would like, owing to the fact that labor is going into pleasanter and more remunerative work for the summer months, with the full knowledge that the mens' old jobs will be open to them in the fall. Mexican lead is coming into this country better, but a car shortage exists in that country the same as here. Lead is also coming in from England, that which has so far been imported being largely American brands. Consumers are not so anxious to take a chance on foreign metal, of which they know nothing, which probably accounts for the fact that more business has not been done. English lead has been freely offered at 7c. per lb., c.i.f., by dealers, including tin brokers who have been attracted by the lead market. This is equivalent to about 8.60c., duty-paid, New York. Lots up to 1,000 tons for August or September shipment can be obtained at this price. The quantity of the English supply is problematical. Duty-paid spot lead is obtainable at 9c. per lb.

We quote both New York and St. Louis spot lead for the week at 8.90@9c.; September at 8.75@9c., and October 8.75c. Our prices for average sales take into account the A. S. & R. price, which remains unchanged at 8.50c. New York and 8.25c. St. Louis.

Zinc

Demand continues very poor. Large producers prefer to accumulate metal rather than sell at present prices. Stocks in general are low, and consumers are probably not supplied with more than one month's production. With limited production and increased freight rates, the leading producers expect zinc to sell at 8c. in the near future. The prices which we quote are for August and September delivery. No demand exists for later deliveries.

Tin

Tin continues woefully dull, though the demand for electrolytic picked up slightly during the week, with sales at 46⅜@47⅜c. There has been 700 tons of Chinese tin on the market, which second-hands are trying to unload at 44@45c. This is equivalent to the best brands of so-called 99 per cent tin. The poorer brands of 99 per cent cannot be sold even at 43@44c.

Straits tin for future delivery: Aug. 5th, 49.25@49.50c.; 6th, 49.50@49.75c.; 7th, 49.00@49.50c.; 9th, 48.50@49.00c.; 10th, 48.00@48.25c.; 11th, 48@48¼c.

Arrivals of tin in long tons: Aug. 3d, Singapore, 100; 4th, China, 25; 5th, China, 475; London, 50; 6th, London, 25; 9th, Singapore, 35; London, 150.

Silver

The London market has been erratic for the last week, with prices ranging between 58¾ and 59⅝d., due to the fluctuations in sterling exchange, and also to buying or selling orders on a narrow market with limited supplies. The demand for the Indian bazaars continues good, with an upward tendency. China exchanges continue below the New York parity. The New York market has ruled firm on moderate demand and limited offerings.

Mexican Dollars—Aug. 5th, 71⅞; 6th, 72⅝; 7th, 72⅝; 9th, 73⅜; 10th, 72⅝; 11th, 71⅞.

Gold

Gold in London on Aug. 5th, 114s.; 6th, 114s. 3d.; 9th, 113s. 3d.; 10th, 113s. 8d.; 11th, 113s. A license is now required for the exportation of gold from Canada.

Foreign Exchange

Heavy offerings of grain and cotton bills in a market made panicky by the Russian-Polish war news have accounted for the recent upsets in the foreign-exchange market. Yesterday, francs were 7.21c., lire, 5.03c. and marks 2.14c. Argentine exchange declined to 86.5c. and Brazilian rios to 20.9c. New York funds in Montreal, 12⅛ per cent premium.

Other Metals

Aluminum—Ingot, 33c. per lb., with 32c. open market for 98@99 per cent virgin.

Antimony—Market continues weak. Spot, 7½c. per lb.; Cookson's "C" grade, 14@15c. Chinese and Japanese brands, 7½c. W. C. C. brand, 7@7¼c. Chinese needle antimony, lump, firm at 9@10c. per lb. Standard powdered needle antimony (200 mesh), 10@12c. per lb.

Bismuth—$2.70 per lb., 500-lb. lots, and $2.72 per lb., 100-lb. lots. Market quiet.

Cadmium—Nominal, $1.40@$1.50 per lb. Market dull.

Cobalt—Metal, $3 per lb.; black oxide, $2 per lb.

Iridium—Nominal, $350 per oz. Heavy demand, but small supplies.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb., for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]Molybdenum Metal in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.; Monel metal, shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—In sympathy with platinum jumped from $80 to $100 per oz.

Platinum — Firm at $100@$105 per oz. $95 per oz. in 100 oz. lots.

Quicksilver — Market steady; $85@$88 per 75-lb. flask. San Francisco wires $85. Weak.

Ruthenium—$200@$220 per troy oz.

[1]Selenium, black, powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb.

[1]Thallium Metal—Ingot, 99 per cent pure, $20 per lb.

Metallic Ores

Bauxite—About 52 per cent alumina content, less than 2 per cent iron oxide, up to 20 per cent silica and artificially dried to contain not more than 4 per cent free moisture, $10 per gross ton at mine; 54 per cent alumina and about 15 per cent silica, $11; averaging 57 per cent alumina, 8 to 12 per cent silica, less than 3 per cent iron oxide, $13 on basis of 8 per cent free moisture. Ores of very low silica content suitable for the manufacture of aluminum oxide and hydrate of alumina command a fancy price.

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a minimum of 6 per cent silica, 80@85c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 60@65c. per unit, f.o.b. mines.

Iron Ores—Lake Superior ores, per ton, delivered at Lower Lake ports: Old Range bessemer, $7.45; Old Range non-bessemer, $6.70; Mesabi bessemer, $7.20; Mesabi non-bessemer, $6.55. Congestion at Lake Erie ports due to car shortage has resulted in decreased tonnage. Other ports show gain in shipments. Shipments of Lake Superior iron ore were 9,638,606 tons during July, according to *Iron Trade Review*.

Manganese Ore — 70@80c. per unit, 50 per cent Mn content, c.i.f. Atlantic seaport; chemical ore (MnO_2) $75@$85 per gross ton.

Molybdenum—85 per cent MoS_2, 75@85c. per lb. of contained sulphide, New York.

[1]Tantalum Ore, guaranteed minimum 60 per cent tantalic acid, 65@70c. per lb. in ton lots.

Titanium Ores—Ilmenite[1], 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $7 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $6@$7, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

Zircon—Washed, iron free, 5c. per lb. Zirkite—$90@$100 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

[1] Furnished by Foote Mineral Co., Philadelphia, Pa.

Zinc and Lead Ore Markets

Joplin, Mo. Aug. 7—Zinc blende, per ton, high, $51.15; basis 60 per cent zinc, premium, $48.50; Prime Western, $47.50@$46; fines and slimes, $45@$42.50; calamine, basis 40 per cent zinc, $36. Average settling prices: Blende, $44.85; calamine, $38.16; all zinc ores, $44.71.

Lead, high, $102.90; basis 80 per cent lead, $100; average settling price, all grades of lead, $99.81 per ton.

Shipments for the week: Blende, 8,178; calamine, 169; lead, 1,267 tons. Value, all ores the week, $499,700.

A considerable tonnage was reported purchased on $46 basis by one purchasing agency, but others report $47.50 basis, Prime Western grades.

The purchase of the week was 9,600 tons and the shipment of zinc 8,400 tons.

Platteville, Wis., Aug. 7—Blende, basis 60 per cent zinc, $49.25 per ton base for high-grade. Lead ore, basis 80 per cent lead, $100 per ton. Shipments for the week: Blende, 1,295; lead, 101; sulphur ore, 35 tons. Shipments for the year: Blende, 43,073; calamine, 2,300; lead, 3,781; sulphur ore, 1,177 tons. Shipped during the week to separating plants, 2,263 tons blende.

Non-Metallic Minerals

Asbestos — Crude, No. 1, $2,400@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax. Freight rate from mines to Sherbrooke, Quebec, over Quebec Central R.R., 20c. per cwt.; from Sherbrooke to New York, 27½c., carload lots; freight to New York for crude No. 1, f.o.b. Thetford mines, $8.45 per ton, carload lots.

Barytes — Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $22@$25 in bags, carload lots; (off-color) $18@$20 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $12 per gross ton; ground (white) $25@$25; ground (off color) $16@$19 per net ton, f.o.b. Cartersville, Ga. Crude, 88 to 94 per cent, $23; ground (white) $40.50; ground (off color) $27 per net ton, less than carload lots, f.o.b. New York. Crude, not less than 98 per cent, $11@$11.25 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—Domestic, extra light, 5@6c. per lb.; light, 4½@5½c.; heavy, 4@5c; English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin) — Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground.

$15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $7.50@$8 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $30, car lots, f.o.b. Baltimore; ground, $17@$20, f.o.b. North Carolina points; $17@$20 per ton, No. 1 ground, f.o.b. New York State; $21@$23 per ton, ground, f.o.b. Maine.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Graphite—Crucible flake, 85 per cent carbon content, 8c. per lb.; 88 per cent, 9½c.; 90 per cent, 10½c., all f.o.b. New York. Crucible grades of Alabama graphite sell as follows, f.o.b. Ashland, Ala.: 80 per cent, 5c.; 90 per cent, 10c. Lubricating grades in increasing demand, with price ranging from 11c. for the 85 per cent guaranteed grade in car lots to 30 and 40c. for higher grades. Mexican, amorphous, $45@$55 per short ton; Korean, 3½c. per lb.; Madagascar, 8c.; Ceylon, 4¾@15½c.

Gypsum—Raw crushed rock, $3.50@$4 per ton; raw ground fine, $4@$4.50; calcined stucco, $9, all f.o.b. works. Containers extra. Wholesale, plaster of paris, carload lots, $3.75 per 250-lb. bbl., alongside dock, New York.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $65@$75 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—Imported block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20@$1.40; No. 4, $2@$3; No. 3, $4.25@$5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $4; No. 3, $5.75; No. 2, $7; No. 1, $9; A1, $14; extra large, $25, all f.o.b. New York; ground, $85@$100 per ton, Philadelphia.

Monazite — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses.

Pumice Stone—Imported, lump, 4@50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish, fines, per unit 12c., c.i.f. Atlantic seaport; furnace size, 16½c.; run of mine, 12@14c.; domestic, fines, f.o.b. mines, 12@14c.

Quartz—(Acid tower) fist to head, $10; 1¼ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines. F.o.b. Wausau, Wis., the price is $16 per ton in car lots, and $22 less quantities, including bags.

Sulphur—$18 per ton for domestic; $20 for export, f.o.b. Texas and Louisiana mines.

Talc — Paper making, $10@$20 per ton; roofing grades, $9@$15; rubber grades, $10@$15, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $15@$20 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60@$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $2.25@$2.50 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15-18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

[1]Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 17@18c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c. f.o.b. works.

Ferromanganese—For 76@80 per cent, prompt delivery, $200@$225 freight allowed; last half, $200@$220; English, $195@$200, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $75@$80, f.o.b. furnace.

Ferromolybdenum—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2.50@$3 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $80@$85; 75 per cent, $150@$160.

Ferrotungsten—70 to 80 per cent W, $1.10@$1.15 per lb. of contained tungsten, f.o.b. works.

Ferro-uranium—35-50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium—Basis 30-40 per cent, $6.50@$8.50 per lb. of V contained, f.o.b. works.

Metal Products

Copper Sheets — Current New York price, 29½c. per lb.; wire quoted, 22½@23c.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver—Unchanged at 39½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 26¾c.; sheathing, 25¾c.; rods, ⅜ to 3 in., 23¾c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $145 per 1,000, f.o.b. Pittsburgh.

Chrome Brick—$90@$100 per net ton, carload lots, eastern shipping points.

Chrome Cement—45 to 50 per cent Cr_2O_3, $50 per net ton, and $55 in sacks, carload lots, eastern shipping points.

Clay Brick — First-quality fire clay, 9-in. shapes, $50@$55 per thousand, Pennsylvania, Ohio, and Kentucky works; second quality, $45@$50. First quality, St. Louis, $45; New Jersey, $75.

Magnesite Brick—$100@$110 per ton, eastern shipping points; 9-in. straights, $90@$100; 9-in. arches, wedges and keys, $95@$105; soaps and splits, $110@$120.

Silica Brick—9-in. per 1,000, $51@$55, Birmingham, Ala.; $55@$60, Mount Union, Pa.; $55, Chicago district.

Iron Trade Review

Pittsburgh, Aug. 10, 1920

Shipping conditions in the iron and steel industry continue to improve in general, although slowly. Some railroads are performing much better than others. There is particular difficulty in the movement of billets and sheet bars, resulting in idleness of finishing plants.

The railroad rate settlement is expected to have a favorable influence upon industry in general, but the steel industry expects no large orders in the near future. It is more anxious to see improved shipping conditions than to receive railroad orders, as the industry's other customers would buy more steel if they had better transportation.

Pig Iron—Basic is quotable up 50c. as a result of recent sales. We quote: Bessemer, $47; basic, $46.50; foundry, $46, f.o.b. Valley furnaces, freight to Pittsburgh being $1.40, to advance about 40 per cent August 26. Pig-iron consumers are interested only in early deliveries, and furnaces, being well sold up, are making no effort to sell for late deliveries.

Steel — Several purchases of sheet bars have been made, at not over $70 in any case. A fortnight ago $75 was being paid. Several mills are anxious to sell billets and sheet bars if they can be shipped. We quote billets at $60@$65 and sheet bars at $68@$70.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $17@$18; foundry, $18@$20.

A Review of the Japanese Lead and Zinc Market

A Statistical Summary of the Activity in Japanese Mines and the Movements of These Metals During the War

PRODUCERS and smelters were encouraged by high prices during the war, according to Vice-Consul H. T. Goodier, by the hope that strikes and political conditions in the United States, Spain, Australia, and Mexico, the principal lead-producing countries of the world, would create a world-wide shortage. However, this hope does not seem to have fully materialized, and the lead market has become quiet as a consequence. Paint manufacturers, having lost a considerable share of their trade with Singapore, the East Indies, and India, as a result of renewed competition from Europe, are buying lead only for actual needs. This, together with increased cost of materials for smelting, and higher wages, has caused a considerable reduction in output as compared with 1917. If the 1919 figures were available they would undoubtedly show a still more noticeable decrease in amount and value, many of the companies being in greater financial difficulties than in 1918.

The quantity and value of the annual production of lead in Japan from 1913 to 1918 is given as follows:

Year	Pounds	Value	Year	Pounds	Value
1913	8,393,138	$308,006	1916	25,268,685	$1,872,332
1914	10,138,205	412,400	1917	35,127,077	2,822,018
1915	10,567,457	486,729	1918	23,742,236	2,070,266

Prices for lead (Australian) reached their highest in September, 1918, when 1 picul was worth $15.52 in Yokohama. The lowest was $5.85 per picul, in June, 1914. In March, 1920, the price was $13.21. The cost of production of refined lead is estimated at about $8 per picul at the smelters.

Imports of lead and lead ore into Japan from 1915 to 1919, largely from Australia (for lead ingots and slabs), are stated as follows:

Years	Lead Ore Pounds	Lead Ore Value	Lead Ingots and Slabs Pounds	Lead Ingots and Slabs Value	Other Pounds	Other Value
1915	(a)	(a)	32,279,973	$1,450,656	2,872,805	$175,860
1916	(a)	(a)	46,230,232	3,720,089	3,460,964	278,704
1917	50,520,532	$1,253,759	35,024,068	2,926,798	1,567,652	144,154
1918	7,989,466	191,130	120,283,002	7,351,379	1,447,808	153,538
1919	330,667	8,007	79,607,814	5,432,046	(b)	(b)

(a) Not known. (b) Statistics not yet available.

In 1915 Australia sold to Japan 24,599,868 lb. of lead ingots and slabs, valued at $1,102,933. The same year the United States sold to Japan 5,790,156 lb., valued at $248,307. In 1919, while imports of lead slabs and ingots from Australia had increased to only 32,366,341 lb., valued at $2,551,042, imports from the United States jumped to 27,239,280 lb., valued at $1,604,866.

In 1914 Japanese consumption of lead was estimated at 43,753,000 lb., a great share of which was imported from Australia. In 1918 the estimated consumption had reached 144,025,000 lb.

Only since 1913 has Japan engaged in zinc smelting. Prior to that time zinc ore was shipped abroad and the refined product then imported. The estimated consumption of zinc in Japan increased from 25,512,000 lb. in 1914 to 60,761,000 lb. in 1918. Consumption has, however, materially decreased since 1918.

The following table shows that the production of zinc has been steadily declining since 1913, but that the output of refined zinc increased until 1918, in which year it decreased.

Years	Zinc Ore Metric Tons	Zinc Ore Value	Refined Zinc Pounds	Refined Zinc Value
1913	34,676	$472,303	(a)	(a)
1914	14,138	140,752	13,140,265	$682,454
1915	6,121	179,845	46,958,601	6,456,866
1916	2,187	91,257	86,652,236	13,567,052
1917	163	13,576	121,596,436	13,462,153
1918	(a)	(a)	88,701,073	8,838,867

(a) Production not stated.

When the war broke out, zinc experienced a boom in Japan, due to heavy demands from Great Britain and Russia. Prices went up, and many new companies, both mining and smelting, were formed. Though there was a marked disparity between costs and selling prices, these companies all made good profits. However, with the beginning of summer, 1916, prices started to go down. With decreased foreign demands, and increased cost of production and transportation charges, many companies have had to either temporarily suspend operations or considerably restrict their activities, the latter course being taken by even several of the middle-sized companies. Much of this financial trouble noticeable among the smaller zinc operators is probably due to pyramiding subscribed capital on the basis of abnormal profits and excessive dividends.

The estimated cost of production of refined zinc at the smelters is about $11 per picul, or 8¼c. per lb. Prices of 98 per cent pure zinc per picul ranged from $6.41 in June, 1914, to $27.40 in December, 1915. Since then prices have hovered around $12 as an average. In March, 1920, the price per picul was $13.96. The margin of profit, considering transportation charges, is thus proportionately low at present.

The imports into Japan of zinc ore, of ingots, slabs, and grains, of sheets, and of waste during the past five years were as follows:

Year	Ore Pounds	Ore Value	Ingots, Slabs and Grains Pounds	Ingots, Slabs and Grains Value	Sheets Pounds	Sheets Value	Waste Pounds	Waste Value
1915	(a)	(a)	6,487,784	$637,056	1,210,100	$157,277	11,125,057	$769,465
1916	(a)	(a)	7,218,985	980,277	1,203,998	228,577	4,401,937	427,889
1917	207,450,533	$3,899,905	10,015,693	879,392	2,694,150	595,171	1,633,445	110,124
1918	133,093,068	2,433,883	5,443,656	681,263	2,981,136	759,511	1,622,656	122,903
1919	61,845,733	1,122,932	12,629,181	1,463,480	3,276,672	555,480	722,444	36,661

(a) Not known.

During 1917 and 1918 a great deal of zinc ore was imported for smelting, mostly from Australia. However, since 1918 imports of zinc ore have decreased considerably, owing to a smaller foreign demand for the refined article, thus causing many smaller smelters in Japan to suspend operations.

Although no definite statistics in support thereof can be presented, indications are that foreign refined zinc and zinc manufactures, principally sheets from the United States, will once again find a growing market in Japan, owing to transshipping and speculative activities in connection with the increased demand for plating in China.

The exports of zinc ore have shown a steady decline since 1915, when they amounted to 13,618,250 lb. On the other hand, exports of zinc ingots and slabs increased until 1917, since when they have shown a noticeable decrease. Japanese exports of zinc ore and of ingots and slabs from 1915 to 1919 are given as follows:

Year	Zinc Ore Pounds	Zinc Ore Value	Zinc Ingots and Slabs Pounds	Zinc Ingots and Slabs Value
1915	13,618,260	$179,846	(a)	(a)
1916	4,865,332	91,258	51,586,452	$9,596,461
1917	362,400	13,576	81,853,012	10,442,511
1918	11,332	234	37,739,584	4,519,766
1919	(a)	(a)	12,629,180	1,463,480

(a) Statistics not available

The principal countries of destination for the exports of zinc ingots and slabs during the last three years were as follows:

Countries	1917 Pounds	1917 Value	1918 Pounds	1918 Value	1919 Pounds	1919 Value
Asiatic Russia	16,370,736	$1,943,703				
British India			7,851,343	$931,442		
China					2,912,616	$296,935
France	13,277,885	1,777,815	15,802,908	1,753,365		
Great Britain	42,452,701	5,472,124	9,330,916	1,166,264	8,586,588	1,048,423
Kwangtung Province					357,452	30,946

In Japan, the principal uses of lead are in the manufacture of paint, cables, and piping and in producing acetic acid. The principal uses of zinc are for galvanizing and paint manufacture.

Both primitive and modern mining methods are used.

INDUSTRIAL NEWS

S. E. Atkins Co., Alworth Building, Duluth, Minn., contract diamond and churn drilling, has just been organized to take over the drilling work of the Duluth Diamond Drilling Co., which is retiring from the contract drilling field.

Wilson Welder & Metals Co., Inc., formerly at 2 Rector St., New York City, has moved its general office to 253 Thirty-Sixth St., Bush Terminal, Brooklyn, N. Y. The offices of the Wilson Welding Repair Co. are now at 263 First St., Jersey City, N. J.

The Associated Petroleum Engineers, 120 Broadway, New York City, N. Y., resulted from a reorganization of The Associated Geological Engineers. It remains an association of experts. The principal difference from its predecessor is one of greater specialization in personnel and facilities for professional work in the petroleum field. The business of the organization is to furnish the services of oil geologists and petroleum engineers throughout the various domestic and foreign fields.

In the field work the more detailed and routine phases of the work are usually done by the less experienced men under the general supervision of the more experienced geological engineers. The result is economy to the clients, and increased reliability of the results by bringing to bear on a given piece of work at least two points of view.

The organization is also equipped to take charge of geological surveying, examinations, and reports on all classes of mineral deposits, metalliferous or non-metalliferous, in any part of the world. Such testing and chemical analyses are undertaken as are necessary to determine the quality or extent of any deposits investigated. Other classes of work undertaken are the examination or testing of foundations and dam sites and the supervision of borings for coal or other minerals. In fact, the same ground is covered as by any geological or mining engineering organization.

Thew Shovel Co., an Ohio corporation (F. A. Smythe, president), has acquired all the outstanding capital stock of the Thew Automatic Shovel Co., Lorain, Ohio, and the two companies have been consolidated. The former has assumed all the assets and business of the latter, together with the legal liabilities and obligations. The consolidation gives the Thew Shovel Company net assets of $2,000,000.

Reliance Weighing Machine Co., Mallers Building, Chicago, Ill., announces the purchase of the business of National Automatic Scale Co., makers of the Reliance automatic grain scale and other automatic recording continuous weighing machinery.

Suggestions to Sellers in China

Parades and Storytellers Best Ad Media

Two interesting suggestions to those introducing goods into China are made in *Commerce Reports* by Trade Commissioner J. W. Sanger and Consul Stuart J. Fuller of Tientsin. Mr. Sanger suggests that as the effectiveness of advertising in Chinese papers is somewhat nullified by the fact that their circulation is small when compared to the population, many of whom cannot afford to buy papers and could not read them if they did, the employment of itinerant storytellers and narrative parades should receive consideration, as these means have proved their effectiveness in some cases. This indicates a new field for ingenious advertisers.

Machine-Shop Trucks Keep the Fleet Moving

Slight Repairs Promptly Made Save Large Repairs Later, Avoid Long Halts and Hasten Deliveries

Moving repair shops, mounted on motor trucks, which were extensively used by the Government during the war to care for its large fleets of trucks at home and abroad, are destined to play an important part in facilitating the successful operation of the ever increasing fleets of trucks operated by large companies, contractors, and road builders throughout the country, according to C. J. Van Landeghem, transportation engineer of the Four Wheel Drive Auto Co., Clintonville, Wis. With the increasing use of fleets of trucks in various lines of business, the machine-

F. W. D. REPAIR TRUCK OPEN SHOWING COMPLETE EQUIPMENT FOR HANDLING ANY REPAIR JOB

F. W. D. REPAIR TRUCK PACKED AND CLOSED BY TURNING UP SIDE AND END PANELS

shop truck, as a flexible medium for keeping fleets of trucks in constant running order, at a minimum loss of time, will become as necessary and vital a factor for commercial use as it was during the war, is his prediction.

"The continuous operation of every truck is an important consideration with a fleet owner, and in this respect the machine-shop truck has proved itself a time and money saver through its ability to go direct to the crippled truck and put it in condition at a minimum of time" says Mr. Van Landeghem. "Mounted on the chassis is a complete equipment to handle any kind of repair job. A separate motor furnishes the power for operating the various machine tools. These embrace such mechanical apparatus as a drill press, screw-cutting lathe, electric grinder, blow torch, welding outfit, forge, and more than 1,000 other pieces of machinery and tools.

"Each tool and piece of machinery has its own place, insuring compactness when the end and side panels are up and the truck is in motion. A great number of these moving repair shops were furnished the United States Government by the Four Wheel Drive Auto Co. during the war. With the increasing tendency to operate fleets of trucks in various industries, the efficiency of the machine-shop truck will soon make it an important factor with every fleet owner."

New Colorado Zinc Oxide

By F. N. SPENCER

Due to increasing zinc oxide needs, South American and West Indian importers interested in the paint and rubber industries are informed that ores are are now being roasted in the Empire Zinc Co.'s new plant at Cañon City, Col., preparatory to actual production of the Palmerton, Pa., grade of zinc oxide. The concern is a subsidiary of the New Jersey Zinc Co. Construction work on its new furnaces at this point was started in February, but progress has since been rapid, despite serious obstacles, and full capacity production may be a fact by October.

Deister Plateau Patents Sustained

Diester Machine Co. announces that earlier this year the United States Court of Appeals at Chicago sustained its three main plateau patents. One of the main features of these PLAT-O concentrating table is the plateau covered by patents owned and controlled exclusively by the Deister Company. The plateau consists of the mineral-cleaning zone somewhat higher than the general stratifying or concentrating portion of the table, and these two surfaces are substantially parallel. Intervening the plateau and the concentrating portion of the deck there is a resistance plane or incline along a diagonal line. The ends of the riffles are slightly bevelled to conform to the slope of this resistance plane.

Oxweld Cuttings and Welding Aided Hibbing, Minn., Removal

An interesting feature of the partial removal of Hibbing, Minn., was the oxwelding of about 35,000 ft. of pipe for the new gas distributing system. This is an example of the new way in which gas-pipe lines are now installed, a continuous length of pipe being oxwelded and doing away entirely with the old threaded connections at the joints. The new process requires only the Oxweld cutting and welding blowpipes and the necessary supplies of oxygen and acetylene, which are conveniently conveyed to the work in Linde and Prest-o-Lite cylinders, the whole outfit being moved along with the work as it progresses. This is the first time that two-inch pipe has been welded in the Mesabi region. About 8,000 ft. of the new Hibbing gas piping is of this size, the rest being four-inch and eight-inch pipe. Oxwelding of pipe lines has been found satisfactory, both as to serviceability of the lines and economy of installation.

The new Hibbing will lose little by its change of foundations, and it will gain much in the way of general improvements.

Efficient Steam Power Plant Needs No Coal

The various sizes and shapes of Conneaut shovel blanks, handles, and complementary tools are now being put through their preliminary steps of shaping under the plant's own steam-generated electric power.

All the drainage from the heating systems, from the many drinking fountains that supply spring water to the men, and the condensation from the engine, goes through a filter and a heater and is used again in the boilers, making a continuous operation and in this way effecting a saving of considerable water.

By means of conveyors, shavings and waste wood are conveyed from the handle plant to the boilers and automatically fed to them. When the handle plant is running full capacity, no coal has to be bought. For emergency use, two tanks on top of the engine room, storing 180 tons of coal, feed by gravity to the chain grate stokers. This coal is elevated from the track to these bins by a conveyor. The ashes from the chain grate stokers are dropped into a pit back of the stokers and by a conveyor carried from there into an ash bin storage. One man can operate the entire plant. Only the conveyors, and other machines and gages, need to be watched.

Atlantic Smelting & Refining Works, Inc., announces the removal of their offices to room 1987-1989, Woolworth Building, New York City, ('phones Barclay 8872 and 8019). Their factory has been moved to Plum Point Lane and Doremus Ave., Newark, N. J., ('phones Market 6720 and 6721.)

TRADE CATALOGS

Armored Hose—The Sprague Electric Works, of 527 West 34th St., New York, in their illustrated pamphlet No. B-3567, list and describe the various parts of their flexible armored hose for industrial work. The highly flexible, yet steel-hard, spiral armor makes such hose both handy and durable for air or steam installations, and the perfected couplings and mending devices facilitate rapid set-up and take-down that will be appreciated by rock-drill men. The air-brake hose of this company is specially illustrated and described in Bulletin 44553.1 for June, 1920.

Still—The many commercial needs for clean pure water, whether for drinking, manufacturing, for storage batteries, or for the laboratory; and the economy today in recovering alcohol lost by water dilution. make the subject of water stills always important. The Barnstead Still & Sterilizer Co., Forest Hills, Boston, Mass., shows in its recent annual catalogue a line of proved appliances adapted to this great variety of needs. The publication aims to be exhaustive, and will be useful to anyone interested in these devices.

Ore-Handling Machinery—The Wellman-Seaver-Morgan Co. has recently issued Bulletin 41, together with several others dealing with the various types of machinery manufactured by the company. This bulletin, "Coal- and Ore-Handling Machinery," contains reproductions of photographs showing unloaders, traveling bridges with grab buckets, car dumpers, car haulages, transfer cars, boat loaders, bucket handling cranes, excavating buckets, and weighing larries. A short description of each, together with a sectional drawing, is included.

Belt Fasteners—Crescent Belt Fastener Co. has issued a new circular entitled "Modern Scientific Methods in Belt Joining." It contains practical belt-joining data for the practical man. This information is of permanent value to anyone interested in belt upkeep, and it is so designed that when opened up and tacked to a wall it presents on one page full information for joining the belt to insure its best service under all conditions of work. Copies of this illustrated circular, Form N. Y. 227, will be sent on request. Address Mining Engineering Service Department of Crescent Belt Fastener Co., 381 Fourth Ave., New York City.

Fuel Oil Burner—John Foerst & Sons, 80 West 22d St., Bayonne, N. J., have issued a catalog illustrating and describing the various types (conical and fan tail), of fuel oil burners which they manufacture. The catalogue also contains illustrations of the burners and their application to various equipment.

Are We at War With Russia?

UNDER the above title we commented editorially on the Bolshevist menace in our issue of Jan. 24, 1920. In this editorial we observed:

Every now and then some Congressman gets up in the House and puts the above question, demanding that our engineers and their guards be withdrawn from Siberia. Similar protestations against the trade embargo against Russia are urged by various kindly and fatuous groups of lovers of all mankind.

We should be interested in psychological tests made on these Congressmen.

Very recently we hear less from these people—since the Russian-bred revolutionary plot in this country has been unearthed.

We *are* at war with Russia. Russia—a murderous outlaw—is making war on us, and winning—not here, but abroad.

Will we take as long to wake up as we did in the case of Germany? A firm and prompt policy now will save untold misery.

If there were anything in spiritualism, do you think all the powers of the air could keep Roosevelt from talking to us in this crisis?

We have been unable since then to note a statement of the relations of the United States to the Bolshevist government quite so bald and forcible till the letter of Frank H. Simonds on "The Polish Question," published by the McClure Syndicate on Aug. 12. Mr. Simonds (perhaps the clearest of analysts of current events) says: "The present hour is as critical for our civilization as that six years ago this month, when the German hosts, victorious in the battles of the frontiers in France and Belgium, rushed down toward the Marne. If it is not faced we shall lose the larger benefit of the Marne victory, and presently be forced to fight at a great disadvantage, *for fight we shall have to, in the end. Willy-nilly, we are again at war, the United States quite as much as France or Britain.*"

We are at war with Bolshevistic Russia: what are we doing? Ostrich-like, we have been hiding the fact from our vision for a year, until the smell of the powder is under our noses. The war is between the Western system of democracy and liberty, which it has taken our forefathers, since Magna Charta, seven hundred years to painfully attain, and the new and unprincipled despotism which drives forward the semi-barbarous Slavonic hordes of the East. The frontiers of American democracy and liberty lie east of Warsaw. During the Great War, it was remarked at times that our middle states showed less concern than our eastern states, as being secure from invasion; and we are suffering from precisely the same stupidity if we unintelligently watch unmoved the foe driving his frontiers nearer and nearer Washington.

The strange genius who rules in the White House, who has so often disappointed the American people, has unexpectedly sounded a true and firm note in his announcement of unchangeable hostility to the autocratic government of Russia (which has so long boldly declared its warfare on us), but friendship to the Russian people. The announcement is culpably late in coming, as was our announcement of our attitude in the Great War; but it is a sane one. Just such a conception and announcement in the case of Germany, and especially Austria, as we may recall, hastened immeasurably the débâcle of the Central Powers. It is especially heartening as against the sorry spectacle and plight of Britain, who, with the Russian tyrants' revolver at her head and traitors in her house, throws up her hands and grins a sickly friendship at an enemy that she knows has no honor. France, however, the indomitable, sounds the same true and sturdy note as America; and thus the two most advanced democracies of the world confront the latest hideous menace to their liberties.

The Shaft-Sinking Medal Of the Engineering and Mining Journal

IN OUR ISSUE of May 15 it was announced that *Engineering and Mining Journal* would present a gold medal to the crew breaking the world's shaft-sinking record, which at that time was stated to be 310 ft., this distance having been made in thirty-one days by the Crown Mines, Ltd., Johannesburg, South Africa, during July, 1919. In addition to the gold medal award, a silver medal is to be presented to each qualified member of the sinking crew. It was further announced that rules governing the award would be published at a later date.

Members of the committee who have been appointed to judge such records are as follows: George S. Rice, William Young Westervelt, and D. E. A. Charlton, these men having been designated by the Director of the Bureau of Mines, the Secretary of the American Mining Congress, and the Editor of the *Engineering and Mining Journal*, respectively.

It will be appreciated that any attempt to specify conditions as to cross-section area or shape of shaft, hardness of ground, number of men employed, or any other condition which would have bearing on the progress made in shaft sinking, would introduce complications in the judging of the contest, and such complications would undoubtedly prove to be a source of discussion and difference of opinion, to say nothing of probable dissatisfaction on the part of the contestants with the final decision of the judges. In the formulation of the rules the question of specifying weighted values to certain conditions and making the award on the greatest number of points seemed to have possibilities, but after due consideration it was deemed best to hold strictly to the first announcement in its simplest interpretation, i.e., that the medal be awarded to the crew breaking the record in footage within the time limit specified.

In order to obviate any ambiguity which may exist in view of the first announcement made, it was necessary to make a definite ruling with respect to the following consideration: Is the medal to be given to the crew sinking more than 310 ft. in thirty-one days, the distance being made (*a*) at any date; (*b*) only if subsequent to July, 1919 (the time when the present record, which according to our figures is correct, was made); or (*c*) only if subsequent to May 15 (the date of the announcement)?

After due consideration it has been decided that the date of the announcement marks the opening of the contest, and inasmuch as the record announced at that time remains unchallenged to the present date, it is presumed that this is correct. In making the award, therefore, the committee will be guided only by the following rules:

1. The footage shall have been made during a period commencing on or after May 15, 1920.

2. The footage made must involve operations in which the sinking process is carried on at the bottom of the shaft during the entire period. It is understood that this performance shall be accomplished by manual labor, with the assistance of power drills and such other mechanical appliances as are necessary.

3. Shafts must be those pertaining to, or sunk in conjunction with, metal mines, and the slope shall be steeper than 45 degrees.

4. The measurement shall include the distance sunk during any consecutive thirty-one-day period, and shall be measured with a steel tape from well-established bench marks.

5. The measurements shall be made and sworn to by three witnesses, preferably the mine superintendent, the foreman in actual charge of the sinking, and a reputable engineer.

6. Records coming within one foot of each other shall be considered a tie, in order to allow for inevitable discrepancies in measuring to the irregular bottom of a shaft in process of being sunk. Therefore the committee will not consider less than 312 ft. as a new record.

7. The award is to be made to the crew whose reported figures, exceeding the record as stated and conforming to the conditions above mentioned, are first received at the *Engineering and Mining Journal* office. Telegraphic report stating the shaft, company, distance sunk, and date will be accepted as reported at the time of the receipt by the *Engineering and Mining Journal* of such telegram, provided the rules are in due course complied with through the mails or otherwise.

The Increased Freight Rates A Benefit to Industry

BETWEEN 50 and 60 per cent of the total tonnage carried by the railroads of this country is said to be the product of our mineral industry. Mining interests should, therefore, be particularly concerned in the increased rates awarded to the railroads by the Interstate Commerce Commission. Briefly, freight rates in the so-called Western group of roads will be increased 35 per cent; on the Mountain-Pacific group, 25 per cent; on the Southern group, 25 per cent; and on the Eastern roads, 40 per cent. Passenger fares will be increased 20 per cent, and Pullman fares, 50 per cent. The present fare from New York to San Francisco, including sleeper, is $120; this will be increased to about $157.

Fair-minded persons know that the railroads deserve this increase. No industry has been more closely controlled by the Government than that of interstate commerce, a special commission for its regulation having been established over thirty years ago. The reluctance of the Interstate Commerce Commission to advance rates to accord with increased costs is well known. With general commodity and labor costs at least double the pre-war figures, freight and passenger rates have probably not averaged more than a 35 per cent advance.

We see no reason why the increases which have been granted should cause more than a temporary increase in the cost of living; in a few months they should have just the opposite effect. One reason why prices have kept up this year is that transportation conditions have been demoralized. With an increased income, suitable equipment can be provided, and delays, uncertainties, special expensive forms of transportation, carrying charges on goods in transit, and like expenses, should be materially reduced. Furthermore, the railroads have been subsidized to the extent of about $75,000,000 monthly by Government guarantees, which expire at the end of this month. This expense to the taxpayer will be eliminated, thereby partially offsetting the increased rates.

We have heard little criticism of the commission's ruling, and we believe that time will prove it just. When the cost of operation is materially reduced, as we hope will be the case in two or three years, the rates can be revised downward. This may be something which the next administration will seek to do, in order to have good campaign arguments four years hence.

The Progress of Ore Deposition Theory

ACTIONS and reactions, ebb and flow, upswings and downswings, are characteristic of many other things than the stock market. It is true of political life, of history, of our individual goings and comings. Even it is true of science. Geology—as, for example, the geology of ore deposits—first dealt in theories of abrupt action—things done with a bang.

To him who gets up in the morning and goes to bed at night, without using overmuch of observation and deduction, the most impressive thing, amid the scurry of animal life, and the rustling activity of plant life, is the immovability of the hills, the "eternal sameness" of the rocks. "Rock of Ages," sings the hymn. What more graphic symbol of unchange? When we note that the earth has been rent and torn, the primitive conclusion is that it is due to one of the catastrophes of nature—like violent storms, earthquakes, floods, hurricanes, lightning-bolts; or we imagine others of like character, of which we have no knowledge, and so conceive of as still more violent. The first geological essay is possibly in Genesis, where it is written that God created the earth in six days, and rested from His labors on the seventh.

In common conception, in fiction or travel writing, and in movie captions, we find that a canyon is commonly ascribed to "some tremendous convulsion of nature," and even a glacial moraine or a talus slope will be laid to the "sport of nature in prehistoric times."

Our early geologists followed this natural trend of thought. So also, in course of time, when geologists began to study ore deposits specially, did they ascribe similar catastrophic explanations to mineral deposits, especially to the phenomena of vulcanism.

With the growth of geologic knowledge, it became convincingly plain, little by little, that the processes which carve rocks like putty, which mix rocks like dough, are not by any means dead—that they are working today, but very, very slowly; so that the stupendous work accomplished must have gone on for an inconceivable length of time. It became clear that the rocks were not made in seven days, nor in seven thousand years, nor yet in seven million years: that erosion, uplift, and metamorphism are going on during the quietest days in June, when the rocks seem most eternal; and that the natural catastrophes, like volcanic outbursts, landslides, and tidal waves, so far from being the cause of all geologic phenomena, are only the slips and starts of an ordinarily well-oiled and effective machinery.

This discovery was applied to mineral veins. The finding out that waters in the soil and rocks were capable of dissolving and redeposition, and the proof of the efficacy of these processes, led naturally to the thought that all, or most, mineral deposits have been so formed. The formation of iron and manganese deposits in this way seemed fairly clear; and later there was demonstrated the formation of rich copper deposits out of very lean ones.

The uniformitarian theory, again, has spent its force. It went too far, as the early catastrophic theory did. Nature, it appears, in her rock work is not so much of a humdrum plodder as we thought. She has fits and starts, periods of quiescence and of relatively great activity. So in the last few decades the relation of many ore deposits to igneous rocks has been narrowly observed; next, their relation to certain phases of igneous activity. This study is furnishing an accumulating fund of more and more accurate knowledge.

Human thought on a subject like this is like a pendulum, which, on being released, swings first to one side and then to the other, far past the true direction of gravity, but tends finally to find the true position of the earth's center and to remain fixed in that discovery.

Experimenting on the Olfactory Nerves of Miners

THAT the use of volatile ill-smelling compounds is preferable to electric bells as a warning to miners of unsafe conditions such as mine fires we do not doubt. The Bureau of Mines has recently been testing the idea and has just issued a report on the subject. Electric bells cannot be heard far and are likely to get out of order. A telephone system is better, but has obvious drawbacks. Sometimes cutting off the compressed-air supply has been used as a warning, but this may bring miners to the surface when they are not wanted. Or, water may be put in the air line, and when the driller gets drenched he is supposed to give up his work and demand an explanation at the surface.

Some time ago the Butte & Superior company tried the experiment of introducing a little valeric acid into the intake of the air compressor. This is the substance we used while in the chemical laboratory at college when the devilish instinct got the better of our normal cultivated angelic character. As we remember it, the *iso* variety smells like the concentrated extract of the choicest old cheese; that is, choicest to the cheese hound. But other and more effective odors have been found by the Bureau, such as ethyl and butyl mercaptan, butyric acid, and amyl acetate. The mercaptans are organic sulphur compounds. We do not remember ever having been in the path of their fragrance, but the effect of sulphur on such inoffensive elements as hydrogen is well known and if butyric acid be used in the compound the effect can be imagined; or rather, it can't be. Butyric acid is what makes rancid butter rancid, to speak as kindly of it as possible. Amyl acetate has the odor of bananas and is pleasant to most people, and so is frowned upon by the Bureau, which says that a more disagreeable odor makes a more suitable warning.

However, the use of amyl acetate suggests to us another field for investigation. Why not surcharge the mine with pleasant odors and make working conditions there more bearable, thereby promoting the efficiency of the miners? The burning of incense near the compressor intake should be particularly efficacious in spurring Chinese miners to an honest day's work. To give European workers the proper enthusiasm, we suggest a spray of allyl sulphide, this being the business principle of garlic.

A possibility also exists of evading the Eighteenth Amendment, for we understand the law does not cover the inhaling of alcohol for commercial purposes. Think how a properly impregnated mine air would stimulate production! The only reward that we ask for this suggestion is that we be given a job as shift boss in the mine in which the experiments are made.

New York Buys Radium

THE recent purchase of two and one-quarter grams of radium by the State of New York for use in cancer research is noteworthy. All the radium produced should be reserved for this purpose until a more essential one is found, if that be conceivable. Such radium as has been recovered has not been put to the beneficent use in which it finds its most important application. Much of it, if not most of it, seems doomed to be wasted in the manufacture of luminous paint. Wasted it certainly is, for not only is such use non-essential, but the paint itself has a very short life.

The Federal Government could well improve on the step New York has taken by either purchasing the existing supply of this substance or, as we have suggested before, by placing the control of its distribution in the hands of some Federal agency, such as the Bureau of Mines, in the public interest.

Porcelain Coins—What Next?

GERMANY is using porcelain coins. After unloading upon the world large quantities of silver coins in an effort to sell the remaining vestige of tangible and maketable wealth, and contributing to the decline in the price of silver, Germany is compelled to resort to the use of "siliceous" coinage—our own classification for this type of currency. No doubt it will be easier to keep in circulation coins with negligible intrinsic value, such as copper and porcelain, than precious-metal pieces. The disappearance of silver from circulation has caused much confusion and trouble to European governments, but Germany has offered one solution.

However rife speculation may be regarding the effect of this step, we are reminded of an admonition which a waggish acquaintance was frequently wont to use as a parting shot on leaving us, and which is peculiarly appropriate for the present trend in the reorganization of some of the world's currency systems. We give it for what it is worth: "Don't take any wooden money."

WHAT OTHERS THINK

The Licensing of Engineers

Through ignorance of political engineering, and perhaps by not doing our utmost everywhere, we engineers failed to secure the nomination of our candidate for President, notwithstanding the great advantage that he was probably also the popular choice. The regular politicians would not permit it.

Unless signs fail we will soon be again lifting our voices in lamentation, this time over the passage of as many different laws relating to licensing engineers as there are states in the Union. A good start at the confusion has already been made by the passage of such laws in eleven states, mostly without the serious attention of the engineers concerned, and in some cases apparently without their knowledge.

We should be grateful for the fine work of the committee of Engineering Council on licensing engineers, but being grateful will not be enough. That particular "George" is not going to finish the job. We must do it ourselves by agreeing definitely on what we want and then going after it through our organizations.

In Los Angeles we have a joint committee of the local sections of seven national societies at work on the problem, and it is to be hoped that similar action is taking place generally and that agreement will be quickly reached on the fundamentals of a licensing law.

It seems to me that the draft of the committee of Engineering Council is the nearest approach to a law upon which we could unite, but that it has the defect of dodging a definition of the matter it proposes to regulate, that is, professional engineering.

Most proposals (and some of the laws passed) have undertaken to define the term "professional engineering" by specifying every possible activity relating to engineering of every kind, and prohibiting the practice of any of them without a license. This has come so near to a *reductio ad absurdum* that the difference is scarcely noticeable.

There is a simpler plan which I wish to urge, and upon which I think we can all unite and carry through. The simpler laws are, the better. Therefore it is suggested that a licensing law should be simply a prohibition against *advertising, claiming* or *representing* oneself to be a professional engineer of *any branch* without a license, rather than a prohibition against practicing.

In effect it is proposed to provide a means by which engineers can be licensed or registered if they want to call themselves engineers, which licensing or registration would be subject to conditions to be specified in the law (and which could well be identical with those in the Engineering Council draft), and would give licensed engineers just as much state endorsement as they are entitled to, and the public just as much protection as any law could do. The public will demand evidence of licensing as a condition of employment when it is known that such a law is in effect, and if it considers it as a protection.

This would eliminate the impossible feat of so defining the activities of an engineer as to permit other proper and necessary activities so closely bordering on and interwoven with engineering as to preclude the possibility of a sharp line of division. The licensed engineers would immediately become a "blue ribbon" class, outside of which no engineer of consequence could afford to be.

Such a law would be a preliminary skeleton, to which could afterward be added such further conditions as experience might show to be desirable.

Los Angeles, Cal. W. F. STAUNTON.

Engineering and Mining Journal Lead Quotations

As corroders of lead purchased chiefly on average price contracts based on *Engineering and Mining Journal* quotations of prices, we urge that you should continue your quotations.

Steadiness of supply of raw materials and minimum fluctuations in price afford the best conditions of production in any manufacturing business, and strongly tend toward stabilization of prices of the finished product. In the white-lead business an interval of some weeks frequently occurs between the asking of prices and the placing of orders to fill contracts for painting, during which it is desirable that prices should change very little, if at all, to prevent the evils of options or of price protection, with their consequent tendency toward speculation. Both the sellers and the buyers of white lead appreciate the benefit of the existing price policy of few changes, based on the long-swing movements of the price of pig lead, but recognize that this policy is feasible only in the absence of erratic, speculative changes in the price of pig lead.

We believe that your independent, unbiased estimate of prices is of high value in steadying the market.

Scranton, Pa. EUSTON PROCESS CO.,
Edwin Euston, President.

The Arkansas Miner

It is with considerable astonishment, not unmixed with awe, that I read the communication of George Allen, of Little Rock, Ark., captioned "Making Miners Out of Farmers," which appears in the *Engineering and Mining Journal* of July 24. My astonishment is about equally divided between the *Journal* and the Mr. Roderick mentioned—at the *Journal* for publishing such misinformation and the Mr. Roderick for his truly marvelous performance at such an advanced age. Mr. Roderick, having introduced underground mining to Arkansas, must be well over ninety years old.

I am not sure when the first mine was opened in the State of Arkansas, but in 1888 Dr. T. B. Comstock visited the Confederate shaft, and states on page five of the Annual Report of the Arkansas Geological Survey for 1888: "The history of exploration in this place (Confederate shaft), according to apparently authentic traditions, dates back more than forty years." Therefore, the Confederate shaft workings must be today

approximately seventy-two years old, and taking the child labor laws into consideration, Mr. Roderick was probably at least eighteen years old at the time he introduced underground mining at this place, which, for sake of argument, we will assume was the first underground mining in the state.

I can imagine the astonishment of our friends mining coal and zinc in the state to learn that their workings are all on the surface, in spite of the fact that they have sunk shafts to reach their deposits.

With regard to the Arkansas farmer—he is no different from the farmer of any other state. I have introduced many farmers to both underground and surface mining, and have found no greater proportion of Arkansans averse to underground mining than those of any other state.

I have no statistical information at hand, but it is probably true that the mining industry draws more extensively on the farming class than any other for its supply of miners.

The attention of the Carnegie Hero Committee should surely be drawn to this case. Because of Mr. Roderick's advanced age, he will probably not be with us much longer, and it might be well to give this tip to the directors of the Hall of Fame.

As to Mr. Allen, he seems to have made the common mistake of taking in too much territory.

Bauxite, Ark. JOHN T. FULLER.

Aids to Cyanide Plant Recoveries

A perusal of the interesting article "A Cyanide Plant Without Frills," by Leroy A. Palmer, in your issue of June 5, 1920, suggests that the low recovery of gold and of mercury may possibly be increased by agitation of the sand residues in a puddler on their way to the dump. If the use of the tube mill were continued a liner of the South African type would also probably recover much amalgam. Both these methods proved of service in South Africa. WEST COUNTRY MINER.

London, England.

Boosting the Gold Assay

The article "Stories From the Laboratory," by A. R. Ledoux, in *Engineering and Mining Journal* of July 24, reminds me of a story told by the late Prof. P. de P. Ricketts to his class in assaying at the Columbia School of Mines some thirty years ago.

A man came to him and in perfect honesty claimed that he had discovered a method of assaying for gold which gave higher returns than the usual method of fire assaying. His method was to add a definite weight of trichloride of gold, $AuCl_3$, to the charge, run the assay in the usual way, and, after weighing the parted gold, to deduct the gold added in the trichloride.

Tests made in Prof. Ricketts' laboratory showed that things worked out as the man had claimed, and the returns were higher than when no trichloride was added.

Then an investigation followed as to why. The trichloride used was suspected, so a fresh supply of c.p. trichloride was purchased and used, but still the returns were higher. Finally a definite weight of pure gold was dissolved in aqua regia and the whole amount of the resulting gold chloride was added to a charge, the assay run, and the weight of the gold used in making the chloride was deducted from the weight of the parted gold obtained. The corrected weight agreed exactly with a parallel fire assay made without the addition of chloride of gold, showing that the trichloride of gold, even the c.p. brand, contained more gold than its formula, $AuCl_3$, would indicate, due probably to the presence of lower chlorides. E. B. DURHAM.

Canonsburg, Pa.

Lead and Automobiles

In common with the production of gasoline, which is now at the point of limiting the manufacture of internal-combustion machinery, the production of lead must be considered. Gasoline and oil shortages are also the limiting factors in the design of a cheap machine for city transportation work.

To relieve congestion in cities, for the poor and other populations, so that one can easily enjoy life in the suburbs, with cheaper living conditions, some cheap invention is necessary, that will make the transportation of great populations inexpensive and practicable. In the *Popular Science Monthly* of July, 1920, occurs a description of a cheap automobile, employing electric drive, that is a step in the right direction.

This uses the storage battery, which can be easily recharged and stored, and is good for thirty miles under almost any condition of weather and service.

The battery is made mostly of lead. Edison's battery made of nickel and cobalt will do, but the first cost is treble that of lead, though with longer serviceability. Cobalt and nickel are rare in occurrence. Experts believe that lead will be the storage-battery metal for the future, for auto and isolated lighting sets. Already the consumption of lead for automobile work is alarming those who know intimately the facts of production. It begins to look as if street railways in cities are doomed to greatly curtailed operation under the competition of gasoline automobiles, and their outlet from present competitive conditions may lie through conversion to charging centers for the use of electric-current autos. Streets are due to be cleared of rails, cars, and other impediments and given up to the use of electric and other automobiles.

We know from study that lead production in the United States is in a bad way for the future. It could be easily and quickly overtaken by an inflated demand, due to an invention satisfying the popular need, which is precisely what the use of automobile and truck has done for the gasoline industry. The present prices of lead are indicative of the short supply, and the lack of fresh shippers for years, producing in sufficient volume to take the place of old dug-out mines, confirms the suspicion of shortage.

We have had a high tariff fence around lead, particularly in its raw form as ore, since the Windom Decision of 1882, inside of which we have depleted our supplies with great rapidity. The war pushed production to the point of exhaustion of every old dump, stope, and tailing pile, with no increase of new tonnage; coupling with this, the fact of an almost complete stoppage of development work.

We would be greatly embarrassed should a sudden popular demand occur in connection with the automobile industry, as lately befell the production of gasoline and oil GEORGE HUSTON.

Estimates of Mesabi Range Orebodies

All Factors Which Influence the Determination of Mining Methods Are Given Consideration, Preliminary to the Development of Minnesota Open-Pit Mines—Cross-Section Method Of Estimation Permits Accurate Interpretation of Available Data

Written for *Engineering and Mining Journal*

THE initial exploration of the iron orebodies of the Mesabi Range, in Minnesota, is done with churn and diamond drills. Different systems of locating the drill holes are employed by the companies operating, depending somewhat on the part of the range to be explored and on other local conditions. A common system is to locate holes at intersections of north and south and east and west co-ordinates, spaced either 200 ft. or 300 ft. apart. Intermediate holes between these are drilled also, if necessary, to determine more accurately the outline and structure of the orebody.

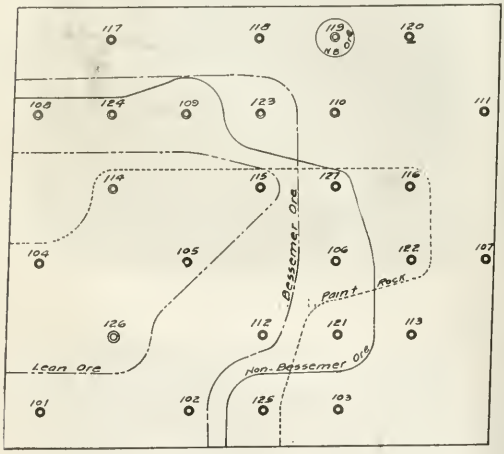

FIG. 1. MAP OF 40-ACRE TRACT, SHOWING OUTLINES OF ORE LAYERS

If the 300-ft. spacing is used, and all intersections are drilled, twenty-five holes will be required per forty-acre tract, which is the unit of property ownership. Forty-nine holes per forty-acre tract are required with the 200-ft. spacing system. Experience has proved that the latter spacing is not too close for most parts of the range.

After the explorations are completed, estimates of tonnage can be made preliminary to operating plans or estimates. Engineers in estimating ore reserves usually employ the method of average depths and the cross-section method. Inactive properties usually are estimated first by the method of average depths, and the cross-section method ordinarily is used in estimating mines which are being operated, or for which operating plans are being made.

Average-Depth Method in Ore Estimation

To use the average-depth method, the drill holes are platted on a map drawn to a scale of 100 to 200 ft. to the inch. On this map the area of the deposit is outlined by drawing a line inclosing all the drill holes containing ore. A frequent method used to locate such a line is as follows: Draw arcs on the outside of all outside ore holes, using the holes as centers, and connect the arcs of adjoining holes with straight lines tangent to the arcs. The radii of the arcs depend on the thickness of the ore in the holes. If the ore is 50 ft. or more thick, a 100-ft. radius is used; if between 25 ft. and 50 ft. thick, a 50-ft. radius, and if less than 25 ft. thick, a 25-ft. radius is used. This method is purely empirical but has proved fairly conservative, and is acceptable for ordinary reserve estimating purposes. However, if the ore samples from the drill holes are properly classified as to structural subdivisions, and if structural cross sections of the orebody are prepared, intermediate holes being drilled to determine the structure accurately if necessary, it is possible to determine the limits of the orebody between drill holes on the surface map and cross sections with a considerable degree of accuracy, much more accurately than by the use of the above-described empirical method.

Limits of Ore Analysis Differ With Various Companies

The most common classifications of Mesabi iron ores are the following:

1. Standard ores (most of which are of merchantable grade and can be shipped direct to docks).
2. Washable ores.
3. Lean, non-washable ores.

All ores analyzing above 49 or 50 per cent dry iron are classified as standard ores. Some companies use one limit, some the other. Standard ores are subdivided into bessemer and non-bessemer. A bessemer ore is one which can be used with suitable fluxes to make a bessemer pig iron. According to the current furnace practice on Mesabi Range ores, those ores which contain .00075 to .00085 per cent or less of phosphorus for each 1 per cent of iron are classified as bessemer in ore-reserve estimates. The particular ratio to be used depends on the phosphorus content of the limestone and coke which furnaces use. Actual bessemer ore shipments are graded closer to the higher ratio than to the lower. All standard ores not bessemer are classified as non-bessemer.

Washable ores are those in which fine free sand is interbedded with lenses and layers of clean ore, the classifications being made from an examination of samples, the texture and structure governing more than the iron analysis. Lean, non-washable ores are all churn-drilled material analyzing less than 49 or 50 per cent dry iron and over 35 or 40 per cent. It is the general practice to classify all the diamond-drilled material analyzing less than 49 or 50 per cent dry iron as taconite, the local name for the iron-formation rock.

From the classification and analyses of ore samples, each orebody should be divided into its structural subdivisions or layers on the cross sections (described in the following), and such layers further divided into

FIG. 4. SUMMARY SHEET FOR OPERATING ESTIMATES

Description Sub-Div.	S.	T	R.	Layer	Class	Open Pit Ore: Steam-Shovel Tons	Iron	Phos.	Sil.	Milling and Scram Tons	Iron	Phos.	Sil.	Underground Ore Tons	Iron	Phos.	Sil.	Underlying Low-Grade Ore Tons	Iron	Phos.	Sil.	Stockpiles Tons	Iron	Phos.	Sil.	Cu. Ft. per Ton	Total Reserve Tons	Iron	Phos.	Sil.	Remarks

bessemer, non-bessemer, and lean-ore layers. Areas of such layers can be shown on the plan map also. Most orebodies contain a layer of low-grade ore material, which is the alteration product of an interbedded slate layer. It is called the intermediate paint-rock layer and is not merchantable, because of its high moisture and consequent low natural-iron content. It is desirable to outline this layer separate from the ores above 49 or 50 per cent iron on the cross sections, for structural reasons.

Average-Depth Methods—The tonnage of ore in the main body is obtained by multiplying the planimeter area reduced to square feet by the average depth of the layer and dividing by the factor for cubic feet per ton. If a drill hole shows an isolated ore area surrounded by rock, a circle is drawn around this hole having a radius of 25 or 50 ft., and this volume is estimated as a cylinder. The average analysis of each layer is found by adding the foot units of all the drill holes in the layer and dividing by the total depth of ore in the holes. The several layers of ore being estimated separately, the tonnages and also ton-units of the layers of standard ore are combined. The total ton-units divided by the total tonnage gives the average analysis of the whole deposit. A map illustrating the outline of an orebody is shown in Fig. 1, and an estimate sheet in Fig. 2.

Cross Section Method—Standard cross sections are made on a natural scale of 30, 40 or 50 ft. to the inch. A convenient size of these cross sections is 18 x 42 in. for a 40-acre tract, using a scale of 40 ft. per in. They are made on plain tracing cloth and are ruled one inch vertically, and horizontally to show 100-ft. intervals. Thus, a sheet will include a distance of 1,400 of 1,500 ft. horizontally and 520 ft. vertically, drawn to a 40-ft. to 1-in. scale. They are made looking either north or west, depending on the trend of the orebody, and are taken on the north and south or east and west co-ordinates 50 or 100 ft. apart. If the strike of the orebody is not approximately north and south or east and west, the cross sections may be taken at right angles to a line parallel to the strike. On the tracings are platted profiles of the natural surface, top of ore, and annual profiles of the open pit, if the property is being operated as such. The top of ore may be shown by a dotted line to distinguish it from the other profiles. If there are any underground workings, the drifts and stopes are platted on the sections. The stopes are cross-hatched and the level numbers are given corresponding to the level maps. Drill holes and analyses of samples are shown also.

All companies have iron and phosphorus determinations made of drill samples. Some have silica and manganese analyses made also, and some add alumina. The structure of the ore body obtained from a classification of the drill samples is shown by lines drawn on the backs of the tracings. These lines mark the top of the upper slaty, upper cherty, lower slaty and lower cherty horizons and the top of quartzite and several minor subdivisions of the major ore horizons. All of these horizons do not occur in all orebodies. Their presence depends on the location of the orebody in the iron formation outcrop and the amount of erosion which has occurred from the top of the orebody.

The structure of the Mesabi ore deposits is described by J. F. Wolff in *Engineering and Mining Journal* in a series of articles beginning July 17, 1915, and in *Transactions* of the A. I. M. E., February, 1917.

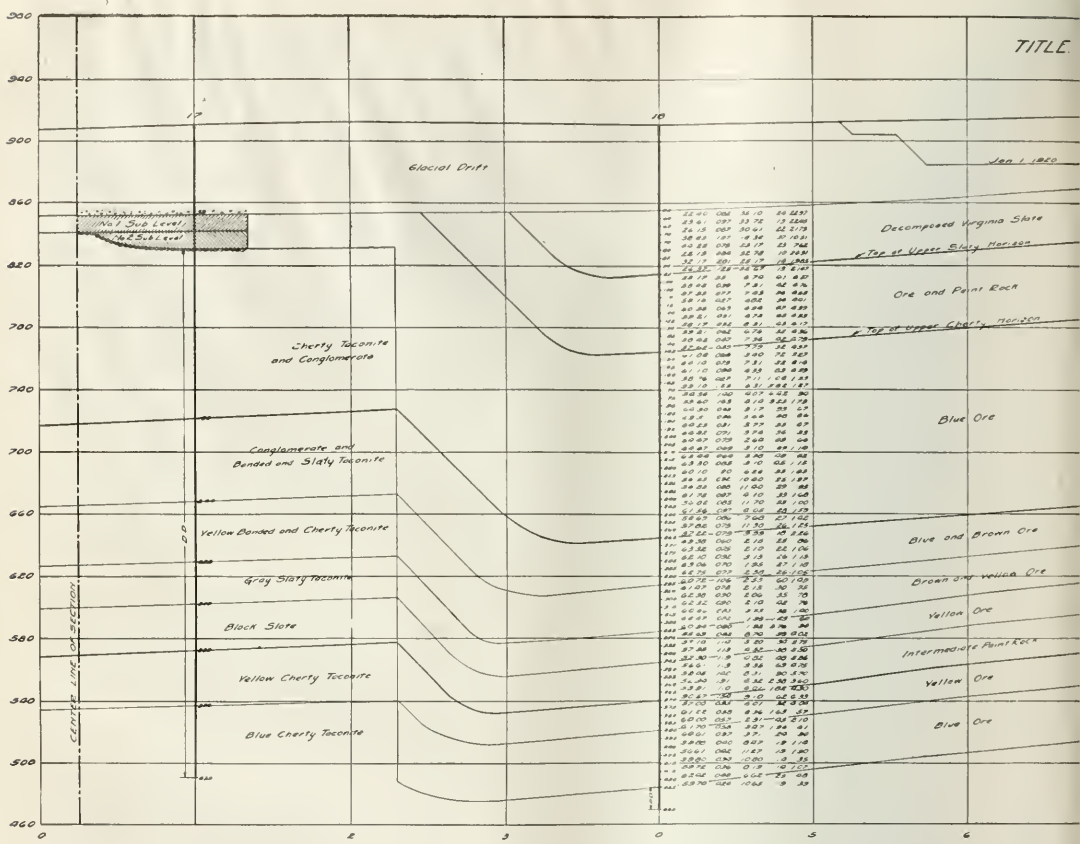

FIG. 3. TYPICAL CROSS-SECTION OF OREBODY

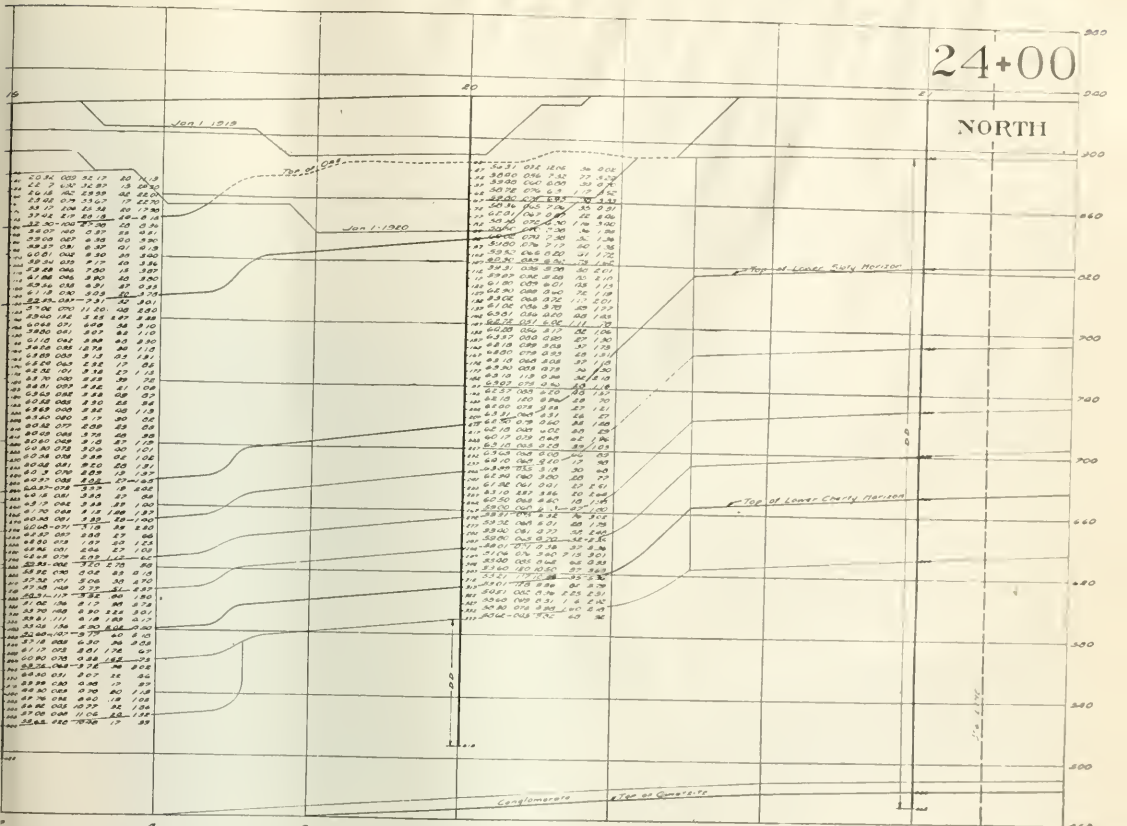
For purposes of determining the number of cubic feet per ton to use in the estimates, density tests are made as follows, wherever possible: A box without top or bottom is made out of steel sheeting, three-sixteenths of an inch thick. The sides of the box are held together by angle-iron pieces, to which they are bolted and should be reinforced by a narrow strip around the top. A convenient size to use is 2 ft. 6 in. square by 2 ft. deep, and this has a capacity of 12.5 cu.ft. The floor of the open pit, drift, or stope is leveled off, care being taken that no loose ore remains and the box is driven down into the ore layer to be tested until the top is flush with surface of ore. As the driving progresses the ore is dug out with a pick and shovel and weighed. If it is not possible to drive the box flush, the depth of the void can be obtained by measuring down from the top of the box. The volume of the ore in cubic feet multiplied by 2,240 and divided by the weight of the ore in pounds gives the number of cubic feet per ton. Such tests should be made in as many different horizons and parts of the orebody as possible, because the density will vary in different layers and positions in an orebody. In properties that are undeveloped, a tonnage curve is used.

Three methods of mining are used commonly on the Mesabi Range, namely, open pit, steam shovel and locomotive method; open-pit milling method; and underground mining method. Operating estimates are made to determine the best method of mining the ore on a basis of cost per ton. When part of the ore can be mined more cheaply by the open-pit method, there is usually an area around the edges which must be mined by underground methods on account of the thickness of the overburden as compared with the depth of the ore and because of the occurrence of the ore layers in taconite walls. Sometimes part of the ore is too deep to be hauled out of an open pit with locomotives and must be milled down to haulage drifts near the bottom of the orebody and hoisted through a shaft. The ore remaining under open-pit tracks must be mined by this method also. The ore in slopes of the open pit is mined by the underground or open-stope method. The ore reserve, therefore, is to be divided among steam shovel, milling and underground ore.

To outline the proposed open pit the following interpretation is placed on the data secured from each drill hole: A unit area of 27 sq.ft. is taken around each hole so that each foot in depth will then contain one cubic yard. A cubic yard of ore may be considered as equal to two tons. The cost of mining the ore under each unit area is computed by open-pit and by underground methods. Assume the following prices in making a comparison of cost by each method:



ON MESABI, SHOWING ROCK AND ORE LAYERS

Stripping surface	$ .60	per cubic yard
Stripping broken rock	1.20	per cubic yard
Stripping solid rock	1.80	per cubic yard
Steam shovel ore	.40	per ton or .80 per cu.yd.
Milling ore	.80	per ton or 1.60 per cu.yd.
Underground ore	2.50	per ton or 5.00 per cu.yd.

As an example, assume a drill hole with surface 60 ft., solid rock 22 ft. and ore 30 ft.

Stripping 60 ft. of surface at	$ .60	$36.00
Stripping 22 ft. of solid rock at	1.80	39.60
Steam shovel ore 30 ft. at	.80	24.00
Total		$99.60
Underground ore, 30 ft. at	5.00	150.00
Difference in favor of open-pit mining		50.40 = $.84 per ton

The above costs represent neither average nor any specific Mesabi Range costs, but are assumed for purpose of illustration. The engineer uses such costs as in his judgment will be incurred in each specific case.

After determining which holes are to be included in an open-pit area, an outline of the proposed pit is drawn on a map of the property on the scale of 1 in. = 100 ft. The cross-sections are used in determining such an outline, and the crest of the ore pit is located so as to include in the pit all ore for which the open-pit mining cost does not exceed the underground mining cost. In determining such a division the same comparative test can be applied at any point on the cross section which was applied to all the drill holes as above described. Attention must be given, of course, to making the shape of the open pit such as can be operated by ordinary steam-shovel and locomotive methods. Some ore may have to be excluded from the open-pit area because of inaccessibility to steam shovels and locomotives in the general operating plan which is most advantageous for the maximum tonnage in the orebody.

Outside of the crest of ore line a berm of 25 ft. is allowed to the toe of the proposed surface stripping slope. In ordinary glacial drift, composed of clay, boulders and gravel, a slope of 1 to 1 is allowed up from the toe of slope located as described. If the surface is known to be composed of gravel and sand only, and is very deep, flatter slopes up to 1½ to 1 should be used. A proper approach to the pit should be noted on the map, its location being made with regard to maximum tonnage possible to mine by steam shovel and locomotive haul, location of stripping dumps, general topography of surface, surface plant, and minimum yardage necessary to remove for such approach. A track system is planned in the ore pit next, using the map and cross sections

jointly in locating the track alignment. A map showing contours of top and bottom of ore is preferable for such use.

The following specifications are used generally in establishing track locations and grades and slopes of ore banks: For the ultimate track plan maximum grades of 3 per cent compensated on curves are allowed. Maximum curves of 15 deg. on main-line tracks are used. For final clean-up switchback tracks much steeper grades and sharper curves are and have been used. Grades as steep as 7 or 8 per cent and curves as sharp as 30 deg. have been used in actual operations. Where the depth of ore is less than 100 ft. a slope of 1 to 1 is allowed in the ore on the track side of the pit. A slope of ½ to 1 may be used in ore on the other sides of the pit, unless there be a structural rock wall of the orebody on such other sides, and in this case all of the ore up to such walls and to the limit of locomotive operations in depth is included in the "steam shovel and locomotive ore."

On ore banks higher than 100 ft. the allowed slopes should be increased to 1½ to 1 and 1 to 1 respectively. For milling pits a slope of ½ to 1 is used where the ore banks are less than 100 ft. high, and 1 to 1 where they much exceed 100 ft. If structural rock walls bound the orebody the milling ore should include all ore up to such walls, the above-mentioned slopes being used only where a wall of ore will be left exposed, such as at a property line where the orebody continues on to an adjoining idle property.

The character of material in the bank and the natural dips of ore layers in the orebody must be considered in determining slopes. Where the structural cross sections indicate marked dip of ore layers into the main ore trough, of course flatter slopes than those specified must be used to guard against slides of ore which would ruin a track system and seriously interfere with mining operations. The location and dip of the paint-rock layer, which is soft and yields easily, must be regarded with special care in locating tracks and establishing slopes.

Consideration of Wall Slopes

If the structural rock walls of the orebody are high, and any considerable thickness of them exists above the so-called "intermediate slate" layer, which is at the base of the Lower Slaty horizon, this thickness may have to be trimmed off to a slope of ¼ to 1 down to the bottom of the slate layer so as to eliminate the danger of slides of rock into the open pit from the walls above the slate as the ore is being removed from the pit. This feature should be provided for in drawing up the stripping plans so that the surface may be removed far enough back either in the first stripping work or in subsequent stripping extensions. Where something is known as to character of rock walls from operations on adjoining properties such wall-sloping can be anticipated. Walls which are somewhat decomposed, or contain fissures extending into them, must be sloped. One rock wall of some orebodies may overhang somewhat, and such walls must be sloped also. In most instances the rock walls of the Lower Cherty horizon (below the "intermediate slate" layer) are so solid that they do not require sloping.

Using the specifications and precautions given, the engineer denotes track alignments and ore slopes on both map and cross sections. On the latter the orebody is thus naturally divided according to the mining method to be applied to its different parts, i.e., (1) locomotive and steam-shovel ore: (2) milling ore, and (3) underground ore. The last classification may be divided in some cases into (a) ore which can be dumped into an open pit and hauled out by locomotives, and (b) ore which must be hoisted through a shaft.

Average areas of surface stripping, steam shovel, milling and underground ore of the several grades can be platted on the map also.

The quantities of stripping and ore, subdivided as noted, then can be estimated from the cross sections or from the map, using the method of average depths. The engineer can judge from the conditions, such as shape of orebody and open pit, which method will be more accurate. One method may be used for part of the estimate and the other for the remainder if greatest accuracy is obtained thereby. A convenient summary sheet for such an operating estimate is shown in Fig. 4.

British Columbia Mineral Production Decreased

The monetary value of the mineral output of British Columbia for the year 1919 was $33,296,313, as compared with $41,782,474 for 1918, according to official figures given in the Annual Report of the Minister of Mines, which has just been issued and now is available for distribution.

The decrease, though considerable, is not serious when placed against the greater decline in mineral production shown by returns from the various states south of the line where the mining industry is an important factor. In fact from this point of view it is indicated that British Columbia did not experience to the same extent the falling off in demand for metals following the cessation of war.

An interesting comparative table is published which, in part, follows:

QUANTITIES AND VALUE OF MINERAL PRODUCTS FOR 1918 AND 1919

	1918		1919	
	Quantity	Value	Quantity	Value
Gold, placer, oz	16,000	$320,000	14,325	$286,500
Gold, lode, oz	164,674	3,403,812	152,426	3,150,645
Silver, oz	3,498,172	3,215,870	3,403,119	3,592,673
Lead, lb	43,899,661	2,928,107	29,475,968	1,526,855
Copper, lb	61,483,754	15,143,449	42,459,339	7,939,896
Zinc, lb	41,772,916	2,899,040	56,737,651	3,540,429
Coal, 2,240 lb	2,302,245	11,511,225	2,267,541	11,337,705
Coke, 2,240 lb	188,967	1,322,769	91,138	637,966
Miscellaneous products		1,038,202		1,203,644
Totals		$41,782,474		$33,296,313

One interesting feature of the above is the increase shown in silver production, reflecting the increased quotations for the metal and, to some extent, the opening up of promising northern fields. Another worthy of note, but not of such an encouraging nature, especially from an industrial standpoint, is the marked decline in coke manufacture.

The report includes the usual detailed accounts of mining activity during the year in the several districts of the province by the resident mining engineers.

Quicksilver and Tin Mining in Bolivia

The central office of the important Bolivian silver and tin mining company, the Cia. Gallofa-Consolidada de Colquechaca, is in Sucre, says a report issued by the Department of Commerce, where most of the stock is held. A "junta consultativa," or subdirectorate, of the Chilean "Cia. Minera y Agricula Oploca de Bolivia" also has its offices in Sucre.

The Copper Ores of Lake Superior

Conglomerates and Basaltic Flows Afforded Zones for the Circulation of Powerful Ascending Mineral-Bearing Solutions During a Period of Great Volcanic Activity—Depth Of Mineralization Shows Deep-Seated Origin

By J. E. Spurr

Written for *Engineering and Mining Journal*

THE copper deposits of the Keweenaw Peninsula, in northern Michigan, have been mined for fifty years on an important scale, and show no signs of exhaustion, although several of the mines have reached a vertical depth of over 5,000 ft. These ores as described by Pumpelly and Irving, together with their associated rocks, have long formed one of the classics of economic geology; and many writers have followed in the footsteps of the early masters. I shall not attempt to summarize the voluminous literature, but will unconventionally begin by stating my own notes, taken in the course of a few days' visit to the district, in which I was guided and enlightened as to local geological conditions by Prof. A. E. Seaman, of the Michigan College of Mines. It should be made clear that my visit was a hasty one to parts of only t[illegible] of an extensive district; and, therefore, these preliminary notes do not pretend to the dignity of an article, and are presented with all apologies for inevitable shortcomings and inaccuracies.

STOPE IN THE CALUMET & HECLA

The copper-bearing formation is a thick series of intercalated conglomerates and thin flows of dense basic (basaltic) surface lavas. The upper part of each flow as a rule was vesicular, and hence by subsequent filling has become amygdaloidal. The conglomerates contain rounded pebbles of this basalt, including the amygdaloidal variety, as well as other rocks, like quartzite, siliceous igneous rocks, like quartz-porphyry, and denser (felsitic) igneous rocks. The upper surface of the basaltic flows was fissured and broken up, evidently from rapid contraction or cooling, at the surface, and sand sifted down and filled these fissures.

The copper ores occur as scales, shots, threads or masses of almost any size, of metallic copper, scattered through certain lode-like zones parallel to the upturned layers of beds of sandstone and conglomerate. The mineralized zone may be a conglomerate, as in the case of the Calumet & Hecla, or an amygdaloidal ancient basalt, as in the case of the Champion mine, both of which were visited. It is perfectly clear, therefore, that there is no special virtue in either rock—the ore is not native to either, and hence was introduced from foreign sources.

Mineralization in Conglomerate by Replacement and Impregnation

In the Calumet & Hecla, amygdaloidal basalt (I prefer to call it by this name, instead of "diabase" or "trap," as is the custom) in the foot wall of the ore-bearing conglomerate is barren; even amygdaloidal pebbles in the conglomerate itself are usually unaltered, and the amygdules (fillings of the original gas holes or vesicles by calcite and other minerals) are unreplaced by copper. One bed of conglomerate, varying in thickness from twelve feet or more down to less than one foot, has been especially mineralized, and there are many similar parallel barren conglomerates developed in the mine crosscuts. We must conclude that the lode is due to this conglomerate having afforded an especially open zone for circulating solutions—that it was either originally so (of which there is no evidence), or was made so by dynamic strain ofter becoming a part of the rock mass. Even of this latter, however, I found scant evidence.

The pebbles are not notably deformed or crushed except (according to Prof. Seaman) in certain zones where the crushing is quite marked. But that solutions passed freely through this lode-bed zone is shown by the irregular small dissolution cavities which are so common, and which are now filled with calcite and other minerals. They are often several inches long. The solutions must therefore have been powerful and they must have passed through the sandy matrix of the conglomerate while it was still open and porous; and as the dissolution cavities are mainly in this sandy matrix, they must have dissolved silica with ease.

The ore is entirely native copper, often with calcite as contemporaneous gangue. Native silver is common, and is contemporaneous, and of the same genesis. Besides impregnating and replacing the sandstone matrix of the conglomerate, it often occurs as a casing or shell around pebbles, of various sizes. In all instances which I saw the pebble had been thoroughly decomposed. Either the peripheries of certain kinds of pebbles created chemical reactions with the mineralizing solutions, which caused deposition, or the shrinkage of the pebbles during decomposition afforded a peripheral opening.

The mine workings inspected are at the vertical depth of a mile, or over 8,000 ft., on an average 34-37 deg. dip. Therefore, the mineralization was of deep-seated, and not of superficial, origin. It had nothing to do with surface water at any relatively recent period, as these lower workings are quite dry.

In the Champion mine, the lodes are parallel to the bedding, as in the Calumet & Hecla, but in a horizon hundreds of feet stratigraphically lower. In the Champion workings there is shown a series of numerous thin basaltic (diabase) flows, the average thickness of each being from 50 to 75 ft., and each flow being amygdaloidal in its upper portion. There are a number of parallel lodes, but the strongest and the only one inspected is the Baltic, which is from 25 to 30 ft. wide and is in basalt ("trap"). It is a zone of strain and fracturing generally parallel to the bedding, but not, in detail, regularly parallel. Where seen it was mainly in the dense or non-vesicular basalt, but it includes vesicular portions.

Owing, doubtless, to the greater rigidity of this rock over the conglomerate of the Calumet & Hecla, this basalt shows up the character of the Baltic lode as along a strain zone more clearly, by the frequent brecciation of the basalt and by thin, very straight, and persistent fissure veins of quartz, calcite, and other carbonates, and metallic minerals. These, where seen, were one inch or less thick. They strike parallel to the main lode, but in general dip more steeply, dipping 80-85 deg., though the lode is about 70 deg. This is, of course, a familiar type of lode. Nevertheless, relatively slight total dynamic action is indicated.

The effects of circulating waters are strongly marked, not only by the thin fissure seams, but by irregular dissolution cavities, never more than a few inches wide, especially around breccia fragments, as they are around the pebbles of the Calumet & Hecla conglomerate. These cavities are mainly filled with calcite. Solutions capable of dissolving silica and later precipitating calcite, or of replacing silica and other constituents by calcite, are indicated. The small amount of alteration of the rocks of the lode is, however, remarkable. The rock of the lode is apparently little more altered than are the wall rocks. Such rock, however, was pervious, as shown by the appearance of spots of copper away from any visible fracture. Much of the copper occurs in the rock without gangue. Where it occurs in the seam veinlets, it occupies the center, but here is intercrystallized and contemporaneous with the quartz and calcite, especially the former.

Evidences of Consecutive Deposition From Mineralizing Solutions

These thin veinlets are indeed the most direct and tangible evidence which we have as to the origin of the ore deposits; so that, although they are very minor quantitatively, as compared with the native copper impregnations in the rock, they merit special consideration. The metallic portion of the seams is generally in the center, and contains little gangue, in which quartz predominates. Chalcocite, often silver-bearing, and metallic copper are the chief minerals. They are found intercrystallized and contemporaneous, and are both plainly primary minerals.

Native silver is frequent. Other veinlets show contemporaneous bornite and chalcopyrite. Many of the veinlets show a white band of quartz (and calcite) on either side of the central metallic mineral, and the tendency to a fine comblike structure of the quartz, per-

pendicular to the wall, indicates that the crack stood open for a while, and that its walls became lined with quartz before the injection of the strong copper solutions. Elsewhere we find these seam-veinlets (mostly of native copper only) in the rock, without, or almost without, selvage or gangue. Essentially, therefore, the copper injection and deposition was without much accompanying gangue.

Besides the seam-veinlets in the Champion mine, which strike parallel to the lode, there are others at right angles to it. These have a tendency to widen the lode, and the lode is more productive where many of these parallel or cross-seams occur.

The observations in the Champion were at 1,300 ft., and here also the rocks are dry, the only water in the mine being surface water, which is caught above.

Others of these veinlets contain highly interesting minerals—domeykite (copper arsenide), smaltite-cloanthite (nickel-cobalt arsenide), with niccolite (nickel arsenide), all contemporaneous, with sparse quartz-calcite gangue.[1] What the paragenesis of these varied metallic minerals is I am unable to say. It could be decided largely by a study of the interesting collection in charge of Prof. Seaman, at Houghton; but essentially they are all part of one period, and the native copper is determined as a primary precipitation contemporaneous with the sulphides. Does not its intercrystallization with chalcocite indicate a scarcity of sulphur in the copper solution-magma? It will be noted that chalcocite has the least sulphur and the most copper of the copper sulphides—20 per cent sulphur and 80 per cent copper—while, referring to the bornite-chalcopyrite veinlet above described, bornite has 28 per cent sulphur, 55 per cent copper, and the remainder iron, and chalcopyrite contains 35 per cent sulphur, 35 per cent copper, and the rest iron. In general, therefore, it appears that the solutions contained, comparatively speaking, little sulphur or iron; that they were rich magma-solutions of copper, with a little arsenic, sulphur, cobalt, and nickel.

This preliminary examination has led me to infer an injection, at a definite period, of cupreous solution at depths which are demonstrated at present to be 8,000 ft., and which, at the time of deposition, were much greater,[2] and that the solutions therefore were presumably ascending.

The total amount of copper deposited was enormous. This has been for many years one of the most productive copper districts of the world. The attendant rocks are not thoroughly decomposed and leached; indeed, their alteration is noticeably less than we are accustomed to see in the neighborhood of ore deposits of plainly igneous-magma origin. Ground water is scanty or wanting in the deeper portions of the mines. The concentration of the copper gradually from the inclosing or surrounding rocks is an explanation so evidently unreasonable and inadequate as not to merit a second thought. The expectation, then, is that this deposit, like many others whose origin is better demonstrated, is of igneous-magma origin; and this seems plausible, as it followed such plentiful extrusions of basic rocks, and, as Irving and the other geologists have shown, both extrusions and intrusions of siliceous igneous rocks in the same great series, which is held to be about 25,000 ft. thick.

Siliceous porphyries, with and without quartz phenocrysts, are described as follows: Augite syenite, becoming granitic and granite, are found in large intrusive masses, apparently stocks or laccolites ("great irregular mountain masses," as Irving says) near the base of these Keweenawan basic rocks. There is a gradation between the granite, through the syenite to a gabbro—and the occurrence of augite, in all, even sparsely in the granite, where it has largely changed to hornblende, indicates the consanguinity of all. A magma which has differentiated in depth, of which the basalts and the intercalated siliceous rocks (rhyolites) may be considered complementary dense-textured surface eruptions, and the granite syenite and gabbro coarsely crystalline deep intrusive forms, is indicated. It is likely, by all analogy, that the ore deposition was one phase of this immense igneous activity.[3]

As to the age of this igneous activity, we only know that great series of surface volcanoes as Keweenawan, although they were formerly supposed to be pre-Cambrian, but now are considered by some as "more largely Cambrian than pre-Cambrian," as Lane says.[4] How much later the stock intrusions of granite and syenite rocks rose up into the buried base of the series we do not know, but they were in part, at least, in a rough way contemporaneous.[5] The formation of the lodes by strain —the rendering more permeable thereby, of certain beds —would appear to have been connected with the steep tilting which attended the formation of the great fault (Keweenaw fault) which limits on the east this copper-bearing zone. The fault itself is not known to be mineralized; therefore, the vein-formation followed the first slight movement in the growth of displacements, a history strikingly analogous with others described elsewhere.[6] The faulting continued, in successive stages, till after Devonian or later, according to Lane.

---

[1]The following extract is from the News Section of *Engineering and Mining Journal* of July 3: "Copper arsenides have been found in a number of the Lake Superior copper mines. At present Ahmeek is producing varying quantities of algodonite, domeykite, and whitneyite, these three minerals occurring in rich pockets. In the Mohawk mine there are pockets of the same ores, and, in addition, a fourth arsenide, mohawkite. Algodonite carries 83 per cent copper and 16 per cent arsenic. It must be handled in lots that will give a smelter furnace a full charge. Domeykite ordinarily carries 71 per cent copper and 28 per cent arsenic. Whitneyite was found on surface at the old Pewabic property, at the Cliff, and at the Minnesota mine, in Ontonagon County, now the Michigan.

"The showing of this arsenical copper ore, to be distinguished from the native copper, keeps increasing at both Mohawk and Ahmeek, and is a factor in their total output. At present much of it is stocked at the smelters awaiting its special treatment. Seneca is expected to find this sort of ore in paying quantities. The Copper Range mines on the Baltice lode have opened up some of it, indicating that it is not exclusively a Kearsarge lode product."

[2]The very narrow fissure fillings may indicate great pressure, and, therefore, great depth, although I believe that in one of the mines there is a fissure vein several feet wide, which has been mined.

[3]Diverse views as to the origin of the Lake Superior copper ores have been held in the past. Pumpelly originally regarded the copper as precipitated from sea water with the sedimentaries; afterwards, carried down in solution and coming in contact with the igneous rocks, metallic copper was precipitated by the ferrous oxide of the ferruginous silicates. By Irving they were supposed to have been due to leaching from the basaltic rocks during the ordinary processes of weathering. Lane considered that they were due to leaching by sea water, while still under the sea, and that there was still some chlorolic activity going on as an after-effect of the volcanism, which would explain some of the igneous minerals. Van Hise at first believed them due to [illegible] waters, but believed the waters not magmatic, but of [illegible] origin. In a later and more exhaustive analysis of the problem in a general monograph on the Lake Superior region (1911), Van Hise and Leith emphasized the magmatic source of the ore-bearing solutions, but did not entirely exclude the possible [illegible] of meteoric waters. Smyth believed that the waters were not only ascending, but of magmatic origin, and this view has also been held by Graton, although not published. Lewis, as a result of his study of allied deposits in the New Jersey trap (basalts), came to the conclusion that the copper here was of magmatic origin, and inferentially extended his conclusions to the Lake Superior country.

Modern Coal-Pulverizing Plant at the United Verde

Jeffrey Breakers Followed by Ruggles Coles Driers and Raymond Pulverizers—Powdered Coal Carried to Smelter Bins by Screw Conveyors and Blown to Drier Burners With 40-lb. Air—A 750-ton Plant Cost $725,000

By J. B. Johnson
Chief Engineer, United Verde Copper Co.
Written for *Engineering and Mining Journal*

EARLY in 1918 the United Verde Copper Co. decided to build a plant for the preparation of powdered coal, owing to the increasing prices of fuel oil used in reverberatory smelting. The year previous a report on the saving through the use of coal instead of oil had been prepared by the assistant smelter superintendent, C. R. Kuzell, and the estimated economy fully warranted the construction of a plant.

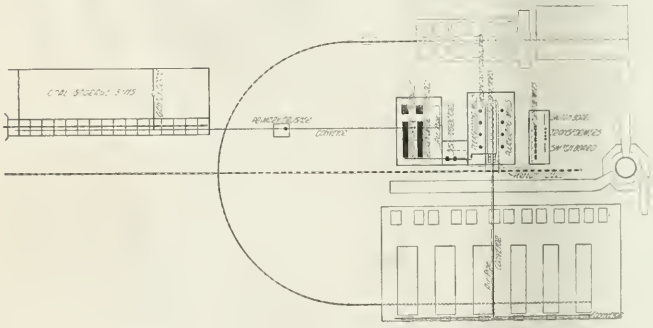

FIG. 1. GENERAL PLAN OF COAL-PULVERIZING PLANT

Two main types of plants were considered: the one in which the coal dust and air for burning are kept separate until mixed in the furnace burners, and the other type in which the air and coal dust are mixed in the coal plant and the mixture is conducted to the furnace burners in a manner similar to that employed in feeding gas. Of the two types the former was favored. The plant was designed by the local engineering department and actual construction began in November, 1918.

In general the plant consists of a 14,000-ton storage plant, a Jeffrey primary coal breaker, two No. A-14 Ruggles Coles driers, two Jeffrey coal disintegrators, eight Raymond pulverizer mills, six General Electric centrifugal 15-oz. blowers, and accessory equipment. A general plan of the plant is shown in Fig. 1.

The storage plant is divided into two parts; the main division consists of large reinforced-concrete bunkers holding a total of 12,000 tons of either slack or run-of-mine coal. These bunkers were made watertight, so that coal can be stored under water to prevent spontaneous fires. The storing as well as reclaiming is done by a five-ton Alliance gantry-type crane, which spans the main bunkers and has an overhang reaching over the railroad track which serves the bunkers. Coal is shipped in gondola cars and can be dumped directly into the track bunkers which constitute the second division of the storage plant. These smaller bunkers hold 200 tons, and when full any excess of coal shipped above the current demand can be stored in the main bunkers, such excess coal being handled directly from the cars into the main storage space by means of the gantry crane and 2½-yd. bucket.

Underneath the track bunkers, which are also built of reinforced concrete, is a conveyor tunnel and 30-in. belt conveyor fed by a traveling feeder from gates in the bottom of the bunkers. The conveyor system carries the coal to the primary breaker, designed to crush all lumps down to 1-in. size. To date this crusher has been by-passed, owing to the fact that all coal received so far has been slack or has been crushed at the mine. From the breaker a 26-in. inclined belt conveyor takes the coal to the driers, delivering to bins holding 100 tons. Feeders at the bottom of these bins supply the driers. Powdered coal is used in the driers for fuel, the ratio of fuel to coal dried averaging about 1:40, with the coal dried from 15 to 3 per cent moisture. The maximum temperature in the gas uptake adjacent to the drier drum is 160 deg. F.

From the driers the dried coal is conveyed in 14-in. screw conveyors, of the Webster make, to the disintegrators and to the pulverizers in the main building. In Fig. 2 is shown an exterior view of the plant—the drier plant in the foreground and the main mill building behind it. These buildings are of steel and brick construction—steel sash windows and steel and concrete floors throughout. The drier uptakes are each connected up to two cyclone dust collectors mounted on top of the building and a stack 50 ft. high is built on

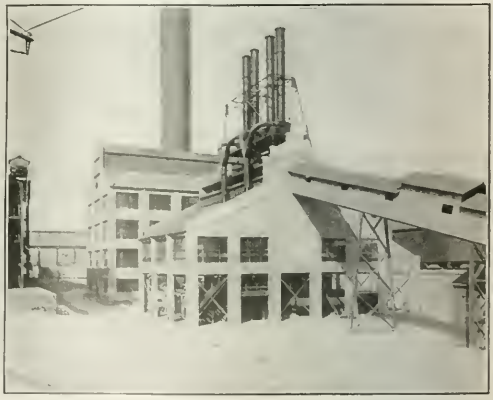

FIG. 2. THE DRIER PLANT IN THE FOREGROUND AND THE MILL BUILDING IN THE REAR

top of each collector. So efficient is this system in collecting the dust from the driers that scarcely any black smoke is visible from the stacks during the running of the driers.

The main mill building houses the eight Raymond pulverizers, exhausters, collectors, dust filter, blow tank,

FIG. 3. THE PULVERIZER MILL BUILDING. MAIN AISLE

and conveyors. Fig. 3 is a view of the main aisle, showing the pulverizer mills arranged four on each side. Fig. 4 shows the exhausters which are on the second floor of the building, one over each mill.

Each mill is driven by a 75-hp., 2,200-volt squirrel-cage motor, and each exhauster by a 40-hp., 440-volt motor of the same type. Each mill is connected through the exhauster to its own dust collector, the outlet of which is connected by means of a downcast duct to the mill, thus completing the return in the mill circuit. Each outlet is connected also to a small auxiliary cyclone collector 4 ft. in diameter, eight of these

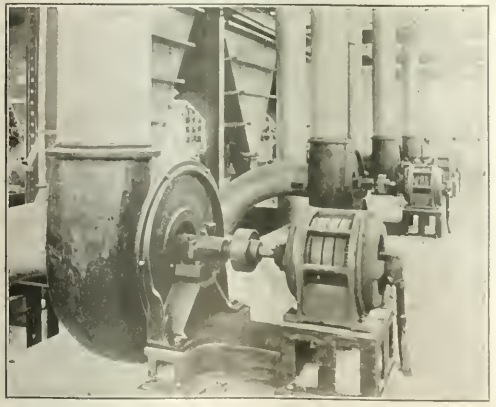

FIG. 4. THE EXHAUSTERS ON THE SECOND FLOOR

small collectors being inter-connected by means of a header which leads to the dust filter. This filter is a six-compartment muslin tube, automatic shaker type, supplied by the Dust Recovering & Conveying Co., of Cleveland. The tops of these filters are shown in Fig. 5.

An additional exhaust fan of 12,000 cu.ft. capacity at 4-oz. static pressure is installed beyond the filters, thus maintaining a slight vacuum in all of the mill circuits, which makes for an unusually clean building. The exhaust fan outlet connects directly with the main vent stack, and the efficiency of the filters so far is evidenced by the entire absence of black smoke from the vent stack. A 30-hp. motor drives the main exhaust fan. The dust collected by the filters is delivered into the main dust conveyor, and is thus utilized in the plant.

The conveying of dust into the smelter building is by means of 14-in. screw conveyors, direct connected to their respective motors through Poole turbo-gear speed reducers. This method of driving these conveyors has proved very successful, and the installation takes only a small amount of room and floor space as compared with chain drives and countershafts.

The conveying of coal dust to the driers is accomplished by means of a blow tank and transport pipe, as the tonnage involved is comparatively small. This blow tank is illustrated in Fig. 6, and was supplied by the Quigley Furnace Specialties Co. The air pressure used is 40 lb. and the tank capacity is three tons of dust. The tank is filled from a spout overhead, and

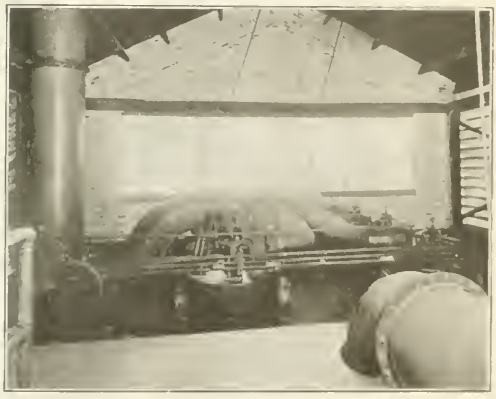

FIG. 5. TOPS OF COAL-DUST FILTERS

after the filling valve is closed the air is turned on, which shoots the dust through a 4-in. pipe to the two coal-dust bins at the driers. A specially constructed valve in this 4-in. line switches the load into either of the two bins. A cyclone air separator is mounted over each of these two bins which separates the air from the dust, allowing the dust to settle in the bins, the air being drawn through the air vent into the exhaust stacks of the driers. This transport system has given no trouble and is an excellent method of conveying coal dust. The capacity of the installation is about 10 tons per hour. With a larger tank the tonnage capacity could be increased. The feasible limits of transport distance and tonnage for this method of conveying dust are uncertain.

The coal dust as delivered to the reverberatory furnaces is pulverized to a fineness of 80 per cent through 200 mesh, and the moisture content is usually kept under 5 per cent. The burners were designed locally, and consist of the usual feed screw dropping the dust on to a jet of air supplied by the blowers.

The efficiency of the burners depends largely on that of the primary air jet in inducing sufficient secondary

air into the mixing chamber of the burner nearly to oxidize the coal during combustion. The remainder of the air required is drawn into the furnace through the furnace walls and ports. The burners were designed to feed an intimate mixture of coal dust and air into the furnaces. Several tests were conducted on burners, using different kinds of air nozzles, with a view to determining the relationship existing between different shapes of primary air nozzle and diverging air cone and to ascertain how these different factors affect efficiency. The conclusion is that the primary air pressure at the burners need not exceed 8 oz. per sq.in., and that the primary air volume (i.e. blower volume) need not exceed 25 per cent of the entire air volume necessary completely to oxidize the quantity of coal burned, provided the burners have properly designed air nozzles.

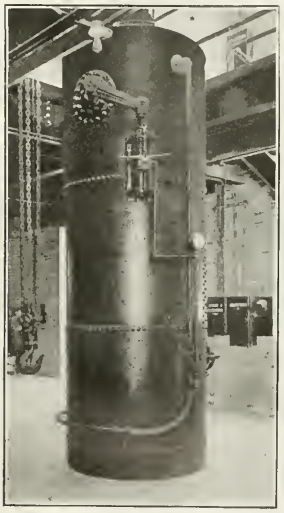

FIG. 6. TANK FOR BLOWING POWDERED COAL TO DRIER BINS

The air pressure is generated in the blower house by six General Electric turbo blowers, rated at 15 oz. per sq.in., and 10,000 cu.ft. per min. each. These blowers are Y-connected into a common header. Each blower is driven by a 75-hp. motor, direct-connected to the impeller through a solid shaft.

The capacity of the plant is 750 tons of coal dust per day, working three shifts. The dust bins at the reverberatory furnaces hold 65 tons each—enough for a maximum twelve-hour run for each furnace. The total cost of the plant, including storage plant, was approximately $725,000.

The fuel used at present is New Mexican coal from the Gallup district. This is classed as a lignitic bituminous coal, and has an average ash content of 8 per cent, and a maximum heat value of 11,300 B.t.u.

Gypsum in 1919

According to a preliminary estimate by the U. S. Geological Survey, 2,451,000 short tons of gypsum, valued at $16,000,000, was sold in 1919. This is an increase of 393,985 tons and of $4,529,146 compared with the sales in 1918.

Tin in the Malay Peninsula

The largest tin-smelting center of the world is Singapore, where the Straits Trading Co. and the Eastern Smelting Co., both British owned, and a Chinese-owned smelter, have a combined capacity of 58,000 metric tons of metal a year.

The backbone of the Malay Peninsula is composed of granite which is intrusive into limestone, shale, and quartzite. Tin has been found in place in practically all of the rock formations. Owing to the intense weathering and erosion of the tin-bearing formations, great accumulations of detritus, mixed with clay, all of which carry cassiterite, are found in almost all parts of the peninsula. The original deposits are so softened by weathering that they can be worked hydraulically.

Pahang, on the eastern side of the mountains, has many widely scattered tin deposits, both lodes and placers. The chief workings at present are in the mountains near the Selangor boundary, at Bentong, Tras and Machi. Some mining is also done at various places along the Kuantan River and its tributaries. Transportation is a serious item in working tin mines in Pahang.

The Kinta district, in the State of Perak, is the most important tin-producing area in the Federated States. A structural valley eroded in soft limestones between granite ridges is the location of most of the workings. The valley is filled with clays and boulder clays carrying tin, and the present stream channels are also stanniferous. Mining is in progress around fifteen or more settlements in this district. Most of the mining is by open cuts and dredges, but some lode mining is done on pipes in limestones. Next in importance to Kinta is the Larut district, northwest of the former. Placer deposits are the chief source of tin in the district, but lodes are worked at Selma and Blanda Mabok. In the south of Perak, at Bruseh, stockworks in schist are worked by hydraulicking, yielding about three-fourths of a pound to the cubic yard of material worked.[1]

Artificial Graphite

Graphite is manufactured by the Acheson Graphite Co. at Niagara Falls, N. Y. This company utilizes the electric power generated at the Falls to manufacture graphite from anthracite coal or from petroleum coke. This product is used mainly in lubricants, but it is also used in paints, foundry facing, preventives of boiler scale, and fillers for batteries.

Artificial graphite may be used for any purpose for which natural graphite is employed, according to the U. S. Geological Survey, except in the manufacture of large crucibles. Patents have been issued recently, however, for methods of manufacturing crucibles in which artificial graphite may be used. Artificial graphite is peculiarly adapted to the manufacture of certain graphite products, among them graphite electrodes, which are not made from natural graphite and for which the demand has greatly increased in recent years. The table below, published by permission of the Acheson Graphite Co., represents only the manufactured graphite that comes into competition with natural graphite.

GRAPHITE MANUFACTURED BY THE ACHESON GRAPHITE CO., 1915-1919

	Pounds
1915	5,084,000
1916	8,397,281
1917	10,474,649
1918	9,182,272
1919	8,163,177

Designing Mine Signal Systems

Safety, Reliability, and Maintenance Costs Should Be Considered in the Selection of Electrical Circuit Equipment—Installation and Operation Dependent Upon Existing Conditions—Expense Involved Commensurate With Service and Results Obtained

By R. H. Bacon*

Written for *Engineering and Mining Journal*

IMPORTANT as the mine-signal system is to continuous operation, safety, and speed of hoisting, it is rather peculiar that comparatively little attention has been given to the subject. Some of the newer installations might be termed modern, but for the most part the older and deeper shafts still remain dependent on the old, mechanical pull bell. Undoubtedly first cost and ultra conservatism have been the two main stumbling blocks to improved practice.

In the preliminary consideration of a system to be adopted, the first essential point in the design is to adapt it to the particular operating conditions. These vary at almost every property, and particularly in the different districts. If the shaft is a single compartment, two compartments, or one that has two hoisting compartments and a man, or "chippy" compartment, the electrical layout must be designed accordingly. By careful consultation with the operating men, the electrical department can lay out a system that will provide for every possible condition or emergency.

All systems should be designed with the following points in mind, given the weight of their numerical orders: (1) safety, (2) reliability, (3) speed of operation, (4) low maintenance cost, and (5) simplicity.

Safety Paramount in Signal Design

Safety is placed first because this is one of the weightiest arguments in favor of the electric system. It is exceedingly simple, while designing the system, to arrange the bells, buzzers, or lights so that at any place in the shaft, shaft house, or engine house it will be possible to tell what is going on, and for the sender of a signal to know that the signal was received correctly. If this is not provided for in the design one of the important features is lost. Nothing gives a greater feeling of confidence and security than to hear a signal repeated back.

Numerous accidents and consequent fatalities have been traceable to the old pull bells. I know of several, of which the following is an instance: In a shaft using dumpers the men had signaled to be lowered to the next level and were standing on the skip. Due either to a wrong signal having been given or to a misunderstanding of the right one, the engineer hoisted as for ore. The men, being totally unprepared for the sudden start, were thrown from the bail, one going down the shaft, while the others luckily managed to recover their balance and escaped injury. There have been cases where men working in the shaft, between shifts, have been crushed by the cage, due to similar errors. Repeated signals practically remove this possibility. From a cold-blooded business standpoint it is evident that such compensation saved would go far toward the first cost of a complete safety system.

Reliability is self-explanatory. Without it the system loses the confidence of the men and is a serious handicap to production if time is lost in changing over to the pull bell. Reliability can be attained only through the careful planning of all details of the equipment, as will be pointed out.

Speed of operation is essential in a busy shaft, but safety or reliability should not be sacrificed to obtain it. As a rule signals can be sent on any electric system as fast as they can be interpreted.

Rugged Equipment Recommended

Low maintenance cost is not necessarily an offshoot of reliability. Sometimes the latter is attained at the expense of high maintenance costs due to continuous inspection. To cut down the cost of maintenance a system should be so designed that reliability will be attained through rugged equipment and not by constantly going over the switches, buzzers, bells and other equipment to see that they are in good condition. Any system should operate a year without attention if properly designed and no unusual accidents, such as falling ground, occur. Maintenance costs can be reduced by laying out the system with a view of locating trouble quickly. No system will be entirely free from breakdowns, and with careful preliminary study it is possible to arrange for sectionalizing the main feeds and consequently reducing the time required to get the system back into service.

Simplicity is important because undue complications in the wiring make it hard for a new man on the job to follow. Consistent with the operating conditions to be met, a system should be as simple as possible to accomplish the purpose for which it is designed. Necessarily a wiring layout for a three-compartment shaft with two hoists is more complicated than a single-compartment shaft.

Selection of the Circuit Layout

As a typical example of how the circuit layout may be chosen, the work of the Copper Range Co. at Painesdale, Mich., with which I am familiar, is given. The work was begun in 1916 with an experimental installation in Champion No. 4, and five shafts were installed as rapidly as possible, varying in depth from 2,100 ft. to 3,500 ft. The systems were designed for 5,000 ft. of depth. The No. 4 shaft of the Champion Copper Co. at the time of the design was hoisting to practically absolute capacity, and any additional speed in signaling was therefore valuable.

In this district a lander is employed, and he does all signaling to the engineer. With the idea of relieving the lander of Sunday work it was desirable to design the system for dual operation, i.e., straight through from underground or through the lander. In each case, however, the signals were to be repeated back underground before starting the hoisting engine.

*Assistant engineering editor, *Electrical World*. Formerly assistant electrical engineer, Copper Range Co.

Referring to Fig. 1 it will be seen that the underground circuit consists of three wires and a ground return. As the shaft is two compartment, with ringing for one side (i.e., to ring the north side up ring the south side down), there is one bell in the engine house and one for the lander. The wires therefore consist of a feed, a bell wire, and a buzzer wire, using the ground return for both the bell and the buzzer circuit.

With the double-throw switch, in the lander's station, in the down position the operation is as follows. On closing the level switch buzzers on every level buzz, the lander's bell rings, and a set of green lamps light up in the landers' station. A set of four green lamps in the engine house also light up, giving the engineer a preliminary signal. On receiving the signal the lander repeats the signal to the engineer, causing the bell to

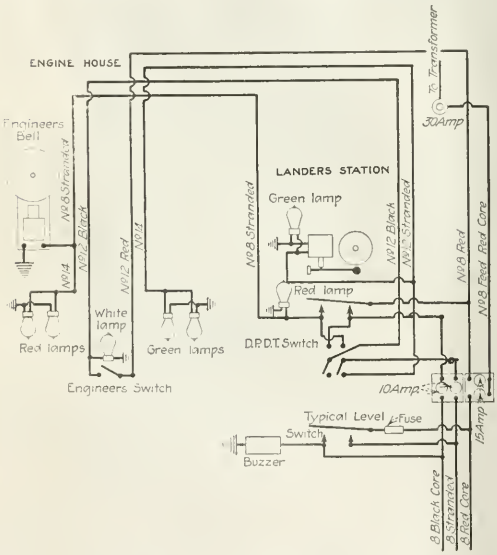

FIG. 1. DIAGRAM OF UNDERGROUND SIGNALING CONNECTIONS, CHAMPION COPPER CO.

ring and red lamps to light in the engine house. At the same time, however, the current flows back down the buzzer wire and all buzzers in the mine operate. As the lander rings the engineer's red lamps light in the lander's station, showing him that the signal system is operating correctly. The sender of the original signal knows that his signal has been correctly sent, as he hears the identical one sent to the engineer by the lander. The engineer has already had a duck signal on his green lamps, and if the signal from the lander should not agree the error would be evident. Three men are therefore on the job, and each knows what is going on. If by any chance the signal is not correct as repeated back the sender has an opportunity to stop the movement of the hoist, or if he is riding a skip he has an opportunity to jump off.

If it is desired to ring direct from underground to the engineer the double-throw switch in the lander station is thrown in the up position. In this case as soon as the switch at the level is closed the current flows up the bell wire directly to the engineer's bell, lighting the red lamp in the lander's station and also the red lamps in the engine house. It will be noted that in this contingency the green lamps are entirely cut off, as the circuit is open when the switch is thrown into the up position.

By following up the buzzer wire and passing through one pole of the switch it will be found that this wire also goes to the engine for a white light. As the buzzers operate underground this light illuminates, showing the engineer at once that the signal on his bell came directly from underground. By using the switch on his stand he repeats the signal back. While the engineer thus has definite knowledge that the system is operating direct from underground the lander always notifies him of the throwing of the switch making the change.

It might seem that there would be a loss of time in the repeating of signals, but in the handling of men a time interval must be allowed invariably, and in this case there is an actual saving of time, due to the fact that the men underground know exactly when their signal has been received. The engineer has been able to cut his time of waiting on that account. For hoisting ore there is a possible loss of time, but it is almost infinitesimal.

In this layout the telephone system has no part, as it is entirely independent. In some installations the telephones are a part of the circuit system, the wires running in the same conduit or cable. It is the belief of the electrical department of the Copper Range Co. that the two systems should be entirely independent and have no related functions. Though additional expense is involved in such a scheme it does away with the possibility of electrical troubles on the signal system, which might place the telephone service out of operation. In the telephone system of this company it is possible to talk from any surface location to about every third level in all shafts.

In the Butte district operations are carried out in a different way than in the Michigan copper country. A typical example of a more complicated system is shown in Fig. 2, which outlines the plan followed at the Pittsmont mine of the East Butte Copper Mining Co., Butte, Mont. There are in this case two distinct types of signals: (1) The signals that the station tenders use to connect with the hoisting engineer and top man, which none in the mine except the station tenders are supposed to use, and (2) a system of buzzer signals that are used by others in the mine for the purpose of getting the station tenders and in connection with the mine telephones.

As shown in the wiring diagram in Fig. 2 there are ten wires, as follows: East shaft compartment; west shaft compartment; "chippy" compartment; top man; telephone, (2); buzzer system, (3), and common return wire.

Each compartment of the shaft has a separate bell located in the engine house, and all pull switches operating in their respective compartments are in multiple. The buzzer system used for signaling station tenders and top men, and also as a call for the mine telephones, consists of one buzzer on each level, one at the surface, and one in the engine room. All buzzers operate when any buzzer switch is closed.

A system for a two-compartment shaft with a separate bell for each compartment is shown in Fig. 3. This system is in use at the Butte & Superior mine, Butte, Mont. From the sketch it will be seen that the general wiring scheme comprises one wire, No. 2, as a

common return wire, wires No. 1 and No. 3 as bell wires, and No. 4 and No. 5 taking care of the buzzer circuit. Pull switches are placed upon each level and in skip pockets within easy reach of the cage tenders. There is also a buzzer and push button on the engineer's stand. In case of a misunderstanding of signal the engineer can call for the signal to be repeated. The buzzers are independent of the hoist signals and are used for signaling cage tenders or by the engineer, as stated.

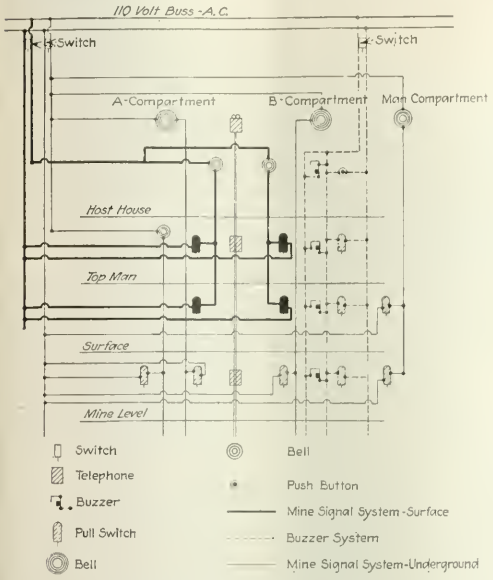

FIG. 2. DIAGRAM OF WIRING FOR MINE SIGNAL SYSTEM, EAST BUTTE COPPER MINING CO.

At the Ahmeek and Osceola mines of the Calumet & Hecla Mining Co. a system has been in use for a number of years that employs relays for the closing of the bell circuit. The system is operated on 220-volt direct current furnished by motor generator sets. The bell circuits are closed through relays, the shaft wires carrying only the current to operate the relays and the lamp in each switch box. These lamps, however, show only the flashes of the sending signal.

Having chosen the circuit layout, the most difficult part remains—that of selecting the equipment and the proper installation. Though designing the circuit on paper and determining what it is to do is important, the problem of meeting the severe operating conditions is the real stumbling block. The next logical step is the selection of the voltage and deciding whether alternating or direct current is to be used.

Numerous systems are operating on direct current through motor generator sets or storage batteries or both. There are some advantages to be gained, but on the whole the use of ordinary standard 60-cycle, 110-v. lighting current simplifies the problem. With the large systems electrified as they are, continuity of service is essential to other operations as well as to the signal system. This point may be dismissed as not so important as it might seem. Unless batteries are used, nothing is gained from the standpoint of service interruptions by using direct current. In mines that do not use the pull bell as a standby, but have an auxiliary electric system for emergency, the point should be considered more carefully. In such a case the system can be designed to operate on either current, storage batteries being used for emergency.

Single-stroke bells seem to be far more preferable to signaling work of this class than the vibrating type. The strokes being distinct and easily read, code signals with slight time intervals can be used. In the Michigan district the half bell is used extensively, in which case the hoist is moved slowly until the switch is released and the bell plunge or core drops back. The Copper Range Co. has developed a powerful engineer's bell of this single-stroke core type, with an 18-in. gong.

Reliability of bells is desirable and should not be left to guesswork. It is a simple matter to run a life test on a bell by devising a motor-driven circuit-closing apparatus. It is possible to produce in this way the effect of several years' operation in a week. The mechanical defects may then be corrected in the design, or the bell discarded entirely and another type tried. A bell should stand service for a year without repairs or inspection.

Buzzers suitable for mine use have been developed within recent years. They should be rugged and as near waterproof as possible. No adjustments should be required, and the life of the tongue should be as long as possible. The tone should not be unpleasant.

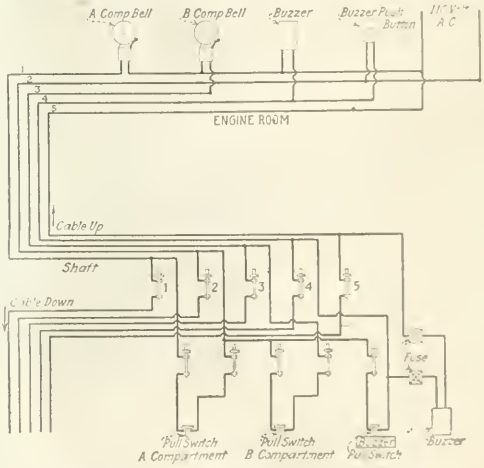

FIG. 3. WIRING DIAGRAM FOR TWO-COMPARTMENT SHAFT, SHOWING ONE METHOD OF LOOPING CABLE INTO JUNCTION BOX TO FACILITATE TROUBLE SHOOTING

Rugged types of switches for mine signal use have not been developed extensively. In the Butte district the switch developed by the Anaconda Copper Mining Co. has given good service. In the design of the Copper Range Co. a rugged oil switch has been built for this work. As shown in Fig. 4, this switch and the buzzer are mounted on a creosoted 2-in. plank as a standard station unit. The switch may be held in the closed position by means of the latch *A*. This is used by the dumpers to prevent the skip being rung away. While the switch is in the closed position all of the buzzers in the mine are sounding as a warning that the skip is being held. It would not be possible, however, to signal

the engineer by closing any other switch in the system.

Oil switches are used for several reasons. There is always a certain amount of arcing connected with breaking a solenoid circuit and in time this arcing burns through the contacts. The oil eliminates this source of possible trouble. The oil also lubricates the bearing surface of the plunger and prevents dust from making the switch sluggish. In case the switch is not operated for long periods the oil protects the contacts and spring from corrosion.

All of these items of equipment are important, and no thought should be spared in working out the design to obviate all possible defects. There will be breakdowns of various kinds, but if the mechanical details are

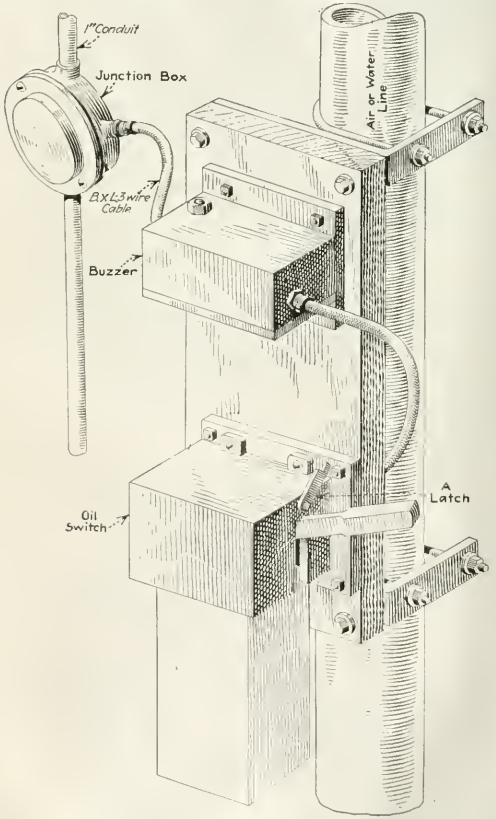

FIG. 4. GENERAL ARRANGEMENT OF OIL SWITCH AND BUZZER UNIT USED AT ALL LEVEL STATIONS AT MINES OF COPPER RANGE CO.

as perfect as possible the next source of trouble will be in the circuit.

Two methods of installation are in use for placing signal circuits in the shaft, one lead cable and the other conduit. In either case all wiring should be totally inclosed from the engine house to the last shaft station. Lead cable has the advantage of being waterproof, providing the entrances to junction boxes, buzzers, and switches are also watertight. Conduit circuits have given good service in many cases, and afford an easier method of pulling out a section for repairs. In the Butte district the practice has been to favor the lead cable for signal use. In the Michigan mines conduit is used. By placing junction boxes at every level with a conduit union above the box sections can be taken out easily in case of grounded circuits. Mechanical strength is essential, and partly for that reason No. 8 rubber-covered wire in one-inch conduit has been used in the system of the Copper Range Co.

To facilitate the location of troubles arrangement should be made for sectionalizing the line. In Fig. 3 this is done by the use of single-pole knife switches in the junction boxes. Each wire may be disconnected from the lower levels and by another switch from the circuit on the level. In Fig. 1 terminal lugs are used instead of switches for this purpose. In case of a ground on a wire in a 3,000-ft. shaft the line is opened at the 1,500-ft. level. If the trouble remains it is evident that the location of the ground is in the upper half. By repeating the sectionalizing the point may be located within a few levels, and by climbing the ladders and making an inspection of each station the trouble can usually be found quickly.

From an operating standpoint this is important. Cages and skips are for production use, and not for electricians to ride in looking for trouble on a signaling system. It is manifestly unreasonable to ask a wireman to climb several thousand feet looking for circuit troubles. By using the cage and sectionalizing half an hour is usually sufficient to locate the trouble within a comparatively short section. After this is done it is simple to climb the few hundred feet necessary to make the final examination.

Fuses should be so arranged that protection will be had on all parts of the circuit and in such a way that a blown fuse will indicate which wire is grounded.

First cost of a system is usually indicative of careful thought and may be the most economical expenditure in the course of time. The system of the Copper Range Co. showed a cost of approximately $1,985 for a 3,000-ft. shaft, including all possible items. All bells, buzzers, and switches were built in the shops of the company, and all materials were of the best. There has been practically no maintenance expense since the installation. The following table details the costs:

COST OF SIGNAL SYSTEM INSTALLATION FOR 3,000-FT. SHAFT

Underground Feed:		
3,000 ft. 1-in. conduit at $170 per 1,000	$510 00	
9,000 ft. No. 8 R.C. wire at $33 per 1,000	297 00	
30 PRX junction boxes at $3.48	104 40	
Fiber cleats, 30 at 20c.	6.00	
Labor (timbermen on conduit and boxes), three men at $4.75, two shifts	28.50	
Labor (electrician pulling main feeds), three men at $4.25, two shifts	25.50	
		$971.40
Underground Stations:		
Switch and buzzer units, twenty-nine at $26	$754 00	
Labor of installing at $1.25 per unit	36 25	
		790 25
Lander's Station:		
Material (wire, small switches, and necessary equipment)	$3 00	
Signal switch (already installed)	12 00	
Lander's bell	25 00	
Labor, two men, two shifts, at $4	16.00	
		56 00
Engine House Wiring:		
100 ft. 1-in. conduit at $17	$17 00	
300 ft. No. 8 R.C. Wire at $3.30 per 100	9 90	
Signal switch	12 00	
Engineer's bell	30 00	
Material, miscellaneous	5 00	
Labor, two men, five shifts, at $4	40 00	
		113 90
Line Work Between Shaft House and Engine House:		
500 ft. No. 6 W.P. wire	$20 00	
2,000 ft. No. 8 iron wire	26 00	
Labor, two men one day at $4	8 00	
		54 00
Total		$1,985 55

Mining Engineers of Note

Robert Matthew Raymond

THE eminent professional standing of Robert Matthew Raymond is largely due to an unusually wide experience in mining and metallurgical matters and the rare personal qualities that are his. In the apt words of a close friend and a fellow engineer of Mr. Raymond's, "Whatever his task, whether directing practical mining operations, examining and reporting on mines, acting as managing director in a foreign country, or the expert adviser of boards of directors, his executive ability, resourcefulness, personal initiative, good sense and tact have brought him success and distinction." His career is an illustration of the globe-trotting exactions of the mining profession, and there is not a continent which has not been the scene of his activities at one time or other. South Carolina Montana, Arizona, Australia, South Africa, China, Mexico, London and New York indicate the wide range of his fields of activity and the mining conditions with which he is acquainted. Mr. Raymond was born in Norton, Province of New Brunswick, Canada, and educated at the University of New Brunswick and the Columbia University School of Mines, interspersing his education with practical mining work. In fact, it was due to several years' experience as assistant assayer in the assay office of the State of Maine, and four years at the Haile gold mines, in South Carolina, under the late E. Gybbon Spilsbury, after his graduation in New Brunswick, that a definite decision to make mining his life's work matured. Graduating from the School of Mines in 1889, he immediately, as an assayer, entered the service of the noted metallurgist, Anton Eilers, who had built the Montana Smelting Co. plant at Great Falls, Mont., afterward becoming assistant to Robert Sticht, superintendent of the company, receiving valuable training under the guidance of these two able metallurgists.

R. M. RAYMOND

From 1891 to 1894 he was superintendent of the Diamond R. Mining Co. in Neihart, Mont., and then for two years general manager of the Harquahald Gold Mining Co. in Arizona, operated by an English company, in whose interest he next traveled to West Australia. It was during his stay in Australia in 1898 that he was engaged by the Exploration Co., Ltd., of London, a successful and well-known British mining enterprise and a syndicate which has been identified with large mining operations in all parts of the world. This connection is still maintained. Leaving Australia, Mr. Raymond was sent to South Africa by the Exploration company, where he remained for two years engaged in deep mining upon the Rand. The next jump landed him in central and western China, where he made some important examinations for his company. In 1902 he became general manager of the El Oro Mining & Railway Co. of El Oro, Mexico, one of the largest gold-mining properties in Mexico and controlled by the Exploration company, where the first cyanide plant in Mexico was erected. This successful installation paved the way for the general introduction of the process throughout Mexico and in many other parts of the world. Mr. Raymond gives much of the credit for the success of this work to Mr. A. F. Main, later superintendent of the El Oro company. In 1913 Mr. Raymond was promoted to managing director of the El Oro company and the Exploration Co. of England and Mexico, a subsidiary of the parent company, to reside at Mexico City, where he exercised not only the functions of an engineer but also those of a diplomat in the troublous and dangerous revolutionary periods.

Were it not for the fact that strong representations were made upon Mr. Raymond to accept the chair of mining in Columbia University left vacant by Prof. H. S. Munroe in 1916, and had he not been allowed to retain his connection with the Exploration company, it is doubtful whether he would have accepted the professorship tendered him.

Professor Raymond is a vice-president of the A. I. M. E., a member of the Mining and Metallurgical Society of America and the Institution of Mining and Metallurgy of London. In his retiring way, he requested us not to consider him in any biographical sketch—which modesty seems to us to constitute all the more reason for our directing the limelight this week in his direction.

BY THE WAY

New Mexico

Residents of New Mexico have started another move, it is said, to change the name of the state so that Easterners may really be convinced that New Mexico is part of the United States and not situated south of the Rio Grande. The promoters of the scheme hope to carry it to the state legislature. This is really very foolish. Since Villa raided Columbus everybody knows where New Mexico is. Incidentally, some are wondering, now that Villa has gone and got religion and a coat of whitewash, what we are going to do about it. New Mexicans who really want to prove that they are Americans might introduce a bill at Albuquerque providing that the sessions of the state legislature be conducted only in the English language. Some one told us some time ago that Spanish is practically as "official" there as English. Just as charity should begin at home, Americanization movements may well begin in state capitols.

Mining in Petticoats

The Seven Sisters Mica & Gold Mining Co. is reported by the press to have been organized by seven women who desire incorporation in Alabama for the mining of gold. This project is based upon the reported discovery of bits of gold in Cleburne County. Those who scoff can give no good reason why the venture should not succeed. Many men have fallen down on "Southern gold"; the ladies cannot do worse. Perhaps some day a successful mine will be opened in one of the districts that has a black eye today. These ladies will not be the first of their sex to enter into mining. Chloride, Ariz., has a new company opening up a promising body of silver ore, which has been very successful in its brief existence to date. Its president is a woman. The radium-bearing ore recently discovered in the White Signal district of New Mexico is said to have been recognized as such largely through the work of a woman. It is mill operation to which we would like most to see the ladies turn. We imagine they would be perfectly at home in the midst of a slopover. Would they clean out the launder first or run for a scrubbing brush? During the war, when many women entered industry usually monopolized by males, it was reported from one camp that the "lady mill-workers" showed a great fondness for cleaning house. There is more than one mill so carelessly and slovenly managed that the employment of a woman operative or two might be of benefit.

He Can Locate Deposits Of Platinum or Whiskey

A correspondent who claims to have phenomenal powers that enable him to read earth's secrets writes us as follows:

I have made some small mistakes due more to my enthusiasm than anything else, but we all have to learn our lesson, and I have much yet to learn, but I have also learned much that others would give a great deal to know, and one most positive feature of my method is that I need waste no time studying the mineralogical or geological formations first, but I can very quickly determine whether there is anything there of value and be on my way.

I claim and am ready to prove that I can locate and determine platinum and most all minerals of value from platinum down; also coal, oil, and gas. The only doubt that I have in regard to oil is the possibility of getting oil shale, but conditions would go far toward a determination. Gas gave me much experimenting, but I succeeded and can prove it. I have a general coal locator and one each for anthracite and bituminous coal that have proved entirely satisfactory on coal of both kinds received and sold here by several coal dealers.

I find most positive evidence of what I think must be a great deposit of coal that probably extends from the central states across Massachusetts and on into the provinces. This coal changes from anthracite to bituminous near the Massachusetts coast.

I have attractors for diamonds and other precious stones, and if you are yet sceptical and consider that I am an imposter I will come to New York and demonstrate my system, and I hope you will have a few gems that you will put up against my ability. We will go to any metal-supply house, and I will locate the different metals and outline them from any floor above them. I also forgot to say that if you have any alcoholic liquor in your building to beware, as I might be tempted to get on the trail.

I can locate fire and determine the extent of it. This, I think, may be useful in case of fires in mines. I also have an attractor for sugar, but have not yet made an effort to determine between sugar and molasses.

I am now experimenting to determine both hard and soft deep water streams. I am very sure now that I am right, but I will thoroughly prove that I am right or not by testing several hard and soft water veins that have been driven into near Boston.

A human body I can locate anywhere, but it would be rather difficult to determine the body of a baby from any other animal body unless it was known that a baby was buried there, but I can get the shape or position of a body and in that way I can tell the difference between a human body and an animal body.

All deep water streams run a few degrees east of north and a few degrees west of south. Do you know in which direction they flow?

I find two substances in connection with coal and oil and three substances in connection with coal and gas. Who knows what they are?

Also I would like nothing better than to meet a few of the best mining engineers that the country can produce and we will each be allowed one-half hour to find any faulted vein that you may know of, and if a reward can be offered let the one who finds it within the time limit take it (of course I mean the reward and not the vein).

No chance of passing a lead quarter on this gentleman, and as for gold bricks the gilt would not deceive him for a minute. Like all others of his kind, however, he keeps his secret to himself.

Municipal Oil Wells

It is reported that two oil wells were opened in Los Angeles in the last week in July by one of the minor earthquakes that have recently been disturbing the peace of mind of that city's inhabitants. Both of them, fortunately for the municipality, are on city property. One is said to be gushing great quantities of oil over the paved roadway, though the number of barrels produced per day is not mentioned. If this would happen more often earthquakes might lose some of their ill repute. There would also be something else to boost and boast about to visitors. With every shock, too, the secretary of the Chamber of Commerce or the Chamber of Mines can now be heard, no doubt, to murmur, "Another fault fissure opened," and then seen to rush his optimism into print in predictions of the city's future greatness. The skeptic might ridicule, but that would never affect the right kind of a secretary of a chamber of mines and commerce.

CONSULTATION

Delivered-Copper Quotations

"As operators selling our metals subject to quotations we would appreciate information on the change you have made in quoting copper prices. In your market report of April 10, 1920, under the subject of 'Metal Markets,' and under heading of 'Copper Markets,' you say: 'The prices obtained for actual large sales were fairly uniform at around 19c. delivered, or 18.80@18.85 net refinery, which we quote.' We presume this was the basis of quotations from April 1 to April 7 inclusive. On the first of this year we made selling arrangements for our copper for which we receive settlement as per terms and prices made by you at that time. We understand your quotations since April 1, or at least since April 10, are calculated at 0.15c. per lb. less than those of January; in other words, operators selling under the terms of your January quotations would be underpaid 0.15c. per lb. for April, May, June and July when settled on quotations given since April 10. In your Market Report of May 8, 1920, you mention 'delivered price.' Where is copper required to be delivered to receive this price and from what points or refineries are prices 0.15c. less than the New York delivered price?"

In the issue of April 3 the explanation of the deduction of 0.15c. from the average delivered price of copper as reported to us by the producers was first made. This deduction had been made before that; in fact, has always been made in making up the *Engineering and Mining Journal* quotations, and the matter was only explained so that those who followed these quotations would understand that the price was not the delivered price. Copper is usually sold nowadays by the producers on a "delivered" basis. Also, the price charged to the consumer is the same, regardless of the distance of the consumer from the producer's refinery; that is, a buyer in New York would be charged the same price for copper as a buyer in Massachusetts, although the former had his plant right alongside of the refinery. It is assumed that this delivery charge amounts to 0.15c. on the average, and this deduction is made to arrive at the net price which the producer receives. The confusion in the interpretation of the significance of the price arises solely out of the mistaken premise that the *Engineering and Mining Journal* has changed the basis upon which the copper quotations are recorded. This assumption is not true.

Zinc Oxide Literature

"Can you let me know where I can obtain some information on the subject of zinc oxide? A cursory examination has not enabled me to find any literature on the subject. Do you know of any book treating its occurrence, production and market? It does not appear to be quoted in the section of the *Engineering and Mining Journal* dealing with such subjects. If you can give me any brief general information as to its price, markets and distribution this would be much appreciated."

An extensive and authoritative article on zinc oxide appeared in the *Transactions* of the American Institute of Mining Engineers, Vol. 57, 1917, entitled "Zinc Oxide," by George C. Stone. This is the most valuable contribution to the technology of the subject of which we know. The U. S. Geological Survey records statistics of production and consumption and a communication addressed to that body will elicit information in that regard. The *Engineering and Mining Journal* does not quote prices for zinc oxide, as it is a chemical product. Furnishing such information would also involve quoting upon very many other chemical products in the same category. Although zinc oxide is commonly supposed to be used chiefly in paints, rubber compounds consume the largest quantity. Thus in 1919 about 60 per cent of the consumption was used in rubber manufacture, or about 71,000 short tons. There was sold 117,639 tons, in 1919, an increase of 17,363 tons from 1918, due to the larger demand from the rubber-tire industry. Present prices of zinc oxide are between 17c. and 25c. per lb. in carload lots.

The Ferromolybdenum Market

"I am anxious to get some up-to-date information on the present status of the ferromolybdenum industry. Any assistance you can give me as to the sources of information will be much appreciated."

Quietness characterizes the situation in the ferromolybdenum industry at present. This is due, according to one of the leading producers, to the slowness with which the alloy is finding application in steel manufacture—not to any shortcomings in the physical properties of molybdenum steel but rather to the newness of the introduction. It will take some time, according to this producer, before the use of molybdenum steel becomes more general. Substantial improvement in the near future is not looked for; instead, a gradual betterment and wider application in the use of molybdenum steel is anticipated. Comparison of this situation is likened with that when chrome and vanadium steels were introduced—an introduction that took many years before it could be called commercially successful and which required time for the alloy steel consumers, such as automobile manufacturers, through their own experimental work, to become thoroughly familiar with these two special steels so as to be able to use them to advantage. Although many exaggerated claims have been made regarding the properties of molybdenum steel, some of which no doubt have done more harm than good to the industry, this alloy steel has more than measured up to expectations.

The Climax Molybdenum Co., of 61 Broadway, New York, has issued a valuable booklet upon molybdenum steels which contains the records of much experimental data upon the behavior of this alloy steel.

As to sources of information, both the U. S. Bureau of Mines and U. S. Geological Survey may be able to give you production data and technological information. Then there are the producers and consumers of the metal itself, who in certain cases seem willing to supply information; but sometimes a narrow policy leads to unwarranted and unhealthy secretiveness. A suggestion would be to communicate with the sources mentioned, and accumulate a bibliography on the subject, which will help greatly in the work.

THE PETROLEUM INDUSTRY

Oil Possibilities in the Dry Piney and Big Piney Districts, Lincoln County, Wyo.

BY G. B. MORGAN*

ALTHOUGH oil has been discovered so far only in Secs. 1 and 12—28—114, of Lincoln County, Wyo., prospect wells are being drilled six miles north, eight miles south, and ten miles southeast of the proved area. The results obtained in these wells will determine whether or not there is just one structure or a system of north and south parallel folds or anticlines containing oil in the Cretaceous formations, which structures are practically concealed by the overlying Tertiary beds.

The Dry Piney field proper is about sixty miles north of Kemmerer and about the same distance from Opal, Wyo., both on the Union Pacific Ry. The structure covers about 1,000 acres in Secs. 6 and 7—28—113, and Secs. 1 and 12—28—114. The topography is characterized by a high north and south ridge, called the La Barge Ridge, on or near the crest of which the oil wells are situated.

Structurally, the La Barge anticline presents some rather unusual features in the Dry Piney field. The coal-bearing Adaville formation, of Montana Age, is exposed on the surface in a narrow strip through Sec. 12—28—114 W, and Secs. 7 and 18—28—113 W. These rocks are sharply flexed, dipping at an angle of about 25 or 30 deg. on each side of the axis of the anticline, which axis bears about N., 30 deg. W. Immediately to the east of the axis the Knight formation, of Eocene (Tertiary) Age, is found resting uncomformably on the Adaville, but dipping also to the east at an angle of about five degrees. On the top of the ridge in places and on the western flank the overlying rocks are pre-Carboniferous and consist of limestone, quartzite and conglomerate. They were pushed up in that position by the same forces that caused the folding, and the result is a tremendous overthrust fault of probably 20,000 ft. displacement. Much older rocks are thus over-riding the Cretaceous formations, and on either side of the ridge the younger Tertiary formations are resting unconformably on the Cretaceous to the east and the Cambrian to the west. The Tertiary beds are slightly arched, coincidently with the older formations. This arching in the Tertiary beds over the pronounced anticlines in the Cretaceous and older rocks, especially in this field where oil has been found, has given rise to the theory that slight folding in the surface beds of the Tertiary indicates underlying structures in the Cretaceous and possible oil reservoirs. A number of operating companies are working on this theory and have found several such structures, in which they are drilling test holes.

The oil in the Dry Piney field is found at a depth of about 1,000 ft. in a sand of the Hilliard formation, which probably corresponds to the Pierre or Steele shale of central and eastern Wyoming. The sand is reported to be 43 ft. thick in one well and much thicker in another, and is believed by some to be a lens rather than a sheet sandstone. The belief held by some geologists is that the Hilliard contains a number of such lenses which are more than likely oil-bearing, and, if so, the oil-bearing possibilities will not be so much governed by structural conditions for the reason that lenses are generally sealed off by inclosing shale beds. Above the sand there is a sandy shale which gives up a small amount of shale oil and contains a thin water sand. The Hilliard, as measured by Schultz, is about 3,000 ft. thick and is underlain by the coal-bearing Frontier formation. The Frontier in central Wyoming is the principal oil-bearing formation and is not coal-bearing. It is not improbable that the Hilliard will be found to contain the producing oil sands in this district.

More systematic and deeper drilling in this field should produce good results. More care should be taken to shut off the water before entering the sand in drilling shallow wells. Also, if proper precautions are not soon taken to shut off the water from the sand in the producing wells, the production from the first sand will be greatly impaired in this field.

*Abstract of Bulletin 9, Wyoming Geological Survey.

Drilling Activities in Arkansas

It has been announced that work will begin at once on drilling two wells for oil in Bradley County, Ark. The Southern Lumber Co. has entered into a contract with the Caldwell Oil Co., of Oklahoma, to sink five wells on the lumber company's holdings. A crew from Shreveport, La., has erected two derricks, one in the southern end of the county, near Morobay, and the other near Blue Springs.

The Southern Lumber Co. and the Arkansas Lumber Co. have a contract with the Standard Oil Co. by the terms of which the Standard will take over 10,000 acres owned by the lumber companies in the vicinity of Vick. The contract stipulates that the first well is to go down in the Vick vicinity within 120 days from the date of contract.

Petroleum in Bolivia

Interest is being manifested in the petroleum field of the Province of Azero, Bolivia, according to a report issued by the Department of Commerce, and indications seem to show that there exists in this region a substantial basis for the development of the oil industry. Vast concessions of lands in the area have been acquired and serious reconnaissance work has been carried on. A local company organized in Sucre and known as "Sindicato de Sucre" holds 65,000 hectares in the provinces of Azero and O'Connor and has a nominal capital of 1,000,000 bolivianos and a paid-up capital of 550,000 bolivianos. It posseses two drills, with which it intends to bore five or six wells. On the basis of the results which it anticipates from these wells the promoters of the company plan to organize a larger company to work their holdings.

NEWS FROM THE OIL FIELDS

Texas Co. Increases Capital Stock

From Our Special Correspondent

An amendment to its charter has been filed at Austin by the Texas Co., increasing its capital stock from $85,000,000 to $135,000,000. This is the formal filing of the amendment, although the stock increase was made at a regular stockholders' meeting last autumn. The stock was paid up 30 per cent Jan. 9, 30 per cent April 9 and 40 per cent July 9.

The Texas Co. gusher at West Columbia, Brazoria County, continues to flow at the rate of 25,000 to 30,000 bbl. per day, according to the last report. This well has caused the prices of leases in and near the field to increase tremendously. A one-half royalty on two and one-half acres is said to have sold for $15,000. Leases on many other tracts have sold for from $3,500 per acre down to several hundred dollars, depending on location. One tract of twenty acres, a considerable distance from the gusher and near which a dry hole was drilled some time ago, brought $600 per acre with a one-eighth royalty held out.

The Gonzales Creek Oil Co., which owns twelve acres within the city limits of Breckenridge, Stephens County, brought in a well recently which made an initial production of 1,500 bbl. daily, and later increased to 7,500 bbl. Considerable oil was lost before the big flow could be handled. The company was organized four months ago, and is capitalized for $90,000. The larger part of the stock is said to be held by Breckenridge men.

Extensive wildcat drilling is being done in the western part of Lampasas County. Possibly a dozen wells are being put down, and seven of them range in depth from 1,200 ft. to over 2,000 ft. Though no producing well has yet been completed it is claimed good oil and gas showings have been found.

Red River Boundary Case Holds Hearing

From Our Special Correspondent

Taking of evidence in the Red River boundary case between Oklahoma and Texas has begun in Oklahoma City before Special Commissioner Frederick S. Tyler, of Washington, D.C. Attorney General Prince Freeling, of Oklahoma, and Attorney General C. M. Cureton, of Texas, are present. Several hundred witnesses have been summoned, and it is expected that it will require over two weeks to take the testimony. The first witness for Oklahoma was Judge George S. Marsh, of Madill, Okla., whose testimony was supported by old Spanish treaties and by a diary of President Adams regarding the boundaries now in dispute.

Tar Sands in Alberta To Be Tested for Oil Recovery

From Our Special Correspondent

The Canadian government has withdrawn from sale, lease, or settlement approximately 55,000 acres of land along the Athabasca River in Alberta, subject to leases already issued under the petroleum and natural gas regulation. This action is taken because representations have been made to the Department of the Interior that as the result of investigations recently undertaken it is confidently expected that a successful process will soon be evolved for the extraction from the tar sands of the Athabasca River of oil, bitumen, and other hydro-carbons in commercial quantity. In 1913, Dr. Bosworth, of the Imperial Oil Co.'s research laboratories, estimated that sufficient oil could be obtained from the Athabasca tar sands to supply the world demand for many years. Before the war Germany sent a number of chemists to make surveys of the tar sands, to obtain a supply of oil and gasoline. One of these chemists had secured a lease in 1913, but died on his return voyage to Germany. Attempts have been made to compute the amount of the tar sands available for reductions, but the nearest estimate that can be at present made runs into billions of tons. The one drawback to development is the scarcity of fuel to withdraw the oils for which heat is necessary, but there are hopes that this can be overcome by the finding of natural gas at McMurray.

The Canadian government has granted tar sand rights to 1920 acres to General William Lindsay, who claims that investigations conducted on behalf of himself and associates have resulted in the discovery of a successful process for the extraction of the oil, bitumen, and other hydro-carbons contained in the tar sands.

During the last two weeks the U. S. Geological Survey has required an average of only four days for passing on the geological features of permits under the Mineral Leasing (Oil Lands Leasing) Law. The work has been so systematized that little delay now results in establishing whether the permit applies to an area within or without a geological structure of a known oil field.

The Midwest Co. is sinking a new well north of Boulder, Col. Plans call for sinking the well to a depth of 4,200 to 5,000 ft., with the view of putting it through the Benton shale. The hole is started with a 20-in. diameter. The Midwest holds drilling contracts on about 500 acres of land adjoining the tract on which they are now working.

Kentucky Production Decreases

From Our Special Correspondent

Production in Kentucky decreased considerably last month. Wells completed number 189, a falling off of 107. New production was 7,529 bbl., a decrease of 559 bbl. Work under way totals 979 wells.

Whittle No. 1, a small well on the Bailey farm near Bowling Green, Warren County, has suddenly developed into a sensation, for conservative Kentucky. When the tools were pulled on Aug. 13, the flow from the well increased to 100 bbl. per hour, or about 2,000 bbl. a day. The tools had been left in the hole six weeks ago when there was a fire at the well. Whittle No. 3 is expected in early next week, and has practically the same formations and other indications as No. 1, according to O. F. Whittle, the owner.

The big gas well found two weeks ago on the Smith farm near Temple Hill, Barren County, by the Merry Brothers, has settled down to a production of 15,000,000 cu.ft. daily, according to the mercury test. The well is characterized by experienced oil and gas observers from Louisiana as the best one north of their own fields. Merry Brothers already have begun another well across the creek, and intend to put down four others as soon as possible.

James & Watkins of Chattanooga, owners of No. 2 on the Perkins lease on the Barren River Pike, report that the well is pumping 200 bbl. a day, which has continued for two days.

The Hugh Potter gusher brought in a short while ago seven miles south of Bowling Green, is now rated at about 700 bbl. production daily.

Japanese Oil Discoveries

Although a number of wells sunk in Formosa have proven failures or disappointments, one well recently sunk in Kagi Prefecture, Formosa, is reported as producing 400 gal. of oil an hour, from a depth of 400 ft., while another bore on that island failed entirely. It is reported that a new gusher had been struck at Kami-Shin-jomura, Minami Akita-gori, after boring to a depth of over 667 ft., which yielded about 3,400 gal. of oil per hour. Due to a shortage of vessels to transport the oil, large reservoirs are being dug in which to store it.

The Pomona Oil Co., which is owned largely by Riverside, Cal., interests and which is drilling its first well south in the hills of that county, is now down 1,700 ft and is being utilized by the management for the fires under the boring and water boiling machinery.

COURT DECISIONS IN MINING CASES

By Wellington Gustin

Demurrage Claim on Frozen Ore Shipments Valid

U. S. Supreme Court Allows Charge of Pennsylvania R.R. Against Kittaning Iron & Steel Co.

In the demurrage case of the Pennsylvania R.R. Co. vs. the Kittaning Iron & Steel Manufacturing Co., the Supreme Court of the United States has reversed the judgment of the Supreme Court of Pennsylvania. Mr. Justice Brandeis delivered the opinion of the court.

It appears that the Uniform Demurrage Code was duly published as a part of the freight tariffs of the Pennsylvania R.R. prior to Nov. 1, 1912. On various dates from Nov. 1, 1912, to April, 1913, the Kittaning Iron & Steel Manufacturing Co. received from the railroad an aggregate of 227 cars of iron ore, all interstate shipments; and on them the railroad claimed $1,209 for demurrage. The company refused to pay these and other demurrage charges, and this action was brought to recover the amount. The trial court disallowed the claim and the judgment was affirmed by the State Supreme Court.

Before the ore cars were received the Kittaning company had entered into an average agreement with the railroad, as provided in Rule 9 of the code. The aggregate number of days' detention of these cars after they reached the company's interchange tracks (in excess of the free time under the average agreement), was 1,209; and the demurrage charge fixed by Rule 7 was $1 per day, or fraction thereof, that a car is detained after the expiration of the free time. The ore of these cars was frozen in transit; and the company insisted that this detention of the cars beyond the "free time" had resulted from this fact, and claimed exemption from demurrage charges under Rule 8.

"When shipments are frozen while in transit so as to prevent unloading during the prescribed free time, this exemption shall not include shipments which are tendered to consignee in condition to unload. Under this rule consignees will be required to make diligent efforts to unload such shipments."

The Kittaning company had at its plant a device for thawing cars of frozen ore through "steaming." By this means it was able to unload as much as five cars of frozen ore a day. The daily average number of cars of frozen ore received during the period involved was far less than five cars. On some days only one or two cars were received, though on others as many as thirty-five arrived.

The railroad contended that the determination in any case whether a detention was due to the fact that the contents of a car was frozen could not be affected by the circumstances that a large number of such cars happened to have been "bunched"; and that, as each car, considered separately, could have been unloaded within the free time, the consignee must bear whatever hardship might result from many having arrived on the same day, unless relief were available to him either under the "bunching rule" or under the "average agreement." The question presented, says the court, is that of construing and applying the frozen-shipments clause.

The purpose of demurrage charges is to promote car efficiency by penalizing undue detention of cars. The circumstances of the particular shipper was not considered in fixing the free time of the Uniform Code. When the framers of this code prescribed forty-eight hours as the free time, they fixed the period they considered reasonable for the average shipper to unload. In many cases more time would be required, and, in many, less.

In applying the allowance of free time and the charges for demurrage the single car was treated throughout as the unit, just as it is in the making of carload freight rates. The effect on the charges of there being several cars involved was, however, provided for by two rules: (1) The bunching rule, under which the shipper is relieved from charges if, by reason of the carrier's fault, the cars are accumulated and detention results. (2) The average-agreement rule, under which a monthly debit and credit account is kept of detention, and the shipper is relieved of charges for detaining cars more than forty-eight hours by credit for other cars which have been released within twenty-four hours.

From the hardship resulting from excessive receipts of cars even where shipments are not frozen, either the bunching rule or the average agreement ordinarily furnishes relief. If the company had not elected to enter into the average agreement the bunching rule might have afforded relief under the circumstances which attended the deliveries here in question. As any one of the 227 cars on which demurrage was assessed might have been unloaded within the forty-eight hours free time, the undue detention was not the necessary result of the ore therein being frozen, but was the result of there being an accumulation of cars so great as to exceed the unloading capacity. And the court thought that the frozen shipment rule did not depart from the established policy of treating the single car as the unit in applying demurrage charges as well as in applying carload freight rates.

The judgment of the Supreme Court of Pennsylvania was reversed.

Public Use of Tract on Grand Canyon Affirmed

Cameron Denied Title to Claims About The Head of Bright Angel Trail, In Colorado

The Supreme Court of the United States has affirmed judgment in the case of the United States against Ralph H. Cameron and others, enjoining the defendants from occupying, using for business purposes, asserting any right to, or interfering with the public use of, a tract of land in Arizona, approximately 1,500 ft. long and 600 ft. wide, which Cameron was claiming as a lode mining claim.

The tract is on the southern rim of the Grand Canyon of the Colorado and embraces the head of the Bright Angel Trail. Since 1908 all but a minor part of it has been a part of the Tusayan National Forest reserve. This was withdrawn from operation of the public land laws, except the mineral land law, but therein was a saving clause in respect of any "valid" mining claim theretofore acquired. The court herein holds that Cameron's mining claim is not valid.

This claim is known as the Cape Horn lode claim, and was located by Cameron in 1902, after the creation of the forest reserve, and before the creation of the monument reserve. To make the claim valid, or to invest the locator with a right to the possession, it was essential that the land be mineral in character, and that there be an adequate mineral discovery within the limits of the claim as located (Revised Statutes, No. 2320), and the discovery must have preceded the creation of the reserve.

Cameron also had sought patents for other claims embracing other portions of the trail into the Canyon. Protests to his claims were made, charging that the land was not mineral and that there had been no supporting mineral discoveries. After a hearing the Commissioner of the General Land Office held the claims were not valuable for mining purposes, and therefore invalid. The matter was appealed to the Secretary of the Interior, who said, among other things:

"With that possible exception (in the case of the Magician lode claim), the probabilities of such deposits occurring are no stronger or more evident at the present time than upon the day the claims were located. The evidence wholly fails to show that there are veins or lodes carrying valuable and workable deposits of gold, silver, or copper, or any other minerals within the limits of the locations. Sufficient time has elapsed since these claims were located for a fair demonstration of their mineral possibilities."

ECHOES FROM THE FRATERNITY

SOCIETIES, ADDRESSES, AND REPORTS

Society of Economic Geologists Organized

New International Society of Geological Engineers Will Advance Geology as Applied to Mining and Other Industries

As the result of a movement which began in December, 1919, a special society for professional practitioners of applied geology, or geological engineers, has just been organized. The objects of the society, as stated in the preamble to the constitution, are:

The advancement of the science of geology in its application to mining and other industries; the diffusion of knowledge concerning such application; the advancement and the protection of the status of the profession; the definition and maintenance of an adequate professional standard; and the formulation and maintenance of a code of professional ethics.

The name of the new society will be the Society of Economic Geologists. This was selected as the result of a ballot in which the names Society of Applied Geology and Society for Geological Engineers were also balloted for.

The following officers have been elected:

President R. A. F. Penrose, Jr., Philadelphia, Pa.; vice-president, E. S. Bastin, Chicago, Ill.; secretary and treasurer, J. Volney Lewis, New Brunswick, N. J. The other directors are W. H. Emmons, Minneapolis, Minn.; Hoyt S. Gale, Washington, D. C.; Waldemar Lindgren, Boston, Mass.; A. C. Veatch, New York City; and H. V. Winchell, Minneapolis, Minn.

The official organization meeting of the society, which will begin its first official calendar year, will be held in Chicago, Dec. 28 to 30, 1920, at the same time and place as the meeting of the Geological Society of America. The new society is intended to be not only national but international in its scope, and for this reason the word American has been omitted from its name.

The organization was effected by a selected committee of sixty from among the most prominent geological engineers of the country. However, the constitution provides that the charter members shall be those elected during the first year of the society.

Extracts from the Constitution follow:

Membership

The society shall comprise members, who, by knowledge, experience and honorable standing are qualified to advance the objects of the society, and who shall be elected to membership as hereinafter provided.

It may also comprise associates, who shall have the privilege of attendance at meetings, presentation of papers, and receipt of proceedings, if any.

A candidate for membership must have had eight years' professional experience, including not less than five years of work principally devoted to geology applied to mining or other industries, of which three years must have been in positions of responsibility. Graduates in geology or engineering of approved schools shall be credited, as to the eight years, with one-half of the time prescribed for graduation. Geologists or engineers who have rendered signal service in application of geology to mining or other industries may also be eligible.

A candidate for associateship shall have been engaged in studying or practicing the science of applied geology for at least two years. The object of the associate class is to open the advantages of the society to students and younger workers.

Officers and Directors

The affairs of the society shall be managed by a board of directors, who shall be elected annually by letter ballot in the manner hereafter prescribed.

The board of directors shall consist of the officers of the society named below, and five other directors. The officers of the society shall consist of a president and vice-president, who shall be elected annually as hereinafter provided, and a secretary and treasurer, who shall be elected by the board of directors. The offices of secretary and treasurer may be combined in one person by vote of the board of directors. The term of office of the other directors shall be two years. At the first election five directors shall be elected, three to serve two years, and two to serve one year. In the event of a vacancy in the board of directors the remaining directors of the board may elect a successor to fill the vacancy until the next election. Directors are permitted to vote by proxy.

Stated Meetings

There shall be two regular meetings at times and places to be decided on by the board of directors.

Admissions

A candidate for membership must be proposed by three members; and if approved by the board of directors, shall, after investigation, then be elected by a direct ballot vote of all the members of the society, subject to final confirmation by the board of directors. In the election of members by the society three-fourths of all votes cast shall be be required to elect; provided that if ten votes be cast against the candidate he shall be considered rejected. A candidate for associateship must be proposed by three members, and shall be elected by the board of directors. In the confirmation of membership and election of associates by the board of directors a majority vote is necessary for acceptance; provided that two adverse votes in the board may defer the acceptance, in which case the board may again consider the candidate and vote on him for acceptance at any meeting after the lapse of one year.

Annual Dues and Life Membership

The annual dues of members shall be $5. The annual dues of associates shall be $5. Life membership shall be $75.

Nominations

A feature of the by-laws of the society is in regard to nominations and elections:

In all elections of officers, members shall be provided with tickets containing the nominations of at least three candidates for each office.

In advance of the annual meeting the board of directors shall appoint a nominating committee of three members, not more than one of which shall be a member of the board. This committee shall nominate three candidates for each office to be filled by election at the ensuing annual meeting, and these nominations will be sent to the members at least ninety days before the time of the annual meeting. To this ballot shall be added any further nomination which is proposed and supported by ten or more members. Such further nomination must be received by the board at least sixty days before the date of the annual meeting, and the nominating committee shall send out ballots containing a complete list of nominees at least forty-five days before the meeting. Votes to be counted must be received by the committee of tellers on the day previous to the first day of the annual meeting.

A plurality vote shall elect.

Another feature provides for the retirement of the officers if their actions are not approved of by the society.

Vote of Confidence

The board of directors by a [illegible] fifths vote of the directors or upon the request in writing of 20 per cent of the members of the society shall submit any question upon which they have passed to the membership for a vote of confidence. Such vote must be inaugurated within fifteen days after action for a vote of confidence has been passed by the board or a request in writing by 20 per cent of the members of the society has been received by the secre-

tary; and the majority of votes received within thirty days after the mailing of a ballot shall decide. In case such question is decided against the board, the members thereof shall forthwith resign office, their resignations to take effect on election of their successors, and a new election of the whole board shall be immediately ordered to be conducted as provided in the bylaws.

Interest in and Utilization of Liquid Fuels in France

The following from *Echo des Mines et de la Métallurgie* is a summary of a recent address by M. Dumanois, chief engineer of the Marine, before Société d'Encouragement:

Before the war, coal formed France's chief source of fuel. Her coal production, which was becoming deficient, had been further diminished by subsequent conditions, and attention has now turned to the possibility of substituting liquid fuels, especially petroleum and its derivatives. Some delude themselves with the belief that liquid fuels can permanently replace coal and that their use can end the fuel crisis. In the first place, petroleum is an imported product which, under unfavorable exchange, at present is procurable at a high rate, and this condition is likely to continue.

Since abandoning their rights in Upper Mesopotamia and in Kurdistan, no oil source is under the control of French interests and their domestic and colonial production is insignificant.

But France has to fear a crisis in quantity rather than in price of liquid fuel. The world production of mineral liquid fuels is really notably less than the world's consumption. The United States, which furnishes 70 per cent of the world's total supply, while consuming 85 per cent, must import oil (e.g. 5,000,000 tons of Mexican oil in 1919), and drew more than 3,000,000 tons from their reserves in both 1918 and 1919. Their consumption in 1918 amounted to one twentieth of their underground reserves.

In 1918 the world's production of crude oil was less than 80,000,000 tons, which is the equivalent of annual consumption in coal of France. If one considers the great excess in calorific power of gasoline over coal, and its better thermic utilization, it is seen that to replace only 20 per cent of the French coal consumption by gasoline they should have to absorb more than one-tenth of the world's oil production. The fuel crisis is world-wide, however. One may say, then, that in the near future, France will be altogether without petroleum and its derivatives.

Nevertheless it is of the first importance, for the national defense, that France have a supply of liquid fuel. M. Dumanois, therefore, is of the opinion that liquid fuel, being the fuel de luxe, should be specially reserved for Diesel engines, and that modifications in existing installations should aim at improving both the rational use of solid fuel and the technical efficiency of the personnel in charge.

In closing the speaker pointed out the value and interest of the following: Searches for oil in France and her colonies; the development of the bituminous shale (shale oil) industry, and of winning oil from coal. He was quite in agreement with Barbet as to the possibility of securing cheap and adequate supplies of alcohol from the colonies, e.g., of banana alcohol, and stated that it was possible to secure supplies of castor oil from the colonies to take the place of mineral oil lubricants. Such a measure would insure France against future needs and enable her to decrease importations of petroleum and its derivatives.

Robert W. Hunt Medal Committee Proposes Portrait of Medallist

The Robert W. Hunt Medal Committee of the A. I. M. E. was organized for the purpose of raising funds for the Robert W. Hunt Medal, but the partners and employees of Robert W. Hunt & Co. insisted on presenting these funds to the Institute, and therefore raised and paid over a fund of $7,500 in addition to the $1,000 paid for designs and die-cutting. Its proceeds provide the annual medal and money prize. The committee, therefore, now proposes to the members of the Institute that a fund be raised by subscription among the members for the painting of a portrait of Captain Hunt to be presented to the Institute and placed in its Members' Rooms along with the portraits of Dr. Rossiter W. Raymond and others. Captain Hunt has been twice president of the A. I. M. E. He has served for several years as a member of its governing body. He was also the recipient of the John Fritz Medal.

It is desired that the tribute be made as popular as possible by having a large number of members subscribe. Sums of $1 or less will be gladly received. The excess over the $25 subscribed by any individual will be returned, provided the necessary amount for the portrait is oversubscribed. Checks should be made out to the Robert W. Hunt Fund and addressed Secretary, American Institute of Mining and Metallurgical Engineers, 29 West 39th St., New York City, N. Y.

Engineers' Club of Duluth Elects New Officers

At the annual meeting this year The Duluth Engineer's Club elected W. S. Heald, president; O. B. Bjorge and Ray S. Huey, vice-presidents; Geo. C. Olmsted, secretary; and A. U. Shipman, treasurer. Other members of the board of directors will be A. M. Frazee, Frank Hutchinson, W. J. Mathews, and Col. F. A. Pope. The club's representative on the Minnesota Joint Engineering Board will be W. H. Woodbury, the former secretary; and ex-director J. L. Pickles was elected delegate to the organization Committee of the Minnesota Federation of Engineers.

Federated Engineering Societies Invites Others To Join

Joint Conference Committee, Acting Ad Interim, Sends Cordial Letter

It has been frequently insisted that the recently organized "Federated American Engineering Societies" should be spoken with the accent on the last word—the federation does indeed aim to unite societies into an effective union. In furtherance of this ambition the Joint Conference Committee of the A. S. C. E., A. I. M. E., A. S. M. E., and A. I. E. E., acting under the authority of the Organizing Conference, is mailing the following invitation to the engineering and allied technical organizations of the country.

THE FEDERATED AMERICAN ENGINEERING SOCIETIES
JOINT CONFERENCE COMMITTEE
29 West 39th Street, New York
July 26, 1920.

My dear Sir:

The Joint Conference Committee of the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers, acting as the Ad Interim Committee in accordance with the authorization of the Organizing Conference held in Washington, D. C., June 3-4, 1920, extends to your organization a cordial invitation to become a charter member of the Federated American Engineering Societies, and to appoint delegates to the first meeting of the American Engineering Council, of which due notice will be given, to be held in the fall of this year.

There has been previously sent to you an abstract of the minutes of the Organizing Conference, at which there were in attendance 140 delegates, representing seventy-one engineering and allied technical organizations. It was the unanimous opinion of the conference that there should be created an organization "to further the public welfare wherever technical knowledge and engineering experience are involved and to consider and act upon matters of common concern in the engineering and allied technical professions," and that this organization should consist of societies or affiliations, and not of individual members.

On the basis of these fundamentals the attached constitution and by-laws were unanimously adopted by the conference.[1] These contain full information concerning the Federated American Engineering Societies, the American Engineering Council, its executive board, and of the various officers and committees. The basis of representation therein stated for the American Engineering Council is one representative for from 100 to 1,000 members and an additional representative for each 1,000 members or major fraction thereof.

At the gathering in Washington, which was the greatest event in the history of the engineering and allied technical organizations in this country, steps were taken which created "The Federated American Engineering Societies," which will have a far-reaching influence on the future of these professions. The fact that this action was taken without a dissenting vote indicates that the psychological moment had arrived and that there was a unanimous desire on the part of the representatives of these professions for the organization formed.

The Joint Conference Committee, the Ad Interim Committee, would ask each organization invited to take favorable action in the matter of membership in the organization at the earliest possible moment and to advise the committee promptly of the names of the delegates who will attend the first meeting of the American Engineering Council in November of this year.

The Joint Conference Committee is confident that with the universally acknowledged need for such an organization there will be a prompt affirmative response to this invitation. Very truly yours,

JOINT CONFERENCE COMMITTEE of
American Society of Civil Engineers
American Institute of Mining and Metallurgical Engineers
American Society of Mechanical Engineers
American Institute of Electrical Engineers

Book Reviews

The Magnetite Deposits of the Eastern Mesabi Range, Minnesota. By Frank F. Grout and T. M. Broderick. Bull. 17, Minnesota Geological Survey. 54 pages.

This bulletin deals with the eastern end of the Mesabi Range, where the iron-bearing formation has undergone metamorphism, resulting in a notable change of the iron into magnetite and the development of silicates, such as amphibole and pyroxene, especially close to the intrusive (Keweenawan) gabbro, which has been the cause of metamorphism. The immediate incentive to the study was the possibility of commercial magnetic concentrations of the low-phosphorous magnetic ores. The results of the study indicate that the metamorphism has not modified the iron distribution, the concentration having been antecedent; and that most of the beds showing iron concentration are conglomeratic. These are valuable observations, as is the separation of the iron-bearing formation (350-500 ft. thick) into a number of separate beds which have different economic importance, and so form valuable aids in prospecting. Even intrusive diabase sills may serve as markers.

Amphibole (mainly actinolite) is abundant, intergrown with quartz and magnetite and probably resulted from metamorphism of the glauconite mineral greenalite. Metamorphic minerals also include fayalite and garnet. Greenalite was found in the western part of the area, but is metamorphosed near the gabbro. The authors have checked the low alkali content, which is like that on the western Mesabi.

"Most of the rocks are derived from an original sediment containing granules that may have been greenalite, but the greenalite is so altered in most specimens that the name greenalite-rock is applicable to very few." "The so-called 'cherts' are derived by alterations from the rocks with granules like those of greenalite." "For the rocks of the east Mesabi there are several reasons why the name chert is not very satisfactory" (p. 14). All this, though we believe true, is not new, though it is stated here apparently as an original proposition. The original mineral of the Mesabi iron was discovered and described by Spurr in Bull. X, Minn. Geol. Survey, as an alkali-poor glauconitic mineral, and the nature of its disintegration into iron oxide and so-called "cherty silica," as shown with exemplary clearness under the microscope, was described; further the segregation of these products into separate bands or masses, producing the so-called banded "jasper and iron," was fully followed and described. These conclusions were accepted and followed by Leith and Van Hise, who called the glauconitic mineral greenalite. The discussion in the bulletin under review does not add to the clarity of the conception; indeed it would be difficult for the uninitiated to form a clear idea of the genesis of the iron and silica from this bulletin. The Lake Superior geologist suffers under the same handicaps of provincialism and inherited dogma as does the Mississippi Valley geologist: and in the Lake Superior district it appears to be impossible to break away from the hazy and mazy conception of original precipitation of "cherty siderite and sideritic chert," the like of which was never seen on sea or land. This conception antedated the discovery of the glauconitic mineral greenalite on the Mesabi, where Spurr showed that the "cherty siderites and sideritic cherts" was one phase resulting from the disintegration of the original iron silicate; and the attempt to embrace the new knowledge, without giving up the conclusions from the old data, leads to a great burden of confusion. Thus some beds of this Mesabi iron-bearing formation, which altogether is only a few hundred feet thick, are apparently conceived of by the writers of the bulletin under review as direct chemical precipitates of silica and iron—in this case assumed to have been mainly limonite (p. 4)—whereas others are believed to have yielded the same products of silica and iron oxide from the disintegration of the green iron silicate. Other and younger glauconitic formations in other regions, which are agreed to have formed under analogous conditions, offer no warrant for the theory of the primary precipitation in sea water of banded colloidal or cryptocrystalline silica, and iron carbonate or oxide; and we are inclined to regard the theory as unwarrantably imaginative.

As an example of a flight of fancy we may quote the following: "This assumption of leaching of silica in a sea where silica was accumulating does not appear plausible unless, as was true in this case, some alternative of conditions is indicated. In a shallow sea the contribution of iron and silica from magmatic or other source may furnish plenty of material for deposition. But at a distance from the source any addition of fresh water, *say from a heavy rain on the adjoining land*, would crowd back the depositing solutions and replace them by water that would dissolve and oxidize the deposits, until diffusion and convection again brought in the stronger solution." We are tempted to fall back on the desperate remark of the hero of Booth Tarkington's "Seventeen," and say "Ye Gods!"

An interesting and valuable contribution is the discovery, in certain beds of the iron-bearing formation, of markings apparently representing algae (seaweeds) which grew in the accumulating sediment and which are similar to those observed by Dr. E. S. Moore in the iron formations near Hudson Bay, and very much like those described by C. D. Walcott from the Pre-Cambrian in Arizona and Montana. J. E. S.

Nickel Smelting—The August Bulletin of the Canadian Mining Institute (503 Drummond Building, Montreal) gives a complete description (pp. 40) of the International Nickel Co.'s smelter.

Technical Papers

Accident Prevention—In 1916, five of the largest mines in the Butte district had 630 fatal and serious accidents underground in 4,893,258 shifts worked. "At this rate, if the miner should average 300 underground shifts a year, the chances of a fatal or serious accident happening to him would be at the average rate of one in 26 years." This is quite often enough, it seems to us, particularly if the accident should be one of the fatal kind. However, a lot has been accomplished in the Butte district in making conditions safe. Educational and social service work also come within the province of the safety department. Those interested should send 10c. to the Superintendent of Documents, Washington, D. C., for Bureau of Mines Technical Paper 229, "Accident Prevention in the Mines of Butte, Montana."

Earth Temperatures — The U. S. Geological Survey has just issued Bulletin 701 (price 20c. from the Superintendent of Documents, Washington, D. C.), entitled "Geothermal Data of the United States." All available data on the rate of increase of temperature with depth in this country is presented. The information is given by states and no general average is attempted. The rate of temperature increase varies with the conductivity of rocks, underground tension, mineralization, volcanic influences, movement of underground waters, the presence of large bodies of surface water and possibly with variations of radio-activity.

Research—The problem of research has generally been conducted in a somewhat hit-or-miss system in this country. Recently the National Research Council has been formed to assist in meeting some of the needs of scientific organization. "The Development of Research in the United States," by James R. Angell, states broadly some of the problems to be solved. This address may be obtained for 25c. from the National Research Council, 1201 16th St., Washington, D. C.

Concrete Mine Shafts—With shafts sunk in porphyry, considerable trouble often occurs from "swelling" due to air and moisture altering the rock structure. This seems to be prevented by a comparatively thin coating of concrete. The shaft is also made safer and more permanent. It is fireproof, and the ingress of water is easily controlled. In the *Salt Lake Mining Review* of July 15, (Salt Lake City, Utah; price 15c.) the method of concreting the [illegible] compartment No. 2 shaft of the Chief Consolidated, at Eureka, [illegible] described.

Storage Batteries—We advise any of our readers [illegible] paint... storage-battery trucks or tractors [illegible] sent free, to the Superintendent of Documents, Washington, D. C., for Bureau of Standards Circular No. 92, 74 pages. It is devoted to the operation and care of vehicle-type batteries.

MEN YOU SHOULD KNOW ABOUT

E. P. Mathewson, mining enginer, has gone to Arizona on a professional engagement.

D. S. Dean inspected the Menominee and Gogebic range mines of the Keweenaw Association August 7 to 11.

William J. Deavitt has been retained by the Manta Mining Co., of Chihuahua, Mex., as consulting engineer.

J. M. Brocks, Jr., has succeeded **Paul Steger** as manager of the Santa Eulalia unit of the Cia. Minerales y Metales.

H. S. Gale, who recently returned from South America, has resigned from the Geological Survey to enter private employ.

A. E. Drucker, mining engineer, is examining copper mines in the Olympic Range of Washington, for Aberdeen, Wash., interests.

David H. Collier, for the last two years engaged as a mining engineer in Burma, is temporarily in New York, where he recently arrived from London.

Dwight E. Woodbridge, mining engineer of Duluth, Minn., has recently returned from an extended trip into the Hudson Bay country, where he has been exploring for mines.

Stewart Thorne, manager of the Trethewey mine, Gowganda, Ont., has resigned on account of ill-health. **Murray Kennedy** formerly with the Beaver mine, Cobalt, succeeds him as manager.

Dr. Waldemar T. Schaller has severed his connection with the Great Southern Sulphur Co., Inc., of New Orleans, La., and has returned to the United States Geological Survey, Washington, D. C.

Frank M. Manson, president and general manager of the Western Ore Purchasing Co., was in Nogales recently, and is now in Mexico, seeking a suitable location for an ore-buying agency in Sonora.

D. C. Jackling has been in Salt Lake City, Utah, in conference with **C. B. Lakenan**, general manager of Nevada Consolidated Copper Co., and **G. L. Hinckley**, general manager of the Nevada Northern R.R., of Ely, Nev.

George A. Laird, consulting engineer, who has recently returned from Mexico, has been appointed general manager of Guiana Development Co. and will leave for South America about Sept. 1. His present address is in care of R. T. Wilson & Co., 120 Broadway, New York, N. Y.

S. W. Stratton, director U. S. Bureau of Standards, sailed for Europe recently to attend the session of the International Bureau of Weights and Measures at Paris during September. Dr. Stratton will be the official representative of the United States at the session.

Allen Murray Yonge, of Staunton, Va., returned at the end of July from his trip to the West Indies, and is now in Washington, where he will open an office as consulting engineer in mining and economic geology. He may be addressed at Buckingham Hotel, Washington, D. C.

Freeman F. Burr, M. A., geologist to the Maine State Water Power Commission and to the Central Maine Power Co., Augusta, Me., is spending much of his time this summer investigating

FREEMAN F. BURR

mineral deposits in Maine with a view to their development by means of electric power. At the same time he also has to pass judgment on the suitability of rock structures at prospective power sites and search for construction materials. His geologic work for the past six years, under the State Water Storage, Public Utilities and Water Power Commissions, has taken him into nearly every part of Maine and he is probably more familiar with that state's geology and mineral resources than is any other person today. His special studies in the character and distribution of peat and of feldspar have been of special value to Maine, and were based on preparatory work in geology and botany at Lawrence Scientific School, Cambridge, Mass., from which he graduated in 1900, at Columbia University from which he received the M. A. degree in 1913, and at other schools. Mr. Burr has had field experience in all the New England and some of the Middle Atlantic and Central States. In view of the above it was quite proper to elect him a member of the Association of State Geologists, although Maine herself has not yet seen fit to follow the lead of many other states and establish for her own benefit an adequate modern survey of her mineral and other natural resources.

John Borg, of New York City, was recently elected president and chairman of the executive board of the Callahan Zinc Lead Co., to serve the unexpired term of the late John A. Percival. Charles H. Borg, of New York, brother of the new president, was elected to the vacancy on the board of directors, and **Gust Carlson**, of Duluth, was elected a member of the executive committee.

Carroll R. Forbes is still professor of mining at the head of the mining department of the Missouri School of Mines and Metallurgy at Rolla, Mo. Prof. **Charles H. Fulton**, who recently resigned from the Case School of Applied Science, was appointed to the directorship of the University of Missouri School of Mines and Metallurgy at Rolla and does not supplant Professor Forbes, as our note of Aug. 7 seemed to indicate.

OBITUARY

J. George Leyner, inventor of the Leyner drill, and founder of the Leyner Engineering Works, died in his 60th year on August 5 at his home in Littleton, Col., from injuries received in an automobile accident on the Denver-Littleton road August 3. Mr. Leyner was the first white child born in Boulder County, Col., and had been in business in Denver for nearly 40 years. When a young man he invented the rock drill which bears his name and which was responsible for the success of the J. George Leyner Engineering Works, later taken over by the Ingersoll-Rand Co. At the time of his death Mr. Leyner was president of the Leyner Engineering and Manufacturing Co. For some time he had been working on the invention of a farm tractor. The plans were completed before his death, and the Leyner tractor is now in process of construction at the Vulcan Iron Works.

SOCIETY MEETINGS ANNOUNCED

American Chemical Society will hold its fall meeting with its **Chicago Section** at Chicago, Ill., Sept. 6 to 10, inclusive. Hotel headquarters will be at the Congress Hotel, Michigan Boulevard and Congress Street, where registration will begin Sept. 7, and an information bureau located. The Division of Industrial & Engineering Chemistry, H. E. Howe, Woods Hole, Mass., secretary, plans for its second session a symposium on fuels, arranged by A. C. Fieldner of U. S. Bureau of Mines and including eleven papers. Prof. W. A. Noyes will deliver the presidential address on the evening of Sept. 8, and the banquet ($4.00) will be held on Sept. 9 at the Congress Hotel. Secretary Chas. L. Parsons is at 1709 G St., N. W., Washington, D. C.

THE MINING NEWS

LEADING EVENTS

GENERAL VIEW OF FLIN FLON PROPERTY ON FLIN FLON LAKE, NORTHERN MANITOBA. SHOWING PLANT UNDER CONSTRUCTION AND HEADFRAMES AT TWO SHAFTS ABOUT 1,000 FT. APART. THE SMALL HILL BETWEEN SHAFTS IS A HORSE IN THE OREBODY

Pushing Flin Flon Development

Keen Interest in Results on Which Depend Railroad from The Pas—Lead-Silver Strike at Herb Lake

Development work at the Flin Flon property in northern Manitoba is progressing rapidly, No. 1 shaft now being down 200 ft. and No. 2 100 ft. Drifting and crosscutting are being done on the orebody in No. 2 shaft at the 100-ft. level and encouraging results are reported. Considerable interest is being taken in this property and the present work being done because on the results of development will depend the building of a railway from The Pas to the property. This line, if built, will also tap several other districts where promising orebodies are under development. Inasmuch as a good part of the line will go through the heart of Manitoba's mineral district, prospecting and mining are being vigorously carried on in the sections affected. Diamond drilling is still going on at the Gordon claims at Copper Lake. These are the claims that were staked last season on a promising discovery of gold quartz, resulting in a rush of prospectors to the Copper Lake district. It has been stated that the owner, J. P. Gordon, will spend $50,000 on the claims.

A recent discovery on the north side of Herb Lake, in northern Manitoba, is attracting considerable interest. Here a body of silver-lead ore has been found, the first one of such ore to be found in this district. It is understood that the body is very large. The indications, judging from the surface capping, would suggest that it is about 100 ft. wide and about 1,000 ft. long. The assays from surface samples run about 12 oz. silver and 20 per cent lead, with only slight recovery in gold values.

WEEKLY RÉSUMÉ

Development of the Flin Flon property in Northern Manitoba is progressing rapidly. A plan for refinancing the Canada Copper Corporation has been put before the stockholders. Reports from Quebec indicate that the asbestos industry continues to thrive. The Premier, near Stewart, B. C., is said to have cut new ore. In Idaho, control of the Kill Buck property has been obtained by the Interstate Callahan. In California, high costs have forced the shut-down of the Shawmut mine. In New Mexico, Phelps Dodge has started its new Burro Mountain concentrator. In Arizona, the San Carlos Reservation is to be opened to prospectors. The Crater Mining Co. is prospecting for a huge meteor in the crater near Winslow, Ariz.

At Washington, witnesses were heard by Secretary Payne on August 10 in regard to war powers relief. The Bureau of Mines has formed a division of non-ferrous metallurgy. A new mine-rescue car has been destroyed by fire in the N. Y. Central shops.

Valuation of Mexican Industry Announced

The total valuation placed on three industries in Mexico by the Mexican government is 1,230 million dollars Mexican, according to a recent official announcement in *El Universal*, Mexico City. The oil industry, including 1,100 wells, railroads, pipe lines, machinery and capital invested, is valued at $660,000,000. The mining industry, including 3,136 mines, railroads, machinery and capital invested, is second, its valuation being $400,000,000. The textile industry is third with $170,000,000, this including the value of 190 factories, railroads, machinery, power plants and capital invested. The textile industry is the one that yields most revenue to the Federal Government. How it is possible to arrive at such figures at the present time is not known.

To Reorganize Canada Copper

Company Seeks To Raise Half Million —Fifty-Cent Assessment Levied— Defaults on July Interest

The Canada Copper Corporation, whose 2,000-ton concentrator has been standing idle at Allenby, B. C., ever since its completion late in 1919, is to be reorganized. It is understood that the erection of the plant cost considerably above the estimate. The company is a Virginia corporation capitalized at $10,000,000. A plan proposed by a readjustment committee composed of August Heckscher, Colgate Hoyt and Lucius W. Mayer provides for reorganization under Canadian laws, the capital and number of shares to be the same as at present. The new company will acquire all the property and assets of the old and will assume all its obligations. Stockholders are to be permitted to exchange the stock of the present company for that of the new company share for share upon paying an assessment of 50c. per share. Without such payment a stockholder will obtain only one new share for three of the old issue. The company has defaulted interest, due July 1, on its first mortgage bonds. The total sum needed by the company is $500,000, which is wanted for the following purposes: July 1 bond interest $75,000; bills payable $175,000; readjustment expense $25,000, and working capital $225,000.

"The original plan called for the operation of the plant in July, 1919," says the company's statement, "at which time the railroad and power facilities to be provided by the Canadian Pacific Railroad were also to be ready. The program covering the work under our control, viz., development of the mine and the construction work in connection with the mine, as well as the

construction of the mill, was well maintained until it became obvious that the interests building the railroad and power lines would not have them completed in the time specified. The delay of over a year's duration has been caused by circumstances over which your company has had no control, and is due entirely to the failure of the railroad and power companies to complete their construction. During this period of enforced inactivity your company has been burdened with heavy overhead charges, though every economy has been practiced, including reduction and in some instances discontinuance of salaries of your officials. Certain necessary expense to maintain the property, such as the maintenance of a skeleton organization, insurance and other overhead charges, could not be avoided. The necessity of hauling materials by truck to the mill and mine incurred another considerable unanticipated expense. Had the railroad and power lines been completed on schedule, the plant would now be in operation and the company receiving income. The mine has for some time been ready for extraction of ores, and since the concentrator is completed, the plant can be placed in operation as soon as the railroad can deliver ores to it. We are now advised that the railroad will be fully completed in September and the power line shortly thereafter, so that extraction of ore and the transportation thereof to the mill may be expected to commence during October, and the company's product should be available for disposal immediately thereafter."

Anaconda and Clark Interests Effect Compromise

Details of the compromise agreement between Anaconda and the W. A. Clark interests whereby Anaconda gives to the latter a portion of the Emily vein under the surface of the Pilot-Butte claim have not been disclosed, but it is said to be a victory for the Clark interests. A vein apexing in the Elm Orlu claim, the prior location, was found to unite with the Emily on dip at about the 2,400-ft. level of the Pilot-Butte, where the orebody has a width of about 50 ft. with the grade ranging up to 6 per cent copper with some silver.

Anaconda years ago instituted suit against the Pilot-Butte, claiming the Pilot-Butte's chief fissure, the Emily, on the ground of extralateral rights, purchasing the property later for $1,125,000. This sum was later alleged to be insufficient by certain interests who had been connected with the Pilot-Butte.

To Open San Carlos Reserve

The San Carlos Indian Reservation is to be opened at once for prospecting. The western section is known to be especially rich in asbestos, generally found in localities so rough that airplanes or dirigibles have been suggested as means for bringing out the ore.

Prospecting for a Buried Meteor at Winslow, Ariz.

Newly Organized Mining Company Drilling on Edge of Famous Crater, Over 4,000 Ft. Across

It is reported that the famous Meteor crater, west of Winslow, Ariz., is to be drilled by a new corporation, the Crater Mining Co. Two Standard drilling rigs have been purchased and will be erected near the inner edge of the pit, which is 4,100 ft. wide. The theory is held that the celestial visitor sought plunged into the earth at an angle from the vertical. Exploration was conducted for a period of years within the pit by a Philadelphia company that found almost insuperable the difficulty of handling the quicksand that filled in the great hole. Drilling discovered fragments of the meteor, however, though it is believed that the main mass has not been located. The metal, as shown by analyses of the fragments within and around the pit, shows a very high percentage of nickel and will possibly be of considerable value if it can be handled. It has been estimated that the meteor need not have been over 500 ft. in diameter to have made the crater, but it is hoped that there will be found a mass from 1,000 to 2,000 ft. in diameter. Specimens of the metal, generally labeled as from the Canyon Diablo Meteor, are on exhibition at many Eastern museums, the largest of the pieces being at the Field Columbian Museum in Chicago.

Homestake Co. Holds First-Aid Contest

In the first-aid and mine-rescue contest held on Aug. 8 at Lead, S. D., in the Black Hills, between teams from the Homestake Mining Co., Team 1, composed of E. English, captain, L. B. Wright, J. B. Chastain, T. G. Houston, J. R. Treweek and T. V. McNally, took first place. This team will represent the Homestake company at the Bureau of Mines meet in Denver early next month. Team 3, captained by Abe Aladalo, was awarded second place and Team 2, W. S. Primrose, captain, was third. The company gave cash prizes to the three winning teams as follows: $150, $120 and $60. The contests were in charge of B. W. Dyer, engineer in charge of Bureau of Mines Rescue Car No. 5.

New Producers in Arizona

The following new properties were added to the list of producers in Arizona in 1920: Arizona Asbestos Association, valuation $119,060.50; Pierce & Gardiner property at Patagonia, assessed at $20,908; Leadville Mining Co., in Cochise County, assessed at $42,261; Copper Basin Group, formerly the Senator Group, in Yavapai County, assessed at $48,544; and El Tiro Leasing Co., in Pima County, assessed at $183,148. The Arizona Copper Co. asked a decrease of at least $1,000,000 from the tentative estimate.

Quebec Asbestos Industry Still Thriving

Contract System Has Offset Labor Scarcity—U. S. Alloys Mill Started in Chrome District

Industrial conditions have been particularly active in the asbestos business this season; the working companies have been aiming at maximum production and all potential sources are being exploited for raw material. Companies with low-grade propositions are striving to earn dividends and the high-grade properties are using up some of their excess profits to effect betterments in their working plants as well as to stabilize their capital account, both of which were seriously neglected during the lean years of the industry.

Labor conditions have been very satisfactory, the shortage in men being largely overcome by the adoption of the contract system in the mines, thereby increasing the tonnage per man to a point where the net cost per ton of ore hoisted was not materially increased. The result has been a marked increase in the efficiency of the miners and a considerable influx of labor which has been drawn from the surrounding industries. The Bell Asbestos Mines have recently adopted this system, leaving only the Johnson company employing the wage system. The old argument that under any form of contract work it is impossible to sort the ore properly in the pit is well founded, but at a time when the best tonnage obtainable is insufficient for the growing needs it is generally agreed that a small loss in the high-grade crudes may be overlooked in the effort to keep up with the demand. Undoubtedly when the market for the shorter grades has been met it will again be the proper policy to obtain a maximum saving of the crude asbestos.

Properties changing hands or being reopened under new conditions are as follows: At East Broughton the Poulin mine has been sold to the S. W. Cohen interests at Montreal, with G. P. Angus as superintendent; the Boston property, part lot 13, R./V, has been leased to J. A. Jacobs under the name of the Asbestos Mines, Ltd., H. W. Edmondson, local manager; and the Montreal property, lot 13, R./VIII, has been purchased through H. B. Lee for the Mutual Chemical Co. This company has added this asbestos holding to its present large holdings in the chrome district in the Black Lake-Coleraine district. Work was undertaken on the property in 1910 but lack of capital prevented the plant from being put into operation. The present intention is to complete equipment for operation as soon as possible.

In the chrome district, the 200-ton mill of the U. S. Alloys on the Belanger property on Caribou Lake has been started, and the "Old Red Mill" of the Black Lake Asbestos & Chrome Co. is being re-equipped to handle a large tonnage of low-grade ore which has accumulated from underground operations of the last two years.

Discovery at Nixon Fork, Alaska, Cause of Excitement

Promising Claims Being Worked by Alaska-Treadwell—Little Quartz Previously Discovered

BY J. G RIVERS

Flat, Alaska, June 26—There has been considerable excitement of late in connection with a discovery of a conglomerate ledge on the Nixon Fork, which is one of the tributaries of the Kuskokwim River and about 60 miles northeast of the town of McGrath. This ledge extends along the ridge between the head of Ilidden and Ruby creeks, both of which have shown placer prospects, and several mineral locations have been made and some development work done on this ledge. On one claim the ledge is said to be 24 ft. wide and on another claim a shaft 60 ft. deep has shown good values to that depth, the ledge averaging about 6 ft. in width.

Last summer Thomas P. Aitken took an option on the property and during the winter of 1919-20 sacked enough ore for shipment to pay for his development work but as his assayer did not give out any information there is no telling what the mine run will average. It is reported that some of the best ore assays around $200 per ton and from that down to $20 and that the average is well over $100 per ton. However, this is not authoritative. The ore is said to carry gold, silver and copper, free gold being visible in the samples seen by the writer.

Aitken allowed his options to lapse this spring and the owners of the ground have let options to the Alaska Treadwell Gold Mining Co., which now has a crew at work doing development work. This company has paid $20,000 on the option price of the property which is approximately $1,250,000, the balance to be paid in installments distributed over a period of four years.

It is significant that the payments already made were made solely upon the strength of the showing of Aitken's development work without any additional development by the Alaska Treadwell, which would indicate that the latter is very favorably impressed with the proposition.

If this goes through it will mean a great deal to this part of Alaska as heretofore no quartz worthy of mention has been discovered. It will stimulate prospecting and may be the means of getting the Government to extend a branch of the railroad to the headwaters of the Kuskokwim River.

New Rail Rates May Affect Steel Mills Adversely

Readjustment of rail rates between upper Lake ports and the seaboard so as to make Lake transportation of grain more profitable may have an adverse effect on the iron and steel industry, it is pointed out, in that it will take ships out of the ore-carrying trade at a time when it is desirable to increase iron-ore stocks at steel mills.

Australian Notes

Settlement of Broken Hill Dispute Sought—Commission Reports on Health of Miners

From Our Special Correspondent

Melbourne, July 19—The New South Wales Government called a compulsory conference of the parties to the labor dispute at Broken Hill under the chairmanship of Mr. Holme, State Commissioner of Conciliation. It was agreed to submit the whole matter to an independent tribunal consisting of a judge or other chairman (to be selected by the Prime Minister and the Premier of New South Wales) and five representatives of each side. They further agreed to bind themselves to abide by the decision of this tribunal, it being understood that where they, through their representatives, fail to agree, the judge or chairman shall decide the question.

REPORT ON HEALTH OF MINERS

An interim report to the Premier by the technical commission of inquiry of the Board of Trade, appointed by the government to inquire into the dust conditions and health of the miners at Broken Hill, has been issued. As a result of an examination of about 2,800 workers the report sets out that ankylostomiasis (hookworm) is not present at Broken Hill; that no person suffering from tuberculosis should be permitted to work in the mines, either on the surface or below ground; that compensation should be given to all persons found to have been affected with progressive tubercular disease of the lungs; that some scheme for providing employment for those persons withdrawn from the mine should be prepared so that no obligation is thrown on the mine worker removed from the mine to find himself a fresh avenue of employment; that individuals affected with pneumoconiosis and withdrawn from work on the mines should be kept under observation; that should they become affected with tuberculosis they should receive compensation, since it will be only a question of time before a fatal termination is reached.

The majority of those who work in the mines at Broken Hill, continues the report, have shown no signs of the accumulation of dust in their respiratory organs. If a resumption of work should take place at Broken Hill the remaining 3,500 men, who have not been before the commission, should be subjected to immediate medical examination. The commission is of the opinion that a thorough investigation of the ventilation and dust conditions of the mines should be undertaken when the mines resume work. The operation of mining can be carried on at Broken Hill with complete safety as far as any material injury to the lungs of the mine workers is concerned.

NEW WESTRALIAN COMPANY ORGANIZED

The Knowna Red Hill Mining Co., with a nominal capital of £100,000, has been formed to work an area at Knowna, Western Australia, which has been favorably reported on by D. L. Doolette, promoter of the Bullfinch gold mine, Southern Cross, and son of G. P. Doolette, chairman of the Great Boulder Proprietary.

MT. MORGAN EXPERIMENTS CEASE

Experiments have been proceeding for some time in roasting, leaching and chlorinating certain types of Mt. Morgan ore, but have now been discontinued, the conclusion having been reached that the extra recovery gained would not justify the large capital outlay required for treatment plant. The industrial court granted increased wages to the employees during the half-year ended May 30, that involved an additional annual expenditure of £32,-800. Further claims amounting to £24,-000 per annum are now being heard.

Recent Production Reports

Utah Copper produced 8,500,000 lb. copper in July, against 10,000,000 in June.

Chino Copper's July output was 4,360,932 lb. of copper against 4,010,-069 in June.

Ray Consolidated's production in July was 4,500,000 lb. copper as against 4,520,000 in June.

Nevada Consolidated produced 4,650,-000 lb. copper in July, the same as in June.

Granby Consolidated M. S. & P. Co. produced 2,400,000 lb. copper in July, compared with 2,079,000 in June.

The Rand's gold output in July was 736,000 fine ounces, against 715,000 in June, 699,000 in May and 686,000 in April.

Shipments of domestic copper ore from Alaska to the United States in July totaled 8,510 gross tons, containing 5,797,645 lb. valued at $1,107,969.

Greene Cananea in July produced 3,500,000 lb. copper, 130,750 oz. silver and 770 oz. gold.

North Butte produced 1,505,079 lb. copper in July compared with 1,616,822 in June.

Kerr Lake produced 52,228 oz. silver in July against 52,831 in June.

Research in Metallurgy of Iron Successful

Investigations carried on by Prof. Alfred Stansfield of McGill University, Montreal, into the reduction of iron ores by gases at low temperature and with the electric furnace, are stated by the Advisory Council for Scientific and Industrial Research to have been attended with satisfactory results. On some of the findings patents have been applied for to permit of the commercial development of methods that will enable the utilization of Canadian low grade iron ores. The investigation was assisted by a grant of $1,[illegible] from the Advisory Council.

The American Metal Co. is reported to have purchased the smelter of the Arkansas Zinc & Smelting Corporation at Van Buren, Ark. The plant has 3,200 retorts and has been in operation for several years.

War Mineral Relief Arguments Heard by Secretary Payne

Witnesses Object to Commission's Interpretation of Law—Right of Appeal Claimed

Before a large gathering on August 10 of those interested in the War Minerals Relief Act, the Secretary of the Interior heard the arguments of witnesses presented by the American Mining Congress. Objection was made to the manner in which the War Minerals Relief Commission is interpreting various phases of the Relief Act and it was urged that the Secretary of the Interior make it clear that he is not opposed to an amendment which will permit claimants to appeal their cases to the Court of Claims. The point was made that the law specifically provides that the Government may have this right of appeal and, as a consequence, it was contended that it was inequitable for the other parties concerned not to have a similar privilege. This is particularly glaring, it was held, from the fact that the War Department claimants, given relief in the same act, have the right to appeal to the Court of Claims.

Secretary Payne stated at the hearing that he has no objection to the enactment by Congress of a measure giving the claimants the right of appeal to the Court of Claims. He agreed also to choose, with the consent of the claimants, typical cases covering contested points which he would hear personally with the idea of establishing precedents which should be followed in decisions in similar cases.

The principal argument for the American Mining Congress was made by Herbert Wilson Smith. Henry R. Harriman and Edgar Watkins, attorneys for certain claimants, also spoke, as did James F. Callbreath, the secretary of the American Mining Congress. Senator Shafroth, the chairman of the War Minerals Relief Commission, presented the commission's side of the case.

During the course of the hearing, Secretary Payne characterized the work of the commission as having been very diligent. He also called attention to the fact that he gives individual attention to many of these cases.

In his arguments Mr. Watkins, who had assisted in presenting the claim of the Chestatee Pyrites & Chemical Co., declared that the commission has assumed the rôle of prosecutor for the Government rather than serving as an impartial tribunal interested alike in the equities of each party to the case.

Awards recommended by the War Minerals Relief Commission, during the week ended August 7 aggregated $15,225.99. The recommendations were as follows (the name of the claimant, the mineral, the amount recommended and its percentage relationship to the amount claimed are shown): J. F. & J. W. Barneberg, manganese, $11.117.27, 54 per cent; the Kromore Company, chrome, $2,645.50, 24 per cent; L. C. Chrome Co., chrome, $1,035.22, 61 per cent; Schwartz & Geisendorfer, chrome, $428, 4 per cent.

Bureau of Mines Forms Division of Non-Ferrous Metallurgy

A division of non-ferrous metallurgy has been created in the U. S. Bureau of Mines. It will be under the immediate direction of A. E. Wells, who will have the title of chief metallurgical engineer. The headquarters of the division will be maintained in Salt Lake City. Mr. Wells just has taken up work for the bureau again, after having been on detached duty with the Anaconda Smoke Commission.

Mine Rescue Car Destroyed

One of the new mine rescue cars of the U. S. Bureau of Mines was destroyed by fire last week while in the shops of the New York Central R.R. for minor repairs. It will be replaced by the railroad company. Owing to the rapidly increasing demand for this type of equipment, the loss of this car will curtail the bureau's work to an important extent during the nine months which will be required to construct a new car.

Question of Smelter for Alaska To Be Considered

With the idea of stimulating mining activities in Alaska, an intensive study of mining and metallurgical conditions in that territory is being conducted jointly by the U. S. Bureau of Mines and the Geological Survey. At the special request of the Secretary of the Interior, A. H. Brooks has been looking into the oil situation in Alaska and now, in co-operation with O. C. Ralston, of the Bureau of Mines, he will study metallurgical problems. One of the questions to receive immediate attention is that of determining the advisability of establishing a smelter in Alaska.

Federal Power Commission Completes Plans

The Federal Power Commission has perfected its internal organization plans. It will be sub-divided into engineering, accounting, statistical, regulatory, licensing, legal, and operation divisions. The country has been divided into five districts, each to have a branch office as follows: No. 1, Washington; No. 2, St. Paul; No. 3, St. Louis; No. 4, Denver; No. 5, San Francisco.

Few Technical Men in Training for Government Work

Number of Graduates Entering Survey or Bureau of Mines Small—Better Salaries Elsewhere

Apprehension is felt in the U. S. Bureau of Mines and other Government bureaus as to the outcome of their work a few years hence, as few new technical men are being trained in the work of these bureaus. At present the initial salaries of $1,200 to $1,500 paid by the Government are not attractive to the young men who are being graduated from engineering schools. A survey of the class graduated this year at one of the large schools shows that these graduates are readily absorbed by private industry at salaries ranging from $2,000 to $3,000.

The tendency in the Government's technical bureaus is for the men in the more important offices to pay less attention to offers of higher salaries in private employment. Although the turnover is much smaller among such men the positions must occasionally be filled by some one who has a thorough understanding of Government practice. Some years ago, when Government salaries were more attractive to engineers who just had completed their education, a considerable number of such young men were absorbed by the bureaus each year. These men eventually became the successors of the division chiefs and the more important executive technical specialists. Now that there is no new class being trained the fear is expressed that vacancies in the more important positions cannot be filled with the same type of men as in the past.

Quicksilver Dropped This Year

No field work in quicksilver will be undertaken by the U. S. Geological Survey this season. F. L. Ransome, who is in charge of that subject, will remain in Washington to continue work on his report on the geology and ore deposits of Arizona as a whole.

Many Prospecting Permits Under Mineral Leasing Act Sought

Applications for prospecting permits under the Mineral Leasing Act now number 2,000. The General Land Office, on receipt of the application, sends them to the land application board of the Geological Survey for report. These applications are given a preferential status, with the idea of facilitating exploration and development under the new law.

Purchases of silver by the Bureau of the Mint under the Pittman Act totaled 10,603,354 oz. on Aug. 10.

NEWS BY MINING DISTRICTS

MEXICO

Many Companies Preparing To Operate Under New Regime

Mexico City—An immediate improvement is reported as a result of the recent decree removing fines for failure to pay mining taxes throughout Mexico during the last six or seven years. Large numbers of mine owners, particularly in the northern states, are responding and the Department of Commerce and Industry reports that to the end of the first week in August 400 smaller properties in the State of Chihuahua alone had availed themselves of the conditions of the decree and are preparing to begin operations. Seventy-seven applications were made in the State of Jalisco, eleven in Zacatecas, thirteen in the State of Mexico, twenty-two in Hidalgo, nine in Guerrero, and thirty-four in the State of Guanajuato.

The surrender of Villa has also had the effect of starting some work going in the State of Chihuahua, where the depredations of this particular bandit have paralyzed the mining industry for the last four years.

The Xacualpam district is returning to some of its oldtime, pre-revolution activity. Eleven American companies have resumed work during the last two months and are shipping high-grade ores, mostly to the Minerales y Metales smelter at Monterrey. Considerable money is being expended in reopening roads and putting the camp in shape.

In the district of Temescaltepec several of the larger mines have begun work again and others are preparing.

The Sultepec district remains rather quiet. Two of the old properties have resumed but the major portion of the companies find themselves short of funds. Labor conditions in all these camps are bad, that is, labor is scarce and every available man is being secured.

Querétaro

The Amoles Mining & Reduction Co. at Pinal de Amoles, district of Jalpan, is developing two of its principal properties by running large working tunnels in from the ravine and cutting under all the old workings for the purpose of drainage and cheaper extraction of ore. One of the tunnels is to be 420 meters and the other 700 meters long. The company is running one stack steadily at present and the silver and lead bullion is being shipped to the A. S. & R. smelter at Aguascalientes. As soon as the rainy season is over a second furnace will be blown in.

El Doctor mine, belonging to the Braniffs, in the same district is running its smelter and shipping two cars of bullion per week. It has just acquired a new Holt Caterpillar and Troy wagons which haul 15 tons each trip over a distance of 150 kilometers to railroad.

Oaxaca

Tavichi District Coming To Life

The old Tavichi district, most important in the state, after being absolutely abandoned for four years is again showing signs of life. George Huston has struck a parallel vein in the old Escuadra mine and is making weekly shipments to Aguascalientes.

The Vichachi mine, property of the Hamiltons, has been unwatered and is taking out shipping ore.

The Juanita has begun work and is sinking a new shaft near the San Juan shaft. The latter property is still in litigation and is being administered by the courts.

Guerrero

Mines Department Refuses Denouncements Made by J. C. Flournoy

The Puerta del Sol, an old gold property in the Minas district belonging to a Spanish syndicate, has resumed work and is erecting a flotation plant.

The Campo Morado property, one of the most famous in Mexico, which has been in the hands of the bandits for the last six years, has been turned over to the owners by the new government and steps have been taken to reopen the property. Owing to the activities of "highgraders" the mine is said to be in a rather bad condition.

The Department of Mines, City of Mexico, has just rendered a decision refusing denouncements made during the Carranza regime by James Campbell Flournoy, of Washington, D. C., on the Santa Ana, San José de Cuitzuitla, San Basalio, Socavon de Guadalupe, Ampliacion de Mina Grande, Haines, La Cruz del Sur and San Antonio properties of the Balsas Valley Co., of St. Louis, Mo. The decision is important and far reaching as these properties were only a few of a large number of mines in various parts of the country which had been denounced on the pretext of failure to pay taxes, special decrees, etc. The action of the department indicates the intention of the government to respect all interests legitimately acquired and that no advantage will be taken because of failure to live up to the letter of the law during these turbulent times.

Guanajuato

Guanajuato—A. A. Taylor, of Taylor Bros., Chihuahua, Casas Grandes and El Paso, has purchased an interest in the Ruby Silver Tunnel property situated four and a half miles west of the City of Guanajuato on the automobile highway to La Luz. Development has begun and drifting is in progress on a vein many feet in width, 5 ft. on its foot wall averaging around half a kilo in silver with 30 to 80 grams gold, or above $40 U. S. currency, per ton. This property has been a steady producer for years. In fact, during the entire revolutionary period it has been worked on the "buscon" system, shipping its ores to the smelters and local mills. The Ruby Silver Tunnel is rather a historic property, Baron von Humboldt in his writings on Guanajuato stating that it was the most highly mineralized piece of ground in the entire La Luz district.

The Pasadena mine, situated four and a half miles east of Guanajuato and directly adjoining the famous El Monte San Nicolas property, is being reopened after six years of idleness. Surface equipment, machinery and houses destroyed or stolen during the revolutionary period are being reconstructed and replaced under the management of C. Bartholomai, many years with the Moctezuma Copper Co. of Nacozari, Son. Work is being rushed at the Pasadena. The present shaft, which is almost 1,000 ft. deep, is to be enlarged to one of three compartments. It is also to be deepened.

At the Esperanza mine, work of building the new tramway to the San Matias mill on the outskirts of the city has been under way for some time. A mill for treating Esperanza ores is being remodeled into a continuous-process counter-current cyanide plant with a capacity of about 9,000 tons monthly. The Esperanza was taken over from the "Casa Castenada" after long idleness.

Guanajuato camp was one of the few not affected by the almost general strike that recently occurred throughout Mexico. The utmost harmony is said to exist between the workmen and mine owners.

Nayarit

Esperanza Exploration Co. Acquiring Holdings Near Cuale

The Esperanza Exploration Co., of El Oro, has acquired large holdings in and near Cuale, in the State of Nayarit (formally Tepic). The mines are situated about 25 miles from the port of Las Peñas, to which point a truck road is being built. Large quantities of machinery have been ordered and will be transported over this road. The company has acquired all the properties in this district, some of them having been large producers of gold and silver in the days of Spanish mining; others were acquired through denouncement. Altogether this is looked upon as quite significant of the fact that confidence is returning in Mexican mining.

The Cucharas mine was recently examined by engineers with a view to purchasing. This is a silver-copper property located near Acaponeta in the State of Nayarit, and belongs to the Lacy interests of Los Angeles, Cal. There is a matting furnace on the property which has been operated to some extent in years past.

Messrs. Newman and York are traveling through the West Coast looking for mining properties for a New York syndicate.

The property of J. B. Shepard, of Denver, Col., situated in the Santiago de los Caballeros district, is under option to Pasadena, Cal., capitalists, who are to start cleaning out the caved workings for examination, with a view to purchase. A truck road is projected to connect this district with the Southern Pacific de Mexico, at the station of Guamuchil. This proposed road will open up a large silver and lead producing district, and will undoubtedly be the direct cause of the development of many promising prospects, as well as the reopening of many large mines which were worked successfully before the revolution.

Chihuahua

Santa Eulalia—Read Miller and associates have ceased operating a sub-lease of the Santander.

Durango

It is reported that the Hayden Stone interests have also taken an option on the famous mines at Cianori, Durango. These mines belong to the house of Wohler Bartning, of Mazatlan, and have records of very large silver production. The export ore from these properties carries about 1,000 oz. silver to the ton with a trace of gold. The low-grade ore was formally treated with cyanide with good results. There is a twenty-stamp mill with cyanide equipment on the property.

Copalquin District—The Rocha Mining Co., owners of the San Igancio, Soledad and Chiuhuahvilla mines, are doing extensive development work. There is a 10-stamp mill with cyanide equipment on each of these properties, and their normal production is about 60,000 oz. silver per month and 3,000 oz. gold. Sr. Don Everisto Paredes is general manager and Charles Hitchler is metallurgist in charge. These mines have been large producers for many years. The San Ignacio has produced to date about $6,000,000 gross, the Soledad about $500,000, and the Chiuhuahvilla about $200,000. In times gone by, the miner's wage consisted of one tablespoonful of ore each day, it is said, for which they were perfectly contented to work twelve hours per day.

Mocorito—The Palmarito and Potrero companies, in the Mocorito district, are both working full capacity in spite of the recent decrease in foreign silver. The mining agency in Mocorito reports an increase in the number of denouncements being made by foreigners.

Capt. R. D. Adams and Col. J. E. Leckie, of San Francisco, expect to be in Mexico this fall with an exploration and development company. They have options on a number of promising prospects, as well as partially developed mines, and will occupy themselves principally with the development of mining properties in Sinaloa and Western Durango.

CANADA

British Columbia

New Ore Reported in Premier—Ward Difficulties Finally Settled

Stewart—R. K. Neil, part owner of the Premier mine, recently stated that a 100-ton cyanide plant is being installed and will be ready for use early next year. It is reported that a new orebody has been cut in Tunnel 2. About 150 men are employed.

There are about 100 claims staked in the Marmot River section of Portland Canal and on many development work is in progress. George Clothier, government mining engineer, recently made a tour of inspection through the district with a view to ascertaining the extent of the necessary road and trail improvements. The B. C. Exploration Company is heavily interested in this section. P. D. I. Honeyman has a small crew of men at work for this company on the Salmon River Lode Mining Co.'s property, near the Big Missouri group.

One of the two diamond drills on the Big Missouri has been closed down, that at work on the E Pluribus claim being continued. This is the claim on which high-grade ore is being opened.

The Northern Light and Spider groups on Salmon River and the Fitzgerald Group on the Bear River are being thoroughly explored by the Algunican Development Co., whose operations are more extensive than those of any other concern interested in the district, with the exception of the Premier Mining Co.

Alice Arm—The Dolly Varden is shipping 150 tons of ore a day and preparations are being made for the extension of the railway to the Wolf Group. The Toric, Tiger, Musk, Silver Horde, Climax and other prospects are being opened up. Surface stripping is being done on La Rose Group.

Quesnel—Once again R. T. Ward, of the Bullion Placer Leases, Cariboo, has been heard of in connection with litigation. Having won his long drawn-out suit with John Hopp it was thought that the operation of the long-disused property would follow without delay. Some of Mr. Ward's associates, however, challenged his right to retain control of the management of the project. A settlement has been reached

Nelson—The Provincial Prospectors' Protective Association continues to gather strength. Local organizations representing the Grand Forks and Smithers districts have applied to the central body for copies of the constitution and there is every reason to believe that they will become affiliated. It has been decided that the Provincial Attorney General shall be asked what action will be taken to protect prospectors' cabins and caches from the depredations of thieves. It appears that members of the association have been put to expense and annoyance in many instances by finding their headquarters in the hills rifled on returning from their periodical trips.

Ontario

Hollinger's Costs Increased—New Company To Take Over Bewing-Moreing Interests

Porcupine—It is stated that a new company is being organized to take over the interests of the Bewing-Moreing company, an English concern, which in the early days of the Porcupine camp purchased a number of claims in the area. They were unable to develop their holdings owing to the war. The financing of the new company is said to have been arranged looking to active operations in the immediate future.

Mining costs at the Hollinger Consolidated have increased to a greater extent than was anticipated owing to the increase in wages. It was expected that the higher pay would add about 25c per ton to the cost of treatment, as the management calculated that larger forces would be attracted and that increased efficiency would result, neither of which anticipations has been realized, the increase in operating costs being about 50c per ton. While in some respects the result of the raise in wages has been disappointing, it is realized that it was a wise measure, as otherwise the company might have been unable to retain sufficient labor to continue in operation.

The McIntyre has purchased the Blue Diamond Coal Mines, of Brule, Alta, with an area of about 3,300 acres, and has secured an option on the Canadian Coalfields, Ltd., in the same vicinity, with a larger area. The Blue Diamond is producing over 500 tons of steam and coking coal daily. It is capitalized at $1,500,000 and the Canadian Coalfields at $10,000,000. A 50 per cent interest in the transaction has been offered to the Temiskaming Mining Co.

Cobalt—At the Bailey a shoot of high-grade ore 4 to 5 in. wide has been cut at the 5th level.

The case against the Mining Corporation of Canada, charged with conducting blasting operations without taking proper precautions, was sent by the Police Magistrate to a higher court for trial.

Kirkland Lake—At the annual meeting of the Kirkland Lake on August 10. President F. L. Culver stated that a spectacular new find had been made in No. 8 drift on the 400-ft. level in virgin territory. Questioned as to reports of a possible merger of the company with the Orr and Teck-Hughes mines, Mr. Culver stated that the suggestion of an amalgamation had been made but that the matter had gone no further.

The new mine plant of the Hunton-Kirkland has been installed and is ready for operation. It is planned to put the shaft down to the 300-ft. level where lateral work will be undertaken.

South Lorrain—The Keeley is installing the old Trethewey mill equipment, which is expected to handle about 80 tons of low-grade ore daily. Underground work is being carried on at the 300-ft. level.

Quebec

Harricanaw River.—A report of an important discovery of silver in this district some 30 miles south from Amos on the Transcontinental Ry., caused a rush of prospectors. The report turned out to be erroneous, the alleged discovery proving to be a crack in the mica schist which had been salted by the insertion of a small amount of leaf silver.

CALIFORNIA

Shawmut Mine Suspends Because of High Costs—Morning Star Mill Erected

Portola—The mill at the Gruss mine is now installed and crushing is expected to begin about August 20. Recent developments have exposed much high-grade ore, running $104 to $120 per ton.

Shawmut—Operations have been suspended at the Shawmut mine, the largest producer of Tuolumne County. The mine is owned by the Tonopah Belmont Development Co., of Tonopah, Nev. Although the ore is of good grade with a large tonnage blocked out, the steadily mounting labor and material costs have made it advisable to shut down.

Jackson—A large mill has been erected at the Morning Star group, seven miles southeast of Jackson in Amador County. The property contains large bodies of medium-grade ore near the surface and is to be worked on a large scale. The group was formerly named the Boston.

Washington—A new compressor and auxiliary equipment have been added to the plant at the Red Ledge mine near Washington, Nevada County. Several new buildings are also being erected. Efforts are being made to place the Red Ledge on a sound productive basis.

Columbia Hill District—Three miles of new ditch between Bloody Run and Grizzley Canyon, in the Columbia Hill section, are being built by the Delhi Mines Co. A 900-ft. tunnel has been completed and will be used to carry water through the mountain; it will be ready for use in thirty days. The new water line will eliminate the use of the old two-mile ditch and 2,000-ft. flume line around Whistle Point, which has been practically useless all winter.

Sutter Creek—Drifting on the 3,500-ft. level of the Old Eureka is progressing well, and it is expected that the laterals will enter territory where extensions of rich veins are thought to be.

Darwin—The Darwin Silver Co., owning the Lucky Jim, Defiance and Lane properties, is working about fifty men on the Lucky Jim putting old workings into condition for active development. Heretofore the mine has been worked only for shipping ore but now there is a substantial quantity of low-grade ore. It is intended to install a mill which will treat all ores under $50. The process will probably be water concentration followed by cyaniding. A. G. Kirby is manager.

Swicegood, Putnam & Shea are installing jigs on the Wonder property for treating low-grade ores in mine and on dump. Water is to be pumped from Darwin Wash.

Recent attempts by Porter & Seaman to sulphide and float the chloride and carbonate ores from the Lane and Jackass mines at the Lane mill have proven unsuccessful. The mill is being dismantled and efforts are now being concentrated on the Jackass mine, where shipping ore of good grade has been opened up.

At 100 ft. depth on the property of the Argus Sterling Co., 12 miles south of Darwin, a drift has been advanced 75 ft. on a shoot of lead carbonate ore which has an average width of 3 ft. The smelter valuation of the first carload shipped was $110.50 per ton, the lead content being 47 per cent. A second carload is now in transit. A. C. Taylor, of Los Angeles, is manager.

Trona—Certain improvements in the process have been made at the plant of the American Trona Corp. in the Searles Lake district. Working forces are being increased as rapidly as possible.

At the Copper Queen, operated by the Slate Range Minerals Co., a winze which is being sunk from the lowest level in the mine is now down 90 ft. and galena carrying high silver values is coming in. The combination table and flotation mill is being operated to full capacity on lead-carbonate ores, which receive a sulphidizing bath before flotation. Shipments of both crude ore and concentrates are going forward to the smelter regularly. L. D. Hirschfeldt, of Bakersfield, Cal., is manager.

NEVADA

United Comstock Installing Equipment for Driving New Tunnel—Rochester Mines To Continue Shut Down

Tule Canyon — The Silver Hills Nevada Mines Co. is now operating the three-stamp mill recently brought from California by W. J. Loring, manager, and it is thought that it will handle about 18 tons daily. The stamps weigh 1,050 lb. each. It is expected to run the mill in conjunction with the five light stamps that were on the property when it was taken over by the present company. The three-stamp mill is the one used by Mr. Loring to test the ore in the Calaveras and Morgan mines and he considered it a mascot.

Virginia City—Work of installing the compressor and other surface equipment for driving the big electric haulage tunnel of the United Comstock Mines Co. was started July 31. The tunnel will be 8 x 8 ft. in the clear, the portal being located at American Flat at the site of the 1,000-ton mill that is to be built later. The V. & T. Railroad Co. is to build a spur track from its station at Scales to the millsite.

Simon—In answer to a direct question, P. A. Simon has denied to a representative of the *Engineering and Mining Journal* the reports that the control of the Simon Silver-Lead mine has passed to the International Nickel Co. and that Charles D. Kaeding is to have charge of the property. Mr. Simon states that the resignation of Albert Burch was a matter of economy and that while Mr. Kaeding is being consulted by him at times he is not on the payroll of the company. Tom McNamara, who has worked under Kaeding for years, is foreman at the Simon mine, succeeding Ed Orr, who held the position under Mr. Burch.

Searchlight—The last of several carload shipments by Burdick & Perkins, lessees at the Duplex mine at Searchlight, is said to have yielded the shippers $9,000.

Snake Range—A 1,200-ft. tunnel has been driven on the lead-silver property of Dearden & Johnson near the head of Snake Creek, about 40 miles southeast of Ely. The vein is 18 in. wide and is said to carry high values.

Rochester—It is expected that the mines at Rochester and Packard which were forced to close down as a result of lack of power, due to a shortage of water for generating electricity, will have to remain idle for some weeks. After the irrigating season is over there will be water enough for power.

MONTANA

Jefferson Mines Plan Leaching Plant—Tuolumne To Use Own Trucks

Butte—Crosscutting by North Butte for the Edith May vein on the 3,600-ft. level continues, with the belief that the ledge will be reached within a week or two.

The Tuolumne Copper Co. is planning to install its own system of trucks for transporting ore from its Main Range properties to the loading platforms alongside of the Northern Pacific tracks, about a mile distant.

Four-hundred steel lockers have been purchased by Davis Daly for the new dry house to be installed at the Colorado mine. A new blacksmith shop and a framing plant of modern construction have been completed and a tool sharpening works will also be installed. Storage rooms for mine supplies have been built and a garage for trucks. The ore showing on the 2,700 level is reported to be good.

Potomac District—From 4 to 5 ft. of ore carrying up to 4 per cent copper has been opened by Potomac Copper in the No. 4 tunnel being driven for the Copper Cliff property. The objective will not be reached before 60 days, according to the company's Butte office.

Whitehall District—A two-compartment shaft has been sunk by the Jefferson Mines Co. to a depth of 218 ft. with the 300 level as the objective, at which point the ore deposit will be crosscut. The installation of a leaching plant to treat the upper oxidized portions of the deposit, which carry varying amounts of copper, ranging from 2 to 6 per cent, is planned.

IDAHO

Coeur d'Alene District

Nabob Shipping Lead and Zinc Concentrates — Interstate-Callahan Takes Up Option on Kill Buck

Pine Creek—The Nabob Consolidated Mining Co. is now hauling both lead and zinc concentrates to the railroad. The 150-ton mill is running only one shift, but will add two more as soon as a raise is completed to the Denver tunnel level, which will make much ore available.

Wallace—The Consolidated Interstate-Callahan has exercised the option held on the control of the Kill Buck Mining Co., which was owned by Senator W. A. Clark and associates of Butte. The Kill Buck property joins the Chicago-Boston, control of which was recently purchased by the Interstate-Callahan, and the two properties will be jointly developed and eventually consolidated. The Chicago-Boston company is sinking from the 200 to 400 level, at which point the vein will be explored, while sinking will continue. A large body of lead-silver ore has been opened on the 200 level.

The Friend Mining Co., operating on Beaver Creek, is arranging to construct a mill that will handle about 10 tons of ore per day, the company now using a hand jig. It is intended to handle both mine and mill with the same working force. As soon as there is a sufficient accumulation of ore the men will come out of the mine and run the mill, and when the ore is cleaned up they will return to the mine and repeat the operation. In this way the management expects to pay for development. A shoot of lead and zinc ore has been followed about 400 ft. in the main tunnel. It carries from 6 to 18 inches of good ore.

The Jack Waite Mining Co. has two motor trucks hauling ore to the railroad at Prichard, 13 miles from the mine, each truck hauling 3 tons and making two round trips per day. Much of the ore is hand-sorted and the lower grade is hand-jigged. Two jigs are working and two more will soon be added. The mine is reported to be in good condition for production and would easily supply a 100-ton mill for several years. The ore being shipped is running above 50 per cent lead but low in silver.

COLORADO

To Increase Capacity of Boulder County Mill—First Unit Completed at Telegraph Mine at Ward

Victor—The Bonanza property is being developed and operated by the Granite Gold Mining Co. under lease from the United Gold Mines Co. A winze is being sunk in ore. Recent development work has produced a carload assaying $60 a ton.

Breckenridge—The Tymos Mines Co. is equipping and developing its property at Shock Hill. A transmission line has been completed to connect with the Colorado Power Co.'s system. Electrically driven pumps and other equipment will be installed. It is planned to drive a crosscut 1,000 ft. from the 300-ft. level toward the Brooks-Snyder and Ground Hog properties. George B. Tyler is president of the Tymos company.

Two shifts are employed in sinking the shaft on the Missouri property, which is being developed under lease. The shaft has reached a depth of 115 ft. and will be sunk an additional 50 ft.

Ward—The American Gold & Platinum Co. has completed the first 25-ton unit of its plant for treating gold-platinum ores from the Telegraph mine. Preliminary tests are reported to have been successful, and indicate that the ore averages $14 gold and $200 platinum per ton. John Ogden is manager.

Cardinal—The new flotation equipment recently installed in the Boulder County mill is in successful operation. The capacity of the plant will be increased from 40 to 100 tons per day. It is estimated that the ore supply will keep the mill running for about two years. The Boulder County Tunnel has been advanced 2,700 ft. on the vein, of which about 1,200 ft. is in ore.

Silverton—The Bandora mine is reported to have been sold by William Sullivan to Denver capitalists for $100,000. It will be operated under the management of Henry Wycoff. Arrangements are being made to purchase the Eucon mill and move it to the Bandora mine. The mill is owned by J. F. Sweet, of Boston.

ARIZONA

Hardshell to Reopen—Diamond Drilling at Three R Encouraging

Patagonia — The Hardshell mine, which has been shut down since May, is ready to be reopened. Owing to the shortage of fuel oil caused by the railroad strike the company was forced to suspend. Advantage was taken of the shutdown to enlarge the surface plant. New hoisting equipment has been added and everything is ready now except for completing additional fuel oil storage tanks. There is ample boiler and pump capacity and no difficulty is expected in unwatering the mine.

At the Flux property the mill is being overhauled and will shortly be put into operation.

Diamond drilling with one machine continues at the Three R mine. Results are not being announced. It is said they are encouraging. Ten holes have been drilled to cut a parallel vein to the main workings. The Colossus tunnel is being advanced.

At the Blue Nose, jigs are being built to treat some fairly high-grade ore from the dumps.

Duquesne—The Bonanza mine is being unwatered from the 160 level to the 300. Lessees are working on different parts of the property. The railroad point nearest to this property is Zorilla, a station on the Southern Pacific de Mexico, in Sonora. The ore is hauled to this point, crossed in bond and brought out at Naco, Ariz., where the S. P. de M. connects with the El Paso & Southwestern R.R.

Dragoon—Mills & Co., lessees on the Texas-Arizona, who struck high-grade lead-silver ore several months ago, are installing a compressor, direct-connected to a fuel-oil engine. A drift has been started on the 350 level, which should cut the orebody within 150 ft. Stoping will be started on this level when the vein is reached.

Johnson—Installation of a hoist and compressor at the Mammoth has been completed and two shifts are working breaking ground and hoisting.

Dos Cabezas—Sill & Sill, of Los Angeles, have been retained as consulting engineers for the Dives mines. The ore being mined and treated at the company's mill is running about $20 per ton, a large part of which is being recovered on the plates.

Good progress is being made in the tunnel of the Gold Prince Mining Co., where it is expected the main vein will be reached within 30 ft. Installation of tables and electric wiring will complete the new mill. A test run is to be made about Aug. 20.

Bert Macey, of Tombstone, has arrived with miners to start work on the Le Roy Con. Mining Co.'s property.

Globe—The Northwest Inspiration is crosscutting at 300-ft. depth in a 700-ft. tunnel with the expectation of picking up the Warrior vein within a couple of hundred feet. The main shaft is to be sunk from 340 to 540 ft. Jack Huston is in charge.

The cutting of Old Dominion's Maggie vein on the 19th level is considered important as affecting the future of the Old Dominion. The vein is practically new and undeveloped. The ore cut thus far runs over 5 per cent. Operations are to be continued down to the 20th level to secure drainage.

Willcox—The Grand Reef property, in the Aravaipa district, 60 miles north of Willcox, is reported to have been sold by Richard V. Dey, of New York, to the Aravaipa Leasing Co., a corporation controlled within the American Lead & Zinc Co. An immense dyke, cut by a canyon to a depth of several hundred feet, shows a number of paystreaks of silver ore, the broadest being 20 ft. in width. A mill has been operated at the mine by lessees, though the long wagon haul to the nearest railroad point is understood to have consumed all profits. It is though that a railroad route can be found to Willcox. The lease was recently abandoned and it was announced that the mill would be junked.

Jerome—The Shea tunnel is within 100 ft. of the main shaft. The heading is now in 1,140 ft., with a vertical depth of 460 ft., and is in ore. Shipments are being made to the U. V. Extension smelter, the ore coming from the 350 level.

Creditors of the Verde Apex have brought a $24,000 suit against the company for unpaid bills.

NEW MEXICO

Burro Mountain Mill in Operation

Tyrone—The first unit of the new mill of the Burro Mountain Branch of the Phelps-Dodge Corporation was put into operation Aug. 2. This marks the resumption of regular operations at this property. A year ago the mill was shut down and since that time has been remodeled, various improvements being installed.

Silver City—A meeting of the stockholders of the Silver Spot Mines Co. was held Aug. 3. R. I. Kirchman is in charge of developments.

SOUTH DAKOTA

Trojan Shaft Below 100 ft.—Operations Curtailed by Labor Shortage and High Costs

Deadwood—The Iron Hill tunnel has been advanced 1,285 ft. and it is expected that the old Iron Hill workings will be tapped very soon. The tunnel will cut the mine at a depth of 300 ft. and will drain the property and allow further development of this one-time famous silver mine.

The Cutting property is being developed by means of a drift on the 200-ft. level. The shaft has been sunk to 500 ft. depth and a short lateral driven at that depth. A drift has also been driven on the 350-ft. level but the work is being confined to the 200 level until suitable pumps can be installed to handle the large amount of water.

Trojan—Sinking of the Trojan shaft is now below the 100-ft. point and continuing. From the surface the shaft has been concreted to a depth of 70 ft. The shaft will be continued to a depth of from 600 to 700 ft. The plant and mines of the company are in continuous operation although at reduced capacity owing to labor shortage and high costs.

MICHIGAN

Gogebic Range

Installing New Hoisting Equipment at Winona Shaft of Ironton Mine

Ironwood—The new electric hoists and flywheel set for the Winona shaft of the Ironton mine at Bessemer, Mich., are now erected, and the switching apparatus is being installed. Power will be purchased from the street railway company and used to drive the motor-generator-flywheel set, which will supply the direct current for the hoists. The cage hoist has two drums clutched to the main shaft, which is driven through gears. The ore hoist also has two clutched drums, but its motor is connected directly to the main shaft. It is rated at 1,650 hp., using 2,550 amp. at 525 v. All four drums are fitted with post brakes. The two skips and two cages will be run in balance as much as possible. Practically all of the hoisting for this mine will be done at this shaft. Electric-driven air compressors are to be installed in the new engine house also.

Two of the three 400-gal. pumps ordered for the Davis mine have been received. They are four-pole, pot-form, center-packed plunger pumps. The plungers are 4¾-in. in diameter with a 24-in. stroke, and the pumps will be driven at 52 r.p.m. through herringbone gears by 300-hp. induction motors. They will work against a head of about 2,600 ft., to withstand which pressure the water ends are made of forged steel.

Continued delay in delivery of material is holding up the erection of the transmission line from the Davis and Puritan mines to the power station at the Pabst mine.

The district offices of the McKinney Steel Co. have been moved from the Colby mine into a new building at the Ironton mine.

The Republic Iron & Steel Co. is installing a 600-gal. pump on the 12th level of the Plumer mine at Pence, Wis.

ALABAMA

Preparing for Deeper Mining in Birmingham District—Electrification of Mines Being Pushed

Birmingham—The Woodward Iron Co. will not make use of its new shaft for some time, but is simply preparing for the time when its present workings are exhausted. The shaft was sunk during the last year and a half. It has been concreted and the hoisting machinery installed so that it is ready whenever needed. According to a company official the ore in the shaft at depth is better than that nearer the surface. The ores near the lower end of Red Mountain, where the Woodward properties are located, are self-fluxing. The shaft is of sufficient capacity to supply the company's five furnaces.

Together with the Shannon mines of the Gulf States Steel Co., the Woodward mine is part of the plans for deep mining in this district. Borings are now being made on virgin ground. The two projects mentioned promise large outputs, which will cover demands for years to come.

Electrification of the iron mines of the Birmingham district continues, with the Sloss-Sheffield Steel & Iron Co. building transmission lines from its power plant at North Birmingham, near the byproduct coke ovens, while the Tennessee Coal, Iron & R.R. Co. and others are using power from the Alabama Power Co., which has a hydro-electric plant on the Coosa River. The latter company is adding a fifth unit to the plant, which will increase the total capacity to 105,000 hp. The flow of water in the Coosa is not sufficient the year around to operate all five units but it is believed that water can be stored while the river is up. The Alabama Power Co. is furnishing power not only to ore mines but to coal mines, cotton mills and various other manufacturing plants.

The Tennessee C., I. & R.R. Co. is giving much attention to all developments on Red Mountain, the little communities established being looked after, and welfare work is said to be securing excellent results.

JOPLIN-MIAMI DISTRICT

Oklahoma-Missouri-Kansas

Niangua Mining Co. Operated by Receiver—Hawkins Company Opening Rich Lead Property Four Miles from Baxter

Commerce, Okla.—The Tydings & Seals Mining Co. has recently taken a lease on the tract of the Commerce Mining & Royalty Co. adjoining Commerce, and has started two concentrators on it and will start a third within a few weeks. The mills placed in operation are the Turkey Fat and the Cactus, the latter having been renamed the "Dinty Moore." The dirt for the latter mill is being taken from the old Midas shaft. The Never Sweat mill has been renamed the "Maggie" by the company and will be placed in operation as soon as necessary overhauling and new installations are completed. Included in the company are John Newton, general superintendent for the Commerce Mining & Royalty Co., with many years' experience in this district, and Homer Seals and T. Rader, formerly operators at Joplin, and Walter Tydings, of Commerce.

Baxter Springs, Kan.—A new lead mine of exceptional richness has been opened up by the Hawkins Mining Co. on the Dawes land, four miles southeast of Baxter. The lead is found at 100 ft. and the run extends down to 150 ft., many large chunks weighing up to a ton or more having been recovered. Hand jigs have been installed and the company plans to erect a mill. Harry Hawkins, of Miami, is general manager for the company.

Picher, Okla.—The Niangua Mining Co. recently went into bankruptcy and is being operated under the management of W. S. O'Bannon, as receiver. The No. 1 mill of the company burned down some months ago, and the No. 2 plant has not been sufficient to pay on the lease at the rate contracted. The receivership, therefore, is more a mutual agreement proposition on the part of the creditors, calculated to give the company a better chance. Since it was created, the company has driven a 600-ft. drift connecting the No. 2 mill with the No. 1 mine. In addition, better dirt has been found in the No. 2 mine, so a good production is being recorded at present.

The Keltner Mining Co. is installing a 150-hp. gas engine and a 580-ft. compressor for operating the Gold shaft recently completed 200 yd. north of mill.

The new 300-ton mill of the Aztec Mining Co. has been placed in operation. It includes a sludge room with a 50-ft. Dorr thickener. Electric power is used throughout except for one compressor. H. G. Tarsh, Joplin, Mo., is president.

The Red Bird Mining Co. has completed a small concentrator on the 40-acre lease adjoining Aztec, the lease on the southeast. Frank Childress, of Galena, and R. L. Kidner, of Joplin, are the principal owners.

THE MARKET REPORT

Daily Prices of Metals in New York

Aug.	Copper	Tin		Lead		Zinc
	Electrolytic	99 Per Cent	Straits	N. Y.	St. L.	St. L.
12	18.35@18.50	44.50	47.75@48.00	9.00	8.75@9.15	7.80@7.85
13	18.35@18.50	44.50	48.00@48.25	8.90@9.00	8.75@9.15	7.85@7.90
14	18.35@18.50	44.50	48.00@48.25	9.00	8.75@9.15	7.90@7.95
16	18.35@18.45	44.50	47.75@48.00	9.00	8.75@9.15	7.95@8.00
17	18.35	44.50	48.00@48.25	9.00	8.75@9.15	7.90@8.00
18	18.35	44.50	47.75@48.25	9.00	8.75@9.15	7.90@7.95

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point. All prices are in cents per pound.

Copper is commonly sold on terms "delivered" which means that the seller pays the freight from refinery to buyer's destination. The delivery cost varies, and it would be confusing to figure net prices on individual transactions. Consequently, an average deduction is made from the "delivered" price. At present the average cost of delivery from New York refineries is 0.15c. per lb., and that deduction is made to arrive at the New York price. When copper is sold f.o.b. or f.a.s. New York, of course no deduction is made.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. We quote New York price at 35c. per 100 lb. above St. Louis. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Aug.	Copper			Tin		Lead		Zinc	
	Standard		Electro-lytic						
	Spot	3 M		Spot	3 M	Spot	3 M	Spot	3 M
12	93 1/4	95 1/4	112	276 1/2	283 1/2	36	36 1/4	41 3/4	43 1/4
13	94 1/2	96 1/4	112	276 3/4	283 1/2	35 1/4	35 3/4	41 1/2	43
14	....	....	...	..	....			...	..
16	94	95 3/4	111	274 1/2	282	35 3/8	36	41	42 1/2
17	93 1/4	95	111	274 3/4	281 3/4	35 1/4	36 3/8	41 3/8	43 1/2
18	93 7/8	95 1/2	111	274 1/2	281 1/2	35 1/2	36	41 1/4	42 3/4

The above table gives the closing quotations on the London Metal Exchange. All prices are in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Aug.	Sterling Exchange	Silver			Aug.	Sterling Exchange	Silver		
		New York, Domestic Origin	New York, Foreign Origin	London			New York, Domestic Origin	New York, Foreign Origin	London
12	365	99 1/2	95 3/8	58 3/4	16	363	99 1/2	95 7/8	59 3/8
13	362	99 1/2	95 3/8	59 1/4	17	363	99 1/2	97 1/4	59 3/4
14	363	99 1/2	95 3/8	59 1/8	18	362 1/2	99 1/2	98	60 1/2

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States. This quotation is retroactive to May 13.

Metal Markets

New York, Aug. 18, 1920

Possibly in no week this year have the metal markets exhibited less activity than in that just past. Consumers are, in general, showing no interest, nor are conditions expected to improve much until after Labor Day.

Copper

The fair buying which we reported last week proved to be only a flash in the pan. Consumers are not in the market, and there also seems to be little inclination to sell at current prices. Inquiries for reasonaby large lots would soon push the market up at least ½c. above current quotations. Some small lots of metal are reported as being offered by second-hands from the Middle West. Near-by metal in small lots can be obtained at our prices. Larger lots of copper for forward delivery we quote at 18.50@18.85c.

Lead

The only event of importance during the last week was the action of the A. S. & R. in advancing its contract price to 9c., New York, on Thursday. At this price, lead from Europe can be brought into this country and sold at a very attractive profit, and international traders have not been slow to take advantage of the situation. Several thousand tons have arrived or been contracted for, largely American, Australian and Mexican brands, although Spanish and German lead is also included. The demand, however, is not as large as might be supposed, consumers rightly assuming that the price is not likely to go higher, so that, outside of contract business, only present demands are being provided for. Large producers are turning down orders and making no promises regarding shipment. We quote lead for near-by delivery, both New York and St. Louis, at 9.00@9.25c.

Zinc

The feeling in the zinc market is decidedly more cheerful. Demand is much more active at the higher prices now prevailing, though business is not yet what might be termed strong. Those who are selling now are, in general, resellers, who bought at 8¼c. and less and are willing to take a reasonable profit. Producers are not anxious to get rid of their metal, for they believe that prices will go still higher. Production continues to be curtailed, and one Western smelter bought outside zinc to fill his contracts. It would not be at all surprising to see zinc gradually approach 8¾c., at which point importations from Europe would begin to pay at current London prices.

Forward deliveries command 5 to 10 points premium over the prices which we quote, which represent the near-by market. There is little or no demand.

Tin

No signs of life are yet apparent in the tin market. Demand is equally lacking for all grades and deliveries, and prices are largely nominal.

Straits tin for future delivery: Aug. 12th, 48.00@48.25c.; 13th, 48.25@48.50c.; 14th, 48.25@48.50; 16th, 48.00@48.25c.; 17th, 48.00@48.50c.; 18th, 48.00@48.50c.

Arrivals of tin in long tons: Aug. 10th, Australia, 100; 12th, China, 50; Straits, 25; 17th, Liverpool, 60; London, 85.

Silver

The silver market has been steady the last week in London, on buying for China and Indian bazaars, and closes with advancing tendency on higher rates from China. The New York market has been above London parity on a good demand from China banks which has developed this week, and closes strong. Offerings of foreign silver continue limited. If Chinese and Indian

demand continue urgent, it is possible the silver export price will pass the limit of $1 per fine oz., fixed for domestic production under the Pittman Act, in which event the export and industrial demand must take care of all domestic production to maintain price level over the Government figure.

Last week, some copies of the *Engineering and Mining Journal* appeared with the prices of New York domestic and foreign silver interchanged. The 99¼c. price of course applied to silver of domestic origin.

Mexican Dollars—Aug. 12th, 72⅝; 13th, 72⅝; 14th, 72⅝; 16th, 73; 17th, 74¼; 18th, 75.

Gold

Gold in London on Aug. 12th, 111s. 11d.; 13th, 112s. 11d.; 16th, 113s. 3d.; 17th, 114s.; 18th, 114s.

Foreign Exchange

Price changes during the week were narrow. Sterling is not likely to advance materially for some weeks, owing to the large volume of grain and cotton bills which will be thrown on the market. Yesterday, francs were 7.28c.; lire, 4.86c. and marks 2.10c. New York funds in Montreal, 13⅞ per cent premium.

Other Metals

Aluminum—The Aluminum Co. of America has announced a price increase of about 2c. per lb. effective Aug. 10: Ingot, 99 per cent and purer, 35.1c.; 98@99 per cent, 34.9c. Virgin metal still obtainable in open market at about 32.5c. for 98@99 grade.

Antimony—Market continues weak. Spot, 7c. per lb.; Cookson's "C" grade, 14@15c. Chinese and Japanese brands, 7c. W. C. C. brand, 9@9¼c. Chinese needle antimony, lump, firm at 9@10c. per lb. Standard powdered needle antimony (200 mesh), 10@12c. per lb.

Bismuth—$2.70 per lb., 500-lb. lots, and $2.72 per lb., 100-lb. lots. Market quiet.

Cadmium—Nominal, $1.40@$1.50 per lb. Market dull.

Cobalt—Metal, $3 per lb.; black oxide, $2 per lb.

Iridium—Nominal, $350 per oz. Heavy demand, but small supplies.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb., for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]Molybdenum Metal in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.; Monel metal, shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$95@$110 per oz.

Platinum — Firm at $110@$115 per oz. $105 per oz. in 100 oz. lots.

Quicksilver — Market steady; $85@$88 per 75-lb. flask. San Francisco wires $83. Steady.

Ruthenium—$200@$220 per troy oz.

[1]Selenium, black, powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb.

[1]Thallium Metal—Ingot, 99 per cent pure, $20 per lb.

Metallic Ores

Bauxite—About 52 per cent alumina content, less than 2 per cent iron oxide, up to 20 per cent silica and artificially dried to contain not more than 4 per cent free moisture, $10 per gross ton at mine; 54 per cent alumina and about 15 per cent silica, $11; averaging 57 per cent alumina, 8 to 12 per cent silica, less than 3 per cent iron oxide, $13 on basis of 8 per cent free moisture. Ores of very low silica content suitable for the manufacture of aluminum oxide and hydrate of alumina command a fancy price.

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a minimum of 6 per cent silica, 80@85c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 60@65c. per unit, f.o.b. mines.

Iron Ores—Lake Superior ores, per ton, delivered at Lower Lake ports: Old Range bessemer, $7.45; Old Range non-bessemer, $6.70; Mesabi bessemer, $7.20; Mesabi non-bessemer, $6.55. Congestion at Lake Erie ports due to car shortage has resulted in decreased tonnage. Operators claim it will be necessary to advance ore prices, owing to increased cost of production.

Manganese Ore — 70@80c. per unit, 50 per cent Mn content, c.i.f. Atlantic seaport; chemical ore (MnO_2) $75@$85 per gross ton.

Molybdenum ore—85 per cent MoS_2, 75@85c. per lb. of contained sulphide, New York.

[1]Tantalum Ore, guaranteed minimum 60 per cent tantalic acid, 65@70c. per lb. in ton lots.

Titanium Ores—Ilmenite[1], 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $7 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $6@$7, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

Zircon—Washed, iron free, 6c. per lb. Zirkite—$90@$100 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

[1] Furnished by Foote Mineral Co., Philadelphia, Pa.

Zinc and Lead Ore Markets

Joplin, Mo., Aug. 11—Zinc blende, per ton, high $51.75; basis 60 per cent zinc, premium, $48.50; Prime Western $47.50@$45; fines and slimes, $45@$42.50; calamine, basis 40 per cent zinc, $36. Average settling prices: Blende, $45.73; calamine, $38.86; all zinc ores, $44.54.

Lead, high, $104.30; basis 80 per cent lead, $100; average settling price, all grades of lead, $99.20 per ton.

Shipments for the week: Blende, 7,916; calamine, 211; lead, 1,344 tons. Value all ores the week, $503,610.

Eighty tons were reported purchased on $45 basis, 2,600 tons on $46 basis, largely purchased by a smelting company from a subsidiary mining company, and the balance of 12,000 tons purchased, except the premium and fines and slimes grades, was on $47.50 basis.

Platteville, Wis., Aug. 11—Blende, basis 60 per cent zinc, $50 per ton for high-grade. Lead ore, base 80 per cent lead, $100 per ton. Shipments for the week: Blende, 1,551; calamine, 30; lead, 26; sulphur ore, 32 tons. Shipments for the year: Blende, 44,624; calamine, 2,330; lead, 387; sulphur ore, 1,209 tons. Shipped during the week to separating plants, 2,124 tons blende.

Non-Metallic Minerals

Asbestos — Crude, No. 1, $2,400@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax. Freight rate from mines to Sherbrooke, Quebec, over Quebec Central R.R., 20c. per cwt.; from Sherbrooke to New York, 27½c., carload lots; freight to New York for crude No. 1, f.o.b. Thetford mines, $8.45 per ton, carload lots.

Barytes — Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $22@$25 in bags, carload lots; (off-color) $18@$20 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $12 per gross ton; ground (white) $23@$25; ground (off color) $16@$19 per net ton, f.o.b. Cartersville, Ga. Crude, 88 to 94 per cent, $23; ground (white) $40.50; ground (off color) $27 per net ton, less than carload lots, f.o.b. New York. Crude, not less than 98 per cent, $11@$11.25 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—Domestic, extra light, 5@6c. per lb.; light, 4½@5½c.; heavy, 4@5c; English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin) — Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground.

$15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$18 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $25@$30 car lots, f.o.b. Baltimore; ground, $17@$20, f.o.b. North Carolina points; $17@$20 per ton, No. 1 ground, f.o.b. New York State; $21@$23 per ton, ground, f.o.b. Maine.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Graphite—Crucible flake, 85 per cent carbon content, 8c. per lb.; 88 per cent, 9½c.; 90 per cent, 10½c., all f.o.b. New York. Crucible grades of Alabama graphite sell as follows, f.o.b. Ashland, Ala.: 80 per cent, 5c.; 90 per cent, 10c. Lubricating grades in increasing demand, with price ranging from 11c. for the 85 per cent guaranteed grade in car lots to 30 and 40c. for higher grades. Mexican, amorphous, $45@$55 per short ton; Korean, 3¾c. per lb.; Madagascar, 8c.; Ceylon, 4¾@15½c.

Gypsum—Raw crushed rock, $3.50@$4 per ton; raw ground fine, $4@$4.50; calcined stucco, $9, all f.o.b. works. Containers extra. Wholesale, plaster of paris, carload lots, $3.75 per 250-lb. bbl., alongside dock, New York.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $65@$75 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—Imported block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20 @$1.40; No. 4, $2@$3; No. 3, $4.25@$5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $4; No. 3, $5.75; No. 2, $7; No. 1, $9; A1, $14; extra large, $25, all f.o.b. New York; ground, $85@$100 per ton, Philadelphia.

Monazite — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses.

Pumice Stone—Imported, lump, 4@50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish, fines, per unit 12c., c.i.f. Atlantic seaport; furnace size, 16½c.; run of mine, 12@14c.; domestic, fines, f.o.b. mines, 12@14c.

Quartz—(Acid tower) fist to head, $10; 1½ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines. F.o.b. Wausau, Wis., the price is $16 per ton in car lots, and $22 less quantities, including bags.

Sulphur—$18 per ton for domestic; $20 for export, f.o.b. Texas and Louisiana mines.

Talc — Paper making, $10@$20 per ton; roofing grades, $9@$15; rubber grades, $10@$15, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $15@$20 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60 @$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $2.25 @$2.50 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15-18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

[1]Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 17@18c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c. f.o.b. works.

Ferromanganese—For 76@80 per cent, prompt delivery, $200@$225 freight allowed; last half, $200@$220; English, $195@$200, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $75@$80, f.o.b. furnace.

Ferromolybdenum—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2.50@$3 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $80@$85; 75 per cent, $150 @$160.

Ferrotungsten—70 to 80 per cent W, $1.10@$1.15 per lb. of contained tungsten, f.o.b. works.

Ferro-uranium—35-50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium—Basis 30-40 per cent, $6.50@$9.50 per lb. of V contained, f.o.b. works.

Metal Products

Copper Sheets — Current New York price, 29½c. per lb.; wire quoted, 22¼@23c.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver—Unchanged at 39½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 26¾c.; sheathing, 25¾c.; rods, ½ to 3 in., 23¾c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $145 per 1,000, f.o.b. Pittsburgh.

Chrome Brick—$90@$100 per net ton, carload lots, eastern shipping points.

Chrome Cement—45 to 50 per cent Cr_2O_3, $50 per net ton, and $55 in sacks, carload lots, eastern shipping points.

Clay Brick — First-quality fire clay, 9-in. shapes, $50@$55 per thousand, Pennsylvania, Ohio, and Kentucky works; second quality, $45@$50. First quality, St. Louis, $45; New Jersey, $75.

Magnesite Brick—$100@$110 per ton, eastern shipping points; 9-in. straights, $90@$100; 9-in. arches, wedges and keys, $95@$105; soaps and splits, $110 @$120.

Silica Brick—9-in. per 1,000, $51@$55, Birmingham, Ala.; $55@$60, Mount Union, Pa.; $55, Chicago district.

Iron Trade Review

Pittsburgh, Aug. 17, 1920

Production of steel ingots in July was at the rate of about 39,900,000 gross tons a year, representing a decline of 6 per cent from the June rate. Pig-iron production by steel interests decreased in lower ratio and some seems to have accumulated. There was also accumulation of semi-finished steel, on account of car shortage, and shipments of finished steel were nearly equal to the amount produced.

Pig Iron—Claims are made of a recent transaction in basic setting the market at $48.50 Valley, but there are some uncertainties connected with the report, and the reported $2 advance is not confirmed. Bessemer is said to have sold in several small lots at $47, in one case at $50, and one sale of 500 tons of foundry for the balance of the year at $50.50, Valley basis, is reported. Transactions are only a small fraction in volume of those that have hitherto occurred when the whole market was advancing, hence we quote last week's prices, subject to premiums for delivery: Bessemer, $47; basic, $46.50; foundry, $46, f.o.b. Valley furnaces, freight to Pittsburgh being $1.40, but to advance 40 per cent next week.

Steel—A week ago sheet bars were reportable at $70, a decline of $5, and now it appears that $70 could be shaded slightly. Billets are quiet at $60@$65.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $17@$18; foundry, $18@$20.

An Analysis of the Copper Situation

Record for Half Year Satisfactory, but Present Condition Exhibits Tendency To Lose Gains—Domestic Consumption About Twice Pre-War Rate—Foreign Demand Was Encouraging—Need of Co-operative Policy in the Industry

THE copper market is still in the doldrums. With the exception of the first three or four months of the year, when buying of copper occurred on an unprecedented scale, the copper trade has sunk into a lethargic state from which relief is not yet in sight. The table presented herewith records the statistical position of the metal so far as can be ascertained from available figures, a close inspection of which indicates that the results of the trade during the first half of the year were satisfactory, but that there is a tendency at the present time to lose a measure of the improvement gained.

Export trade, which has been largely counted upon to assist the copper market in its troubles, has exhibited encouraging aspects, the total exports for the half year being about 373,000,000 lb., or at the rate of 746,000,000 lb. annually, which compares favorably with exports averaging about 800,000,000 lb. for the five years preceding the war. Imports were a little above the pre-war rate of 360,000,000 lb. annually. The figures indicate that despite financial difficulties European nations and Japan were factors in the copper market whose importance should not be underestimated. The net balance of exports over imports of copper was maintained in the varying monthly amounts indicated with the exception of June, when a small adverse balance was recorded. Results over one month, however, are never of any particular significance, but should this condition be maintained for several months it will impair part of the export record made earlier in the year.

Domestic smelter production of blister copper has not varied much—always within a few per cent of the preceding month—and is at the rate of 1,415,000,000 lb. yearly, about 17 per cent more than the pre-war rate of 1,210,000,000 lb. Refinery production is also above the pre-war rate. Owing to the large stocks of crude copper on hand at the refineries, transporation troubles did not affect refining as much as expected.

The estimates of sales into foreign and domestic consumption total about 860,000,000 lb. for the first half of 1920. Domestic deliveries of copper for the same period are estimated at 680,000,000 lb. Exports were 373,000,000 lb., a large portion of domestic deliveries and exports the conclusion of heavy sales in the latter part of 1919. The estimate of domestic deliveries or consumption would indicate a consumption of copper of 1,360,000,000 lb. annually, or on a scale much larger than the pre-war rate of 741,000,000 lb.—almost twice as much, in fact. This is one of the most optimistic indications in the copper industry, and were it not for one other factor which seemingly the copper industry is unable to eliminate, the market would be in a highly satisfactory condition. This factor, of course, is the large stock of both crude and refined copper still on hand. Domestic consumption is doing its share, but enlarged buying from foreign quarters, from France, England, Italy and particularly Germany, is necessary before any great inroads into surplus stocks can be made.

On Jan. 1, 1919, according to the U. S. Geological Survey, there were on hand refined stocks amounting to 180,000,000 lb., and of blister copper, 562,000,000 lb. On Jan. 1, 1920, there was 631,000,000 lb. of refined copper on hand and 310,000,000 lb. of blister copper, or a total of 940,000,000 lb. of copper. Let us say an average cost of 14c. per lb. had been expended upon this product, or a total outlay of $131,600,000, which is quite a bit of capital to have tied up in unmarketed copper in these days of stringent credit facilities. The good record made in the first half of the year indicates that the stocks of refined copper were reduced, and are now between 475,000,000 and 500,000,000 lb., though there is probability that stocks of blister copper, if they show any change, exhibit an upward trend. It is probable that for the first few months of the year decided inroads were being made into the refined copper stocks, but that this improvement diminished monthly, so that now practically no reduction is recorded.

The price of copper has in general moved in sympathy with the situation in the metal. The lowest average price for electrolytic this year was recorded in June (18.07c.), but in comparison with the conditions existing a year ago with copper between 14c. and 17c. the present averages are a pleasing comparison. The current stagnation in the copper market comes at a time when demand should be particularly brisk, when requirements for the latter part of the year are ordinarily covered. August last year, it will be remembered, was the month in which the peak prices of copper for the year were attained (over 22c.). That copper will go much above its present level before the end of the year seems unlikely unless there is a material change in the fundamental difficulties hampering the industry. Twenty-cent copper is a low price, but if attained would be a creditable showing, considering the adverse conditions.

The seriousness of the present condition demands emphasis. The United States, which is the world's leading copper-producing country, is marketing a wasting asset at a cost but little above the cost of production. Every pound of copper sold diminishes by so much the nation's copper resources, which, although tremendous, are not of such a character as to warrant producing them and supplying the world at prices which represent an exceedingly small return. The obvious remedy that first comes to mind is to curtail production, thereby creating a smaller supply and easing the acute labor situation in other fields. In some cases, such as a step, by increasing the overhead expenses, might increase the cost of production. All producers have decreased their production drastically from war rates, and generally to the economic limit, refraining from a further decrease not only for business reasons but for the certain measure of responsibility that they have toward the mining communities which depend for their existence upon the continued operation of the mines. Nevertheless, the situation is critical, and copper producers would be justified in forming plans whereby this valuable resource may be conserved to the best advantage and no one producer will take unfair advantage over his neighbor.

ANALYSIS OF THE COPPER SITUATION FOR FIRST HALF OF 1920

In Pounds

Month	Crude Copper Production	Imports	Exports	Net Exports	Estimated Sales Foreign and Domestic	Estimated Stocks of Refined Copper on First of Month	Estimated Domestic Delivered	Average Price
Jan.....	121,900,000	34,220,000	49,680,000	15,460,000	239,000,000	(a)631,000,000		18 92
Feb.....	117,450,000	39,170,000	57,600,000	18,430,000	89,000,000	612,000,000	500,000,000	18 57

Semi-finished nuts sell at the following discounts from list price:

	Current	One Year Ago
New York	30%	50-10%
Chicago	50%	50%
Cleveland	50%	60-10-10%

MACHINE BOLTS—Warehouse discounts in the following cities:

	New York	Cleveland	Chicago
¾ by 4 in. and smaller	+20%	20%	20%
Larger and longer up to 1 in. by 30 in.	+20%	20%	20%

WASHERS—From warehouses at the places named the following amount is deducted from list price:

For wrought-iron washers:
New York...... List Cleveland ... $2 50 Chicago $3 00

For cast-iron washers the base price per 100 lb. is as follows:
New York...... $7.00 Cleveland...... $4.50 Chicago....... $4 75

CONSTRUCTION MATERIALS

PREPARED ROOFINGS—Standard grade rubbered surface, complete with nails and cement, costs per square as follows at manufacturing points:

	New York 1-Ply c.l.	New York 2-Ply l.c.l.	New York 3-Ply c.l.	Philadelphia 1-Ply c.l.	Philadelphia 2-Ply l.c.l.	Philadelphia 3-Ply c.l.
No. 1 grade	$2 50	$3 00	$3 55	$2 40	$2 90	$3 45
No. 2 grade	2.25	2 70	3 20	2 15	2 00	3 10

Slate-surfaced roofing (red and green) in rolls of 108 sq.ft. costs $4 25 per roll in carload lots and $4 50 for smaller quantities.

Shingles, red and green slate finish, cost $7.75 per square in carloads, $8 00 smaller quantities, in Philadelphia.

ROOFING MATERIALS—Prices per ton f.o.b. New York and Chicago:

Tar felt (14 lb. per square of 100 sq ft.) per roll	$[illegible]
Tar pitch (in 400-lb. bbl.) per 100 lb.	[illegible]
Asphalt pitch (in barrels) per ton	[illegible]
Asphalt felt (light) per ton	[illegible] 10
Asphalt felt (heavy) per ton	127 00

HOLLOW TILE

	4 x 12 x 12	[illegible] x 12 x 12	12 x 12 x 12
Minneapolis	$0 1152	$[illegible] 2 16	$[illegible]

Denver		42 75			40 25

*Montreal—Up to 22 ft.; over which, $3.00 per M. increase up to 30 ft.
†Base price, 2 x 3's and 2 x 4's, 8 to 14 ft., is $54.00

Detroit—Dimension stuff ranges from $60 to $68. See "ups and downs in the market."

NAILS—The following quotations are per keg from warehouse:

	Mill Pittsburgh	St. Louis	Denver	Chicago	San Francisco
Wire	$3.25@4 50	$6.00	$5.40	$4.15	$6.00
Cut			5.90	5.85	8.50

PORTLAND CEMENT—These prices are for barrels in carload lots, without bags.

	Current	One Month Ago	One Year Ago Without Bags
New York (delivered)	$4.10	$3.80	$2.30
Jersey City (delivered)	3.22	2.97	2.27
Boston	3.42	2.60	2.42
Chicago	2.15	2.15	2.00
Pittsburgh	2.20	2.20	2.05
Cleveland	2.42	2.42	2.32

NOTE—Charge for bags is generally 25c. each, $1 per bbl.

LIME—Warehouse prices:

	Hydrated per Ton		Lump per 200-lb. Barrel	
	Finished	Common	Finished	Common
New York	$19.50	$18.50	$3.50*at plant	$3.30*
Kansas City	27.20	26.20	2.50	2.40
Chicago			2.40	1.75
St. Louis	25.00	21.00		2.25
Boston	27.50	25.25	3.70†	3.40†
San Francisco	23.50	19.50		2.25
Minneapolis	24.00	19.00	2.90†	2.30
New Orleans		2.25†		2.45

NOTE—Refund of $0.10 per barrel.
* 300-lb. barrels. † 180-lb. barrels.

LINSEED OIL—These prices are per gallon:

	New York		Chicago	
	Current	Year Ago	Current	Year Ago
Raw per barrel (5 bbl. lots)	$1.48	$2.15	$1.95	$2.53
5-gal. cans	1.51*	2.28	2.15	2.73

* To this *oil* price must be added the cost of the cans (returnable), which is $2.25 for a case of six.

WHITE AND RED LEADS—500-lb. lots sell as follows in cents per pound:

	Red				White	
	Current		One Year Ago		Current Dry and In Oil	1 Yr. Ago Dry and In Oil
	Dry	In Oil	Dry	In Oil		
100-lb. keg	15.50	17.00	13.00	14.50	15.50	13.00
25- and 50-lb. kegs	15.75	17.25	13.25	14.75	15.75	13.25
12½-lb. keg	16.00	17.50	13.50	15.00	16.00	13.50
5-lb. cans	18.50	20.00	15.00	16.50	18.50	15.00
1-lb. cans	20.50	22.00	16.00	17.50	20.50	16.00

MINING AND MILLING SUPPLIES

HOSE—

	FIRE	50-Ft. Lengths
Underwriters' 2½ in		$0.85 per ft.
Common, 2½-in		30%

STEAM—DISCOUNTS FROM LIST

First grade..... 20% Second grade.... 30% Third grade..... 35%

LEATHER BELTING—Present discounts from fair quantities (½ doz. rolls):

Light Grade	Medium Grade	Heavy Grade
30%	30%	20%

RAWHIDE LACING—For cut, best grade, 25%. 2nd grade, 30%. For laces in sides, 79c. per sq. ft.; 2nd, 75c. For semi-tanned: cut, 20%; sides, 83c. per sq .ft.

MANILA ROPE—For rope smaller than ¾-in. the price is ½ to $0.02 extra while for quantities amounting to less than 600 ft. there is an extra charge of $0.01. The number of feet per pound for the various sizes is as follows: ¾-in., 8 ft., ½-in., 6; ⅜-in., 4½; ¼-in., 1¾-in., 2 ft. 10 in.; 1½-in., 2 ft. 4 in. Following is price per pound for ¾ in. and larger, in 1200-ft. coils:

Boston	$0.30½	Kansas City	0.305
New York	.29	New Orleans	.29
Cincinnati	.27	Seattle	.28
Chicago	.29½	St. Louis	.265
Minneapolis	.29½	Atlanta	.295
San Francisco	.27	Denver	.30

PACKING—Prices per pound:

Rubber and duck for low-pressure steam	$1.00
Asbestos for high-pressure steam	1.70
Duck and rubber for piston packing	1.00
Flax, regular	1.20
Flax, waterproofed	1.70
Compressed asbestos sheet	.90
Wire insertion asbestos sheet	1.50
Rubber sheet	.50
Rubber sheet, wire insertion	.70
Rubber sheet, duck insertion	.50
Rubber sheet, cloth insertion	.30
Asbestos packing, twisted or braided and graphited, for valve stems and stuffing boxes	1.30
Asbestos wick, ½- and 1-lb. balls	.85

RAILWAY TIES—For fair size orders, the following prices per tie hold:

Material	7 In. x 9 In. by 8 Ft. 6 In.	6 In. x 8 In. by 8 Ft.
Chicago—Plain	$1.75	$1.60
Chicago—Creosoted	1 95	1.80
San Francisco—Douglas fir, green	1 74	1.24
San Francisco—Douglas fir, creosoted	3.36	2.38

Prices per tie at Missouri mills; St. Louis prices about 25c. higher:

Untreated A Grade White Oak 6x8x8		Untreated A Grade Red Oak 6x8x8	
No. 1	$0.70	No. 1	$0.55
No. 2	.80	No. 2	.65

The Grand Canyon Mystery

IN OUR ISSUE of Aug. 21, in the Court Decisions in Mining Cases Section, it is recorded that the Supreme Court of the United States has affirmed judgment in the case of the United States against Ralph H. Cameron and others, "enjoining the defendants from occupying, using for business purposes, asserting any right to, or interfering with the public use of, a tract of land in Arizona approximately 1,500 ft. long and 600 ft. wide which Cameron was claiming as a lode mining claim. The tract is on the southern rim of the Grand Canyon of Colorado, and embraces the head of the Bright Angel Trail." It was staked by Cameron in 1902. The report of our legal editor proceeds: "Cameron also had sought patents for other claims embracing other portions of the trail into the Canyon. On these claims Cameron applied for a patent, which would have given him undisputed rights to the surface of this permanently valuable tract. The Commissioner of the General Land Office held that the claims were not valuable for mining purposes, and therefore invalid." The matter was appealed to the Secretary of the Interior, who "reported that with the possible exception of the Magician lode claim the evidence wholly fails to show valuable desposits of gold, silver or copper, or other minerals."

The report of the Secretary fails to mention platinum, which is the principal mineral claimed to exist in these properties by those who staked and held them. These alleged enormous platinum deposits of the Grand Canyon have for years attracted attention and comment. We should like further elucidation of this mystery before the matter is dropped. Has the whole been a bold scheme to defraud the Government and the public by grabbing the Bright Angel Trail under pretense of mining locations? The opinions of the Land Office, the Interior Department and the Supreme Court would seem to so imply. If this is the case the Government should not rest with a simple denial of the property to the claimants, but should take steps to prosecute the fraud.

If fraud has been attempted it has been complex, and has not rested on a passive holding of the claims. Great pretensions to valuable platinum content have been repeatedly and forcibly made for years; and many capitalists have been solicited to interest themselves. At least one prominent mining geologist was retained by the owners, whose final opinion, we believe, was that the sandstone actually contains platinum. On the other hand, engineers and investors who have investigated or attempted to investigate these deposits have given various confidential accounts of their experiences, which clearly imply, in their opinion, the possibility of their samples having been salted with platinum in some mysterious manner, which one engineer opined might be with the ash of platinum prints used in local photography. One large user of platinum has stated that he found platinum in a sample of the ore submitted for assay; but on asking for a hundred pounds or so of the ore was unable to obtain it, and therefore dropped the matter. The assay certificate was, however, used to attempt to interest others.

The halo of romance has never left this fabulous platinum wealth on the brink of a marvelous canyon. Even with the platinum actually infesting the sandstone, it eluded profane and irreverent seekers. Therefore, a Philadelphia man invented a machine which would and did recover it (he said); whereas the crude and discredited fire assay did not recover it. Where have we heard something like that before?

Selective vs. Tonnage Mining

ONE of the most important developments of modern mining is tonnage mining or low-grade ore mining on a large scale. The Alaska Treadwell mine was an excellent example of this kind of mining. The "porphyry coppers" represent without much doubt the best development in this respect. The principle thus established has to a considerable extent influenced mining operations of lesser magnitude. As a consequence there was less and less discrimination in the selection of ore in stoping operations. A low unit cost for mining and milling extended stoping limits. Milling capacity was increased to enable large tonnages to be handled.

The changed economic and labor conditions during and since the war have pinched in on the mining industry to such an extent that profit margins have been greatly curtailed. This is true of both small and large operations, and particularly so with reference to gold mines. A modification of the tonnage system has been recognized, and wherever it is possible to change mining consistently to conform to the new order it is being done. Higher-grade ore is being mined. Stope limits are curtailed and ores are more carefully selected.

It costs just as much to mine and mill a ton of waste as a ton of ore. Reduction in the amount of waste mined is the order of the day. Hand picking of waste out of the ore stream was at one time practiced, but tonnage mining cut this out to a considerable degree: it is not practical to reintroduce it under existing labor costs and efficiencies except in a few cases, and in its absence the stope becomes the important factor.

Consistent and thorough underground sampling is essential, that discrimination between ore and waste be properly made. The net result will be to increase the unit cost of mining and to reduce the tonnage mined. Milling capacity must necessarily be curtailed either by operating on one shift or two shifts, instead of three, or by shutting down some of the units in

the mill. Overhead costs can under the circumstances be lessened, although not in proportion as capacity is reduced.

No one can foresee how long existing conditions are to last, but while they last the technical men in charge of mining operations are put to a greater test than ever before. That they have responded to the test is shown by the continuation of mining. It is true that there is, on the whole, some curtailment, but the intensive study and work required to maintain the industry will react beneficially in the long run. It has established the importance of good leadership and the wisdom of close technical control of mining operations.

The Reports of the "Porphyry Coppers"

THE reports of the "porphyry coppers" for the second quarter of 1920 were issued a few days ago, and are published elsewhere in this issue, all of which reflect the lamentable situation in the copper market. Not one of the four companies, Utah, Nevada Consolidated, Chino, or Ray Consolidated, was able to show a profit from copper production equivalent to the disbursement to stockholders. Including even the support of miscellaneous income, only one company, Chino, was able to show a profit greater than dividend disbursements. The following comparative table brings out this point:

PORPHYRY COPPERS SECOND QUARTER OF 1920

	Production in Pounds	Net Profit From Copper Production	Total Net Profit	Disbursements to Stockholders
Utah	29,004,381	$1,254,033	$2,240,470	$2,436,735
Nevada Cons	13,063,677	47,276	384,000	499,864
Chino	11,989,451	260,032	330,152	326,242
Ray Cons	12,965,596	343,651	387,255	394,294
	FIRST QUARTER OF 1920			
Utah	27,257,546	$2,291,012	$2,870,590	$2,436,735
Nevada Cons	11,138,225	132,529	215,583	499,864
Chino	10,621,276	737,605	809,727	326,242
Ray Cons	11,650,443	587,166	637,300	394,294

During the first quarter of 1920 a better average record was made, although the record for this period failed to indicate the improvement desired. Production increased during the second quarter, but financial results —due entirely to the low selling price of copper—were comparatively poorer. Were it not for the substantial financial assistance rendered by miscellaneous income, through returns from byproduct precious-metal recovery, and railway dividends, the statements would have been worse, and surplus accounts would have been used to a greater extent. In the case of Nevada Consolidated, the miscellaneous income, chiefly a heavy credit from the Nevada Northern Ry., was about seven times as large as the operating profit.

In the matter of costs, all the porphyry companies with the exception of the one making the best general showing, Chino, were able to show a reduction in comparison with costs for the first quarter:

	—Net Cost per Pound— Second Quarter	First Quarter	Average Sales Price of Copper Second Quarter	First Quarter
Utah	11 77	11 94	18 21	21 99
Nevada Cons	15 56	20 72	18 50	22 66
Chino	15 29	13 91	18 17	21 88
Ray Cons	15 34	16 30	18 42	21 96

The reduction in costs may be attributed principally to the greater production for the second quarter. Chino's exceptional increase is accounted for by the lowering in the tenor and quality of the ore.

Considered collectively, the four porphyry copper companies are bearing up particularly well under the depressing influence in the industry, and are giving an exhibition of operating results which, although not satisfactory as expressed in dollars and cents, record splendid "staying" powers. These companies are essentially large-scale producers, a fact which has been held against them for times such as these, but considering the many adverse industrial and economic contingencies which they have had to surmount, their statements are of prime importance in illustrating what they can do with copper at a bottom price.

A possible further curtailment in dividend rate is likely with a continuation of the present conditions, but a relatively small and warranted increase in copper prices will greatly assist in lifting the "porphyries" out of their troubles.

Higher Freights May Be Temporarily Troublesome

LAST week we spoke of the freight rate increases, which we believe are fully justified in promoting railroad and, indirectly, industrial efficiency. The mining industry will be affected adversely, however, until the general improvement of conditions overtakes the temporary hardship which has been imposed. Precious-metal mines which are in a position to ship a finished product in the form of bullion will be affected only in so far as the cost of supplies, fuel, timber, steel, lubricants, and machinery are concerned. In the case of lead-silver mines shipping either first-class ore or concentrates there will be a considerable increase in cost for the movement between mine and smelter. Necessarily these mines will also have to meet increased freightage on their supplies.

With the copper mines there will be an increase in the cost of coal, fuel oil, and supplies, as well as increased cost for the shipment of copper bullion to tidewater. Already, with the decreased production, many copper mines will find the narrow margin upon which they are operating still further reduced. That there will be internal readjustments to meet such increases is obvious, and we may expect some copper mines to shut down.

Excepting lead and silver, metal prices have sagged or else have remained at low levels. There does not appear to be the possibility of passing on the increase, and for the time being the small producer as well as the large company will be compelled to strive for greater economy and higher labor efficiency.

The Search for a Meteorite

LEGEND has it that a vast store of Inca treasure lies at the bottom of some Peruvian lake, and on this basis many a tale of adventure has been written. The quest for hidden treasure, whether for rainbow gold or Ponzi's millions, is always alluring, and man is never wearied even though the work be fruitless. Today, the search is being renewed in Arizona for the great meteorite that is held responsible for the huge crater near Winslow. In its fascination this enterprise far surpasses any mere hunt for buried gold. One is reminded of the craters made by the projectiles in which the Martians in H. G. Wells' "War of the Worlds" invade the earth to conquer it, save that the Winslow crater is vastly larger. In diameter it is well over 4,000

ft., and the meteorite that caused it must have been of huge proportions, though it undoubtedly was much smaller than the crater itself.

Attempts to locate the meteorite have been made before. One company found its sinking operations, which were well within the crater, frustrated by quicksand which it could not handle. Today, a new organization known as the Crater Mining Co. is working on a different theory and is drilling with two Standard rigs on the chasm's inner edge. It is thought that the projectile from the heavens may have struck at an angle to the vertical, so that the mass does not lie directly below the crater's center but off to one side. Fragments of meteoric nickel have been found from time to time, supporting the theory of the meteorite's existence. The mass of metal that it is hoped to find is a prize worth searching for. But there is interest in the enterprise aside from that of possible financial return upon the investment.

This search for a meteorite is merely one of the many fascinations of the mining game, fascinations that generally hold the player even though the game yield an inadequate return. According to Emerson, everything has its just compensation, and the engineer may, and often must, accept the romance of the industry in part payment of what is due him.

Safeguarding Government Co-operation With Industry

THE Bureau of Standards has been during recent weeks establishing a number of so-called "industrial fellowships." The fellows so appointed are detailed to work at the Bureau by individual companies or associations on problems which are of common interest to the industry and the Bureau. By this means more intimate acquaintance with Bureau work will be gained by the industry, it is expected, and a considerable measure of support not previously available is given to the Government investigations.

The direct and rather obvious advantages of this co-operation should not, however, obscure certain possible disadvantages which may follow if each such project is not well considered and properly safeguarded. One of our Government bureaus, not, however, the Bureau of Standards, was recently referred to by a prominent engineer as being operated mainly "by and for appropriations." This tendency, indeed, is apparent from time to time in almost all of our bureaucratic activities, where there is a disposition to place expediency first in planning investigations, and effectiveness or appropriateness of work second.

Individual companies co-operating with any Government body are likely to stir up the suspicion, if not an actual public charge, of favoritism in the use of public funds. This is a charge easily made and difficult to refute at times, even when not justified. Another evil equally difficult to guard against is that of subordinating fundamental general investigations, which should be foremost in the program of the Government, to industrial studies of more specialized interest, which are for the moment more attractive, promising the individual investigator more immediate recognition.

It is to be hoped that none of these difficulties will be encountered by the Bureau of Standards in its new activities. We see no reason why these pitfalls may not be wholly avoided. Our industries, however, must co-operate to this end and avoid all appearances of leading any bureau into a false position by approaching it with offers of co-operative investigation where special interest or commercial, rather than fundamental, problems are involved.

Deflation No Menace to the Mining Industry

THE long-expected and much-postponed decline in commodity prices seems at last to have set in in earnest. The textile industry appears to have borne the brunt of the first onslaught, the woolen, cotton and silk mills now being operated at considerably reduced capacities or having shut down entirely. Merchants are confronted with daily losses on their inventoried stocks, which induce them to turn to bargain sales in order to unload. Sugar, which advanced possibly more than any other commodity equally widely used, has dropped from 25 to 19c. retail. It is surprising how easy it is to secure it now compared with the difficulty several months ago when the market was advancing.

Although business interests cannot expect to prosper in the next two or three years as they have in the term just passed, we can see no reason for alarm in the mining industry. Rather the contrary. Mining supplies and labor are almost certain to fall more than metal prices. The latter, with the exception of lead and iron, are too near the cost of production to be seriously affected. Iron is too badly needed for reconstruction purposes to experience any great dullness. Then, too, much construction work in which iron is used has been delayed during the last few years.

Lead may slump some, but, even with present high prices, production is too curtailed to allow much of a drop. Silver, of course, is pretty well pegged. Copper and zinc should be in greater demand month by month as normal conditions are restored. We think it unlikely that any great increase in price will take place in either of these metals, for general conditions do not favor such a change. Rather will these industries prosper through reduced costs of production.

So, although the big manufacturing industries may look on the period of deflation with some qualms, and the profiteers and speculators with actual dismay, the rest of us may profit. Things, as someone has said, affect different people differently. Adam, William Tell, and Isaac Newton each had his little affair with an apple, but with quite different results.

In Re "Coyote Howlings"

IN THE *Engineering and Mining Journal* of July 31, 1920, p. 228, in the news item on "Minerals Separation Hearings End at Salt Lake," our correspondent used the following sentence: "The term 'coyote howlings' is used to designate licensees making complaints." On investigation we find that the term was a facetious one used in certain correspondence between officials of Minerals Separation. It was not applied to licensees, but to attacks on Minerals Separation by certain sections of the technical press. It is an injustice to both the licensees and to Minerals Separation to permit the erroneous implication of the expression to remain unacknowledged, and we make correction.

WHAT OTHERS THINK

Pebble-Mill Grinding, and Amalgamation

I have read with a great deal of interest the article by Jesse Scobey on the operation of the La Luz & Los Angeles Mine, in Nicaragua, in your July 3 issue. There are some points which I hope Mr. Scobey will be able to explain to me, and in addition, from my long experience in amalgamation with stamps and Hardinge mills, I wish to comment upon the findings as expressed in Mr. Scobey's article, and may, in some small way, aid not only him but operators who have an amalgamation problem involving stamps and pebble mills.

From the summary of eleven years' amalgamation mill reports, it would appear that the Huntington mills were the best amalgamators; following them the stamps were the best, and last of all the stamps and regrinding pebble mills. I presume that the efficiency in amalgamation of the Huntington mills was due to the original character of the ore rather than to the efficiency of these machines as amalgamators. As described by Mr. Scobey, the ore which the Huntington mills treated carried the gold in a form very easy for amalgamation. What I am interested in is whether the results shown for 1919, using stamps only, with an extraction of 69 per cent, can be directly compared to the results for 1918, when the ten stamps, one ball mill and two pebble mills were used. If the ore treated in both years was the same, then stamps are the better amalgamators. This is contrary to my experience, particularly in work on ore from the Plymouth Consolidated Gold Mines, Ltd., Plymouth, Cal.

The original test work on the Plymouth Consolidated was carried out in a small two-stamp battery and showed a 69 per cent extraction by amalgamation. The equipment, as finally installed, consisted of thirty stamps grinding to 2 or 4 mesh, followed by Hardinge pebble mills regrinding in open circuit, as was used at the La Luz & Los Angeles. After their preliminary difficulties had been overcome the first eighteen months showed an average extraction by amalgamation of 71 per cent, the highest being 75 per cent and the low 55 per cent. These variations were due to the variations in the character of the ore. I have always explained the higher amalgamation recovery in the final plant as being due to the polishing action of the pebble mill regrinding, which put the gold in better condition for amalgamation than when broken loose from the gangue by the cracking action of the stamps.

The low recovery with the stamps, ball mill, and two pebble mills at La Luz & Los Angeles may be due to failure to use sufficient amalgamating devices. I have found that one cannot use too many such, particularly where tube or ball mills are used to regrind after stamps. At the Plymouth Consolidated Gold Mines, Ltd., the Hardinge patent amalgamators are used on the discharge of the pebble mills, followed by riffles similar to those employed in placer mining, then lip plates, then amalgam traps, then finally the stationary plates as used in most amalgamation practice. A similar method of amalgamation is practiced by the Gold Hill & Iowa Mines Co., Quartzburg, Idaho, and the Carson Hill Gold Mining Co., Melones, Cal. The chief reason for the Hardinge amalgamator on the discharge end of the mill, as well as the riffles, lip plates and traps, is that it has been found that when the gold is released by the rubbing action of the regrinding mill it is in ideal condition for amalgamation. It is also in ideal condition for coating, particularly if there is a considerable quantity of iron sulphide in the ore. If the gold is taken from the discharge of the pebble mill to the stationary plates through launders from 12 to 16 ft. long it has been found that amalgamation recovery on the plates is not as good.

At one property on the Mother Lode in which I was interested free gold was found in the concentrates on the tables where the discharge from the mill was sent to the stationary plates through distributing launders about 16 ft. long. Upon the addition of lip plates and amalgam traps immediately following the discharge of the mill this fine free gold in the concentrates disappeared and the extraction by amalgamation was materially increased. It may be wise to describe briefly here the lip plate used. For a 100-ton plant the lip plate is usually about 4-ft. wide by 6-ft. long, silver plated with 4 oz. of silver to the square foot and set at a slope of 2½ in. to the foot. This plate is only dressed every two days to a week, depending upon the richness of the ore, and the attempt is made to keep the amalgam thick and pasty. The amalgam traps are usually simple devices where the pulp flows in and is agitated by water under pressure, either ascending or descending, and flows out the other side of the trap after coming into intimate contact with a bath of quicksilver in the bottom of the trap.

Another point I have found which amalgamators overlook is that the treatment of the stationary plates after regrinding in a mill is considerably different from the treatment usually practiced after reducing in stamps. In mills using regrinding the best practice appears to be to dress the plates every morning, putting on only enough quicksilver so that when rubbed up it will be soft enough to roll up under the finger. Quicksilver is usually rubbed in with a burlap cloth or any rough piece of cloth, then brushed with a soft whiskbroom. This seems to be the best practice for the stationary plates, and keeps them in the best condition for amalgamating after regrinding mills. The Hardinge amalgamator is a rather simple device bolting onto the discharge end of the mill in place of the discharge bell, and was devised particularly for the Plymouth ores, in which there were considerable arsenical pyrites, so as to amalgamate as close to the grinding medium as possible but without actually feeding quicksilver into the grinding medium. However, on an ore containing no arsenical pyrites and showing no tendency for the quicksilver to flour and be lost, such as at the plant of the Gold Hill & Iowa Mines Co., quicksilver is fed directly into the feed of the pebble mill and the amalgamator is used purely as an accessory amalgamation device.

Mr. Scobey states that the test between the ball mill and the stamps could not be continued because of the lack of comparative data, and that both were retained. It is regrettable that actual data were not taken on the comparative work of the stamps and the ball mills as metallurgical devices, as well as mechanical devices, for the reduction of ore. The theory has been advanced, and seems to be well authenticated, that with small smooth balls in the mill the gold in the ore is beaten into cup shapes, which flow over the plates, through the amalgamating devices, and finally are only caught on the concentrating tables. This theory has been advanced to me by those in charge at the Gold Hill & Iowa Mines Co. In their particular case, as in that at the La Luz & Los Angeles, the ball mill which was installed had to be relegated to the place of a mechanical reducer, and the discharge from the mill was sent to the pebble mill and to the amalgamating devices. E. E. Carter, general manager of this company, told me that when an attempt was made to amalgamate after the ball mill the millmen could not make the proper amalgamation recovery and that they had to put the ball mill back to a primary reducer, sending the pulp produced by it through the pebble mill, before extraction by amalgamation became normal. I should like to hear from Mr. Scobey on this point as well as from any other readers of the *Engineering and Mining Journal* who have had a similar or a different experience in this kind of work.

Mr. Scobey also says that one of the pebble mills was operated in open circuit, "although not orthodox." I wish to state that in all of the plants mentioned above, where I have closely studied amalgamation after ball mills, and particularly the operation of pebble mills regrinding after stamps, none of these mills have been actually close-circuited with a classifier. In fact, it was found that at the plant of the Original Amador Consolidated Mining Co., Amador City, Cal., when the regrinding mills were close-circuited with a classifier, the gold was trapped in the circuit and ground so fine that amalgamation results were very poor, and this fine free gold was caught only in the cyanide plant. A change to mills in open circuit gave much better results. As the La Luz & Los Angeles had a mill in open circuit, followed by amalgamation, and also a mill in closed circuit, it might be interesting, if possible, to determine which gave the better amalgamation results. The usual practice has been to send the mill product, diluted as Mr. Scobey states in his article, over the plates, the tailings from the plates being elevated to the classifier, making as a rule three products. The first spigot discharge is an oversize, which is sent back to the mill for regrinding. The second and third spigot discharges are sent to sand tables, and the overflow from the classifier is thickened for concentration on vanners or other types of slime concentrators.

Hard ore from the mine is being used for regrinding mediums, according to Mr. Scobey. I should like to know if he has any data indicating whether the change from Danish flint pebbles to mine rock had any effect upon the capacity of the mill. I have found, as a rule, that it does have an effect upon the capacity, because energy is wasted in rounding off the chunks of ore before they become efficient as grinding mediums. I found, however, that one way to overcome this loss of efficiency in grinding is to speed the mill up several revolutions, thereby increasing the action in the mill and rounding off the chunks of ore just that much sooner. In the case of the Utah Leasing Co., Newhouse, Utah, where the change was made from Danish flint pebbles to a local quartzite, material economies were at once apparent in the cost of grinding, but the mills had to be run considerably faster than ordinarily. These mills were 8-ft. x 48-in. Hardinge pebble mills, and, with an El Oro type of lining, were operating at 28½ revolutions. Ordinarily the practice would have been to operate them at about 26 revolutions. However, the change to mine rock had no material effect upon the capacity of these mills, owing, in my opinion, mainly to the high speed at which the mills were operating.

I have one last point to comment upon in Mr. Scobey's article. He states that with the pebble mill running in open circuit, delivering a finished product, the practice developed of making a very wet discharge direct to the plates: "An excess of water permitted a classification in the mill that held back the oversize." This is a point very little recognized in the operation of a Hardinge mill, and something about which every operator of this machine should know. However, instead of making the feed to the mill dilute, the better practice is to insert a water pipe at the discharge end of the mill. This pipe is usually ¾-in. pipe with a ½-in. nozzle, and it is led into the discharge trunnion of the mill on the lifting side. The spray from the nozzle is then directed at an angle so as to hit as near as possible the point in the mill where the pulp and pebbles are cascading. The flow of water is regulated so that the pulp will not get beyond 18 in. to 2 ft. from the discharge end of the mill and therefore does not dilute the portion of the mill where the most grinding is being done. With this device the pulp in the feed to the mill is kept thick and the discharge is diluted so as to release the oversize particles, allowing only the finer material to discharge. The installation of such a device at the Bluestone Mining & Smelting Co., Mason, Nev., increased the capacity of the mill almost 10 per cent and had no effect whatever upon the consumption of grinding mediums, because the pulp in the effective grinding portion of the mill was still kept at from 75 to 80 per cent solids by weight. V. A. STOUT.

New York, N. Y.

Suggests a Gold Producers' Bank

The position of the gold producers today suggests to my mind that there is something fundamentally wrong that they should consider. Briefly, under the gold standard gold establishes the basis for money credit, but the producers of gold do not get the credit. The producer turns in his gold for about $20 per oz. That same ounce of gold has a money credit, which the banking interests get.

The gold producers in my opinion can correct this situation, and come into their own, only by forming a "Gold Producers' Bank," where all production would be deposited. The banking or industrial interests would then obtain the gold by payment of the credit value for gold, or it may be possible for the Government to issue currency to such a "Gold Producers' Bank" upon the credit system in operation.

In any event the gold producer would get what belongs to them rightfully, and the credit they established would be in their control.

I am advised that there is no law compelling gold producers to sell their production to the Government.

Reno, Nev. F. A. WRIGHT.

Ore Deposits of Arctic Canada

Occurrences of Iron and Copper Most Promising Discoveries Reported to Date—Latter Metal Widely Distributed—Gold Apparently Scarce, Though Pyrites Is Not Uncommon—Silver, Lead, and Zinc Ores and Other Minerals Found in Minor Quantity

By E. S. Moore
Written exclusively for *Engineering and Mining Journal*

WITH the extension of the railroads northward into the previously little known regions of northern Canada, interest in the possibility of finding ore deposits in Arctic Canada is daily increasing. The airplane has developed such efficiency as a new means of exploration that many mining men look forward to the time when rapid excursions may be made into the areas hitherto beyond the reach of all except a few adventurous souls who were willing to make long and perilous expeditions.

Through the explorations of Low, Bell, Tyrrell, Stefansson, O'Neill and many others the world has learned a little of the possibilities of that tremendous area which should surely harbor somewhere another Keweenaw Point, another Sudbury, Cobalt, or Mesabi. It has been known for some time that the rocks in the north-central part of the continent are chiefly pre-Cambrian and that they possess many characteristics similar to those of the great ore-bearing regions farther south. The Upper Huronian iron formations have been found underlying considerable areas in a number of localities, and the Keweenawan rocks, the parents of the Michigan copper, the Sudbury nickel, and the Cobalt silver deposits, are spread over a great expanse from the southern end of Hudson Bay northeastward to the Atlantic and northward and northwestward to the Arctic. During the Keweenawan period a great curved, volcanic zone extended from the Lake Superior basin through the Sudbury and Cobalt fields, along the Hudson Bay basin to the Arctic, and in this disturbed zone extensive igneous activity manifested itself. The time during which this occurred was one of the most notable metallogenetic epochs in the earth's history.

MAP OF NORTHERN CANADA, SHOWING DISTRIBUTION OF ORE DEPOSITS IN ARCTIC REGION. "C" INDICATES COPPER. HEAVY LINE INDICATES AREA WITHDRAWN FROM STAKING.

In a description of the ore deposits of Arctic Canada it seems wise to include a discussion of some areas not strictly in the Arctic regions. These areas are so far north that the problems connected with their exploitation are much the same as those of the Arctic regions.

These areas are interesting chiefly because of their iron deposits, and this metal has not been reported in large amounts from within the Arctic Circle.

The metals which so far have attracted much attention in the Far North are iron and copper, but gold, silver, lead, and zinc have all been found, and among the non-metallic minerals mica and graphite are reported in commercial quantities. It has long been known that coal exists in considerable quantities north of the Circle. The accompanying map indicates the distribution of the main areas of copper lands discovered up to the present time.

Most Interesting Iron Areas in Labrador and on Islands in Hudson Bay

A number of areas of the Huronian iron formation have been mentioned in geological reports under the head of Cambrian or other systems. Those which have been of most interest are the Nastapoka and Belcher Islands, in Hudson Bay, and the Koksoak River area, in the Labrador Peninsula near Hudson Strait.

LEFT, TYPICAL SCENE IN LABRADOR WHERE COUNTRY IS ALMOST TREELESS. RIGHT, AUTHOR'S CAMP NEAR MOUTH OF GREAT WHALE RIVER, HUDSON BAY

According to Low[1], the Nastapoka Islands form a group about 120 miles long made up of sixty-five islands situated along the east coast of Hudson Bay. They rise to a maximum altitude of 500 ft. and are separated from the mainland by Nastapoka Sound, one to three miles wide and deep enough for the navigation of the largest ships. They consist chiefly of sedimentary rocks, which include iron formation, shale, sandstone, and dolomite and which appear to be Upper Huronian in age.

The iron formation is similar to that found in the Lake Superior region, and consists of banded jasper, hematite, magnetite, and cherty iron carbonate. The formation is exposed on practically all the islands, but the bands of ore in the jasper are thin. No analyses are given by Low, but his descriptions indicate that as a whole the ore is very siliceous and of low grade. The thickest band of good ore mentioned is 4 ft. thick, and this band outcrops on Clarke and Gillies islands. All the sections indicate that, although there are numerous bands of ore, they are distributed through too much jasper to make them of much economic importance. The occurrence of these extensive areas of iron formation with bands of ore does, however, justify thorough prospecting for larger concentrations.

The Belcher Islands have been known locally for a long time, but it was not until 1914 that they were brought to the attention of people outside of Hudson Bay by R. J. Flaherty. In search of mineral deposits for the Northlands Exploration Co., Mr. Flaherty heard of the iron on these islands and visited them in the fall of that year. During the following year he studied this group and prepared a reconnaissance map of the islands. In the summer of 1916, I prepared a report on the iron deposits for Sir William Mackenzie, president of the Northlands company, and found considerable areas of iron formation. The results of this investigation have been previously published in the *Journal of Geology*[2] and the *Transactions* of the Canadian Mining Institute[3]. In making this trip some of the difficulties to be met in navigating Hudson and James bays were experienced. While in the midst of James Bay on July 1, 1916, our small steamer was surrounded by drifting ice, which continued to fill the bay for about five days. The ice snapped the propeller from the ship, and it was only after considerable difficulty that repairs were made. A new propeller was fitted on by dragging the stern of the ship up on the shore of a small island near by at high tide and adjusting it at low tide. The weather was stormy during much of the time, and it was only after many difficulties and numerous vexatious delays that the islands were reached and that the return journey was accomplished.

The Belcher group has usually been indicated on maps as small dots in the southeastern portion of Hudson Bay, but the main islands are of large size, the length being estimated at about ninety miles. One island has a lake within its borders about forty miles in length, according to Mr. Flaherty.

The rocks on these islands are Huronian and Keweenawan. The Huronian series contains sandstone, quartzite, limestone, dolomite, graywacke, shale and iron formation. One of the peculiar features of the limestone is the presence of thick beds of concretions formed by the low and primitive plants known as algæ. The largest of these concretions, which are made up of concentric spheres, are about 15 in. in diameter and the smallest are the little oölites which in some places are replaced by iron oxide, iron carbonate, or iron silicate. It appears that these primitive plants and the closely related iron bacteria have had an important influence in the precipitation of the iron compounds from solution

and the formation of the little granules of iron silicate and iron oxide which are similar to those found in the Mesabi Range of Minnesota.

The sediments on these islands are a continuation of those on the Nastapoka Islands, having been brought above the sea level in this region by folding. They are interbedded with sills of diabase and overlain by flows of basalt of Keweenawan age, the conditions resembling those found around the northern shore of Lake Superior. The islands are treeless, and in many places the rocks are perfectly bare of soil and vegetation, so the strata are as open to observation as the pages of a book. The great bands of jasper and red shale scoured off by the glacier make a very striking appearance, and naturally quicken the pulse of any prospector. The maximum thickness of the iron formation is about 275 ft., but the great bulk of the formation is hard, highly siliceous jasper with bands of slate or graywacke, the whole averaging less than 30 per cent iron. One band 35 ft. thick, measured in the best portion of the formation and carefully sampled, averaged 30.1 per cent iron, with 37.97 per cent silica, 0.039 per cent phosphorus, and a trace of sulphur. There are considerable bodies of this low-grade material close to tidewater. The highest-grade sample taken and analyzed ran 50.7 per cent iron.

The structure of the rock formations is comparatively simple, the dips running from almost nothing to 75 deg., and there is little faulting. There are frequent alternations of igneous instrusions or flows and sedimentary rocks. The iron formation lies immediately underneath a great flow of ellipsoidal basalt, which has spread practically all over the islands.

There has been much discussion as to whether the iron deposits on the Belchers are of economic value. It is my opinion that they are so lean, and the climatic

ALGAL CONCRETIONS IN LIMESTONE ON BELCHER ISLANDS

conditions are so unfavorable, that they cannot be worked at present. Electric smelting with power developed at the falls on the numerous rivers entering the east coast of Hudson Bay might be employed, but even then the conditions do not seem promising. The experiences which I had with the ice in James Bay early in July, in a year when everyone in that part of the country said the ice had broken early, convinced me that only specially constructed ships are safe in those waters. It is probable that as a rule the islands cannot be approached much before July 10, and in some seasons ice is said to remain around the islands until some time in August. Specially constructed ships might safely count on an open season from early July until the latter part of November in normal seasons, but they always run the risk of encountering heavy ice in Hudson Straits during that period. Eskimo labor may be employed for some purposes, but it cannot be relied upon for extensive mining operations.

Koksoak River Area Merits Further Prospecting

On the lower stretches of the Koksoak River, which empties into the head of Ungava Bay, Low[1] has found an extensive area of iron formation, and, although he states that much of the ore is low grade, he speaks of hundreds of millions of tons of ore and an almost inexhaustible supply of high-grade ore. He quotes a number of analyses which show that the metallic iron runs from 19.14 per cent in the lean jasper and garnet-

DOLOMITE MASS, IMPREGNATED WITH CHALCOPYRITE, ENCLOSED IN DIABASE SILL, BELCHER ISLANDS

iferous shale to 54.35 per cent in the better ore. The thickness of iron formation exposed is in some places over 400 ft. The rocks are described as Cambrian in age, but from all descriptions they appear to be the same as those around Hudson Bay, which are almost certainly Huronian.

From Mr. Low's description of this region and other areas one cannot but feel that he was a little sanguine regarding the quantities of high-grade ore seen. Nevertheless, there is no doubt that these areas merit much more extensive and detailed prospecting than Mr. Low was able to give them in his hurried reconnaissance expeditions through that hitherto unexplored country. The main outcrops of the iron formation mentioned occur in the vicinity of Shale Chute, Cambrian Lake, and the mouth of Swampybay River, on the Koksoak River. The locations are such that it should be possible to construct a railroad to the coast without great difficulty.

Scattered areas of iron formation carrying hematite and magnetite ore, but for the most part consisting of lean jasper, have also been reported by Low on the upper portions of the Hamilton River in Labrador. For example, at the narrows into Lake Petitsikapan, a band 20 ft. wide analysed 30.43 per cent iron. On Astray Lake and in a number of other places there are areas which may offer opportunities to prospectors in the future.

Copper Widely Distributed in Arctic Canada

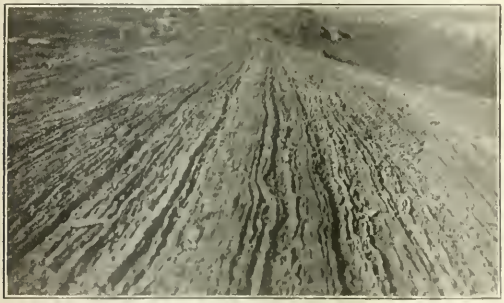
Since the early days of exploration in and around Hudson Bay and on the Arctic islands great interest has attached to the occurrence of native copper in Arctic Canada. The Eskimos, like the primitive inhabitants of Michigan, have long made use of this metal for tools and for other purposes. They have been known to make pilgrimages to the sources of the metal, and many

[1] A. P. Low: "Report on Explorations in the Labrador Peninsula"; Geol. Surv. of Canada, Annual Report, Vol. 8, Rept. L.

attempts have been made by white men, since that of Samuel Hearne in 1771 until the present day, to locate the mother lode. For a summary of the accounts of these expeditions the reader is referred to the articles by Tyrrell,[5] Douglas[6] and O'Neill[7].

There are certain conclusions on which most of the explorers agree. These are: (1) Native copper occurs widely distributed over the mainland and on some of the Arctic islands, and a few pieces of considerable size have been found; (2) the rocks are Keweenawan in age, and in nearly all respects closely resemble those of the copper-bearing area of the Lake Superior basin; (3) few of the areas so far examined contain extensive bodies of pay ore; (4) the probabilities of finding pay ore on a large scale seem promising; (5) great difficulty is experienced in carrying on explorations because of the remoteness of the area and the severe climatic conditions.

The areas in which native copper has so far been found by white men are on the Coppermine River, on Bathurst Inlet and on Boothia Peninsula. According to Stefansson and the members of the Canadian Arctic Expedition, the Eskimos also report deposits at the head of Prince Albert Sound, on Victoria Island. Two other places which have been mentioned are on the shores of Prince of Wales Island and on the Princess Royal Islands. The accompanying map shows the general distribution of these deposits and also the area which was withdrawn from staking for minerals by the Canadian government in 1918. This area lies north of 65 deg. N. latitude and between 105 deg. and 106 deg. W. longitude.



LEFT, A GLACIATED SURFACE ON VERY LEAN IRON FORMATION, SHOWING EFFECT OF DIFFERENTIAL WEATHERING. RIGHT, IRON FORMATION OVERLAIN BY BASALT FLOW, BELCHER ISLANDS

Bathurst Inlet and Coppermine River Deposits Not Directly Connected

According to O'Neill[7], the deposits on Bathurst Inlet are not directly connected with those on the Coppermine River, as formerly supposed. He describes the series as consisting of flows of basic rock with thin beds of sediments and with specks of copper distributed through the ground-mass of the basalt as well as in the amygdules. Copper also occurs as fissure filling. The disseminated copper runs about 0.25 per cent and the amygdaloidal copper will reach several per cent in some localities. The thickness of the amygdaloidal zone will vary from a few inches to several feet. The amygdules also carry chlorite, epidote, prehnite, opal, and agate. In some places the veins are important and carry several per cent of copper. Copper is found on practically all the islands and on the mainland in the vicinity of Bathurst Inlet.

In the Coppermine River area, the Copper Mountains are cut by the river about forty miles from its mouth and form a ridge about sixteen miles wide by forty miles or more long. They consist of interbedded basalt flows and sediments such as conglomerates and sandstones. According to Douglas[6], these rocks assayed in copper as follows: Conglomerates, 0.016-0.09 per cent; sandstone, 0.002; amygdaloid, 0.008-7.77; float, 0.09-43.39. There are traces of chalcocite with the native copper in some places. The most favorable locality mentioned is one on Burnt Creek.

From all descriptions of the copper-bearing rocks of Arctic Canada, a remarkable similarity is seen between the rocks and their copper deposits and the rocks of the Lake Superior basin, and one cannot but marvel at the tremendous amount of metal associated with the basic rocks of the Keweenawan system. Probably in no period of igneous activity in the earth's history has there been a more definite connection between a series of rocks and a particular type of metalliferous deposit. In some cases the zeolites of the Lake Superior region are lacking in the deposits of the Arctic, but they are reported from other areas.

As to climatic conditions, O'Neill claims that the temperature seldom gets lower than 40 deg. F. below zero and that the snowfall is not heavy. There is lignite and bituminous coal on Great Bear Lake and on some of the Arctic Islands. At present, the field is reached by sailing around the north coast of Alaska or by way of Great Bear Lake, and the navigating conditions are extremely difficult. The obstacles in the way of constructing a railroad through the country are not insurmountable, and an abundance of water power is available. From his experiences, Mr. O'Neill seems to be of the opinion that mining operations on a large scale are quite within the bounds of possibility in this region.

Copper sulphide deposits have been found in a number of places. Probably the most important is that mentioned by O'Neill[7] in the southern and western portions of Bathurst Inlet. Here bornite (Cu_5FeS_4) replaces dolomite which immediately underlies the

copper-bearing basalts. One layer is mentioned which is 6 in. thick and assayed 49.87 per cent copper. Another analysis of diabase from a sill showed 1.18 per cent copper in disseminated chalcopyrite ($CuFeS_2$).

On the Belcher Islands, in Hudson Bay, I have seen small masses of chalcopyrite in the dolomite at the contact with diabase sills. A. P. Low[11] mentions the occurrence of several large bands of pyrite, pyrrhotite, and chalcopyrite on the shores of the bay into which the Kogaluk River flows. This bay lies about forty-two miles north of Portland Promontory, Hudson Bay. These are probably the only copper sulphide deposits reported so far that might be of interest to prospectors.

In writing of his explorations in the Labrador Peninsula, Low mentions deposits of pyrites in a number of places. They usually occur in the Huronian schists near the contact with granite. In addition to the deposit mentioned, there are quartz veins charged with pyrites and galena near the mouth of the Stillwater River on the Koksoak River. Half a mile above the mouth of Wabaminsk River, in the eastern portion of the peninsula, a deposit of pure pyrites 100 ft. long by 10 ft. thick is mentioned as occurring in green chloritic schists.

STEAMER SURROUNDED BY ICE, JAMES BAY, JULY 1, 1916

The Paint Hills on the east coast of James Bay are described as consisting of squeezed trap carrying large segregation masses of pyrites, which contain a small amount of silver but no gold. On one of his expeditions Tyrrell[12] found a mass of dark green Huronian schist cut by a highly altered diabase dike 75 ft. wide and containing a large amount of arsenical pyrites. This occurs north of Rabbit Island, on the shore of Hudson Bay.

Very little gold has been found in these northern regions, but it seems probable that with more detailed work the extensive deposits of pyrites will be found to yield this metal. Silver has been found in small amounts in several places. It occurs in the pyrites of the Paint Hills, as before mentioned, and in the galena which is associated with zinc near Little Whale River, on the shore of Hudson Bay. Assays of from 5.1 to 12.03 oz. silver have been reported by Low from this galena.

The lead and zinc ore occurs in a band about twenty-two miles long between Little Whale River and Richmond Gulf, and has been prospected to some extent but without marked success. The ore occurs in limestone or dolomite in this locality, as it does in a number of other areas where these Upper Huronian rocks outcrop.

In a small calcite vein on the Belcher Islands I have seen smaltite and cobalt bloom near a diabase sill. This is interesting chiefly because of its similarity to the occurrence of these minerals at Cobalt, Ont. According to reports, mica has been mined for a number of years by the Scotch whalers on the coast of Hudson Straits, and deposits of graphite have also been mentioned.

From the widespread occurrence of ores and the still more extensive distribution of rock series long notable for their metals, the chances of discoveries of extensive ore deposits in Arctic Canada and adjacent lands seem bright. The very severe glacial scouring which most of that country has undergone has no doubt injured some of the less resistant and more exposed iron deposits. The present climatic conditions are very severe, and they make traveling and mining operations difficult, but detailed prospecting should bring to light some very valuable deposit in that tremendous area, which will make it worth while to overcome climatic obstacles by modern engineering methods.

Mining in Bolivia Hampered by Poor Transportation

The Department of Chuquisaca does not rank with Oruro and Potosi departments as among the important mining regions of Bolivia, according to the U. S. Department of Commerce. The working of such mineral deposits as do exist has been prevented by almost insuperable difficulties of transportation. During 1918 concessions for mining lands covering every class of mineral, from salt to radium, were presented to the departmental government, yet in reality little mining of any kind is carried on, although there is good evidence of existence of copper, silver, lead, and iron ores in the country to the east of Sucre. The presence of copper deposits in the Tarabuco district, about twelve leagues from Sucre, offers probably the best possibility for mineral development. The natives in the country about Lagunillas carry on some alluvial gold mining, and the fact that quantities of precious stones exist in the Tarabuco district is strongly insisted upon in Sucre.

Lake Tahoe Has Shrunken

Lake Tahoe, in California, is often said to occupy an old volcanic crater. This is not a fact. It is true that the region about the lake shows evidence of volcanic activity of various kinds and that the water has at times probably been dammed by outpourings of lava, but the lake itself lies in a structural depression—a dropped block of the earth's crust.

The prehistoric Lake Tahoe was larger and deeper than the present lake, according to the U. S. Geological Survey. During the Neocene epoch and the earlier part of the Pleistocene epoch its water stood much higher than now, but in its overflow it has since cut through the lava dams that maintained it at that height. Distinct beaches that mark the former higher levels of the lake stand about 100 ft. above its present surface, but the water doubtless once stood at even greater heights. At Tahoe City the most distinct of these old beaches is a terrace that stands 35 to 40 ft. above the level of the lake.

Physiological Effect of High Temperatures and High Humidities in Metal Mines*

A Preliminary Study of the Results of Atmospheric Conditions Underground—The Observations Show the Importance of Low Humidity and Rapid Circulation of Air in Hot Working Places

BY R. R. SAYERS[1] AND D. HARRINGTON[2]

ONE of the important problems encountered in present-day metal mining practice is that of providing efficient ventilation, especially in those mines which have high air temperatures and high relative humidities in extensive workings at considerable depths, or in workings where mine fires are found or where there is much oxidation of timber or of ore.

It has long been recognized that mine workers subjected to hot, humid, stagnant air, and to certain harmful dusts in many of our metal mines, contract miners' consumption and possibly other diseases; and though considerable study has been made as to dusts, as well as of temperatures and humidities, in mines in England,[3] South Africa, and of some European countries,[4] little has been done in the United States, especiallly in respect to the effect of high temperatures and high relative humidity.

The following study was made in two comparatively deep copper mines, both with fairly high temperatures and humidities, one in which there was practically no attempt at ventilation and one with a ventilation system of a much more efficient kind than is generally found in metal mines. In both mines, the data were taken at points over 2,000 ft. below the surface and with surrounding rock temperatures generally in excess of 90 deg. F.

In general, the following data were obtained: Surface air temperatures and relative humidities and body temperatures, blood pressure readings, pulse, and time of day. Underground data at each place visited included temperature and humidity readings of air in working places, occasionally rock and water temperatures, temperature of compressed-air blowers, air movement or velocity, kind of work performed, number of workers, exact time each day, as well as body temperature, blood pressure, pulse rate, and other data as to those upon whom or by whom the experimental work was being done.

INVESTIGATIONS IN MINE "ONE"

On three consecutive days, the investigators entered a mine (designated "One") for the purpose of taking data as to the effect of high temperatures and high relative humidity in stagnant air, there being no attempt at ventilation other than from compressed-air blowers, which, however, furnished sufficient air to prevent excessive vitiation. On the first day, data were taken on five subjects, A, B, C, D, and E; and on the two succeeding days on A, B, and C. No work was done other than to walk slowly a few thousand feet underground and to take the necessary readings as to temperature, humidity, velocity, and blood pressure, and in only one instance did the investigators leave the level to climb a few feet into a stope.

The compiled data taken on the three days in mine "One," show that the investigators were in the hot region 120 minutes on the first day, 90 minutes on the second, and 115 minutes on the third. It had been the intention to remain underground at least four or five hours each day, but the effect of the hot, humid, stagnant air was so great that the investigators were physically unable to remain underground much longer than the length of time indicated.

EFFECT OF HOT STAGNANT AIR

It is significant that although A, B, and C had been accustomed to go underground on investigative work regularly prior to making this investigation, at the end of the three days in this hot stagnant air, during which time a total of but 5 hours and 25 minutes were spent underground doing only such light work as walking on level ground and taking temperature, blood pressure, and other readings, A lost six pounds and B lost over five pounds in weight, and though C did not weigh, he lost perceptibly in weight, and all were seriously fatigued each day after leaving the mine.

During the three days in mine "One" there was no period during which the investigators were in temperature (either wet- or dry-bulb) lower than 90 deg. F., and in many cases the dry-bulb reading was 95 deg. F.

At all times there was absolutely no perceptible movement of air except what could be obtained immediately in the current from compressed-air blowers. Even the air from the compressed-air blowers had dry-bulb temperatures above 85 deg. F., and in many tests the air was over 90 deg. F., temperatures being taken at the end of the nozzle of the compressed-air hose. Though compressed-air temperatures were nearly as high as those of the surrounding air, the high velocity and comparatively low humidity when in the direct current gave at least a temporary measure of relief, and this constituted the only relief from the extremely depressing conditions.

The blood pressure fell decidedly when the subjects were exposed to stagnant, humid air with temperatures over 90 deg. F. and below 100 deg. F., and a marked fall in blood pressure was found immediately upon reaching the cooler, purer air of the surface after having been exposed for about two hours to the unfavorable conditions noted. For a considerable time after reaching the surface the rise in blood pressure was slow, even when the subjects took a hot shower bath with a finishing dash of cold water. It was not until after eating, an hour to two hours later, that the blood pressure rose, and then it mounted somewhat higher than before the subjects went underground.

[4]Oliver: "Diseases of Occupation."

Body temperature rose at the rate of approximately 1 deg. F. per hour when exposed to hot, stagnant air with wet- and dry-bulb temperatures between 90 and 97 deg. F., even when no work was being done other than leisurely walking along level haulage roads. This increase of body temperature continued until 102.8 deg. F. was reached in one case and approximately 102 deg. F. in the other cases, or fever temperatures throughout. After having been underground for about two hours under the conditions described, temperature decrease took place in still surface air at about 70 deg. F. and 50 to 60 per cent relative humidity, at the rate of about 1 deg. F. per hour, there appearing to be comparatively little influence in taking the hot shower bath with the final dash of cold water.

The pulse increased rapidly upon entering and remaining in the hot, humid air, and after having been in this atmosphere for about two hours, doing little or no work, as above described, the pulse had reached as high as 130 and occasionally 140 or over. Upon returning to the surface a comparatively rapid decrease of pulse rate was noticed. It, however, did not reach for several hours the same rate as before going underground. In general, pulse rate was high in the hot, humid, stagnant air, and it seemed to be abnormally sensitive to even the slightest exercise. It was found to rise rapidly even in subjects who had been accustomed to hard work under such conditions, as well as in the subjects of this experiment.

Physical Effects Noted

During the first day, all five subjects said that they felt dizzy within twenty minutes after entering the hot, humid, stagnant air, and within an hour all felt weak. B was very nervous after an hour's exposure, and later had alternate hot and cold sensations. C had a dull headache. All subjects perspired very freely, and all appeared unable to think quickly or accurately after less than one hour's exposure. On reaching the surface, all felt well except B, who was very weak for about fifteen minutes. All five complained of feeling somewhat weak for the remainder of the day, and A, B, and C did not sleep well that night, though D and E, who were more accustomed to hard physical work, slept well.

On the second and third days, only A, B, and C went underground, and the symptoms experienced on these days were similar to those felt on the first day, but in a somewhat milder degree. However, after the three days' experimentation, in which a total of less than five and a half hours was spent underground, the exhausting effect of stagnant, humid air with temperatures between 90 and 97 deg. F. was shown in the fact that A and B (C not weighing) had each lost over five pounds in weight, though no work was done, the subjects of the test walking leisurely in unobstructed level drifts.

Observations were made on five miners who volunteered, all being healthy, robust men except V, who was pale and thin (he had worked fourteen years in this mine). While underground the men dressed in shoes and trousers or overalls, usually cut off just above the knees. Underwear or shirts were not worn. Except in case of Z, blood pressure fell perceptibly after seven and a half hours underground in humid, stagnant air with temperature between 90 and 95 deg. F. Blood pressure reacted practically to normal with W and Z after the shower bath, these two men having worked in this mine eleven days and four months respectively; and in the case of X, who had worked twelve days, blood pressure increased perceptibly after the bath. On the other hand, in the case of Y, who had worked his first day in six months, blood pressure fell perceptibly after the bath, this apparently indicating that workers who were accustomed to the conditions had acquired a degree of tolerance, or at least were not as sensitive as were the newcomers. But in the case of V, who did not bathe after returning to the surface, there was a slight drop of blood pressure. He had worked in this mine fourteen years, and was pale and thin, but was active and apparently not physically exhausted by seven and a half hours underground to the same extent as the other more robust men. His work is much less arduous than the other men's, as he is a shift boss.

The pulse rate had risen perceptibly after the men had spent seven and a half hours underground, and, except in case of W, fell quickly after they reached the surface. W showed a pulse rate increase as well as increase of blood pressure after reaching the surface. However, after having been on the surface practically one-half hour after the end of the underground shift, the pulse rate remained perceptibly above normal in every case.

How the Men Were Kept "Fit"

Notwithstanding the obviously unhealthful conditions in this mine, the miners present a generally robust and healthy appearance, this probably being due to three reasons: First, knowing the conditions, the foreman employs only strong, healthy appearing men; second, the men are never hurried or rushed by the shift boss, and in fact are told to "go easy" and "take five" frequently; third, men employed continuously in the hot, humid, stagnant air generally remain for only a few months.

The foreman said that at least 50 per cent of the men employed worked one shift or less, but that if they can last a week they usually remain several months. Though the monthly labor turnover was over 100 per cent, plenty of men were available, as the mine is close to the heart of a large mining community. The men are expected to work a seven instead of the customary eight-hour shift, for which they receive 25c. per day more than employees of neighboring mines with eight-hour shifts; and, as before stated, the workers are rarely if ever hurried by the bosses.

The efficiency of the workers is somewhat difficult to gage, but it is certainly much less than 50 per cent of that of similar workers in other mines. At working faces, while one machine man or mucker works, his companion rests in the full stream of a compressed-air blower, the men exchanging places at intervals of twenty to thirty minutes, and frequently both rest. Moreover, the man working the short interval at the face must work at reduced speed. For example, two men at the face of a drift in this mine, in still air with 96 deg. wet-bulb and 94 per cent relative humidity, muck about twelve tons per shift, though in a drift in an adjoining mine, less than 1,000 ft. away, in moving air, with 82 deg. wet-bulb and 82 per cent relative humidity, two men muck thirty tons or over per shift.

The average of about thirty readings taken at all working faces of this mine gave wet-bulb 93.3 deg. F., dry-bulb 94.4 deg. F., and relative humidity 96 per cent, and at no place was there any perceptible movement of air except at points close to compressed-air blowers. However, though the resultant conditions were undeniably

depressing, little or none of this effect was attributable to air impurity, practically no smoke was encountered, and analyses of air samples taken at working faces showed slight vitiation or none, the large amount of compressed air from blowers apparently keeping the quality of the air good, but not in sufficient quantity to give the necessary velocity to cause cooling by evaporation.

Investigations in Mine "Two"

A second series of readings was taken on two days in mine "Two," a deep mine with extensive workings. This mine, though more efficiently ventilated than most metal mines, has high rock temperatures, and practically any desired condition as to temperature, humidity, and air movement is obtainable. In the mine, the workers are supplied fresh city water at a temperature of about 65 deg. F., and the men say they can drink large quantities of the water without ill effect. They generally work in a suit of underwear, trousers, and shoes, and upon leaving the mine put on a woolen shirt and a heavy coat.

A, B, C, and D entered mine "Two" about two weeks after the completion of the readings in mine "One," spending over an hour the first day at the face of an abandoned crosscut with practically stagnant air, wet-bulb 94½ deg. F., dry-bulb 97½ deg. F., and relative humidity 89 per cent. All were dressed essentially as in the mine "One" investigation, and on the first day A, B, and C remained practically at rest for about seventy minutes. There was comparatively little change in blood pressure during the first forty-five minutes in this atmosphere *at rest*, except that the blood pressure of D fell. At the seventy-minute reading the blood pressure of A and B had fallen perceptibly, though there was little or no change as to the blood pressure of C; and D, who was the youngest and perhaps the most vigorous of the four, had slightly increased blood pressure as compared with the forty-five-minute reading, due probably to slight exercise taken just previous to the last reading.

The body temperature of the four investigators at rest at the face of the crosscut had risen slightly during the first ten minutes after entering the place, and perceptibly at the readings forty-five and seventy minutes after entering, reaching a maximum of 102.6 deg. F. with D at the seventy-minute reading, he having carried a light ladder about 50 ft. during the interval between the forty-five- and seventy-minute readings.

The maximum body temperature of A, B, and C (101.8, 101.4, and 101.5 respectively) was reached at the seventy-minute reading, and none of these men had exerted himself in the slightest other than to take readings of temperatures and blood pressure, and to record similar data. Pulse rate had started to rise slightly at the reading ten minutes after entering the hot, humid, still atmosphere, and continued to rise at the twenty-five,- forty-five,- and seventy-minute readings, except that in case of B and D there was a slight fall in pulse beat between the forty-five- and seventy-minute readings.

After having remained practically at rest for seventy minutes at the face of the abandoned crosscut in stagnant air 97½ deg. F. and 89 per cent relative humidity, all experimenters perspiring freely and having increased body temperature and pulse rate and decreased blood pressure, the men walked about 200 ft. to a point where air was being discharged from the end of a canvas tube at the rate of 2,300 lineal feet per minute, this air having a temperature of 82 deg. wet-bulb, 82½ deg. dry-bulb, and relative humidity of 80 per cent. A, B, and C stopped at the end of this pipe, D going out to the shaft station. A sat with his head in the direct air current about three feet from the end of the canvas tube; B sat at one side somewhat out of the current, C sitting out of the current twelve minutes and partly in the air current three minutes. At the end of fifteen minutes A's temperature fell from 101.8 to 100.9 deg. F., pulse rate fell from 136 to 120, blood pressure rose from 98 systolic to 106 systolic, and from 68 diastolic to 82 diastolic. Meanwhile B, sitting a few feet distant in *still* air with essentially the same temperature and humidity as that of the *moving current* in which A sat, had only a slight bodily temperature decrease of from 101.4 to 101.2, showing the decided influence of *air movement*, even when the air had high temperatures. C, also sitting near A, but within the direct air current only three minutes, showed slight increase of bodily temperature, but had marked rise in blood pressure and definite fall in pulse rate. As in similar readings in mine "One," a definite fall in blood pressure was noted immediately upon reaching the surface, with subsequent slow increase in blood pressure, which returned to normal after the men had eaten a good meal.

Physical Effects Noted

In another series of readings in which the effect of work was studied it was noticeable that there was comparatively little drop in blood presure or increase in bodily temperatures or pulse rate so long as the four investigators remained quiet in the still air with temperature 85½ to 86 deg. wet-bulb and relative humidity 96 per cent. When light work was done, such as climbing up 24 ft. of vertical ladder and then down, with eight to eighteen minutes' rest before taking readings, little or no perceptible change of blood pressure or of bodily temperature was recorded, but the men exhibited a definite increase of pulse rate. When 120 ft. of vertical ladder was climbed up and down in five minutes, with three to fourteen minutes' rest before taking reading, though blood pressure was affected only slightly, there was a perceptible increase in bodily temperature. As climbing up and then down 120 ft. of vertical ladder in five minutes cannot be called strenuous work, it is apparent that attempts at actual sustained performance of hard work under the conditions noted would result in high body temperatures.

Upon coming to the surface the readings were almost normal in all subjects, this being true of blood pressure, pulse rate, and of bodily temperature in all but A, whose bodily temperature remained over 100 deg. F., due presumably to his having exercised somewhat more strenuously than his companions had done. None of the subjects experienced unusual symptoms except A, who thought he became tired more easily than usual.

Summary of Conclusions

In still air in metal mines, with a wet-bulb temperature over 90 deg F., and under 100 deg. F., and with a relative humidity of 89 per cent or above, the following signs and symptoms were found, even when little or no exercise was taken: 1. Blood pressure, systolic and diastolic, fell rapidly. 2. Body temperature rose, and in one case reached 102 deg. F., and this after less than two hours being spent in the hot, humid

air described. 3. Pulse rate increased and seemed more sensitive to exercise than that normally found. 4. Perspiration was very profuse. 5. Dizziness was a common symptom, and sometimes was marked. 6. Physical weakness, or exhaustion, was marked in some cases and was present in all. 7. Inability to think quickly or act accurately was a common symptom. 8. Nausea was occasionally noted. 9. Headache also was occasionally produced. 10. Loss of weight was especially marked in men who have been employed under the conditions of the tests over a period of years, but occurred even after exposure for only a few days.

In still air, with wet-bulb temperatures of from 85 deg. F. to 86 deg. F., and a relative humidity of 96 per cent, there were no marked changes in the blood pressure or body temperature, nor were the symptoms mentioned in the foregoing paragraph, dizziness, physical weakness, and inability to think or act quickly, found so long as the subjects remained at rest or took only light exercise. When moderate exercise was taken—climbing up and down an 8-ft. ladder fifteen times in five minutes—the blood pressure and body temperature rose.

Blood-pressure readings taken after reaching the cool air of the surface were found to vary considerably with men unaccustomed to high temperatures. Under conditions which resulted in rise of body temperature to 100 deg. F. or more, the systolic pressure fell, but where the conditions were such as not to cause the body temperature to rise above 100 deg. F., there was a rise in the systolic pressure when the subjects reached the surface. One man long accustomed to hot, humid air, recorded a fall of systolic pressure. In three others not accustomed to the conditions mentioned, a rise of systolic pressure was noted.

The tests denoted that the body temperatures reached normal in from one to two hours after the subjects reached the cool air of the surface after having been exposed to conditions that caused a rise above 100 deg. F.

It was noted that a shower bath, beginning with tepid water and ending with a dash of cold water, had little immediate effect upon the body temperature.

Dewatering Coarse Concentrates

Such Material May Be Put in Bins and Allowed To Drain, or More Elaborate Methods May Be Employed

REMOVAL of excess water from coarse table concentrates is usually considered a simple problem, as simple as the filtering of flotation concentrates is difficult. The latter, especially when the pulp contains clay or much slime, often causes considerable trouble, and unless the mass is made more porous by the admixture of coarser material, only a very thin filter cake can be made. For this reason, in combined table and flotation plants, all of the concentrates are often run together to the filters, and, where this is necessary, the practice affords a good solution of filtration difficulties which would otherwise be encountered. However, it is a good policy to try to handle at least a part of the coarse concentrates separately, as, in themselves, they do not require filter treatment, and the smelter superintendent is always glad to have a little of the coarser material by itself to sweeten his disposition after trying to get the sticky filter cake from the cars to his roasting furnaces.

The simplest way of removing water from table concentrates is to run them into a wooden bin with enough small openings in the bottom to allow the water to drain out. In this case, however, some provision must be made to take care of the water, and conditions under the bin are very sloppy. Sometimes the planks in the bottom of such a bin are spaced an inch or two apart and the whole is covered with screening or burlap. Some of the water should preferably be removed before the material goes to the bin. One convenient means for doing this is in use at the Arthur mill of the Utah Copper Co. The table and vanner concentrates are dewatered by four three-section Dorr classifiers equipped with filter bottoms made of wire screen, canvas, and burlap, under which a slight suction is maintained. The product is quite dry, but is mixed with the very fine flotation concentrates in order to make a pulp more easily filtered.

Another means for doing the same thing is in use at the mill of the Magma Copper Co., Superior, Ariz. The Wilfley roughing table concentrates are dewatered in an ordinary Akins classifier arranged over a bin into which it discharges. The product runs about five per cent moisture, and the upkeep on the machine is slight.

At the Old Dominion mill at Globe, Ariz., a more elaborate system is used. The concentrates are dewatered in concrete tanks with bottoms covered with coco matting, a slight vacuum being carried underneath. The pulp is distributed by revolving arms so that the tanks are evenly filled. When the concentrates have accumulated to near the top of the tank, the feed is stopped and the water drained off. A plug in the center of the bottom of the tank is then pulled out, and a Blaisdell excavating machine plows the material to the central hole, through which it drops into the cars, which have been spotted underneath. This scheme has the advantage of delivering the dewatered concentrates into cars for shipment.

Iron, Zinc, and Aluminum for Coins

Germany has ceased to use silver for coinage, but is employing iron, aluminum, and zinc for the purpose. In February, 1,168,251 marks were minted in iron 5-pfennig pieces, 2,166,457 marks in zinc 10-pfennig pieces, and 3,605,137 marks in aluminum 50-pfennig pieces. The shortage of nickel and copper has no doubt precluded the use of those metals. In British West Africa, one-shilling notes have been issued as a substitute for the silver coins which have found their way into the melting pot. Twenty-five cent notes are also used to a small extent in Canada, and are convenient for mailing small remittances.

Lead and Zinc in India

The chief deposits of India are those of the Bawdwin mines in the Northern Shan States (Burma). There was estimated Dec. 31, 1917, 4,033,000 tons lead-zinc ore, assaying 24.7 oz. silver, 27.4 per cent lead, and 19.1 per cent zinc. The essential constituents of the ores are galena and sphalerite, with a little pyrite and chalcopyrite. The lead and zinc concentrates are available for the customary methods of smelting. A zinc-distilling and sulphuric-acid plant is being constructed at Sakohi, with the aid of the Indian government, to treat the table-zinc concentrate. The company operates a lead smelter at Nam-Tú, eleven miles from the mines.*

Roasting Zinc Concentrates in Suspension

New Type of Furnace, Developed at the Case School of Applied Science, Appears Worth a Trial On a Commercial Scale — Surrounding Each Sulphide Particle With Heated Air Effects Quick and Efficient Oxidation

BY CHARLES H. FULTON AND J. BURNS READ
Written for *Engineering and Mining Journal*

FINELY divided zinc sulphide ores now produced in large quantity by the flotation process may be roasted in gaseous suspension by the furnace to be described in this article. In furnaces of the ordinary type, in which the fine ore is forwarded through the furnace in the form of a shallow bed or beds, the very fineness of the ore leads to dense impervious bedding, preventing oxygen from reaching the interior of the bed, thus unduly lengthening the time of roasting and preventing the elimination of the last of the sulphur. Normally, the fineness of the concentrate should lead to a rapid and complete roast, for the speed of roasting is a function of the surface exposed to oxygen, which surface is greatest per unit of weight in very fine material.

The difficulty in bed roasting is to get the oxygen to the particle. If the fine ore during the roasting could be freely suspended in oxidizing gases, full advantage could be taken of the great surface conferred by its fineness. This principle is not new. The Stetefeldt furnace, familiar to the older metallurgists, is a classic in this respect. Nevertheless, although the broad conception of roasting in gaseous suspension is not novel, the manner in which this is accomplished may be so.

An analysis of the literature on roasting in gaseous suspension leads to the following classification of apparatus:

Class I. Furnaces in which finely pulverized ore is *dropped* into the furnace, usually of the shaft type, with or without baffles or shelves to break the path of the falling ore. There are three sub-classes:

(a) The ore is dropped from the top of the furnace against a rising current of gaseous products of carbonaceous combustion. (Examples: Stetefeldt, U. S. Patent 43,140; 72,931, reissue, 8,266; J. P. Arey, 103,066; J. H. Ray, 303,456; R. E. Wickham, 829,819.)

(b) The ore is dropped from the top of the furnace against a rising current of air. This may be accomplished by surrounding a vertical muffle with hot products of combustion and dropping the ore down the muffle; or by heating the ore first to a red heat and then dropping it down a vertical shaft. (Examples: J. S. Briggs, U. S. Patent 53,266; M. D. Brett, 188,098; J. E. Rice, 275,272; C. J. Fauvel, 503,839; C. L. Priestone, 534,517; J. E. Greenewalt, 551,725; J. E. Greenewalt, 717,093.)

(c) The ore is dropped down a shaft with the descending current of the products of combustion and air. (Examples: H. Hutchinson, U. S. Patent 414,051; A. S. Wilfley, 898,024; A. S. Wilfley, 930,254.)

Class II. Furnaces in which finely powdered ore is *blown* into a shaft or chamber which is heated by the burning of carbonaceous fuel, by coal burnt on a grate, by pulverized coal, or by oil or gas burners. In all cases the furnace space is filled with the products of carbonaceous combustion, and the ore is blown in either by hot or cold air or by steam. (Examples: J. L. Constable, U. S. Patent 39,257; Whelphley and Storer, 41,250; J. W. Bailey, 117,363; F. W. Wiesebrock, 241,108; C. E. Robinson, 246,690; H. E. Parsons, 292,944; O. H. Tobey, 315,089; W. Brueckner, 321,003; J. J. Storer, 613,828; Sutton and Steele, 729,008; L. S. Hughes, 920,333; L. S. Hughes, 920,334; J. W. Thomas, 1,084,175. Also patents 1,160,621 and 1,164,653, to Klepinger, Krecji and Kuzell for smelting furnaces in

FIG. 1. 30-FT BRICK COMBUSTION CHAMBER ERECTED IN THE CASE LABORATORY

which a mixture of ore and fuel and flux is injected by means of a burner for pulverized coal into a revolving cylinder or a reverberatory furnace by means of air, preheated in regenerative stoves.)

Class III. Roasting devices in which finely divided ore is blown into externally heated coils of pipe by means of air, hot or cold, or steam. (Examples: U. S. Patent 136,261 and 236,739.)

Former Objections to Furnaces of This Type No Longer Hold

The numerous efforts to roast in gaseous suspension point clearly to the fact that the idea is attractive; in fact, an analysis would indicate it to be the most reasonable way to effect the oxidation of ore, provided certain difficulties can be overcome. One of the objections against such a method which formerly had such weight as to counterbalance any possible advantages was that the cost of fine grinding the ore was too great, and, further, that the finely ground product, even after roasting, was unsuited for further metallurgical operations. The former objection, however, has been removed by the production of great quantities of flotation concentrate, which, in point of fineness, present a material that is ideal for roasting in gaseous suspension.

The inception of the experiments on which the information given in this paper is based is due to David B. Jones and March F. Chase[1]. The general type of furnace and the process were suggested to the authors, and the experimental work was carried out in the metallurgical laboratories of the Case School of Applied Science, at Cleveland. The fundamental purpose was to make a furnace for roasting zinc blende flotation concentrate that would use the heat value of the sulphide to accomplish the roast and to produce a gas suitable for making sulphuric acid, i.e. of sufficient concentration in SO_2 and practically free from the products of carbonaceous combustion. Auto-roasting of sphalerite is theoretically possible[2], and also practically, as was demonstrated in the experiments which were conducted.

The flotation concentrate used in the furnace was a complex sulphide containing 31.4 per cent sulphur, 44.3 per cent zinc, and 11.6 per cent iron. With good running conditions, the sulphur was reduced to 3.6 per cent, and a minimum of 2.2 per cent was obtained. Much of this, especially in the finest particles, was in the form of sulphate, due to resulphatization of the roasted ore.

A diagrammatic drawing of the roasting furnace and accessory apparatus as erected is shown in Fig. 2 and

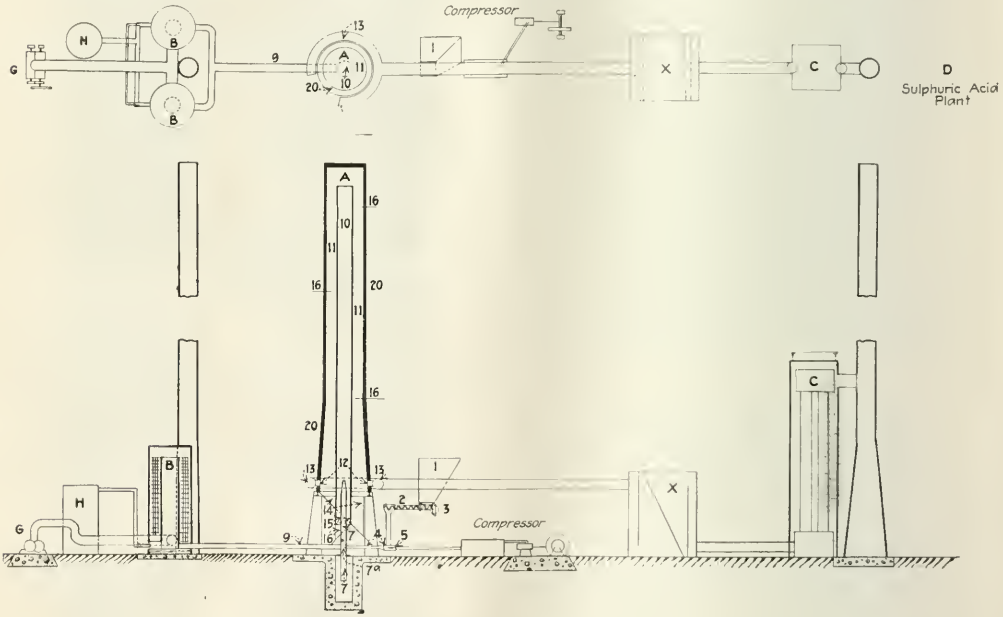

FIG. 2. GENERAL ARRANGEMENT OF EXPERIMENTAL APPARATUS

a photograph of the combustion tube in Fig. 1. In Fig. 2, *A* designates the furnace proper; *B*, the two stoves, heated by natural gas, which serve for pre-heating the air; and *C*, the Cottrell electrical precipitator for the precipitation of flue dust and fume carried from the furnace by the gases, which, in a commercial plant, would pass to a sulphuric-acid plant. *H* indicates the gas supply for the stoves, and *X*, the dust chamber. *G* is the cycloidal blower, furnishing air to carry the ore in suspension in the furnace. The dried, pre-heated ore (60 to 100 deg. C.) is charged into the hopper *I*. The screw conveyor *2*, operated by a variable speed electric motor *3*, permitting a range in the rate of feed, discharges the ore into the pipe *4*, directly above the nozzle *5*. Through this nozzle a stream of high pressure air (20 to 60 lb.), moderately pre-heated, is discharged

[1]The work was carried out for David B. Jones. The authors wish to make grateful acknowledgment to Mr. Jones and Mr. Chase for much aid and many valuable suggestions.

[2]J. W. Richards, "Metallurgical Calculations," One Vol. Ed. p. 620.

in only such quantity as readily to carry the fine ore in suspension through the pipe *4*, into pipe *7*, on the injector principle. Pipe *7*, of larger diameter than pipe *4*, is lined with refractory material and serves as the main injector pipe into the furnace. Air heated to approximately 800 deg. C., coming from one of the stoves *B*, enters the injector pipe *7* through the refractory lined supply pipe *9*, this being the main air supply for roasting the ore.

Regulation of Air Supply

The amount of this air supply is governed by two principles: 1. The quantity must be correct to roast the ore and to furnish a gas of the correct composition for the manufacture of sulphuric acid. Every pound of sphalerite required 35.7 cu. ft. of air (standard conditions) to convert the zinc to oxide, the sulphur to dioxide, and the dioxide to trioxide. Some excess must be carried, and, in the experiments, from 41 to 55 cu. ft., and sometimes 75 to 100 cu. ft., were used, as measured by meter. 2. Such a relation must exist between the quantity of air per minute and the area of the riser tube *10*, that the velocity of the ascending air current will be great enough to carry the largest ore particle to the top of this tube and over the edge. Fortunately, the requirements for both conditions can be fulfilled readily.

Pipe *4* enters the main injector pipe *7*, by means of a nozzle *7a*, turned upward. The mixture of ore and high-pressure air entering the main injector pipe with a rotary motion is caught by the ascending hot air from the pipe *9*, and injected into the riser tube *10*, from the mouth of the injector pipe *7*. The fundamental purpose is to have the temperature of the ore-air mixture at the ignition point of zinc sulphide, (between 650 and 810 deg. C, dependent on size of particle), as it leaves the injector tube to enter the riser tube, so that the full time of the ore particle in the furnace will be available for oxidation. After leaving the riser tube *10*, the ore particle falls in the annular space *11*, the area of this space being large so that the natural velocity of fall shall not be augmented by the velocity of the descending gases.

Time Required

The gas envelope surrounding the ore particle is probably constantly changing, fresh oxygen being supplied to the particle. The time element necessary for the roast is furnished by the time of its travel up the combustion tube and its fall in the surrounding annular space. This is controlled first by the height of the furnace, the length of travel being practically twice the height; and second by the velocity of the ascending air current in the combustion tube. Assuming a definite ratio of cubic feet of air per pound of ore, the velocity will then be determined by the area of the combustion tube. Definite figures on this point are given subsequently in this paper. In any given furnace, i.e. a fixed area of combustion tube, variation is allowable in the velocity of the ascending gas current, obtained by varying the amount of air, which will then vary the time of the ore in the combustion tube. Too high a velocity, obtained either by too much air only or too great an ore feed, with its correspondingly increased amount of air, will shorten the time element too much, so as to eliminate sulphur insufficiently.

The greater part of the ore collects in the hopper *14*, the gases and fine dust passing out through the openings *12* into the flue *13* and thence to the settling chamber *X*, where the coarser dust is settled out. The gas then goes to the Cottrell precipitator, *C*, for the precipitation of the finest dust and fume. This outlines the process and furnace.

The points of importance are as follows:

(a) The ore travels with the gases, and hence cannot be blown from the furnace before it travels the length of its path, which is essentially twice the height of the furnace.

(b) No carbonaceous gases are present, so that the SO_2 can be utilized for sulphuric acid.

(c) The ore is roasted by the heat developed by the combustion of the ore. Some fuel is necessary for preheating a certain amount of air. This pre-heated air is considered essential to obtain early ignition in the furnace, to get a complete roast. What amount of the total air must be pre-heated can be determined only by a commercial-sized furnace. The question of amount of pre-heated air is again discussed further in this paper.

(d) The furnace will make more flue dust than the usual type of mechanically operated furnace. However, this flue dust will be completely roasted, whereas in the usual type it is not.

(e) The furnace contains no mechanical movable parts in the heated zones. This means a low repair and depreciation cost as compared to the usual type of mechanically operated furnace.

(f) The labor cost will be low. One man can take care of a 50-ton furnace.

(g) The power required to operate the furnace will be about the same as that necessary for the usual type of mechanically operated furnace.

Heating the Air

Insufficient data are available with regard to how much of the air must be heated and to what temperature heating should be carried for the most efficient operation of the furnace. Obviously, one of these four methods must be used:

1. Heating all the air and passing all of it through the mixer tube and into the furnace with the ore. This will require large stove construction and will not admit of air changes in various parts of the furnace, as will be desirable for proper control.

2. Heating all the air and passing only a portion of it into the furnace through the mixer. The remainder would be put into the combustion tube at various points. This method is not desirable, as the heat is needed in the bottom of the furnace for heating the ore and bringing about early ignition.

3. Heating none of the air. Present indications are that this will not be possible, as already explained.

4. Heating a part of the air, (say one-fifth), which will be passed into the furnace with the ore through the mixer; the remainder of the air to be admitted cold at points throughout the height of the furnace.

This method will make all the stove heat available for ignition and for holding down the combustion zone, and permit the use of cold air for combustion and temperature control of the top of the furnace. Of course, the stoves should be of ample capacity and of such construction as to permit of changing the temperature and amount of air going into any part of the furnace as necessary.

Under the first condition, assuming 300 deg. C.

necessary for mixer temperature, the air in a 50-ton furnace must be heated to 350 deg. to heat the ore if it is being fed cold. If the ore is coming direct from the drier, this temperature may be reduced somewhat. Three stoves of the following dimensions should be sufficient for a 50-ton furnace: 1,060 sq.ft. heating surface, 246 flues, 4 x 4-in. cross section, 14 ft. long, and 3.25 in. walls. Total height, allowing for gas and air ports, foundation and dome, about 25 ft. Diameter, about 12 ft. Cross section of combustion chamber, 12 sq.ft.

Under condition No. 4, which seems the most promising, such stoves would be larger than required, but not necessarily inefficient, and would provide for emergencies where the heating of all the air was necessary. The ratio of fuel necessary for heating all the air to 350 deg. to that necessary for heating one-fifth to 600 deg. is about 1 to 2.5. This is a material saving in favor of the fractional heating.

Drying the Ore

Feed for this type of furnace must of course be dry, or it will not pass the feeder and injector. Most of the concentrate delivered at the roasting plant probably would have to be dried before feeding, and it was planned to do this drying with the waste heat in the gases leaving the furnace by circulating them beneath the hearth of an ordinary kiln drier. That there is sufficient waste heat available for this purpose can be readily calculated. In the experimental furnace, the gas left the furnace at 800 deg. C. under conditions of best roasting. The volume of this gas (measured under standard conditions) was approximately 50 cu.ft. per lb. of ore roasted, and was made up of about 8 per cent sulphur dioxide, 10 per cent oxygen, and 82 per cent nitrogen. The fact that sufficient waste heat was actually delivered by the small experimental furnace would seem to remove any doubts that enough heat would be available for completing the roast and maintaining furnace temperatures on a furnace of commercial size, well insulated.

The ore from the drier will contain some lumps formed in the drying and some coarse particles that will not work well in the feeder, and it was planned to interpose a vibrating screen between the drier and the feed hopper to remove these.

Capacity Varies With Size of Combustion Tube

Evidently, the capacity of these furnaces will vary as the square of the diameter of the combustion tube. This is substantiated in the results from the 9- and 12-in. combustion tubes that were used in the experimental furnace, which had capacities of 2 and 3.6 tons per twenty-four hours respectively. Assuming similar conditions as to ratio of air and ore, and the velocity in the combustion tube, the diameter necessary in the tube of a 50-ton furnace will be 45 in. For a furnace of this capacity it might be better to use two tubes of a combined area equal to 45 in. diameter, or 32 in. diameter. Such an arrangement would provide for repairs in feeders, nozzles, and injectors on a part of the furnace without complete shutting down, with attendant cooling.

Details of Probable Cost

To give figures of the cost of this type of roasting furnace and its operation that would be applicable to present conditions is impossible, and therefore only a brief analysis of cost based on pre-war conditions for a 50-ton furnace follows:

		Cost per Ton
Labor, 6 men, $19 80 for 24 hours		$0 3960
Power: compressor, blowers, drier and feeder, 26 kw.-hr. @ ¾c.		0 1998
Fuel for heating stoves (coal for producer gas)		0 0820
Interest and depreciation, figured on total costs as follows:		
Producer	$4,500	
Furnace	17,000	
Feeders	500	
Screen	500	
Drier	2,500	
Stoves	18,000	
Cottrell	12,000	
Piping and flues	800	
Compressor	1 200	
Blowers	1,000	
Housing and incidentals	7,000	
	$65,000	0.5290
General charges		0.0791
Repairs		0.1000
Total cost per ton		$1.3859

Many of the most important items in this table were taken from actual bids and were dependable for the time. Repairs, labor, and overhead cannot be definitely determined except in actual operation, but the charges given are the result of careful study and comparison. Repairs should be small compared with other types of roasting furnaces, because of the removal of all movable parts from the heated portions of the furnace. The main repairs will be in the feeder parts and injecting nozzles, which will wear because of the abrasiveness of the ore. Under continuous operation the interior of the furnace would deteriorate little. Therefore, the repair cost, like the other items, is conservative, and the total compares favorably with that of other types of furnaces now in common use.

Leasers and Lessees

An enthusiastic youngster was "Seeing America First" via the Cinderless Limited. At San Antonio the glad-hand expert of an organization of professional boosters edged up toward the good thing and permitted Bertram to break the ice. Soon the longhorn bid the attendant of the observation car to bring cracked ice and a mysterious brand of ginger ale, of which Bertram also partook. The ensuing conversation brought out the fact that a select group of Texans had acquired operating rights in a marvelously rich silver mine in Chihuahua. The narrator had just about decided to mortgage his Oklahoma birthplace, recently inherited, to equip the mine with some necessary machinery for sinking a shaft lower than the ancient workings. About a day later Bertram's father, in New York, received a message from El Paso to the effect, "Stopping over to see valuable silver mine in Old Mexico. Leasers shipping eight-hundred ounce ore from surface workings. Offer me opportunity to purchase half interest. Telegraph Frost National Bank twelve thousand dollars my credit." Father, being a methodical old lawyer, looked up the word "leaser" in the Century Dictionary, page 3,391; and then telegraphed, "Cease dealing with parties of the third part and proceed at once to Grand Cañon."

Increased Value of South African Gold

The Transvaal Chamber of Mines estimates the value of the April, 1920, output of gold at £5.125 per fine ounce, which represents an increase of £600,017 in the total value of the month's production. The amount of gold produced by the gold mines of South Africa in April was 683,962.456 fine ounces.

Prominent Metallurgical Engineers

John Brown Francis Herreshoff

IN OUR issue of May 22 we referred to "the late J. B. F. Herreshoff." "The late J. B." soon after called us up on the phone and convinced us of the truth of Sir Oliver Lodge's theories by inquiring from us if we knew the exact date of his demise. He subsequently materialized and called in person, and to the nude eye seemed not at all "late" but very much on the job. Dr. Herreshoff looks, as his photograph (taken especially for us the other day) shows, possibly a little rising fifty. He still has the biceps of our old hero John L. Sullivan, and the color of youth. When a boy he became interested in hygiene and physical culture, and he ascribes his extraordinary vigor to the pursuit of both. Dr. Herreshoff attended Brown University, and was afterward a member of the faculty, teaching chemistry. Although he did not graduate he was later awarded several degrees by that institution. Both the metallurgical and chemical professions have profited greatly from the inventions of this distinguished engineer. Younger metallurgists are probably not familiar with the Herreshoff blast furnace, inasmuch as it has been superseded by oblong furnaces with greater capacity. This was a circular, steel-jacketed, water-cooled furnace, and even more of an improvement over the old brick furnaces which it displaced than the modern furnaces are over the Herreshoff. It was designed for the Nichols Copper Co.'s Brooklyn plant but was also widely used by the Canadian Copper Co. at Copper Cliff, and in the Ducktown district in Tennessee. A feature of the furnace was a detached, portable forehearth.

J. B. F. HERRESHOFF

Better known today is the Herreshoff roasting furnace, by reason of its extensive use at the Calumet and Arizona smelter and elsewhere. Dr. Herreshoff did not like the way the rabble arms were rigidly attached to the shaft of the old McDougall roasters, and he substituted a light, hollow air-cooled shaft for the solid 8-in. shaft of the original. The principle of quickly-removable rabble arms, first devised by Dr. Herreshoff, has been widely applied.

The refining of copper was not neglected. When Herreshoff began experimenting on this phase of the copper industry, electrolytic refining was practiced only in a very small way in two different works in the United States. The present Nichols Copper refinery, the second largest in the world, is a monument to his genius. The suhphuric-acid industry has also benefited greatly from Dr. Herreshoff's inventive ability. First he greatly improved the atomizers used for the injection of weak acid into the chambers. Great improvements were also made in the Gay-Lussac towers. He then devised the Herreshoff tower, a modification of the Glover tower, of much longer life, and which permitted a much greater concentration of acid. This acid was further concentrated by a distillation apparatus of his own design. It was really in connection with pyrites burning that the Herreshoff roasting furnace, already mentioned, was developed, so that every stage of the chamber process of sulphuric-acid manufacture was much improved. Not content with this, however, he adapted the contact process to American conditions, and economized the operations to such an extent that that method of acid manufacture is thoroughly established.

Throughout his career Dr. Herreshoff has been associated with the same interests. From 1875 to 1890 he was with the firm of G. H. Nichols & Co., from 1890 to 1900 with the Nichols Chemical Co., and after 1900 with both the Nichols Copper Co. and the General Chemical Co. He is now vice-president and trustee of the Nichols Copper Co. and a director of the Granby Consolidated.

The work which Dr. Herreshoff has done has not gone unappreciated. Among other honors he was the first to receive the Perkin medal of the Society of Chemical Industry, given "to that chemist in the United States who had accomplished the most valuable work in applied chemistry during his career." This was awarded in 1908. At that time three predominant traits in Dr. Herreshoff's character were emphasized: his modesty, his simplicity as contrasted with "duplicity," and his freedom from all thought of self. "He has been a scientist in the highest sense of that term."

BY THE WAY

Experienced

The suggestion has been made to Senator Harding that, in the event of his election, it would please engineers generally if Herbert Hoover were made Secretary of the Interior. It certainly would, in our opinion. Then, too, as Food Administrator, Hoover has already had a lot to do with our interior.

What's in a Name?

The Turkey Fat concentrator near Commerce, Okla., has been renamed the "Dinty Moore," and the Never Sweat from now on will be called the "Maggie." A third mill of the same company, now known as the "Cactus," will probably be rechristened by the operators, who are evidently admirers of George McManus and his magnum opus, "Bringing Up Father." The syndicated humor of our daily papers makes us feel at home, whether we go east, west, north or south. It is a common bond which the Reds must destroy if they would disrupt the nation. What will happen when Mutt, Jeff, and the Hall Room Boys make their final bow? But why rename a concentrator unless it be that thus the jinx that has queered the recovery will be dispelled? Naming a mine is like naming a baby, only one need not be so careful. In a recent news item we note that "Porter & Seaman are concentrating their efforts on the Jackass mine." Such a name would never do for one's offspring, but a mine is another matter.

Diversified Industry Again

Inhabitants of desert camps need no longer fear their dependence upon the mining industry alone. A specialist in Buffalo has written an Arizona postmaster seeking five thousand pounds of snakes and offering 30 cents a pound. This, however, is an opportunity only for such camps as are favorably situated near serpentine occurrences. It will also be of benefit only so long as the market remains good. So important would be the establishing of such a supplementary industry that the *Journal's* market editor might be persuaded to quote snakes weekly, if he were approached diplomatically and a sufficient number of people appeared interested. Readers are warned, however, that no matter how firm the market stays, it is inadvisable to introduce snakes into a snakeless community and to attempt to raise them, as if they were squabs or Angora goats. Snakes excel slide rules in multiplying. But for a desert community where the snake supply is steady and not too abundant the idea is worth considering.

A Bar Story

On the loading platform of a forwarding house at old Maricopa, in Arizona, years ago, there was an imposing pile of bullion bars, each weighing about 200 lb. and each stamped as the product of a Mohave County silver mine. The pile was there for months, awaiting settlement of litigation. One morning it was noted that a bar was missing. Investigation soon showed it had been taken by two men, presumably tramps, overcome by a vision of sudden wealth. A short way westward the unweildy bar was found to have been chopped in two with a stolen axe. Each man had then staggered along under his 100-lb. load for several miles further on the way toward California. Then, the load of riches too heavy to be carried further, the half bars had been abandoned. The most interesting feature of the incident is that the glittering metal was about nine-tenths lead.

When Scot Writes Scot

A blue ribbon, if nothing more, should have been given the writer of the following letter, which was received by the manager of a certain copper company in Arizona during the war:

Pardon the liberty I take of addressing you, but I would be pleased to have you help me toward a solution of my desires. First of all, I may state that I am from the land of "peet reek" and the "Dochan Doris," and possibly this is the reason I find myself prompted to take the liberty of writing you, as I understand you are likewise from Caledonia, and therefore may be moved to a spirit of sympathy toward a fellow countryman.

On April 17 I applied to your company for a position as stenographer, and under date of April 20 received from your chief clerk the usual epitaph to applications for jobs: "Your application has been placed on file for future reference." Now, I am asking that you have your chief clerk refer to his files and show you said application, with attached references, and if you have anything to offer me, and consider same worthy of your consideration, I would be pleased to have a line from your facile pen.

I may state that I am willing to turn my hand to anything there is money in, provided the salary is, or exceeds $130 per month, and if you will bear with me a little while I will justify my statement of being able and willing to tackle "anything." In 1915 I was interested, financially, in the local agency of the ——— company at ———, being cashier, at that point, but owing to a misdemeanor of my unscrupulous partner, who absconded with our female stenographer and $1,500 of my money, I got stranded. Being at that time prompted with a desire to serve the old country, I hied myself to Galveston and joined a British ship, then requisitioned by the Admiralty, and signed on as fireman. You will agree with me when I draw the comparison between a cashier's desk and working before the blazing fires in the bowels of an ocean-going "tramp," that this demonstrates Scotch grit. After buffeting the waves for five solid weeks in one of the awfullest storms I ever saw or heard of and being chased by a "U" boat, we put into Le Havre, France, from which point we sailed up the coast to Boulogne, France. At this point I developed a fever, and was sent to a military hospital, where after spending six long weeks in bed I proceeded to my old home in Bonnie Scotland, and after recuperating there was given my passport by the Foreign Office to return to America.

I have been in office work too long and am getting somewhat tired of the confinement, and would like to get something on the outside where the remuneration is equally as good, and would therefore be pleased to have an expression from you as to whether or not you could place me somewhere over there under your jurisdiction, where there would be a chance of getting ahead, and making some money, as I need it, and need it worse, to send it to my old home, surrounded as it is by the horrors of war. As we read in Proverbs, 27-2 "Let another man praise thee and not thine own mouth," will say I can furnish additional references both as to my financial standing, and otherwise, should you so desire.

Thanking you for giving this matter your kind consideration, assuring you same will be appreciated, and with kind regards, I beg to remain,

Yours very truly,

I met a fellow here by the name of ——— (who I understand worked for you once) and his "nose is just a sicht we drink in drams" that I am afraid he will have to betake himself to that state where everybody is like unto a "camel," otherwise I am afraid he will "weaken" over here.

Hope you will not consider that I have been overbearing in these elucidations.

CONSULTATION

Concrete Furnace Hearths

"We would appreciate any information which you may be able to give us relative to the use of concrete in the construction of hearths in mechanical roasting furnaces. We are under the impression that concrete has been used for this purpose by some of the leading copper-smelting plants in the roasting of copper and iron pyrites. We would also thank you to advise us regarding the composition of the concrete used, the temperature which such hearths have stood, and the greatest period of time."

The hearths of mechanical roasting furnaces are commonly made either of fire brick or ordinary red brick. Fire brick will of course stand a higher temperature, but red brick seems perfectly satisfactory for temperatures ordinarily maintained, which will not, in general, exceed 750 deg. C. for roasting copper sulphide ore. Red brick, of course, is cheaper. Sectional cast-iron drier hearths are sometimes used, as at the Copper Queen smelter, and, if sufficient room is allowed for expansion, are satisfactory. The Copper Queen roasters, which are 8-ft. furnaces of the McDougall type, use red brick on all but the drier hearth. Concrete hearths were tried at that smelter several years ago, but would not stand the heat. Concrete hearths have also been tried and condemned by the United Verde at Clarkdale, in Wedge furnaces. The principal trouble there was that the arches swelled, allowing the rabbles to run on the hearth floor and thus wear out quickly, at the same time reducing furnace capacity. We are also under the impression that the Anaconda company once built one of its Anaconda type furnaces of concrete, with the result that it had to be shut down in a week. The company now uses silica brick of its own manufacture. The A. S. & R. Tacoma smelter tried concrete hearths a few years ago, and later threw them out.

We have heard the statement made that if concrete hearths were properly hardened and dried out before use, they would be satisfactory. Possibly some of our readers who have had success with concrete can give a more favorable account of the use of this type of hearth construction. We note that Professor Hoffman, in his "Metallurgy of Copper," states that Evans-Klepetko furnaces at Great Falls, Mont., have been successfully operated with concrete hearths, a mixture of 1 part portland cement, 2 parts tailing sand, and 4 parts crushed slag being used.

Uses of Gypsum

"Will you kindly tell me where I can find detailed information on uses, treatment, and other facts concerning gypsum?"

Gypsum has a wide variety of uses, which during the war found especial application as a structural material and as an ingredient of portland cement. Because of their light weight and fire-resisting qualities gypsum boards, blocks, and tiles are increasing in demand. Particularly in hurried emergency construction are gypsum materials favored. A building plastered with gypsum dries rapidly, enabling construction to proceed with minimum delay. Although as a plaster alone gypsum may be weak, when combined with other materials it is admirably suited for special purposes. Thus plaster board consists of sheets of gypsum plaster fabricated between sheets of some tough, fibrous binding material, such as felt.

As a fertilizer gypsum is advantageously used on some soils and crops, and may play an important part in agricultural pursuits where intensive cultivation is desired. There are other minor uses of gypsum, which, briefly and partly enumerated, are as common blackboard crayons, as a flux in certain methods of lead smelting, in filling cotton cloth and paper, as a base for paint, as an adulterant in food, in the manufacture of buttons, as a bedding for plate glass, in molds for pottery manufacture, in cheap statuary, for surgical casts, and in dental work.

The technology of the treatment of raw gypsum and much valuable information regarding the United States gypsum resources is contained in Technical Paper 155, "Gypsum Products," published by the U. S. Bureau of Mines.

Lime Production

"What percentage of lime production is used in metallurgical work?"

During the year 1918, which is the last year for which the complete statistics are available, 7.9 per cent of the domestic production of lime was used in metallurgy. The largest amount was used for construction purposes, 28.5 per cent; agriculture consumed 12.2 per cent; and paper mills 10.1 per cent. The total production, according to the United States Geological Survey, was 3,206,016 short tons.

Electrostatic Precipitation

"Does electrostatic precipitation successfully separate gases? What is the general principle upon which the electrostatic method works?"

The electrostatic processes of fume precipitation can be applied to practically every fume-carrying gas; that is, to gases in which minute particles are suspended. They will not work upon the gaseous constituents of the gas itself, except where the mixtures of vapors have different temperatures of condensation and allow the formation of mists or particles upon which the high potential current can act. Electrostatic precipitation is occasionally used in the recovery of non-ferrous smelter flue-dust, cement dust, potash fume, and iron blast-furnace dust. Through its agency, many valuable byproducts are recovered which would ordinarily be lost into the air. Essentially, the processes consist in subjecting the gas stream to a high potential electrostatic force sufficient to charge the minute particles in the stream and drive them to the suitable receiving surface of an electrode. For this purpose chains are commonly hung in pipes about 12 in. in diameter.

THE PETROLEUM INDUSTRY

Oil and Gas in Montana

A Compilation From U. S. Geological Survey Bulletins and Other Sources Describing Localities Which Contain Favorable Geological Structures and Horizons for Oil and Gas Occurrence

BY J. P. ROWE

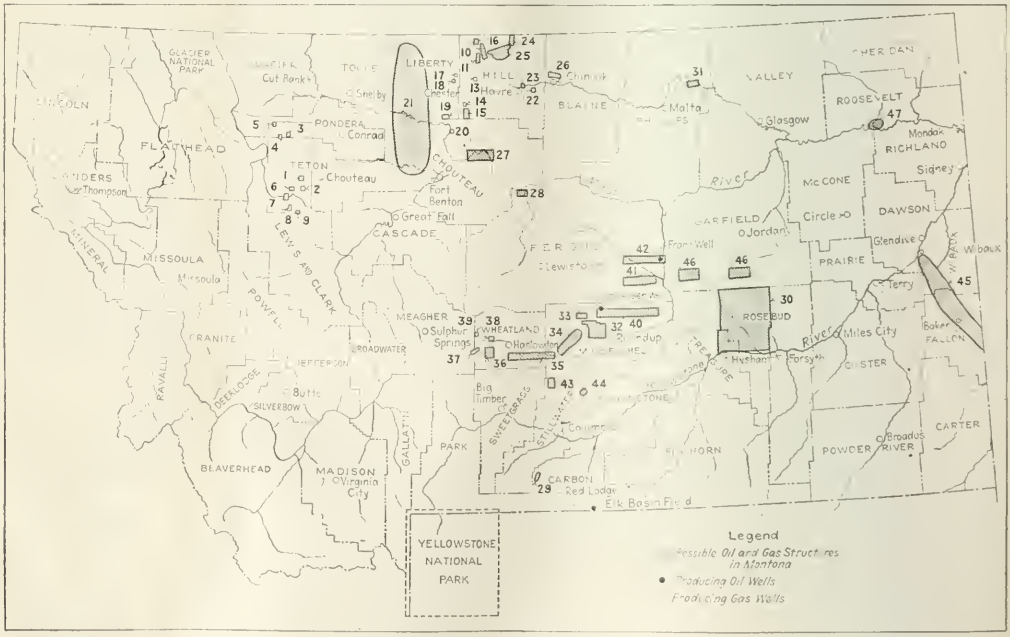
Written for *Engineering and Mining Journal*

THE MATERIAL for this article has been gathered from my field notes, from the bulletins of the U. S. Geological Survey, and from every other available source. The only detailed geological work that has been done in Montana is that of the U. S. Geological Survey. The search for oil and gas in the state has been in progress since 1900. Parties from Butte started to drill a well in that year in the northern part of Flathead County, known as the Kintla Lake district. Several thousand dollars were spent in drilling, but without success. A little later work was done in what is known as the Browning or Swift Current field, about eighty miles north of Browning.

In 1904, a well was drilled in the southern part of Carbon County on a sharply defined anticline. The crest of the anticline is in Jurassic rocks, and therefore no oil was struck, although a splendid flow of water was obtained. Somewhat later, drilling took place on what is known as the Glendive or Cedar Creek anticline, in Dawson County, in the extreme eastern part of the state. A sufficient flow of gas was encountered to be piped a few miles to Glendive, and at present many houses are heated and lighted by the gas.

About this time Havre, the county seat of Hill County, in the northern part of the state, drilled almost directly in the town and secured a fairly good flow of gas. Not long after gas was discovered at Havre several other wells were drilled in the state. Commercial gas was secured at Baker, the county seat of Fallon County. In 1914 a well was drilled at Great Falls. The well was drilled in a flat country and in the Kootenai formation and was a failure.

In 1914 a great oil excitement took place in the Sweet Grass Hills district. This locality is partly in Toole County and partly in Liberty County. The hills are three sets in number, East, Gold and West Buttes, and are laccolithic in structure. The East and Gold Buttes are several miles apart, whereas Gold Butte and West



PETROLEUM AND GAS AREAS OF MONTANA

Butte are close together. In this section conditions are favorable with respect to the geology. However, there are numerous dikes, and, while two or three wells have been drilled, no commercial oil or gas has been discovered, although a flow of gas in one or two of the wells was encountered.

In 1917, a test well was put down in the Glendive or Cedar Creek anticline at a spot selected by a widely known geologist. The company, according to reports, drilled to a depth of over 4,000 ft., going through all of the known oil or gas formations. A flow of gas was encountered at one point, but no oil of commercial value was secured.

In 1918, a well was drilled at Laurel, Yellowstone County, and it was claimed that a slight amount of oil was found. The structural conditions are such that a large amount of oil could not accumulate, as the formations are almost horizontal. There were several other rigs in the district in 1918. Wells were drilled near Conrad and west, in the Birch Creek-Sun River area, in northwestern Montana. A well was drilled to a considerable depth in Carbon County about the same time, without results. Many other wells have been drilled in the state, but, outside of Elk Basin, up to 1919 no oil was found in commercial quantities. Wells were also drilled at Twodot, Wheatland County, Wilsall; in the Shields River Valley, Park County; and also one in the southern part of Stillwater County.

Up to January, 1919, the only commercial natural oil or petroleum found in Montana occurred at Elk Basin. At this locality, in 1915, wells were drilled and a good grade of oil was secured. The Elk Basin field is partly in Carbon County, Montana, and partly in Wyoming. The field is a good producer and may be considered a part of the Wyoming field.

Since 1919 several wells have been drilled in Musselshell, Garfield, and Fergus counties. In fact, at present the area for many miles surrounding Roundup has all been leased except the land that has been withdrawn by the Government. Recently a well on Sec. 24, T. 11 N., R. 24 W. brought in oil. This well is on the Devil's Basin anticline in Musselshell County. The anticline was mentioned by C. F. Bowen, in Professional Paper 90-I of the U. S. Geological Survey. At present, it is claimed that, besides the one before mentioned, the Roundup Oil & Gas Co., well No. 1, Sec. 14, T. 11 N., R. 24 E., and the Roundup, Vandusen and Tri-City joint well, Sec. 30, T. 11 N., R. 25 E., are in operation.

The Roundup well is reported to have struck a good flow of oil, and a good flow of oil is said to have been struck on the Cat Creek anticline in the Cat Creek district near Mosby, in the eastern part of Fergus County. Great excitement prevails in the city of Roundup and in many of the smaller towns near by. An oil boom in Montana, centered around the city of Roundup, may be expected.

Geology of Oil Deposits

It is not thought that oil and gas in commercial quantities in Montana will be found lower than the Upper Carboniferous formation. At several localities where structural conditions are favorable the Upper Carboniferous is entirely missing. A general geologic section in North Central Montana above the Devonian is given in Table 1.

The eastern two-thirds of Montana is within the Great Plains region, and its areal geology, for the most part, belongs to the Tertiary or the Cretaceous formation. The great oil and gas formations in Wyoming are found in the Cretaceous, and principally in the Upper Cretaceous (Colorado and Montana) groups. Some oil has been found in the Embar (Permian) and the Chugwater, above. The oil from these latter formations is a black asphaltic oil, whereas the Upper Cretaceous rocks produce the higher grade light (paraffin) oils. The great producing horizon in Wyoming is the middle Colorado, known as the Frontier sands and shales. Elk Basin, Grass Creek, Salt Creek, Big Muddy, Greybull, and Byron domes all have their producing sands in the Frontier formation. Elk Basin, as stated, is partly in Montana.

TABLE 1. GEOLOGIC SECTION, NORTH CENTRAL MONTANA

System	Series	Group and Formation	Thickness, Feet
Quaternary	Recent	Alluvium	...
	Pleistocene	Glacial drift	0-150.
Tertiary	Pleistocene and late Tertiary	Terrace gravels	5-50
Tertiary (?)	Eocene (?)	St. Mary River formation	650
	Upper Cretaceous	Horsethief sandstone	250-400
		Bearpaw shale	0-500
		Two Medicine formation	1800-2200
		Virgelle sandstone	200-380
		Colorado shale with Blackleaf sand member at base	1800
Cretaceous	Lower Cretaceous	Kootenai formation	890-920
Jurassic	Upper Jurassic	Ellis formation	240-310
		Unconformity	
Carboniferous	Mississippian	Madison and later limestones	1200

Dowling, of the Canadian Geological Survey, in Memoir 52, No. 42 Geological Series, says that "Gas has also been obtained from rocks at about the horizon of the Niobrara at Medicine Hat and in southern Manitoba." He also says, "The great flows of gas at Bow Island and at Pelican Rapids, on the Athabaska, are believed to come from rocks at the horizon of the Dakota." Although Stebinger, in U. S. Geological Survey Bulletin 641, states that "It is probable, however, that this sand is actually in the lower part of the Colorado shale," the Dakota proper has not yet been recognized in Montana.

Stebinger, of the U. S. Geological Survey, in Bulletin 691-E, says, "Because of its association with the Colorado shale, the Virgelle sandstone may contain oil or gas in the rocks of northern Montana. At Medicine Hat, in the southern part of Alberta, a gas field yielding more than 40,000,000 cu.ft. daily from this sandstone has been producing for many years and has led to considerable industrial expansion in that city. More recently large amounts of gas have been obtained from the Virgelle, at Havre, Mont."

I visited the Alberta gas fields at Bow Island and Medicine Hat in 1914. During the same year I traveled across the entire State of Montana, from the Sweet Grass Hills to Marmouth, N. D. Later I spent considerable time in the oil fields of Wyoming, and from observation and all geological knowledge Wyoming Montana, and Alberta are similar geologically. Many oil wells are found in Wyoming in the same geologic formations that occur in Montana. Gas wells in Alberta are found in similar formation to those carrying gas and oil in Wyoming. If, then, as my observation leads me to believe, Montana geological formations were laid down in a similar manner and under similar conditions to the formations in Wyoming and Alberta, the conclusion might well be drawn that where structures are favorable in the geological formations above the Carboniferous, and not eroded and not too deep, dikes and faults being absent, there is reasonable expectation of finding either oil or gas.

The following are geologic formations that probably

contain oil or gas in Montana: The Kootenai—clay, shale, sandstone; the Colorado[1]—shale, sandstone; the Virgelle—sandstone (Lower Montana).

Beginning with the western part of the state, and going eastward, the significant areas will be discussed briefly. The numbers used correspond to those in the map on page 412.

Birch Creek-Sun River Area

The Birch Creek-Sun River area is described in U. S. Geological Survey Bulletin 691 E. It has a maximum length of 53 miles, running from T. 20 N. Lat. 47° 30′ to T. 29 N. Lat. 48° 15′. Its width is 21 miles, running from R. 6 W. Long. 112° 20′ to R. 10 W. Long. 122° 52′. The area is about 750 square miles.

The following anticlines in this area may contain oil or gas.

1. *Willow Creek Anticline* (T. 24 N., R. 6 and 7 W.), Teton County—According to Stebinger, an initial test well can probably be best placed in the "bad-land" area on the crest of the fold near the line between Secs. 19 and 30, T. 24 N., R. 6 W.

2. *Anticlines South of Deep Creek*, Teton County—These structures are south of the Willow Creek anticline. The westernmost anticline has its northern axis in Sec. 34, T. 23 N., R. 6 W. It continues slightly south and east for a little over three miles. The eastern anticline has its northern end in Sec. 35, T. 23 N., R. 6 W. It continues south and east for about three miles.

3. *Anticline on Dupuyer Creek*, Pondera County—Indications of a small anticline the axis of which trends about N. 17 deg. W. appear on Dupuyer Creek, near the center of Sec. 27, T. 28 N., R. 8 W. This fold is exposed only along the valley of Dupuyer Creek. At least two-thirds of the Two Medicine formation (Middle Montana) overlies the Virgelle (Lower Montana) in this locality.

4. *Scoffin Butte Anticline*, Pondera County—In the vicinity of Scoffin Butte there is a well-developed anticline the axis of which trends N. 7 deg. W. through Sec. 36, T. 28 N., R. 9 W. The depth to the Virgelle sandstone along the crest of this anticline is probably not less than 2,500 ft.

5. *Anticlines on Birch Creek*, Pondera County—Six miles northwest of the Scoffin Butte anticline there is a well-defined anticline crossing Birch Creek in Secs. 4 and 9, T. 28 N., R. 9 W., trending about N. 11 deg. W. The fold has a thick cover over the possibly productive beds, thus presenting the same difficulty as the Scoffin Butte anticline. East, one mile from the anticline just described on Birch Creek, is another small fold of doubtful value. Stebinger states that "only a very general production of petroleum in this area would seem to warrant drilling on either the Birch Creek folds, the Scoffin Butte anticline, or the fold on Dupuyer Creek."

6. *Anticlines on Deep Creek*, Teton County—On Deep Creek there are three parallel folds trending north, underlain by the Virgelle sandstone and lower formations which seem to offer the possibility of a small production of oil. The axis of the easternmost anticline crosses the creek about 1,000 ft. west of the east line of Sec. 30, T. 23 N., R. 7 W. The second anticline on Deep Creek is about 1,000 ft. west of the one just described. The third fold on Deep Creek crosses the valley of this creek near the old Goodwin ranch, extending through the southwest quarter Sec. 25, T. 23 N. R. 8 W.

7. *Anticlines on Sun River*, Teton County—There are several north-south parallel anticlines principally in T. 22 N., R. 8 W., in which the Two Medicine formation and Virgelle sandstone are the chief surface formations. The closely spaced parallel nature of these anticlines limits their collecting areas, and there does not seem to be a possibility of more than a small production of oil along their axes.

8. *Anticlines in the Vicinity of Barr Creek*, Lewis and Clark County—There are three well-defined anticlines in the vicinity of Barr Creek. Two wells were drilled on the flanks of the easternmost fold, but probably did not go deep enough to give the locality a thorough test. The easternmost anticline extends across Secs. 24 and 25, T. 21, N., R. 8 W. The second anticline in this region is found in Sec. 26, T. 21 N., R. 8 W., along Barr Creek. The third fold extends through Black Butte, in Sec. 35, T. 21 N., R. 8 W. Because of the small sizes and broken condition of this anticline it seems to offer small inducements for prospecting.

9. *Anticline in T. 20 N., R. 7 W.*—In Sec. 15, T. 20 N., R. 7 W., Lewis and Clark County, there is a well-defined anticline. This might be a fair anticline for further prospecting.

Anticlines of Doubtful Value for Oil or Gas

North of Deep Creek there are several rather large anticlines. They expose for the most part formations below the Kootenai, some being eroded to the lower Carboniferous or Madison limestone. They are, therefore, of doubtful value for oil or gas. The northernmost of the larger folds crosses the three forks of Dupuyer Creek near No Mountains and is designated the Dupuyer anticline.

The Teton anticline, lying parallel to the Dupuyer anticline, and about one and a half miles to the west, is by far the largest fold in the area.

All of the drilling has been done in the southern part of the area. None of the wells reached the Virgelle sandstone or to the probably oil-bearing beds associated with the lower part of the Colorado shale; nor were any of them located on the more favorable structural features of this area, and none of them brought in commercial gas or oil, and the district has not, therefore, been properly tested.

Anticlines in Blackfeet Indian Reservation

North and slightly west of the Birch Creek-Sun River area, running from Lat. 48° 15′ to the 49th parallel north and from the town of Cut Bank on the east, the county seat of the new County of Glacier, to the western boundary of the Blackfeet Indian Reservation, several anticlines have been described by Stebinger in U. S. Geological Survey Bulletin 641, entitled "Anticlines in Blackfeet Indian Reservation, Montana." A short description and location of each anticline is herein given, with their numbers and therefore their easy location on the map:

10. *Milk River Anticline*, Glacier County—This anticline has its northern outcrop in the valley of the North Fork of Milk River in the southwestern part of T. 37 N., R. 12 W. It extends in a southeastern direction and is twelve miles long. It is the largest single fold in the Blackfeet Reservation. The west limb of the fold near the axis of the anticline, and especially Sec. 31 and 32, T. 37 N., R. 12 W.; Sec. 27, 34 and 35, T. 36 N., R. 12 W.; and Sec. 2, 3, 11, 13 and 14, T. 35 N., R. 12 W., seem to be the most favorable localities for drilling.

11. *South Fork Anticline*, Glacier County—This anticline is second in size in the district. It lies east and parallel to the Milk River anticline. It can be traced for about six miles across the principal branches of south fork of Milk River in T. 36 N., R. 11 and 12 W., and in T. 35 N., R. 11 W. The South Fork anticline is probably as valuable as a possible reservoir of oil or gas as the Milk River fold. Stebinger states that "The desirability of prospecting in this anticline is somewhat uncertain, because of the great thickness of rocks that overlie the possible oil and gas sands." He states that "the depth to the Virgelle sandstone is over 3,000 ft. and the depth to the base of the Colorado shale nearly 5,000 ft. However, if other anticlines in this region should prove productive, drilling might be done on this fold."

[1]This formation is probably the most important source of oil and gas in northwestern Montana if not in the entire state.

12. *Blackfeet Anticlines*, Glacier County—These folds seem to offer little chance of finding oil or gas, for the reason that faults on both sides limit the collecting area for oil or gas.

13. *Anticlines on Cut Bank Creek*, Glacier County—On Cut Bank Creek, in Sec. 10, 11, 14 and 15, T. 33 N., R. 11 W., there are two parallel anticlines the axes of which trend about N. 18 deg. W.

14. *Anticline on Two Medicine Creek*, Glacier County—This fold is in the Valley of Two Medicine Creek, in Sec. 22 and 27, T. 31 N., R. 10 W.

15. *Badger Creek Anticline*, Glacier County—This fold lies in the east half of T. 30 N., R. 10 W. The crest of the anticline is so high above the oil-producing sands, and the fold so small, that this structure seems to offer little inducement for prospecting.

16. *Anticline on North Fork of Milk River*, Glacier County—This anticline lies in T. 37 N., R. 11 W., and is a very gentle fold. A well drilled to the nearest productive sands would probably have to attain a depth of 4,500 ft.

17. *Anticline on Cut Bank Creek*, Glacier County—In Sec. 34, T. 34 N., R. 9 W. is found a gentle anticline the axis of which extends north-northwestward. The axis lies approximately along the center of the valley of Willow Creek, which at this point enters Cut Bank Creek from the south. According to Stebinger, the depth to the top of the Virgelle sandstone is about 2,400 ft.

18. *Anticline on Willow Creek*, Glacier County—On Willow Creek, in Sec. 8, 16 and 17, T. 33 N., R. 9 W., there are excellent exposures of the crest of a broad, gentle anticline. To search the Virgelle sandstone a well would have to be sunk about 2,700 ft.

19. *Anticline on Blacktail Creek*, Glacier County—In the Blacktail Creek Valley, in the southeast quarter of T. 30 N., R. 8 W., a fold is clearly outlined in the upper part of the Two Medicine formation. This is a gentle fold, and to reach the base of the Colorado shale from the crest of this anticline a well would have to be sunk about 3,800 ft.

20. *Anticlines on Birch Creek*, Glacier County—This narrow-crested anticline lies in Sec. 4 and 9, T. 28 N., R. 9 W.

No drilling, so far as my information goes, has as yet been done in the Blackfeet Indian Reservation proper, though several wells have been drilled on the east, north and west border of the reservation, all with negative results, primarily for the reason that none was drilled in a locality that was most favorable and that would determine final success or failure for this section. However, Stebinger states that "The negative results obtained at these widely scattered places along the base of the mountain front, and the geologic evidence that the formations on the west edge of the reservation are much disturbed, indicate that this part of the region is unfavorable for oil and gas prospecting.

North-Central Montana

Most of the following discussion is taken from Bulletin 641, U. S. Geological Survey, "Possibilities of Oil and Gas in North-Central Montana," by Eugene Stebinger. The article describes an area of approximately 22,000 square miles, beginning at the northern boundary of the state and running south as far as Great Falls, about 106 miles. Its western limit is R. 8 W. It extends eastward for about 192 miles to Range 24 E. It includes all of the counties of Blaine, Hill, Chester, Toole, and Chouteau, and parts of Fergus, Cascade, Pondera, Teton and Glacier.

The Kootenai formation appears to be the lowest to offer oil or gas possibilities in this section. Above the Kootenai is the Colorado shale, containing in its lower half a number of sandstone beds. Above the Colorado shale throughout north-central Montana there is a group of sandy beds from 250 to 400 ft. thick, which constitute the Eagle sandstone. The lower half is known as the Virgelle sandstone member. The Havre, Montana, and Medicine Hat, Alberta, natural gas comes from the Eagle sandstone. The higher and lower formations are probably more or less barren. The following details the characteristics noted:

21. *Sweet Grass Arch*—The western half of this area is characterized by a very broad anticline or arch. The arch extends southward from the Sweet Grass Hills to the region beyond Teton River, where it flattens out. It extends north into Canada, and the Bow Island gas field in southern Alberta lies near the center of it. The arch for the most part has not been examined geologically, and therefore the occurrence of minor folds has not been determined. Should such folds be found within the arch, they offer the possibility of getting oil or gas from the Colorado shale at comparatively shallow depths.

22. *Box Elder Anticlines*, Hill County—There are two parallel anticlines near Box Elder Creek extending across Sec. 8, 9, 16 and 17, T. 32 N., R. 17 E. Their limits on the northwest and southeast are not determinable, because of the cover of the glacial drift, but they are doubtless parallel to the Meili fault, and their extension toward the immediate vicinity of Havre, where the large quantity of gas has been found, is probable.

23. *Havre Natural Gas Pool*, Hill County—The principal gas well of the Havre Natural Gas Co., brought in early in July, 1915, is in the S.E. ¼ Sec. 33, T. 33 N., R. 16 E., about two miles northeast of Havre, just south of the Great Northern Ry. This well is 947 ft. deep, and had a flow of 10,000,000 cu.ft. in twenty-four hours. The pressure was about 490 lb. to the square inch in 1915. The gas pool in the district of Havre will probably have its greatest extension in a direction S. 70°-75° E.

The probable reason for the failures of wells drilled at Fort Assiniboine, Chinook, and other localities in the Milk River Valley was the lack of knowledge of the kind of structures to drill and of the disregard of expert advice.

24. *Signal Butte Anticline*, Hill County—This structure is in the west half of T. 37 N., R. 15 E. It extends in a direction approximately N. 25° W., and is broken along its crest by a fault.

25. *Hill County*—In many places north of the Bearpaw Mountains there are areas of tilted and folded rocks. The following localities are the most noted: T. 37 N., R. 15 E.; T. 36 N., R. 14 E.; T. 35 N., R. 12 E.; T. 35 N., R. 14 E.; T. 35 N., R. 16 E.; T. 34 N., R. 12 E.; T. 34 N., R. 13 E.; T. 34 N., R. 14 E.

26. *Tilted and Folded Rocks North of Chinook*, Blaine County—On Lodge Creek, in the southwestern part of T. 34 N., R. 19 E.; on Battle Creek in the northeastern part of T. 33 N., R. 19 E.; on Coal Creek, in the west half of T. 33 N., R. 20 E.

27. *Area of Tilted and Folded Rocks South of the Bearpaw Mountains*, Chouteau County—In the vicinity of Virgelle, in T. 26 N., Rs. 11 to 13 E., there are four areas of tilted rocks.

28. *Tilted Rocks of Lower Part of Judith River*, Fergus County—In the north half of T. 22 N., R. 16 E., there is an extensive fault and southwest of this fault there is a very large block.

29. *Oil Prospects in the Upper Stillwater Basin*, Stillwater County—Some years ago several holes were put down in the Upper Stillwater region. All the holes were dry, according to Calvert, although indications of oil were reported. One locality was in the northeastern part of Sec. 4, T. 6 S., R. 18 E., and the other in the S. E. ¼ Sec. 32 of the same township. After passing through surface wash and the lower sandy portion of the Eagle sandstone, the drilling was in dark shale and thin sandstone, presumably of Colorado age. It seems that this section of the southern part of Montana was not properly tested, for the reasons, first, that the holes were of insufficient depth, and, second, because they were put down on the pitching end of the anticline. Another well was drilled at Dean during the summer of 1917. It is reported that it went to a depth of about 1,800 ft. It was a dry hole.

30. *Possibilities of Oil in the Porcupine Dome*, Rosebud

County—The Porcupine dome lies north of Forsyth, east of the Chicago, Milwaukee & St. Paul Ry., and includes T. 7 to 12 N., R. 36 to 40 E. The dominant structure is that of an elongate, roughly triangular dome the outline of which is indicated by the inner margin of the Judith River formation. Within the margin the dome has a maximum north-south diameter of about thirty-three miles and a maximum east-west diameter of twenty-seven miles. Minor folds exist within the domed area. C. F. Bowen says, after a general discussion for and against conditions in this dome, that "The presence or absence of oil or gas in the Porcupine dome field can be demonstrated only by thorough and systematic exploration with the drill. The only positive statement that can now be made regarding their possible occurrence is that the structural and stratigraphic conditions are favorable for their accumulation." The most promising place, according to Bowen, is near the crest of the uplift on the divide between Porcupine and Little Porcupine creeks, probably T. 10 and 11 N., R. 38 E.

31. *The Bowdoin Dome*—This dome is situated on Milk River, partly in Phillips County and partly in Valley County. It is a broadly arched structure from which the strata dip away on all sides. This dome was described a few years ago by A. J. Collier, and a description of it may be found in Bulletin 661-E of the U. S. Geological Survey. The Bowdoin dome is large and of low dip. Collier states that the most favorable place to drill is near the northwest corner of T. 32 N., R. 33 E. Whether a test well has since been put down in this region I do not know. While drilling for water several years ago a small flow of gas was struck at a shallow depth. I do not look with much favor upon the Bowdoin dome, for the reason that the dip of the strata is entirely too low. The size of the Bowdoin dome compares favorably with the size of the Porcupine dome, Rosebud County.

Anticlines in a Part of the Musselshell Valley

In Bulletin 691, U. S. Geological Survey, Bowen describes the anticlines, and the following is taken largely from this bulletin. The area described in Bulletin 691 includes about 1,200 square miles lying chiefly in T. 7 to 9 N., R. 12 to 23 E. Montana principal meridian.

The Musselshell Valley is structurally part of a large syncline that lies between the Big Snowy and Little Belt Mountains on the north and the Crazy, Beartooth and Pryor Mountains on the south and southwest. There are many minor folds within this syncline caused by the compression of the rocks. The most prominent anticlines and domes are described in the following:

32. *Pole Creek Anticline*, Musselshell County—This structure has an extent from northwest to southeast of about sixteen miles, occupying the area from the north side of T. 8 N., R. 24 E., to the southeast quarter of T. 10 N., R. 22 E., where it loses its identity in the south limb of the Devil's Pocket anticline. It is not known whether the axis of the Pole Creek anticline merges with the south limb of the Devil's Pocket anticline or whether the two folds are more or less distinctly separated by a syncline. This relation is critical, for on it may depend the possible accumulation of oil in the Pole Creek anticline. So far as its relation to other structural features is concerned, the Pole Creek anticline is well situated. It has a large collecting ground to the northeast, east, and south. To the southeast the area is small, because of the close proximity of a synclinal axis in that direction. The most unfavorable factor to be weighed in this anticline is the possibility that the oil may have escaped in the direction of the Devil's Pocket anticline. In the opinion of Bowen, the Pole Creek anticline is worth testing.

33. *Devil's Pocket Anticline*, Musselshell County—This anticline is nine miles long and three miles wide. It lies north and west of the Pole Creek anticline, principally in T. 10 N., R. 22 E. It projects from the Big Snowy Mountains, and is open in that direction. In other directions its outline is marked by the Eagle sandstone, so that the Colorado shale is the surface formation over the entire basin. Therefore, this anticline is not a likely source of oil unless the sands below the Colorado are productive, and it is faulted off on the north side and the productive sands have been sealed along the fault plane.

34. *Woman's Pocket Anticline*, Musselshell County—This anticline is about eighteen miles long from northwest to southeast and a little less than four miles wide. It lies southwest of and parallel to the Pole Creek anticline, but, unlike that fold, it has a "closed structure." It occupies portions of T. 7, 8 and 9 N., R. 20, 21 and 22 E. Regarded as an isolated anticline, it seems a favorable one for oil accumulation, as the possibly productive sands in the Colorado are covered and sealed above. It has not, however, a large collecting area.

35. *Shawmut Anticline*, Musselshell County—This anticline is the one mentioned in the Musselshell Valley. It has an east-west extent of about thirty miles and a maximum width of more than eight miles. That part of the anticline east of and including Deadman's Basin is the most favorable place for testing and is the only one that is likely to produce oil from the sands of the Colorado. In the western part of the Shawmut anticline there are three small domes, the east, middle, and west. The east dome is a possible source of oil, if oil has accumulated in the Kootenai sands. All three of the domes present ideal structure if oil is ever discovered in this section in rocks older than the Kootenai.

36. *Big Elk Dome*, Wheatland County—This dome covers an area of approximately one township and lies a few miles south of the town of Twodot. The structure of the dome is almost ideal, but as the most promising sandstone in the Colorado, the Big Elk Member, is exposed in the center of the dome, and as the underlying sands are probably quartzitic and fine grained, it does not seem likely that oil or gas will be found in this formation. The Kootenai sands might be productive.

37. *Little Elk Dome*, Meagher and Wheatland Counties—This structure lies between Little Elk and Fawn Creeks in T. 7 N., R. 11 and 12 E. It has an east and west extent of about eight miles and a north-south extent of four miles. For the reason that the sedimentary rocks are cut by several dikes and masses of igneous rocks, and the most favorable sands of the Colorado are exposed in the center of the dome, it is not probable that oil will be obtained in this dome.

38. *Haymaker Anticline*, Wheatland County—This anticline lies chiefly north of Twodot. Its structure is not "closed." The chances for oil in this anticline are small.

39. *Daisy Dean Anticline*, Wheatland County—The anticline lies five or six miles northeast of Martindale. It is not regarded as being favorably situated for oil accumulation.

In Professional Paper 90-I, U. S. Geological Survey, C. F. Bowen mentions briefly anticlines and domes north and east of the folds described in Bulletin 691. These structures lie in Fergus and Musselshell counties, and are found on the broad symmetrical fold, the Big Snowy anticline. The axis of the Big Snowy anticline trends northwest and pitches to the southeast. The minor folds on the Big Snowy anticline are the Devil's Basin, Flat Willow and Cat Creek anticlines, with intervening synclines. They are symmetrical folds the axes of which pitch to the southeast and trend roughly northwest but are somewhat sinuous in outline. The dips on opposite limbs of the folds as a rule range from two to six degrees and rarely exceed ten degrees. Descriptions follow:

40. *Devil's Basin Anticline*—The fold is in Musselshell County, running through T. 10 and 11 N. and R. 24, 25, 26, 27, 28 and 29 E. At present the greatest development is in T. 11 N., R. 24 E. This is the location of the Van Dusen well, which recently brought in oil, and also of several other wells that are now being drilled.

41. *Flat Willow Anticline*, Fergus County—North of the Devil's Basin anticline, in Fergus County, is the Flat Willow anticline. The fold is but a few miles south of the town of Winnett, and Smith post office is situated directly

upon its crest. It passes through T. 13 and 14 N., and R. 26, 27, 28, and 29 E. The Eagle sandstone is the surface formation over its western portion; the Claggett outcrops over most of the eastern half.

42. *Cat Creek Anticline*, Fergus County—The crest of this fold is north of Winnett about eight miles. It runs through T. 15 and 16 N., and R. 26, 27, 28, and 29, and probably 30 E. It is recently reported that about six miles from Mosby, Fergus County, oil was struck in a well drilled on this fold. It is reported that a 600-bbl. well was brought in across the Musselshell River on March 17. The lands on and surrounding the fold are being or have been leased.

Lake Basin Field

In Bulletin 691, U. S. Geological Survey, E. T. Hancock has an article on the "Geology and Oil and Gas Prospects of the Lake Basin Field." This field is situated in south-central Montana, and includes portions of Sweet Grass, Stillwater, Musselshell, and Yellowstone counties. It embraces an area of about 1,000 square miles. It lies south and east of the Musselshell Valley area, which is mapped and described by Bowen in Bulletin 691.

The two dominating folds in the Lake Basin Field are the Big Coulee-Hailstone dome and the northwest end of the Big Horn Mountain anticline. The highest point of the dome appears to be near the center of the east side of T. 4 N., R. 19 E., and from that place the dome is somewhat elongated in the direction of the Broadview dome, a local uplift about seven miles southwest of Broadview. Only the Big Coulee-Hailstone and the Broadview domes will be discussed.

43. *The Big Coulee-Hailstone Dome*—The highest point of this dome is considered to be near the center of the east side of T. 4 N., R. 19 E., Stillwater County. There is little doubt that the formations present in north-central Wyoming which carry oil and gas extend northward and underlie the Lake Basin field. It is also reasonably certain that the sandstones in the Colorado and Kootenai formations are sufficiently near the surface to be tested by the drill under the most favorable structural features in the Lake Basin field. The principal element of uncertainty for oil is the nature and extent of the sands. From the number of well logs available it appears that well-defined sandstones such as those present in most of the productive Wyoming fields are lacking in the Lake Basin field. It may be, however, that the available drill records fail to represent the true nature of the Colorado sands and that future drilling will establish the existence of sandstones under parts of the Lake Basin field similar to those underlying certain portions of the Musselshell Valley, farther north.

From the well logs it appears that no sandstones were encountered comparable with those at Elk Basin, Wyo., and apparently only meager showings of oil and gas were obtained. In view of the size of the Big Coulee-Hailstone dome, and the location of the 79 Oil Co.'s well and the well in Sec. 17, T. 3 N., R. 21 E., in relation to the crest of the dome, together with the fact that many dry holes are found even in productive fields, it is reasonable to conclude that further drilling of the Big Coulee-Hailstone dome is justified.

44. *The Broadview Dome*—About seven miles southwest of Broadview there is a circular uplift which may be called the Broadview dome. This dome is crossed by the boundary line of Stillwater and Yellowstone counties. Its crest is in Sec. 13, T. 3 N., R. 22 E. The Eagle sandstone outcrops over nearly the entire dome. The dome is greatly faulted on its southeast side. Hancock states that "if the Big Coulee-Hailstone dome proves barren, the possibilities of oil and gas in commercial quantities in this dome and the Lola Basin field are believed to be very slight."

45. *Cedar Creek Anticline*, Prairie and Fallon Counties —In U. S. Geological Survey Bulletin 471, U. R. Colvert briefly described this anticline. He states that "a strongly pronounced anticline extends from Yellowstone River near the mouth of Cedar Creek southeast for about seventy miles into the Dakotas." The same anticline is briefly described on pp. 51 and 52 of the University of Montana Studies—Series No. 1, by J. P. Rowe and Roy A. Wilson. From developments since both of these articles were written, the presence of oil is extremely problematic, although the cities of Glendive and Baker are now supplied with natural gas from this structure. As previously stated, a deep well was drilled, a year or two ago, in a most favorable locality on the anticline, with negative results in respect to oil, although a good flow of gas was struck in one or two places.

46.—According to Bowen, in Professional Paper 125-B, U. S. Geological Survey, there are several local anticlines in T. 14 N., R. 32 and 33, 37 and 38 E. These are north of the Porcupine dome and east of the Flat Willow anticline, as previously described. The anticlines are in the Lance formation, and the distance to the Colorado might be of disadvantage in drilling. They are in the southern part of Garfield County near the Alice and Garfield post offices.

47. *Poplar Dome*—In Professional Paper 120, U. S. Geological Survey, Arthur J. Collier mentions the foregoing, although C. D. Smith had noted the same structure several years previous in the U. S Geological Survey Bulletin 381. Neither writer considers the Poplar Dome, or others which are in the surrounding country, as possible reservoirs for oil or gas. It seems, however, that this dome, unless it has too low a dip, has some promise, for the reason that it "brings up a large elliptical area of Bearpaw shale nearly surrounded by the Lance formation." The dome is a few miles east of Wolf Point, on the Great Northern Ry. The town of Poplar is, according to Smith, near the center of the dome.

48. *The Huntley Field*—There is an anticline south of Ten Mile Creek, in the western part of T. 1 N., R. 30 E., and the eastern part of T. 1 N., R. 29 E., partly in Yellowstone and partly in Big Horn counties. For several reasons this locality does not seem to promise much in the way of commercial oil.

49. *Wolf Point*—South of Wolf Point, in the northern part of McCone County, there is a low structure. It is found largely in T. 25 N., R. 46 E. Owing to its low dip, I do not look upon it with much favor.

The most recent U. S. Geological Survey bulletin on oil and gas in Montana is No. 711-G. It deals with the "Geology and Oil and Gas Prospects of the Huntley Field, in Yellowstone County." This bulletin mentions two or three structures where oil or gas might be found, but gives no special encouragement, for the reason that commercial oil or gas has not yet been discovered in the Lake Basin field.

Natural-Gas Curtailment

Conference of State Public Service Commissions Likely To Result in Restricting Supply to Domestic Requirements

By R. S. McBride

Written for *Engineering and Mining Journal*

PRIORITIES in natural-gas supply similar to those which are from time to time confronting petroleum interests are to be considered on Sept. 10 by a conference of five of the state public service commissions, which meet to decide important policies with respect to elimination of certain industrial users of natural gas. Fundamentally, the question is how to supply the domestic users whose requirements are practically equal to the total production during peak-load periods. The most obvious method is the elimination of industrial users, and unquestionably those who use natural gas under boilers of any appreciable size, and many industrial users in brick manufacture, glass making, carbon-black production, and ceramic industries, are to be affected.

The state commissions involved are those of Pennsylvania, West Virginia, Ohio, Maryland, and New York. The first three named have jurisdiction over districts where 70 per cent of the natural gas in the United States is consumed. Fig. 1 (prepared by E. G. Severs, of the U. S. Geological Survey) shows the importance of this particular territory.

The action of these commissions will, it appears, be based upon the resolutions recently adopted by the national committee on natural-gas conservation, which worked under the auspices of the Department of the Interior, and reported June 11, giving recommendations for the conservation and distribution of the available natural-gas supplies.

Pooling of Interests Will Eliminate Wasteful Oil-Field Methods

One phase of the situation which probably will not receive immediate attention, though it has often been discussed in this connection, is that of the pooling of field interests. Fig. 2, a chart by S. S. Wyer, shows the importance of this, for under the competitive conditions described, it is quite apparent that wasteful field methods in natural-gas development have been encouraged. Only by the pooling of interests in adjoining territory can these problems be solved sucessfully, it is claimed.

The immediate importance of attention to these matters is evident from Fig. 3 (also by Mr. Wyer), which shows the rapid decline in daily production of gas in the McKeesport, Pa., field. Other fields in this tri-state territory have not shown such striking declines, but in each case the production shows signs of early diminution.

Industrial users who can demonstrate special requirements for natural gas which are not easily met by other fuels will have to be prepared to make such demonstration to the state commissions at an early date, as otherwise they can expect that their natural-gas supplies soon will be ordered cut off. For example, it is claimed that certain glass-making processes, such as flattening and annealing of plate glass, require sulphur-free fuel, and for such work it is quite possible that continued service will be permitted.

SOCIETIES, ADDRESSES, AND REPORTS

Council Seeks Advice on Classification of Engineers

Claims Question of Satisfactory Pay for Engineering Service Affects Public Most

Administrative officials of the various states and cities of the country, as well as of Federal bureaus having jurisdiction over engineering work, together with Civil Service Commissioners, were recently addressed by Engineering Council's Classification and Compensation Committee in an effort to secure their advice as to the practicability of putting the committee's proposed classification of engineers into effect in their various organizations. They were sent the following letter:

"It is doubtless known to you that engineers in all branches of the profession have suffered serious hardship during the past three years from the great decrease in buying power of the dollar. In few cases has their pay been increased sufficiently to offset any large proportion of the increased cost of living.

"Engineering Council, which represents over 45,000 engineers in all parts of the United States, has had this matter under investigation for over a year. We send you herewith an abstract of the report of the Council's special committee on the Classification and Compensation of Engineers. This report contains a standard classification of grading for engineering service, with a tentative schedule of standard rates of compensation in each of the proposed grades.

"Engineering Council has approved this classification, and it is believed to be applicable to all branches of engineering service.

"The classification was endorsed by the municipal engineers of the City of New York at a meeting of that society held on May 26, 1920, at which time a schedule was adopted providing for compensation at a rate approximately 20 per cent greater than that tentatively suggested by the committee. The classification has been closely followed by the Congressional Joint Commission of Reclassification of Salaries in its recommendations concerning engineers in the Federal service (see *Engineering News-Record*, April 15, 1920), and it was approved by the executive committee of the American Society for Testing Materials on April 13, 1920. The endorsement of the tentative schedule of compensation was recommended to the Boston Society of Civil Engineers by its Committee on Compensation at a meeting of that society held on May 19, 1920, and is now being made the subject of a letter ballot by the full membership. It will thus be seen that substantial progress has been made in bringing about a recognition of Engineering Council's classification as standard.

"The adopted classification and the corresponding schedule of compensation tentatively suggested are as follows:

Adopted Grades	Tentative Compensation Schedule
Junior Aid	$1,080 to $1,560
Aid	$1,680 to $2,400
Senior Aid	$2,520 to $3,240
Junior Assistant Engineer.....	$1,620 to $2,580
Assistant Engineer	$2,700 to $4,140
Senior Assistant Engineer.....	$4,320 to $5,760
Engineer.....	$5,940 and upwards
Chief Engineer . .	$8,100 and upwards

"We desire especially to urge upon you that this question of satisfactory compensation for engineering service is one which affects the public even more vitally than it does the engineers themselves. Upon the quality of service rendered by the engineers who design, plan and execute construction work, its cost and serviceability will largely depend. Our investigations have shown that the public is already suffering loss as a result of the great reduction in engineers' compensation.

"The need of a standard classification and standard rates of compensation which would be generally recognized as fair and just has long been felt by public authorities and other large employers of engineering service. We believe that this report is worthy of your very careful attention. In nearly all work on which technical engineering service is required, its cost is a very small percentage of the entire cost, so that an increase of engineers' pay to the standard scale will add a hardly noticeable amount to the total, and this in nearly all cases should be far more than offset by the economies which a higher grade of engineering service can effect.

"Nor can the importance be overlooked, at this time of general industrial and social unrest, of maintaining the loyalty of professional men who should be leaders of thought and action to the organizations which they serve. This continued loyalty to professional ideals cannot be expected when men of education and intelligence receive lower pay than many unskilled laborers."

The Mining and Metallurgical Society of America recently announced that the Gold Medal of the society, which will be awarded at the annual meeting in January, 1921, shall be given for: "Distinguished service in increasing the safety of men in mining and metallurgical operations."

Actualities in Industrial Russia Described by Expert

Raw Materials Stores Exhausted—Food and Fuel Vanishing—Disease Rampant

Many people are wondering "What the truth is about Russia." The *Compressed Air Magazine* publishes under the above title an account by one who has spent many years in Russia and, until the Bolshevik era, was associated in Petrograd with a well-known manufacturer of compressed-air machinery. Chaotic industrial conditions in 1917 put an end to this business, but he elected to remain in the country, hoping for improvement; and later he was unable to receive permission to leave. He has just succeeded in getting out of Russia, and has written an interesting description of conditions. We are sorry that we cannot quote the whole article.

"Everyone must be employed by law, particularly males from sixteen to fifty years of age; but to work according to the usual conception of the term simply is not done." They prefer to sit around, smoke, discuss their love affairs and how one can get something special to eat. "The educated middle-class school teachers, clerks and office assistants are having a very difficult existence because the brain-worker is very much underpaid."

The writer secured a job, through influence, in a chemical factory. Owing, however, to the complete lack of raw materials "this industry is at present at a complete standstill, except for the fact that the entire force of laborers and staff were maintained at full strength, doing very little. This factory has about 100 laborers on the payroll who worked only every once in a while at tearing down wooden structures and houses in the vicinity for the lumber, conveying it to the factory premises, where it was redistributed amongst the employees for use as firewood."

This is also the condition in other industrial establishments. "The Obouk-hoff Works are engaged only in repairing railway cars, no new cars are being built, because the necessary raw material and coal for fuel are la[illegible]" "... In order to obtain [illegible], all wooden houses, fences and other structures in the vicinity of the factories are torn down, and forests lying within an area of 20 versts (12 miles) radius from Petrograd are being felled, converted to firewood and transported to the factories and immediately consumed." In fact all has been consumed, as if by a pest of grasshoppers. "Now that the Bolsheviki have rounded up and consumed all known accumula-

tions of foreign supplies and stocks of raw materials, I do not hazard a guess as to how they shall be able to carry on in the immediate future. Everything seems to be lacking; nothing, absolutely nothing remains. I never could have believed that a country could be stripped so completely bare as has been accomplished in Russia within the relatively short period of two years that the Bolsheviki have been in power."

It is quite impossible to subsist on salaries of 5,000 to 8,000 roubles per month; one must have 30,000 to 40,000, and even so will not get enough to eat. Butter is 8,000 roubles per pound; bacon 2,500 to 3,000 roubles; one egg 200 roubles; flour at 800 roubles per pound; and so on. "In our family we had the good fortune to live in a house where the water pipes had not yet been burst by the frost, but in all neighboring houses it was necessary to carry up the water all the way from the street. . . No buildings are being repaired or maintained in condition, there being neither labor nor materials available for this purpose." Housing is governed by a special Soviet committee. "One room is allotted for an individual and so my parents with a family of three, who occupied a five-room apartment, were forced to take in two sailors as lodgers. . . . As things are, no one attempts to move, there being, in addition to the foregoing troubles, a great scarcity of lodging, due to the fact that almost all wooden houses have already been torn down and used as firewood; and also the luxury of moving costs from 20,000 to 30,000 roubles."

As far as wearing apparel is concerned, that is out of the question. A pair of shoes costs 12,000 to 15,000 roubles; overshoes from 9,000 to 10,000 roubles. These may be obtained from sailors, who are favored by the government. "In the month of February, 1920, the 'Skorokhod Shoe Factory' produced only enough shoes to enable them to negotiate an exchange for overshoes for themselves with the workers of the 'Treugolnik Rubber Factory.'"

There is, however, one flourishing industry: "Of all the industries in Russia, the state plant of printing and engraving reaches the greatest degree of efficiency, and is working to full capacity. Here the money or leninki is produced. Operation goes on day and night and printing proceeds without interruption. The workers in this plant are shown every consideration."

Of the city of Petrograd, a desolate picture is painted.

"Nevsky Prospekt, once Petrograd's pride [Petrograd's Fifth Avenue, and about four miles long], is now nothing but a country road. All shops have been closed and the windows sealed up with boards; the wooden paving blocks have long since been torn up (for fuel). . . . The sidewalks are crowded with degenerate loafers supposed to be soldiers, or Soviet employees. . . . Along its entire length there are not more than ten tny little shops still open."

Hackmen are scarce. "A truck driver charged 12,000 roubles to haul baggage from the Vassili Ostrov to the Finnish Railway Station. . . . Street cars were still running when I left, but most of them were broken down, and of the former 800 motor trams only about 100 are able to maintain operation. . . . There are only two passenger trains a week between Petrograd and Moscow and they take from five to seven days for the trip, formerly a ten-hour run, being about 400 miles."

However, life is not without its brighter sides. "All theatres are working full blast, and doing a tremendous business. Seats cost from 125 roubles up, and at the Mariensky all seats are permanently taken up by Communists of high rank, so that mere mortals are never so fortunate as to obtain admission, unless, just as in the former days of the Imperial Government, it is possible to procure the influence of some one of powerful position, with the exception that your protector will now possibly be a letter-carrier, whereas formerly he had to be at least a general. The audiences are mostly made up of sailors, soldiers and their feminine appendages. The women are loaded down with jewelry, and the new Mariensky Theater frequenters attempt to ape the brilliant audiences that formerly thronged the building."

There are, however, certain drawbacks. "Apropos of vermin . . . tram cars, railway cars, theatres, prisons, and hospitals swarm with them, and people are dying by hundreds of thousands on their account. In February of 1920, 65,000 died of spotted typhus in Petrograd."

Behold the "New Freedom" of the idealist: "The passport system has been re-established and is even stricter than it ever was during the days of the Imperial Government." "Petrograd has been policed for some time by girls of from 17 to 25 years of age. Male militiamen are rarely seen, because all able-bodied men have been drafted into the Red Army."

As to profiteers: "Running down speculators is a leading passion of the Bolsheviki, but it is to be recorded with sorrow that the worst offenders in this direction are frequently to be found among their own kind, such as unimportant Kommissars, sailors and factory workers originally sent by their own organizations into the provinces in order to obtain produce but who then refuse to relinquish any part thereof, without being assured a personal graft of several hundred per cent."

All schools are free, and literacy has been made mandatory by the government, "but this order, the same as others like it, is universally ignored and the masses remain just as uneducated as ever, only they are by far more rough and cruel. The way things are arranged, it is even possible for any one who is literate to receive what passes for an engineer's diploma after going through a course of study lasting four months."

Institute of Electrical Engineers Becomes Charter Member of F. A. E. S.

At the meeting of the Board of Directors of the American Institute of Electrical Engineers held in New York City recently, the following resolution was unanimously adopted:

"Resolved, That the American Institute of Electrical Engineers accepts the invitation to it to become a Charter Member of the Federated American Engineering Societies, and pledges its hearty co-operation in the work thereof."

This action brings up the present membership of the federation to four societies: American Society of Mechanical Engineers, Detroit Engineering Society, Technical Club of Dallas, Texas, and the American Institute of Electrical Engineers. There is no question as to whether the organization will be formed; the Federated American Engineering Societies already is the largest engineering organization in this country.

Emergency Currency of Madagascar

The *Bulletin du Commerce*, Nouméa, New Caledonia, for July 2, 1920, reports that in Madagascar the shortage in money is being met by using postage stamps. Adhesives are attached to one face of a piece of cardboard bearing on its other face an inscription stating its value, and the whole is given a coat of varnish. These "tickets" are issued in denominations of .05, .10, .25, .50, 1 and 2 francs. When badly soiled or damaged by usage "tickets" are redeemed gratis at any post office. This currency is reported meeting with success, and to be preferred by the natives over nickel coins.

In Papeete, Nouvelle-Caledonie, and Tahiti, the chambers of commerce are putting out paper coupons (coupures) as in France herself, and Nouméa has also decided on this course. The expense of printing an adequate supply of coupons in the United States (200,000 were printed for Papeete) is inclining these colonies toward the Madagascar plan.

The Minnesota Federation

The movement to federate the engineers and the allied technologists is to again bear fruit. Engineers and architects from all parts of the State of Minnesota met at Duluth, Minn., recently and took the first steps toward the formation of a state federation of engineers and architects. It is presumed that this organization will become a member of the Federated American Engineering Societies and it is hoped that the action in Minnesota will be followed by similar action in other states; only through united action of this character can the full strength of the solidarity of the engineering and the allied technical professions be realized.

Book Reviews

The Ore-Deposits of Utah. By B. S. Butler, G. F. Loughlin, V. C. Heikes, and others. Professional Paper 111, U. S. Geological Survey. 1920. pp. 659, 9 x 11½. Price $1.50, from the Superintendent of Documents, Washington, D. C.

We are glad to hail this substantial volume as in our opinion the most notable contribution to economic geology, and perhaps to geology in general, for the year. The geology of Utah is broadly discussed, necessarily involving considerable space, but the language is compressed to a laudable extent. The authors have, to be sure, had the advantage of all the preceding geological studies made in Utah, yet much of their material is original, and more of their deductions are. We recommend students, in and out of universities, to use this work as one of the textbooks of economic geology. We would furthermore suggest to the authors that an abridged edition, leaving out the descriptive part, still further boiling down the rest, and including all the pertinent illustrations, would be well worth while.

In his explanation of the origin and interrelation of most of the ores of Utah, the senior author presents the most elaborate array of facts yet put forward in support of the theory of ore deposition suggested by Spurr in 1904 (p. 200), although since that time many facts and deductions supporting the theory have been presented by numerous geologists, notably (and early) by Sales, at Butte; and also from time to time by the proponent of the theory. The theory argues for the origin of vein-forming solutions as the siliceous extreme differentiation product of crystallizing magmas; and for the successive deposition, with decrease of temperature and pressure, of different metals from these residual solutions. Mr. Butler, however, adds much that is partly or wholly novel in the way of searching analysis and thoughtful deduction. One line of thought, in which Mr. Butler is one of the pioneers, if not the pioneer, is in regard to the economic significance of different horizontal sections of igneous stocks or laccoliths as now truncated by erosion:

"Ore deposits associated with the laccoliths and deeper truncated stocks are of comparatively slight commercial importance, and those associated with the apically truncated stocks are of great value."

This is a classic proposition. We have not tested this in the field, as Mr. Butler has, but the course of reasoning seems sound; and if corroborated in other districts this has a direct and important economic application in prospecting and mining. We should like to have the author develop more clearly the field criteria by which we may know an apically truncated stock from a more deeply truncated one. Certain criteria suggest themselves at once; but in many instances it occurs to us that the distinction may be perplexing. Another valuable generalization, valuable in any case as a working hypothesis, is that the deeper truncated stocks are uniformly the more siliceous. "The apically truncated stocks range in composition from monzonite to diorite and the deeper truncated stocks from granodiorite to granite" (p. 20). This in itself would be a criterion of the truncation horizon, if demonstrated; and is also, as the author points out, a feature supporting the general theory of the origin of ore solutions by magmatic differentiation. Still lower, more basic phases would be expected, according to the author's reasoning.

Other sapient suggestions, among many which the author has put forth, without transgressing from bold inductive reasoning to unfettered fancy, are that "fractures in passing downward should disappear at a level where the material was too liquid to retain a fracture at the time they were formed" (p. 199). There will be many other reasons for "bottoming" a vein, of course, but this deserves to be held in mind. Also that "the extent of the ore deposits associated with laccolithic bodies, other things being equal, is dependent on the size of the laccolith" (p. 198).

A very valuable presentation is that of covering primary sulphates, including gypsum and alunite, as a deposition from magmatic emanations (pp. 181-195). This should be read by every student.

We congratulate the authors at having put the "contact deposits" in their proper position with other mineral deposits. "It is believed that the solutions producing the two types of deposits had a common origin. If the solutions forming the contact deposits and the deposits in the intrusive rocks had a common origin they resulted from differentiation of the magma that formed the main intrusive bodies" (p. 174). We also congratulate them on their sturdy advocacy of intrusion by dynamic force, instead of the "stoping and assimilation" theory, though we should have advised them not to discuss theories for which they find no evidence. There are too many "snakes in Ireland" essays in geological literature.

It is natural, perhaps, as in the above case, to pay at least the deference of opposition to current theories, and in obscure cases to let current theories stand. Nevertheless we wish to protest against the discussion of the "Basin range structure" question, on which the intimidation of authority has procured the acquiescence in views beyond the authors' knowledge. No proof is given of the conclusions as to the ranges having their relief due directly and primarily to faulting. It may or may not be true; possibly in some cases true and others not—certainly the evidence cited in this volume does not support the theory. Some day we hope to see this subject discussed more from a scientific and less from a spiritualistic standpoint than is now the general custom. Visions are swift, and observation is slow. Things like this are airy nothings: "The Sevier Valley, in its middle course at least, has been considered as resulting from the settling of a block between two great faults, forming a fault valley or graben." Geological literature is rotten with faults that "ain't there." For example, we quote from Memoir 117, Canada Department of Mines, 1920 (S. J. Schofield[1]) p. 62:

"The origin of the Purcell trench has been described by Daly[2] in the following words: 'The Rocky Mountain trench and the Purcell trench are likewise located on zones of profound faulting: in each case the constructional profiles may have been grabens as typical as that of the middle Rhine or that of the Dead Sea.' The geology of the Purcell trench in the neighborhood of the international boundary line was worked out in greater detail by the writer in 1913 and *it was found that the faults marked by Daly on the geological map as occurring on each side of the Purcell trench were not present and that the valley in this locality was not a graben.*"

We wish we had space to mention a few more of the good things in the volume: the description and interpretation of the folding, for example—an earlier east-west compression, marked by overthrown folds and faults; and a later series of vertical, in part domical uplifts, with or without faulting, due to a series of general east-west igneous intrusions. We suggest to Mr. Butler in this a possible answer to our east-west vein conundrum, set forth editorially in our issue of Feb. 28.

J. E. S.

Mine Bookkeeping. By Robert McGarraugh, E.M. Cloth, 6¼ x 9½, pp. 118. McGraw-Hill Book Co., New York. Price $2.

In his introduction to this little volume the author states, "The segregation and distribution of cost data is essentially an engineering undertaking, and, as such, should be under the supervision of some one who is familiar with all phases of the work and who clearly understands the results which are desired." This summarizes the intent and purposes of the book, for Mr. McGarraugh has presented his subject matter in a suggestive way which is open to such elaboration as the engineer may devise for his own particular needs. The essentials are not lacking, and the work is most acceptable, as it gives a comprehensive outline of bookkeeping and accounting methods applicable to the requirements of mining operations as carried on by the smaller and less well-organized companies.

MEN YOU SHOULD KNOW ABOUT

G. R. Mansfield is making geological field studies in southeastern Idaho.

W. P. Cloonan has resigned as mill superintendent of the Yellow Pine Mining Co. at Goodsprings, Nev.

C. E. Dobbine has been assigned to geological reconnaissance work in the Powder River region of Montana.

J. H. McLean, general manager, spent Aug. 4 and 5 at the Gogebic and Marquette range mines of the Oliver Iron Mining Co.

H. D. Miser is acting chief of the section of iron and steel alloys of the Geological Survey during the absence of E. F. Burchard.

Dorsey A. Lyon, supervisor of stations for the Bureau of Mines, is paying official visits to the Bartlesville and Pittsburgh stations of the Bureau.

Joseph F. Kunesh, who has been in charge of the office of the U. S. Geological Survey at Tucson, Ariz., has resigned to enter private employ.

Robert G. Wilson, formerly with the Tonopah-Belmont Mining Co., has been placed in charge of the taxation division of the American Mining Congress.

John D. Northrup, of Cheyenne, Wyo., was in New York recently, and expected to sail on Aug. 28 for Peru, where he will spend two years in oil-field examinations.

C. W. Newton, general manager of Consolidated Interstate-Callahan Mining Co., has returned to Wallace, Idaho, from the recent directors' meeting in New York City.

Edward Packard, who controls the Gemini and neighboring properties in Eureka, Utah, has been there recently conferring with the managers in charge of his interests.

J. R. Finlay, of New York, was on the Gogebic Range from August 6 to August 11, having driven there from the copper country, where he has been professionally engaged.

T. F. M. Fitzgerald, for some years with the Tonopah Belmont Development Co., is now in charge of the Homestake Placer Co. operations at Copper Canyon, near Battle Mountain, Nev.

C. Y. Hsieh, a member of the Geological Survey of China, has been employed temporarily by the U. S. Geological Survey and assigned to work with A. E. Fath in the Lost Soldier oil field of Wyoming.

Harry J. Wolf has been retained as consulting engineer to the Richard D. Wyckoff Analytical Staff, and will go West late in August to investigate mining properties in the interest of the staff's associate members.

Alex Grosberg, has resigned his position with the Patino tin mines, Uncia, Bolivia, and has accepted the general managership for D. G. Bricker, mine operator at La Paz. Mr. Grosberg sailed for Bolivia on July 28.

C. D. Woodward, chief electrician of the Anaconda Copper Mining Co., with headquarters at Butte, was recently at the Walker mine in Plumas County, Cal., to inspect the electric haulage tunnel which has been installed there.

Paul Moore, director of War Trade Board's information bureau, becomes secretary of research extension division, National Research Council, next October. He will give special attention to the promotion of research with reference to the industries.

© Harris & Ewing

H. A. C. JENISON

H. A. C. Jenison, of the U. S. Geological Survey, who was recently assigned to assume charge of copper statistics, is in the West making a statistical and general study of our larger copper mines. His advance statement of the copper production of the United States in 1919 has just been distributed.

Bruce Middlemiss, assistant manager of the Chile Copper Co., visited in Hibbing recently after a three years' absence in South America. He was formerly general superintendent of the Mesabi Range operations of the Dean Iron Co. Mr. Middlemiss will return to South America early in September after several months' stay in the United States.

T. Nelson Dale, geologist, of Springfield, Mass., who retired from the U. S. Geological Survey on August 21, has spent six weeks this summer in active field work, collecting material for his bulletin on the limestones of Massachusetts, eastern New York and western Connecticut. Mr. Dale has also completed a revision of his work on New England's commercial granites, and a bulletin on southern commercial marbles.

J. W. D. Moodie, for many years general manager of Britannia Mines, has resigned and was succeeded on August 1 by B. B. Nieding, a mining man now living in Washington State. Mr. Moodie will take a long holiday and will go to California to reside. He has been in charge of operations at Britannia during the era of greatest development there and the company now owns a zone from Howe Sound to Indian River, at the northern end of the north arm of Burrard Inlet.

OBITUARY

F. L. Barker, mining engineer, and professor of mining and geology in Pei Yang University, Tientsin, China, died there on June 9, 1920, of smallpox. Professor Barker had taught in that university for the past five years, and had held a similar position in the University of Oregon from 1908 to 1913.

SOCIETY MEETINGS ANNOUNCED

Independent Oil Men's Association will hold its 12th annual national convention and a petroleum exposition at Denver, Col., on Sept. 28 to Oct. 1 next. The program includes, besides numerous characteristic hospitalities, cinematograph demonstrations of today's oil industry at work, an address of welcome by Governor Shoup, and communications on "International Aspect of the Oil Industry" by Van. H. Manning; "Specifications and Nomenclature," by W. F. Parish; "Production," by J. O. Lewis and A. W. Ambrose; "Present Condition of the Shale Industry in England and Scotland," by V. C. Alderson; "Relation of Bureau of Mines to Oil Industry," by F. C. Cottrell. Headquarters will be at New Albany Hotel, Denver, Col., and the sessions will be held at the Denver Auditorium Building, Curtis and Champa Streets. Secretary E. E. Grant's address is 110 Westminster Building, Chicago, Ill.

The Sixth National Exposition of Chemical Industries, at Grand Central Palace, New York City, Sept. 20 to 25, inclusive, has accepted nearly 400 applications for space. The program, aside from the exhibition proper, is also extensive. The American Institute of Chemical Engineers will hold a meeting in the Palace Sept. 23, and interesting papers will be read. In the evening the engineers will have a dinner at the Technology Club. Three other symposiums will be held during the week, one on fuel economy, one on materials handling, and one on industrial management.

A feature of this year's exposition will be moving pictures showing how American chemistry has advanced and the difficulties that have been overcome.

THE MINING NEWS

LEADING EVENTS

Lawsuit Outgrowth of Cuyuna Range Transaction

H. J. Kruse Seeks Share in Royalty on Ore Land Deal from C. D. Tripp, Former Partner

Claiming that he has been defrauded of valuable royalty rights in property on the Cuyuna Range in Minnesota by the manipulations of his former business associate, Henry J. Kruse has brought suit in district court at Duluth to recover from Chester D. Tripp, of Chicago, $219,744.35 damages. The purchase, optioning and leasing of eighty acres of mineral land in Crow Wing County is involved and dates back to 1910 and 1911 when Tripp and Kruse were both employees of the Rogers Brown Iron Co. in his complaint Kruse claims that on May 21, 1910, he purchased the surface rights of the eighty acres of land described as the south half of the northwest quarter of Sec. 11, 46-29, Crow Wing County, from a farmer with the intention of platting it into townsite and selling lots. Kruse alleges that, pending the closing of this deal, he was informed by Tripp that the latter was negotiating for the purchase of a mining option on a property lying west of the eighty-acre tract and that he would want the surface rights to the property which Kruse had purchased. Kruse claims that at that time it was not known to anyone that there was ore on his property and that it had no apparent value except for platting purposes.

The plaintiff alleges that he was induced to enter into an agreement to let Tripp handle the property on shares, Tripp having informed him that the mining company had abandoned all plans with regard to the eighty. He further alleges that the first arrangement was that Tripp was to handle the sale of the property on equal shares, but that later Tripp informed him that it would be necessary to handle it on thirds and still later on fifths in order to put the deal over through the agency of the Soo railroad. Believing Tripp, he agreed. Later, he alleges, Tripp induced him to deed away his surface rights to the Soo railroad, it being understood that he should receive $6,400, after which the surface rights would be deeded back to him less a strip for right-of-way. This was done in accordance with the plans and after deducting $1,655.65, the original cost of the property to him, he turned the balance of the $6,400 over to Tripp for negotiating the deal.

Kruse claims that Tripp then secretly negotiated with the Weyerhauser interests for an option for lease which later ripened into a lease through which Tripp was to receive 10c. per ton on all ore mined, all of which was part of a fraudulent scheme to cheat him out of his property. Kruse holds the value of the property, out of which he claims to have been defrauded, to be $219,744.35, including interest accrued.

WEEKLY RÉSUMÉ

Manganese ore from Brazil has arrived at Mobile, Ala., for consumers in the Birmingham district. In the Minnesota iron country, suit has been brought by H. J. Kruse against a former partner, C. D. Tripp, to recover a share in royalties from an iron ore land transaction on the Cuyuna Range. In the Joplin-Miami district, the Baker-Howell mine, near Baxter Springs, Kan., has been sold. Zinc operators are seeking to relieve the pressing car shortage by cutting the time in half allowed for unloading. The mine safety contest recently conducted in the Butte district has been won by the Emma mine.

In Washington the U. S. Bureau of Mines has selected Tuscaloosa, Ala., as the site for the new southern mine experiment station. The U. S. Geological Survey is planning greater activity for its foreign minerals section. Frank L. Hess, of the Survey, has returned from Bolivia.

Joplin Zinc Operators Seek To Relieve Car Shortage

An attempt to relieve the car shortage in the Joplin-Miami district is being made by operators through efforts of their own. Ordinarily freight cars that come into the field loaded with coal or other material are given four days for unloading. The mine operators, by mutual agreement, are endeavoring to cut this period exactly in two. Many coal cars are being unloaded at night and loaded with zinc concentrates the following day. An appeal for this effort on the part of the operators was made by Lee Willius, chairman of the car committee of the American Zinc Institute, at the meeting on August 18, and was met with prompt reponse on the part of the operators.

Emma Mine Wins Safety First Contest at Butte

The Emma mine, operated by the Anaconda Copper Mining Co., but owned by the Butte Copper & Zinc Co., was adjudged the winner of the safety-first contest recently held in the Butte district, extending for a period of 30 days. The Emma scored no accidents and was awarded a pennant by C. F. Kelley, president of the Anaconda. Even a scratch suffered by the miners was reported. During the period of the contest accidents in the Butte mines were reduced two-thirds. Sixteen of the mines in the district engaged in the race.

Baker-Howell Mine, Near Baxter Springs, Kan., Sold

Sale of Zinc Property Marks Activity in District Resulting from Chanute Spelter's Rich Strike

Sale of the Baker-Howell mine, situated in Oklahoma about three miles south of Baxter, has been announced. E. R. McClelland and J. W. Perry, of Kansas City, were the purchasers and the price paid is said to have been $50,000. The mine has been developed by T. B. Baker and John W. Howell, principal owner and manager, respectively, of the Connor hotel at Joplin. For a long time development of the property was handicapped by heavy water, but the pumping operations of the Chanute Spelter Co. at its Hartley mine, about two miles to the northwest, solved this problem, and the Baker-Howell Co. had recently been showing a profit on operations with hand jigs only. The new owners, who have operated successfully in this district, plan to erect a concentrator immediately. Their properties also include the St. Regis No. 1, at Duenweg; the No. 2, at Joplin, and the Quebec and Commonwealth mines at Picher.

This sale is the principal feature of the increasing activity in the Baxter camp, following the rich developments at Chanute Spelter Co.'s Hartley mine. At this latter property a drill hole has recently cut rich ore, indicating the existence of an entirely separate orebody from that being worked at present. The company is making approximately 75 tons of concentrates per day, operating single shift, and easily double that could be made, it is said.

Henry Ford Mum on Mining Plans in Michigan Iron Country

Now that Henry Ford has purchased the 400,000 acres of the Michigan Land & Iron Co. in northern Michigan, and is to start a large factory at Iron Mountain, Mich., on the Menominee Range, mining men are wondering what he is to do with the mineral holdings which have come into his possession. There are a few mines which have been worked, including the Imperial, at Michigamme, on the Marquette Range, a producer of limonite ores, and the U. S. Steel Corporation holds the lease on a deposit in the village of Alpha, near Crystal Falls, which has never been touched except by drills. Some of the lands are very likely iron ore, but no statement has been made by Mr. Ford regarding his mining plans. He has furnaces near Detroit and it is believed that he will later enter the mining field.

Manager of Esperanza Co., El Oro, Held for Ransom, Then Released

Captured by Pedro Zamora While on Examination in Jalisco — W. A. Gardiner Still Held by Bandit

Charles Hoyle, general manager of Esperanza, Ltd., of El Oro, Mex., his wife, and W. A. Gardiner, mill superintendent for the Esperanza company at El Oro, were reported on Aug. 21 to have been captured in Jalisco several days before by the bandit, Pedro Zamora, and held for ransom. Mr. Hoyle and a party of diamond drillers had gone to Jalisco before the Zamora revolt to inspect some properties there. Late reports had it that the rest of the party escaped.

An Associated Press dispatch, dated Mexico City, Aug. 23, announcing the release of Mr. and Mrs. Hoyle, reads as follows:

"Pedro Zamora has released six of the Americans who were kidnapped recently by him in the State of Jalisco, but is holding one American, W. A. Gardiner, superintendent of the Esperanza Mining Co., for 100,000 pesos ransom, and W. B. Johnson, a British subject, for 50,000 pesos, according to advices received here today.

"Charles Hoyle, manager of the Esperanza Mining Co. at El Oro, said to be a nephew of John Hays Hammond, and Mrs. Hoyle have been released and are now safe at Penas, on Banderas Bay. The names of the other four Americans set free by Zamora are given as Dietrich, Gillis, Culvert and Nels. These four are at Mesa del Corazon."

The Mexican Embassy at Washington admitted on Aug. 14 that a rebellion against the De la Huerta government had started in the State of Jalisco, the leader of the rebels being Pedro Zamora. It was then stated that the president had ordered 7,000 men to be sent to Jalisco under General Enrique Estrada to quell the rebellion.

Northern Light Title Dispute Decided

The case of C. W. Montague against S. P. McDonald and others, involving the title to what is known as the Northern Light mine, 14 miles from Yerington, Nev., has been decided in favor of the defendants by Judge Emmet Walsh, who has had it under advisement since it was tried some months ago. The mine was at one time under bond to the Mason Valley Mines Co. The plaintiff has asked for a new trial and states that he will appeal if it is denied.

Stockmen in southeastern Arizona have found a menace in the abandoned mine openings of the section, asserting that the old tunnels are the natural winter abiding places and summer breeding grounds of the blowfly, now menacing their herds. It is suggested that all such unused mine openings should be closed tightly.

Manganese Ore from Brazil for Birmingham District

Received at Mobile, Ala.—Intended for Tennessee C. I. & R. R. and Southern Manganese Companies

A shipment of 7,000 tons of high-grade manganese ore arrived recently at Mobile, Ala., bound for the Birmingham district. This ore will be used by the Tennessee Coal, Iron & R.R. Co. and the Southern Manganese Corporation. It is to be transferred to barges, which will come up the Warrior River and also to railroad cars. These shipments from Brazil will continue now that transportation facilities up into the district have been established.

The Government is taking steps to erect a big coal storage plant at Mobile, to handle coal shipped down from the Birmingham district on the Warrior River to permit the coaling of ships touching at that port. A portion of the storage plant is to be set aside for the ore that will be imported. With this apparatus in use unloading the ships and loading the ore on railroad cars or on barges for the river traffic, much expense and trouble will be overcome. The Southern Manganese Corporation has a plant at Anniston and is operating steadily, its product being taken by the Tennessee Coal, Iron & R.R. Co. almost exclusively.

To Study Ore and Peat Reserves on Minnesota State Lands

The committee of the Minnesota senate in charge of the state ore lands has established headquarters at Hibbing, Minn., and will spend considerable time investigating the ore and peat reserves on state lands. It is proposed to enact legislation at this year's session placing the remaining unsold state leases on mineral lands on the market. The leases have been off the market for thirteen years and if they are again offered for sale it is probable that the terms of the lease will be changed. One of the most interesting suggestions for the new leases is that royalties be based on a sliding scale. Under this proposal all ore on state lands would be classified as to quality and accessibility and royalties paid accordingly. Shipments from state properties during the last week totaled 204,745 tons of which the Missabe Mountain pit, at Virginia, shipped 94,944 tons.

Bulkeley Wells To Start Dredge at Dayton, Nev., Soon

September 5 is the date set for beginning operations with the big dredge that has been installed in the placer fields near Dayton, Nev., by Bulkeley Wells and associates. It is planned to make it a gala occasion. Mr. Wells and many of his friends will make the journey to watch the dredge start scooping up the gold-bearing gravel, and, of course, the Governor will be there to make a speech. It was at this place that gold was first discovered in Nevada.

Ontario Mining Association Meets in Sudbury

Members Visit International Nickel's Creighton Mine—New High Falls Dam Completed

The Ontario Mining Association, whose membership comprises over 95 per cent of the operating mines of the province, had its first general meeting in Sudbury on Aug. 17 and 18. The members were the guests of the International Nickel Co., who arranged a visit through the Creighton mine, the smelter and the power plant. The Creighton is supposed to be the largest high-grade mine in the world. Ore reserves are between twelve and fifteen million tons, and the ore carries between 5 and 6 per cent combined copper and nickel, in the proportion of two parts nickel to one of copper. At the present time about 3,000 tons per day is being hoisted and passed through the rock house, and 2,500 tons per day are being shipped to the smelter. At the power plant at High Falls, about 25 miles from the town of Copper Cliff and the smelter, a new storage dam is practically completed. This dam, while not quite so high, is longer than the famous Roosevelt dam in the Southwest, and when completed is expected to cost about $3,000,000. It is of the latest type of construction, and when the storage reservoir is filled with water, a lake 25 miles long will be formed.

On the following day a number of the members stayed over to accept the invitation of the British America Nickel Corporation to visit its mine and smelter at Nickelton.

Recent Production Reports

Calumet & Hecla produced 8,312,025 lb. copper in July. Production by subsidiary companies was as follows: Ahmeek, 1,572,838; Allouez, 262,400; C. & H., 4,684,972; Centennial, 34,600; Isle Royale, 775,200; La Salle, 0.; Osceola, 735,900; Superior, 85,800; and White Pine, 160,315.

Wolverine produced 246,343 lb. copper in July, against 327,683 in June. Mohawk's output in July was 698,558 lb. copper, compared with 754,304 in June.

Burma Corporation produced 3,416,000 lb. refined lead and 190,070 oz. silver in July, compared with 4,733,120 lb. refined lead and 265,620 oz. silver in July. The decrease was owing to changes necessitated by putting the mill in operation.

Butte & Superior in July produced 7,914,024 lb. of zinc in concentrates and 159,778 oz. silver, compared with 8,250,000 lb. zinc in concentrates and 160,000 oz. silver in June.

Cie du Boleo, Santa Rosalía, Baja California, produced 781,613 lb. copper in July, compared with 802,474 in June.

Cerro de Pasco produced 3,652,000 lb. copper in July, against 3,994,000 in June.

East Butte produced 1,537,880 lb. copper in July, compared with 1,396,140 in June.

Geological Survey Has Plans for Foreign Minerals Section

Domestic Producers Should Be Informed on Matters of Economic Significance Abroad

Since early in the war, the U. S. Geological Survey has entertained ambitious plans for its section of foreign minerals. During the war, this section did a large amount of work and from its data many economic conclusions with regard to mineral resources were reached. With the passing of the urgent war demand for this data, the difficulties of securing appropriations and personnel have prevented any great amount of work on the part of the foreign minerals section. The work has been kept going, however, and in the near future an important announcement as to the plans of the section is expected.

It is a very generally held belief that the United States has been particularly slow in acquainting itself with the mineral resources of other countries and in keeping abreast with their development. Had the United States been diligent in that regard during the last decade or two, it is pointed out, it would be in a better position now to compete in the world-wide quest for petroleum. At any rate, it is agreed that the mineral industries of this country are entitled to the help that the Government can extend by keeping them carefully informed on matters of economic importance in foreign countries which affect them. While some of the more highly organized companies may be in a position to keep sufficiently well-advised as to the foreign situation to conduct their operations in a most intelligent manner, it is certain that the smaller operators oftentimes do not become aware of important foreign developments having a bearing on their particular activities until losses have resulted. Many of these losses could have been prevented, had the information become available earlier.

Mining Conditions in Bolivia Discussed by Frank L. Hess

The mining industry in Bolivia has expanded to the point where labor supply has become a limiting factor of unusual seriousness. This is the opinion of Frank L. Hess, of the U. S. Geological Survey, who has just returned from an extended profesisonal visit to that tin-producing republic. Owing to the fact that much of Bolivia's mineral production comes from an altitude in excess of 14,000 ft. and very little of it from below 12,000 ft., the labor can be performed only by persons indigenous to those attitudes.

Because of the rigors of atmospheric conditions, the lack of fuel, proper housing and sufficient nourishment, the population on the high plateaus has been diminishing. Mr. Hess believes that the only solution to the problem is for the mining industry to make it possible for the Indians of that region to better their living conditions. The American companies and others of the more progressive mining concerns have been taking good care of their own employees for some years, but he believes that the welfare work must go further than that and include the entire populations of the upper plateaus.

There is promise of reducing the obstacles of lack of transportation and lack of fuel. The development of petroleum on the eastern side of the Andes in Bolivia, which now seems a certainty, will mean a near-by supply of fuel oil. The Guggenheims, in building a motor road from Eucaliptus, on the railroad, to Caracoles, have demonstrated that automobile transportation is possible. Water power is already being used successfully and important expansion is predicted by Mr. Hess.

The tin mining industry has continued its expansion which began with the war demand. A number of new properties are being opened, the district north of La Paz being the most active. The price of silver has given unprecedented stimulus to that industry. The whole of the famous Potosi hill is now being sampled and probably will be the scene of modern development on a very large scale.

The large amount of tungsten mining done during the war has developed beyond all question the value of the extensive tungsten deposits in Bolivia. When Mr. Hess left that country a few weeks ago, none of the tungsten properties was being operated, but he believes that some of them can be operated at present prices. He anticipates that Bolivia will be an important factor in the tungsten situation in the future.

Mr. Hess' geological studies in tin properties while in Bolivia lead him to think that it is becoming clearer and clearer that tin deposition in Bolivia is governed by the same processes as govern deposition of tin at other places, which is quite contrary to the opinion expressed by geologists who made earlier investigations of this problem.

Purchases of silver, under the Pittman Act, during the week ended Aug. 21, totalled 296,000 fine oz. This brings the total purchases under the act to 11,718,638 oz. The only purchases were made in the early days of the week, as it became apparent that the price of silver in the open market was going above $1 an ounce and no further offerings were made.

Tuscaloosa, Ala., Gets New Mine Experiment Station

Will Co-operate With University of Alabama—May Do Ferrous and By-product Work

Tuscaloosa, Ala., has been selected as the site for the U. S. Bureau of Mines experiment station that is to be established in the South. This station will co-operate with the University of Alabama at Tuscaloosa. The nature of the experimental work to be done remains to be decided. It was the intention originally to make this station distinctly a chemical one—that is, to confine its activities largely to the nonmetals. There is such demand, however, for ferrous and byproduct work in the South that it is not improbable that this class of experimentation will be undertaken almost exclusively. It is suggested that as Tuscaloosa is near areas producing graphite, talc, clays and fertilizer materials, these subjects should be taken up at the new station.

The University of Alabama has offered laboratory, office and library facilities and will allow general co-operation in the work on the part of its technical staff. Tuscaloosa is 60 miles southwest of Birmingham.

Other contenders for the station were the University of North Carolina, at Chapel Hill, N. C.; Georgia School of Technology, at Atlanta; University of Tennessee, at Knoxville, and the city of Birmingham. Birmingham already has the office of the Bureau of Mines district engineer and a mine rescue station.

Bureau of Mines Must Have More Money

Otherwise Impossible To Make More Intensive Study of Metal-Mining Methods and Conditions

If the U. S. Bureau of Mines is to meet the increased demand for a more intensive study, from the economic viewpoint, of metal mining methods and conditions, appropriations for that purpose will have to be forthcoming. Officials of the bureau apparently are of the opinion that there can be no important curtailment of the existing program, certainly not enough to provide for substantial additional expenditures for a metal mining program if the total fund available is to remain the same. Roughly, the bureau's appropriation is divided among the following activities: Investigations as to the cause of mine explosions; the prevention of accidents in mines; technologic investigations pertinent to the mining industry; investigation of mineral fuels for the use of the United States; metallurgical investigations; petroleum work; min-

ing experiment work at stations and the operation of mine-rescue cars. The Government fuel yard is self-sustaining.

It is practically certain that the next Congress will be more generous in the matter of appropriations than was the last, so far as the Government's civil activities are concerned. With the pressure that is certain to come from the metal-mining sections of the country, it is regarded as highly probable that Congress will provide for an expansion of the Bureau of Mines' metal mining activities.

War Minerals Relief Awards

Awards recommended by the War Minerals Relief Commission, during the week ended Aug. 14, totalled $6,397.12, were as follows (the name of the claimant, the mineral, the amount recommended and its percentage relationship to the amount claimed are shown): Munitions Metals Co., chrome, $496.72, 8 per cent; G. C. Grimmett, chrome and manganese, $1,633.37, 41 per cent; C. G. Hughes, chrome, $1,052.40, 42 per cent; Moyle & Secco, chrome, $631.30, 95 per cent; Puterbaugh & Tuohy, chrome, $6,273.88, 78 per cent; J. S. Shepherd, manganese, $1,331.53, 86 per cent; A. H. Noyes, chrome, $971.80, 27 per cent. In the claim of Puterbaugh & Tuohy, the amount shown includes $280, which has been added to an award already reported during the week ended July 17.

The U. S. Bureau of Mines has agreed to furnish an exhibit at the convention of the American Mining Congress, which will be held this fall in Denver, Colo.

NEWS BY MINING DISTRICTS

MEXICO

Sonora

Las Chispas Property Examined

Las Chispas — Frank M. Manson, president of the Western Ore Purchasing Co., of Reno, Nev., recently inspected mining properties in the State of Sonora. One of the objects of his trip was to look into the desirability of establishing several samplers in Mexico and Arizona, but he took the opportunity to make a thorough examination of the property of the Las Chispas Extension Mining Co. in which he is interested. The mine is located in the Arizpe mining district, Sonora, 140 miles south of the border at Naco, and is the western extension of the Minas Pedrazzini holdings, the veins of which pass through it, according to the report of Frank W. Royer, who made an examination of both properties.

The country rock in which the productive veins of the district are found is a series of lava flows, consisting, in order, of rhyolite breccia, trachyte, another rhyolite breccia called locally "606" breccia, and then other trachytes. From the surface down to about 600 ft. depth the country rock consists of horizontally-bedded rhyolite breccia and tuffs, and it is in this formation that most of the large bonanza orebodies in the Minas Pedrazzini have been found. Immediately below the rhyolites and bedded tuffs is from 300 to 400 ft. of white trachyte. The vein continues through this formation but the orebodies found are, as a rule, not as big as those found in the rhyolite breccia. The vein continues into the "606" breccia and some bodies of ore are found. The lower trachyte has not been opened in any of the workings, so it is impossible to say if the veins continue into this formation.

The San Gotardo tunnel of the Pedrazzini Company opens up the Las Chispas vein at a depth of 600 ft. below the surface for a length of 4,000 ft. along its strike. The vein at this depth runs from the thickness of a knife blade up to 6 and 8 ft. wide.

The orebodies encountered in the Las Chispas vein, as related in Mr. Royer's report, are usually found by following quartz stringers which are scarcely more than seams in the rock; after following for several hundred feet, the vein opens up into an orebody. These stringers frequently contain no values whatever. The orebodies when opened up are from one to 6 and 8 ft. wide, and several hundred feet long, and as high as $3,500,000 is claimed to have been taken from some of the bodies first opened near the surface. The ore consists of quartz containing argentite, and the two antimonial silver sulphides polybasite and stephanite.

There has not been a great deal of development on the ground of the Las Chispas Extension company, but as it is said to have the extension of the Las Chispas vein, from which practically the entire production of the Pedrazzini company has been obtained, and as it is in the same ore-bearing formation, the outlook is thought to be encouraging. For a length of 200 ft. on Extension ground the Las Chispas vein is intersected by numerous cross veins and stringers, and it is expected that as depth is gained there shipping ore will be encountered. The vein was sampled, where exposed, by Mr. Royer and $88 values obtained from a 2-ft. streak and as high as $284 from a 2-in. streak. The samples were of soft, oxidized, leached material.

There is also a large vein, from two to 15 ft. wide, on Extension ground, along a contact of rhyolite breccia and andesite. Two 1-ft. samples from this vein gave returns of $23 and $60.80 per ton and while it probably will not be as productive as the Las Chispas vein, Mr. Royer has recommended its development.

Zacatecas

El Refugio mine, Pinos district, Zacatecas, 15 kilometers from the station of Sotol on the Aguascalientes-San Luis line, and adjoining the Benito Juarez property, is putting up a 50-ton mill and the owners expect to be operating by the end of the year. The district has been quiet for the last seven years on account of the depredation of small groups of bandits.

The Camp Bird (British) interests are doing a large amount of development work at Fresnillo, where they have taken over several large low-grade propositions, which have been idle for years owing to low price of silver and difficulties of handling the ores. A large cyanide plant is in course of construction for working the ores of the district and it is expected to be in operation by Dec. 1.

The old Mina Grande, on the outskirts of Zacatecas, has been taken under option and extensive development work is being done with the intention of erecting a crushing and cyanide plant in the near future. It is also understood that the Mina Grande people propose to build a railway between Salinas and the main line of the old Central railway at or near the city of Zacatecas for the purpose of avoiding the long haul for fuel oil that is at present being pulled from Salinas to Aguascalientes and back to Zacatecas.

The Mexican Mines Development Co. has taken a working option on the Noria property of Walter C. Palmer and has a considerable force of engineers on the ground making examinations. New York capital has also taken options on several less important properties in the same district (Sombrerete) and has its engineers there now making examinations and reports.

CHILE

At Chuquicamata the Chile Copper Co. is installing 35 fuel oil tanks, a new crushing plant, a dust-removal and recovery plant, 48-in. conveyors and feeders, three additional leaching vats and eight more solution sumps. This work is to be completed before next year. The output in June decreased, owing to the failure of the Union Oil Co. of California to deliver fuel oil according to contract. From 50,000 to 80,000 bbl. of fuel oil are used monthly at the company's power station at Tocopilla and 25,000 to 30,000 at Chuquicamata for the smelter and locomotives.

CANADA

British Columbia

Delta Copper To Be Drilled—Consolidated's Emma Mine To Resume

Hazleton—The Delta Copper Co.'s property, on Rocher de Boule Mountain, is to be diamond drilled. Tunneling that was being done has been found too slow and a drill will be installed as soon as possible. If results are satisfactory further tunneling will be done.

J. D. Galloway, resident engineer with headquarters at Hazleton, has been continuing Keystone drilling operations on the placer areas at Harper's Camp. This work was started last year but, for various reasons, could not be finished. An expert crew of men has been engaged by Mr. Galloway and operations have been underway for some weeks.

Trail—Four men were more or less seriously hurt recently in the copper refinery of the Consolidated Mining & Smelting Co. All were burned about the face and one may not recover his sight.

Ore shipments received at the Consolidated smelter during the week ended Aug. 7 are given in the following table:

Mine.	Location.	Gross tons
Canada Copper,	Greenwood	11
Index,	Zwicky	12
Josie,	Rossland	228
Mandy, Le Pas,	Man.	733
North Star,	Kimberley	120
Providence,	Greenwood	42
Velvet,	Velvet	34
Company mines		9,038
Total		10,221

Nelson—The Emma mine of the Consolidated Mining & Smelting Co. will resume operations immediately with 50 men. This property formerly shipped about six cars of ore a week but work ceased last year when production was discontinued at the Rossland mines. Now that the latter have been placed on a shipping basis Emma ore is required as flux. The ore is low-grade gold, silver and copper.

Vancouver—Conditions at Keno Hill, Mayo District, Yukon Territory, where the discovery of rich silver ore has been reported, are described by a miner recently returned from the North, who is quoted as saying:

"Preliminary prospecting has uncovered evidence of as many as nine separate leads of silver-galena shipping ore. The present known depth and length of these are such that shipping ore now in sight will require many years of considerable activity to mine.

"Taken from one of the leads on the plateau of Keno Hill is what the miners call the 'War Baby' silver galena nugget. It is one oblong piece of solid silver galena, similar in shape to a large potato, weight estimated to be 1,200 lb. From the same vein or ledge from which this piece came are four other nuggets or slabs. These are nearly solid silver galena and by comparison the weight of the smallest is easily 800 lb.

"On either side of these slabs and also below and above, the vein is in evidence, with manganese capping, carbonates and footwall.

"Owing to the surface character of some of the leads it has been possible to develop with comparatively little effort to a point where ore can be shipped. In places one man can pick down or mine a quarter of a ton of shipping ore per working day."

It is stated by the same individual that the holdings of the Yukon Silver Lead Mining Co. were located and partially developed before the discovery of the Keno Hill properties. The former are situated on Mount Haldane or Lookout Mountain and are in direct line with Keno Hill and the Silver King, from one pocket of which silver is said to have been taken valued at $500,000. Much development has been done on Lookout Mountain, tunnels and shafts having been driven aggregating 1,200 ft. It is stated that the vein has been followed for 400 ft. perpendicularly, disclosing good shipping ore. Development on such properties as the Silver King, Mount Rambler and others in the section, as well as in the Twelve Mile area, should prove the extent of the area of the silver-lead orebodies in the Yukon.

Ontario

Dome Shareholders Asked to Ratify Purchase of Dome Extension—Conditions at Cobalt Improved

Porcupine—A diamond drill hole put down recently by Hollinger to test geological conditions cut ore at a depth of 2,400 ft. It is understood that an English syndicate has acquired a number of claims lying west of the Hollinger. These are in a sand plain and are covered by about 70 ft. of overburden. About 20,000 ft. of diamond drilling will be done in an effort to locate the contacts and the extension of the Hollinger orebodies.

A special shareholders' meeting of the Dome has been called for Sept. 4 to ratify the purchase of the Dome Extension property by the issue of 76,000 shares of Dome. The purchase has received the unanimous approval of the directors.

The Davidson, which is now closed, is understood to have received sufficient English money, through the sale of stock, to permit the resumption of operations on an extensive scale.

On Sept. 7 a special shareholders meeting of the Vipond will be held for the purpose of ratifying the proposal to sell a block of treasury shares to a syndicate headed by H. B. Wills. The mine will be pumped out and the shaft deepened from the 600 to 900-ft. level.

The supply of labor in the camp, though still below the demand, is increasing. An influx of British miners is anticipated owing to the dullness of the English mining industry, and it is stated that the Hollinger Consolidated has already arranged to take on fifty English mine workers.

Kirkland Lake—The Granby Kirkland has uncovered six veins on the Bain. Telluride is said to have been found in a vein 15 ft. wide.

Boston Creek—The Miller Independence is offering 40,000 shares of treasury stock to present shareholders at $1 per share. Development work latterly has consisted chiefly in cross-cutting and drifting on the 500 level. The main cross cut is in 300 ft., and is believed to be within 70 ft. of the gold telluride deposit opened in an incline.

Gowganda—The mines of this district with the exception of the Miller Lake-O'Brien, the Castle and a few others are inactive, operations having been suspended in the majority of cases owing to the excessive cost of labor and supplies and the drop in the price of silver.

The management of the Big Four mine has decided to employ oil-burning engines to overcome the fuel difficulty. A shaft is down 40 ft. and has cut ore.

Cobalt—In Cobalt, the rising price of silver has caused a more optimistic feeling, and this, together with a better labor supply, is responsible for increased activity throughout the district. A certain amount of foreign labor is coming in and despite the heavy drain of men for the harvesting in the West, the supply for the mines is sufficient.

The Crown Reserve will do 5,000 ft. of diamond drilling to locate the diabase sill definitely.

The Kerr Lake is now treating dump ore in the Dominion Reduction mill and results are understood to be better than had been estimated.

The Peterson Lake has struck three narrow veins in cross cutting on the 200 level. A large orebody is being blocked out.

The Provincial, situated in the Gillies timber limit, has opened up a high-grade vein on the 200 level for 50 ft. Raises show that the vein extends upwards for at least 50 ft.

The July ore shipments over the T. & N. O. Ry. were as follows: Coniagas, 64; Dom. Reduction, 65; Hudson Bay, 30; La Rose, 89; Mining Corporation, 64; McKinley-Darragh, 42; Northern Customs, 48; Nipissing, 447; O'Brien, 97; and Temiskaming, 41; total 988. This was consigned as follows: Deloro S. & R., 763 tons; Coniagas Reduction Co., 33 tons; A. S. & R., Perth Amboy plant, 42; A. S. & R., Pueblo plant 150 tons.

Manitoba

Gold Pan and Pan Extension Form Agreement

Rice Lake—The Gold Pan and Pan Extension Companies have come to an agreement under which the Pan Extension will supply power to the Gold Pan. J. A. Borthwick, superintendent of the Pan Extension, will have charge of both mines, which will both work double shifts. The shaft of the Pan Extension will be put down from its present depth of 115 ft. to the 500-ft. level.

NORWAY

Glomfjord Smelter To Start Zinc Refining on German Shell Cases

Glomfjord—The new hydro-electric plant is ready to furnish 50,000 hp. and the capacity is being increased. The smelter company, which has a capital of 12,000,000 kroner, will start operations next month with zinc refining. The zinc consists of shell cases purchased from Germany, of which the company has several shiploads. The Germans had to revert to zinc for their cases when the supply of copper ran out. Later the smelter will treat zinc ore purchased from Sweden. The company has leased about 50,000 hp. from the state power station, which is ready at any time to furnish it.

It has been decided to operate the Dunderland mines again in about a year's time. A new method of dealing with the ore has been experimentally tried, but high freights and coal prices have necessitated a waiting period before recommencing work. The company has expended 40,000,000 kroner in construction and mining, including the 22-kilometer Dunderland railway. Since the mines closed down in 1908 a number of men have been employed in maintenance and repair work in connection with the buildings and equipment.

MINNESOTA

Cuyuna Range

North Range Iron Co. Leases Onondaga Co.'s Land

Ironton—The North Range Iron Co., controlled by R. M. Adams, has taken a lease of Lots 1, 2 and 5 of Section 4—46—29, from the Onondaga Iron Co., of Duluth, controlled by G. G. Hartley. The property will in turn become part of the Marquette Ore Co.'s operations. The land just leased fronts on Mahnomen Lake, and will be valuable for water supply for hydraulic stripping and for wastage of tailings from the washing plant now being erected at the Maroco mine of the Marquette company. The shaft at the Maroco has reached a depth of 210 ft. The property will be stripped hydraulically.

The Cuyuna-Duluth mine has completed installation of a triplex electric pump on the new 340-ft. level. The operators are planning to use motors for haulage on the new main level.

Crosby—The Croft mine will sink two new shafts for drainage and handling of timber purposes. One shaft, 6 ft. by 9 ft., has been started at a point about 1,000 ft. east of the main shaft.

Mesabi Range

Shipments Increasing from Hibbing District—Thirty-Five Drill Holes on Stubler Project Find Ore

Hibbing—Shipments from this district, although not yet up to capacity, have increased considerably during the last two weeks. The Oliver Iron Mining Co. is shipping from 1,200 to 1,500 cars daily from the Hull-Rust, Morris, Sellers, Kerr, Sweeny, and Philbin mines. Screening is in progress at the Morris and Webb mines and at the latter the screening plant product is also being washed.

Winston-Deare have finished the drag-line excavator work at the Scranton and are tearing the machine down for shipment to the Sagamore pit on the Cuyuna Range where they now have a similar machine in operation.

Buhl—The Great Northern Power Co. is completing a central power-distributing station to serve the Wabigon, Frantz and Thorne properties of the Hanna Ore Mining Co. The Wabigon will be the scene of the first electrical shovel operation on the Mesabi Range and it is expected that stripping will start early this fall.

The forty-fifth hole has been completed at the Stubler exploration project and it is reported that thirty-five of the holes have found ore. It is now proposed to sink a small shaft for the purpose of exploratory drifting.

Mountain Iron—The U. S. Bureau of Mines car is at Brunt mine of the Hanna Ore Mining Co. where it will remain four or five days, later going to Hibbing where it will be stationed at the Leetonia mine.

MICHIGAN

Marquette Range

Cliffs Shaft Change House Burned—Diamond Drilling Standard Property

Republic—Cole & McDonald have two diamond drills working on the old Standard property, but no information has been given out regarding those who are back of the project. Considerable work was done in this vicinity several years back, but no mines of importance were ever opened. Some ore was found, but not in sufficient quantity.

Ishpeming—On August 17 a part of the change house at the Cliffs Shaft mine was destroyed by fire. Many of the several hundred miners who make use of the building lost their underground clothes. The building is to be rebuilt immediately.

Menominee Range

Crystal Falls—The railroad serving the Odgers was tied up recently for a time because of a cave in of the surface at the Bristol mine. The St. Paul road is not using the North Western tracks to the mine and will probably not be able to use them for the remainder of the season. The cave was expected at the Bristol and caused no interruption of mining work.

ALABAMA

Iron Ore and Lands in Demand by Interests Outside Birmingham District

Birmingham—Representatives of interests outside the Birmingham district have been examining certain iron-ore lands in Alabama. Most of the iron land in the state is already under lease to or owned by companies using the output. There are a few independent ore mining companies which have no trouble in selling their output. When the Gulf States Steel Co. gets its deep mining project at the Shannon mines under way, it will be unnecessary for it to look to independent companies for any of its needs. At present the Gulf States company is getting some ore from the Crudup mines near Gadsden. The owners of the Crudup property are said to be not in the least disturbed at the prospect of losing a customer, as there are almost daily inquiries for ore and various propositions for taking over the mines altogether have been heard of lately. The property has been recently appraised, inquiries being made looking to the purchase of the Trussville blast furnace, which would make it necessary to secure ore from the Crudup mines.

Development of brown ore in the vicinity of Russellville, in northwestern Alabama, is being pushed, the Sloss-Sheffield Steel & Iron Co., the Sheffield Coal & Iron Co., the Alabama Fuel & Iron Co. and others being operated steadily in this section. Brown ores in the vicinity of Woodstock, Ala., property of the Republic Iron & Steel Co., are also under development.

Ashland—The new plant of the Dixie Consolidated Graphite Co. is nearing completion. It will have a capacity of 400 tons of ore per day.

ARIZONA

Van Dyke Shaft Bottomed — Jerome Verde Property Closed Down—U.V.X. Commissary for Jerome

Ajo—Two 25-ton Trent cyanide machines have been purchased by A. W. Bramwell, to recover values lost in amalgamating silver-gold ores of a Gunsight property operated by him.

Globe—The Van Dyke Copper Co.'s shaft has been bottomed at 1,692 ft. and levels will be opened at 1,215 and 1,550 ft. The shaft cut ore on the dip at 1,180 ft. which continued for 40 ft.

Tombstone—The Solstice M. & M. Co. has made final payment to L. F. Winters of the purchase price of its local holdings, in which it is claimed that $120,000 worth of ore has been blocked out. Plans are being made for a 50-ton mill, with cyanide equipment and for a hoist and compressor. The ore is said to run $18 a ton.

Bisbee—About three-fourths of the overburden of the Sacramento Hill has now been removed by the steam shovels that have been operating on the hill benches for several years past, and it is expected that the copper-bearing schist will be exposed for mining early in the new year, about the same time that the new concentrator is completed. Although an enormous tonnage of low-grade disseminated schist will be available at Sacramento Hill, more will come to the mill from the Copper Queen stopes, where the ore has already been developed, though passed by as too poor for profitable smelting. The

Sacramento Hill operations will extend up Mule Pass almost into the city of Bisbee and will radically change the face of nature in their locality.

Jerome—Samples taken across the 5-ft. face of the Shea tunnel are reported to average 15.6 per cent copper, 15 oz. silver, 1.04 oz. gold, or a total of $88.30 a ton. The face of the tunnel is in chalcopyrite.

U. V. Extension has bought a lot in Jerome and is expected to build a commissary on it such as the one at Clemenceau.

Joe Cavanaugh and Harold Caldwell, of Jerome, are reported to be preparing to erect a flotation plant on the Blue John property at Walker. They are shipping some ore.

The Jerome Verde property has been closed down indefinitely and the pumps pulled. Lack of funds is given as the reason.

Turkey — The Howard Copper Co. states that it is not affiliated with the Howard Silver Mining Co., in the Black Canyon district, as reported in the issue of July 31.

Poland—Only the ties and rails of the abandoned Poland railroad are to be removed. Under an agreement with Yavapai County the road bed and bridges will be left intact and will be used for making a county road, over which ore may be trucked to the nearest railway shipping point.

Bouse—Plans have been made for development of water power on Bill Williams Fork by R. M. Stene and associates, as an annex to the operations of the Stene Consolidated Copper Co., which has a large acreage of low-grade carbonate ores in the southeastern corner of Mohave County. Plans have been filed with the State Water Commissioner for a dam 144 ft. long, its crest to be 110 ft. above the river bed, and for a concrete conduit leading to irrigable lands situated near Bouse.

Greaterville — The Liberty Silver Mining Co., operating the Saint Louis group, has its main shaft down 200 ft on a vein that shows 3 ft. of silver-leaf ore, with copper coming in on the footwall.

Tucson—S. W. Purcell has bought a fluorspar deposit in the Sierritas from the estate of Gus Holstein.

NEW MEXICO

Co-operative Ships High Grade—Unwatering Silver King Near Central

Lordsburg—The Bonney Consolidated Copper Co. is working about 40 men on outside development work with good results. Several new strikes of high-grade surface ores carrying copper and silver have been made. A strong vein of silver-lead ore opened on the east end of the property will be further developed.

The main shaft of Calumet & Arizona's 85 mine is reported to have reached the 900-ft. level.

The Co-operative mine shipped a car of ore, half of it high grade, to the El Paso smelter on Aug. 12.

The Octo is pushing work on the new drift on the 300-ft. level. Good carbonate copper ore was struck in cutting the station. About thirty men are working. Fred C. Semmek is superintendent.

Silver City—T. C. McSherry and eastern associates have started operations at the Silver King near Central. At present the mine is being unwatered. The property consists of five claims and has been worked occasionally since the 80's. Development consists of a main shaft, 117 ft. deep, and several hundred feet of drifts and cross-cuts.

The Silver Spot mine is continuing to open good ore. No. 2 shaft has been sunk to 73 ft. and the silver-bearing vein has opened to 10 inches.

LOOKING NORTH OVER PLANT OF UNITED VERDE EXTENSION MINING CO., JEROME, ARIZ. DOUGLAS RESIDENCE AT RIGHT

COLORADO

Valley View Concentrator Completed—North Boulder Creek Co. Erecting Mill

San Bernardo—The new 100-ton concentrator of the Valley View Leasing & Mining Co. has been completed and test mill runs are being made for the purpose of adjusting the machinery. Walter L. Reid, of Telluride, is designer of the plant, and Harry Doyle was engineer in charge of construction. The mill will treat ore from the San Bernardo mine. The milling process includes ball mill crushing and oil flotation.

Telluride—Shipments of concentrates from Telluride for July were as follows: Tomboy, 60 cars; Smuggler-Union, 35 cars; total, 95 cars.

Ophir—Development of a lease on the Favorite mine under the direction of Gideon Baril has opened payable shipping ore. A carload has been shipped to the smelter at Durango.

Boulder—Shaft sinking is under way on the Blue Bird mine, of the North Boulder Creek Mines Co. A new mill is under construction. The foundations are completed, and some of the machinery is being installed. The process to be used will require the installation of flotation equipment.

Mayday—Curtet & Moigg, lessees on the Southern Boy, have completed their cross cut, having penetrated the ore-body after eight-months' work. The vein is 1 ft. wide and is said to run in gold.

The Mayday Leasing Co. continues operations on the Mayday dumps. Two cars have been shipped to the Durango smelter. The screenings run $16 to $28.50, with some crude assaying as high as $70 per ton in gold and silver.

The Jumbo continues shipping from the 800-oz. silver vein recently found in the raise. Another raise is being driven to explore the fissure vein and lime stratum at contact.

W. A. Becker, manager of the Little La Plata and Boren Gulch, is having a compressor installed at the latter property. Mine operation will then be resumed.

The cross cut at the Little La Plata property, which has been pushed continuously since last winter, has not proved as beneficial as was expected. Part of the force employed on this has been put to work on the vein at surface, from where lessees have made shipments of ore.

R. E. Hutchinson, of Durango, owner of the Puzzle in La Plata Canon, is to begin work soon on the property. The 700-ft. tunnel will be extended to cut the Southern Boy vein. Hutchinson is owner of the Southern Boy, which is being worked by lessees who are mining some good ore from a small streak.

Work of installing a 12-mile telephone line from Mayday to La Plata has been completed. This line was built by the operators in La Plata Canon, and will be connected with the Cumberland, Allard and Ten Broeck, as well as with the postoffice at La Plata.

MONTANA

Work Stopped at Mt. Washington Mine in Wickes District—Planned To Reopen Comet

Butte—Drifting upon the orebody recently opened by Anaconda at a depth of 3,800 ft. in the Stewart shaft shows a shoot 10 ft. wide averaging 12 per cent copper. Portions of the orebody will run up to 20 per cent. Anaconda has opened an orebody said to be 80 ft. wide in the Nettie mine that carries good milling values in silver, lead, zinc and gold, together with considerable first class ore. The July production of Anaconda was 1,000,000 lb. of copper less than in June. Operations are curtailed over 50 per cent.

Butte & Superior's Black Rock mine in July produced 31,702 tons of ore from which 7,348 tons of concentrates was made, as compared with 34,200 and 7,800 respectively the preceding month. The output of zinc in concentrates was 7,914,024 lb. with the silver yield 159,778 oz. as against 8,250,000 lb. zinc and 160,000 oz. silver in June. Mill recovery in July was 97 per cent. This is somewhat greater (about 3 per cent) than in recent months owing to a general mill cleanup that was made, in the course of which small lots of ore more amenable to treatment were handled.

The North Butte company's Granite Mountain mine in July produced 1,555,079 lb. of copper, 65,324.92 oz. of silver and 98.88 oz. of gold as compared with 1,616,822 lb. copper, 67,534.45 oz. silver and 97.65 oz. gold in June. A feature of development work at present at the Granite Mountain is the driving for the Edith May vein on the 3,600-ft. level to reach points under the 3,400 and the 3,200-ft. levels, where a high-grade showing of ore in substantial tonnage is in evidence.

Shipments from Tuolumne Copper's Main Range mine continue at a rate of from 100 to 150 tons daily. A good tonnage is reported either in sight or indicated. Arrangements are being made with a view of starting to sink the Main Range shaft from the 1,200 to the 2,000-ft. level.

The ore showing on the 2,700-ft. level of the Colorado mine is said to be the best in the property's history as regards the tonnage of high grade indicated. The output is being held down to 200 tons daily with the grade ranging from 7 to 8 per cent copper and 6 to 8 oz. silver.

Sinking of the Plutus shaft has reached a depth of 300 ft., with the 400 level as the objective, at which point crosscutting for the Norwich vein will be started.

Shipments from the Crystal Copper Co.'s Goldsmith mine are continuing regularly with the 600-ft. level showing well.

East Butte plans to resume drifting on a new orebody on the 1,800-ft. level opened several months ago. The flow of water has been so heavy that it has been almost impossible to keep men at work in the face, but the situation is improving.

The Barnes-King Development Co.'s North Moccasin mine in Fergus County produced $1,350 in gold bullion in July and the Shannon, in the Marysville district, produced $24,600. The Piegan-Gloster mine was closed during the month, its operations last year having cost the company about $80,000.

Champion District—Ten cars of ore have been shipped by Butte Jardine from the Champion mine since the company took over the operation of the property. The ore showing in the tunnel level has been disclosed for a distance of 400 ft., with the milling ore as much as 8 ft. wide, and with high-grade ore about 18 in. wide. This is at a depth of 550 ft. The winze from this tunnel is about 20 ft. deep and shows a continuation of the present ore. Milling ore is averaging about 18 oz. of silver and $1.20 gold.

Wickes District—Operations at the Mount Washington property have been suspended, apparently awaiting the construction of a mill. A large tonnage of first class ore has been shipped from the upper levels.

Comet District—The Montana Consolidated is planning to resume operations at the Comet mine, an old time silver producer. The presence of considerable zinc in years past served to prevent profitable treatment.

Schoettner Studios, Butte

PLANT OF TUOLUMNE COPPER CO.'S BUTTE MAIN RANGE MINE, BUTTE

Lump Gulch District—Opening of a high-grade body of silver ore is reported at the Free Coinage mine of the Amalgamated Silver Mines.

Regular shipments of silver ore of good grade are being made by Liverpool Mines, the orebody on the 700-ft. level showing an improvement with drifting.

The ore continues to show well on the 100-ft. level of the Vera Cruz property.

IDAHO

Sandpoint—The Ten of Diamonds and Lone Star claims have been sold by J. W. Lloyd to the Trail Mining Co., of Sandpoint. The property is on Pine Creek in the Priest River district.

Wallace—The Pine Creek R.R. will be extended to the forks of the creek and about four miles up the west fork, by Fred Herrick, of the Milwaukee Lumber Co.

UTAH

Chief Consolidated Finds New Ore Near Plutus Ground—Judge M. & S. Commissary in Operation

Eureka—Low-grade ore with streaks of higher grade has been opened in the Chief Consolidated, promising a new ore zone, as the find, made on the 1,800 level, about 1,200 ft. from the new shaft, is 1,300 ft. to the east of known ore deposits. This new development is of interest in prospecting the Plutus holdings of the company, as the new ore zone, if developed, would make directly through this ground. Accompanying the list dividend checks, paid Aug. 3 and amounting to $88,423, was a statement presaging a possible reduction or omission of the dividend for the coming quarter, owing to the drop in the price of silver, which had left the quarter practically without net earnings. The management expressed itself as expecting to be able to make adjustments such as would bring about a restoration of earnings, but deemed it best to issue the precautionary note.

Shipments from the Tintic district amounted to 150 cars the week ended Aug. 7 as compared with 140 cars the week preceding.

The Griggs-Huish mill has been warmed up, and is reported to have made a good saving on ore from the May Day dumps. Connections are being made with the Yankee workings, so that the mill may be able to handle low-grade ore accumulated here. The Yankee has never before made any attempt to utilize its low-grade ores.

It is reported that some of the freight cars handling ores from the Tintic district may be diverted to the coal fields, which might cause a car shortage for the metal mines. Work is going on as usual at the Eureka Bullion following the brief shut-down for repairs.

At the Bullion Beck seven cars of ore have been shipped since the retimbering of the shaft. More leases have been given. There is considerable ore left in old workings here.

Salt Lake City—The U. S. Geological Survey is making preparations to continue the survey of the mines of the Cottonwood district. This survey, begun last year, will be resumed in American Fork Cañon, also.

Park City—The store of Judge Mining & Smelting Co., furnishing supplies to employees at cost, is now in operation.

The Park-Utah shipped a car of ore the week ended Aug. 7. The company has secured enough miners for one full shift, and as soon as more men are available, will put on two shifts.

Shipments from Park City for the week ended Aug. 7 were 2,328 tons of ore and concentrates as compared with 1,901 tons the week preceding. Shippers were: Judge Mining & Smelting, 721 tons; Judge Mining & Smelting (spelter), 20 tons; Ontario Silver, 540 tons; Silver King Coalition, 524 tons; Daly West, 339 tons; Park-Utah, 64 tons; and Naildriver, 120 tons.

CALIFORNIA

Extension of Walker Orebody Cut by Diamond Drills—Unwatering of Fremont Progressing

Drytown—Dewatering of the Fremont near Drytown is advancing at the rate of 25 ft. daily. It will be possible to resume development soon. The Gover shaft has been put in good shape. The new owners are planning extensive development.

Amador City—The new orebody recently found on the 2,800 level of the Bunker Hill is reported to be developing satisfactorily. The deposit is being opened by drifts and cross cuts and shows much ribbon quartz. The money derived from the new assessment, delinquent August 24, will be used in seeking extensions of the new ledge for development.

Portola—Diamond drilling has opened extensions of the Walker copper lode 2,100 ft. north of the Walker mine. The first drill holes cut the deposit 1,500 ft. north of the Walker group, and a second series of holes tapped the lode 500 ft. farther north. The discovery has stirred much interest throughout the Plumas copper field. In the Walker mine proper the main orebody has been opened to a depth of 300 ft. and shows a width of 18 to 20 ft. on the third level, with the ore sampling 4 per cent copper and $2.20 gold and silver per ton.

Preparations are being completed for extensive operation of the Five Bears, Tri-Metallic, Copper Cliff and Eagle Groups.

The Five Bears claims have passed into the hands of a syndicate of Arizona copper men, and the Tri-Metallic is controlled by San Francisco interests. Nevada capital has acquired the Copper Cliff, and Seattle interests have taken over the Eagle.

The Gruss mill is now in place and when oil is obtained the new plant will be put in commission. Large reserves of excellent ore are awaiting treatment at the present time.

Prospecting of the Poor Boy with drills is proceeding preliminary to driving a 3,000-foot tunnel. The present work is designed to establish the depth of the bedrock and probable dimensions of the channel.

Keeler—A drift has been advanced 75 ft. in an oreshoot at 100-ft. depth in a winze from the Morning Glory tunnel of the Estelle Mining Co., whose property adjoins the Cerro Gordo mine. A raise has been put up 25 ft., at which point the ore is 15 ft. wide. This new oreshoot, which is from 9 to 16 feet in width, shows higher lead values than other shoots, the ore averaging about $45 per ton in gold, silver and lead. It also carries some copper, bismuth and antimony. Shipment is by means of a tramway, 7,000 ft. long, to the Cerro Gordo road and thence by trucks four miles to Keeler. It is planned to ship about 20 tons per day but truck trouble has been experienced, which is apt to delay the program.

NEVADA

Rochester Silver's Report Out—Holmquist Mine Near Ely Shipping Manganese Ore

Rochester—The Rochester Silver Corporation has just released the report signed by F. M. Manson, chairman of the executive committee, and C. D. Kaeding, consulting engineer, for the period from January 1, to June 30, 1920, together with a statement of earnings, and an outline of conditions existing at this date. The report shows a profit of $151,614.77 for the six months but attention is called to conditions which will preclude the probability of making equal profits during the current six months—among them being the drop in silver and the cessation of milling operations owing to lack of power.

In all 26,570 tons was milled averaging 12.91 oz. silver and 0.153 oz. gold per ton. The bullion recovery per ton milled was $14.94. Ninety-two per cent of the gold and 81.3 per cent of the silver were recovered. The value of the bullion sold was $396,955.76. Five and four-tenths tons of ore was milled per foot of development.

The total operating expenses were at the rate of $9.23 per ton, of which $2.45 is charged to stoping, $1.80 to development, and $2.81 to milling and refining. Of the net operating profit of $151,614.77 there was credited to depletion and depreciation reserve $36,145.01 and $115,469.76 as net surplus to balance sheet.

Mr. Kaeding calls attention to the unusually large amount of development for a mine producing only 150 tons daily—the footage being 4,871—but adds that "the results of this work have not been nearly so favorable as during the last quarter of 1919." He estimates that there is not more than six months' reserve of ore in the mine, much that was considered ore when silver was selling at $1.25 or better being now below pay.

The balance sheet shows an excess of current assets over current liabilities of $269,991.19—most of which is in the form of cash, bullion or working for mines and mill.

Goldfield—The Deep Mines Co. has started a small force at work preliminary to sinking an old shaft on the southern end of the Combination claim, east of the Atlanta ground. The present shaft has two compartments and is down nearly 600 ft. It is planned to enlarge to four compartments and [illegible] to the 3,000 level.

Spruce Monarch—From 70 to 100 tons of ore is now going out from the Spruce Monarch mine daily, some going to Tobar on the Western Pacific and some to Currie on the Nevada Northern, but all going to Utah smelters. One caterpillar, hauling from 25 to 30 tons of ore, is said to make the round trip to Tobar every 24 hours.

Sulphur—A. J. Crowley, former superintendent of the Nevada Sulphur Mining Co., has interested the Red

River Lumber Co. in the property and it has advanced $50,000 for necessary additional machinery and improvements. He will put in an electric lighting plant, and has ordered a Chicago Pneumatic compressor, Cochise drills, ore cars, and other equipment from the Western Machinery & Engineering Co., of Reno. The Red River is one of the largest lumber companies and is owned by Walker Brothers, of Minneapolis.

Reno—Work will begin at once on a 1½-mile transmission line to the Black Panther mine, three miles north of Reno. It is planned to put in an electric hoist and pump. The shaft is down 190 ft. and shows some good copper ore. Al Marsal is manager.

The mill of the Standard Metals, 12 miles north of Reno, is shut down and only development work is being carried on at the mine.

Ely—A report issued from the office of the White Pine County assessor shows that the gross yield from the mines of White Pine County for the quarter ended July 31 amounted to 794,030 tons of ore of a total value of $2,663,576.22.

Three hundred tons of manganese ore per month is to be shipped to Chicago from the Holmquist mine near Ely, under a contract recently entered into by Schultz, Clark & Hamilton, lessees. The first shipment went forward recently.

Death Valley—The Standard Oil Co. has purchased a deposit of sandstone in Death Valley, north of the deposits owned by the Associated Oil Co. according to John T. Overbury who is interested in that section.

Carlin—The Tri-O-Lite Products Co. expects to start the mill soon that was recently completed for handling the kieselguhr deposits near Carlin.

Schellbourne—Two trucks have been hauling ore from the old Siegel mines at Schellbourne, in Spring Valley, in eastern Nevada, but bad roads resulting from recent storms have delayed shipments.

Mina—Milling ore and what is believed to be the downward extension of the hanging-wall orebody developed on the 4th, 5th and 6th levels of the Simon Silver-Lead mine has been struck in a raise 50 ft. above the 7th level. It has been driven on for a width of 17 ft. with no wall in sight. Assays show it to be of better grade than the average milling ore on the upper levels. Crosscutting has been started to the northwest in which direction the orebody pitches and it is expected that it will be cut within 40 ft. Surveying for the mill site is under way and grading will begin in the near future. An initial unit of 100-125 tons capacity will be built. Lloyd C. White, of Burch, Hershey & White, San Francisco, is designing the mill.

New Pass—The mill on the gold property at New Pass, 25 miles across the Reese River valley from Austin, is being dismantled by W. C. Pitt, controlling owner. The quantity and grade of ore were insufficient.

Boyd Siding—I. R. Landis, of Los Angeles, has purchased some kaolin claims near Boyd Siding, on the Salt Lake Railroad, from N. E. Williams and T. J. Parker. The price is said to have been $30,000, with $5,000 paid down. Landis is said to have contracted to sell the output to the Empire China Co., Los Angeles. The deal was made on the report of John C. Charles, of Hollywood, Cal.

Jackrabbit District—The Bay State Mining & Leasing Co. is shipping high-grade silver, lead and copper ore from the Ida May property in this district. Arthur Murphy is president and manager.

JOPLIN-MIAMI DISTRICT

Oklahoma-Kansas-Missouri

Rakowsky Sinking on Blue Bird Lease —Anna Beaver Using First Surface "Hopper" at Tar River

Webb City, Mo.—The Webb City & Carterville Development Co. reports finding lead in two drill holes put down on "Sucker Flats," southeast of Webb City, and will sink a shaft on the lease at once.

Baxter Springs, Kan.—Miller & Holcomb are driving a drift on the 102-ft. level of the Lucky Joe property at Sunnyside to a drill hole put down some time ago. A Cornish lift pump is handling the water. The mill at this mine was sold to the Wolverine Co. some months ago and has been moved to the Portis land, west of Quapaw, where it has been re-erected and is now in operation. I. M. Holcomb, manager of M. & H. Co., plans to erect a small custom mill at old Lucky Joe site.

George Meese, of Joplin, is preparing to sink a shaft on the Ebbenstein land, a short distance west of the Chanute property.

Victor Rakowsky and associates are putting down a shaft on what is to be known as the Blue Bird lease, immediately north of the Chanute.

Tar River, Okla.—The Anna Beaver Mining Co. is successfully handling ore from its No. 3 mine by a surface railroad and a surface hopper at No. 2 mill. This is the first surface hopper in the field. About 75 tons of ore is being hoisted per hour and more could be handled by the new equipment if the hoisting capacity were greater. The output of the mine is now largely lead, owing to the uncovering of rich lead-bearing ground at No. 1 mine.

WASHINGTON

Valley—The American Minerals Production Co. is shipping 6,000 tons of crude magnesite a month, according to H. F. Wierum, general manager. "The company has a kiln designed for making a superior calcined product for flooring and use in the stucco trades," said Mr. Weirum. "It was designed after about $20,000 had been expended in determining how to design it. About 80 per cent of the construction on the plant has been completed. The remainder awaits the receipt of machinery ordered in the East and shipped in May. This machine will produce a calcined product that will make stucco for floors superior to any produced."

CHRONOLOGY OF MINING JULY, 1920

July 1.—Experiment station of U. S. Bureau of Mines, forced to move from Golden, Col., by action of Colorado School of Mines, relocated at Reno, Nev.—British Columbia's Placer Mining Act amendments went into effect.—Federal Mining & Smelting Co., Wallace, Idaho, insured lives of employees for benefit of their dependents.

July 4.—Drilling contest at Idaho Springs, Col.

July 6.—Minerals Separation, Ltd., hearings resumed in San Francisco, Cal., continued to July 10.

July 9.—Metals Extraction Corporation's baghouse at Joplin, Mo., damaged by fire.

July 10.—Northern Minnesota Ore Co. closed down Northland mine and pulled pumps.—Ferro mine buildings and equipment near Trommald, Minn., sold by sheriff.

July 13.—Minerals Separation, Ltd.'s, petition to hold Miami Copper Co. in contempt dismissed by Judge Morris, U. S. District Court, Wilmington, Del. —Minerals Separation, Ltd., hearings adjourned from San Francisco, resumed at Salt Lake City, Utah.

July 14.—United Verde Copper Co.'s old coke bins and quantity of fuel oil burned.

July 15.—Philippine Islands Mint at Manila began operations.

July 18.—Central Eureka shaft at Sutter Creek, Cal., completed.—Lightning and fire destroyed Omaha Mining Co.'s compressor building at Wallace, Idaho.

July 19.—Northwest Magnesite Co. dividends to amount of $500,000 involved in suit brought by R. S. Talbot, Spokane, Wash., against William H. Crocker, San Francisco, Cal.

July 20.—International Mining Convention held for third time at Nelson, B. C.—Safety-first contest started in Butte, Mont., district, to end Aug. 21. —Mexican decree concerning delinquent mining taxes published in Diario Oficial.

July 23.—American Mining Congress' Utah Chapter discussed with H. N. Lawrie plan for premium of $10 per ounce on newly mined gold.

July 26—New York State purchased 2.25 gm. of radium for use of state research at Buffalo, N. Y.

July 27.—Striking mine and oil workers of Mexico return to work in large numbers at request of President. —American Smelting & Refining Co.'s sampling mill No. 4 at Murray, Utah, burned down.—Vipond-North-Thompson (Porcupine, Ont.) shareholders ratified sale of 600,000 shares to an English syndicate.

THE MARKET REPORT

Daily Prices of Metals in New York

Aug.	Copper	Tin		Lead		Zinc
	Electrolytic	99 Per Cent	Straits	N. Y.	St. L.	St. L.
19	18.25@18.35	43.25	47.00@47.75	8.75@9.00	8.85	7.90@7.95
20	18.25	43.00@43.50	46.75@47.25	8.50@9.00	8.75	7.95@8.00
21	18.10@18.25	43.00@43.50	46.75@47.25	8.50@9.00	8.75	8.00@8.05
23	18.10@18.25	42.50@43.50	46.50@46.75	8.25@9.00	8.50@8.75	8.00@8.05
24	18.10@18.25	41.75@42.75	45.50@45.75	8.25@9.00	8.50@8.75	7.95@8.00
25	18.10@18.25	41.75@42.75	45.50@45.75	8.25@9.00	8.50@8.75	7.95@8.00

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point. All prices are in cents per pound.

Copper is commonly sold on terms "delivered" which means that the seller pays the freight from refinery to buyer's destination. The delivery cost varies, and it would be confusing to figure net prices on individual transactions. Consequently, an average deduction is made from the "delivered" price. At present the average cost of delivery from New York refineries is 0.15c. per lb., and that deduction is made to arrive at the New York price. When copper is sold f.o.b. or f.a.s. New York, of course no deduction is made.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a diacount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. We quote New York price at 35c. per 100 lb. above St. Louis. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Aug.	Copper			Tin		Lead		Zinc	
	Standard		Electro-lytic						
	Spot	3 M		Spot	3 M	Spot	3 M	Spot	3 M
19	93½	95	111	275¼	282	35½	36	41	42½
20	93½	95¼	111	270	278	35¾	36⅛	41⅛	42⅜
21	....	....	....	....	....	....	....	....	....
23	94	95½	111	267½	274	35⅞	36½	40¾	42½
24	94½	95⅝	111	262¼	269½	35⅞	36¼	40¼	41¾
25	94¼	95¾	111	262½	269½	35¾	36	40	41½

The above table gives the closing quotations on the London Metal Exchange. All prices are in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Aug.	Sterling Exchange	Silver			Aug.	Sterling Exchange	Silver		
		New York, Domestic Origin	New York, Foreign Origin	London			New York, Domestic Origin	New York, Foreign Origin	London
19	360	99½	98½	61	23	358	99½	97¼	60⅞
20	358½	101⅜	101⅜	63⅜	24	354	99½	96	60⅞
21	359	101⅜	101⅜	63⅜	25	354½	99½	97	61

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States. This quotation is retroactive to May 13.

Metal Markets

New York, Aug. 25, 1920

Conditions show little change from last week. In general, buying is on a small scale, and only the immediate requirements of consumers are apparently being provided for. Potential buyers consider that, with the general price decline and tight money conditions, purchases can well be postponed. It is extremely unlikely, however, that the price of any of the major metals will experience any drop of consequence during the next few months. The big depressing influence just now is the London market.

Transportation conditions are generally satisfactory, and movements to and from the Eastern refineries are approaching normal. Transatlantic freight rates are weaker.

Copper

The stagnation has continued during the last week, with selling confined to small lots of spot metal by second-hands who were forced to unload at 18¼c. delivered. Some of the smaller producers were asking 18½@18¾c. and the larger producers 18¾c. The latter, however, did no business except in special shapes, such as billets, which could not be procured elsewhere. Prices for forward delivery are purely nominal.

Lead

Importations from Europe have gone far to satisfy the demand for prompt lead due to increased consumption and decreased domestic production. About 6,000 to 8,000 tons have been purchased abroad so far this month. Those who have imported direct have been able to secure metal for September delivery at about 8¼c., duty paid, New York, or even less, but when bought through dealers here 8½@8¾c. has been asked. Surprise has been shown that the price of lead in London has not advanced. Available stocks seem to be larger than supposed and Spanish lead is being received in England which formerly went to France. Very heavy offers, fifteen to eighteen thousand tons, have been made in this market of antimonial lead, as used for shrapnel bullets, at as low as 6¼c. duty paid. This contains 9 to 12 per cent of antimony and is suitable for certain purposes, such as type metal. Forward lead is quoted at 8@8¼c. New York and St. Louis, depending upon time of delivery.

Zinc

The large producers got ahead of the market during the last week and quoted 8.20@8.25c. but were unable to make sales, for all of the smaller interests were busy unloading at close to 8c. Yesterday a new factor entered the market in the shape of European offers of American and other zinc at slightly under 8c., duty paid, New York. Two lots of 500 tons each are reported taken. It is difficult to see how importation of this zinc can pay under current conditions, for it is unlikely that it can be proved not to be dutiable. Its effect may be more sentimental than direct, but the fact remains that it has temporarily killed the domestic market, just when producers were beginning to feel more cheerful. The statistical position of domestic zinc continues strong, and slight premiums are being asked for forward delivery.

Tin

The dearth of interest in tin continues. The London price governs the New York market and the price there has dropped continuously during the last week. Former large consumers are buying only from hand to mouth.

Straits tin for future delivery: Aug. 19th, 47.50@48.00c.; 20th, 47.00@47.50c.; 21st, 47.00@47.25c.; 23d, 46.50@47.00c.; 24th, 45.50@46.00; 25th, 45.75@46.00c.

Arrivals of tin in long tons: Aug. 17th, London, 20; 19th, Straits, 40; 20th, Liverpool, 95; Singapore, 100; 21st,

China, 400; Liverpool, 35; Straits, 975: 24th, London, 25.

Silver

The silver market last week continued strong, with advancing tendency on buying for China account, with China banks paying prices in New York which were higher than the equivalent of the London quotation. On Aug. 20 and 21, however, the London market jumped to 63¾d., which made the London bid price about 2c. higher than the U. S. Treasury price for silver under the Pittman Act. This sharp advance brought out large offerings of silver, both "Domestic" and "Foreign," which were thrown on the London market, with the result that buyers were satisfied and a sharp reaction occurred on Aug. 23 to 60⅞d. Since the culmination of this advance the market has been quiet, with small business, but the closing tendency appears to be firmer on improvement of both London and Far Eastern exchanges.

Mexican Dollars—Aug. 19th, 75; 20th, 76⅛; 21st, 76⅛; 23d, 74¼; 24th, 73⅜; 25th, 74¼.

Gold

Gold in London on Aug 19th, 114s. 7d.; 20th, 115s.; 23d, 115s. 3d.; 24th, 115s. 6d.; 25th, 116s.

Foreign Exchange

Weakness, due to conditions mentioned before, continues. Yesterday francs were 6.84c.; lire, 4.55c.; and marks, 1.94c. New York funds in Montreal, 13⅛ per cent premium.

Other Metals

Aluminum — Ingot, 99 per cent and purer, 35.1c.; 98@99 per cent, 34.9c. Virgin metal still obtainable in open market at about 32.5c. for 98@99 grade.

Antimony—Market continues weak. Spot, 7c. per lb.; Cookson's "C" grade, 14@15c. Chinese and Japanese brands, 7c. W. C. C. brand, 9@9½c. [1]Chinese needle antimony, lump, firm at 8@9c. per lb. Standard powdered needle antimony (200 mesh), 10@12c. per lb.

Bismuth—$2.70 per lb., 500-lb. lots, and $2.72 per lb., 100-lb. lots. Market quiet.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady.

Cobalt—Metal, $3 per lb.; black oxide, $2 per lb.

Iridium—Nominal, $350 per oz. Heavy demand, but small supplies.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb., for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]**Molybdenum** Metal in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.; Monel metal, shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$100@$110 per oz.

Platinum — Firm at $115@$120 per oz. $105 per oz. in 100 oz. lots.

Quicksilver — Market quiet; $83 per 75-lb. flask. San Francisco wires $81. Dull.

Ruthenium—$200@$220 per troy oz.

[1]**Selenium**, black, powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]**Thallium Metal**—Ingot, 99 per cent pure, $20 per lb.

Metallic Ores

Bauxite—About 52 per cent alumina content, less than 2 per cent iron oxide, up to 20 per cent silica and artificially dried to contain not more than 4 per cent free moisture, $10 per gross ton at mine; 54 per cent alumina and about 15 per cent silica, $11; averaging 57 per cent alumina, 8 to 12 per cent silica, less than 3 per cent iron oxide, $13 on basis of 8 per cent free moisture. Ores of very low silica content suitable for the manufacture of aluminum oxide and hydrate of alumina command a fancy price.

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a minimum of 6 per cent silica, 80@85c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 60@65c.

Iron Ores—Lake Superior ores, per ton, delivered at Lower Lake ports: Old Range bessemer, $7.45; Old Range non-bessemer, $6.70; Mesabi bessemer, $7.20; Mesabi non-bessemer, $6.55. Congestion at Lake Erie ports due to car shortage has resulted in decreased tonnage. The movement of ore to inland furnaces is not satisfactory.

Manganese Ore — 70@80c. per unit, 50 per cent Mn content, c.i.f. Atlantic seaport; chemical ore (MnO_2) $75@$85 per gross ton.

Molybdenum ore—85 per cent MoS_2, 75@85c. per lb. of contained sulphide, New York.

[1]**Tantalum Ore**, guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots, against recent price of 65@70c.

Titanium Ores—Ilmenite[1], 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $7 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $6@$7, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[1]**Zircon**—Washed, iron free, 5c. per lb.

[1]**Zirkite**—$90@$100 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

[1] Furnished by **Foote Mineral Co.**, Philadelphia, Pa.

Zinc and Lead Ore Markets

Joplin, Mo., Aug. 21.—Zinc blende, per ton, high, $51.40; basis 60 per cent zinc, premium, $48.50; Prime Western, $47.50; fines and slimes, $45@$42.50. calamine, basis 40 per cent zinc, $36. Average settling prices: Blende, $46.25; calamine, $38.20; all zinc ores, $46.

Lead, high, $107.50; basis 80 per cent lead, $100@$110; average settling price, all grades of lead, $102.40 per ton.

Shipments for the week: Blende, 10,543; calamine, 195; lead, 1,355 tons. Value, all ores the week, $633,710.

The receipt of a larger number of cars this week afforded slight relief to the transportation shortage.

Platteville, Wis., Aug. 21.—Blende, basis 60 per cent zinc, $51@$53 per ton for high-grade. Lead ore, basis 80 per cent lead, $105 per ton. Shipments for the week: Blende, 1,146; lead, 33 tons. Shipments for the year: Blende, 45,770; calamine, 2,330; lead, 3,840; sulphur ore, 1,209 tons. Shipped during the week to separating plants, 1,685 tons blende.

Non-Metallic Minerals

Asbestos — Crude, No. 1, $2,400@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax. Freight rate from mines to Sherbrooke, Quebec, over Quebec Central R.R., 20c. per cwt.; from Sherbrooke to New York, 27½c., carload lots; freight to New York for crude No. 1, f.o.b. Thetford mines, $8.45 per ton, carload lots. Market very strong, owing to heavy demand and a production that is 25 per cent below normal. Higher prices for all grades of material are expected soon.

Barytes — Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $22@$25 in bags, carload lots; (off-color) $18@$20 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $12 per gross ton; ground (white) $23@$25; ground (off color) $16@$19 per net ton, f.o.b. Cartersville, Ga. Crude, 88 to 94 per cent, $23; ground (white) $40.50; ground (off color) $27 per net ton, less than carload lots, f.o.b. New York. Crude, not less than 98 per cent, $11@$11.25 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—Domestic, extra light, 5@6c. per lb.; light, 4½@5½c.; heavy, 4@5c; English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin) — Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground,

$15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$18 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $25@$30 car lots, f.o.b. Baltimore; ground, $17@$20, f.o.b. North Carolina points; $17@$20 per ton, No. 1 ground, f.o.b. New York State; $21@$23 per ton, ground, f.o.b. Maine.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Graphite—Crucible flake, 85 per cent carbon content, 8c. per lb.; 88 per cent, 9¼c.; 90 per cent, 10½c., all f.o.b. New York. Crucible grades of Alabama graphite sell as follows, f.o.b. Ashland, Ala.: 80 per cent, 5c.; 90 per cent, 10c. Lubricating grades in increasing demand, with price ranging from 11c. for the 85 per cent guaranteed grade in car lots to 30 and 40c. for higher grades. Mexican, amorphous, $45@$55 per short ton; Korean, 3½c. per lb.; Madagascar, 8c.; Ceylon, 4½@15½c.

Gypsum—Raw crushed rock, $3.50@$4 per ton; raw ground fine, $4@$4.50; calcined stucco, $9, all f.o.b. works. Containers extra. The last price quoted for plaster of paris in carload lots was $4.25 per 250-lb. bbl., alongside dock, New York; but a new price, not yet made public, went into effect on Aug. 26.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $65@$75 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—Imported block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20@$1.40; No. 4, $2@$3; No. 3, $4.25@$5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $4; No. 3, $5.75; No. 2, $7; No. 1, $9; A1, $14; extra large, $25, all f.o.b. New York; ground, $85@$100 per ton, Philadelphia.

[1]**Monazite** — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses.

Pumice Stone—Imported, lump, 4@50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish, fines, per unit 12c., c.i.f. Atlantic seaport; furnace size, 17½c.; run of mine, 12@14c.; domestic, fines, f.o.b. mines, 12@14c.

Quartz—(Acid tower) fist to head, $10; 1¼ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines. F.o.b. Wausau, Wis., the price is $16 per ton in car lots, and $22 less quantities, including bags.

Sulphur—$18 per ton for domestic; $20 for export, f.o.b. Texas and Louisiana mines.

Talc — Paper making, $10@$20 per ton; roofing grades, $9@$15; rubber grades, $10@$15, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $15@$20 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60@$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $2.25@$2.50 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15-18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 17@18c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c. f.o.b. works.

Ferromanganese—For 76@80 per cent, prompt delivery, $200@$210, freight allowed; last half, $200@$220; English, $190@$200, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $75@$80, f.o.b. furnace.

Ferromolybdenum—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2.50@$3 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $80@$85; 75 per cent, $150@$160.

Ferrotungsten—70 to 80 per cent W, $1.10@$1.15 per lb. of contained tungsten, f.o.b. works.

Ferro-uranium—35-50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium—Basis 30-40 per cent, $6.50@$9.50 per lb. of V contained, f.o.b. works.

Metal Products

Copper Sheets — Current New York price, 29½c. per lb.; wire quoted, 22½@23c.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver—Unchanged at 39½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 26¾c.; sheathing, 25¾c.; rods, ½ to 3 in., 23¾c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $145 per 1,000, f.o.b. Pittsburgh.

Chrome Brick—$90@$100 per net ton, carload lots, eastern shipping points.

Chrome Cement—45 to 50 per cent Cr_2O_3, $50 per net ton, and $55 in sacks, carload lots, eastern shipping points.

Clay Brick — First-quality fire clay, 9-in. shapes, $50@$55 per thousand, Pennsylvania, Ohio, and Kentucky works; second quality, $45@$50. First quality, St. Louis, $45; New Jersey, $75.

Magnesite Brick—$100@$110 per ton, eastern shipping points; 9-in. straights, $90@$100; 9-in. arches, wedges and keys, $95@$105; soaps and splits, $110@$120.

Silica Brick—9-in. per 1,000, $51@$55, Birmingham, Ala.; $55@$60, Mount Union, Pa.; $55, Chicago district.

Iron Trade Review

Pittsburgh, Aug. 24, 1920

With a dull market in the iron and steel trade generally, an advance of $4 a ton in the quotation price of foundry pig iron at Valley furnaces, to a $50 level, stands out as spectacular, and the advance is none the less interesting through its being based upon relatively light transactions.

Pig Iron.—Sales of foundry iron totaling probably between 5,000 and 10,000 tons have been made at $50, Valley, chiefly for early deliveries, but in a few instances for shipment during the remainder of the year, and the market is thus established at a $4 advance. Bessemer and basic are reported to have sold at $50 or thereabouts, but transactions have been too light to establish a new basis definitely, and the market is quotable as follows: Bessemer, nominal, $47; basic, nominal, $46.50; foundry, $50, f.o.b. Valley furnaces, existing freight to Pittsburgh being $1.40, to advance this week by 10 per cent. Most pig-iron buyers are disposed to avoid the market, doubting whether present prices are justified.

Steel.—Several sales of sheet bars have been made at $67.50, Pittsburgh, and some buyers now in the market express confidence that they will be able to do $65. The market is quotable at $67.50@$70 for sheet bars, with billets at $60@$65, and quite inactive.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $17@$18; foundry, $18@$20.

The Importance of European Copper Purchases

Copper Industry Would Be Relieved of Its Difficulties If Export Trade Increased — Other Nations Must Replace Germany's Important Position Before Pre-War Scale of Buying Is Assured—Electrical Developments Portend Important Copper Purchases

THE copper industry is waiting for the important export trade which it possessed in the years before the war, to assist it out of its present difficulties. Some measure of relief from the unfortunate condition of the copper industry was afforded through export business during the last half year, and domestic business also helped magnificently. The great obstacle to dependence upon foreign copper orders is not only the important financial disabilities that must be overcome, but the uncertainty attached to European and Asiatic requirements and to the ability of foreign countries to use more copper than that required for their own needs. The assumption that Europe is generally bare of copper stocks, or nearly so, may be true, but there are undoubtedly large stocks of scrap metal and second-hand material left over from the war which are ready to be consumed in peace-time use.

Aside from the question of scrap copper, the record of the various European nations as importers of American copper is highly significant. Roughly, over half of all the refined copper produced in the United States was shipped abroad in the five years before the war. At the same time the annual domestic consumption of copper was a little under 50 per cent of production. Practically all of the copper exported was shipped to Europe, Canada being the only other consumer of note, but only to a relatively small extent, taking about 3,000,000 lb. of refined copper monthly. England, France, Germany, The Netherlands, and Italy were the important destinations for exported copper, and all combined to sustain a brisk and exceedingly important export trade. The accompanying table gives a record of the quantities of copper consumed by these countries during the last ten years.

The most important customers from 1910 to 1914 were Germany and The Netherlands, both together accounting for over half the exports of copper from the United States. However, it is now generally understood that the heavy purchases of The Netherlands and also some other European countries were principally for the German market. Thus, to obtain the true significance of German copper importations, the copper imports of The Netherlands, Belgium, and Denmark should be added to those of Germany. Proceeding a logical step farther, and including the buying of Austria-Hungary (35,000,000 lb. annually), the foreign copper consumption by the Central Powers is much more than that of all other countries combined. Enormous quantities of copper were required by these countries. A warrantable estimate would be 500,000,000 to 550,000,000 lb. annually. This great buying power is now withdrawn from the market, except for driblets of copper that occasionally find their way to the former enemy countries. Nor is there immediate prospect of a resumption of this trade. The German price of United States copper at 9 to 10 marks per pound is prohibitive. Furthermore, financial and industrial conditions in Germany are in no condition to warrant hope that the nation will soon resume the development and expansion of her electrical industries on a scale approaching that prevailing before the war.

If Germany is unable to occupy her former important position in the copper market, are any other countries likely to supplant her? The indications point to just such a state of affairs at this time. The United States is consuming copper at an unprecedented peace-time scale, and although a good portion of this consumption is answering the call of construction curtailed during the war, much of it is being used in the electrical and other manufacturing trades for export purposes. The United States undoubtedly has a splendid opportunity to capture export fields formerly monopolized by other powers, and the copper industry will readily reflect the measure of success coming from such an attempt.

The demand for copper by the European nations was originally predicated upon their being compelled to replace the copper lost through the devastation of the war—not upon the ability of these nations to export copper manufactures, which is a subordinate consideration and an opportunity thrust upon them by the results of the war. The financial difficulties which must be overcome, and which were thought to have been surmounted by the plans of the Copper Export Association, are evidently still of serious moment, for consistent buying from France and Europe in general has not been manifested. Foreign support from unusual quarters—from Japan and Scandinavia—was a feature of the market in the last eighteen months. Japan had never figured prominently in export trade, but consumed large quantities of copper in 1919 and 1920 in anticipation of satisfying Asiatic requirements for copper and copper manufactures, thereby replacing Germany in a field which that country formerly tried to monopolize. The financial crash in Japan, and its attendant results, have put a temporary brake on such Japanese plans for expansion. Incidentally, there is little reason why American manufacturers cannot become strong contenders for Asiatic markets for copper and copper goods.

Another element in foreign copper purchases is the fact that industry and commerce are adopting electricity in an effort to conserve fuel. The acute coal shortage in Europe —and in the United States—is forcing nations to resort to "white coal," the fuel of the future. France, Italy and Switzerland have outlined extensive programs for hydro-electric development which if consummated should use large quantities of copper.

The world is turning more and more to oil and electricity for a solution of its fuel problems, and of these two, electricity will become of continually greater importance. Hydro-electric projects all over the world should draw increasing amounts of copper from the United States. But everything depends upon Europe obtaining the financial assistance which it needs before it is in a position to purchase much copper. An official of an important copper-producing company aptly summed up the situation a few days ago to this effect: "Foreign exchange rates are seriously hampering these countries in their efforts at reconstruction, so that their purchases of raw materials, such as copper, of which they are vitally in need, will be delayed until such time as they can more advantageously fill their requirements."

EXPORTS OF METALLIC COPPER FROM THE UNITED STATES IN POUNDS

				(A) Exports in Per Cent of United States Production.									
Year	To England	(A)	To France	(A)	To Germany	(A)	To Netherlands	(A)	To Italy	(A)	Total Exports	(A)
1910	98,000,000	6.8	116,000,000	8 1	176,000,000	12 2	222,000,000	15 5	34,000,000	2 4	708,000,000	49.8

In pre-war years Austria-Hungary imported about 35,000,000 lb. United States copper, and Belgium 7,000,000 lb., annually.

COMPANY REPORTS

Second Quarter of 1920

Utah Copper Co.

Copper; Utah

A comparative production statement of the Utah Copper Co. follows:

Second Quarter 1920	Lb.	First Quarter 1920	Lb.
April	9,313,227	January	9,151,144
May	9,829,781	February	9,211,806
June	9,554,119	March	8,894,596
Totals	28,697,127		27,257,546
Average monthly production	9,565,709		9,085,849

In addition to the above, 307,254 lb. of copper was contained in precipitates from the leaching plant.

The average cost per pound of net copper produced, including plant depreciation and all fixed and general charges, but excluding Federal taxes, and without credit for gold and silver or miscellaneous income, was 13.697c., as compared with 13.202c. for the previous quarter, calculated in the same way. The value of the gold and silver in the concentrates totaled $235,544.54, and the miscellaneous income amounted to $300,767.25. These items combined are equal to 1.929c. per net lb. of copper produced.

Financial results compare as follows:

	Second Quarter 1920	First Quarter 1920
Net profit from copper production only	$1,254,033.15	$2,291,012.91
Miscellaneous income, including payment for precious metals	536,311.79	329,451.95
Income from Nevada Consolidated Copper Co.	250,125.00	250,125.00
Income from Bingham & Garfield Railway Co.	200,000.00	.....
Total net profit	$2,240,469.94	$2,870,589.86
Disbursements to stockholders	2,436,735.00	2,436,735.00
Net surplus for the first quarter		$ 433,854.86
Net deficit for the second quarter	$ 196,265.06	

The earnings for the second quarter are computed on the basis of 18.209c. for copper, as against 21.994c. for the previous quarter. The regular quarterly disbursement of $1.50 per share was paid on June 30.

Nevada Consolidated Copper Co.

Copper; Nevada

Nevada Consolidated Copper Co.'s production compares:

Second Quarter 1920	Lb.	First Quarter 1920	Lb.
April	4,061,237	January	3,687,098
May	4,351,712	February	3,700,106
June	4,650,718	March	3,751,021
Totals	13,063,667		11,138,225
Average monthly production	4,354,556		3,712,742

The cost of production of copper for the quarter, including the fixed charges to cover depreciation of plant and equipment and all administrative and general overhead expenses, and after crediting miscellaneous income, was 15.56c. per lb., as compared with a cost of 20.72c. per lb. for the preceding quarter.

Financial results compare as follows:

	Second Quarter 1920	First Quarter 1920
Operating profit	$17,276.49	$132,529.28
Miscellaneous income, including that from Nevada Northern Railway Co. and payment for precious metals	336,723.69	83,053.86
Net gain	$384,000.18	$215,583.14
Distributions to stockholders	499,864.25	499,864.25
Net deficit	$115,864.07	$284,281.11

The operating earnings for the quarter are based upon an average carrying price of 18.50c. per lb. of copper produced, as compared with an average basing price of 22.66c. per lb. for the quarter ending March 31, 1920. A quarterly distribution of 25c. per share was made on June 30.

Chino Copper Co.

Copper; New Mexico

Chino Copper Co.'s production compares as follows:

Second Quarter 1920	Lb.	First Quarter 1920	Lb.
April	3,750,975	January	3,081,937
May	3,916,684	February	3,129,776
June	4,282,956	March	4,409,563
Totals	11,980,615		10,621,276
Average monthly production	3,993,538		3,540,425

In addition to the copper derived from the concentrating ores, a total of 8,836 lb. of copper was contained in ores sent direct to the smelter.

The cost per pound of net copper produced during the second quarter of 1920, including plant depreciation and all other items except charges for Federal taxes, but without credit for precious metals and miscellaneous income, was 15.90c., compared with 14.62c. for the first quarter of 1920. The value of gold and silver and miscellaneous earnings was $70,120.39, or 0.61c. per lb. of net copper produced.

Financial results compare as follows:

	Second Quarter 1920	First Quarter 1920
Net income from copper production only	$260,031.67	$737,605.40
Miscellaneous income, including payments for precious metals	70,120.39	72,121.75
Totals	$330,152.06	$809,727.15
Distribution to stockholders	326,242.50	326,242.50
Surplus after distribution to stockholders	$ 3,909.56	$483,484.65

The earnings for the second quarter of 1920 are based on a price for copper of 18.175c. per lb., compared with 21.88c. for the first quarter of the year. A quarterly distribution to stockholders amounting to 37½c. per share was paid.

Ray Consolidated Copper Co.

Copper; Arizona

Ray Consolidated Copper Co.'s production compares:

Second Quarter 1920	Lb.	First Quarter 1920	Lb.
April	4,153,305	January	3,891,710
May	4,211,886	February	3,781,044
June	4,515,414	March	3,872,349
Totals	12,880,605		11,547,103
Average monthly production	4,293,535		3,849,034

In addition to the copper derived from concentrating ores, a total of 84,991 lb. of copper was contained in ores sent direct to the smelter. The average cost per pound of all net copper produced for the quarter was 15.688c. This does not take into account any credit for the gold and silver or for miscellaneous income, and compares with a cost of 16.745c. for the previous quarter. These costs include a charge of 15c. per ton of ore treated, for the retirement of mine development expense, but are exclusive of estimate of Federal income and profit taxes. Miscellaneous income for the quarter, including net income from gold and silver produced, amounted to 0.347c. per lb.

Financial results compare as follows:

	Second Quarter 1920	First Quarter 1920
Operating profit	$343,650.73	$587,146.50
Miscellaneous income	43,604.72	50,134.59
Totals	$387,255.45	$637,281.09
Disbursement to stockholders	394,294.75	394,294.75
Net surplus for the quarter	$ 7,039.30*	$243,000.34

*Deficit.

The average carrying price of copper for the quarter was 18.426c., as compared with 21.960c. for the previous quarter. A quarterly distribution to stockholders of 25c. per share was paid June 30, 1920, and amounted to $394,294.75.

INDUSTRIAL NEWS

The Easton Car & Construction Co. announces the opening of a new office in the Peoples Gas Building, Chicago, to take care of the increasing business in the West and Middle West districts.

Denver Rock Drill Manufacturing Co., of Colorado, announces the opening, on Aug. 1, of a branch office at 421 Manhattan Building, Duluth, Minn.

Olin H. Landreth, consulting engineer, 156 Fifth Ave., New York City, announces that he is now consulting engineer to the Eastern Potash Corporation, New Brunswick, N. J., and therefore has time available for other engagements in like capacity. ('phone Chelsea 9992).

T. Nelson Dale, geologist, recently with the U. S. Geological Survey, announces that on Aug. 21 last he took up the work of a consulting geologist in problems pertaining to slate, granite, marble, lime-rocks, and drilling for water. Mr. Dale is the author of many authoritative papers on ornamental and building stones of the eastern United States. His address is "The Oaks," Springfield, Mass.

Yale & Towne Manufacturing Co., Stamford, Conn., has moved its general offices to Stamford, Conn., to which all mail should be addressed.

New Convertible Shovel Has Six Changes Simply Made

The Bucyrus Co., South Milwaukee, Wis., has recently described in its bulletin C-301 a new revolving shovel, known as the 30-B, which supersedes the company's 18-B ¾-yard revolving shovel. The 30-B is in fact a universal machine. It may be used as a revolving shovel, or, with the addition of a few extra parts, as a dragline excavator, a clamshell excavator, a locomotive crane, a sewer shovel, or with a long boom and dipper sticks for work requiring unusually high lifts. It is so designed that these changes may be made with the minimum of labor, delay, and expense by those who have provided the necessary parts in advance.

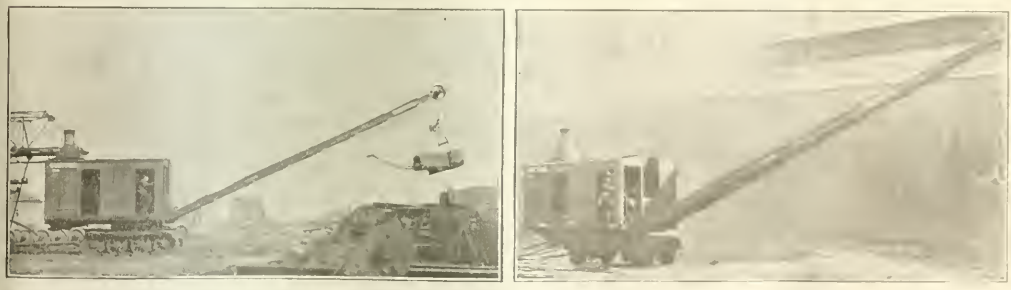
As Clamshell Excavator

The hand machine will carry a 1-yard clamshell bucket with a 35-ft. boom or a ¾-yd. clamshell bucket with a 40-ft. boom. All the change required in this installation is an additional drum on the main hoist shaft, with the necessary brake, clutch, thrust cylinder, and operating levers, additional ropes, boom, bucket, tag line, and trolley. The changes are simply and readily made.

As Crane

As a crane this shovel has a capacity of 9¾ tons at 20 ft. when mounted on caterpillars, and 9 tons at the same radius when mounted on trucks or traction wheels. To make this change, the same parts are required as for the clamshell machine, with the addition of the hook.

BUCYRUS 30-B AS A REVOLVING SHOVEL AND AS A CLAMSHELL EXCAVATOR



BUCYRUS 30-B AS A DRAGLINE EXCAVATOR AND AS A CRANE

As a Revolving Shovel

As a revolving shovel it carries a 1-yard dipper truck measure. When heaped up, this capacity is about 1¼ cu.yd. Its truck frame is so designed that it will accommodate caterpillar traction, traction wheels or railroad trucks of any gage from 3 ft. 3 in. to 5 ft. These three mountings are absolutely interchangeable. Such a change can be made in the field at a small expense. The working weight of the 30-B shovel on caterpillars is about thirty-four tons, on traction wheels thirty-one tons, and on railroad trucks 29½ tons. It has sufficient ruggedness and possesses ample power for work in clay pits, rock quarries, and for mining and stripping operations.

As Dragline Excavator

To convert to a dragline excavator requires the changes named for the clamshell except that the tag line and trolley are not necessary and a fair lead, drag-bucket and rope must be ordered. It carries a 1-yd. bucket on a 35-ft. boom, or ¾-yd. bucket on a 40-ft. boom.

As Sewer Excavator

The conversion to a sewer shovel is simple. Two combinations of dipper handles are offered. With a 30-ft. handle it will dig a trench 20 ft. deep and with a 24-ft. handle a trench 14 ft. in depth. It carries a special ¾-yd. sewer dipper, although it may be noted that the standard steam-shovel dipper

may be used for this purpose when the sewer work is not extensive. It may be seen in the illustration that this dipper has no bail, the padlock being pin-connected directly to the dipper-back and the side frames being eliminated. This gives an unobstructed cutting edge with the corners, as well as with the front of the dipper.

FOR HIGH LIFTS

It often happens that a contractor desires an exceptionally high lift and reach, as his work may require loading wagons from deep excavation or for special work of some character. To fulfill this demand, a 26-ft. boom and 17-ft. handle may be purchased.

Special Post-Graduate Training for Technical Men

Arrangements have been completed by the educational authorities of the Western Electric Co. and the faculty of Columbia University, to enable employees of the former to carry on post-graduate courses coincident with their regular duties. This system has been limited to the members of the engineering department, where more than three thousand technical students are eligible to take advantage of the offer. Approved graduates of colleges and scientific schools may pursue graduate work for masters' degrees and fulfill the requirements in two calendar years under certain conditions.

Admission is dependent on an adequate grounding in mathematics and physics. After the candidates are nominated by the officials of their departments, they must meet the academic qualifications of the university. A special course of training in technical work has also been started by the company itself to instruct graduates of arts colleges in its engineering methods. A month is set aside by the educational authorities for groundwork, which is followed by work in the laboratories. The entire course takes nine months. Outside reading and lectures are required during that period.

International Refrigeration Institute

An International Conference of Refrigeration, at which 42 governments, states, dominions and colonies were represented, was held in Paris, on June 21, the French Minister of Agriculture, M. Picard, presiding. The object of the conference was the signing of a convention which creates an International Institute of Refrigeration in Paris, supported by annual subsidies from all the participant states. The aim of this Institute is to stimulate the progress of the science and technics of refrigeration.

The director of the Institute is Emile Gouault and the chairman of the executive committee is André Lebon. They may be addressed care of Institute International du Froid, 9, avenue Carnot, Paris, France.

Some Refillable Fuses Are Reliable

A circular letter recently sent out by the Associated Factory Mutual Laboratories to its associated companies makes the following very important statement affecting every manufacturer in the United States:

"We believe that this test of Underwriters Laboratories on refillable (insertion of new links by consumer) fuses does not bring out the real hazard in the field connected with the type of fuse in question. The Underwriters Laboratories assume no responsibility for the action of the fuses after they have been refilled by the users. Improper refilling can easily occur.

"The Factory Mutual Laboratories are not planning to follow the course of the Underwriters Laboratories. We do not believe that our laboratory should approve a type of fuse whose satisfactory operation depends so greatly upon the treatment it receives by the users."

There is much food for thought in this statement and no manufacturer can ignore its far reaching possibilities and the question each manufacturer should ask himself is, What can I gain by continuing the use of a fuse which *may* cause trouble? Better avoid this possibility by using a fuse which the Factory Mutual Laboratories *approve*, particularly when you can save money by so doing. Factory Mutual Laboratories approve "Atlas" fuses in both 250 and 600 v. up to 100 amp.

Improved Water-Softener Eliminates Scale and Sludge

The hot-process water softener is described in a book recently issued by the H. S. B. W.-Cochrane Corporation, formerly the Harrison Safety Boiler Works, of Philadelphia, Pa. The device differs from the well-known lime-soda process softener, in that the chemicals are added to the water only after it has been heated to 205 deg. F. or higher, which results in a considerable reduction in the time required for the sedimentation, so that the apparatus can usually be installed within power-plant buildings and without requiring special foundations or housing. The feed-water heater is a part of the apparatus, thus reducing the complication and the expense of piping. It is also claimed that there is no after-precipitation of scale and sludge in pumps, piping, feedwater heaters, and boilers and that the minimum amount of sludge-forming solids enters the boiler and the tendency to priming and foaming is consequently minimized.

Uehling Instrument Co., 71 Broadway, New York, N. Y., combustion chemists, will exhibit fuel-saving devices at the Chemical Industries Exposition, Grand Central Palace on Sept. 20-26, and at the National Association of Stationary Engineers convention to be held at Milwaukee, Wis., Sept. 13 to 17, next.

TRADE CATALOGS

Flanged and Screened Fittings.—The Reading Valve Fittings Co., Reading, Pa., has issued a catalog of steel and iron flanged and screwed fittings and flanges.

Crushers.—The Kennedy-Van Saun Manufacturing and Engineering Corporation, 120 Broadway, New York City, illustrate and describe the Kennedy Gearless Crusher in a ten-page bulletin, No. 2. The advantages of this construction are greater speed and capacity resulting from rope or belt drive, reversible concaves because set vertically, improved material and design of construction, relatively low power consumption, and minimum abrasion of the stone-breaking parts. Garfield & Co., Hearst Building, San Francisco, are the Western general agents.

Separators. — The Griscom - Russell Co., 90 West St., New York City, is manufacturing a line of oil and steam separators of ingenious design which is described in the company's illustrated bulletins Nos. 1,120 and 1,140. The Stratton Junior Oil Separator (Bulletin 1,120) separating oil from oil-charged steam, has a special modification for use when pressures are below one atmosphere. The standard Stratton steam separator (Bulletin 1,140) removes water from the steam centrifugally, also, and stands guard between steam pulsation, flying water, sand, and scale, and the engine or turbine. Illustrations and tables in both bulletins aid in selecting the device suited for the particular need.

Dewaterer.—H. R. Wahl & Co., milling and mining machinery, First National Bank Building, Chicago, is building a simple machine for dewatering granular solids, which is fully illustrated and described in the company's bulletin D-1. The machine operates without scraping action, does not create slimes, lifts and drains the solids without contamination at any point, and permits close regulation of the water discharged with the solids. Three models are built, to meet varying conditions of size of material, tonnage per hour, dilution of feed, and limiting size of particle escaping with overflow.

Air Compressors—The Pennsylvania Pump & Compressor Co., Easton, Pa., has issued Bulletin No. 100, "Pennsylvania Air Compressors," which describes the company's Class A, power driven, single-stage, straight-line air compressors. Attention is called to a new type of ring plate valve, and an oil float gage for determining at all times the level of oil in the crank basin. The compressors embody, in addition to the above, a number of improved features of design, such as the use of a solid forged crank-shaft, forged connecting rod with solid box eyes, and removable bronze shell main bearings.

The Difference Between Silver And Other Commodities

ONE of the strongest arguments advanced by those who feel that "dollar silver" is inimical to the best interests of the country and the trade in general implies that the action of the Government in purchasing domestic silver at the fixed dollar price—which has now ruled generally above the foreign price—is a policy that might logically be extended to cover other industries, particularly those that had the value of their product, be it wheat, copper, or other commodity, stabilized during the war. It assumes that the same conditions held for silver as for other natural products, and that inasmuch as stabilization during wartime was followed by a repeal of any restrictive price measures in the post-war period for all commodities except silver, the Pittman Act should also be repealed.

It is true that under the present economic system silver is considered a commodity and subject to the same economic laws governing trade in any other mineral or agricultural product, but there are important differences between the precious metals and other commodities which make necessary sharp distinction between their treatment. The demand for silver—gold also—is subservient to the vicissitudes of governmental requirements—both metals discharge important functions and responsibilities in monetary matters, predominating characteristics in their use which cannot be underestimated in considering the moving influences in the silver market. It is not the demand in the arts which is the controlling market factor. Furthermore, quantities of silver and gold, unlike other most ordinary commodities, are being continually added to the world's wealth, and do not deteriorate like the ferrous or nonferrous metals, and are not consumed like wheat or leather, for instance. The precious metals also represent, in small volume and weight, a concentration of relatively great value, a concentration that can be readily accumulated and circulated.

With these essential points in mind the disparity between the precious metals and other commodities indicates why different treatment must be accorded them. Any generalization which sweepingly applies the rules and regulations governing trade in commodities without allowing for any intrinsic differences in certain ones, such as the precious metals, easily leads to the erroneous conclusions mentioned above.

During the last year of the war, the United States, with its large stock of silver, was able to be of very material assistance to the British government and the winning of the war, and under the authority of the Pittman Act unloaded upon the silver market some 207,000,000 oz. of silver, which ultimately found its way to India. In other words, through a governmental agency there was released upon the market about 7 per cent more silver than the entire world's production for that year. Imagine some other agency accumulating stocks of a commodity such as wheat or copper equivalent to the whole world's output and then dumping it upon the market! That is virtually a parallel to what happened in silver. The United States Government stabilized the silver market at $1 per ounce, but only by using a tremendous stock of silver for the purpose.

The necessity of stabilization during wartime is self-apparent, but the benefit accruing from stabilization in periods of peace may not be so clear, although it was shown last year how perilously near the varying price of silver came to upsetting existing currency systems by sending silver coins to the melting pot. It is of lasting good to governments to have a price for silver that is not amenable to speculative manipulation by bullion dealers, whether foreign or domestic. We are inclined to believe that the present silver situation, whereby the entire production of the United States is diverted to the Treasury at a fixed price, is not to the liking of those interests which have always been looked upon as controlling the world's silver market. No longer does the silver producer in this country find that manipulation with the market is playing havoc with his silver. Even foreign silver is exhibiting great reluctance to break more than a few cents away from the dollar quotation, and is strongly feeling the effect of the smaller available world supply.

News From Mexico

TAKEN at its face value, the news received from many parts of Mexico is encouraging and indicates that attempts are being made to revive mining projects, long dormant, but which now, under a seemingly friendlier government, stand a chance of getting a square deal. During the long period of revolutionary unrest taxes accumulated and many claims were jumped. The new government, however, to induce small owners to resume paying taxes, recently issued a decree annulling all previous edicts confiscating property for non-payment, and will permit arrears to be paid in easy instalments. This is not benevolence, it is said, but rather a method of enrolling property owners, for in many sections the official records have been completely destroyed. Those whose claims have been jumped thus have a means of regaining possession of their property.

Statistics of varying nature are issued at intervals from official sources. Indeed, in this respect, the new government, as seen from a distance, appears to be functioning normally. Recently it was announced that 365 companies, working 3,138 mines, are actually operating in the republic today. This, with the information that in many districts the records have been completely destroyed, is to be taken with a grain of salt. Other figures giving the total valuation of the oil, mining, and textile industries in Mexico have recently been issued, but here, too, the data are to be accepted with due reservations.

Some individuals are professedly skeptical of the present government's intentions, saying that it is seeking to secure American recognition by promising everything and giving but little. Such opinions at this time, however, seem most unjust, for in what other way could a new government make its start than this? Assuredly all it can do at the present time is to promise and announce its good intentions. Economic conditions are still too badly upset to permit it to do more.

It would doubtless be hard to find any one person who is sufficiently familiar with all sections of Mexico to judge with complete accuracy of the reliability of news received regarding the widely varying conditions there. The *Engineering and Mining Journal* is seeking to give its readers information obtained from reliable correspondents in this respect, but too much cannot be expected. Indulgence is asked, therefore, until such time as the rehabilitation of rail, telegraph, and postal facilities across the Rio Grande will permit more intimate communication with the southern republic.

Smelting With Enriched Air

ENRICHING the air blown into blast furnaces by the addition of pure oxygen has often been considered, but so far as we know has never been tried on a commercial scale, at least in non-ferrous metallurgical practice. Dr. F. G. Cottrell prepared a short paper on the subject for the New York meeting of the American Iron and Steel Institute last May, though the discussion was confined to the application of the practice to iron blast furnace work.

The reason that the idea has not received wider experimental or commercial application lies, of course, in the cost of the oxygen. Present production in this country amounts to about 3,000,000 cu.ft., or 130 tons of oxygen, per day. About 25 per cent of this is manufactured by the electrical decomposition of water. Theoretically, such oxygen should be produced at about $12 per ton for the electric energy consumed, assuming electric power at 0.2c. per horsepower-hour. The remainder is made by the liquefaction and distillation of air by the Linde and Claude methods, and sells, in large quantities, for 1c. per cu.ft., or about $225 per ton.

The largest single installation for air separation, according to Dr. Cottrell, is at the Government nitrogen plant at Muscle Shoals, Ala., which could produce about 3,000,000 cu.ft. per day, though at what cost we do not know. The use of ozone has also been considered by the International Nickel Co., which collected considerable data on the subject a few years ago, but the cost of production seemed to be too great to offset the indefinite improvement in furnace operation which would be secured by its use.

The use of oxygen-enriched air would result in a more intense heat in the combustion zone of a furnace. Coke could probably be reduced. Its use as an aid to secure pyritic smelting may well be considered. It might prove valuable in connection with the firing of copper and lead blast furnaces with pulverized coal, especially if the ore were refractory. Some of the new volatilization methods might make use of it. Enriched air might also be temporarily used to restore a cold or badly blocked furnace to normal running; in case of blower trouble it might mean the saving of a furnace which would otherwise have to be dug out. The field for experimental work is large, and arrangements could possibly be made with one of the two large producers of oxygen, or manufacturers of ozonizing equipment, for securing the necessary supplies or equipment at cost.

Dressing a Mine for Sale

SALTING is a subject which perforce is continually on the mind of the examining engineer, but which does not receive much mention in the literature of the profession. It may even be held by some that it is dangerous to introduce it into literature, on account of the suggestion which may lead to the practice of fraud, and because of the instruction which it might afford to those who are willing to cheat but are not fully acquainted with the art. However, it is probable that for those who have actually given much thought to the matter as a preliminary for practice, there is little that can be learned. The wiles of trickery are age-old, and they have flourished in the soil of mining venture and mining speculation as everywhere else.

There are all kinds of salting—some questionable, some wholly depraved. What of the very common practice of "dressing" a mine for sale, for example? The recipe is easy: Stop all faces in wide and good ore. The mine makes thereby an unduly good impression on any but the most expert, and in just so far, an incorrect impression is calculatingly produced. Is that reprehensible? It will not fool the wise; but is it not the "children and fools," the half-baked of mining, who should be especially protected, granted that Providence, which otherwise is supposed to take care of this class, apparently abandons them when they pass the portals of a mining tunnel, or step (if so bold) into the bucket to be let down the shaft? On the other hand, the window-dressers would argue, you could not expect them to take out all the visible ore and stop the faces at lean points, when every chance points to other orebodies on further development. They would hold this an unfair and false presentation. They would argue that when a man presents himself to a prospective employer he takes care to shave, put on his best clothes, and make the best impression possible; that the prospective employer assumes this, and would underestimate a man who appears in the guise he often assumes at the end of a particularly hard day's work.

The truth, of course, is midway. The man who courts his prospective wife with vast show of presents, and unduly deferential chivalry, which he does not intend to last forever or perhaps cannot possibly keep up after marriage, is laying the foundation for future disillusionment on the part of the wife, and accusations of having failed to make good. The sample which he displays of his pecuniary and personal resources and attributes must be an average sample, of the kind that will wear. The prospective employee must not by implication or otherwise make impressions or promises which he cannot make absolutely good in the long run. Many choose rather the opposite course, preferring to let deeds speak instead of promises. A mine should not be dressed for sale, but should remain as operation left it; or should be continued working as good judgment suggests, without thought of the impression it may make on a purchaser. A competent purchaser will see and take consideration; and a mine owner should not seek to deceive an incompetent.

The experienced miner who understands the tricks of his mine may use many wiles other than the simple

one noted above. He may progress a step further along the road to iniquity, and suppress bad showings. Winzes may be filled with waste or flooded, because they show the disappearance of ore at the bottom. "Caves" may be allowed to take place by calculated neglect, or helped along, more or less, so as to make inaccessible faults or intrusions which cut off the ore; while the cheerful parts of the mine may be more especially kept open for inspection. Often the unwatering of winzes, or the cleaning out of caves, would take more time than the prospective purchaser has at his disposal, and he must guess at what is not shown and decide with this evidence in doubt.

Sometimes a mine "dresses" itself automatically for sale, and the dishonesty of the owner comes in not explaining to the examining engineer the mine's peculiarities. If the engineer is secretive and given to rebuff, and advises the owner that he knows more than the owner can ever tell him about the mine, and wants to pointers, then indeed the duty of the owner is harder to define.

We remember a case where lead-silver ore replaced limestone, working out from certain almost invisible straight and regular fractures, vertical and intersecting one another at right angles; and the mineralization was confined to a certain limestone bed about ten feet thick. Drifts had been driven along the center of each of the principal fractures, and the natural ore thus stoped out: but the walls were still ore, though of lower grade. The mine was thus developed into blocks by the intersecting drifts, as if all the bed were ore and had been systematically blocked out as a scheme of development; and so the owner dishonestly gave the investigator to understand. Obviously sampling would have indicated a great body of mill ore, on the latter assumption; but with a knowledge of the ore occurrence it would be realized that the assay values would fade away from the walls of the drifts toward a barren center in each block. The fact that ore is blocked out on four sides does not make it safe to calculate it as there, unless one understands the occurrence; but with such expert knowledge, ore exposed on one side only may sometimes more safely be assumed. The only real "ore in sight" is that which is broken down and sampled; and in sampling a mine, the main thing is not the necessary mechanical sampling of faces, with all the usual expert safeguards, but a knowledge of how the ore lies; and in this way the closest approximation to the amount and value of standing ore may be made.

Welfare Work as an Investment

WELFARE work has been defined as the "humanizing of industry." Production, as generally understood, implies the result of industrial application. We have, all told, made tremendous strides in the standardization and improvement of the methods of doing things, with the result, in general, that production has increased; at any rate the necessary program has been outlined for the securing of greater output. Instances where the latter has not kept stride with a rising curve have been due to the failure of some contributing factor: lack of motive power, inability of machines to meet capacity, shortage of raw materials, or the whims of labor and capital.

Increased production usually means lowered costs, and a calculation of the net financial return can usually be made. Money spent in welfare work is productive of no monetary returns; no tangible cash dividends are paid out to the individuals or companies engaging in the work. But the expenditure of money for "humanizing industry" goes on apace, and each year shows greater and greater sums spent for the work. Why? The protection of the workman from accidents, the encouragement of personal and community hygiene, the care of the sick, financial aid to those who are disabled or who have grown old in service, the upbuilding and instruction of a coming generation, Americanization—all these benefits, which are the result of effort in human engineering, are the returns of the investment. Certainly no work that has been done for this object has failed to give bigger and more satisfactory returns.

Labor-Saving Equipment

A CHANGE in point of view on the part of the technical managers of plants, due to present economic and labor conditions, is worthy of note. Formerly there were two distinct motives for the introduction of mechanical equipment. One was the reduction in the amount of manual labor and the other decrease in unit cost. As tonnages handled increased, the practicability of introducing mechanical handling of material, with consequent lowering of unit costs, became more and more apparent.

The last fifteen years represents a notable epoch in the mining industry in that there was extensive mechanization of surface and underground plants. Recently the superintendent of a smelting plant said, "I have just put in an additional conveyor belt in my ore-handling equipment and as a result have saved the labor of eight men. These men I will use elsewhere in the plant where they are greatly needed." The dearth of common labor, as well as its increased cost, not to mention the lessened efficiency so apparent, has caused superintendents of plants to study more minutely the detail of handling ore and ore products with the objective of conserving labor. Numerous appliances are available, but owing to the already intensive application of labor-saving devices the opportunities for further installations are comparatively restricted.

The problem in each individual plant will warrant close study, with a view to improving existing conditions and adding extensions. With an increase in the amount of mechanical equipment the repair force of a plant becomes of additional importance. Mechanical equipment without thorough maintenance may increase gross expense to a prohibitive degree through delays and interference with sequential operations. Maintenance of mechanical equipment under existing economic and labor difficulties has not been easy. There is a scarcity of good mechanics, and here as elsewhere efficiency has fallen off. Plant superintendents are under the necessity of thoroughly developing their mechanical maintenance force, and mechanical engineers can contribute their share by simplifying mechanical devices and substituting better materials for their construction. There is a wide field here for machinery that will stand up to the work with a minimum of maintenance. Manufacturers who can meet this condition will co-operate in a broad way with the industry and assist mining companies in maintaining proper margins between income and outgo.

Twenty-yard, air-operated dump cars used on stripping, Mesabi Range. 9. 350-ton revolving steam shovel, Mesabi Range. 10. Street in Morgan Park, Duluth, Minn., built by the Minnesota Steel Co. for employees. 11. The Minnesota Steel Co.'s plant; Morgan Park, near Duluth, at left.

THE Lake trip from Buffalo to Houghton included part of the route taken by iron-ore and other carriers in their journey from and to the iron- and copper-shipping points of the Lake Superior districts. At Sault Ste. Marie the "Tionesta" passed through the famous locks. A partial conception of the commerce through these canals may be gathered from recent statistics prepared by the Bureau of Foreign and Domestic Commerce which state that during June, 1920, a total tonnage of 10,647,819 was registered. Of this 3,063 tons was copper and 8,725,046 tons iron ore. An excellent example of reinforced-concrete construction is shown at the No. 2 shaft hoist house of the Quincy Mining Co., Hancock, Mich. The walls of this building are of brick veneer and the roof is covered with green tile. Among notable pump installations in the Lake Superior district is that at the Athens mine. In illustration 4 one of the 500-gal. pumps is shown. At the Curry mine, in the Menominee district, a reinforced-concrete structure has been built into and around the steel headframe for the purpose of supporting a gyratory crusher and bin installation. At Minneapolis several of the technical sessions were held at the Mining Building of the University of Minnesota. The Trout Lake concentrator of the Oliver Iron Mining Co. at Coleraine, Minn., has a maximum capacity of 900 tons of crude ore per hour. Mesabi Range stripping equipment has rapidly increased in capacity. In the early operations, cars of 1-cu.yd. capacity were used, whereas modern practice specifies the 20-cu.yd. cars, as shown. This is also true of steam shovels. A 70-ton shovel with a 2-cu.yd. bucket is now replaced by a 350-ton shovel with a 7-cu.ft. bucket.

Lake Superior Meeting A. I. M. E.

Institute Holds 122d Conclave in Michigan Copper and Iron Country — Enunciation of Constructive National Policy by Hoover at Close of Technical Sessions Pledges Engineers to Public Service — Gathering Noteworthy for Display of Patriotic Spirit and Hospitality of Local Industries and Officials

THE 122d meeting of the American Institute of Mining and Metallurgical Engineers was held in the Lake Superior region on Aug. 23 to 28, with the principal stop and banquet at Minneapolis. Technical sessions were held in Minneapolis and Houghton, Mich., and in Hibbing., Minn.

A large party of members of the Institute sailed from Buffalo on Friday, Aug. 20, on the steamship "Tionesta," and were met at Houghton, Mich., by another large group, including the president, Herbert Hoover. At Houghton, the center of Lake Superior mining, elaborate hospitality was provided in the form of facilities for investigation of mines, mills, and smelters. The party then split into two sections, which went each by special train to the Marquette and Menominee iron ranges in Michigan; and each of these trips was replete with interesting technical exhibits and with courteous consideration. The united parties then proceeded to Minneapolis, where technical sessions were held, together with an official lunch in St. Paul and a banquet at Minneapolis. Hoover's speech was the feature of the banquet. The party then proceeded to the Mesabi Range in its special train, where the wonders of the world's greatest iron-mining region were displayed. Returning to Duluth, the engineers of that port arranged a program; and the trip ended at that city.

THE successful meeting of the Institute demonstrates anew the advantages of mixing. For such a summer excursion, the benefits may be summarized as follows, according to importance:

1. The contact and conversation with other engineers, with different themes of specialization, and different geographic experience.

2. The inspiration of mining districts and the study of mining details with which we are not familiar.

3. The reading and discussion of technical papers.

In the winter meetings, the third division, of course, moves up into second place, with the corresponding importance.

It is a condition of further human growth and evolution, collectively and individually, that we shall keep in constant contact with individuals representing other sectors of the component whole, which alone is competent for rounded action; and that out of that contact mutual understanding and concerted action shall arise. In the mining industry we shall more and more need this broader understanding.

The Boat Trip

LEWIS CARROL once wrote something about "T'was brillig——" we forget just how it goes—but in that short bit of nonsense we somehow or other gathered the fact that it was hot; that there was heat of an oppressive and depressive sort. And it was with a similar feeling that the New York contingent of the A. I. M. E. left the Grand Central terminal the evening of Aug. 19. The sweltering heat of the last ten days had done much to upset the normally affable disposition of the mining engineer, so that it was not to be expected that he would "warm up"—that is, in the broad sense. Bnt despite the heat there was some show of enthusiasm, and toward bedtime it began to be evident that the "heat-treated" shell showed signs of breaking.

At Buffalo, amid new surroundings and well fortified with a good breakfast, we were met by other engineers from various points, and made our way to the wharf of the Great Lakes Transit Corporation, where the "Tionesta" was docked. After the usual formalities had been completed, the boat got under way and the first lap of the Lake Superior trip began.

About 150 members and guests made the trip. Those on board included:

Miss Anna W. Jewett,
Miss Louise R. Jewett,
Mrs. John S. Watson,
Mr. and Mrs. Harrison Souder,
Mr. and Mrs. Frank C. Hooper,
Mr. and Mrs. Ell T. Conner,
Mr. and Mrs. J. R. Underwood,
Robert Linton,
Charlton Reynders,
A. J. Strane,
Mr. and Mrs. H. N. Spicer,
Mr. and Mrs. F. L. Estep,
V. E. Edwards,
D. Oliver Brooke,
Mr. and Mrs. P. E. Barbour,
C. P. Perin,
T. W. Tuhyiler,
A. R. Bench,
Walter M. Sanders,
G. F. Woodsmith,
J. Stephenson,
Arthur Thacher,
J. W. Richards,
Mr. and Mrs. J. C. Dick,
G. H. Clevenger,
Alfred W. G. Wilson,
Mr. and Mrs. R. C. Greenfield,
W. R. Hibbard,
Mr. and Mrs. R. V. Norris,
John Stephenson, Jr.,
Geo. L. Collord,
Wm. C. Snyder, Jr.,
Mr. and Mrs. G. H. R. Harris,
J. T. Morrow,
Geo. A. Guess,
H. E. T. Haultain,
H. A. Coy,
R. Dawson Hall,
John T. Breunich,
Arthur L. Walker,
A. M. Cummings,
Earl C. Henry,
Stuart Hazlewood,
J. W. Knowlton,
E. P. McCrorken,
R. H. Richards,
Mr. and Mrs. A. C. Parsons,
S. LeFevre,
H. Kamura,
Philip N. Moore,
J. F. Culbreath,
Mr. and Mrs. J. S. Cunningham,
Mr. and Mrs. W. W. Miller,
Col. and Mrs. A. S. Dwight,
Mr. and Mrs. F. W. O'Neil
Prof. H. Stock and
Miss Stock,
Mr. and Mrs. F. G. Jewett,
John R. Freeman, Jr.,
E. E. Thum,
Bradley Stoughton,
R. C. Allen,
Mr. and Mrs. C. C. Burger,
Mr. and Mrs. C. K. Baldwin,
Mr. and Mrs. Geo. D. Barren,
Richard G. Wood,
J. E. Spurr,
D. E. A. Charlton.

According to a custom which is excellent, the members wore badges in which their last names were prominently displayed, as Hall, Dudley, Siebenthal, and Croasdale. A few, however, apparently elected to use their first names, evidently assuming that they were sufficiently well known. Among these were noted Dick, Arthur, James, Henry, and Ruth.

To those engineers who have not been so fortunate as to include in their list of travels a trip on the Great Lakes we offer condolence, for it will always be with pleasure that we recall that brief journey on the great inland sea. The big blue expanse stretching out in every direction, the splashing of the waves against the ship, the steady throb of the engines—but why continue, for we grow poetical, and, indeed, all we intend to do is to emphasize the delightful calm and the pleasure which accompanied those hours of relaxation. Be it said of Lake Erie that not once did that great body of water express its disapproval of American engineers.

Cleveland was passed during the late hours, so that there was little opportunity for impressions of that thriving Lake city, known the world over as one of the greatest iron-ore receiving ports. At Detroit, the engineers were more fortunate, for promptly at 7 (standard time, although the inhabitants set their Ingersolls one hour ahead, thereby taking advantage of the extra light and good Michigan air) the boat docked, and various parties took advantage of the busses to get a glimpse of the fourth city of our United States. In this connection—we are speaking now of Detroit—it is a matter of regret that Mr. Ford did not avail himself of the opportunity to join the engineers on a visit to the iron ranges, where he has recently acquired extensive interests.

Making Heavy Weather

Leaving Detroit about noon we wound our way through the St. Clair Flats, generally known as the Venice of America, where, according to Ed Wynn, the comedian, any good swimmer can get a job as a traffic cop. Lake Huron, not so well disposed as her southern neighbor, Lake Erie, saw fit to offer a little variation to our previous placid existence. It may be well to pass briefly over this period. There were a few vacant chairs at dinner, some scattering absentees at breakfast, but by noon, as we approached Mackinac Island, all hands were on deck. The storm lasted most of the night, resulted in a delay of four hours, and gave ample evidence of the fact that the landlubber isn't the only one who has his ups and downs.

Mackinac Island boasts of two things: its history and the fact that there are no automobiles on the place. The first is pardonable, because every place must have its beginning. The second is inconceivable, and we are at a loss to understand why Henry Ford and the rest of Michigan's automobile autocracy exert such a slight influence in state politics and permit the passage of laws that allot this domain to the exclusive use of the horse and open victoria.

Owing to the lateness of the hour it was impossible for the visitors to obtain a good view of the Soo locks, which we passed through at 11. In the bright moonlight, however, there was opportunity to view the huge concrete trough into which we slid; the lock-gates closed behind us, the water rose, bringing us up to the level of the water in the channel above, and slowly we moved out into the great expanse of the mighty Superior. Forgotten then, and for some time before, was the heat and sultriness of the city, for the invigorating air raced the pulse, and those who had not already sought their berths were well aware that to stand still was to shiver.

Ocha Potter, who came aboard at the Soo, stated that the copper country delegation whom he represented had ordered a special brand of weather for our benefit. This, be it said, was in absolute harmony with the usual class of entertainment that those good people offer. To one who is familiar with the vagaries of temperature, wind, storm, sleet, and snow that abound in the North Country, it is a remarkable fact that our hosts proved to be such good prophets, for certainly a better stage could not have been set for our reception.

At the present writing—1:30 p.m.—(It is remarkable how this air gets one's appetite, the latter being a very good reason why we will "continue in our next"), we are entering Keweenaw Bay, soon to wind our way through Portage Lake and dock at Houghton.

The Copper Country Meeting

COPPER COUNTRY people do not stint themselves when preparing for or entertaining visitors, and the last gathering of the A. I. M. E. was no exception. Those aboard the "Tionesta" were given a rousing welcome, the whistles of the various plants bursting into sound at the first sign of the boat and continuing until the docking was complete. And this reception was only a beginning, for the streets were decorated with bunting; students of the Michigan College of Mines attended to the transfer of baggage; automobiles were on hand to convey the visitors to Institute headquarters at the Houghton Club or other points—in fact no detail was overlooked to make the stay of the engineers a most pleasant and long-remembered one. The arrangements were in charge of the copper country section of the Alumni Association of the Michigan College of Mines, under the chairmanship of John Knox and the assistance of prominent citizens of Houghton, Hancock, and Calumet.

Registration of delegates began Monday morning at the Houghton Club headquarters. Herbert Hoover, president of the A. I. M. E., arrived by train early in the day and others on the noon train. Owing to the late arrival of the "Tionesta," it was impossible to carry out the complete plans for the day, although those arriving by train were able to visit the Quincy stamp mills, Calumet & Hecla smelter, electrolytic refinery, stamp mills and reclamation plant. After dinner, which was served to members and their guests on dining cars attached to the special train, the visitors were taken to the Onigaming Yacht Club, where an informal dance was held.

Tuesday's program included nine technical visits taken by automobile from the Houghton Club, according to individual preference. These consisted of a geological expedition through the country, trips to the Champion mine, at Painesdale, the Calumet & Hecla mine, the Mohawk mine, the Michigan and Quincy smelters, the Quincy and Calumet & Hecla surface plants, the Calumet & Hecla smelter and electrolytic refinery, the Calumet & Hecla mills and reclamation plant and a general tour of the copper country. This last was arranged for all ladies, members, and guests who were not particularly interested in the mining or metallurgy of the district.

Visit to Ahmeek Mine

The geological trip included a visit to the Ahmeek mine. This was well attended and was chaperoned by the several distinguished geologists that are at present identified with the copper country, including Messrs. Seaman, Graton, Butler, Palache, and Locke. The chief interest was in the steeply dipping cross-fissures of the sixteenth level of this Calumet & Hecla subsidiary. One of the fissures is characterized by native copper, and another by arsenides of copper, and both cut across the main bedded lode without being displaced, and with only slight displacement of the bedded lode by the cross-fissures. A similar cross-fissure vein was inspected at the old Phoenix mine. The early miners first discovered these fissure veins and mined the native copper (mass copper) from them before the discovery of the bedded lodes.

At the Champion mine the visitors were taken to the tenth level, where the methods of drifting and ore removal were explained. The lode at this mine is removed for the entire width, overhand stoping is practised, and the waste rock used in dry walling. A system of selective stoping is used, and by this method it is possible to secure a high grade of copper rock. Where the amygdaloidal rock is rich in copper and there is a little barren rock remaining for dry walling it has been the practice to use stamp sand for filling the stopes above the drifts. The stamp sand is brought into the stopes under pressure through 4-in. pipes. The chutes from main levels through which the copper rock (the copper country miner does not use the term "ore") is dropped are dry walled and are circular in shape.

At the Champion a bell signal system is installed which insures perfect safety and obviates all possibility of error in the transmission of signals to the engineer from any station in the mine. This system was explained in detail in an article by R. H. Bacon which appeared in the *Engineering and Mining Journal* of Aug. 21.

Unique Tempering Furnace

On the surface the machine and tool sharpening shop was inspected. A tempering furnace and conveyor which is in use here embodies some unusual features, including a pyrometer-control forge. It was unfortunate that time did not permit an inspection of the regenerating heating plant. A paper on this subject was read by W. H. Schacht, general manager of the Copper Range Co., at the technical session held that evening.

At the smelters, the straight line and Walker casting machines which are used in connection with large melting and refining furnaces were seen. At the Calumet & Hecla mills at Lake Linden there was much of interest to the mill man: The use of Woodbury classifiers in connection with Wilfley tables, the tailings reclamation and regrinding plant, including leaching and flotation, the 7,500-kw. mixed pressure steam turbines, and the large tailing sand wheels.

To Eagle Harbor for Recreation

Toward noon the visitors headed for Eagle Harbor, where lunch and an elaborate program had been arranged. The first actual copper mining in the Lake Superior district was in 1844, and the first product was secured at Copper Harbor. The trip to Eagle Harbor was through a country rich in the history of the early copper mining of the district, and many of the old mines, now abandoned, were seen. Everyone in the Copper Country swears by the Calumet & Hecla band, and certainly those good people have reason to be proud of their musical organization. During and immediately following lunch the band played several selections that were greatly appreciated by the visitors. The *piece de resistance* of the excellent lunch was Cornish pasties. In the afternoon the visitors were treated to some real Cornish wrestling.

In the evening there were two sessions, one of which was technical and held at the mining building of the Michigan College of Mines, and the other a meeting of the ladies' auxiliary at which Mrs. Dwight presided.

This was held at the college gymnasium. At the session on mine practice, Dr. F. W. McNair presided. The papers "Mechanical Ventilation at the Lake Mine," the "Athens System of Mining," and "Building Reinforced-Concrete Shaft Houses" were all read and discussed by Lucien Eaton. Following the presentation of the last named, William Kelly drew the distinction between shaft houses and headframes. T. L. Condron, a structural engineer of Chicago, discussed the physical structure of concrete in connection with such buildings and pointed out the necessity of taking into account the shrinkage and temperature stresses. H. T. Mercer discussed his paper, "Handling and Treatment of Rock-drill Steel at the Copper Range Mines," and stated that by the adoption of the methods now in use the personal element is entirely obviated. A. C. Paulson, co-author of this paper, explained the pyrometric feature as it is used in the Champion shop. W. H. Schacht, discussed his paper, "Steam Regenerators Reduce Coal Consumption." O. P. Hood stated that the original installation at the Champion mine represented a remarkable achivement at the time, and that recent developments had accomplished a higher percentage of efficiency. He also outlined the coal-saving steps which were adopted by the Government during the war. At the close of the session Dr. McNair introduced President Herbert Hoover.

Mr. Hoover spoke briefly on recent developments in Russia and made a distinction between the Soviet and the Bolsheviki. The situation, said Mr. Hoover, is one which merits the attention of engineers. In closing, Mr. Hoover paid tribute to the people of the Copper Country, the Alumni Association of the Michigan College of Mines, and other local committees which had done so much to make the stay of the engineers a pleasant one. Following this session an informal dance was held at the gymnasium of the Michigan College of Mines. The special trains, one going to the Marquette Range and the other to Iron Mountain, left at 1:30.

Across the Michigan Iron Ranges

THE excursion on the Menominee iron range of Michigan on Wednesday, Aug. 25, was marked by royal weather and a precision of organization and carrying out of plans. The printed schedule which was placed in the hands of the engineers in the morning was followed throughout the day without hitch; and the sun set again at Iron Mountain for them as they returned to their trains at the close of a perfect day. O. C. Davidson, William Kelly, and C. E. Lawrence, prominent Menominee Range mining men, arranged the program, which in the morning included visits to several shafts of the Chapin mine, where the surface installations and underground were inspected, as were the hydro-electric plants in the vicinity, which offer not only engineering attractions, but scenic qualities as well. Luncheon was taken under the trees at the golf grounds, and a busy afternoon was spent visiting the Brier Hill mine and the various shafts of the Vulcan mine of the Midvale Steel Co. Great interest was shown in the various devices for economy and safety and in improved modern styles of change houses, especially that at the East Vulcan, with the overhead system of hanging and drying mine clothes. The electro-hydraulic steam shovel at the Curry shaft of the Vulcan mine, operated by a single man, received a great deal of attention. It is the invention of Frank Armstrong, the mechanical engineer at the Vulcan.

Pioneer Furnace and Chemical Plant Inspected

Engineers who elected to take the Marquette Range trip found much of interest. Arriving at Marquette about 8 in the morning, the visitors were met by automobiles and were taken to the Pioneer furnace and chemical plant of the Cleveland-Cliffs Iron Co. The furnace and also the chemical plant are thoroughly modern; the furnace is equipped with a self-dumping device for the charcoal, has steel ore bins, motor-driven scale cars, skip hoist, and revolving top. In addition to the basic products (wood alcohol, methyl acetone, acetate of lime), the chemical plant produces c. p. acetone, acetic acid, formaldehyde, flotation oils, insulating pitch, sodium acetate, sulphuric acid, iron liquor, methyl acetate, special solvents, hexamethylenamine, and pure creosote. During the visit a pouring of pig iron was made at the furnace for the entertainment of the engineers.

Athens and Negaunee Model Mines

At noon lunch was served at the Wawonowin Golf Club and, following this, many of the visitors indulged in a game of golf. The Athens and the Negaunee mines were visited, and those who wished to do so were permitted to inspect the underground pump room of the former. Both of these mines are models in equipment and the clean and orderly appearance which they present was the subject of much favorable comment.

At the Athens mine the water is raised 2,400 ft. in a single lift by two Prescott horizontal duplex plunger pumps, each having a capacity of 500 gal. per minute. As far as known this is the deepest direct lift installation in the world. At the Negaunee mine a steel stocking trestle was noted. This is supported by circular reinforced-concrete columns placed at intervals of 114 ft. These columns are 6 ft. in diameter at the base and 4 ft. at the top. They are attached to pyramid-shape reinforced-concrete bases 12 ft. x 26 ft. x 6 ft. deep. The reinforcing was made with $\frac{3}{4}$-in. rods, which extend up into the columns for a distance of 20 ft. The length of the trestle is 2,329 ft., with 2,090 ft. available for stocking ore.

On Wednesday evening the two groups, from the Marquette and the Menominee ranges, were reunited at Iron Mountain. Through the courtesy of the Midvale Steel Co., a moving picture film, showing iron ore from mine to finished product, was shown at a local theatre. The various stages of operation were explained by Mr. Richardson, of that company. Following this, William Kelly spoke with respect to an earlier visit of the Institute to the Menominee Range some thirty years ago. Mr. Kelly then introduced Mr. Hoover, who spoke briefly on the engineer's connection with reconstruction problems.

At Minneapolis and St. Paul

UPON the arrival at Minneapolis, many of the members went to the Curtis Hotel, the temporary headquarters in that city. At 10 o'clock the technical sessions at the University of Minnesota commenced, and were as follows:

Session on Mine Practice, Herbert Hoover presiding; session on Geology and Resources, W. H. Emmons, presiding; session on Oil and Gas and on Non-Ferrous Metallography, C. E. Julihn presiding. At the session on mine practice, A. J. Strane presented his paper on "Modern Commercial Explosives and Their Uses." Robert Linton in presenting a discussion of his paper, "Standardizing of North Butte Mining Co.," used a number of stereopticon as well as cinema views, thereby adding greatly to the interest of his paper. The plan now in force at the North Butte has been most successful in securing efficient results, and the methods employed have the full confidence and approval of the men.

The paper, "Mining Methods and Costs at the United Verde Mine," by H. De Witt Smith and W. H. Sirdevan, was read by Mr. Smith and was illustrated by stereopticon views. F. A. Wildes, State Superintendent of Mines, outlined the work of his department in keeping in touch with the work done by operators on state properties. This department maintains a full corps of mining engineers and assistants.

Oil and Gas To Be Discussed at St. Louis

The other papers included in the session were omitted owing to lack of time. There being no discussion at the session on Oil and Gas, this was postponed until the St. Louis meeting, when it is expected that matters pertaining to those subjects will be fully considered.

At the geological section, over which W. H. Emmons presided, the first paper, "The Dip Needle in Stratigraphy," was presented by the author, H. R. Aldrich, and attracted considerable discussion. The possibility of the further use of the dip needle, even outside of the iron regions, in detecting and following formations beneath a moderate thickness of overburden, was discussed by the author and by W. O. Hotchkiss, and the necessity for caution was emphasized by Carl apffe. The paper on "Exploration Methods on the Gogebic Range," given by Mr. Hotchkiss, was concise and convincing in its delineations of the various factors controlling ore deposition on the Gogebic and the most economical and efficient methods of exploration by diamond drilling and crosscutting. In debate, Mr. Hotchkiss was praised for the spirit he had shown in making public these valuable criteria, which had resulted in substantial saving at various properties.

The paper on "Application of Ball Mills in Southeastern Missouri," by Lewis A. Delano and Harold Rabling, was read by title, the authors not being present, but Mr. Greenfield presented a carefully prepared comment, touching in turn the various features of the original paper. The paper on the "Geology and Ore Deposits of the Jerome District, in Arizona," was presented briefly in abstract by Mr. Harper for the author, Louis E. Reber, Jr., who was absent. This is the geology of the United Verde and neighboring mines, and so is of great interest. The ore deposits are pre-Cambrian, and presumably genetically connected with a batholithic intrusion which outcrops in a neighboring area.

While at the University of Minnesota, many of the engineers visited the Mines Experiment Station, on the college campus, where a magnetic concentration test was in progress throughout the day. The test included magnetic cobbing at coarse sizes, followed by fine closed-circuit grinding in a ball mill, with concentration in a magnetic log washer, dewatering in a continuous filter, and sintering.

For the purpose of organizing a chapter in the Twin Cities, Mrs. Arthur S. Dwight, president of the Woman's Auxiliary of the A. I. M. E., met the ladies who are members, and those who are interested, at the home of Mr. and Mrs. H. V. Winchell at 10 o'clock on Thursday morning. Mrs. Dwight explained the activities of the auxiliary, but no steps were taken for the formation of a definite chapter, although Mrs. Winchell was appointed temporary chairman.

Senator Kellogg Speaks

The noon lunch was held at the St. Paul Hotel, St. Paul. U. S. Senator Frank Kellogg was introduced, and gave a short talk on the visit of the engineers to northern Minnesota. Following Mr. Kellogg, the Rev. Mr. Ferguson, who represented the Mayor of St. Paul and who is a member of the City Commission, bade the engineers welcome and paid a splendid compliment to Herbert Hoover for his work during the war. Mr. Hoover spoke briefly on industrial relations and expressed the appreciation of the engineers for the reception that had been tendered them. After the luncheon, automobile parties were formed and the visitors were taken to various points of interest in the Twin Cities. Several of the members played golf at the Interlaken and the Town and Country clubs. Among points of interest visited were the various flour mills and the plant of the Minneapolis Steel & Machinery Co. This company has constructed some of the largest mills and smelters in this country, and is now building the magnetic separation plant at Babbitt, on the eastern Mesabi Range. Some of the members visited the display rooms of the W. H. Ziegler Co., where an exhibit of mine railway equipment and supplies was shown.

The banquet, held Thursday evening at the Curtis Hotel, was preceded by an informal reception in the parlors. Immediately after being seated the guests were surprised to have all the lights extinguished, and a blaze of light at one end of the hall made it evident that several miners, dressed in slickers and wearing the regulation iron-country underground hats, had entered the room. The "miners" burst into song, and following that distributed a number of unique ash trays bearing the seal of the A. I. M. E. These were made and presented by the F. C. Orn Iron Co.

In introducing William C. Edgar, former editor of *The Bellman*, and now editor of the *Northwestern Miller*, Phillip N. Moore, past president of the Institute, announced his function as that of "introducer of introducers." Mr. Edgar acted as toastmaster in a most able manner and soon demonstrated his ability to ap-

pear at home in any company even though he is not an engineer. Fred B. Snyder, president of the Board of Regents, University of Minnesota, was the first speaker, and he outlined the history of the state, calling special attention to the importance of Minnesota as a flour center and as an iron producer. He mentioned the subject of the tonnage tax and spoke of this as being one of the factors that might hamper development of Minnesota's iron-ore resources, unless steps were taken to keep this tax within reasonable limits. He also spoke of the beneficiation work that is being done at the experimental school and elsewhere.

Mr. Edgar then introduced J. E. Spurr, Editor of *Engineering and Mining Journal*, who responded in a light vein. Mr. Spurr said that he was called in as a substitute for Mr. Winchell at the last minute, having been advised of his departure for Alaska only a few days before. Mr. Spurr told of some of his early experiences on the Mesabi Range and outlined the difficulties under which the pioneers worked. John E. Hodge, local committee chairman, then read a telegram from Horace V. Winchell to Mr. Hoover, in which Mr. Winchell congratulated him on his accomplishments and stated that the Institute might indeed be proud to have Herbert Hoover as its president.

In introducing Mr. Hoover as the next speaker, Mr. Edgar referred to him as "the greatest living American." Mr. Hoover chose as his subject the establishment of a Department of Public Works and said that such a step is necessary to a broad-visioned national guidance. Engineers must, said Mr. Hoover, exert themselves in engineering policies, and so bring about the proper co-ordination and co-operation of the various engineering functions of the Government.

The engineers' special train left the Union Depot at Minneapolis for the Mesabi Range at 11:30 p.m.

Mr. Snyder's Address

In his opening address, Fred B. Snyder spoke in part as follows:

Minnesota lies in the heart of the continent. The early voyageur could pass by water and short portages from the Gulf of Mexico by way of the Mississippi, Minnesota and Red rivers to the Arctic Ocean and by way of the Mississippi, St. Louis and St. Lawrence rivers to the Atlantic Ocean. The New England States could be laid upon her surface, and there would be enough of Minnesota left over to cover half of Pennsylvania. If the waters of her inland lakes could be gathered together, Delaware and Rhode Island could be submerged and leave to view only islands marking the high spots.

Doubtless the industry of Minnesota which most interests you as mining engineers and metallurgists is that of iron. There are, as you know, three iron-bearing ranges in Minnesota, the Vermilion, the Mesabi and the Cuyuna. Of these the greatest is the Mesabi. I would not if I could, burden you with a discussion of its geology. It is a flat, not vertical, formation covered by a shallow surface of glacial drift, susceptible by test pitting and drilling, of very accurate determination as to tonnage, metallic content, and structure, in advance of opening up. One-half of the ore in the Mesabi Range is subject to open-pit steam shovel mining at very low cost. Today approximately 70 per cent of the ore produced is won by open-pit methods and the remainder from underground operations where ore is cleanly mined with less than 5 per cent loss.

Work of Winchell and Spurr Praised

The first published scientific data about the Mesabi was issued under the State Geological Survey conducted by the University. N. H. Winchell was at the head of the survey, and he was ably assisted by his son, Horace V. Winchell, who was president of this organization last year, and J. E. Spurr, both of whom have achieved distinction in geological work.

The Mesabi Range has been the controlling raw material factor in the iron markets of the world since the true values of its ores became known. It made possible the organization of the United States Steel Corporation and the entrance of the United States into the steel markets of the world. Many furnaces in the valley districts have been remodeled or built to use exclusively Mesabi ores.

The extent of this influence may be gathered from the following data furnished by O. B. Warren, whose reputation as an authority on all questions relating to the iron ore resources of Minnesota entitles him to full credit. During the three-year period ending with 1917 the United States produced an annual average of 35,000,000 tons of pig iron, which required 70,000,000 tons of iron ore, and was one-half of all the pig iron produced in that period in the world. The increase in production of pig iron in the United States has been far greater than in other countries. This result can be traced largely to the influence of the Mesabi Range.

Mesabi Range Production

The first ore from the Mesabi Range (4,245 tons) was shipped in 1892. The annual average for the three years ending 1907 was 24,000,000 tons and for the three-year period ending 1917, 38,000,000 tons, out of a total of 70,000,000 tons, the yearly average consumed during the same period in the United States from all sources. The United States will annually need from all sources on the average for the three years ending 1927, 101,000,000 tons; for the three-year period ending 1937, 124,000,000 tons and for the three-year period ending 1947, 129,000,000 tons. To produce her proportion of this ore the Mesabi must annually yield on the average for the three-year period ending 1927, 60,000,000 tons; for the three-year period ending 1937, 74,000,000 tons. Then, gentlemen, witness the astonishing result: The Mesabi will have passed the peak of her load and during the last three-year period ending 1947 she will be able to produce only annually 55,000,000 tons. In other words, making allowance for all known ore reserves on the Mesabi and adding thereto 500,000,000 tons for new discoveries, the maximum burden on the Mesabi Range will be reached in less than twenty years. When that day comes, indeed in anticipation of it, the supremacy of Minnesota as an iron-

producing state will have passed unless something is done to change the situation, because furnace men in anticipation will seek supplies in the old ranges in Wisconsin and Michigan and in Sweden, Spain, Chile, Cuba, Brazil or elsewhere, and docks, plants and equipment will be permitted to wear out without new replacements.

And now a word about the ad valorem system of taxing iron properties in vogue in this state. Under the Minnesota law all real estate is valued at its true value, and then for the purpose of taxation is placed upon the tax books at 50 per cent of such value in the case of iron ore, 40 per cent in the case of city property, and 33⅓ per cent in the case of farm property. Doubt has been expressed about the method employed in the various taxing districts of the state for ascertaining the true value of property other than iron ore, but there can be no doubt as to the method employed to determine the value of iron ore. As to this class of property the data of all explorations, the results of test pitting and drilling, with accurate and complete blue prints, must be filed with the Minnesota Tax Commission, which submits the same to the School of Mines for a scientific determination of the tonnage and grade of the ore. The property is then assigned by the Tax Commission to a certain class, based upon the immediate or deferred availability of the ore deposit, and its value for taxation purposes ascertained by multiplying the tonnage by the rate per ton fixed for the class in which the property is placed. As a result of this system iron ore pays enormous taxes, in some cases as high as 60c. per ton on the average annual output of the mine. And yet there are those who clamor for an added or super-tax in the nature of a tonnage tax on the ore as it comes to the mouth of the mine.

I consider the present method of mineral taxation in Minnesota one of the greatest drawbacks to the maintenance of the supremacy of Minnesota as an iron producer beyond the year 1940, for the following reasons: There are many strong magnetic attractions running parallel with and lying north of the Cuyuna and Mesabi ranges and extending to the Dakotas and the Canadian border. These and unexplored available land near the known ranges should be explored, and would be were it not for the fact that the finding of an orebody is penalized by the imposition of taxes too burdensome for individuals to carry. After diligent inquiry I cannot learn of a single drill now at work by private exploration enterprise seeking iron ore in Minnesota. Individuals who now own iron-ore properties which they have developed in the past are, unless they have large outside resources, forced either to become operators, in which case the price of their ore is fixed in Cleveland, and they have no chance, without transportation and furnace facilities, to make up a loss in operation, through profits on the pig iron or finished product—or they must dispose of their property to the large Eastern corporations. Thus all individual initiative is throttled. Iron ore in Minnesota will be mined and removed as fast as possible while reserves in other states where taxes are less burdensome will be held for the future. These objections will all be made more evident if a tonnage tax is added to the present burdensome ad valorem taxes.

The Address of J. E. Spurr

The remarks of J. E. Spurr follow, in part:

Some men are born eloquent, like Mr. Bradley Stoughton; some, like Mr. Hoover, achieve eloquence; and some have eloquence thrust upon them. I do not belong to any of these groups, but of all I come nearest to the third. While we were plowing the placid waters of Lake Erie Stoughton came to me with a telegram indicating that our honored past president, Horace Winchell, had some time before set sail for Alaska, and had designated me his literary, scientific, and post-prandial executor, appointing me his proxy to represent him in and for Minneapolis. I said to Stoughton, "Why did Winchell think I should represent Minneapolis?" "Oh," he said, "It's a very good choice; you could pass for a Swede anywhere." I protested that I had not brought my dress suit. I have had a number of cards printed, addressed to myself, which I shall distribute after the exercises, and if you will put your name and address on one and send it to me I will mail you a picture of my dress suit. You can thereby assure yourself that I have a perfectly good dress suit, of the vintage of 1902, with additions of the Roosevelt period.

Anyhow I have had some very pleasant experiences since then, that have partly compensated for the mental anguish I have suffered between then and the present moment. You know it is a very pleasant thing to be distinguished and popular. I attended the picnic at Eagle Harbor the other day, for example, and I noticed a lady regarding me with the greatest of interest. Finally she spoke to me. "Would you mind," she said, "stepping a little to one side? I want my little girl to see Mr. Hoover."

Now, as a personified proxy, how shall I represent my principal, Mr. Winchell? I am convinced that he did not designate me because of any personal resemblance; but possibly because I long ago spent a year in Minnesota, saw and experienced intensively some of the rough and early days on the Mesabi Range, and was domiciled for a while in Minneapolis. He knew that I knew that Minneapolis is not a suburb of St. Paul. He remembered that at one time we both qualified among the champion bean eaters of the North Country. You know that is one of the hardships of New York, for anyone who was born near Boston and educated in Alaska, with a prep-school course in Minnesota: there isn't a decent beanery in the whole town. They have an Engineers' Club in New York, but I blush to say that you can't get bacon and beans there. Not much like the old Palace Hotel in Tonopah, where they tried to put on style. They had a restaurant, bar-room and roulette game downstairs and six bedrooms upstairs. They had one waiter, who was a graduate of Oxford, and very punctilious. A stranger sat near me one day, and this waiter was altogether correct. "Yes sir. Dinner will be ready in a moment, sir." And then, "Dinner is served sir. Will you take beans, sir?" "No, I don't care for beans." "In that case, sir, dinner is over, sir."

I confess that it gives me a peculiar satisfaction to be able to attend a function of this distinguished asso-

ciation of mining engineers in Minneapolis, and still more to visit once again the great Mesabi iron-bearing range.

I shall not soon forget the Mesabi. And very particularly do I remember Hibbing. Three of us had made a reconnaissance as far south as Cloquet, and when we left the range the furthest place westward which had been cut out of the forest, so far as we knew, was Mountain Iron. Striking north from Cloquet late in the fall, with packsacks, we followed an Indian trail northward. About the time our grub gave out the trail ended in a little lake; and this lake was not frozen thick enough so that we could travel over it, so we started around it northward through fallen timber. It became very cold that night and we huddled around a fire most of the night to keep from freezing. Next day we unexpectedly came to a line which had been newly cut for a railroad, and following along it we discovered the town of Hibbing, which we had never heard of before.

It was a wide-open town, half the population had typhoid and the other forty danced all night in the hotel. The saw and the hammer were going on very busily here; there was already a hotel. The hotel had two rooms: a combination bar and dance-hall downstairs and a bedroom upstairs. One of our party lit out for the East and the other two of us took a bed in the bedroom and tried to sleep. There were a score of beds in the room and no doors and no lights; and as soon as we went to sleep the revelry started in the room below. There would be a dance, a round of drinks, a fight, another dance and so on indefinitely. Whenever a man got too drunk to dance he started for bed and climbed into the first bed at the head of the stairs. This happened to be ours—we kicked him out and he went to the next bed and crawled in with his boots on. Pretty soon the next man came up, and crawled into our bed, was kicked out, and came to anchor in the third bed. In the course of time the next one made the rounds of the first, second and third beds, and finally found peace in the fourth bed. It was not a quiet proceeding either, and when the dawn came the game was still going on and we had not closed an eye.

We got up and traveled down the board sidewalk that was laid on top of the stumps, and we came to a house that a man was putting up for himself. He had one room finished off, and in the corner there was a pile of the nicest, loveliest shavings you ever saw. We asked him how much he would charge to let us spread our blankets on these shavings, and he said, "Go ahead." The weather was zero, but I never saw a hotel that looked more luxurious to me. Looking at it now, however, I can say to you gentlemen from Hibbing, if there are any here tonight, that I don't like your hotel accommodations.

Mr. Hoover's Address

HERBERT HOOVER'S address at the banquet of the American Institute of Mining and Metallurgical Engineers, at the Curtis Hotel, Minneapolis, on the evening of Aug. 26, was in full as follows:

The time has arrived in our national development when we must have a definite national program in the development of our great engineering problems. Our rail and water transport, our water supplies for irrigation, our reclamation, the provision of future fuel resources, the development and distribution of electrical power, all cry out for some broad-visioned national guidance. We must create a national engineering sense of provision for the nation as a whole. If we are to develop this national sense of engineering and its relations to our great human problems it must receive the advocacy of such institutions at this.

We, together with our sister engineering societies, represent the engineers of the United States. It is our duty as citizens to give voice to those critical matters of national policy which our daily contact with this, the fundamentally constructive profession, illuminates to us. Just as our medical associations voice the necessity of safeguards to national health; as the bar associations safeguard our judiciary, so the engineers should exert themselves in our national engineering policies. We have none, but we need some, or the next generation will face a lower instead of a higher standard of living than ours.

Must Co-ordinate Development

The development of our transportation, fuel, power and water under private initiative has been one of the stimuli that have created the greatness of our people. It has been easy to compass when the problems were more local and filled with speculative profits. There, however, arises a time when this haphazard development must be co-ordinated in order to secure its best results to the nation as a whole. This system has given us a 50 per cent result; if we are to have 100 per cent we must have a national conception and national guidance. This last 50 per cent involves problems beyond individual initiative alone.

Not only is individual initiative insufficient because the problems involve political, financial, interstate matters beyond corporate ability, but we have, with practically unanimous consent of the country, adopted a policy of the limitation of profits in the operation of public transportation and power and some other utilities, and through the pressure of public opinion we are rapidly coming to a limitation of profit in the development of other large sections of national resources which tend to become natural monopolies. While the limitations of these profits makes for public good, on the other hand they also militate against individualistic development of national resources and necessitate the co-operation of the community as a whole to secure initiative for wider development in the national sense.

Conservation Is National Concern

Certain of our national resources have always been in national ownership, such as waterways. Certain others, such as reclamation, irrigation, distribution of water for power, are rapidly coming under Government control. In others, such as timber, coal, and oil, the possible exhaustion brings their conservation or provision for the nation's future into national concern. In our railway

problem national action has until recently been directed wholly to limitation of profits. Latterly it has undertaken to regulate wages and give some small recognition to the necessity of equipment. But microscopic attention has been given to the greater problem of how to get more transportation, to get it so organized as to secure real economic operation in its broad sense.

We have a long list of such problems. Some of these have been discussed before the Institute on previous occasions. I may refer to our discussion of eastern bituminous coal. During the past year the Institute undertook to look into the economic situation of this industry as a national whole. It was demonstrated to be the worst functioning industry in the country. Owing to seasonal and other irregularities of demand, the average term of employment in the bituminous industry is less than 190 days per annum. If this industry could be operated a normal work year 125,000 men could be turned to other production. It is an industry in which 30 per cent more capital is invested than would otherwise be necessary. The cost of coal to the consumer and the risks to the operator are greatly increased, and, above all, it presents a great human problem fraught with all the terrible misery and strikes and justified discontent that flow from intermittent employment.

Solution Beyond Individuals

I am not proposing nationalization of the coal mines; far from it. What is required is that we should realize that with our necessary social view of prohibition of combination there remains a national problem beyond the solution of any individual coal operator or any group of operators. It must have national guidance and national plan for its solution, a co-operation of great consumers, railways, operators and miners—but what individual operator can do this?

In respect to our coal supplies again, if we would look forward to the next generation, we have a problem of conservation of immense importance. In this connection, it has been ably proposed by our members that the national government should co-operate in investigating the possibilities of the establishment of a great electrical trunk line throughout the great power consuming districts of the northeast, and that we should feed into this great power road power generated at the mines and available water sources, drawing from it at every town and city. The consummation of this project means cheaper power to all consumers. It means a great economy in consumption of coal. It means more regularity in output. It thus means greater ability to compete in world manufacture. It means great relief to the railways from expansion. It means an increased standard of living and a decreased cost of living to a very large section of our population. We have again much such a problem in providing adequate power resources upon the Pacific Coast, where today hundreds of thousands of acres of fertile land are practically non-producing for lack of pumping power.

Mountain Water Storage Problems

Of other problems akin to this, we are confronted throughout the west with the fact that a large portion of our average low water supply is already under engagement for irrigation and power. The time has come when that expansion of the land available for cultivation, or into more intensive cultivation, is a factor of mountain storage of water to increase our stream flows in the low season. We have thus a storage problem on a scale we have not hitherto dreamed of, and, again, it is a problem involving co-operation in financial, economic, distribution, navigation—interstate questions, in which individual initiative must have the assistance of the community.

Another series of such problems lies in our oil supplies. If we are to have a mercantile marine and to maintain our navy on a basis of equivalent efficiency with foreign navies, if we are to maintain the development of the gas engine—the greatest lift in our standard of living and saving of labor in fifty years—we are confronted with the necessity of securing additional oil supplies from outside our own boundaries. Our own supplies, so far as now known, do not represent twenty-five years at our present rate of consumption. The Institute many months ago was the first to give warning to the Federal Government of the gradual absorption of all of the oil sources of the world by other great powers, and that within a short time we should be dependent upon the good will of those powers for our necessary oil supplies. No private individual can compete with foreign governments in the measures that they are adopting to hog the resources of the world. This problem again is an engineering problem that requires more than private initiative.

Transportation Tax Heavy

A problem of even more pressing importance than these is the whole question of transportation. Our inability to move the commodities which we create is stifling production. It is increasing the cost of distribution and has placed a tax on the American people in decreased production and increased cost of distribution greater than all the taxes imposed by the war.

We have today in Minneapolis ample proof of the frightful cost imposed on the farmer, consumer and public. There is a premium over freight cost from 10 to 20c. a bushel for wheat at the mill door compared to wheat in the elevator a few hundred miles away, solely because cars are not available. Either the farmer is losing the amount or the consumer is paying it. Furthermore, to carry the picture further, the railways, in endeavoring to remedy this, are diverting cars from the lumber industry. Already certain mills are partially closed; men are thrown out of employment in the mills and in the building trades. Is this not a price in human misery and national efficiency that warrants some national concern? It is a problem that does not lie alone in expansion of railway facilities. It lies also in the proper expansion of waterways and their co-ordination with the railway transportation of the country.

Congressional Waste

We have been dabbling in the improvement of water transportation of the United States for 100 years, and so far as I know never yet have we considered it as a problem requiring complete co-ordination of the entire transport problem for the whole country. We have spent enough money improving useless creeks to have made several competent waterways. Every Congressional district in the United States has looked for appropriations for carrying mud from one hole to another as their proper participation in the national plunder. They have never considered that the taxes taken from the people as a whole should be devoted to those points that will benefit the people as a whole.

One result of the policy pursued has been that our waterways have been so badly handled that they have not been able even to compete with the railways, and today, with an enormous increase in railway rates, we find ourselves utterly unable to handle the great bulk commodities of the country at the possible lower charge over our waterways. The opening of the St. Lawrence to ocean-going vessels means 5c. a bushel to every farmer in ten states. Likewise, of no less importance to the people of the entire country are our internal waterways.

These projects have a simple result in the engineer's mind: they make greater production possible with less human effort; they increase the standard of life; they provide for our children. All these problems are much akin, and the time has come when they need some illumination, guidance, and co-operation in their solution from the Federal Government. Nor do I mean a vast extension of Federal bureaucracy in Federal ownership. If, in the first instance, through an agency of the central government, we could have an adequate study and preparation of plan and method made of these problems of engineering development over the next fifty years, viewed solely in their national aspects, we would have taken the first step toward the adequate provision of an increasing standard of living and a lower cost of living for our descendants.

The second step is to determine that our government will be a government of co-operation, limiting profits surely, but holding to individual initiative as the single hope of human development. In order that we shall have some central point in the Federal government where these problems may be adequately considered, from which they can be ventilated for the verdict of public opinion, where the business brains of the country can be called into conference and co-operation with the government, and therefore with the people, the engineers of the United States have proposed time and again that a Cabinet department should be established in Washington, either new or to replace the Interior Department, to which should be assigned the whole question of public works.

You are familiar enough with the advantages of such a department from an everyday administration point of view, and enormous saving to the government from the duplication or competition of the six or seven departments now engaged in engineering construction work of this character, but on this occasion I wish to call your attention to the fact that such a department has become an essential from the point of view of proper consideration and presentation to the American people of these broader national engineering problems, upon which the next generation must depend if our country is to march forward.

Duluth and the Mesabi Range

THE special train arrived at the Leonidas mine at 8 and the visitors were met by members of the Engineers' Club of Northern Minnesota, under whose auspices the entire trip of the Mesabi Range was made. A. Tancig, president of the club, was in general charge of the arrangements, and the various committees were headed by members. The carrying out of all the details was characteristic of the way Minnesota people have of doing things, and the entertainment arranged was complete in every particular.

The Leonidas Concentrator

At Leonidas the party was joined by a number of the officials of the Oliver Iron Mining Co., who made the trip from Duluth by special train. Among these were J. H. Hearding, George D. Swift, and also E. E. Hunner, of the M. A. Hanna Co. As soon as the crowd was assembled parties were made up and the visitors were taken through the Leonidas concentrator. This plant has a capacity of 2,500 tons per ten-hour shift and has a total rated motor capacity of 992 h.p. The water is supplied from Manganika Lake, one mile from the plant, through 12-in. spiral riveted pipe by two 8-in. two-stage centrifugal pumps. The pumps have a capacity of 1,600 gal. per minute each, and are driven by 150-hp. motors. The washing is accomplished by means of a 35-ft., Hutch type, Allis-Chalmers log washer operated by a 50-hp. motor. From the washing plant the visitors were taken by automobiles to Virginia, where an inspection of the Virginia & Rainy Lake Lumber Co.'s mill was made. This mill boasts of being the largest white-pine mill in the world, and has a capacity of one million feet per day.

Before returning to the special train, which was temporarily parked near the headquarters of the Oliver Iron Mining Co. at Virginia, several of the members of the party visited the neighboring mines. At the Missabe Mountain mine, one of the 350-ton steam shovels was seen in operation. Dump cars which are operated by compressed air and have a capacity of 20 cu.yd. are used here on stripping operations. At the Alpena mine the visitors had an opportunity to see an open pit in its last stages, for here all of the steam-shovel work has been completed and the little ore remaining is being removed through the shaft.

Some of the members motored east to Babbitt, where the Mesabi Iron Co. is erecting a mill for concentrating and treating low-grade iron ores on the Eastern Mesabi Range. The initial unit of the plant under construction will have a capacity of 3,000 tons of ore per day, and it is estimated that about three million dollars will be spent in the erection of the plant and the establishment of the town site. The work is in charge of W. G. Swart, and the construction is being done by the Minneapolis Steel & Machinery Co.

The greater number of the visitors were taken to the western portion of the Mesabi Range. The first stop was made at the Wabigon mine, where a 300-ton electrically-operated shovel was in operation. At the Sherango mine the visitors were treated to a little excitement in the form of blasting. A number of blasts were shot off, which demonstrated the methods generally used in open-pit practice. It was impossible to include in the itinerary a trip to the Buffalo pit, as originally planned, owing to some of the delays which had been incurred en route.

Upon reaching the Oliver headquarters at Hibbing the visitors boarded flat cars and were taken through the Hull-Rust, Mahoning, and Sellers mines. During this trip the engineers had ample opportunity to view the up-to-date methods which are used in open-pit practice. All-steel air-dump stripping cars of 20- and 30-cu.yd. capacity are used; and 91-ton steam shovels, having 4½ to 5-cu.yd. dippers, which have a capacity of 9,000 tons per ten hours, as well as 350-ton shovels, having 8 cu.yd. dippers, which can move 10,400 tons per ten hours, were seen in operation. The tracks are laid in 30-ft. sections by a wrecker, the ballasting is done by means of a clam-shell, and the ties are tamped into place by gasoline-driven air tampers. On the stripping dumps the tracks are shifted by means of wreckers and track-lifters, and the dumps are leveled by spreaders.

Returning from the pit, members of the party were driven to Bennett Park, where an elaborate lunch had been prepared, and this was followed by a band concert. Afterward, the ladies of the party were taken to the Public Library and there inspected the building which embodies features seldom seen in mining communities. In addition to an excellent library there is a complete stage equipment; a model flat, completely furnished, is on exhibition, and other features which encourage a community spirit are in evidence.

The Technical Session

The technical session, which was held at the Lincoln High School, was presided over by W. G. Swart. The first paper, "Utilization of Titaniferous Iron Ores," by J. A. Heskett, was presented by title only, and no discussion followed. "Casting and Molding Steel Ingots" was read by the author, Emil Gathmann. There was a little discussion following this, but it was largely on the use of castings. Secretary Stoughton stated that the presentation of the papers of the evening was perhaps out of order, considering the fact that there was little of interest to the iron-ore miner, but there had been, he said, no papers offered from that section for this year. He expressed his appreciation of the excellent arrangements which had been made by the Engineers' Club of Northern Minnesota for the reception of the A. I. M. E. Following the presentation of the paper, "The Acid Bessemer Process," by Richard S. McCaffery, there was some discussion by Mr. Stoughton and Prof. Joseph W. Richards. The last paper, "A New Occurrence of Proeutectoid Ferrite," was commented on briefly by the author, Charles Y. Clayton, and was discussed at some length by E. E. Thum, of *Chemical and Metallurgical Engineering*. Following this session an athletic program was held at the armory.

During the small hours the special was moved from Hibbing to Coleraine, and immediately after breakfast the visitors were taken on flat cars to the Canisteo pit, where part of the ore now being treated at the Trout Lake concentrator is being mined. They were then taken to the concentrator. The Trout Lake concentrator has a capacity of about 20,000 tons per day, with all units operating. The machinery is arranged in five units, each complete and capable of independent operation. Each unit consists of the following:

One crude ore bin and one bar grizzly.

One 20-ft. conical revolving trommel with 2-in. openings.

One picking-belt, to receive and convey the trommel oversize to the concentrate bin. (The taconite chunks are picked off the belt by hand and dropped into a rock bin.)

Two 25-ft. log washers, one on either side of the trommel to treat the trommel "throughs," discharging a product into the concentrate bin.

Two chip-screens, one for either "log," receiving "log" overflow.

Two settling tanks receiving chip-screen "throughs."

Two 18-ft. "turbos" (small log washers to treat fines), receiving the tank settlings, discharging a concentrate directly into the concentrate bin.

Four settling tanks receiving the overflow from turbo and first settling tanks.

Twenty Overstrom tables, arranged in two rows of ten each, to treat the settlings from the four settling tanks just mentioned.

Eight Frenier spiral sand pumps (four primary and four relay), to pump the table concentrates to dewatering tanks from which they discharge directly into the concentrate bin.

At 10 a.m. the party took the special train which had been switched to the tracks at the lower end of the concentrator, and at 1 o'clock Duluth was reached. Immediately upon the arrival of the train representatives of the Engineers' Club of Duluth assigned various parties to several optional trips, all of which were well attended.

At 5 all the parties were on the steamer "Rotarian" for an excursion through the beauties of Duluth Harbor, with its various industrial monuments. This trip took till nearly 9 o'clock, and was the occasion for a general final fraternizing in the spirit which marked the whole meet. A choice of box luncheons was served, a "Mining Lunch" and a "Metallurgical Lunch." The former was the more substantial, though the latter was more delicate and with a couple of extra frills. The State Geologist of Wisconsin, who disappeared with eight "Metallurgical Lunches," established the further formula that eight metallurgical lunches equal one geologist's lunch.

On landing the party split, some to return to Chicago at 9 p.m. by special train, on which the same perfection of arrangements was observed, and part to return to Buffalo by the Lake steamers.

The smoothness of the arrangements and the conduct of the whole trip of the Institute in the Lake Superior country was evidently largely due to the energy of the able Secretary of the Institute, Bradley Stoughton, and his well-chosen aide, J. T. Breunich.

The "Hand Book of Mining"

A write-up of the A. I. M. E. trip would be incomplete unless some mention were made of the various programs which were prepared by the local committees at each point. These were, in every case, most elaborate and represented painstaking preparation on the part of those who had the work in charge. Of intense interest was the "Handbook of Mining," which was prepared jointly by Alexander N. Winchell, the Engineers' Club of Northern Minnesota and the Duluth Engineers' Club. The book consists of 260 pages, is well illustrated with photographs and maps, and contains a wealth of data concerning the districts visited. These were distributed at Buffalo as the party were starting on the Lake trip. Covering every phase of mining, milling, and metallurgy in the Lake Superior district, in addition to other facts, the book proved to be a veritable Bedaeker and was in constant use as a reference.

Mining Methods and Costs at the United Verde Mine

By H. DeWitt Smith, E. M., Jerome, Ariz., and W. H. Sirdevan*

THE mine operated by the United Verde Copper Co. is situated near Jerome, Ariz., at an elevation of approximately 5,500 ft. above sea level. From the time of its location, in 1876, until its purchase by Senator W. A. Clark, of Montana, in 1889, the United Verde mine was worked on a small scale, and shipments of high-grade gold-silver ore were made from the surface workings. The approximate total amount of ore mined up to the end of 1918 is 8,200,000 tons. The production of the five years, from 1914 to 1918 inclusive, represents 40 per cent of the total mine ore production.

For the convenience of smelter operation, the ores mined are divided into four classes, each of which must be handled separately in all mining operations. In addition to these ores, a small amount of precipitate is recovered from the copper-bearing mine waters and shipped directly to the smelter. All present exploration and development work, stoping methods, tramming, hoisting, and ventilation systems, are planned with the definite purpose of providing and maintaining an underground production of 3,000 tons of ore per day, with the possibility of a further increase to 4,500 tons per day, if mine and market conditions should warrant this additional output.

To maintain an underground production of 3,000 tons of ore per day, it is necessary to develop 100 ft. in depth every year, and to drive 25,000 ft. of drifts and raises for exploration and development work. During the last few years, an average of thirty-four tons of ore has been developed per foot of development work. This high figure has been due to the character of the ore-bodies, which are large, persistent, and concentrated within a relatively small area. This advantage is partly offset by a high average cost for all exploration and development.

Working Three Shifts, But a Fourth Now Being Concreted

At present there are three working shafts at the United Verde mine. These are called No. 3, No. 4, and No. 5. A fourth shaft, No. 6, is being concreted and should be in operation by December, 1920.

The most economical interval between levels has been found to be 150 ft. A closer spacing increases proportionately the cost of level development per ton of ore mined. In mining under a filled stope, it is necessary to extract three or four floors directly beneath the level by the use of square sets, a more expensive mining method than the horizontal cut-and-fill method generally used for the remainder of the stope. With a level interval of 100 ft., approximately 20 per cent of the total ore must be mined by the square-set method, whereas the corresponding ratio is only 15 per cent when the level interval is 150 ft.

A 200-ft. level interval (1,000 ft. to 1,200 ft.) was found unsatisfactory. The increased cost for raise development, the high cost for maintenance of the ore chutes in the stopes, and the necessity of providing a sublevel for development halfway between the two levels, more than offset any advantage gained by using the longer lift.

On account of the difficult drilling ground at this mine, it has proved economical to place all drilling operations under the supervision of one engineer. His duties may be enumerated briefly as follows: (1) To keep a detailed record of all drills underground and to see that they are kept in the best working condition; (2) to test new types of drills as they are received from the manufacturers; (3) to record and analyze the work accomplished by the drill bits; (4) to see that the type of round best adapted to the class of ground being drilled is used in all development work; and (5) to carry on experimental work relative to air pressures, hose, hose connections, valve designs, and other operating factors.

Formerly the bottom cut was used exclusively, whereas in the present practice the pyramid cut is standard for all drift rounds from a clean set-up. The bottom cut is still used whenever it is necessary to set up a crossbar before the drift has been cleaned out, as it requires the drilling of only two or three holes from the lower set-up.

Diamond Drilling

Diamond drilling at the United Verde mine serves two purposes: long holes are drilled to determine the different geological formations, and massive sulphide areas are developed and blocked out by numerous short holes. It has been found that the diamond-drill cores from schist areas cannot be relied on for accurate data on the mineralization. Consequently, the drill is used to locate and determine the size of schist areas, and the actual development is performed by drifts and crosscuts. The assays of cores from the massive sulphide areas have been found to check closely with subsequent drift development work. For this reason, and because of the high cost of drifting in such areas, exploration of the massive sulphide areas and the delimitation of the boundaries of large sulphide orebodies are usually done by diamond drilling.

Stoping

The stoping methods and their relative importance are given in the accompanying table. The relative importance of these methods is rapidly changing at this time (December, 1919).

STOPING TONNAGE AT UNITED VERDE MINE, 1918

Method of stoping	Dry Tonnage Mined	Per Cent of Total
Horizontal cut-and-fill	468,000	58.5
Incline cut-and-fill	11,200	1.4
Square-set and fill	68,000	8.5
Shrinkage and fill	117,000	14.6
Glory hole	136,000	17.0
Totals	800,200	100.0

Glory-hole mining will be abandoned in favor of open-cut steam-shovel mining early in 1920. No ground has been developed recently on the lower levels that will permit the use of shrinkage methods. Consequently, in future work, horizontal cut-and-fill and square-set will be the chief methods employed in under-

*Abstract of a paper presented at the Lake Superior meeting of the A. I. M. E., Aug. 23-28, 1920.

ground mining, with subordinate use of the incline cut-and-fill method where applicable. A system of shrinkage stoping with pillar caving will be used for a converter orebody in quartz porphyry.

Shrinkage stopes are used only in hard ground in massive sulphide areas. The shrinkage method shows a lower cost for timbering and waste filling than any other method used, and, in addition, permits the accumulation of a large reserve of broken ore.

The incline cut-and-fill method has been used on a few narrow orebodies, where one wall was too weak for the application of the shrinkage method and where there were no diorite dikes cutting through the orebody.

STEAM-SHOVEL MINING

Most of the orebodies above the 500-ft. level are at present bulkheaded and inaccessible on account of mine fires. As the ground in this area was generally badly fractured, square-set methods were necessarily used. By the use of the plenum system of forcing air under pressure into the fire stopes, it was found possible to mine this ore, but only at an extremely high cost. The present plan, now under way, is to strip a total of 14,000,000 cu.yd. overburden and complete the mining of all the orebodies of the mine to the 500-ft. level by open-pit steam-shovel methods. It is estimated that approximately 5,000,000 tons of direct-smelting ore will be recovered to this depth. This is equivalent to one ton of ore recovered for each 2.8 cu.yd. of overburden removed.

Modern Commercial Explosives And Their Uses

BY A. J. STRANE, E. M.*
Tamaqua, Pa.

EXPLOSIVES may be classified as those that burn and those that detonate. Explosives of the first class include black, blasting, and smokeless powder, and are broadly known as low explosives, or propellants, because they merely burn and do that comparatively slowly. Their action is as if some power behind the projectile or other material were exerting a shoving or pushing action. The high, or detonating explosives produce a smashing or shattering effect upon the material.

In using military explosives of the propellant class, the breach of the gun, or cannon, is proportioned to hold the pressure, so that the projectile will be blown out. Exactly the reverse is true in commercial work; then it is the "breach" or the hole that is to be broken. Therefore, the projectile and the explosive that will rupture the largest "breach" possible are chosen. With the high explosives, it is easy to break out the breach, but with some of the low explosives it is necessary to plug up the muzzle very carefully before shooting.

Doubtless the use of incendiary mixtures of oxidizing and combustible materials led, in the thirteenth century, to the perfection of the mixture which is practically the same as our commercial black blasting powder of today. About 600 years later, nitroglycerine was discovered, but for years its great potential energy could not be used, because, in its liquid state, it could not be safely handled or transported. The accidental discovery that kieselguhr would absorb, and hold fairly well, three times its own weight of nitroglycerine, however, made it available.

"Guhr dynamite," as the combination nitroglycerine and kieselguhr was termed, was soon displaced by dynamites having an active base, such as wood pulp and other carbonaceous combustible materials. These do all that kieselguhr will do, and, in addition, increase the chemical reaction and add materially to the effectiveness of the blast.

An accident is said to have led to the discovery that guncotton will cause the solidifying or gelatinization of nitroglycerine under certain conditions. This discovery gave us "blasting gelatine," which is taken as the standard for *100 per cent explosive*, as its composition is practically 92 parts nitroglycerine and 8 parts guncotton, with a small amount of antacid.

The commercial explosives of today are: Nitroglycerine; blasting gelatine; straight nitroglycerine dynamites of various strengths; straight nitroglycerine gelatines of various strengths; extra or ammonia dynamites and gelatines of various strengths; low-freezing explosives of the above grades; permissible explosives, or coal-mine powders, of various strengths and physical properties; miscellaneous explosives, having special advantages for special work; non-freezing or non-nitroglycerine explosives; and black blasting powder of various sizes.

*Abstract of a paper presented at Lake Superior meeting of the A. I. M. E., Aug. 23-28, 1920.

Hoisting Equipment at Utah Apex Mining Co.

BY J. A. NORDEN AND A. R. WILLSON*
Bingham Canyon, Utah

THE hoisting equipment of the Utah Apex Mining Co. is capable of handling about 1,200 tons per day. It has not been worked to capacity, but 600 to 700 tons, together with men and materials, have been handled in two shifts without great effort.

A Nordberg engine of the double-drum, geared type, designed for a 10-ton load, including rope, at a speed of 1,500 ft. per min., is used. The drums are 7 ft. in diameter, with a 54-in. face, and have a capacity of 3,000 ft. of 1¼-in. rope. The hoist is operated by a 500-hp. 16-pole, round rotor, 450-r.p.m. motor, which drives through a single reduction of 129 to 19. Speed is regulated by the variable resistance of a rheostat of the liquid, weir-control type. A sodium-carbonate solution is used as a conductor.

The current supply is three-phase, 60-cycle, 44,000-volts, which is stepped down to 2,300 volts by a set of three 250-kva., outdoor-type transformers. From the transformers, the 2,300-v. lines are carried to a bus and switchboard in the hoist room. The average load for starting a loaded skip is about 300 amp. for a few seconds; afterward, the full-speed running current is 75 to 125 amp. The hoist is controlled by three levers on the operating platform.

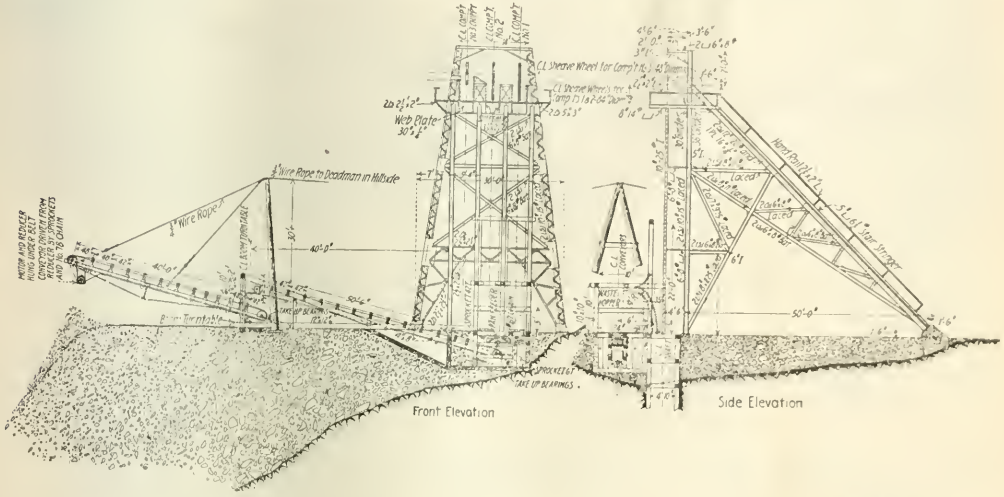
At the present time mining operations are in progress on the 100-, 1,150-, 1,300-, 1,500-, and 1,800-ft. levels. Three classes of material are produced on most of the levels: First-class or direct-smelting ore, second-class or milling ore, and waste. Hence, it was necessary to provide for handling at least two kinds of material simultaneously at the shaft. The 100-ft. level, being as adit, has its own waste dump, but some waste is hoisted to the surface from all of the other levels.

The ore pocket cut on the lower levels is divided into

*Abstract of a paper presented at Lake Superior meeting of the A. I. M. E., Aug. 23-28, 1920.

two parts by a reinforced-concrete wall. The ground is hard, requiring no timber, and a small pillar was left between the main storage pocket and the shaft. Below the storage pockets are measuring pockets which hold one skip load. The top of the storage pocket is covered by an 8-in. grizzly made of 30-lb. rail. On the 100-ft. level, owing to soft ground, it was necessary to build the entire pocket in direct connection with the shaft.

directly over the skip box, leaving only enough room for the latter to work freely. This arrangement would interfere with loading; therefore the floor was made in four sections, hinged so that it can be folded back when rock is being hoisted. The floor is of 4-in. plate and is supported by 4 x 4-in. angles, which are bolted to the bail and braces. When men are being hoisted or lowered, doors are used.



STEEL HEADFRAME, SKIP DUMP, HOPPER AND CONVEYORS FOR WASTE DISPOSAL AT PARVENU SHAFT

All ore is dumped at what is known as the 900-ft. level dumps. From here it goes through chutes to the large receiving pockets of the 100-ft. level. Reinforced concrete was used, as the ground would not stand without support.

A belt conveyor transports the waste from the hopper at the skip dump to the edge of the waste pile. Because of the steep slope of the hillside at the shaft collar, the waste dump is inclined to creep, especially during the spring thaw. Therefore, a continuous stationary conveyor would be impracticable, and two conveyors were used. The first, which takes its feed from a pan feeder under the skip-dump hopper, is of the stationary type and was extended as far from the shaft as was deemed safe, about 40 ft. The main members of the framework for this conveyor are anchored to the concrete walls of the pit, making it practically self-supporting. The second conveyor is of the swinging-boom type, and has steel framework, which is suspended from a bipod. The lower end is hinged on especially designed bearings on a turntable under the head pulley of the first conveyor. This construction not only makes the conveyors independent of the sliding dump, but, as the boom may swing in an arc of about 90 deg., the total capacity of the piling system is greatly increased. The conveyors are operated with 5-hp., 440-volt, 3-phase, 60-cycle, induction motors, rated at 1,700 r.p.m.

The headframe contains no particularly new features. It is a sturdy well-built affair, but is not high enough for present purposes. An additional 10 or 15 ft. clearance over the skip when it is in dumping position would be desirable.

The skip and cage are combined. On account of the low headframe, it is necessary to put the cage floor

The capacity of the skip box is about 70 cu.ft., or 4½ tons of ore. The total weight of the skip and cage is about 5,000 lb.

Standardizing at North Butte Mining Co.

BY ROBERT LINTON*

This paper deals with the work that has been carried on for over three years by the management and staff of the North Butte Mining Co. in an effort to standardize mining methods, to eliminate lost motion in the operating organization and to improve the efficiency of the individual workman.

Such items as the selection of machine drills and equipment, the proper type of drill, steel, ventilating equipment, ore handling, drill rounds and timbering were given special attention in order to ascertain the correct method of work and use of equipment. All sorts of experimental efforts were expended in the desire to determine the best method of performing any particular task. The studies developed some features which it is believed are new.

The paper is replete with tables and illustrations showing the basis of the results obtained and the application of the principle of standardization to some special problem. The human factor is given its share of importance, and time studies were made of drilling, timbering and other operations so as to form an intelligent basis for rating a day's work.

Regular instruction in promoting efficiency in underground work is carried on and shift bosses are trained "from the ranks."

*Abstract of a paper presented at the Lake Superior meeting of the A. I. M. E., Aug. 23-28, 1920.

HEADFRAME AT CONCRETE LINED SHAFT OF CHIEF CONSOLIDATED MINING CO.

Concreting the Chief Consolidated Shaft At Eureka, Utah

Work of Lining Carried on Simultaneously With Sinking and Was Done in Stages of 50 to 60 Ft., According to the Nature of the Ground—Average Advance, 61 Ft. Per Month—Precast Dividers Used

By R. D. Gardner
Foreman, Walter Fitch, Jr., Co.
Written for *Engineering and Mining Journal*

THE use of concrete in the construction of mine shafts has become more and more extensive during the last decade. The apparent permanency and safety from fire, together with the low upkeep, have done much to stimulate such shaft construction throughout the mining districts of the world.

At the Chief Consolidated mine in Eureka, Utah, 2,000 ft. of shaft was to be constructed through a soft monzonite porphyry, so the main problem was to use material and construction capable of holding the heavy swelling ground. The shaft has three compartments, 4 ft. 2 in., 4 ft. 2 in., and 6 ft. 1 in., respectively, in width. It was decided to concrete and carry the concreting and sinking along, as far as possible, at the same time.

Villadsen Brothers, engineers and contractors of Salt Lake City, worked out the concrete plans and specifications and did the precasting and mixing. The Walter Fitch, Jr., Co., shaft and tunnel contractors, performed the sinking and concrete construction.

Through the first 50 ft. the shaft sets were replaced by inside forms and a solid wall of concrete was poured. This was necessary because for that distance the porphyry was very loose and so affected by surface conditions that any other construction would hardly have sufficed to hold the ground. For the remaining distance a wall of reinforced concrete 8 in. thick was constructed. This wall was braced every 10 ft. by allowing the concrete to extend to the ground for a thickness of 5 ft. from the sides and ends. It was supported by a solid bearer, or support collar, constructed at intervals of 100 ft. The bearer consists of a heavily reinforced panel of concrete completely surrounding the shaft and running out for 5 ft. into special hitches cut in the country rock on each side of the shaft. It is designed to hold about three times the weight of the concrete resting on it; thus providing for any local disturbance of the country rock itself.

As sinking progressed, 6 by 6-in. wall plates, centers and end pieces, with 4 by 6-in. posts, were hung every 2½ ft. and blocked in the usual manner. These were tightly lagged and served as the outside forms for the concrete. The work was done in stages averaging from 50 to 60 ft., according to the nature of the ground and dependent entirely on the length of time the outside forms would hold the ground without being pushed out of alignment. As soon as stress was detected sinking was discontinued, inside forms were placed, and concreting was begun. Thirty-five feet was the shortest stage and 75 ft. the longest, although about 50 ft. was the usual distance.

Before concreting was begun the cross timbers from which hang the pump and bulkhead were lowered so as to rest upon the third set from the bottom. They were then below the lowest point concreted during that stage. As the weight of the first four or five pourings bears directly upon this point, it was necessary to brace and bulkhead it exceptionally well. The permanent dividers were then lowered to replace the 6 by 6-in. centers. They consist of precast concrete beams 2½ ft. high and 5½ ft. wide, of hollow web construction and designed to withstand a diagonal thrust as well as ordinary lateral pressure. They are heavily reinforced and so constructed as to make a bond with the wall of concrete over their entire height.

Near the collar of the shaft a concrete mixing tower was constructed, at the top of which were four bins large enough to hold sand and gravel for making 40

cu.yd. of concrete. Each bin was lined with steam pipes to prevent the material from freezing. The sand and gravel were hoisted to these bins by means of a bucket elevator. Measuring hoppers were placed directly under the bins, and from these the material was emptied into the mixer. Center-trip buckets, on trucks, transferred the concrete from the mixer to the shaft and were lowered through two compartments by separate hoists, discharging their contents directly into the forms.

I-beams and timber from the force of the blast, also served as a shelf on which a bulkhead of lagging could be placed. In this way any or all of the compartments could be bulkheaded tightly and thus afford excellent protection for the men below. The bulkhead was swung from cross timbers resting on the wall plates of the form sets by means of one-ton chain blocks over each end compartment. Before hanging a set the bulkhead was lowered by means of the chain blocks for the required distance and the timber let down upon it. The

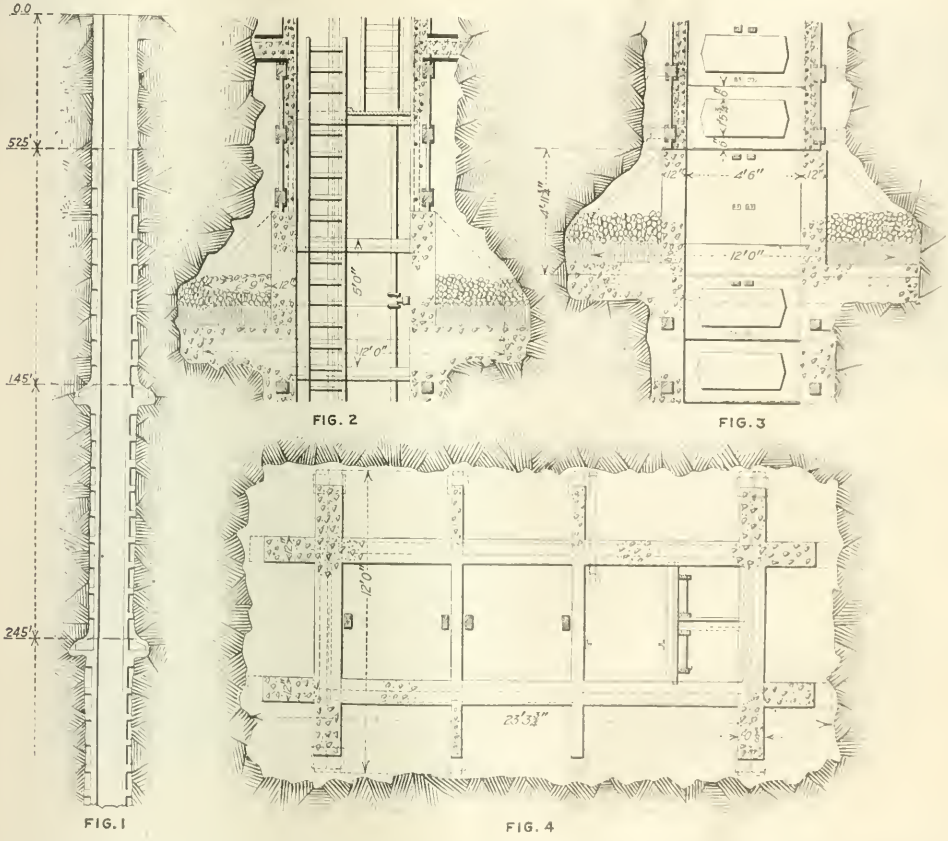


FIG. 1. SKETCH SHOWING FIRST 245 FT. OF LINING OF CHIEF CONSOLIDATED SHAFT. FIG. 2. VERTICAL SECTION THROUGH END OF SUPPORT COLLAR. FIG. 3. VERTICAL SECTION THROUGH MIDDLE COMPARTMENT, SHOWING PRECAST DIVIDERS. FIG. 4. HORIZONTAL SECTION AT SUPPORT COLLAR

A steel bulkhead was used below the bottom set, which allowed the placing of the timber or outside forms without delaying the drilling or mucking. The bulkhead was made of 8-inch standard I-beams and measured 17 ft. 6 in. long by 6 ft. 2 in. wide. The main or side beams were tied together with cross beams, one on each end, and two cross beams or dividers, 4 ft. 7½ in. and 11 ft. 2 in. respectively, formed the south end. The cross beams were placed so as to come directly under the end-form timber and the false, or temporary, dividers of the form sets. Bolted on this frame were sheets of steel ⅜ in. thick and wide enough to cover the I-beams and overlap 10 in. on the inside of the beam. This overlapping, besides protecting the timbermen working on top of the bulkhead then proceeded to install the set.

The work of sinking was made somewhat difficult by a flow of water of from 60 to 150 gal. per min. This water was raised from the bottom to a pump station by means of an air-driven sinker. On the pump station was installed an electrically driven plunger pump, which lifted the water to the station above. These stations were constructed at intervals of 300 ft., the maximum lift of the sinker. The crew consisted of four or five shaftmen and a shift boss, in the bottom; a pumpman, topman, and two hoistmen on each shift.

The best progress was made by drilling one-half of the shaft at a time. In this way mucking continued

up to the time the round was finished. A round of fourteen holes was sufficient to break half of the shaft for a depth of 5 ft., or an average of two rounds a day made a 5-ft. advance. The holes varied in depth from 7-ft. cut holes to 5½-ft. end holes. Forty to fifty pounds of 50 per cent gelatin powder was used to break the round. Ordinary water proof fuse, well crimped into a cap and dipped in P. & B. paint, gave good service, and little trouble was experienced with missed holes. When the shaft passed the 1,100-ft. mark, however, it was considered safer to use delayed action exploders.

LOOKING DOWN CONCRETE LINED SHAFT AT CHIEF CONSOLIDATED MINE

An average advance per month of 61 ft. of finished shaft, including pump stations, was maintained. Actual sinking operations consumed 70 per cent of the total time, and concrete construction 30 per cent.

The Future of the Swedish Iron Industry

Sweden is compelled to import large quantities of iron products, although possessing immense iron deposits, according to *Commerce Reports*, and this is owing to the fact that Sweden has practically no coal mines, and being unable to obtain coal from Germany, prices on this article are so high as to be almost prohibitive. It is well known that many finished articles imported into Sweden are made from Swedish steel.

Another factor is the chemical quality of the ore, which in many instances requires mixing with imported ores to produce desired properties in the steel.

In this connection it is of interest to refer to an article by a well-known Swedish mining engineer regarding the future of the Swedish iron industry:

> The answer to the question why the iron industry seeks the coal industry is simply this: It is cheaper to transport the ore to the coal than vice versa. A simple calculation will tell us that for each ton of finished iron is required about 2 tons of coal and 1.6 tons of ore (for rich ore). These relations are not, however, permanent. About thirty and forty years ago it was 3 and 4 tons, and it is not impossible that in a not very distant future the relations may be 2 tons of ore to 1.5 tons of coal per ton of finished iron.
>
> Then the conditions shall have moved in favor of the countries rich in ore. In the beginning of 1870 Sweden was compelled to turn over its quantitative superiority on the iron market to countries richer in coal. Regarding the quality production of the malleable iron, however, our iron industry retained its place. Our good raw material and inherited trade skill enabled us to back up our position.
>
> That we have succeeded in holding our place so far has its root in the ever-increasing demand for quality products and our endeavoring to meet the new requirements through technical improvements. The burning question for Sweden's iron industry will be whether or not electro-steel will, in greater degree than other cast iron, be able to replace the Swedish quality iron and place a weapon in the hands of our foreign competitors to reduce the importance of the quality inherited from our charcoal pig iron.
>
> Another technical factor is the production of excellent steel by adding metals such as nickel, chrome, and other hardening and toughening elements to foreign raw material, thus becoming independent of Swedish iron.

Italy's Sulphur Production

The war has imposed a serious check on the development of the Italian sulphur industry, according to Attaché Alfred Dennis. Italian production has been cut from 330,000 tons in 1914 to 180,000 tons in 1919. The reasons adduced for this decline are lack of labor and the difficulty of keeping up the mechanical equipment of the mines.

The cost of production has increased tremendously. Before the war, sulphur was mined at from 80 to 85 lire per ton (all sulphur figures are given in short tons). Since the last advance in wages (May, 1920), production costs are estimated at from 420 to 430 lire per ton. Pre-war prices f. o. b. Sicilian ports ranged from 110 to 115 lire per ton; the last price advance (May 1) brought the quotation up to 650 lire.

Whereas in former times Italian sulphur found a wide market throughout the European countries, its sale is now practically limited to the Mediterranean Basin, the consuming countries being identical with the wine-producing regions of southern Europe. Sulphur is an indispensable adjunct to the cultivation of the vine as an antidote for the mildew which attacks the flower of the grape. Sulphate of copper is also employed to spray the vines as a protection against parasites. On account of the scarcity and high prices of fuel in Sicily, a wasteful process for the recovery of sulphur has to be employed.

It is not strictly correct to imply that Italy's sources of sulphur supply are limited to the Island of Sicily. There is a district on the Adriatic near the cities of Rimini and Pesaro where sulphur is mined. One small mine is in operation on the east coast of southern Calabria. The amount of sulphur produced on the mainland, however, amounts to only about 10 per cent of the total for all Italy.

Chinese Antimony

Since 1908 over 50 per cent of the world's total antimony production has come from China. In 1913 the output was estimated to be the equivalent of 10,800 tons of metallic antimony, that of the whole world being about 20,000 tons.

The Wah Chang Mining & Smelting Co. virtually controls the production of antimony ore, regulus, and crude in the Province of Hunan. This company operates smelters in Changsha and owns low-grade mines. It possesses a complete monopoly, granted by the Peking government, for the manufacture of regulus in Hunan, and owns the patent rights in China for the Herrenschmidt furnace, the most successful means of reducing low-grade antimony ores. The mines themselves are mostly native owned, and worked in a small way.*

Through Villa Territory

A Mining Engineer Journeys From Juarez to Santa Barbara, Chihuahua, Before the Bandit's Surrender — No Casualties Reported en Route but Many Inconveniences — Rags, Ruins, and Native Fear of Bandits Chief Features of Trip

Written for *Engineering and Mining Journal**

BEFORE one can cross the border today between Mexico and the United States a passport must be obtained. This necessitates some special photos—*specially* bad, that is, since the State Department is not interested in our good looks, but wants them natural, unretouched, of ourselves alone.

With these in hand, then, we went to the United States Immigration Office at the International Bridge between El Paso and Juarez, where a special border permit was issued and one of our artistic photos mounted on it. A duplicate is kept in the office. With this border permit we proceeded to the Mexican consul in El Paso, who viséd it, charged $2.50, and filed a couple more of our photos. We then took a taxi and crossed the bridge into Juarez and called on U. S. Consul Dow, who also viséd our passport and wrote thereon a special permit for one trip to Santa Barbara.

Next we went to the Mexican Customs, where an official of the latest government affixed a revenue stamp —50 *centavos*. We now had an emergency passport, good for one trip to our destination, but had to have a regular passport if we intended to stay in the country. Hence we proceeded to the clerk of the Federal Court in El Paso and made application, fee $2, which had to be accompanied by birth certificate, and photos, and affidavit of some person knowing the applicant two years or more. This was forwarded to Washington and in due time a permanent or six-months passport may be expected.

We then set out to our destination, which we were to reach, God and Villa willing. Hold on! I overlooked a few yards of tape. After crossing the bridge into Mexico and calling on Consul Dow, one cannot re-enter the United States without passing inspection for vaccination. If he can show a recent scar, or lie strongly enough about the one he has, he may get by. Otherwise, he gets a shot in the arm. I lied ten years about mine, but did not go strongly enough, so the doctor gave me the shot.

SANTA BARBARA, CHIHUAHUA, A TYPICAL MEXICAN 'DOBE TOWN

Of course, there is the regular customs inspection of both governments. The United States inspectors search outgoing passengers for firearms, which are not permitted to be taken across the border. The Mexican customs look for dutiable goods and other things.

We went to Juarez the evening before our train left, so as to get used to the local color, which is here laid on with a bold brush. Juarez is a typical 'dobe town of the northern Mexican states. The buildings along the principal streets present a solid 'dobe front, one-story high, flat topped and broken with doors and windows, the latter, however, not very numerous. Light can be had without building houses to let it in. Some of the better houses have courtyards after the Spanish style,

*Written before Villa's surrender.

and even some of the poorest and most squalid tenements open on a common court. There are a number of more imposing buildings housing government offices, including the Custom House and a school. Then there is the Bull Ring, and a couple of brick- or stone-front business blocks.

The population appears to be made up of very poor Mexicans, Chinamen, American sightseers, American saloon-keepers, gamblers, and all sorts of border riff-raff; a sprinkling of people who, like myself, were going somewhere, and the better Mexican class, officials and business men, who fill in the background.

Two Hundred Ragged Guards per Train

Our train left Juarez at 7 a.m. There were a dozen freight cars, a second-class coach, one first-class coach (in name only), and two steel "gondola" cars, one ahead of the coaches and one behind. In these steel

TRAIN GUARDS IN STEEL "GONDOLA" CAR

cars rode our guard, federal soldiers who guard every train. There were about two hundred men on this train. Every one has read of the barefoot army and the tatterdemalion soldiers of Mexico. I want to say to your imagination, Go as far as you can. Imagine everything grotesque, unkept, undisciplined, underfed, and unfit. You can hardly match the truth. I did not see a pair of shoes in the outfit except those worn by officers. Some wore a rough sandal, home made, of old leather or whatever came to hand; worn-out auto tires, belting, rubber, or fabric of any kind. Some were bare of foot except for the coating freely supplied by Mother Earth. Ragged breeches or overalls, and shirts in various stages of fragmentation, generally constituted the sole clothing. All wore the grotesque, large straw hats of Mexico, in every degree of decrepitude. Some had a ragged dirty blanket or *serape* thrown loosely over the shoulder or worn like a shawl.

Their weapons were as grotesque as their clothing, a varied assortment of rifles, Winchesters, Springfields, Spanish Mausers, German Mausers, and others, all looking as though they had been taken from a museum. A tin canteen, a small coarse provision bag, and one or two cartridge belts completed the accoutrement.

Our train had hardly got away from the station when we began to see evidence of the battles that have taken place during the many revolutions and counter revolutions that have torn Mexico during the last ten years. There were 'dobe houses shot full of bullet holes, or blown up; small circular forts of 'dobe three to five feet high; barbed wire entanglements; trenches and holes in the desert large enough for only one man. We passed the cemetery where victims of battle are buried like rats in trenches.

South of the border, for forty or fifty miles, the country is mostly uninhabited desert, sparsely strewn with grease wood, mesquite, and other desert shrubs, and many varieties of cacti. There is some grass, however, and at this season of the year cattle can still find fairly good grazing. We saw only a few isolated head, however. As we went further south, the land improved rapidly, so that when the train stopped for lunch at a small station, we were in a splendid agricultural and stock-raising region. We saw some small irrigation ditches, with cottonwood trees growing along them, and green fields adjacent, green with weeds for the most part. The village where the train stopped for lunch bore the scars of battle—water tanks blown up, a small circular 'dobe fort, houses abandoned and crumbling, a recently made graveyard beside the track, and dead horses rotting where they fell.

Mexican Troops Sans Commissary

A swarm of natives met the train with baskets of food to sell to the soldiers and passengers. These vendors do a lively business, as there does not appear to be any commissary in the Mexican army, and the train guards are obliged to feed themselves by buying stuff from the natives along the line. The offering consisted of *tortillas* and *frijoles*, the two great national dishes of the poorer Mexicans. There were also *enchiladas*, pancake-like cheeses, bread, cakes, fruit, and bottles of milk.

The first-class passengers went to a Chinese restaurant (the Chinaman is the national caterer in Mexico), and had a dinner consisting of much the same dishes; *enchiladas*, *frijoles*, stuffed peppers and rice with chili sauce. There was pie, but let that pass. The business of supplying food to the passing troops seems to be the only occupation of the handful of wretched people living in these shattered 'dobe villages.

During the afternoon, the train was running continuously through fat, green land, hundreds of thousands of acres, where formerly great herds of cattle grazed but which now lie deserted. It is said that the cattle were raided and run across the border into Texas, where they were sold to American stockmen or to the market, such as were not consumed by the raiders themselves. Villa and his followers have the credit for the job.

We passed over about forty miles of track, which had been rebuilt after having been destroyed with explosives. The old rails lay alongside of the track, warped and twisted into useless shapes. Everywhere bridges had been burned or dynamited, and rebuilt. Late in the afternoon we saw the *hacienda* where the Terrazas family, renowned for their wealth, formerly lived. This

family owned all the valley from the border to Chihuahua City and ranged great herds of cattle. It is said that they branded three hundred thousand calves yearly, and their herds totaled over a million head. Now all is deserted save for a few ragged peons living in crumbling 'dobes along the railway.

Stopovers Allowed on All Tickets

Our train arrived at Chihuahua City at 7 o'clock in the evening, and as the trains do not run at night, we unloaded ourselves and baggage, and had a bus convey us to the Hotel Palacio, a fine, large building in the Spanish style, three stories high, with big rooms opening on a court.

Beside myself there were two other guests, Americans, whom I had met on the train, and who were connected with the same company as myself, but going to different destinations. We were the sole occupants of a hostelry capable of accommodating several hundred persons. There were a number of other hotels, all seemingly in the same condition of vacancy. After dinner, we, the three guests, took a car and drove around the city. Stone-front business blocks gave evidence of former activity, but we did not see a single American. Away from the heart of the city, the streets were lined with the common 'dobes, outside of which the peons sat or reclined on the ground. The number of ragged and nearly naked children was astonishing, but evidently in harmony with biological law.

After covering the town, our driver, who had been instructed to show us everything, stopping in a particularly narrow and ill-appearing street, informed us that this was *"La Calle de Muchachas."* We all thought that there was no particular fascination for us in *"La Calle de Muchachas"* and told the driver to *"vamos."* We remarked the extraordinary number of plazas in the city, and some one found the explanation in the fact that the Mexicans were a plaza-loving people.

In the morning, while waiting for breakfast, I walked across the plaza and looked into the cathedral. Mass was being said, and many women were on their knees in devout attitudes. But the music—what was it that the organist was playing? Ah! I have it—the *"Barcarolle"* from the "Tales of Hoffman." I could not draw my face into as solemn an aspect as the occasion demanded, as I passed out and slipped a coin into the palm of a beggar at the church door.

As we drove to the station in the early morning to resume our journey, we saw more activity than one would think possible, judging from the inertia of the evening before. Donkeys laden with milk cans, and the milk man were coming to market. Other donkeys with fruit and vegetables made up a colorful caravan. Along the streets, the sidewalk merchants had spread their wares; bottles of milk, *tortillas* patted out in the hand and cooked on a piece of sheet iron or tin over a few coals in the street, while you wait; *frijoles*, *enchiladas*, coffee, cakes, and fruit—a variety of stuff to alleviate hunger, but hardly appealing to an appetite cultivated above the Rio Grande.

Better Halves (?) Have Makeshift Quarters

The scene at the railway station was colorful and fascinating. There were several troop trains in the yards, and the guards on our train and the one going in the opposite direction added to the flux of life. The regular troop trains carried swarms of camp followers, degenerate females—one hesitates to call them more—who served the men. They had numerous children, naked little savages, and carried their household goods, reduced to the primitive minimum, with them. These women camp followers lived in box cars, cattle cars, flat cars, underneath, on top, anywhere—while the decrepit train was in motion. While in the yards on sidings, they lived underneath, on the ground. They prepared the *tortillas* and *frijoles* for the soldiers, thus serving as a commissary. Squalid, filthy, ragged, diseased, they gave the lie to Fiske's "Ascent of Man."

Peddlers and street merchants were hawking their wares, a babel of voices constantly chattering; engine bells were ringing, donkeys braying and strident bugles blowing. In response to a bugle blown by a Yaqui boy, bare-footed, ragged, and rifled, of the color of oxidized copper, a squad of the most villainous looking men, Yaqui Indians, drew up for inspection—a screaming farce—and then mounted a box car for special guard duty.

It appeared that the reason for the Yaqui guards lay in the fact that an officer rode in our car with a large amount of metallic money which was destined to pay the soldiers at the stations south of Chihuahua, where thousands of federal troops were moving north in an attempt to put an end to the depredations of Villa. These Yaquis are said to be the best fighters in Mexico. They do not know what fear is, while the soldiers of the regular—or irregular—armies are inclined to the policy of "Safety First." Yaqui soldiers have been known to turn and shoot their fleeing comrades.

Air Hose and Grease Classed With Jewels

Our train finally got away from the hubbub of the station about half an hour behind schedule. We were delayed somewhat while waiting for the brakeman to bring the connecting air hose from the safe in the depot and attach it to the coaches. Then he went back and got a can of grease-soaked waste, to fill the stuffing boxes on the wheel axles. The humor of these proceedings can hardly be appreciated without seeing them.

The day's run through idle grazing lands in the valley of the Rio Conchos brought us to the town of Jimenez. We passed through only one town on the way to Santa Rosalie. Here the station was filled with troop trains and our aforesaid paymaster detrained with his precious bags. The scene of the morning at Chihuahua was re-enacted here, with the added objectionable features of more filth and stench, and myriads of flies.

Along a cliff under the edge of the town we saw a number of caves inhabited by modern troglodytes. At Jimenez we encountered more troop trains. There were thousands of soldiers here. The railroad yards and streets were filled with them and the ubiquitous *mujeres* patting out their *tortillas* beside a few embers. As our train was to camp again for the night, we had *cargadores* carry our baggage to a hotel, where our company maintained a number of rooms for the convenience of its men traveling back and forth.

This hotel was owned and operated by one Doña Luisa, a woman having something of American pluck and initiative. Doña Luisa had come down here with her husband during the Civil War, to buy hay for Confederate horses. In the meantime, the Confederacy surrendered and Doña Luisa and her husband, not approving of the proceeding, refused to go back. Her husband has since gone further West. Doña Luisa is over eighty, but still manages her hotel. She is said to be the only one in the place who does not fear Villa,

and to have run off a bunch of his bandits with two revolvers, when they tried to raid her stock of liquors. Salud! Doña Luisa.

One other member of the party and myself were to leave the main line here and proceed on a branch line via Parral to Santa Barbara, a mining camp in the Sierras. It was at Parral that Villa was last heard from, when he made an attack on the town in the morning hours of June 2. Our train had the usual guards and also acted as escort for an unmixed freight train behind. If our train got out of sight or around a bend from the freight, it stopped while the latter caught up, and several times we were forced to stop for engine repairs.

Train Does a Serpentine

Near Parral, a railroad bridge across a small stream had been burned by Villa in his recent attack. A temporary track had been laid on the river bar, crossing the channel on an improvised trestle. Looking out of the coach, I saw the cars ahead dropping down a tremendous grade, 20 or 25 per cent. It was a perilous-looking performance, but the train stayed on the rails, crossed the stream and climbed the opposite bank, warping itself to the contour of the earth like a thick-bodied, giant snake.

Just at noon our protesting train came to a stop at Parral. We saw evidence of the recent fight, in breast-works of boulders on the outskirts of the town, and bullet-marked walls, and some recently-erected crosses. The water tank lay a twisted mass of ruins from earlier raids.

The town of Parral had been a prosperous and busy mining camp before the era of revolutions, but continued depredations of bandits have so harrowed the American companies operating there that these have, for the most part, ceased operations. Only one company, and that because of its superior financial strength, diplomacy, and political power, operates in the district today.

After an interminable wait, our train resumed its meandering way toward Santa Barbara, eighteen miles up the valley. Toward evening, it came to a stop in a terrific thunder storm, a mile short of the station, due to an engine derailed ahead. Fortunately, however, we were opposite the mine which was my destination, and a messenger came to meet us with a couple of *mozos*, who carried our baggage to the quarters assigned us in the American Club. Here at dinner we learned that, before attacking Parral, Villa's men had paid their respects to Santa Barbara, looting the principal store in the town and generously giving the mining company a receipt for all of its horses.

Abandoned Mines a Refuge

It is said that the town people were very inconspicuous during the stay of the Villistas in Santa Barbara, many taking to the hills and abandoned mines during the night. One official incumbent is known to have availed himself of the hospitality of some of the company employees and lain hidden in a closet for a night and a day. Previous to the visit, some of the natives employed by the company had twitted the Americans about Villa. "Just wait until Villa comes! You *gringos* will be very scarce." As a matter of fact, when Villa did come, these same individuals lay hidden in an abandoned mine, while the Americans entertained the Villistas at dinner.

But perhaps the greatest fear of Villa was in the hearts of the Chinamen. Mindful of the treatment accorded their countrymen in previous raids, they hid until it became apparent that there was to be no hanging or shooting. The peaceable behavior of the Villistas was, in all likelihood, owing to the fact that they met no opposition. Had they been shot at, they would have made reprisals by organizing a necktie party, or a firing squad; the former probably, as they were short of bullets and in such emergency are wont to resort to the rope.

After being beaten off in his attack on Parral, where he lost ten men, Villa headed in an easterly direction and was last heard of at La Reforma, on the main line, where he burned a small bridge and continued easterly,

SOLDIERS THREE

supposedly to meet a pack train from Eagle Pass, which was carrying ammunition that had been smuggled across the border.

The movement of troops into the district continues, until now there are reported to be over twenty thousand federals hunting for Villistas along the main line from Juarez to Jimenez.

Before Villa Surrendered

The present administration is evidently making a strong effort to bring Villa's career of outlawry to a close. But the federals are handicapped in hunting Villa on his own ground. Better men than Mexican soldiers fell down on the job once. And, too, Villa is better equipped than the federals, with the exception of ammunition, which defect may have been remedied ere now. His men are mounted, and exceedingly mobile. They are fearless fighters under a renowned guerilla leader. The only advantage the federals possess lies in superiority of numbers and control of lines of communication and transportation. The latter Villa may nullify at any time. On the outcome of the hunt for the outlaw, it is believed, rests the immediate fate of Mexico.

Dominant Features Controlling Ore Deposits Of Washington

Formations Genetically Related to Batholithic Intrusions of Granitic Rocks Associated With Dikes in Stevens and Northern Pend Oreille Counties Near Marginal Contacts At Some Other Points Ores of Republic District Excepted

By Ernest N. Patty*
Washington Geological Survey
Written for *Engineering and Mining Journal*

UPON examining the various mining districts of the State of Washington, dominant characteristics of the deposits are noted that continue to develop as field evidence is accumulated. Thus, a generalized perspective is permitted which simplifies the solution of the problems of the individual mines.

First in importance is the fact that practically all the deposits show evidence of direct association with batholithic intrusions of granitic rocks These batholiths related. The intrusions of northeastern Washington have been provisionally assigned to the Mesozoic.[1]

I shall not here attempt to correlate the mining districts of Washington with those of the surrounding, and often better known, districts in the adjoining states and in British Columbia. It is believed, however, that the Washington deposits are a link in the chain of an extensive metalliferous area which will later submit to a broader correlation based on accumulated field observa-

CAMP OF ELECTRIC POINT MINE, TWENTY MILES EAST OF NORTHPORT, WASH., AT AN EARLIER STAGE OF OPERATION. TOPOGRAPHY SHOWN IS TYPICAL OF THAT OF SURROUNDING COUNTRY

form the parent source of practically the entire metal resources of the state. The ore deposits occur in the northern tier of counties bordering the international boundary. This entire section, from the Selkirk range along the Idaho boundary westward across the state to the Cascades, is underlain by a series of batholithic intrusions apparently closely related. These continue northward into British Columbia and eastward into Idaho, where they are found genetically related to the ore deposits of important mining districts. Granodiorite forms the core of the Blue Mountains of northeastern Oregon, and the striking similarity of field evidence observed both in northeastern Oregon and Washington suggests that the two batholiths may be directly

tions. I have not yet undertaken field work in the Cascade Range of western Washington and the generalizations of this report do not include that section. The gold veins of the quite well-known Republic district in Ferry County represent a distinct period of mineralization younger than the surrounding districts and they are not considered in this article.

Topography of Northern Washington Distinctive

In northern Washington, from the Idaho line westward to the Cascade Range, the topography uniformly consists of a series of mountain ranges trending north and south, the forested ranges being separated by broad

*Published by permission of Henry Landes, State Geologist of Washington.

[1]Weaver, C. E.: "The Mineral Resources of Stevens County, Wash." Geological Survey Bulletin 20.

glacial trenches. The floors of these trenches, often one to two miles across, are occupied by streams so small as to be totally out of proportion to the giant troughs. These valleys are at elevations of 1,500 to 2,000 ft. above the sea, and the average elevations of the associated ranges vary between 4,000 and 5,000 ft., with ridges occasionally culminating in peaks attaining maximum elevations of 7,000 ft. This characteristic topography is noted on entering the state from British Columbia and continues southward approximately 100 miles to a latitude a few miles north of Spokane, where the ranges rapidly lose their prominence and disappear beneath the northern extension of the Columbia River basalt plateau.

Dikes Associated with Orebodies in Northeast

Northern Pend Oreille County, in the northeastern corner of the state, and Stevens County, adjoining on the west, are covered with an extensive series of metamorphosed Paleozoic sediments tilted to a steep angle and overlying, for the most part, the intrusive granitic rocks. The ore deposits here occur as irregular replacement bodies in the metamorphosed series. With more extensive development, some of the larger deposits may be found to extend down into the underlying granites. Closely associated with all these deposits are found igneous dikes which mostly approach lamprophyres and granite porphyries in character. In some cases, the ore is found in contact with these dikes, but more often the dike is 10 to 150 ft. from the ore. This association has led to a confusion of ideas and in some cases resulted in exploration work being improperly directed. I believe these dikes, as a general rule, to be feeders from the underlying batholith which forced their way up through the overlying sediments.

The dikes naturally sought out the shattered zones for their entrance into the metamorphosed sedimentary beds; the intrusive force of the dikes further shattered the brittle sediments. The total result was that the shattered ground adjacent to the dikes offered inviting conduits for the mineralized hydrothermal solutions and the gases, which were exhaled from the magma a little later than the dikes. In the United Silver-Copper mine concrete evidence is offered to prove that the dikes are earlier than the ore, for on the 1,200-ft. level a considerable portion of the vein is found filling a shrinkage crack in the dike.

Invaded Formations Have Influenced Ore Deposition

The shape and often the extent and richness of the ore deposits were effected by the character of the formation into which the mineralized solutions were injected. The highly folded and tilted position of the sediments often placed them in a favorable position to receive the mineralized solutions and gases through fractures opened along the bedding and schistosity planes of the formations. The zones of weakness in such formations would naturally be along these planes. However, should the beds be so favorably oriented that the components of shattering forces were applied at certain angles to the planes, then the fractures would tend to cut the formations at angles to the bedding or schistosity planes. These two types of deposits are common to argillites and schistose rocks in Stevens County and are well represented by the Loon Lake deposit, the United Silver-Copper, and by smaller deposits such as the Frisco-Standard and the Bonanza.

Brittle formations, when ruptured, often develop irregular undulating fractures. If such a fissure should later be subjected to faulting along the plane of fracture, some of the walls would be brought into such juxtaposition that pinches and swells would be developed. These conditions are strikingly represented by the Reardon Copper deposit and, to a lesser degree, in the United Silver-Copper vein.

Planes of contact between two formations, such as argillite and quartzite, are in some cases planes of rupture. The quartzite is not as favorable for ore deposition as the argillite, as the argillite yields more readily to metasomatic replacement than does the refractory quartzite; and, further, the organic matter in the argillite has acted as a precipitating agent on ore-bearing solutions.

Limestone, under favorable conditions, is readily susceptible to replacement by mineral-laden solutions and gases. A belt of limestone that has been stressed by folding and then intruded by igneous dikes will ordinarily develop irregular fracture patterns which ore solutions may later use as a conduit. The intersection

KAABA VEIN ON 200-FT. LEVEL OF KAABA MINE, WASHINGTON. TRUE WIDTH NOT SHOWN ON ACCOUNT OF RIB OF WASTE ON FOOT-WALL SIDE

of two or more fractures affords an inviting locus about which heated solutions may work to replace the limestone and deposit ore in irregular pots and chimneys. The Electric Point deposit and the deposits in the Metaline district of Pend Oreille County are striking examples of this phenomenon.

Deposits Occur in Igneous Rocks

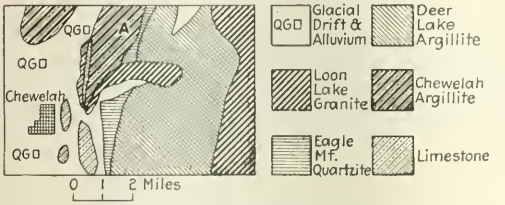
In southern Pend Oreille County and westward in Ferry and Okanogan counties, the metamorphosed roof rocks are less conspicuous, and large areas of granitic rocks, varying in composition from true granite to diorite, are exposed. Here the ore deposits are more often found inclosed in the granitic rocks. It is particularly pertinent, however, that some of the most promising deposits occur near the marginal contact of the granitic rocks and the older intruded formations as marginal veins. In the Newport, Nespelem, Concunully, and Oroville-Nighthawk districts and near Danville there are veins near the roof of the batholith adjacent to its contact with the older intruded rocks. Near the Nespelem deposits the roof rocks have been completely removed by erosion, but, judging from the surrounding horizons, the present granite outcroppings on Mineral Hill repre-

sent the upper limits of the batholith near this particular locality.

As the laws governing the formation of veins and other types of metalliferous deposits are better understood, it seems safe to predict, the occurrence of ore deposits near the margins of the intrusive rocks will be more readily appreciated. It is logical that, following the invasion of a batholitic mass, the margins of the magma in contact with the older rocks would be the first to crystallize. Crustal tensions developed by shrinkage and recurrent heavings originating deeper in the partially cooled magma would develop fissures in the granitic rocks and even across the contact into the intruded formations. Such fissures would offer excellent conduits for mineralized solutions and gases which might be exhaled by the cooling interior of the magma.

Localizing Influences Discussed

If the protective roof rocks overlying a batholith could be suddenly stripped off, the underlying granites would probably be found not with flat relief, but with an uneven undulating surface and with cupolas or dome-like projections above the general level, this irregular relief originating from a series of complex conditions



AREAL GEOLOGY OF CHEWELAH DISTRICT, WASHINGTON, SHOWING OCCURRENCE OF PRINCIPAL ORE DEPOSITS AROUND A GRANITE STOCK

which caused the distribution of the intrusive forces unequally over the marginal surfaces of the mass. The idea is not new; the phenomenon has been recognized and described by numerous observers. These so-called cupolas are admirably exposed in Stevens County, where erosion has stripped off part of the old roof rocks and bared small sections of the underlying batholith. An excellent example is the Chewelah district, where the ore deposits occur principally in the argillites, but around the periphery of a granite stock or cupola.

When plunging contacts, rather than those approaching the horizontal, appear, pendants or blocks of the old roof rocks are suspended down into a batholith 2,000 feet or more, and often of such horizontal extent as to measure two or three miles in diameter, all boundaries of the pendant except the upper being surrounded by the intrusive rocks. In northern Okanogan County one of these pendants was observed to be continuously connected with the roof rocks of the area, which proves that it is not a detached block immersed in the batholith but a roof pendant projecting downward into the mass, and which represents a lower portion of the roof rocks. This phenomenon of roof pendants as occurring in the Okanogan Highlands was first interpreted by Daly.[2]

Along the marginal contact of such a pendant it would seem that favorable conditions could exist for the development of fissures which might later become channels for mineralized hydrothermal solutions and gases. Complementary to the pendant there could ordinarily exist the margin of a granitic stock. The function of the stock or cupola would be to collect and concentrate the ore-bearing solutions and gases from the remainder of the batholith. The function of the pendant would be to encourage the development of fissures by chilling the margins of the batholith. I advance this hypothesis as a possible influencing factor on certain Western ore deposits.

The mechanics of fissure development is none too well understood, and there is generally a tendency to pass it by with a vague sentence or two about regional compressive or tensional strains. There is little doubt that these offer the best fitting explanation for many districts, but I feel that, at least in certain districts, the factors governing the development of fissures can be traced to local causes. Particularly in the Oroville-Nighthawk district of Washington there are found several large marginal veins which satisfactorily bear out this conclusion. In fact, it was while I was engaged in field work in this area that this theory first suggested itself.

At the Kaaba and Four Metals mines field evidence favors such conclusions. Large quartz veins occur at the margin of the quartz batholith. The contact between a roof pendant and the granite stands nearly vertical. The veins trend across the contact and into the pendant a distance of several hundred feet, then gradually "tail" out. They gain their maximum width (up to 15 ft.) on the granite side of the contact several hundred feet from the margin. As these veins are traced further away from the contact and into the granite, they are found to grow more narrow gradually until one of them was found to be only one foot wide at a point half a mile from where the contact was crossed. All of the oreshoots so far developed have been found within a few hundred feet of this margin.

Post-mineral faulting is quite prevalent in the vicinity of the deposits, but the vein displacement is usually not over 10 ft.. and more often it is 2 or 3 ft. The operator who finds his vein cut off by a fault should not be too readily discouraged. The United Silver-Copper vein exhibits a series of lateral step-faults with displacements averaging about 2 or 3 ft. Of larger faults, the Morgan fault, in the Loon Lake Copper deposit, with a throw of 50 ft. to the north, and the fault which displaces the east segment of the Bead Lake vein 135 ft. to the north, were the largest observed. There are many unmeasurable faults along the plane of the veins, as evidenced by slickensided wall rocks and streaks of gouge painting the walls of many of the deposits.

Few Bonanza Deposits in Washington

Washington has produced few ore deposits of the bonanza type. The Electric Point mine, discovered in 1914, is one of the really spectacular mines. There are several disseminated low-grade deposits of gold and copper ore in northern Okanogan County which show some promise of developing extensive tonnages of low-grade ore, but at present not enough systematic sampling or development work has been done to prove the properties. There exist, however, a number of small to medium-sized veins and other types of deposits, which, with the proper application of brains and capital, could be made to pay good returns. Barring a few isolated examples, the grade of ore in deposits throughout the

[2]Daly, R. A.: C. G. S. Memoir No. 38, p. 429.

state is not sufficiently high to be steadily and economically worked without concentration.

As a general statement, it can be said that the veins are capable of an average length that is good for veins of their width. Many of them have already been proved to extend to a good depth. The United Silver-Copper vein has been followed to a depth of 1,140 ft. below the outcrop, without decrease in size or metallic contents. Several of the other properties have attained depths of 500 to 800 ft. with no signs of the ore bottoming. Many of the smaller mines are worked intermittently and with limited capital, which condition has served to confine the developments to shallow workings.

Necessity of Concentrating Better Recognized

So far as can be foretold, Washington will not lose ground as a producer of metals during the next decade. The production can be expected to come largely from concentrated ore. The state as a whole has been backward in employing efficient methods of concentration, but decided improvement has been made in the last two years, and several well-designed, small mills are now under construction. A number of worthy properties are now idle because of lack of capital to permit work on an efficient scale and the need of skillful management. A number of such properties should develop into paying mines.

The promising ore deposits of the Northwestern States have not been combed over so thoroughly by capable mining organizations as is generally believed. The haphazard methods of development, often of the "shoe-string" kind, now in vogue, do not achieve satisfactory results. The gap between the promising prospect or semi-developed mine and a producing mine can best be bridged by well-organized and well-financed mining development companies with a staff of competent engineers. When there is a more dependable market, prospecting will be accelerated and new finds made.

Summary

In summarizing it may be said that:

1. The metalliferous ore deposits of Washington are genetically related to batholithic intrusions of granitic rocks.

2. In Stevens County and northern Pend Oreille County the ore deposits are found inclosed in Paleozoic metamorphosed sediments and closely associated with dikes genetically related to underlying granite. The dike intrusions are believed to have preceded the veins and assisted in opening channels in the roof rocks for the hydrothermal ore-bearing solutions and gases which soon followed the dikes.

3. In Ferry, Okanogan and southern Pend Oreille counties the vein deposits for the most part are inclosed in granitic rocks but near marginal contacts.

4. The character of the invaded formations plays an important rôle in determining the size, shape, and character of the orebodies.

5. Favorable local conditions for the formation of veins are found around the periphery of granitic cupolas and near marginal contacts of granitic and intruded rocks. For example, several commercial deposits are found near the margins of a plunging contact between granite and a roof pendant of the intruded rocks.

6. The gold-silver ores of the Republic district represent a distinctly separate period of mineralization, and for that reason are not included in these generalizations. Field work has not been attempted in the western part of the Cascades, and no effort has been made to include that area in this report.

7. Most of the deposits are believed to have been formed at intermediate depths below the surface.

8. Active erosion has prevented the formation of extensive zones of secondary enrichment.

9. No mammoth, low-grade deposits have so far been developed, and as a general rule the deposits are not of the bonanza type. There are a number of medium-sized, worth-while deposits that contain considerable tonnages of commercial ore of milling grade.

10. There are promising properties, now semi-dormant, which should yield returns if operated by well-financed and well organized mining-development companies.

Manganese in India

In India, on the east coast in the Vizagapatam and Ganjam districts, Madras, is a unique group of rocks known as the Kodurite series, containing manganese garnet, manganese pyroxene, potash feldspar, apatite, and quartz. These rocks, supposed to be of igneous origin, have been deeply weathered and the manganese concentrated as oxides in the surface zone.

The manganese-bearing districts form a belt that extends from Baroda, on the west coast, across northern India nearly to Calcutta on the east, a distance of 700 miles. In these districts, beds of manganese oxides, with manganese, garnet, and rhodonite, form a rock type known as gondite, which is interlayered with quartzite and mica schist.

The orebodies are lenses and layers. The largest single deposit, Balaghat, has the form of a shallow trough, is 1¾ miles long and 45 to 50 feet thick, and yielded from 1901 to 1913 a total of 725,248 tons of ore. In 1913, thirteen distinct deposits had yielded more than 100,000 tons each, the range being from 101,721 to 725,248 tons.

The annual production of manganese ore in India rose steadily from 1892, when the first shipments were made, to 1907, when 899,055 tons was shipped; and since then has ranged from 450,000 to 815,000 tons. The total production, up to and including 1916, was 8,748,000 tons.*

Cost of Building the Alaskan Railroad

Colonel Frederick Mears, chairman of the Alaskan Engineering Commission, has recently submitted the cost of several sections of the Alaskan Government Railroad. The most expensive section is an 11-mile stretch from Riley Creek to the foot of Nenana Canyon, which it is estimated will cost about $157,000 per mile upon completion. The northernmost section of fifty-six miles along the north bank of the Tanana River to Fairbanks is the cheapest part, at $43,700 per mile. Most of the first 260 miles has now been completed, as well as the last 100 miles. The total length is 468 miles.

Early Use of Copper Coins

Coins made from copper mined on the Island of Cyprus by the Phœnicians were used as medium of exchange by the early Meediterranean traders.

Leaching and Concentrating Mixed Copper Ores

Method Used at Experimental Plant of Arizona Copper Co., Ltd., at Clifton, on Old Tailings, Consists in Regrinding, Dissolution of Oxidized Copper in Weak Sulphuric Acid, and Flotation of the Sulphide Slimes

By Arthur Crowfoot and Kenneth H. Donaldson
Superintendent of Concentrators and General Foreman of No. 4 Concentrator
Written for *Engineering and Mining Journal*

EARLY in 1917, experiments made by the metallurgical staff of the concentrating division of the Arizona Copper Co. on mixed ores showed that 75 per cent of the acid-soluble copper was readily soluble in a dilute sulphuric-acid solution, if the ore were crushed to pass 35 mesh. Finer grinding was recommended to hasten the results and to increase the extraction. Coincident tests made upon old tailing material from the Clifton ponds indicated that these tailing deposits could be worked successfully by a combined leaching and flotation process. A continuation of the experiments during 1917 and 1918 on a larger scale resulted in the presentation of several proposed flow sheets for a combined leaching and flotation plant, using a counter-current decantation tank system for the recovery of the copper-bearing solution from the pulp, precipitating launders containing scrap iron for the precipitation of the copper from solution, and flotation cells for the recovery of the sulphide copper. Also, a ten-ton experimental leaching and decantation plant was erected at the Clifton concentrator, to treat current tailing product from the mill for the recovery of the contained acid-soluble copper.

Experiments were made on the current mill tailings from concentrator No. 4 for the recovery of its acid-soluble copper content during the period September to November inclusive, 1918. These were discontinued because the acid-soluble copper of the ore treated in the mill dropped to a point which made consideration of its recovery by a leaching process inadvisable. In this process the acid-soluble copper content of the mill tailings was concentrated in the slime portion of the tailings by a de-sanding operation performed by an Allen cone which preceded leaching and decanting operations.

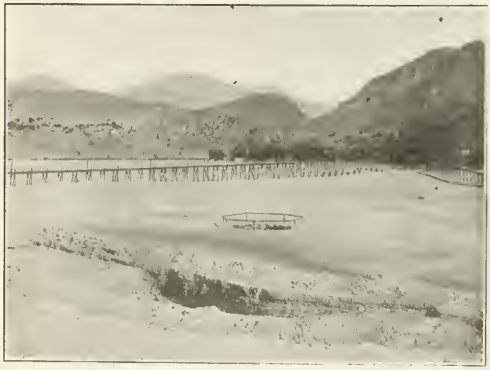
THE SLIME TAILING PONDS IN SOUTH CLIFTON

The treatment of the old Clifton tailings in the experimental leaching plant had been considered, and it was decided during November, 1918, to make the necessary changes in the plant for the treatment of this material. These consisted chiefly in the addition of a pebble tube mill to reduce to the required size any coarse sand which might be encountered and also to act as a disintegrator for lumps of slime; and in the addition of a flotation unit so that the sulphide copper might be recovered from the underflow of the last decanting tank. The required changes were started in December, 1918, and finished in January, 1919.

The plant was put into operation on the treatment of the old tailing material on Jan. 25, 1919, and operated under the conditions of flow sheet No. 1 until May 13, 1919, when flow sheet No. 2 was put into operation. The plant operated under the conditions of flow sheet No. 2 until July 10, 1919.

Material in Old Tailing Ponds Utilized

The material upon which the test work was performed consisted of representative samples of the tailing slime contained in the old tailing ponds in South Clifton. The banks of these tailing ponds are constructed of tailing sand having a maximum size of grain of between 1.5 and 2 mm.; and 93 per cent of the material in the ponds is fine enough to pass through a 200-mesh sieve which has openings .074 mm. square. The sandy material forming the banks of the ponds constitutes only a small



SOUTH CLIFTON SLIME TAILING POND, SHOWING PRELIMINARY SAMPLE CUT IN FOREGROUND AND TEST PIT IMMEDIATELY BEYOND

percentage of the total deposit, and this material was not included in the feed to the test plant. The copper in this sandy material will, however, be readily amenable to recovery by the same flow sheet proposed for the treatment of the slime.

The deposit consists of a mixture of practically untreated "oxide" slime and the slime tailings from a sulphide mill. The "oxide" slime originated in a concentrating plant which preceded the old leaching plant at Clifton, the oxide ore being treated in a Hancock jig for the removal of a coarse concentrate before leaching. The slime was then removed from the jig middling and sent direct to the ponds without further treatment. The deslimed jig middling was sent to the leaching plant. (See Greenawalt's "Hydro-metallurgy of Copper," p. 183.) The tailings from the sulphide mill were desanded by the use of a special form of elevator, the slime joining the "oxide" slime in the ponds, and the sand being hauled away in railroad cars to form the banks of the ponds and for other purposes.

The slime mixture as it occurs in the ponds has the appearance of a stiff clay and contains 20 per cent by weight of moisture. The material settles slowly, average results showing that about 30 sq.ft. of settling area is required per dry ton of material to obtain a Dorr tank underflow with a density of 50 per cent solids, as was required. Large tank areas are therefore necessary. For instance, to settle 100 tons of the slime from a density of about 25 per cent solids (the density leaving flotation cells) to a density of 50 per cent solids, a tank 60 ft. in diameter is required.

The thorough sampling of the slime deposit progressed with the experimental leaching and flotation work. In all, thirty test pits were sunk, these being regularly at the corners of rectangles. These pits were 8 ft. square and were continued to the bottom of the deposit, varying from 9 to 16 ft. in depth. A hole about 2 ft. square was dug 2 ft. deep in the center of the bottom of each test pit to prove the bottom. A total sample of about 1,200 dry tons was obtained, which assayed as follows:

	Total Cu	Acid-Sol. Cu	Water-Sol. Cu	Sul. Cu
Assay, per cent	1.39	0.85	0.06	0.48
Per cent of total Cu	100.00	61.20	4.30	34.50

Small- and large-scale laboratory tests indicated that at least 75 per cent of the total copper in the slime was readily recoverable by subjecting the slime to a comparatively short dilute sulphuric-acid leach for obtaining the acid-soluble copper, and to treatment by flotation for the sulphide copper.

On account of the finely divided character of the material, and its cohesive nature when moist, the percolation method was not practicable. Therefore, the leaching solution had to be applied after the slime had been brought into the form of a pulp by the aid of additional water.

The density of the pulp had to be kept as high as was consistent with the necessity of obtaining thorough agitation with the leaching solution, so that the required degree of acidity in the leaching solution might be maintained without excessive use of acid.

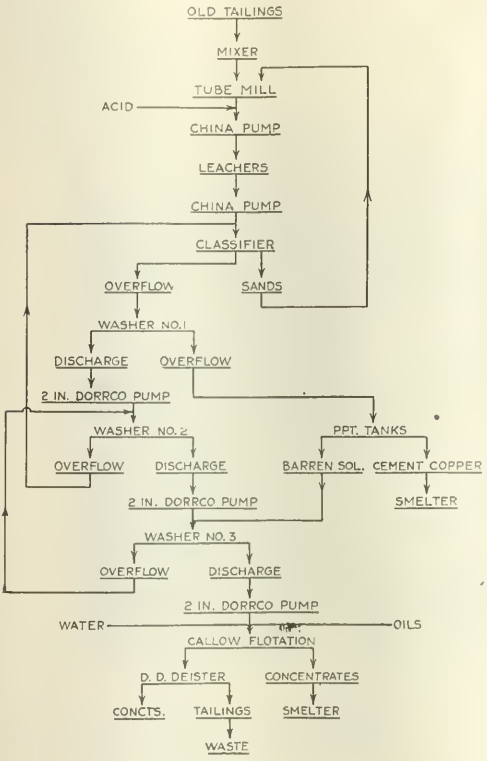
For the separation of the copper-bearing solution from the leached pulp, counter-current washing and decantation was employed, the conditions being analogous to those existing in cyanide plants working on finely divided gold. Flow sheet No. 1 shows the arrangement. The slime lumps were first broken in a mixer somewhat similar to a small-scale log washer, water being added to bring the density of the discharge to 50 per cent solids. The mixer put the slime in condition to be picked up by the scoop feeder of the tube mill which immediately followed it. The tube mill used was 5 ft. in diameter by 12 ft. long, direct-connected to a motor, and lined with Danish pebbles set in cement. Danish pebbles were also used for a grinding medium. Sulphuric acid was added at the discharge of the mill, the pulp then being delivered to the leaching tanks. Nos. 1, 2, and 3 were wood-stave tanks 9 ft. 6 in. in diameter and 10 ft. deep, these tanks being in place and available for use for this purpose.

Pulp was transferred from one tank to the next by the use of air lifts. These consisted of a square wooden pipe of 2 in. inside cross-section, made up of two pieces of 2 x 2 and two pieces of 2 x 6 nailed together with copper nails. The air pipe was a ¾-in. rubber hose which discharged directly into the pulp, no footpiece being used. Although this type of lift was not efficient in the use of air, it worked satisfactorily for test purposes, and with a pulp containing 50 per cent solids the submergence was frequently as low as 25 per cent.

The air used for regular operation was that supplied by a No. 3 Root blower, which also supplied the air for flotation and the air lifts for the washing tanks. The discharge launders from the air lifts were arranged so that any proportion of the material lifted could be returned to the same tank. The return gave an excellent mixture of the pulp as well as simplifying the regula-

tion of the advance. These air lifts have since been replaced with Dorrco pumps, as it was desired to test this type of pump. They will probably be more economical in the use of power.

The leached pulp from the tanks was delivered to a drag-belt classifier, which returned the sands to the tube mill for regrinding and a slime product to the washing



FLOW SHEET NO. 1

and decanting tanks. The necessary dilution of the leaching tank discharge preceding classification was accomplished by the use of return solution from the overflow of the second decanting tank in the three-tank system.

Air Lifts Replaced by Dorrco Pumps

The washing and decanting tanks used in flow sheet No. 1 were 16 ft. square, and were in place, having been used in a previous test on current mill tailings. They were equipped with air lifts for the transfer of the settled solids, similar to those already described. These lifts were not satisfactory, owing to difficulty in controlling the amount of thickened pulp raised. They were therefore replaced with 2-in. Dorrco pumps, which gave good service, requiring a minimum of repairs and operating attention.

The pulp discharge from the third washer in the series was sent to a standard Callow 8-ft. flotation cell, which produced a rough concentrate and a tailing product. No cleaner cell was installed, but periodical tests showed that a high-grade sulphide concentrate could be produced.

The tailings from the flotation cell were at first retreated on a Deister table, but this operation was later discontinued as unnecessary.

The results obtained with flow sheet No. 1 were as follows:

	Assay, per Cent			
	Total Cu	A.-S. Cu	Sul. Cu	W.-S. Cu
Feed to plant	1.41	0.87	0.51	0.03
Leaching-tank discharge	1.14	0.22	0.43	0.49
Washing-tank discharge	0.73	0.21	0.42	0.10
Flotation tailings	0.31	0.13	0.11	0.07

Acid Consumption (Lb. 60 Deg. Bé.)

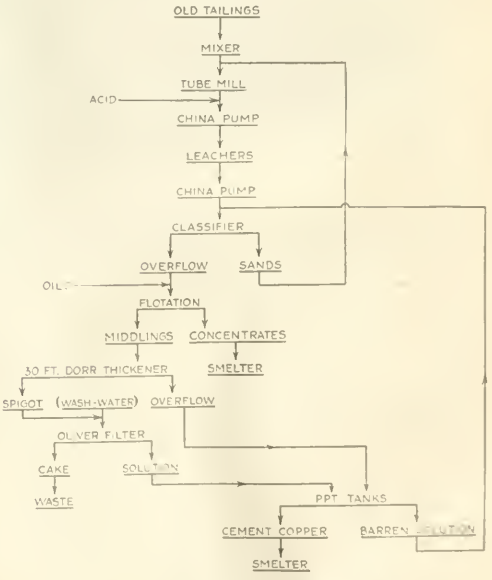
Per dry ton of material treated	51.14
Per lb. of total copper in feed	1.81
Per lb. of A.-S. copper in feed	2.94
Per lb. of A.-S. copper recovered	3.71

Over-All Extraction or Recovery

Per cent of total copper	79.57
Per cent of acid-soluble copper	79.35
Per cent of sulphide copper	79.96
Per cent of water-soluble copper	86.72

The recovery of water-soluble copper would have been increased had not some difficulty been encountered in holding the discharge of the washing tanks at the correct density.

Because of the slow settling of the suspended matter, already mentioned, it was decided to try out a combined decanting tank and vacuum filter flow sheet, limiting the decantation to one tank followed by a continuous vacuum filter. The flow sheet was, therefore, rearranged as shown in flow sheet No. 2. Both flow sheets are identical up to the point where the discharge from the leaching tanks is sent to the classifier. Following this



FLOW SHEET NO. 2

point, in flow sheet No. 2, the copper-bearing solution is recovered partly by tank decantation and partly by filter decantation; also, there is a notable difference in the location of the flotation system in the flow sheet. In No. 1 flotation is the final operation, the table which followed having been discarded as unnecessary, the

sulphide copper being floated from a pulp containing practically barren solution.

In flow sheet No. 2 flotation precedes the decanting and filtering system and receives its feed from the overflow of the classifier which immediately follows the leaching tanks. The sulphide copper is, therefore, floated from the solids contained in a lean copper-sulphate solution. The flotation tailings are sent to the decanting and filtering system, and the final waste tailings of the process form the filter cake. Laboratory tests had proved that sulphides can be floated as readily in lean copper-sulphate solutions as in barren solutions, and this has been checked and confirmed in test-plant operations.

Arranging the flotation system as in flow sheet No. 2 eliminates the necessity of re-pulping the filter cake for flotation treatment, and the problem of disposing of the tailings is simplified.

That the results obtained under No. 2 conditions were more satisfactory than under those in flow sheet No. 1 was due largely to a higher recovery of water-soluble copper. Also, the flotation tailings produced were 0.04 per cent lower in sulphide copper, and it was considered that the presence of a slight amount of free acid was beneficial to the flotation process.

A summary of the principal results obtained under flow sheet No. 2 conditions is given below:

	Assay, per Cent			
	Total Cu	A.-S. Cu	Sul. Cu	W.-S Cu
Feed to plant	1 36	0 79	0 44	0 13
Leaching-tank discharge	1 12	0 22	0 35	0 55
Flotation feed	1 43	0 23	0 47	0 73
Flotation tailings	0 90	0 12	0 09	0 69
Washing-tank discharge	0 33	0 09	0 08	0 16
Filter-cake tailings	0 22	0 10	0 07	0 05

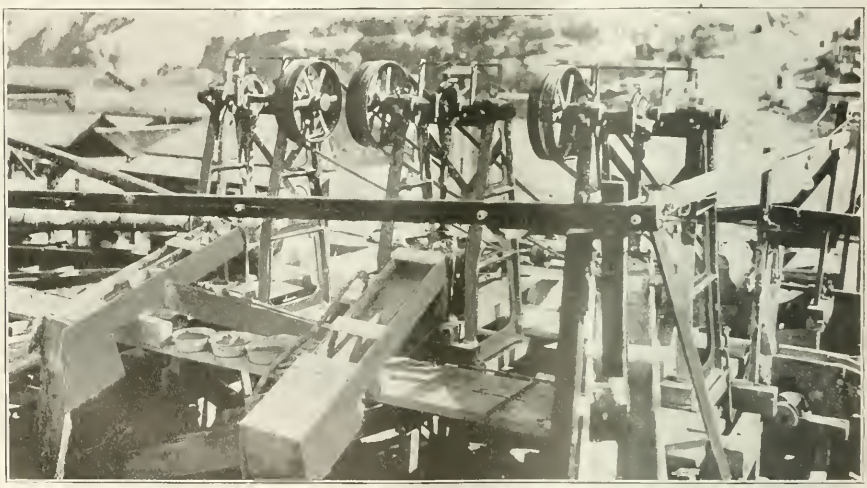
Acid Consumption	Lb., 60 Deg. Bé.
Per dry ton of material treated	59 08
Per lb. of total copper in feed	2 17
Per lb. of A.-S. copper in feed	3 74
Per lb. of A.-S. copper recovered	4 40

Over-All Extraction or Recovery	
Per cent of total copper	84 57
Per cent of acid-soluble copper	84 93
Per cent of sulphide copper	82 70
Per cent of water-soluble copper	91 18

The sands from the classifier being returned to the tube mill, the total copper is lower in the leaching tank discharge than in the feed to the plant, in both flow sheets Nos. 1 and 2. The tube mill, leaching tanks, and classifier operate in a closed circuit. The flotation feed is higher in total copper than the feed to the plant, because the return solution used for diluting the classifier feed contained a small amount of copper in solution, which material was included in the flotation-feed assays.

Flow sheet No. 2 gave satisfactory results if the copper was to be precipitated by the use of scrap iron or sponge iron, and for the slime deposit this method of depositing the copper no doubt will prove to be the most economical.

Recovering all copper-bearing solution by the use of continuous vacuum filters is now proposed, in which operation the leaching-tank discharge will be sent directly to a filter equipped to produce possibly three grades of solution. Recovery of the sulphide copper will not then be attempted until after the copper-bearing solution has been removed from the pulp. The filter cake will be repulped and sent to the flotation system, the flotation rougher cell tailings again forming the general tailings of the system.



DORRCO PUMPS TRANSFERRING PULP FROM ONE LEACHING TANK TO ANOTHER

If it is found possible to construct tailing dams from this dilute tailing pulp of very finely divided solids, so that clear water may be recovered, the use of tanks for the reclamation of solution or of water will be entirely superseded. However, employing of tanks to reclaim the tailing water may be found economical if used in conjunction with the tailing dams as water reclaimers. The main benefit to be derived from the use of the tanks will probably be a better control of the dilution of the copper solution and the production of a higher grade of copper solution.

Crusher, screen, roll, and primary table equipment have been added to the plant to make possible the handling of mixed run-of-mine ores. A roasting furnace and SO_2-leaching drum are also being installed at the plant, so that the cheaper sulphur dioxide may be tried on ores which contain a high percentage of acid-soluble gangue.

Mine Operators of Note

James MacNaughton

VISITING Institute members in the Michigan Copper country were impressed by several interesting facts, and among them was the realization that of all the influences which have directly affected the upbuilding of that section perhaps the greatest is the Calumet & Hecla Mining Co.—the largest operating company in the district. The mines, mills and smelter operated by the C. & H. (no one ever speaks of the company by its full title) all show the influence of a guiding spirit; the effect is that of a well-balanced piece of machinery, each unit working with precision under the touch of a master engineer. Large-scale operations require big-thinking, able men who are learned in the school of experience and who combine with their acquired knowledge of affairs a keen understanding of human nature. Such a man is James MacNaughton, vice-president and general manager of the Calumet & Hecla Mining Co., and, in addition, general manager of all the subsidiary companies of the parent organization. Born in Canada in 1864, of Scotch parents, young MacNaughton, after attending high school, entered the University of Michigan, where he studied civil engineering. There were no frills in those days, and his education was obtained by dint of hard work which brought out those admirable qualities that Mr. MacNaughton so well displays in his management of affairs today. He played football, and, as with everything else, successfully. It is the remembrance of those early days that has produced the enthusiasm and interest which he shows in the sports of the copper district and in the excellent school system that stands second to none in the country. It is quite probable that Mr. MacNaughton would have attended the Michigan School of Mines had that institution been established at the time he entered college, but it was not until 1885 that this excellent college—now the Michigan College of Mines—was founded. However, Mr. MacNaughton has always displayed a keen interest in the school at Houghton, and much of the prestige enjoyed by its graduates and the school itself is due to his advice and counsel. Many of the able members of his staff are "M. C. M." men, and frequently he consents to address the student body on matters concerning their chosen profession. As with many others, Mr. MacNaughton's course in civil engineering was merely the stepping stone to mining, and upon entering the employ of the Calumet & Hecla company his advance was rapid. He was, and is, big, generous, intelligent and resourceful, and above all has that deep insight into human nature which has come to be recognized as prerequisite in the modern administrator and which is the biggest asset of the successful man. One has only to study the record of the Calumet & Hecla to note what that organization has accomplished in the development of a community spirit in the copper country, its methods of handling men, the bonus and pension systems, free insurance for its workmen, and other examples of welfare work, to realize that such undertakings must require the supervisory services of a man of broad mental measurement. Certainly the copper country and the Calumet & Hecla are to be congratulated on "Jim" MacNaughton. He is a member of the American Institute of Mining and Metallurgical Engineers, of the Lake Superior Mining Institute and of the Institution of Mining and Metallurgy (London). He was, and is, keenly interested in politics, having been a delegate to the Republican National Convention at St. Louis in 1896, and also a delegate-at-large from Michigan to the Republican National Convention in 1908. From this we may assume that politics, contrary to the opinions expressed by many engineers, was considered by James MacNaughton to be a good game, for if it were not he would have had little to do with it. His devotion to the welfare of the industrial communities of Michigan should prove an inspiration to the engineering profession.

JAMES MacNAUGHTON

Despite Mr. MacNaughton's many interests he finds time to give consideration to good roads and to the programs for other public improvements which his section of northern Michigan has so well put into practice. He is a member of the University Club of Chicago, the Tennis and Racquet Club of Boston and the Links Club of New York.

The Railroad Situation

By R. S. McBride
Engineering Representative, Washington, D. C.

NEVER within any similar short period have three such far-reaching steps been taken in the American railroad industry as have been made during the last few weeks. The railroad wage award has doubtless affected more workers and influenced wages in a larger total sum than any other similar award in history. Certainly at no time has a regulating authority ever before in one single order created rate increases amounting to a billion and a half dollars per year.

The discharge of nearly 10 per cent of its workers by one of the large eastern railway systems is almost correspondingly drastic in its significance. Apparently labor as well as the rest of the community understands this last event to mean that slothful service in return for reasonable wage is no longer going to be tolerated. Persistent report of appreciable unemployment throughout the country indicates that the railway labor situation is not alone affected thus. The limited ability of the transportation systems to move materials needed for construction and industrial-plant operation accounts in part for the appreciable shortage of employment, but there seems to be at present a general feeling that a decision on the part of management officials is even more potent an influence to this end.

Almost without exception those who have commented upon the railway labor situation believe that increasing efficiency in performance of labor will certainly result from recent events. The increase in wage will render willing workers more content and better disposed toward their employment; the executive policy referred to will mean the elimination of the unwilling employee. It is, therefore, not too much to expect an increase in operating efficiency during the coming months which will perhaps amount to as much as $100,000,000 per year in benefit to the railway systems.

The Accounting Significance

The Interstate Commerce Commission is specifically instructed by Congress in the transportation act of 1920 to regard 5½ per cent as a fair return upon railway values plus an allowance of not to exceed one-half of 1 per cent, this to be fixed in the judgment of the Commission as an allowance for improvements, betterments, or equipment which are chargeable to capital account. The recent decision, therefore, is based upon these terms and is intended to provide a net operating income to the utilities of 6 per cent upon a value of approximately ninteen billion dollars.

There has been very general favorable comment upon this finding. By some it is regarded purely as a reasonable return for current operation of these public corporations. Others, however, believe that the Interstate Commerce Commission took an even more advanced view. Those who hold this latter opinion say that the Commission, realizing that earlier returns had been wholly inadequate, intended to fix the returns at a point which would permit the utilities to catch up on their deferred maintenance work. Of course, if this is the fact it makes little difference whether it is considered to be a recognition of need for adjustment of past returns, which were too low, or it be assumed that these items were deferred from earlier periods, when they were properly chargeable to operating expense, and now, therefore, are properly included in the coming years' operating expenses. The economic significance is the same, though the accounting and legal meanings may be quite different. No matter which one of the several views mentioned is held, it is almost always found that railway students regard the rate increase and the present situation most encouraging to industries as a whole. Great improvement in transportation facilities and service are generally anticipated. If they are realized, all industrial activity will quickly profit.

The effect of the railway situation upon cost of living by and large to the community is too complicated to forecast for the immediate future. However, even though the ultimate user finds the whole increase passed on to him in the prices of commodities which he buys, he can feel some degree of reassurance in the fact that facilities are being provided whereby *future* transportation of *similar* commodities can be more effectively accomplished. Taking the present coal situation as a striking example of the benefit of this, it is evident that the user of this commodity will ultimately profit greatly by paying the higher transportation charges. The coal situation is as follows:

Factors Affecting Coal Prices

The high prices of coal, both bituminous and anthracite, have been in large measure, if not wholly, the result of two factors: (1) a slight under-supply, and (2) an excessive panic with respect to shortage. It is well known that even a very small percentage of demand above supply creates large percentage increase in prices. This has been all too evident in the coal situation recently. Spot coal prices have been extremely high, and wholesalers handling coal on contract from the mines for current sales not under contract naturally have taken advantage of the current spot market. The margin between the spot market and the contract market has thus been very great, and hence the temptation to break contracts has been most unusual. Doubtless the violation of contracts by producers of coal has, therefore, been unprecedented in amount recently; and what should have been contract coal became spot coal subject to all the fluctuations and competitive demand. As a result almost everyone who had to buy during recent months has been compelled to pay a high price.

The fundamental cause of the entire coal shortage has, however, been the inability to provide cars for the prompt movement of coal, which coal could be produced in quantity far in excess of current demand were cars available. Let us assume that a reasonable policy of improved coal-handling facilities is adopted and that part of the billion dollars per year increase in railway net income is expended for this needed equipment. In a single year the purchasers of coal should be relieved of all fear of coal shortages and excessive prices similar to those now confronting them.

Krupps After Russian Iron Ore

A Berlin correspondent of *The Iron Age* reports that Krupp prospectors are investigating the large fields of magnetic iron ore located by the late Professor Leydt at Kursk, in South Central Russia. These so-far unworked ore fields, according to Leydt and two Swedish engineers who have checked his observations, extend in parallel bands for a distance of 180 kilometers, and are among the greatest deposits of magnetic ore in the world.

BY THE WAY

More Points on Technical Writing

During the course of a dinner at which the members of the Bureau of Mines staff gathered recently, John L. Cochrane, the director of the Bureau's publicity division, was asked to discuss the following topic: "If you had the power to develop a writer of technical matter, what course would you adopt?" A portion of Mr. Cochrane's reply is as follows:

First of all I would catch him young and feed him on alphabetical crackers to insure that he became a man of letters. Then I would give him a careful diet of raw bull to strengthen his nerve—the one most essential thing to technical writing.

I would teach him that the other man in the same line of work is always wrong: can't possibly ever be right. (You could prove that through the fact that he indulges in technical writing.) I would attempt to teach him that clearness is fatal to any technical writer. I would drill into him daily, "Kid, obscure your meaning, and you will become famous." Then it will give you a convenient loophole to escape if you ever have to. If anyone attacks you then you can very easily call him "another," because in reality you, yourself, if honest with yourself, as you sometimes should be, do not quite know what you mean yourself. In that way, you'll have it on him, even though he won't know. Anyway, a conscience is sometimes convenient, even to a technical man.

If you want to throw a few additional smoke screens into the article, which is always desirable, puncture it with stars, asterisks, crosses and other mysterious marks, the harder to understand the better. Then have a number of footnotes that correspond, but mean nothing. Be sure that you refer as authority to some society that you defy him to find out anything about, such as "Flannigan in the May, 1852, proceedings of Erin-go-Bragh." Make it as difficult as possible for your reader to follow; that's genius.

And here is some advice that ought to be italicized: If you disagree with another author and want to pillorize him before your technical disciple (you really care about nobody else), put in an extra footnote and refer to him as the authority for something you know is wrong. If done naively, it has the effect of T.N.T. The ordinary effort of the layman in such matters is childish in comparison.

Always quarrel with your scientific brother in a dignified manner. Begin with, "May I have the honor to explain." The beauty about such open, gentlemanly controversy is that you may quite as often be as near right or as near wrong as the other fellow. I stress this, because I feel it is an important accomplishment in technical writing. How fully equipped is a technical writer who can tell a man he is a damn fool in language that leaves him flattered!

Then by all means, if you are a Government technical employee, have at least three or four other technical employees read critically your manuscript before it is ready for the printed page. The beauty here lies in the fact that when they get through with it all such annoying superfluities as personality of the author have disappeared. Don't bother about the lack of capabilities of those who read the manuscript. The chances are that unconsciously they may improve it, as in the case of the hitherto homely person who developed into a handsome man after a horse had stepped on his face. And during this process of critique, if you ever wince when they put the hot iron into your soul, you will never make a technical writer, and therefore there may be some hope for you.

And please remember as a technical writer that nothing is ever perfect. If you are in a great art gallery and the simple-minded folk are admiring the Venus de Milo in their crude, enthusiastic way, remember your training and take issue with the work. Suggest that it is not true to nature because it does not have one or two warts on the feet. Point out that there are no varicose veins on the leg.

I almost forgot to say that brevity, being the soul of wit, has no place in a technical article.

If the dream child that I have instructed (and he is no synthetic kid) can follow me, it may be said of him with apologies to Kipling "Then you'll be a man, my son; you'll be a man."

Typewritten in the Clouds

P. R. Coldren, editor in charge of editorials and mining for the *Joplin Globe*, believes he is the first newspaper man in the country to write an editorial in an aeroplane. He made his first flight on Friday, Aug. 13, just to show his scorn of superstition, and in order to feel perfectly at home, took along a small portable typewriter, tied securely to his knees. The editorial he wrote he admits was not literature, but he is going to claim that it is the first written on a typewriter in an aeroplane, until he learns differently. Mr. Coldren is an honorary member of the American Zinc Institute and had a place on the program at the recent annual meeting in Chicago.

Engineer and Inventor

Pedro Zamora, the Mexican bandit, recently captured Charles Hoyle, of Esperanza, Ltd., as recounted in the daily press, whereupon a certain New York paper stated, "Hoyle is a nephew of the American inventor, John Hays Hammond." What's the use of being an engineer, after all, and famous (so we think) at that?

Rolling Stones

That mining need not be an ephemeral occupation is indicated by the records of a few old-timers in the Globe district in Arizona. Sam Richmond, who worked the first silver claim in Richmond Basin about forty years ago, is still working a claim there at the age of seventy-seven and recently received $200 from a single sackful of silver ore shipped by him. Fred Ilefty, also seventy-seven years old, has lived at McMillen for forty-three years, and Charles Newton, caretaker at the old McMillen mine, has been in the camp for over forty years, though it has long been practically deserted.

A Classic Allusion

"On one occasion in 1849, for instance," says Hittel in his "History of California," "when William B. Almond was trying a trivial case in San Francisco, the attorney for the plaintiff, in what he considered a sudden burst of inspiration, called his opponent an oscillating Tarquin. 'A what?' exclaimed the judge in a stentorian voice. 'An oscillating Tarquin, Your Honor.' At this the judge, who was entirely unacquainted with Tarquin and had probably never before heard the word 'oscillating,' removed his feet from the table in front of him; and, leaning forward and pointing his index finger toward the offending disciple of Blackstone, he ejaculated in a voice of thunder, 'If this Honorable Court knows herself, and she thinks she do, that remark is an insult to this Honorable Court. You are fined two ounces and stand committed till you down with the dust.' 'But, Your Honor—' remonstrated the attorney. 'Silence, sir,' roared the judge, 'this Honorable Court won't tolerate 'cussing' and never goes back on her decisions.' It is almost needless to add that the fine was paid and the attorney more careful of classical allusions for the future."

CONSULTATION

The Future of Barytes

"In your Aug. 7 issue of the *Engineering and Mining Journal*, first article, the statement is made that the demand for barytes is increasing and its future is excellent. I would be glad to know why."

The demand for barytes is dependent upon its useful properties. There are three major uses for this material, which, in order of importance, are, in the manufacture of lithopone, as ground barytes (a white pigment, or base for paints), and in the manufacture of barium chemicals. Barytes has a wide variety of important applications that are continually being expanded. The greatest consumption is absorbed by the growing lithopone industry in the United States, whereby barytes and zinc are chemically and physically treated to form a valuable pigment (see July 17 issue of *Engineering and Mining Journal*.) It is the great demand for paint in the United States in connection with building and other construction which accounts for the present pressure to produce as much barytes as possible. The demand for barytes at the present time is larger than the supply, a condition that shows no indication of being mitigated for some time unless unexpected shipments of crude barytes from abroad should occur. It is essentially a producers' market.

The critical shortage of barytes is directly the result of the almost complete curtailment of imports of this material from Germany, where most of the foreign barytes formerly coming to the United States was produced. In previous years 25,000 to 30,000 short tons was imported annually. In 1916, 1917, and 1918 the imports totaled only twenty-three tons. Under these circumstances the domestic resources of barytes were called upon to fill the void left by decreased imports, with the result that the price of the product gradually increased. In previous years $3.50 per ton was considered a fair price for crude barytes. Present prices for the same class of material are between $10 and $12 per ton, an advance of about 250 per cent.

The attempt to replace the shortage of foreign ore by greater activities in the domestic barytes fields was handicapped by the smallness and frequently the isolation of the deposits. Ready accessibility is so lacking in some barytes mines that only with a high price of barytes —such as is ruling at the present time—can these operations continue. However, inaccessibility today may be accessibility tomorrow. The chief source—also the chief market—for barytes is in the East, and those mines in the Appalachians conveniently located as to markets are in for a prosperous period. The only dark outlook on the barytes horizon is the probability of the resumption of imports from Germany. There is little doubt but what Germany will be anxious to ship this material to the United States and furnish competition along the Atlantic seaboard which it will be difficult to meet under existing tariff regulations. The large deposits of Germany can be mined cheaply and the ad valorem duty of 15 per cent is a small protection to the industry. However, the possibility of Germany resuming the export trade quickly is not as probable as it may seem. Many difficulties will have to be surmounted before the readily available shipping facilities which that nation was accustomed to have before the war are again at its disposal. Furthermore, labor and political troubles have not been entirely eliminated. The importation of German barytes is still an uncertain element in the situation. Then there is the possibility, which ought not to be overlooked, that higher tariffs may be imposed to protect the American industry.

How long the present period of prosperity may continue no one can prophesy, but it seems certain that it will be for some time—until heavy importations from abroad are made. A much larger production than the present one could be easily absorbed, and search is being continually made for other deposits. A great part of the country's output is in the hands of the lithopone and other manufacturers, but these interests have been unable to fill their own requirements and are constantly in the market for the crude material. It is unlikely that the demand for this useful mineral will decrease in the next few years.

The following table summarizes the development of the industry in the ten years previous to 1919.

BARYTES PRODUCTION IN THE UNITED STATES, IMPORTS, AND AVERAGE PRICE 1910-1918

	Produced and Marketed in U. S.	Imports	Average Price
1910-1914 Average	43,389	28,800	$3.31
1915	108,547	2,504	3.51
1916	221,952	17	4.56
1917	206,888	6	5.66
1918	155,368	0	6.73

Cobalt-Nickel Smelters

"I would appreciate it very much if you would give me the names of some smelting companies that treat cobalt-nickel ores. There are some, I believe, in Eastern Canada and a few in England."

The following comprises a list of companies producing cobalt in North America:

	Location of Works	Post Office Address
Deloro Smelting & Refining Co., Ltd.	Deloro	Deloro, Ont.
Coniagas Reduction Co., Ltd.	Thorold	St. Catharines, Ont.
*Metals Chemical, Ltd.	Welland	Welland, Ont.
Standard Smelting & Refining Co., Ltd.	Chippawa	Niagara Falls, Ont.

In the United States, the Haynes Stellite Co. has a plant at Kokomo, Ind., in which it reduces cobalt ores mined at its property in Idaho. A former cobalt-nickel refinery at Fredericktown, Mo., was shut down in 1909. and to the best of our knowledge is not operating at the present time.

The domestic resources of nickel and cobalt are small. The nickel smelters and refineries in the United States, such as the International Nickel Co., work wholly on imported ore and matte coming from Canada or New Caledonia. The United States is not self-supporting in nickel requirements.

*Not operating.

THE PETROLEUM INDUSTRY

A Numerical Expression for Production-Decline Curves of Oil Wells

By Means of Mathematical Interpretation and Records of Formulæ Which Express Well Production It Is Possible To Avoid Bulky Data, and Curves May Be Conveniently Constructed as Desired

BY J. O. LEWIS* AND W. W. CUTLER, JR.†
Written for *Engineering and Mining Journal*‡

EXPERIENCE has shown that the production-decline curve follows an exponential equation of the type formula $y - a = k\ (x - b)^{-n}$. These curves have usually been recorded graphically on rectilinear or logarithmic co-ordinate paper. The recording of such curves by numerical rather than graphical expressions has certain features which are useful, particularly as thereby much data may be presented in condensed form. The method of deriving and recording numerical expressions for production-decline curves will be briefly outlined.

The production-decline curve shows the production of a well, tract, or field for successive periods, in terms of production. Thus for a well which produced during successive years 8,200, 4,900, 3,800, 2,450, 2,300, and 1,850 bbl., the production-decline curve would at successive equal horizontal intervals pass through points 8,200, 4,900, 3,800, 2,450, 2,300, and 1,850, respectively, on the vertical scale.

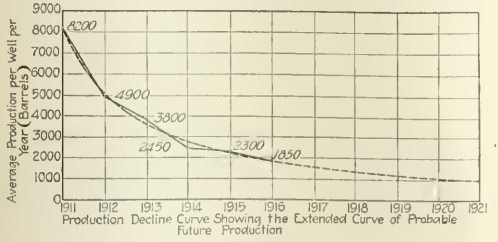


FIG. 1. PRODUCTION-DECLINE CURVE

Fig. 1, which illustrates a production-decline curve, is taken from p. 70 of the "Manual for the Oil & Gas Industry," for 1918, published by the Treasury Department. Such curves may be used to read past production and to estimate production in the future. Curves can be made by various methods for different fields or properties which usually reduce to hyperbolas when "ironed out." A collection of plotted curves is bulky and inconvenient to carry, whereas a simple numerical expression for each curve may easily be formed which will permit the reproduction of the curve when desired, and thus the curves for many fields may be carried on a single sheet of a notebook. The use of this method is confined to curves which closely follow a true hyperbola.

The method is as follows: Transfer the production-decline curve to logarithmic paper. Shift all points of the logarithmic curve the same number of units to the right or left until the curve approximates a straight line. To straighten always move the curve in the direction of its convex side. It may require several trials to determine the proper position of the curve.

In the accompanying illustration (Fig. 2) curves 1, 2, and 3 represent the same curve in different positions

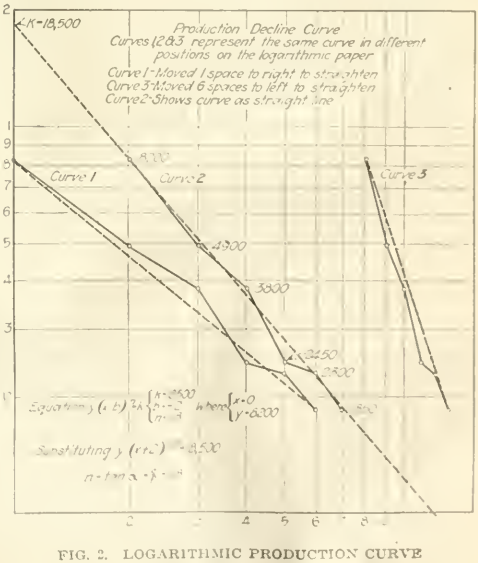

FIG. 2. LOGARITHMIC PRODUCTION CURVE

on logarithmic paper. Curve 1 was moved one unit to the right until it approached a straight line, as shown by Curve 2. Curve 3 was moved six units to the left until it occupied the position of Curve 2. A straight line can be drawn through Curve 2 so that it passes through or lies between all points of the curve and

*Chief petroleum technologist, Bureau of Mines.
†Petroleum technologist, Bureau of Mines.
‡Published by permission of the Director, Bureau of Mines.

represents the mean average of the curve. This straight line represents the "ironed-out" curve and may be extended downward to read estimated future production, or may be extended upward in case the past production is not known.

Two points of a straight line on logarithmic paper establish a curve, and thus by recording the co-ordinates of two points on the "ironed-out," straightened, logarithmic curve a numerical expression for the production-decline curve is obtained.

To show which part of the curve represents the actual productive life of the wells choose the two points on the "ironed-out" curve where it crosses the beginning and the end of the period of production.

Thus in the accompanying illustration the record of these two points establishes that part of the curve representing the period of actual production:

$Y = 8200$ $\quad Y = 1850$
$X = 2$ $\quad X = 7$

(y = production in barrels, x = relative time in years; thus 2 = 1 actual time and 7 = 6 actual time).

These two points may be plotted on logarithmic paper and joined by a straight line when it is desired to reproduce the curve.

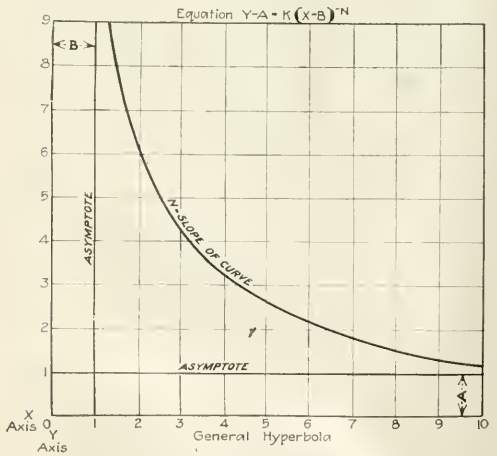

FIG. 3. HYPERBOLIC PRODUCTION CURVE

Fig. 3 shows the type of hyperbola which the production-decline curve approaches. The type equation for this curve is $Y - a = K\ (x - b)^{-n}$ where a and b are the distances of the asymptotes from the X and Y axes respectively, n the slope of the curve, and K, a constant.

It is to be noted that this type of hyperbolic curve is the curve for expanding gases. The production of an oil well generally represents the work accomplished by the expansion of the compressed natural gas associated with the oil in the sands. The production of oil in fields where recovery is caused mainly by expanding gases is essentially a problem in thermodynamics.

A production-decline curve begins theoretically at infinity production and zero time, but actually at some definite production, and the Y axis may be moved to pass through this point, thus throwing the asymptote to the left of the Y axis and making b a minus quantity. All points to the left of the Y axis thus become minus quantities, and hence imaginary so far as the well or wells are concerned. Time for the particular curve begins in the Y axis; thus in Curve 2, Fig. 2, 2 on the time scale becomes the first year, 3 the second year, and 7 the sixth year.

The production curve may be theoretically considered as ending at zero production and at infinity time. Thus a becomes zero and the asymptote coincides with the X axis. Actually the curve terminates where production ceases for whatever reason—usually where it has reached, or is estimated will reach, the economic minimum of production. n, the slope of the curve, may be determined by plotting the production decline curve as a stright line on logarithmic paper and then scaling the tangent of the slope as in Fig. 2, where tan

$$\alpha = \frac{e}{f} = 1.18.$$

K is a constant and may be determined graphically from the straightened logarithmic curve, as it is the value of Y where the curve crosses the left side of the logarithmic paper at one on the abscissa from the asymptote. In Fig. 2, $K = 18{,}500$. K may be determined mathematically by substituting the already determined values of n, b, and x and y for any point in the equation:

$$y - a = k\ (x - b)^{-n} \text{ where } a = o,\ y = \frac{k}{(x - b)^n} \text{ or}$$

$$y(x - b)^n = k.$$

In Fig. 2 n was recorded as 1.18. The highest recorded production was 8,200, which lies on the straightened logarithmic curve where the abscissa equals 2. b, therefore, for this curve, is —2. K, which equals value of y where curve lies at abscissa 1, equals 18,500.

The formula for this curve thus becomes

$$y(x - b)^n = K, \text{ or } Y(x + 2)^{1.18} = 18{,}500.$$

Where $x = o$, $Y = 8{,}200$.

When the value of n is high, and it sometimes approaches 20, the determination of n must be very exact, and is difficult to obtain. A small error in the value of n introduces a large error in the calculation.

It is, therefore, preferable to record the co-ordinates of two points of the curve instead of the equation.

New Oil Area in Colombia

Colombian engineers and geologists are investigating a reported new oil area in the southeastern part of Colombia and about thirty-five miles from a navigable affluent of the Amazon. Some drilling has already been done, and good results are claimed. So far, no foreign interests are in the field.

The attention of the American and British operators has recently been directed to the Pacific littoral south of Buena Ventura, where excellent oil indications and structure are reported. This formation is supposed to be a continuation of the horizons yielding high-grade oil, exploited in northwestern Peru and developed by shallow native operations at Santa Elena, in Ecuador.

The Union Oil Co. of California has reported that its first well in Mexico proves to be a 42,000-bbl. gusher, according to word received by the local office from Mexico. The well in a twelve-hour day is said to have delivered 20,891 bbl. through a pipe line for three miles and kept the pressure at 350 lb. in the line. Oil men on the ground, according to the report, estimated that if the oil was flowing into tanks that were closer the well would run as high as 80,000 bbl. a day.

NEWS FROM THE OIL FIELDS

Lost Soldier Field, in Wyoming, Shows Promise at Depth

From Our Special Correspondent

The Blair Oil Co. has completed its No. 22 well in the Lost Soldier field, flowing 600 bbl. daily from the fifth sand at 1,375 ft. Four other sands above this fifth sand were penetrated, each showing oil in commercial quantity. After being cased and deepened the flow increased to 1,500 bbl. This hole is of considerable importance, as it shows that the Lost Soldier field is of much greater importance at depth than was formerly believed.

Several wells have been brought in near Casper recently. The Iowa-Wyoming Oil Co. completed its No. 3 well in the Bolton Creek field, producing several hundred barrels of oil daily. The other wells are being drilled, and the location for a fourth has been made. The Chappell Oil Co. is also spudding in on land of the Victor-Wyoming Oil Co. In the Osage field a gusher was brought in at 1,320 ft. on land in which the Casper-Osage Oil Co. holds a one-half lease interest.

Considerable work is under way on the Mahoney dome, north of Rawlins. The Utah Refining Co. has struck a good oil showing at 2,100 ft. This has been cased off and the well deepened to the lower sand at about 2,400 ft.

The Midwest Refining Co. is drilling its first well in the Elk Basin field on Section 19-58-99. This well will be drilled to 2,500 ft. at least. Wells producing 50 bbl. daily have been brought in at 1,600 ft. in this field.

The Anglo-United Oil Co., Ltd., has a well 130 ft. deep to the top of a 50-ft. sand in the Dallas field, Lander County, producing about 50 bbl. of heavy oil daily. This is one of the shallowest wells in Wyoming. In contrast to this well oil has been struck in the General Petroleum Co.'s well on Sect. 17, Ferris field, 4,400 ft. deep. Two sands were passed through, but these gave no indication of being oil-bearing until drilling was stopped to permit casing to be set when the hole started to cave at the bottom.

Considerable drilling is being done on wildcat wells in the Muskrat field, thirty miles south of Shoshoni. It is stated that the Midwest Refining Co. has found a good showing of oil and gas at 1,380 ft. in this section.

Deep drilling in the Alkali Butte field, near Riverton, is being done by the Inland Oil & Refining Co. Its No. 2 well is over 2,780 ft. deep, and the first Wall Creek sand, it is expected, will be struck soon. The Cheno-Myrin-Midwest Companies' well in the northern part of the field is down 900 ft. This will also be a deep test. The Myrin Oil Co. will drill twenty wells to the proved shallow sand of this field. These wells will be on property of the Cheno Oil Co. recently taken over on a working basis by the Myrin Co. There are already eight producing wells on this land. The Carter Oil Co. will extract casinghead gas from its gas well, which came in making 35,000,000 ft. of wet gas.

High-Grade Well Rekindles Oil Interest in Montana

From Our Special Correspondent

Cleaning of a shale cave-in at the Frantz No. 2 well in the Cat Creek field, in Fergus County, in the central part of Montana, resulted in the well blowing itself in with a production of 1,200 bbl. of high-grade oil daily. This output at one time showed a flush of 1,800 bbl. The oil runs as high as 50 per cent gasoline, and, for the volume of high-grade flow, the well, it is claimed, will stand alone in the country. Up to the time the well had been cleaned it had an output of about 350 bbl. A pipe line has been constructed from the well to Winnet, about fourteen miles distant, on a branch line of the Chicago, Milwaukee & St. Paul Ry., capable of carrying about 1,200 bbl. daily. This well has kindled anew the oil excitement in Montana, and about 100 drilling rigs are in operation throughout the state.

Oil Struck Within Arctic Circle

From Our Special Correspondent

The Imperial Oil Co. makes the announcement that after two years' exploration and drilling, oil has been struck at Fort Norman, just within the Arctic Circle, north of Great Slave Lake and close to the Mackenzie River. Oil was found at a depth of 480 ft. with a flow of 10 bbl. per day. The company has eleven rigs operating at various points in Western Canada, carrying out the program as announced at the annual meeting last February, comprising the exploration of all prospective oil areas in the country.

Few people appreciate the immensity of this undertaking. Fort Norman is 1,000 miles north of the nearest railway, and the complete drilling outfit had to be taken by water down the Peace and Slave Rivers, through Great Slave Lake and down the Mackenzie River. Fur traders in those far posts receive mail only once a year. The crew and outfit started down the river early in the summer of 1919, but on account of low water had to winter at Great Slave Lake, the journey being completed this year.

At Czar, Alberta, where one well is already 2,000 ft. down, it is thought the prospects of striking oil between that point and 2,500 ft. are good.

1,000-bbl. Gusher in Kentucky Kills the Driller

From Our Special Correspondent

A gusher which flowed 250 bbl. the first four hours was brought in Aug. 18 on the S. A. Kelly farm near Bowling Green, Warren County, Ky. It was completed at 484 ft. and is estimated good for 1,000 bbl. a day. Fred Fulton, sixty years old, driller, was burned to death when the well came in. Other drillers succumbed temporarily to the gas fumes from the well.

A well was completed Aug. 20 on the farm of General W. L. Sibert, offsetting the Tarrants wells near Bowling Green. Oil was thrown 60 ft. into the air and a continuous stream shot skyward for forty-five minutes before it was put under control. The initial flow was 100 bbl. an hour.

The Leon Producing Co. recently brought in a 500-bbl. well on the Davenport lease in Warren County. The well was standing 700 feet in oil when it was shot. Location is being staked out for No. 2, on which work will begin as soon as No. 1 is put on the pump.

Interest in oil is growing in Cumberland County, eastern Kentucky. The Southern Oil & Refining Co. brought in what is described as a "real good well" on the Russ Gilbert farm, near Bakerton. A strong stream has been flowing from the well to the Cumberland River, a half mile distant. It is located a short distance from the "Old English" well, drilled in 1866, and which produced 1,200 bbl. daily. No. 2 of the Carter Oil Co. is reported from Menifee County on the John Powers lease, rated at 100 bbl. Oil operators report this to be a promising field. The Turtle Oil & Gas Co. is drilling south of Paintsville, Harlan County, and expects to be in the sand soon.

Colorado Wildcat Strikes Oil

From Our Special Correspondent

It is reported that the Nee-No-She Oil Co. has struck oil at 2,550 ft. in its well in Sect. 18, T.20S., R.46W. in Kiowa County, Col. The well has not yet been bailed, so it is impossible to state what its possible production will be. Naturally, the discovery of oil in a wildcat well of this character has created great excitement locally, and leases are selling at high figures.

The Producers & Refiners Corporation has secured leases on a block of 8,000 acres in Routt County. This area covers, it is believed, two possible oil bearing structures. The first well will be drilled near the center of the southeast one-quarter of Sect. 25, [illegible]. Machinery and building material are being hauled in from Hayden, the nearest railway station, about twenty miles southwest. Several years ago gas was found at shallow depth in the section.

COURT DECISIONS IN MINING CASES

By Wellington Gustin

Deister Machine Co. Patents Held Valid

U. S. Circuit Court of Appeals Rules Claim Not Void, Though Not Included in Co-pending Application

The Circuit Court of Appeals of the United States, Seventh Circuit, recently affirmed the judgment of the District Court holding the patent of the Deister Machine Co. for improvements in concentrator tables valid and infringed by the Deister Concentrator Co. In the appeal the Concentrator company attacked the decree of the District Court upholding certain claims in three patents covering improvements in concentrating tables, asserting that all the patents were invalid and that its structures do not infringe any of the claims involved. It also claimed that as to the first two patents issued there had been double patenting.

Speaking for the court, Judge Evans says that various types of concentrating tables were well known to the trade in 1912. Some were covered by patents, and certain factors in the successful operation of all concentrating tables were well recognized at that date. Among the well-known types were the Gilpin County bumping table, the Gold Coast of Africa table, the Overstrom table, and the Butchart bent-riffle table. From these types, as well as from various patents, it was found that riffles were old, resistance planes were old, and the reciprocal longitudinal movement and the tipping or tilting of the table were all well known, and had been commonly practiced for many years prior to the appearance of the Deister Machine Co.'s tables.

The inventors of this company's table were far from being pioneers in the art. However, they conceived and worked out what they claimed was an improvement over other tables. A new element was added to these older ones, which, co-operating with them, doubled, it was claimed, the capacity of the table, without increasing the loss in the tailings, secured a cleaner and greater quantity of ore values, and reduced the item of labor cost. The court found some evidence to support these assertions. That an increased capacity without loss in the tailings resulted was not seriously disputed.

The Machine company's Claim 4 of Patent 1,040,164, for concentrating table, one element of which is a plateau having its surface above, but substantially parallel with, the general surface of the table, and Claim 1 of Patent 1,040,165, having the same element, were held valid and infringed, though the plateau of the Concentrator company's table was not precisely parallel with the surface of the table.

Defining the terms "substantially parallel," the court says the patentee was seeking apparently to prevent congestion of material on the dam or incline connecting the plateau with the main surface of the table. If the plateau was approximately parallel, the material leaving the apex of the dam or incline would move more rapidly than it traveled while ascending the incline, with the result that the minerals would spread out and the wash water would remove the slime or sand that was carried up the incline by the values. Thus, "substantially parallel" as used here is a relative term, and not synonymous with exactly or precisely parallel. And defendant's plateau was sufficiently parallel, said the court, to constitute infringement of the patent.

Applications by the same person for the two above-numbered patents were co-pending in the U. S. Patent Office, and the patents were issued on the same day. The defendant contended the claim of the latter was void because it was only a broader or more generic claim and might have been joined with the claims of the first patent. The court ruled against the contention that there had been a double patenting, and said it could not be assumed that the issuance of the one with the smaller number preceded the issuance of the other.

Claims 1, 4 and 5 of the Deister patent, No. 1,088,685, for a concentrating table having a plurality of plateaus, with the front edge of the final plateau forming the mineral-discharge edge, were held valid and infringed, though defendant's final plateau was rounded near the edge. But, the patentee having specified as one element of his combination a plurality of plateaus, with the front edge of the final plateau forming the mineral-discharge edge, he was limited to a table in which the front edge of the final plateau formed the mineral-discharge edge, though such element was valueless.

Thomas Et Al Guilty of Contempt in South Butte Suit

In the contempt proceedings of the South Butte Mining Co. against Thomas B. Thomas, in which the Circuit Court of Appeals, Ninth Circuit, held Thomas and others in contempt for attempting to obtain a patent from the Land Department to the Resurrection lode claim, the Supreme Court of the United States has denied the petition of Thomas for a writ of certiorari to the Court of Appeals, making the judgment of that court conclusive in holding them in contempt.

Arizona Supreme Court Defines Private Nuisance Law

Rules as to Conditions Under Which Mines Are Liable for Noise, Smoke, and Offensive Odors

Judgment against the Arizona Hercules Copper Company, in its condemnation proceedings against the Methodist Church at Ray, and the Ray Consolidated Mining Company, has been affirmed in the Supreme Court of Arizona.

In its opinion the court says that a mine had the right to construct ore bins at the mouth of its shaft on its own property, and the fact that they were in close proximity to a church, and that in their reasonable use the noise therefrom disturbed public worship or other functions of the church, and thereby diminished the value of the church's property, gave the church no right of action for damages.

And where a mine condemns property and lays tracks for its private use, the principles applied to common carriers when acting in their private capacity should be adapted in fixing the liability of the mine owner for damages to private property.

Further, a mine which condemns a small strip of land for a track and in the general plan of construction intends to construct several other tracks on a highway, tracks being for the private use of the mine, the rule of consequential damages should be extended to all the tracks and their operation, and the land owner is entitled to damages by reason of noise, smoke, cinders, vibration, or other nuisance or injury; the improvements amounting to a private nuisance under the Arizona law.

Judgment Against Brant Independent Mining Co. Reversed

In another action arising out of the foreclosure proceedings against the Brant Independent Mining Co., the U. S. Circuit Court of Appeals has again reversed the judgment of the District Court for Colorado, which had awarded to the trustee in the mortgage a deficiency judgment in the sum of $108,373 against the mining company.

The judgment was the difference between the amount found due upon the bonds issued by the mining company, with interest and costs, less the amount received from the sale of the mortgage property. The Court of Appeals ruled that a trustee in a corporation mortgage securing bonds, on foreclosure of the mortgage, is not entitled as such trustee to recover a deficiency judgment for the amount found due on the bonds over and above the proceeds of the sale, unless such right is given him by the mortgage.

SOCIETIES, ADDRESSES, AND REPORTS

Bisbee To Remain American, If Possible, Says Dowell

Large Number of Mexicans on Sacramento Hill a Temporary Condition —Operations Must Continue

"Present Plans and Plans for the Future in Company Operation," was the subject of a recent talk at Bisbee, Ariz., by G. H. Dowell, manager of the Copper Queen branch of the Phelps Dodge Corporation. Mr. Dowell made the first authoritative remarks that have been heard there in some time, as to the views of the company on the labor situation and the prospect for the future in the matter of ore reserves. He said in part:

"The company that I represent depends largely on the income from this property for the development of other properties. As you all know, operations have been restricted during the last year or so on account of the inability of the company to market copper, but all look forward to a time when we shall be able to market all the copper we can produce.

"In addition to normal mining operations, there has been the work on Sacramento Hill. The company has invested there already about $5,000,000 and before the project is ready for operation will have invested more than $8,000,000. I remember that a speaker here some time ago remarked that Sacramento Hill is an illustration of the saying that faith will move mountains, but I have found that it takes something more than faith to move Sacramento Hill. The project is really just begun. We have moved, up to date, about 10,000,000 tons, but before the project is completed shall have to move more than 80,000,000 tons.

"The companies and the community here, as elsewhere, have the problem of labor supply. We have had and have now all the labor we need under present production conditions. I think we shall have enough when the time comes to attain our normal output of about eight millions pounds of copper a month.

"It has been the policy of the company to employ English-speaking men under ground. About 80 per cent of those now working under ground are Americans. I hope the company may be able to continue this policy. On Sacramento Hill the company has been forced to employ much Mexican labor, but you should understand that this is only a temporary condition. When the Sacramento Hill project has been completed, most of these will be laid off.

"The problem of obtaining American labor devolves on three conditions. The wage scale is the first. This camp has the reputation of paying as high or higher than other places. The company desires to maintain this reputation. To a certain extent, however, the company's hands are tied. It would be destructive to depart very far from the scale of wages paid for similar labor in other camps.

"The second point in obtaining American labor is the treatment of men on the job. We are trying to bring about a system whereby a man gets a square deal on the job. Under such conditions men become and continue contented, and will want to stay.

"The third point is community environment. There is no other locality in the Southwest that can compare with Bisbee in climate and public schools. We have done what we can in the matter of providing recreation. Men who are working hard must have recreation. We have endeavored to assist in the matter of housing. It has been the policy of the company to employ married men and to enable them to provide a home. We have encouraged home building, but in the last few years have been hampered by the war and high costs in this respect. Many employees provide their own homes through the Building and Loan Association. Married men, as a rule, are the most dependable and efficient and lose less time on the job.

"Another matter of importance is that of community spirit. Men who come into this camp must be made to feel that they are one of us. It makes no difference what occupation a man is in if he is an honest man earning an honest living.

"We hope to maintain our policy of employing Americans in this camp. It would be disastrous to have to shut down the mines in order to carry out this policy, and if the worst came to the worst we would employ what men we could get. This is a matter in which all are vitally interested. The company will carry out the policy of employing Americans to the fullest extent, but we need your assistance.

"With regard to the future of Bisbee, we have as much ore reserves now as we ever had. A large part of the earnings of this property will be put back into it."

The Société de Chrome has been having some difficulty in completing the installation on Yaté of the extensive hydro-metallurgical installations ordered from France. The local canaques, by advice of their religious leaders, are refusing to recognize the validity of sales of land regularly agreed on and ratified by current usage and decrees. The colonial government has been hesitating in face of the native opposition, writes *Le Bulletin du Commerce* of Nouméa, and work has been held up.

Stolen Platinum Recovered by Aid of Bureau of Standards

One of the noteworthy features in the industrial chemist's year of 1919-1920 has been the theft and subsequent recovery of large quantities of platinum laboratory utensils belonging to government and private laboratories. Two men were arrested last April while attempting to dispose of 280 troy ounces of platinum "sponge," the porous state of the metal. They had left small lots with two firms who, having circulars concerning various thefts, notified the authorities.

A general round-up was ordered and inventories of all Government platinum in various bureaus and in munitions manufacture were made.

Chemical analysis indicated that the seized supply had come neither from the New Jersey plant nor from the laboratory of the Bureau of Standards. The Government agents did not believe the story of one of the men that he and a friend had obtained the metal by placer mining about 100 miles north of Parry Sound, Ont., because there had never been any of the metal found there.

In its quality the captured consignment closely resembled the stocks at the War Department Plant at Nitro, W. Va., where the inventory showed there should be 5,000 ounces of sponge, and also the stock at a Government military plant at Jacksonville, Tenn. As some of the platinum at Nitro was known to contain a large percentage of palladium that in the satchel seemed to have come from Jacksonville.

One of the men, although he said that he was a Canadian, spoke with a marked Southern drawl, which suggested that he had been born not far from the Blue Ridge. He had a certain indolence of manner, which made the detectives think he would not work his imagination any more than he was compelled to do. Finally they located a Maxwell House in Nashville, Tenn. Government agents immediately were dispatched to this hotel and working from it discovered that one of the men arrested had been employed in the Old Hickory Powder Plant at Jacksonville. The investigation led from the powder plant to the Government reservation and resulted in the arrest of an assistant chemist who was implicated in a confession as the man who had abstracted the precious metal.

According to the chemical society's account, investigation disclosed that the chemist had abstracted the platinum sponge and in its place put mercury and ordinary moist dirt. The Government agents declared that the plan was to steal eighty-six cans, each containing twenty-five ounces of platinum, selling the metal for $100 an ounce.

Book Reviews

The Iron Ores of Lake Superior. By Crowell & Murray. Cloth; 6¼ x 9½; pp. 392; maps; Penton Publishing Co., Cleveland, Ohio.

This fourth edition includes revised and up-to-date information concerning the iron mines and ores of the Lake Superior district. Supplementing the data covered in the earlier editions, a chapter describing modern methods for mixing ores and figures showing average analyses and shipments since 1917 have been added. The book serves not only as a valuable reference work to the operators in that section but as a guide to the student of iron ore mining, as all of the chapters, with the exception of 9, 11, and 12, relate to some phase of mining or marketing iron ores. The arrangement of the data is such as to afford an excellent conception of the manner in which operations are carried on, and although a further elaboration on the subject of mining methods might be given, it is questionable if such is warranted in the preparation of a book that fulfils in such a complete manner the demand for information regarding operating mines.

Mining Directory of Minnesota for 1920. Compiled by the Minnesota School of Mines Experiment Station. Paper, 3⅜ x 6, pp. 153. Published by the University of Minnesota, Minneapolis, Minn.

Part I contains thirteen maps reproduced from the originals, prepared by the Mines Experiment Station. These show a general map of the iron ranges and separate maps of the Mesabi, Vermilion and Cuyuna ranges. Part II contains a list of all mines and properties that have shipped ore or are listed on the tax records as containing taxable ore. The name, location, and legal description of each are given. Part III includes a list of the various companies, together with the names of the officials, subsidiary companies and the properties with which they are associated. Part IV contains a list of the men associated with the mining industry of the state.

The compilation is issued in a most convenient form and will be found valuable to those in any way connected with the iron industry. Much of the excellent work of data collection which has been done in this section must be credited to the Experiment Station of the Minnesota School of Mines.

Earthwork and Its Cost. By Halbert Powers Gillette. Flexible binding, 4¾ x 7; illustrated; pp. 1350. McGraw-Hill Book Co., New York. Price $6.

The author of the book is too well known to need introduction to engineers, and the same thoroughness which has characterized his earlier works is noticeable in this handbook of earth excavation. In his preface and introduction, Mr. Gillette emphasizes the value to the engineer of the careful collecting and analyzing of cost data. The subsequent chapters of the book are proof sufficient that his contentions are well taken, for the data relating to each object leave little to be desired. Among the subjects covered are the following: Properties of earth; measurement, classification and cost estimating; boring and sounding; clearing and grubbing; loosening and shoveling earth; spreading, trimming, and rolling earth; haulage and earth removal and excavation, and the design and construction of embankments, earth dams, and similar works.

Technical Papers

Flotation in Australia—"Some Controlling Factors in Flotation," by Ralph D. Nevett, with subsequent discussion, occupies seventeen pages in the March *Proceedings* of the Australasian Institute of Mining and Metallurgy (Melbourne). The paper discusses the principal things which must be watched to secure satisfactory results in Australian selective flotation practice. 1. *Crushing.* The ideal feed is slime. 2 *Rate and Regularity of Feed.* It is absolutely necessary to have a regular flow of feed for the best results. A large storage tank should be provided, as an agitator or Dorr thickener. 3 *Density of Pulp* This is very important, and it is necessary to find what density will give the largest capacity and best metallurgical results; that density must be kept constant by frequent tests. 4. *Temperature.* The temperature must be watched closely, both in the SO_2 and the Palmer-Seale-Nevett processes. A difference of two or three deg. F. may have a marked effect. Some external heat is usually necessary: introduction of high-pressure steam into the pulp is the favorite method. 5. *Addition Agents.* These should be added generally as far ahead of the flotation machine as possible. 6. *Condition of Circuit Liquor.* The water must be clean. Other requirements are indefinite. A certain quantity of salts in solution seems to improve the results. The addition of elemental sulphur seems often to be beneficial in the P.-S.-N. process. Oil must be emulsified. 7. *Agitation.* "Agitation is beneficial in all methods of flotation of all classes of ore." An agitator ahead of the flotation machine is recommended. Sometimes bucket elevators provide sufficient agitation. 8. *Aëration* Air must be admitted in minute bubbles only, and under the agitating impellers. In the discussion following the reading of the paper Mr. Henderson said soluble salts could be present up to 8,000 gr. per imperial gallon. He was against the use of compressed air in any form. Mr. Nevett replied that compressed air increased capacity when treating slime. Mr. Chomley said primary slime (colloids) had a bad effect. Regularity of flow was very important, and underflow from a Dorr thickener was not as satisfactory as material from an agitating tank for this purpose. Mr. Read said he had no trouble using compressed air as long as it was properly atomized. A density of 45 per cent was found much better than one of 50 per cent in one instance. Mr. Wincey said best results were obtained on slime and that troubles from that source were probably due to dirty circuit water. Large amounts of salts in solution caused no trouble provided the SO_2 process was used.

Bolshevik Russia—Two very informative articles written in a most interesting manner are "Actualities in Industrial Russia of Today," in the August number of the *Compressed Air Magazine* (11 Broadway, New York City, 25c.) and "Bolshevism From the Inside," in the August *Atlantic Monthly* (Boston 9, Mass., 40c.). Is is plain that Russia is no place for a white man; it is a proper territory only for Reds.

Chrome—*The Colorado School of Mines Magazine* for July (Golden, Col., 25c.) publishes a seven-page article on the concentration of a Montana chrome ore, a "black sand" from Oregon, and a slag resulting from the production of ferrochromium in the electric furnace.

Chloride, Arizona—The history and prospects of the Chloride district are discussed in the August number of the *Arizona Mining Journal* (price 20c., Phœnix, Ariz.). Special mention is made of the Chloride Queen, the Dardanelles, the Molly Gibson-Chloride, and the Tuckahoe properties. The author admits that the district is dead, but thinks that modern metallurgy will solve the complex ore problem there if capable management and sane financing can be obtained.

Talc and Soapstone—In *Reports of Investigations* for July, Serial No. 2,142 (Department of the Interior, Washington, D. C.), R. B. Ladoo discusses talc and soapstone (five pages). The common physical and chemical tests which determine the grade of product are outlined and a plea is made for standardization so that definite and comparable price schedules can be formulated.

Federated Engineering Societies—Those of our readers who wish to know all about the organization and purpose of the Federated American Engineering Societies will be interested in a pamphlet entitled "Engineers Unite," which may be obtained free of charge from the McGraw-Hill Co., New York. It consists of reprints of news articles and editorials from the pages of the publications of the societies and the engineering and industrial journals.

Barite—"Barite Deposits in Upper East Tennessee" is the title of a six-page paper in Bulletin 23 of the Tennessee State Geological Survey (Nashville, Tenn.). Short references to known deposits are made.

MEN YOU SHOULD KNOW ABOUT

J. Leonard Replogle returned to the United States from Europe on Aug. 21.

W. E. Malm, of the Malm-Wolf Co., is in New York City on professional business.

J. Parke Channing, of New York, recently spent two weeks in the Michigan iron and copper fields.

M. H. Alworth, owner of several Mesabi Range operations, has completed an inspection of his properties.

Bailey Willis is working out the geology of the Washington magnesite deposits for the Northwest Magnesite Co.

Walter Harvey Weed has completed and reported on his examination of the Boston Montana Development Co. property.

Sir John Cadman, professor of mining at the University of Birmingham, England, recently resigned from that chair.

Roy J. Colony, instructor in geology in Columbia University, New York, is examining gold properties on Long Lake, Manitoba.

Eugene Dawson, mining engineer, will sail for South America on Sept. 7. He will examine mining properties in Brazil and Bolivia.

E. E. Hunter, general manager of the Hanna Ore Mining Co., has returned to Duluth, Minn., after a business trip to Cleveland, Ohio.

R. M. Overbeck, of the U. S. Geological Survey, has returned from a trip to South America where he has been on petroleum work.

A. K. Knickerbocker, superintendent for the Northern Minnesota Ore Co., is in charge of manganese operations for his company at Cushman, Ark.

F. A. Vestal, superintendent of the Bureau of Mines helium plant at Petrolia, Tex., has been paying a visit to the Washington offices of the bureau.

William H. Hubbard, Jr., of the Northport Smelting & Refining Co., is spending a few months at the affiliated works of the Pennsylvania Smelting Co., Pittsburgh, Pa.

Dwight E. Woodbridge and **George H. Rupp**, mining engineers, have completed a trip into the Hudson Bay country.

Lewis A. Levensaler, consulting mining engineer, 902 Hoge Building, Seattle, Wash., has gone to Nome and other Seward Peninsula points on examination work and will not return before October.

C. D. Young, general supervisor of stores, Pennsylvania R.R. system, Broad St. Station, Philadelphia, Pa., and vice-president of the American Society for Testing Materials, has been appointed as representative of that society on Engineering Council.

John D. Ryan, chairman of the board of directors of Anaconda Copper Mining Co., was in Butte recently inspecting the mining properties of his company and in conference with C. F. Kelley, president of the corporation.

J. Henderson, an English oil expert who was at Baku for a number of years looking after British oil interests, is in Canada on behalf of the Anglo-Persian Oil Co., which has secured oil leases in the neighborhood of Moncton, N. B.

E. J. Maney, general manager of the ore mines of the Shenango Furnace Co., has returned from a lake trip on one of the company's ore boats in company with **W. P. Snyder**, president, and **C. D. Dyer**, vice-president, of the company.

Harris & Ewing

ARTHUR E. WELLS

Arthur E. Wells, formerly assistant chief metallurgist and assistant supervisor of stations at the Salt Lake City station, has been made chief metallurgical engineer in charge of the new non-ferrous metallurgical division of the U. S. Bureau of Mines. Mr. Wells' headquarters will continue to be at Salt Lake City, Utah. He has been a member of A. I. M. E. since 1916.

D. D. Irvin, of Douglas, Ariz., has been appointed general superintendent of Moctezuma Copper Co. (the Phelps Dodge subsidiary) with headquarters at Nacozari, Sonora, Mex., where **H. T. Hamilton** continues as general manager.

Charles Camsell, who is leaving Vancouver to take up the duties of Deputy Minister of Mines at Ottawa, was given a farewell banquet on Aug. 18 by the British Columbia division of the Canadian Institute of Mining and Metallurgy.

Capt. M. L. Fay, one of the pioneer prospectors of the Lake Superior iron country, and who has for several years been on the Mesabi and Cuyuna ranges, has returned to the scenes of his earlier work on the Gogebic range to study the more recent developments of geologic interest

OBITUARY

Clyde M. Ney, a mining engineer thirty years old, employed at the Old Dominion mine, Miami, Ariz., was instantly killed on Aug. 2, last, by a blast on the mine's eighteenth level.

Jared Everett Gaylord, formerly manager of the Parrot Silver & Copper Co., a prominent copper producer of Butte, Mont., died at the age of seventy-six, in Bridgeport, Conn., on July 22 last. Mr. Gaylord was born at Liberty, Sullivan County, N. Y., Jan. 14, 1844, and went to Butte, Mont., in 1882, where he remained until his return in 1898. He took an active part in all that related to the development of Utah.

J. C. Gwillim, professor of mining in Queen's University, Kingston, Ont., from 1903 to 1919, died on Aug. 19 after a long illness in his fifty-second year. He was a graduate in mining engineering of McGill University. Professor Gwillim spent several summers exploring coal lands and oil properties of the Canadian Pacific Ry. In 1919 he explored the Peace River oil fields for the British Columbia government.

SOCIETY MEETINGS ANNOUNCED

Iron & Steel Institute, 28 Victoria St., London, S.W.1, will hold its fall meeting at Cardiff, Wales, on Sept. 21-24 next, in the rooms of the South Wales Institute of Engineers. G. C. Lloyd, secretary, is at the above address.

A First-Aid and Mine-Rescue Contest will be held Sept. 9, 10, and 11, in Denver, under the auspices of the U. S. Bureau of Mines in co-operation with the Rocky Mountain Coal Mining Institute, Colorado Metal Mining Association, and the Colorado Chapter of American Mining Congress, which will hold meetings in Denver on the dates mentioned.

The Sixth National Exposition of Chemical Industries at Grand Central Palace, New York City, Sept. 20-25, has just issued its revised official program. Among the cinema displays at 8 p.m. of particular interest to our readers are noted:

Sept. 21, (1) "The Story of Sulphuric Acid," one reel.

Sept. 23. (1) "Modern Coke and Gas Manufacture," three reels.
(2) "Story of Petroleum Oil," three reels.

Sept. 24. (2) "Building, Mining and Quarrying Machinery," two reels. (4) "Silver Mining," and (5) Gold Mining in Ontario," one reel each.

Sept 25. (1) "Manufacture of Asbestos," one reel.

THE MINING NEWS

LEADING EVENTS

WEEKLY RÉSUMÉ

Little of the spectacular has occurred recently: Calumet & Hecla has shut down three of its smaller subsidiaries. Lake ore carriers are to be allowed to raise their rates. An ore boat was sunk by collision on Lake Superior. The village of Kinney, Minn., has been awarded the decision in its case with the Cleveland-Cliffs Iron Co. In Missouri the St. Joseph Lead Co., in line with its practice in the past, has announced another stock dividend. In the Joplin district, a new boom is looked for in the section near the old Badger-Peacock camp, 12 miles away. In the Coeur d'Alenes, it has been announced that the Pine Creek railroad will be extended 6½ miles, thus benefiting several operators. The New Mexico Mining Association was recently organized.

St. Joseph Lead Co. To Resume Paying Stock Dividends

Will Cut Another Melon After Lapse of Several Years, Continuing Former Practice

After a hiatus of several years, the St. Joseph Lead Co. has decided to resume paying stock dividends. A 10-per cent stock dividend will be paid Sept. 20 on the 1,464,798 shares of outstanding stock. The authorized capital is 2,000,000 shares of $10 each, or $20,000,000 capital in gross, of which 535,202 shares are in the treasury. When the company was incorporated in 1864, the capital was $1,000,000 which was mainly issued to pay for about 900 acres of land and promotion expenses. The capital was increased in 1886 to $1,500,000 to take over the original Desloge Lead Co.'s lands at Bonne Terre in exchange for stock. The Doe Run Lead Co. was also absorbed in 1916 by an exchange of stock. Otherwise the present outstanding stock represents stock dividends that have been paid from time to time.

It was these occasional melons that for years kept the stock in the St. Louis market at such high prices that it only yielded 4 to 5 per cent on the market price and was the highest priced mining stock in the country. Up to 1912 the annual cash dividend rate for the previous twenty-seven years was only 6 per cent, whereas the stock ranged from $12 to $16 per share (par value $10) on the St. Louis market. That these stock dividends were more than justified is shown by the market putting a value of over $20,000,000 on the property, as millions have been put back into the property from earnings in past years.

A quarterly cash dividend of 50c. per share will also be paid on Sept. 9, which will bring the total cash dividends to nearly $22,000,000.

M. B. Dudley Interests Reopening Old Producers in Mohave County, Ariz.

Several Properties, Including C. O. D., I. X. L., Rural, Golden Star and Others, Equipped and Under Development — Many Features Being Worked Out for Group as Whole

BY S. FORD EATON

Activity in mining throughout Mohave County, Ariz., has evidenced a decided rejuvenation during the last few years. New operations are under way, old properties being reopened and mines forced to close down on account of wartime conditions are resuming work. Of the various projects brought into being none is more worthy of note than what is generally called the Dudley interests.

M. B. Dudley, a pioneer of Goldfield, Tonopah and Hilltop, Nev., and eastern associates are the operators and they are furnishing the capital. To Mr. Dudley, however, can rightfully be given credit for the conception, planning and general management of the various operations.

Early in 1917 Mr. Dudley's attention was first attracted to Mohave County in general and the Cerbat Range in particular. At that time he came into this section to examine the old Twins mine in the Cerbat district. With him, as consulting engineer, came W. W. Widdowson. The results of the examination were such that the Twins was purchased outright by the Dudley interests during the latter part of 1917. Since that time considerable development work has been done under the name of the Daisell Mining Co.

During 1918, under the direction of Mr. Widdowson, an extensive program of investigation and examination was carried on in the districts of Cerbat, Mineral Park and Stockton Hill. Early in 1919 four properties were purchased in the Mineral Park District. These were the Golden Star & Queen Bee, Rural & Buckeye, Toledo & Argo (now called Mineral Park Mines), and the Cherum Peak Silver.

In the Stockton Hills section, a three-months examination of the C. O. D. and I. X. L. was made. September, 1919, witnessed the purchase of the C. O. D. and early in 1920 the I. X. L. was taken over under option. Combined holdings aggregate over 100 claims. Separate corporations handle each property but with the exception of the Rural Mines, Inc., they are all more or less interlocking.

The financing of the various enterprises is said to be amply provided for. In a sense, all are closed corporations and there is no stock for sale. To date the preliminary steps represent an outlay of over half a million dollars. Present monthly expenditures are between sixty and seventy thousand.

Inasmuch as the mines are within comparatively short distances of one another and the general management is centralized, numerous features are being worked out with regard to the group as a whole. Active development is being pushed as rapidly as local conditions permit. At present work is going on at the C. O. D., I. X. L., Rural, Golden Star and the Daisell. Each of these is operated as an independent unit under a capable superintendent. F. H. Lerchen is general superintendent in charge of all underground work.

The various properties taken over are mostly mines having recorded production during the past. Practically all of them have produced ore of shipping grade. None of the workings were carried to a very great depth, the former operators having mined only the high-grade surface deposits. In most cases it is the mining and treatment of the large lower-grade bodies which constitute the basis of the present projects.

C. O. D. PROPERTY OF MOST IMPORTANCE

The C. O. D. at present occupies the most prominent position in the group and might be termed the pet of the organization. It is located in the Cerbat Range, seven miles south of Chloride in the Stockton Hill district. Though several other veins show on the property, development and interest center at present in what is known as the C. O. D. vein. This passes through the C. O. D. claim lengthwise with a general strike of N 80 deg. W. Near the middle of the claim the vein, at the surface, is split by an elliptical horse of country rock about 500 ft. long. The workings are on the north spur, which has a dip of 75 deg. N. Indications are that these two spurs converge to the west and join at depth. Croppings to the east of the split are very strong and it is probable that further and deeper development will prove the vein to be extremely wide. Schrader classifies the country rock in the main as porphyritic granite associated with chloritic schist. The gangue is quartz with some talc stringers found in the vein filling. High-grade ore lenses vary in width from 6 in. to 7 ft. with milling ore much wider. The average vein width is problematical as nowhere at a depth

of 300 ft. have the true walls been uncovered. Ore values are in gold, silver, lead and zinc. Recent tests by Mr. Widdowson have proven the existence of an unusual condition; namely, the gold is associated with the lead, the silver with the iron, the zinc being practically free.

On taking over the mine the new management unwatered the No. 2 shaft with the old steam equipment on the ground. As soon as retimbering and lining were completed this shaft was sunk to the 300 level and the long 300 drift cleaned out.

New electrical equipment has been installed. The hoist is a Denver Engineering electric, driven by a 75-hp. motor. It has a ⅝-in. cable and is capable of lifting a two-ton live load from a depth of 1,100-ft. A 15 x 9 x 12-in. Ingersoll-Rand compressor, short coupled to a 100-hp. motor, is installed in the same large concrete-floored building. There are also a commodious blacksmith shop equipped with a No. 5 Leyner drill sharpener and punch, timber sheds with crosscut and band saws for framing, change rooms, unit bunk houses, mess house, laboratory and office buildings. The laboratory is completely equipped for ore analysis and testing.

Power is obtained from the Desert Power & Water Co. at Kingman. Tramways and bins are being erected and the old mill near the shaft is being remodeled into a 100-ton pilot mill. Crushing to 1½ in. will be done at the shaft. Three products, lead, iron and zinc, will be made from the C. O. D. ores. The Colorado Iron Works is providing the milling equipment. It is hoped to have this pilot mill running within the next three or four months. There is sufficient material in the old dumps to supply the mill for three months. The mine will then be in shape to supply more ore than is required, and of an excellent milling grade. Mill runs will also be made here with ores from the other mines before any treatment plants are constructed.

Underground work is progressing steadily. The 4½ x 7-ft. development shaft has the same dip as the vein and goes down in the ledge matter. At this writing it is nearing the 400 level. From a 3-ft. lense in the bottom ore running $8 in gold, 37 oz. silver, 5 per cent lead, 6 per cent zinc and 8 per cent iron is being taken out. A hand-sorted test shipment of this ore will be made soon to the smelter. The west drift samples $45 per ton in gold and silver alone over a distance of 219 ft. Ultimate plans call for a large three-compartment shaft east of the present workings. From this shaft the ore will be conveyed by aërial tram to a large mill located on the I. X. L. property.

Geological Conditions Same at I. X. L.

One mile and a half south of the C. O. D. are the I. X. L. claims. A proposed auto road of moderate grade and easy construction will eventually connect the two properties. Geological conditions here are practically the same as at the C. O. D.; the main I. X. L. vein is apparently the southeastern continuation of the C. O. D. vein. In the I. X. L ground this ledge has a more northerly strike and dips about 80 deg. NE. The bend required to bring it into the C. O. D. claim probably has some relation to a cross ledge called the Hyson vein. This vein strikes about N 45 deg. W and was also a surface producer in the old days. It crosses the main C. O. D.-I. X. L. croppings about 1,400 ft. north of the I. X. L. shaft.

The character of the I. X. L. sulphide ores differs somewhat from those of the C. O. D. in that the lead content is much higher and zinc is practically absent. Mill tests on a combination of the two classes have been completely successful.

Early this year the Dudley Interests began work under their option. G. B. Atlee, a former operator, was engaged as superintendent, and the well appointed Wrigley camp, near by, was leased. A 15-hp. gasoline hoist and a two-drill portable gasoline-driven compressor were installed. The old shaft was cleaned out and sunk to a depth of 268 ft. At the 250-ft. level a station was cut and a 28-ft. crosscut driven through the ledge. Here the vein matter proved to be 19 ft. wide. A 200-ft. drift to the south on the vein is under way and will give access to the ground under the old stopes. When I visited the property the face of this drift was carrying a streak of high-grade 12 in. wide at the top and 24 in. wide at the bottom. This ore assayed $2 in gold, 200 oz. silver, 29 per cent lead and no zinc. Drifting north on the vein and deepening of the shaft will be started as soon as new electrical equipment has been installed. The water flow is about 15,000 gal. daily. This is handled by a jack-head plunger pump driven by a 3-hp. gasoline engine.

The possibilities of the I. X. L. ledge as regards milling ore are great. North of the shaft 350 ft. the vein shows in an enormous cropping. Surface trenching indicates a total width of 90 ft. at this point. This entire width is said to average close to $18 per ton in gold and silver. It is on this showing that the future plans for mining and milling are building. In conjunction with the prospective tonnage from the C. O. D. there is available a large amount of good milling ore. The I. X. L. basin offers a number of splendid mill sites and indications are that the two mines will supply ample water. The lower altitude of the I. X. L. ground makes the bringing of the ore from the C. O. D. a simple gravity problem.

Rural-Buckeye Another Old Producer

Less than two miles northwest from the I. X. L. on the southern slope of Cherum Peak are the Rural-Buckeye claims, operated under the name of Rural Mines Co., Inc. The location is in what is called the Mineral Park district, about four miles due southeast from Chloride.

The vein is a fissure in medium-grained granite striking nearly east and west, with a dip of 72 deg. N. Some schist is found associated with the granite. As a rule the walls are hard and require little timbering. Vein stringers shoot off at intervals into the wall rock. The gangue is quartz and has a marked tendency to "freeze" to the country rock. A short distance beyond where the vein leaves the Buckeye claim and enters the Rural (about 250 ft. west of the present main shaft) it is cut at nearly right angles by a granite porphyry dike. This has resulted in a pronounced faulting. West of this fault line there are five parallel vein croppings, so it is to be presumed that one of these is the continuation of the Rural-Buckeye vein. This vein to the east of the fault is remarkable for its persistency and varies in width from 1 to 8 ft. The ore values are in gold and silver; there is considerable arsenical iron, with very little lead and zinc.

New electrical equipment of ample capacity is housed in well constructed buildings. The hoist is a counterpart of that at the C. O. D. A 17 x 19-in. two-stage Ingersoll-Rand compressor driven by a 100-hp. motor supplies air for the jackhammers, Leyners and a No. 3 Cameron pump at the 160-level station. The blacksmith shop has a No. 5 Leyner drill sharpener and punch. The camp in general is well appointed.

A new double-compartment vertical shaft, 4½ x 8½ ft. in the clear, has been sunk in the footwall between the two old shafts. Work is being pushed in a number of faces. A north crosscut west of the fault line is expected to supply information regarding the veins on that side. The long adit is advancing east toward a point where a fourth ore shoot shows at the surface. A raise from the 160-ft. level in an unexplored portion of the Buckeye vein has broken into excellent ore 40 ft. above the level. This ore carries 1 oz. gold and 170 oz. silver.

Golden Star Ore More Refractory

Adjoining the Rural on the south but about 300 ft. lower, is the Golden Star mine, formerly called the Lone Star. The more refractory nature of the ore found in the lower levels apparently was responsible for the cessation of work about 1900. Here the country rock is mostly granite, with some chloritic and mica schist. The main fissure is from 2 to 9 ft. wide, striking about west northwest. At the surface it dips 60 deg. S, but at depth flattens to 55 deg. A pronounced tendency to assume a more vertical dip is indicated at the 230 ft. point. Two minor parallel veins come to the surface a short distance south of the main vein. The sulphide ores show considerable arsenopyrite carrying gold, silver and lead. Wire and ruby silver occur in varying quantities.

The first step of the Dudley operations was to clean out the old shaft. At the 100-ft. level a drift was driven in 40 ft. east on a vein seam traced from the old workings. Breaking into the hanging wall uncovered a 24-in. streak of ore carrying 0.8 oz. gold and 17 oz. silver.

While cleaning up and widening the old 185-ft. level to the west the hanging wall was broken into about 100 ft. from the shaft. A high-grade lens 12 in. wide was disclosed in the bottom carrying 9 oz. gold and 240 oz. silver. Both of these finds will be opened up as soon as working conditions permit. Early in 1920 new equipment was installed in concrete-floored buildings. This included a Denver Engineering Co. single-drum hoist with 3,500-lb. rope pull driven by a 75-hp. electric motor, a 12 x 10-in. Ingersoll-Rand compressor with a 150-hp. motor and a No. 5 Leyner drill sharpener. New camp buildings are complete. A vertical two-compartment shaft, 4½ x 8½ ft. in the clear, has been sunk in the hanging wall east of the old shaft. This is now down 200 ft. with a large, well-designed station and an ore pocket at the 160-ft level. Lateral development is in progress.

Daisell a Milling Proposition

Formerly known as the Twins group of five claims, the Daisell in the Cerbat district lies three miles east of the Santa Fe branch line to Chloride and about three-fourths of a mile from the Chloride-Kingman highway. An excellent road has been constructed to the mine. The deposit is essentially a milling proposition. The old incline shaft on the vein was sunk 300 ft. This vein strikes about east and west with a dip of 78 deg. N. The country rock consists of pre-Cambrian granite and schists. The intrusion of a strong trap rock dike striking practically the same as the ledge but with a nearly vertical dip has caused considerable faulting. This is most evident on the 300 level, but the old operators lost the vein at a depth of 130 ft. Recent work has shown that the dike is on the hanging wall of the vein at the 130 level but forms the foot wall at the 300.

The vein varies in width from 6 to 20 ft. The ores are secondary and exceedingly complex, carrying gold, silver, lead, zinc and copper. Three carloads of sorted ore were shipped by the Dudley interests which ran close to $50 per ton. Surface samples along the vein show from 0.75 to 2.5 oz. in gold.

During the last two years much development work has been done with gasoline equipment at the old shaft. An 8 x 10-in. compressor driven by a 40-hp. engine supplies air for the drills. The hoist is a 25-hp. Fairbanks-Morse.

With the old shaft working, a new level was started at the 130 ft. point. This was driven 90 ft. east and 530 ft. west, the latter drift leaving the faulted zone about 250 ft. west of the shaft. The old 300-ft. level to the west was cleaned out, widened and retimbered. During this operation the ore was picked up on the footwall side of the drift. Further work proved the ore to be from 13 to 20 ft. wide.

The necessity of a new working shaft and working out of the milling problems have caused work to be suspended for the time being. The management wishes to concentrate efforts on the C. O. D. mill.

Other Dudley properties include the Mineral Park Mines, Inc., holdings which embrace the old Toledo, Argo and twenty surrounding claims northwest of the Rural. Cherum Peak Silver, Inc., lies to the northeast. The latter includes seventeen claims. The high elevation of these claims on the southern slope of the Cherum Peak makes them particularly adaptable to development by adit.

Tennessee Copper Temporarily Leases School Property

Copper Pyrites Corporation Makes Tentative Agreement—Ore Now Going to T. C. Smelter

The Copper Pyrites Corporation, in the Ducktown Basin of Tennessee, has made a temporary lease to the Tennessee Copper Co. subject to two months' notice from either party, of its School Property, the "A" shaft workings of which were illustrated in the Aug. 7 issue of the *Journal*. Tennessee Copper is shipping 75 to 100 tons of ore per day at present over the Copper Pyrites Corporation's tracks and those of the Louisville & Nashville R.R. to the Tennessee company's smelter at Copperhill. The latter company has built a trestle directly from "A" shaft collar out over the Pyrites Corporation's railroad tracks below the shaft and is shipping run-of-mine ore without crushing or sizing other than to grizzly out the fines as the ore runs down the chute leading from the mine-car tipple to the railroad cars. They are thus avoiding the cost of operating the Pyrites Corporation's crushing and sizing plant which was built to prepare ore for use in acid manufacturers' roasters.

SULPHURIC ACID PLANTS NO. 1 AND NO. 2 AND COPPER SMELTER OF TENNESSEE COPPER & CHEMICAL CORPO PLANT IS SEEN ON SUMMIT OF HILL; NO. 2 PLANT IS LONG

Object to Freight Increase on Low-Grade Ores

A protest against a proposed increase in freight rates on low-grade ores is being made by the Utah chapter of the American Mining Congress to the State Public Utilities Commission. The increase has been asked by the railroads in a request for a general blanket raise in rates to conform to the rates authorized by the I. C. C.

New Mexico Mining Association Organized

Step Preliminary To Forming State Chapter of American Mining Congress

Mining men of New Mexico met in Silver City recently and organized the New Mexico Mining Association as a preliminary step to organizing a state chapter of the American Mining Congress. John M. Sully, general manager of the Chino Copper Co., was named chairman of the association and N. C. Cross, Mr. Sully's assistant, was appointed secretary. These two officers were empowered to take the steps necessary to perfect the organization of a chapter of the Mining Congress. Out of a list of fifty representative mining men thirty-three were present.

The executive committee of ten members, including the chairman of the newly formed association, was named, as follows: B. B. Hanger, Albuquerque; Powell Stackhouse, Jr., San Antonio; S. J. Kidder, Mogollon; E. M. Sawyer, Tyrone; Ira L. Wright, Silver City; C. T. Brown, Socorro; J. B. Gilchrist, Fierro; M. W. Porterfield, Silver City, and John M. Sully.

Canada's Deepest Diamond Drill Hole Completed

What is reported to be the deepest diamond drill hole in Canada was recently completed near Chelmsford, Ont., on the Soo branch of the C. P. R. The hole, which attained a depth of 2,007 ft., was put down for W. McVittie, of Sudbury, who was prospecting for coal. A small surface deposit, which certain geologists claimed was anthraxolite, was responsible for the undertaking.

New Boom Expected in Zinc Camp Near Joplin

Recent development in a new field about 12 miles northwest of Joplin, Mo., near the old Badger-Peacock camp, has encouraged mining men to look for a pronounced boom for that section in the months to come. At least two of the larger companies have taken big acreages there. Two new mills are in operation and considerable drilling is under way. One of the new plants is that of the Kanoak Mining Co., of which A. M. Gaines, Picher, Okla., is manager. After a hard fight against water, this plant is turning out a large tonnage of lead ore, which is proving exceptionally rich. The water still prevents the company from going after the zinc run deeper down. Since the successful start of this property, the Huttig Lead & Zince Co. has made contracts for approximately 880 acres one mile immediately north of the Kanoak mine, and in between the two the Chanute Metal Co., a subsidiary of the American Metal Co., has taken a lease. In addition to this, the Chanute company at the present time holds a tract comprising over 1,000 acres.

Mining men of the district believe that this field will prove equally as rich as the new one recently proved up immediately west of Baxter by the Chanute Spelter Co. The Huttig company placed a drill on its acreage in the Badger-Crestline camp on Aug. 26, and will send other drills there at once. The Kanoak company is continuing drilling. The Oakey Mining Co. has completed and placed in operation its new mill immediately east of the Kanoak plant, with highly satisfactory results.

Lake Ore Rates May Go Up

Steamship Companies Privileged To Ask 40 Cents More—Extra Charge To Come Out of Shippers' Profits

Steamship companies operating on the Great Lakes have been given the privilege of raising rates about 40c. per ton from the head of Lake Superior to Lake Erie ports, and it is almost certain that they will take advantage of the offer. New rates can be made immediately, and shippers of iron ore from the Lake Superior district believe that they will have to pay more to have their product transported from Lake Superior to the East. There will be no change in the price of iron ore to offset this extra burden, the iron prices for the year having been fixed. It simply means that the operators will be deprived of a part of their profits.

The ore is now going down the lake at a steady rate, and the August movement will be in excess of 9,000,000 tons. The Oliver Iron Mining Co. is about 2,000,000 short tons short to date, but there is some hope that this will be made up prior to the closing of navigation. Coal is now coming into the district in far greater quantities and there is little fear that the mines will experience a shortage during the winter. The boats are moving more freely and there are not the long delays at lower lake ports which held back the ore and coal movement during the early months of the 1920 season. There is no doubt that the ruling of the Government with regard to delivering coal to the Northwest relieved the anxiety of a lot of mining men of the region.

Ore cars are not so plentiful as they might be, and it is reported that some of the railroads are to add more equip-

RATION, COPPERHILL, TENN. TOTAL CAPACITY OF ACID PLANTS IS 350,000 TONS OF ACID PER YEAR. NO. 1 ACID LOW BUILDING AT LEFT. SMELTER IS IN LEFT CENTER

ment before next year. The old wooden cars are fast disappearing, and steel cars are now more numerous than the others. There is a possibility of the Lake Superior & Ishpeming road being electrified between Ishpeming and Marquette, on the Marquette Range, and engineers have already gone over the system and made estimates. The company has waterpower that can be used, and it is believed that a saving would result. There is a drop of close to 800 ft. in the fifteen-mile haul, and power could be generated and returned to the line during a part of the run. The L. S. & I. hauls most of the ore that is mined on the Marquette Range, being principally an ore road.

Calumet & Hecla Shuts Down Three Mines

The Allouez, Centennial and Superior mines have been closed down by the Calumet & Hecla Mining Co., which means a further curtailment of about 8 per cent in the company's output. The total output of the company and its subsidiaries in July was 8,312,025 lb., of which Allouez yielded 262,400, Centennial 34,600 and Superior 85,800, the output of the three being 382,800, or about 4.6 per cent of the total. It is said that the company intends to shut down the Osceola mine also shortly, the force there having already been reduced.

Cage Falls in German Mine, Killing Twenty-five

On the morning of Aug. 8 the hoisting rope broke at the Kaiserstuhl mine in Germany. The cage fell to the bottom, a distance of 360 m., and twenty-five miners were killed.

Mine Shaft on Rand Collapses

The Robinson shaft of the Randfontein Central Gold Mining Co., Johannesburg, South Africa, is reported, somewhat belatedly, to have collapsed on July 29. It is said that it cannot be repaired and that its loss will affect the tonnage hoisted until the north vertical shaft comes into commission this October. The company hopes to make a small profit in the meantime. The expense of maintaining this shaft has been heavy. It had been intended to abandon it toward the end of the year, when the new shaft should become available.

Lake Ore Carrier Sunk

The steamer "Superior City," of the fleet of the U. S. Steel Corporation, was sunk in Lake Superior in collision with the steamer "Willis L. King," of the Jones & Laughlin fleet, on the night of Aug. 20. Twenty-nine lives were lost. The first boat was bound south with ore and the "King" upbound with a light cargo of coal when the accident occurred off Keweenaw Point. It is reported that the night was clear and fogless and that the accident was due to a misunderstanding of signals. The Federal authorities are now investigating.

Wisconsin Zinc District Output Below 1919 Average

Eighteen Concentrators Active—Operating Conditions Bad

The curtailment of operations in the Wisconsin zinc district has reduced the weekly production of raw blende concentrates to 2,000 tons, which is 33 per cent below the average for 1919. Only eighteen standard concentrating mills are now active, their combined maximum daily capacity for the hours operated approximating 6,000 tons. Only six mills are being run double shift or twenty hours, the rest being run only one shift of ten hours or less. Four roasters, not including the Mineral Point Zinc Works, are running part time and part capacity. Approximate figures show only 4,500 tons of finished blende in bins and 8,000 tons stock of separator low-grade concentrates.

General operating conditions remain bad. Labor is somewhat more plentiful for those continuing to operate. At Highland the Mineral Point Zinc Co. is dismantling its remaining mill. Only one mill, the Lampe, remains intact at this old carbonate-producing camp. Linden's last active producer, the Fearless, has just closed. At Mifflin, the two Cokers of the Mineral Point Zinc Co. and the Yewdall of the Vinegar Hill Zinc Co. have kept going, and the B. M. & B. has just been reopened as the Fearless No. 2.

Platteville camp has one steady producer, the Blockhouse. Cuba City camp has the Big Dick and Connecting Link No. 2. The Connecting Link Co. has its No. 1 mill completed and ready to go. The Zinc Hill Co., owner of the Big Dick, plans to build a 100-ton mill this fall on the Tom Lee lease and to erect a roaster as soon as construction conditions improve. At Benton-New Diggins, the Mineral Point Zinc Co. continues to operate the Hoskins and Penna Benton. Here the Vinegar Hill is operating a new property, the Fields-Meloy. The Frontier Mining Co. is running the Bull Moose and Middie. The Lawrence Mines Co. operates the Indian Mound. The Wisconsin Zinc Co. has closed its string of producers, but continues prospect work and is re-milling tailings. At Hazel Green, the Vinegar Hill has just closed the Jefferson, but has taken over the Monmouth and reopened it. At Shullsburg, the Rodham and Imperial are active. At Galena, the Mineral Point Zinc Co. operates the Black Jack and the Vinegar Hill Zinc Co. the North Unity.

Lead-Silver Discovery Reported in Alberta

The discovery of lead-silver ore at Milk River, Alberta, is said to have created a little excitement in that part of Canada. It is said that the usual rush of would-be stakers has taken place and that some drilling is being done. The report has not been verified up to the present.

MONUMENT ON BOUNDARY BETWEEN ALASKA AND BRITISH COLUMBIA. THE RE-SURVEY OF WHICH LINE IS NOW UNDER WAY

Boundary Re-Survey Under Way in Portland Canal District

Both Governments Seek To Obviate Chance of Dispute as to Nationality of Mineral Ground

The work of re-defining the international boundary between Alaska and British Columbia in the Portland Canal district is under way at the present time. Parties representing the United States and Canadian governments are doing the work, erecting stone cairns and bronze monuments on the mountains, and hewing a lane twenty feet wide through the forest. This is the second time in about sixteen years that this has been done, the line having become overgrown in the meantime and difficult to recognize. The Canadian party is in charge of J. D. Craig. The chief purpose in making this resurvey is to obviate all chance of dispute as to the nationality of valuable mineral claims located or that may be located in the district. The Premier mine is the most important property of the district but there are others of promise.

To Extend Pine Creek Railroad in Coeur d'Alenes

Milwaukee Lumber Co. Reaches Agreement With O.-W. R. & N.—Will Benefit Mining Companies

Definite announcement has been made that an agreement has been reached between the Oregon-Washington Ry. & Navigation Co. and the Milwaukee Lumber Co. by which the latter will take over the Pine Creek branch and extend it to the forks of the creek, two miles and a half, and thence four miles up the west fork to a large body of timber owned by the lumber company. The track now extends up Pine Creek a little more than two miles and the right of way is cleared to the forks. The road is in the Coeur d'Alenes.

The construction of this branch will be of great benefit to the mining interests of the section. The Nabob, in particular, which has its mill near the forks of the creek, will at once be relieved of a wagon-road haul of five miles, which will mean a direct saving of at least $4 per ton on all shipments. The Highland-Surprise, which has a 100-ton mill, is preparing to ship and the railroad will reduce its wagon haul by half. Other properties, with ore available for shipment, that will be directly benefited, are the Douglas and Constitution, the latter of which has a 125-ton mill. Numerous development companies will be encouraged in the work of finding new mines.

Kinney, Minn., Wins Case Against Cleveland-Cliffs

The U. S. Circuit Court of Appeals has sustained the District Court in its findings for the Village of Kinney, Minn., in the case of the Cleveland-Cliffs Iron Co. versus the Village of Kinney. The case involved the annexation of property in and around the Wade mine by the village and has been long fought out. Starting with an injunction to stop the initial election called for the purpose of sanctioning the annexation, it was later taken to the district court in an effort to overturn the outcome of the election on the ground of illegality. Losing there, it was referred to the Court of Appeals, which court has now sustained the voters and the lower court. About 2,500,000 tons of developed ore are involved.

Fifteen-minute speeches will be made at the ceremonies to be held at the end of the Mine Rescue Meet in Denver next week. The speakers will be: Governor Oliver H. Shoup, of Colorado; Mayor Dewey C. Bailey, of Denver; W. H. Huff, of the Victor American Fuel Co.; J. F. Callbreath, secretary of the American Mining Congress, and John L. Lewis, president of the United Mine Workers of America. Dr. F. G. Cottrell, the director of the U. S. Bureau of Mines, will present two sets of prizes; namely, the Joseph A. Holmes medals and the prizes for the winning teams.

Sulphide Cut by Boras Leasing Co., at Warren, Ariz.

First To Be Found in This Section of District

The Boras Leasing Co., at Warren, Ariz., has struck sulphide ore in a drift on the 600 level in the Space claim. Although this section of the Warren district has produced considerable oxidized copper ore, the sulphide now being opened up is the first to be discovered. The new strike will therefore be watched with much interest.

Civil Service Examinations

Those interested in the following examinations should apply to the Civil Service Commission, Washington, D. C., for form 1,312, stating the title of examination desired:

Associate physicist qualified in physical metallurgy, $2,000-$2,800; assistant physicist qualified in physical metallurgy, $1,400-$1,800; both sexes. An open competitive examination; no date given. Vacancies in the Bureau of Standards, Washington, D. C., may be filled from the results of this examination.

Metallurgical laboratorian, $4.80 per day (or higher or lower salaries); both sexes. An open competitive examination; no date given. Vacancies at the Engineering Experiment Station, U. S. Naval Academy, Annapolis, Md., may be filled from results.

NEWS FROM WASHINGTON

By PAUL WOOTON
Special Correspondent

Bureau of Mines Analyzes Its Expenditures

Research on Metalliferous Minerals Accounts for 60 Per Cent of Money Spent on Stations

An analysis has been made of its expenditures by the U. S. Bureau of Mines. Expenditures chargeable to mineral mining, ore dressing, and metallurgy, and to mining and preparation of earthy minerals are calculated by the bureau to be as follows: Mine accidents, $52,669; mineral mining, $125,000; mine rescue cars and stations, $90,223, and engineering experiment stations, $170,000. This makes a total of $437,892, or if ceramics and earthy minerals be deducted the total would be $400,892.

Expenditures classed as chargeable to coal mining and combustion are as follows: Mine accidents, $268,682; fuel testing, $142,510; mine rescue cars and stations, $64,444, and engineering experiment station, $5,000.

The bureau figures that metal mining, ore dressing and metallurgical research on metalliferous minerals account for 60 per cent of the total for mining experiment stations; ceramics, 12½ per cent; petroleum, 12½ per cent; non-metallics, not including coal, 12½ per cent, and coal, 3½ per cent. Two-thirds of the mine accident appropriation is spent in coal mining districts and one-third in metal mining regions. The ratio of coal miners to metal miners is figured at 4 to 1 and the bureau holds that its division of the appropriation is a natural one. In that connection the following figures were compiled as to the value of mineral products in 1918. They are as follows:

VALUE OF MINERAL PRODUCTS IN 1918

	Value of Product	Percentage of Total
Coal	$1,801,480,347	32 63
Petroleum	690,190,000	12 51
All other non-metallic	874,653,000	15 84
Pig iron and ferro-alloys	1,296,193,500	23 47
All other metallic	856,945,500	15 55
Total	$5,519,462,347	

May Revise Income Tax Forms

Suggestions for the revision of income tax forms may be made at a hearing which will be conducted in Washington, Sept. 15, under the auspices of the commissioner of internal revenue.

War Minerals Awards

Awards recommended by the War Minerals Relief Commission during the week ended Aug. 21 aggregate $10,945. They are as follows (the name of the company, the mineral, the amount recommended and its percentage relationship to the amount claimed are shown): Southern Pyrites Ore Co., pyrites, $8,790.39, 12 per cent; Booker, Booker & Gibbs, chrome, $101.45, 26 per cent; D. McDonald, manganese, $639.31, 12 per cent, and W. G. Fitzgerald, chrome, $413.85, 58 per cent.

Chamber of Commerce on Mining Conditions

A report to the Chamber of Commerce of the United States by its Committee on Statistics and Standards has the following to say in regard to mining conditions:

"Whether mining is busy and prosperous or the reverse depends upon the nature of the metal. Gold mining still suffers from high costs of production and the stationary price of gold. Silver mining feels the effect of the decline in its price. The price of zinc is low and the demand is not equal to

the possibilities of supplies. Lead is higher because of increased demand. Copper is dull because of a supply not yet disposed of. Iron mining is good. Phosphate mines in the South are doing well after many lean years.

"Contraction and financial credits have put wildcatting in the oil regions out of business. This makes for dullness because supplies for drilling oil wells are no longer called for.

Farmer vs. Mine Operator

That the Federal Government is much more generous to agriculture than it is to the mining industry is shown by the fact that it spends only one-thirteenth as much for the promotion of the interests of the mining industry as it expends for the agricultural industry. In 1918 the total value of mineral products was roughly five and one-half billion dollars, while the value of agricultural products totaled twenty-two and one-half billion dollars. Thus the ratio of economic importance was about one to four.

Mineral Shipments Via Panama Reported

The movement of nitrate of soda through the Panama Canal during June totalled 109,953 tons. Two cargoes went to Charleston, S. C.; three to the United Kingdom; one to Norfolk; three to Baltimore; two to Philadelphia; three to Wilmington, N. C.; one to Boston and two to New York.

Only one cargo of copper moved through the canal during the month. It consisted of 2,500 tons and was shipped from Valparaiso to New York.

The fuel oil movement totalled 60,643 tons. This oil originated in Mexico and went to Chilean ports with the exception of one cargo which went to San Francisco.

Four cargoes of sulphur passed through the canal during the month under review. The total tonnage was 14,700. Three cargoes originated at Galveston. Two of them went to Portland, Ore., and one to Vancouver, B. C. A cargo originating at Sabine, Tex., went to Melbourne. A cargo of phosphate rock moved from Tampa, Fla., to Osaka, Japan.

Survey Preparing Estimates for Next Fiscal Year

Estimates are being prepared by the U. S. Geological Survey for its work during the fiscal year beginning July 1, 1921. The estimates will not vary importantly from those made for the current fiscal year, which, however, were reduced somewhat by Congress. The estimates made last year were as follows:

For geologic surveys, $500,000; investigation of the mineral resources of Alaska, $100,000; mineral resources of the United States, $200,000; chemical and physical researches, $60,000; topographic surveys, $600,000; water supply investigation, $200,000; land classification, $400,000; printing and engraving of maps, $140,000, and superpower survey, $250,000. The total of these is $2,450,000.

NEWS BY MINING DISTRICTS

MEXICO

Sonora

Pumps Pulled at Democrata Mine

Cananea — The Democrata mine is now completely shut down and for an indefinite time. The pumps have been pulled and the mine will be allowed to fill. The water will probably rise to about the fourth level. The reopening of the mine will depend upon the price of copper and the possibilities for marketing the same.

Hidalgo

Companies at Pachuca Operating on Larger Scale Than Before

Pachuca—Mines of the Pachuca district have for the most part been running steadily throughout the revolutionary period and are now operating on a larger scale than ever before. The drop in the price of silver, while felt by the companies, has less effect here than elsewhere as the Pachuca ores are of a higher grade than in some other districts. The area of the camp is only 3 by 5 miles and in it about 15,000 workmen are employed, most of them Mexican, there being only about 100 foreigners, mostly Americans, among them.

The largest operator is the Cia. de Real del Monte y Pachuca, which at present is working twelve shafts. Like some other Mexican operators, this company has been hauling its supplies for several years from the border at Laredo in freight trains pulled by its own locomotives. The trains are made up only of cars consigned to the company and run straight through from Laredo to Pachuca, taking about five days for the trip, a distance exceeding 600 miles. The road used is the Government owned main-line, the roadbed of which is and has been kept in excellent condition, the occasional destruction of a bridge excepted. The road, when built years ago, was laid with heavy rails and is said to be in as good shape today as many in the United States. For those supplies that come from within Mexico, such as limestone, the company has its own cars on account of the difficulty of obtaining rolling stock.

Power is obtained from the Mexican Light & Power Co. largely from its principal hydro-electric plant at Necaxa, about 100 miles away. Since operating supplies have been received in requisite amounts operating conditions have been very satisfactory.

Chihuahua

Madera—The Dolores Esperanza Mining Co. is overhauling its mill at the Dolores property and is installing turbo-generators at Madera. The tunnel on the 400 level is being caught up and will give access, when the work is complete, to the old Dolores workings on the 400 level and to the new Esperanza ground. The shaft is being pumped out to the 700-ft. point. At the El Rayo a winze on the bottom level is being unwatered, in which good ore had been cut before the property was shut down.

Zacatecas

Fresnille—The Mexican Corporation has taken a twenty-year lease on the Proano mines in the Fresnillo district and is installing a 2,000-ton mill, which is to be ready early next year.

PERU

Peruvian C. & S. Co. To Start Producing in November

The Peruvian Copper & Smelting Co. has increased its force to 850 men, who are employed in part on the work of finishing the construction of the new auto-truck road. The rest of the men are engaged in mining coal and copper, and in making coke. A number of new strikes of ore running about 20 per cent copper have been made on the G and J levels, the levels being 300 ft. apart, at the Yauricocha mine. It is expected that the new 200-ton blast furnace will be ready to blow in this November, by which time the company will be able to go on a production basis. The company also has a small reverberatory of negligible output. At the coal properties at Jautenhuasi, fourteen tunnels are now being driven on the veins. The announced purpose of the company is to produce copper, coal and coke for shipment. J. N. Vandegrift, the manager in Peru, is at present in New York. The president of the company, J. A. Vandegrift, is now in Peru. It is stated that if development continues as at present in the Yauricocha mines, the company will feel warranted in erecting a thousand-ton smelter.

CHILE

Santiago — Cia. de Minas de Cobre de Gatico has recently installed a powdered-coal-fired reverberatory with a bed 80 ft. long by 18 ft. wide, which is operating successfully on Chilean coal. The furnace is said to be smelting 200 tons of cold charge per day and consuming one ton of coal for five tons of charge smelted.

AUSTRALIA

Queensland

Mt. Elliott Still Down—Mt. Cuthbert's Start in May Fails—Hampden Cloncurry in Full Swing

Brisbane—In the Cloncurry copper field matters are not looking promising for the increased yield that was expected this year. The Mt. Elliott company, having failed to obtain capital from the American financiers to whom they appealed, is still in a state of inactivity, and the prospect of their Mt. Oxide mine, away to the northwest of Cloncurry, being made accessible and consequently productive seems almost as far off as ever. While the state government has authority to extend the Cloncurry railroad to a point nearly twenty miles from this mine, British capitalists have turned down the state premier's personal appeal to them for a loan, and there is not likely, as far as can be seen at present, to be money available for an indefinite period for the building of the authorized extension.

The Mt. Cuthbert company, which in May started what promised to be a successful campaign, closed down on June 21, and had not started again toward the end of July. The reason for the cessation of operations was given out as being the inability of the company to obtain further advances on a large accumulation of copper in transit or at the refining works.

The only other large company in the district, the Hampden-Cloncurry Copper Mines, is still in full swing, and a good many small mines and "gougers," or nomadic individual miners, are operating, but these are being handicapped by the reduced price of copper combined with the high cost and scarcity of mining requisites and commodities generally.

CANADA

Ontario

To Build Flume from Cobalt Mills to Cross Lake—Herrick Mine Plant Completed — McIntyre Shareholders Object to Purchase of Alberta Coal Mine

Cobalt—The lessees of the Ruby property in Cobalt have struck a small vein of high-grade and are preparing to ship.

Three new veins have recently been encountered in the underground workings of the Lumsden, one of which is reported to carry high-grade.

To dispose of about 2,000 tons of tailings a day from the Nipissing, Mining Corporation, Coniagas, and Northern Customs mills, it will be necessary to build a tailings launder to Cross Lake, at a cost of about $25,000. At present, the tailings go into the creek, but the outlet from Cross Lake is becoming blocked. It is thought that if the tailings are carried into the main body of the lake the clear water will cut a channel through them.

West Shining Tree—At the Herrick property in Shining Tree the installation of the mining plant has been completed. The shaft is being enlarged and retimbered and will be continued to a depth of 200 ft. The government has recently completed the building of a wagon road from the railway at Westtree to Shining Tree Lake, a distance of 20 miles.

Porcupine—The Porcupine district has again been ravaged by forest fires. The town of South Porcupine was in serious danger of destruction for two days and was only saved by the most strenuous exertions. No loss to mining properties has been reported.

Gold has been struck in a drill hole put down to the depth of 2,400 ft. below the surface from the 1,250-ft. level of the Hollinger Consolidated. The gold content of the drill core was not large, but a satisfactory result is that the geological formation at depth was found to be the same as that between the 1,250-ft. level and the surface.

The circular recently issued by the Dome Mines Co. to the shareholders, advising the taking over of the Dome Extension, states that a large body of payable ore has been opened up on the 600-ft. level of the latter property.

It is understood that the last four months' operation of the Trethewey in Gowganda has paid for all development and, in addition, has indicated a substantial reserve of high grade.

The Davidson has secured sufficient English money to fully develop and equip the property. Sufficient treasury stock will be sold at 75c. a share to net the company $1,125,000, the purchase to be completed by April 1, 1921. In addition they secure a two-years' option on 2,000,000 vendor's shares, half at $1 and the balance at $1.25 a share. A 500-ton mill is to be constructed in the near future.

A number of McIntyre shareholders are very critical of the company's purchase of a coal mine in Alberta. The company is paying about 15 per cent a year in dividends, but has not been able to build up ore reserves commensurate with the size of its operations. Some shareholders consider that, in view of the expenditures which will have to be made on development account at the McIntyre, they are entitled to larger returns before the surplus is put into another operation as far away as Alberta.

Kirkland Lake—It is understood that the Murray-Mogridge property in the Kirkland Lake section has secured sufficient money to finance development work.

The Lakeview property, adjoining the Murray-Mogridge, is installing a steam plant.

The Ontario Kirkland is proceeding with the construction of a 60-ton mill, and expects to haul in the machinery this winter.

It is officially stated that the Sylvanite is not included in the proposed amalgamation of the Tough Oakes, Burnside and Cobalt Aladdin properties.

Kirkland Lake—The Lake Shore during July produced $52,424 from the treatment of 1,860 tons of ore, the mill heads averaging $28.18 per ton. The total output for the year is now $339,427. A station has been cut at the 400-ft. level and preparations are being made for sinking a 3-compartment shaft to the 800-ft. level.

Blue Mountain—The old Mica mine at the head of Stony Lake, Peterborough County, has been purchased by C. L. Nicholson, of New York, and Norman Miller, of Michigan, who will start operations this fall.

Manitoba

Rice Lake—J. B. Tyrrell has presented a report on the Gabrielle mine, stating that assays offer little promise of returns from the property and advising that work be discontinued. The directors have determined to carry on operations next year.

British Columbia

Trail—Ore shipments received at the Consolidated smelter during the week ended Aug. 21 were as follows:

Mine	Location	Gross Tons
Bluebell, Riondel		314
Josie, Rossland		171
Mandy, Le Pas, Man.		1,080
Molly Hughes, New Denver		23
Monarch, Field		36
Venus, Carcross, Y. T.		34
Company Mines		7,253
		8,911

CALIFORNIA

Champion Plant Being Wrecked—Gruss Copper Co.'s Mill Started—The Trinity Copper Transfer

Grass Valley—All of the underground machinery, pumps, rails and, in fact, everything of any value, has been removed from the depths of the Champion mines and what has not been sold is now on the surface. The hoisting plant at the Providence shaft has been purchased by the Empire Mines. All the men except four have been discharged, those still employed being used in tearing down the large dry house. The milling and hoisting plants on the Champion side are still intact. It is rumored that different parties are planning on securing a bond on the Champion holdings and that the property is not likely to be closed long.

The Boundary Mines Co. has purchased the hoist and power plant of the Empire Mines at the Osborne Hill mine, and will install them at once at the Boundary. A large pump will also be installed. All underground work has been suspended during this work.

Officers of the Tightner Mining Co. were elected at the recent annual meeting as follows: President J. M. O'Brien, of San Francisco; vice-president, Dr. C. P. Jones, of Grass Valley, and secretary, C. H. Taylor, of Grass Valley.

Sonora—Frank Willetts, who for the last two years has operated the Wetmore's Dream mine, will open and develop the Mangente mine near Sonora. Machinery is being removed from the Wetmore properties to the Mangente

mine and a compressor, hoist and engine will be installed at once. Development work will be undertaken.

Quincy—The Kelly quartz mine, nine miles from Quincy, is being prepared for active development work by Kelly brothers, owners. A tramway, approximately 1,500 ft. long, will soon be constructed, and for this purpose all material, such as steel cable, lumber, etc., is on the property.

Redding—Papers filed for record at Redding show that little cash changed hands in the transfer of the claims of the Trinity Copper Co. to the Trinity Copper Corporation, as they bore no revenue stamps. The stockholders in the old company received a proportionate number of shares in the new company and the treasury stock remains in the treasury. The properties lie west of Kennett. The Trinity Copper Co. was organized by Thomas Lawson for trading on the Boston stock market. The deeds filed for record show that the Trinity Copper Co.'s sixty mines near Kennett were sold in Jersey City, N. J., on Jan. 19, 1920, to George A. Haskell, of Boston, for $210,000. Haskell immediately sold all the property to the Trinity Copper Corporation for $1. The latter company is incorporated under Virginia laws, while the old company's charter came from New Jersey. The principal mine of the company is the Shasta King, though sixty or more claims are owned. All tracks were taken out of the mine three years ago, and the Shasta King has become almost forgotten locally.

Portola—The Gruss Copper Co. in Genesee Valley, a few miles from the Engels and Walker properties on the same ridge, started its new 15-stamp mill Aug. 20. A flotation plant has been installed. The bins and dumps are stacked with ore that runs from $15 to $127 per ton and there is estimated to be sufficient ore in sight to keep the mill running for at least one year.

Colfax—The 900-ft. shaft on the Rising Sun gold quartz property has been entirely unwatered for the first time in years. The ledge is said to be 3 ft. wide in the bottom. The mill is running on night shift only. Twenty miners under E. C. Klinker are employed.

Death Valley Junction—The Pacific Coast Borax Co. is planning to enlarge its mill at Death Valley Junction by adding two more roasters which will increase the capacity about 60 tons per day, according to Fred W. Corkhill, mill superintendent. The plant is being operated with a 286-hp. semi-Diesel engine which generates power for the entire plant, lights the town, and operates a one-ton ice plant. Twenty-one miles of a narrow-gage railroad, 3 ft. wide, connect Death Valley Junction with the Lila C. and Ryan mines.

Death Valley is notoriously hot in the summer time, notwithstanding which fact there is less trouble in keeping a good supply of labor than in more favored camps. This is largely due to the methods inaugurated by Major Julian Boyd to make the men employed as comfortable as possible. The bunkhouses are two three-story concrete buildings, with hollow walls, each being 110 ft. in length, and accommodating 400 men. The hollow walls make the buildings comparatively cool in summer and easy to heat in winter, besides which they are said to rival a modern hotel in completeness of appointments.

NEVADA

Large Tonnage of Silver Ore Proved at Candelaria—Silver Peak Chemical's Mill Ready, but No Water

Tonopah—Bullion shipments to date indicate a gross production for August for the Tonopah district of about $500,000. This is normal. The principal mines of the district, the Belmont, West End, Tonopah Mining and Tonopah Extension, report regular development operations with nothing new of importance. Of the smaller mines, the Rescue, California Tonopah, MacNamara, Midway, and Halifax are regular shippers.

The Spanish Belt management have announced through their consulting engineer that their ore reserves in this property consist of 75,000 tons of probable ore of an average grade of between $20 and $30 per ton. This mine is about 60 miles north of Tonopah and about ten miles northwest of the old camp of Belmont.

Divide — Rumors are plenty regarding a new ore estimate for the Tonopah-Divide mine and there seems to be some basis for the optimistic feeling that prevails regarding the ore reserves in this mine at least. Interest is reviving in the smaller properties throughout the Divide district and during the last few days several properties which have been closed down for months resumed operations. The Gold Zone has a very creditable showing and is regarded as a prospective shipper. No other mines have reported development of importance.

Candelaria—The Candelaria Mines Co. is doing about 1,000 ft. of development per month with forty-five men. The work is confined largely to the Lucky Hill, the company's new property. Since the Candelaria mines passed into the control of interests affiliated with International Nickel the property has been thoroughly sampled and from the results of over 8,000 assays a large tonnage of ore has been proved to average between 12 and 15 oz. silver. In addition to the proved ore, and the disclosures made in recent development on the Lucky Hill, there are numerous places with good showings which will be developed later. E. E. Carpenter, who is in charge of operations, states that the Candelaria will soon be a big silver producer. The metallurgy nas been worked out but mill construction is not expected to start for several months. The first unit will have a capacity of from 125 to 150 tons daily, and the process will consist of coarse grinding, roasting and cyaniding. Roasting will be followed by a short leach.

VICTORY SHAFT, TONOPAH EXTENSION MINING CO., TONOPAH, NEV.

Silver Peak—The reduction plant of the Silver Peak Chemical Co., which is expected to turn out about 100 tons of pure potash alum daily from its property near Blair Junction, in Esmeralda County, is reported to be practically completed. Its start has been delayed, however, owing to a failure of the water supply figured on. A well is now being sunk out on the flats.

Arrowhead—The west drift on the 215-ft. level of the Arrowhead Consolidated has recently broken into good ore, according to Dr. Elftman, who is heavily interested. The original Arrowhead mine is making small shipments to the MacNamara mill at Tonopah.

ARIZONA

Jerome Verde Suspends Operations Indefinitely

Jerome—Jerome-Verde recently followed the example of Gadsden and suspended operations indefinitely. The mules have been brought out, the pumps pulled and preparations made to leave the property in good shape. Development work had been planned on the 1,200 level, corresponding with the 1,500 in the U. V. Extension. This was designed to get below promising looking oxidized and leached ground on the 1,100 level, thought to be the top of an orebody. The money was to have come from a bond issue, but the stockholders failed to back the plan. Jerome-Verde has a large acreage in the heart of the Jerome mineralized section. Several small bodies of ore have been tapped and some ore sent to smelter.

Globe—The Superior & Boston has found in resampling that the 1,250-ft. level contains ore available for immediate shipment that runs from 3 to 25 oz. silver and averages 13½ oz. over a 5-ft. width. The stopes in the footwall vein on the 4th level west are in good shipping ore, likewise the raises at the eastern end of the 4th and 6th levels. The south crosscut is expected to cut the Rigby vein soon.

NEW MEXICO

Duncan M. & M. Co. Shut Down, Pending Readjustment

Lake Valley—The Lake Valley Silver Mines Co. continues to ship silver and manganese ores regularly. Some high-grade crystalline manganese ore has been encountered.

Silver City—The Santa Fe has enlarged its ore-loading platform. This is intended to facilitate ferromanganese shipments moving to Pittsburg territory, principally from the Amory Stevens property.

The Silver Spot mine shipped a car of manganese ore to Pittsburg recently. The water flow in the main shaft is under control and mining on the 140-ft. level is under way. Bulkheads have been installed to guard against contingencies.

Carlisle—The old Carlisle mine and mill is being operated under lease by G. A. and L. Utter. A car of concentrates will be shipped to the El Paso smelter at once.

Steeplerock.—The Duncan Mining & Milling Co.'s plant has been shut down pending readjustment of financial affairs. The statement given out by W. H. Evans, former manager, of $20,000 returns from the first clean-up of the cyanide mill made about Aug. 7, has not been confirmed by the engineer in charge, who gives the amount as $1,695.

Lordsburg—The Bonney Cons. is following up a number of high-grade ore showings recently opened on the surface. Twenty men are employed. All mechanical equipment is being overhauled and pumps prepared for heavy work to start soon.

COLORADO

Diamond Drilling Progressing Near Gillett—First Hole Down 1,100 Ft.

Cripple Creek—Prospecting with a diamond drill, financed by the Cresson, Vindicator, and Golden Cycle companies, is under way in the vicinity of Gillett. George A. Stahl, general manager of the Vindicator, and W. H. Trask, of Denver, are in charge. The first hole is down 1,100 ft. At 1,084 ft. the hole is cut through the granite formation, then passed through 6 ft. of breccia, then 3 ft. of quartz and fluorite, then phonolite. The record made by the drill is reported to be gratifying. Mining men who are familiar with the Cripple Creek crater are much interested in the outcome of the enterprise.

Silverton—The Mazeppa mine, in the South Mineral district, is being developed by Samuel Heindel. A shoot of high-grade lead sulphide ore has been opened.

Mayday—Dr. W. B. Cauble, of Peoria, Ill., has secured a half-interest in the Esmeralda Convention group on the south fork of Lightner Creek from George and Milton De Luche and George Smart of Durango. A 35-ton mill will be erected.

The Mayday Leasing Co., which has been working the Mayday dumps, has quit.

Moffat County—During the last summer an attempt was made to operate one of the old placer mines in Moffat County, Col., by its owners. The attempt was not highly successful due to a heavy snow fall late in the spring and the consequent floods which washed out a series of small supply dams. As it is necessary to store the water from early in the season to maintain a supply for the entire summer, work was hampered considerably. In spite of these conditions a small plant was put into operation and run for a short time. Preparations are being made to operate a larger plant on the same ground next season.

The neighboring mines have been idle during the summer and it is doubtful when they will be worked again. During a lull in the operations for the last few years a large percentage of the land has been located for farming purposes and in some cases conflicting with the placer locations.

There are two small dredges in the district, both of which have been worked off and on for several years. It is understood that one of these dredges has been leased to an Eastern stock company and is to be run the coming season.

Very little of the ground has been prospected to any extent and the best average value is between 40 and 50c. per cu.yd. There is however practically no overburden, the dirt running from the surface down 6 to 8 ft. to a soft sandstone bedrock. The source of the mineralization is doubtful but the general theory is that it is from Hahn's Peak or vicinity, about 20 miles to the east.

LOOKING NORTHEAST UP COPPER GULCH, GLOBE DISTRICT, ARIZ. RIGHT FOREGROUND — NO. 1 SHAFT ARIZONA COMMERCIAL MINING CO. LEFT CENTER—MINE PLANT OF IRON CAP COPPER CO., NEW IRON CAP MILL AT LEFT IN DISTANCE. SUPERIOR & BOSTON'S HOLDINGS LIE SOUTHEAST OF THOSE OF ARIZONA COMMERCIAL AND IRON CAP

UTAH

King Con. at Park City Cuts New Fissures—Silver Shield at Bingham Levies Assessment

Silver City—Tintic Milling shipped a car of bullion the week ended Aug. 16. About 150 tons of ore is being treated daily, as the plant, owing to a scarcity of ore, is not running at capacity. One shift is working in the crushing department and three in the leaching and roasting departments. As has been stated before the company is making

changes and improvements in its equipment to permit the separation of the copper from the silver and gold, which will make it possible to ship the bullion directly, without further refining, to the U. S. mint.

Development is being done on the 2,200 level of the Iron Blossom in the hope of finding ore at depth.

Eureka—The Chief Consolidated expects to add to its earnings through its new leasing system whereby entire stopes are given over to groups of miners, who make more money in this way, the company at the same time being safeguarded by especial contracts. The practice of giving other leases where there are only small showings of ore is still in force, the lessee undertaking the work of development.

The Iron King is drifting on both the 1,000 and 1,500 levels, as well as shipping about a car of fluxing iron ore daily. The latter is coming from above the 350-ft. level.

The Eureka Bullion has resumed work after a month's intermission for repairs to equipment.

Active development is being done at the Emerald adjoining the Centennial-Eureka and the Grand Central and Mammoth.

American Fork—The tunnel of the American Consolidated Mines, embracing the old Bog property and adjoining ground, has cut at 1,800 ft. the fissure for which it was being driven. Drifting both ways has been started on the fissure, which is 10 ft. wide at the intersection. Some mineralization shows the fissure to be the same which produced considerable ore in the Bellerophon.

Gold Hill—The Western Utah Copper in the Deep Creek district is to increase its shipments of lead-silver ore largely. A railroad into this district was completed two or three years ago.

Bingham Canyon—The Silver Shield reports that a change in the character of the orebody from which a number of shipments were made has resulted in a loss to the company. The lead ore has been replaced by zinc. Improvements made since the ending of the war have resulted in an indebtedness of about $18,000, to meet which an assessment of 3c. per share has been levied.

Alta—The winze from the 300-level of the Emma Silver shaft has been unwatered to about 75 ft. below the level. Diamond drilling is to be started again when this work has been completed and ore will be shipped from the Emma stope. Prospecting is being done in a number of places in the mine.

The Alta Tunnel & Transportation Co. has let a contract for the extension of its east drift, in the face of which oxidized vein matter with some galena is beginning to show. Ore was opened further back some time ago and is said to be 6 ft. wide with more high-grade showing as development progresses. Poles for a power line have been cut and seasoned. The road from the property is being improved.

Big Cottonwood—Some ore is being taken out at the Woodlawn property. The tunnel face at the Cottonwood King is entering gray limestone showing iron and copper stains.

Park City—The Judge Mining and Smelting is encouraging the employment of married men on its working force.

Silver King Consolidated is reported to have cut another set of fissures in the tunnel which it is driving both for the purpose of exploring new ground and for making connections with its California-Comstock holdings. The tunnel has almost reached its objective point.

The Park-Utah is developing and extracting ore in the south drift from the crosscut. Paul Hunt is superintendent.

IDAHO

R. N. Bell Takes Option on Red Bird at Clayton—Ramshorn Mill at Bayhorse Running

Clayton—Robert N. Bell, the retiring state mine inspector, has secured a long lease and option to purchase the property of the Clayton Mining & Smelting Co. near Clayton in Custer County, the principal claim of which is the Red Bird, which is developed 900 ft. deep through crosscut tunnels. A 50-ton concentrator will be erected and is expected to be in commission within 60 days. The property has a 100,000-ton reserve of 10 to 15 per cent lead ore in the form of sand carbonate associated with a soft limonite gangue. The silver averages about ¾ of an oz. per unit of lead and extensive mill tests indicate a good recovery by simple jigging and table concentration.

The mine is 65 miles from the nearest railway shipping point at Mackay and involves a truck or wagon haul charge of $20 per ton. The mine has produced $1,500,000 in its past operations, $300,000 of which has come from lessees operating on a small scale, who have been "gouging" for rich pockets of high-grade ore during the last three years.

Bayhorse—At Bayhorse the new concentrator of the Ramshorn Mines Co. has been in operation for the last two months. Although difficulty is being experienced in holding down the tailings losses, owing to the large proportion of silver chloride in the ore in spite of a preliminary sulphidizing bath and a modern flotation plant, a product of 300-oz. concentrates is being made that is gradually being improved upon. A lower adit, now being reopened for stoping, carries a more primary ore that will give a much closer saving in milling. The Ramshorn vein is a very persistent steep fissure in slate that was formerly extensively developed by adit tunnel but idle for 25 years until the present operation, which was started two years ago. It has an ore shoot 1,000 ft. long, except for a few short pinches, that varies from 1 to 5 ft. in width.

The Beardsley mine, at Bayhorse, is being operated by lessees and is developing much good ore. Between 700 and 800 tons of ore are now on the dump, that averages 20 per cent lead and 40 oz. silver per ton. This new development, on an old property idle for 25 years with a former record of several million dollars produced, is more definitely related to a pronounced contact of limestone and shale than any of the other ore shoots formerly worked. The inference seems permissible that only the blossoms of this important contact have been developed and that the string of other properties extending for more than 2 miles along the vein may prove equally productive.

Mackay—In the Mackay district of the same county, the Empire Copper Co. is operating 20 small leasing units and shipping about a car of crude 5-per cent copper ore per day to the Salt Lake Valley smelters. The ore also runs well in silver and gold.

In the adjoining limestone-lead belt the U. S. Smelting, Refining & Mining Co. is developing two very promising lead-silver prospects, one of which, the Horseshoe group, is shipping 20 cars a month of low-grade lead-silver ore carrying 12 per cent lead and 10 oz silver and an excess of iron oxide. The Kennedy group, of the same company, now developed 250 ft. deep, has one ore shoot 40 ft. wide and 60 ft. long.

At the Doughboy adjoining, a 25-hp. gasoline hoist is being installed. There is an inclined shaft, 300 ft. deep, sunk on a persistent contact fissure vein 3 to 5 ft. wide, disclosing a pay course of rich jigging ore in the form of hard carbonate and galena carrying silver in a gangue of lime porphyry breccia.

The lead-silver ore of the Mackay copper district occurs in paleozoic limestones extensively intruded with nearly vertical porphyry dikes. The ores have proven almost completely oxidized so far to a maximum depth of 300 ft. They occur usually in a succession of lenses and pipe-like shoots at the contact of the nearly vertical dikes and locally marbleized blue limestones, and give decided evidence of permanency.

Coeur d'Alene District

Red Monarch Con. To Resume—St. James and La Fleur Consolidate

Wallace—The Red Monarch Consolidated Mining Co. is preparing to begin work after a year's suspension. The property is on Beaver Creek and the main development is a crosscut tunnel 4,400 ft. long which has cut three promising veins. The first is 2,900 ft. from the portal and a drift several hundred feet long and a 75-ft. raise have exposed considerable lead-silver ore. It is now proposed to sink on the ore.

The St. James Mining Co., which owns a group of claims on Sunset Peak covering an extension of the famous Sunset vein, and the La Fleur Mountain Copper Mining Co., which has a copper property in Stevens County, Wash., have been consolidated, the new company being called the St. James-La

Fleur Mining Company. In the formal announcement of the merger the president of the St. James states that it is expected that the earnings of the La Fleur will provide funds for the development of the St. James.

An important strike of lead-silver ore is reported in the Bryan property, about five miles from Saltese, Mont., on the west fork of Packer Creek. The strike is described as 7 ft. of ore, having high values in silver. Control of the property is owned by the Days, of Wallace.

MONTANA

Anaconda Experimenting With Storage Battery Locomotives—Butte-Jardine Breaks Ground for 100-Ton Plant

Butte—For some time Anaconda has been experimenting with three different Edison storage battery locomotives. Others have been ordered but deliveries are slow. An official of the company has expressed himself as being highly satisfied with results to date, although no data have as yet been assembled as to relative cost of these compared with trolley locomotives. The chief difficulty that the company had experienced in the use of trolley locomotives had been in protecting the overhead wire at the mouths of chutes, where it was difficult for a workman to avoid striking it with bars.

The Nettie and the Emma mines, the latter the property of the Butte Copper & Zinc Co. but being operated under lease by Anaconda, are popularly considered among the best earning mines of the Anaconda at present. From the Nettie is coming a considerable tonnage of silver ore. Manganese ore is being mined at the Emma, a portion of which is being shipped to the ferromanganese plant at Great Falls, Mont., and the balance direct to eastern rolling mills.

Deeper development at the Black Rock mine of Butte & Superior appears to indicate a lessening of the iron content with an increase in the zinc. Results attending the employment of more than 1 per cent of oil in the flotation process at the Black Rock mill are proving satisfactory, 97 per cent being shown for July, 3 per cent more than the monthly average for the past few months and 4 per cent more than for June. Under the ruling of the United States Supreme Court in the Minerals Separation case, to avoid patent infringement more than 1 per cent of oil must be used per ton of ore, and this the Butte & Superior seems to have accomplished. Butte & Superior ores are averaging from 14 to 15 per cent of zinc and slightly more than 5 ounces of silver per ton.

Net earings of Tuolumne Copper are ranging around $18,000 monthly. Sinking of the Main Range shaft from the 1,200 to the 2,000 ft. level is expected to start within a week or ten days.

The objective vein of the crosscutting on the 2,700 ft. level of the Colorado mine has been reached, showing more than 20 ft. of first-class ore, that is, ore in which the copper content is 5 per cent or more.

Development work by North Butte has increased ore reserves somewhat the last quarter and with improved market conditions it is believed that the present tonnage can be increased.

Monthly shipments from the Crystal Copper Co.'s properties near Basin, Mont., and from the Goldsmith mine in the Butte district are amounting to eight cars. The orebody at the Goldsmith ranges from 18 in. to 7 ft., with the grade high, particularly in silver.

With more of the details coming to light in connection with the compromise reached between the Anaconda and the Elm Orlu over a disputed section of the Pilot-Butte, it appears that the former won something of a victory over the Anaconda, as vein territory of much richness in the Pilot Butte claim of the Anaconda passes to the Elm Orlu through the apexing of a vein in the Elm Orlu which, on dip, united with the Pilot-Butte fissure.

Elkhorn—Boston & Montana continues drifting in ore in the Blue Jay vein on the 300 ft. level. Several smaller veins have been opened carrying ore and the tonnage of milling rock appears to be increasing. Raising for the Park vein is in progress from the 300 level.

Troy—Merger of the Silver Tip Mining Co. with the Troy and the J. P. Lead companies is proposed. The three corporations hold 26 mining claims near Troy, Mont. Spokane interests are behind the proposed consolidation.

Boulder—Work has been resumed at the Robert Emmet and two well defined veins are being opened.

Comet District—Plans are under way by the Montana Cons. for a resumption of milling operations. A large tonnage of silver-zinc ore is available.

Champion District — Ground was broken by Butte Jardine last week for the construction of a 100-ton flotation plant, to cost an estimated $65,000. The flow sheet is so arranged as to permit of increasing the capacity to 200 tons. Timber to the amount of 135,000 ft. has been cut and the power and water lines are in. Since the latter part of June, first class ore to the amount of $16,000 has been shipped. A body of milling ore 351 ft. long with the ore still continuing has been officially reported. This shoot has an everage width of 5 ft. and grades about 18 oz. silver and $1.50 gold.

MICHIGAN

The Copper District

Seneca To Start Development of 5th Level

Houghton—The depression in the copper situation continues to influence adversely the condition of every copper mine in northern Michigan. Perhaps the worst feature is the psychological depression on the men employed in the mines and upon the business people of the community. The coal problem has been relieved to a considerable degree but the price paid for coal is simply another additional problem. The labor problem has been alleviated.

Additions to the cost of production cannot readily be met by Michigan copper mines. Under the circumstances the further increase in freight charges is embarrassing. Rates now will vary from 20 to 40c. a ton, depending upon the distance of the haulage. Two years ago the lowest rate was 10c. a ton and the highest 18 cents.

Calumet & Hecla's operations are now confined to the conglomerate lode and to the extraction of copper from the lake sands. But one shaft continues in operation on the Osceola lode. That is No. 15, No. 16 having suspended.

Mayflower's raise in the west crosscut is in over 70 ft. and fairly good vein matter has been showing for ten days. In the southerly drift, 160 ft. from the shaft, there is more vein matter.

Seneca's work at the Gratiot property has now reached a point 700 ft. to the south on the 13th level. The character of the formation indicates that it ought to run 25 lb. to the ton. For a distance of 200 ft. the Gratiot opening has been in rock of this grade. Practically all the way from the shaft the openings have been in average Kearsarge lode ore which may be mined and milled profitably under normal cost conditions.

Development of the 5th level at the Seneca is about to be started. The depth has been attained and the lateral tunneling to the lode will be under way within a few days. Then the raise to the level above will be driven and the drifts in the vein, both north and south, started. The 4th level south has reached the Ahmeek boundary. The 3rd and 4th levels have now been driven 670 ft. to the north and the only noted improvement has been in the general character of the ground in that direction. The conditions of the ground in the both levels on the south has been indicative of a lode formation that will compare favorably with that which was milled last spring. It is now planned to boost the tonnage to 2,000 daily as soon as the hoisting plans are completed to take care of such an output. The underground development of the average Lake copper mine is ordinarily away behind the equipment of the surface plant.

Menominee Range

Much Diamond Drilling Under Way in Crystal Falls Field

Crystal Falls—Considerable diamond drilling is being conducted in the Crystal Falls field at present, there being more drill outfits in operation than for some time past. New orebodies are being sought, but no results are obtainable. The Cleveland-Cliffs Iron Co. is again drilling on the lands in Sect. 12, 42-33. Ore was found here a few years ago, but sufficient work was not done at that time to prove the extent of the deposit. Oglebay, Norton & Co.

have two drill outfits going on their property in Sect. 24, 25 and 26, 43-33. The McKinney Steel Co. is making a geological survey of its properties on the range and it is likely that drilling will follow. B. C. Neely and associates have a drill in operation on Sect. 7, 42-32. This property has been drilled several times in years past, but the orebody has never been outlined in detail. J. M. Longyear has two drills working on the southward extension of the iron formation of the old Mansfield mine.

Gogebic Range (Including Wisconsin Section)

Mellen, Wis.—At the Berkshire mine near Mellen, Wis., at the western end of the Gogebic range, preparations are being made to resume operation. It is a low-grade, open-cut proposition, and the ore, though largely magnetic, is wet-concentrated with jigs after being crushed. The crushing is not so fine as to require sintering of the concentrates. At the same time this prevents obtaining concentrates of high iron content. If results can be obtained that are satisfactory, it will be of great interest to the district as there are undoubtedly large amounts of low-grade "ore" on the range which would be susceptible to similar treatment. The Gogebic iron range as known at present extends in an east and west direction about 55 or 60 miles, but the producing mines are all contained in the portion beginning at the middle of the range and extending eastward about 18 miles. The Berkshire is 18 miles west of this productive section, but if the concentration process proves successful in the long run, there will undoubtedly be other mines opened up in the section now regarded a barren of merchantable ore. At the eastern end of the productive section the Morgan mine is in the development stage, and eight miles east of that the Whitesides interests of Duluth are still drilling the old Presque Isle mine property.

Ironwood, Mich.—The steel headframe at the "II" shaft of the Pabst mine is about completed as far as the steel work goes.

The Newport mine has built a garage and a large stable, both of concrete.

The Tilden mine is to have an electric haulage system installed in No. 10 shaft; it will be a trolley system supplied from a rotary converter to be placed in the new engine house.

MINNESOTA

Hill-Trumbull Makes First Shipment—Washing Plant Going Up at Mariska Mine

Coleraine—The Hill-Trumbull mine of the Mesaba Cliffs Iron Co. has made its first shipment under the new ownership. It was opened by the Oliver Iron Mining Co. in 1909, but was surrendered at the time the Oliver surrendered all its Great Northern leases. In 1919 it was taken over by the present operators, who have continued the development of the open pit and have installed a one-unit washing plant that can handle 80 cars per shift to care for the siliceous ore. The shipment made was of merchantable ore but the washing plant will be running soon.

Construction of the Hill-Annex washing plant of the Interstate Iron Co., adjoining the Hill-Trumbull, is progressing. Structural steel is practically all in place and the half-mile approach, which has been built of overburden stripped in opening the mine, has been completed. The Hill-Annex has a reserve of approximately 22,000,000 tons, wash and merchantable.

Gilbert—Work is progressing rapidly on reopening the old Mariska mine. Bowe-Burke Co. are the new operators and J. C. Hartness of the Eveleth is in charge. Erection of a small washing plant to serve the mine is under way. It will be the first installation of its kind in the immediate vicinity.

Pickands, Mather & Co. has started to deepen No. 2 shaft at the Corsica mine. It will be deepened about 100 ft. to develop the lower area of the orebody.

ALABAMA

Birmingham Ore Mining Co.'s Washing Plant Near Completion

Birmingham—The recent cargo of manganiferous iron ore brought up from Brazil, via Mobile, is now being delivered to bins and stacks in the yards of the Tennessee Coal, Iron & R.R. Co. at its Ensley plants. Some of it is being brought up the Warrior River on the Government-owned and operated barge lines and some by railroad. There is about 7,500 tons of ore to be moved and it is understood that shipments will continue. Furnaces are desirous of getting a good supply of ore on hand and are making heavy demands on the railroads. Preparations are being made for winter. Reports from the ore mines throughout the district indicate that colored labor which wandered north is gradually returning.

The Sloss-Sheffield Steel & Iron Co. is making some investigations looking to the development of ore deposits around Compton, about 20 miles north of Birmingham. The vein is rather thin but if the demand warrants may be profitably worked.

The Birmingham Ore & Mining Co. will complete its jigging plant in the next fortnight at the Helen Bess mines, on Red Mountain, not far from the heart of Birmingham and will then wash all the ore mined there. Construction was begun months ago but met with delay. It has already been in partial operation.

JOPLIN-MIAMI DISTRICT

Oklahoma-Kansas-Missouri

Tampa Company To Seek Deeper for Better Ore—Hawkins, at Hockerville, Buys Mill

Baxter Springs, Kan.—Although getting all ore from its No. 3 shaft, the Lucky Jew Mining Co. is drifting at No. 1 shaft and sinking at No. 2. The mine, which is eight miles west of Baxter and at the extreme northwestern point of development of the Miami-Picher-Baxter field, was long considered a doubtful proposition by most mining men. Recently it has developed into a steady producer, the average recovery being approximately 11 per cent (in local terms), the company making about 30 tons of concentrates daily, operating the mill single shift. Drifting and sinking now under way at the No. 1 and No. 2 shafts are for the purposes of tapping lead runs indicated by drilling. A very fair percentage of the concentrates now being made are lead of a premium grade. The zinc concentrates also average from 61 to 62 per cent metallic zinc. Operations are conducted at a depth of 320 ft. at the No. 3 shaft, and at slightly shallower depths at the two others. W. C. Bowman is president and M. G. West secretary and manager, both being from Kansas City, Mo. H. Stout is superintendent.

The U. S. Smelting Co. is completing the sinking of a shaft one-half mile west of its No. 2 mill, near Baxter, not far from the Lucky Jew property. The shaft was put down in a lime bar, but heavy water was tapped only a few feet from the bottom, which is at the 320 ft. level. One 3-in. and one 7-in. steam pump have been installed and another will follow. Good lead cuttings have come up in the water but exploration has been impossible. It is planned to connect the shaft with a surface railroad that probably will tap one or two other shafts between this one and the mill. D. R. Muir, Baxter, Kan., is manager.

The Tampa Mining Co. is planning to sink, expecting to find better ore. It is now working at 265 ft. and surrounding mines have ore at 300 ft. and below. This company recently spent $3,000 to drain the water at one of its shafts, preparatory to sinking, only to have its activity stopped by lack of coal. G. C. Warner, recently of Tampa, is principal owner.

Picher, Okla.—The Huttig L. & Z. Co. has completed the first of four field shafts that will be put down between its No. 1 and No. 2 mills northwest of Picher. Dirt from this new shaft will be taken to No. 2 mill over the surface road, for which an 11-ton Davenport locomotive was recently delivered. The site for a second field shaft has been located and sinking begun. Ore from it also will go to No. 2 mill, as well as from the third shaft. Ore from the fourth field shaft will be carried to No. 1 mill by an incline tramway. This plan will obviate the necessity of the company taking its surface railroad across the tracks of the Southwest Missouri interurban railroad. The first field shaft has gone into good ore.

Hockerville, Okla.—The Hawkins Mining Co., which recently discovered a rich deposit of lead ore on a lease just south of town, has purchased a concentrator at Sunnyside, three miles distant, and is moving it to the mine. The mine continues to be a big lead producer. One chunk of ore weighing about 1,000 lb. will be sent to the Missouri State Fair at Sedalia.

THE MARKET REPORT

Daily Prices of Metals in New York

Aug.	Copper	Tin		Lead		Zinc
	Electrolytic	99 Per Cent	Straits	N. Y.	St. L.	St. L.
26	18.10@18.30	43.00	46.75@47.00	8.50	8.60@8.75	7.90@7.95
27	18.10@18.30	43.50	47.00@47.50	8.40	8.75	7.90@7.95
28	18.10@18.30	43.50	47.00@47.50	8.35	8.75	7.85@7.95
30	18.10@18.30	43.00	46.25@46.75	8.35	8.75	7.85
31	18.10@18.30	42.50	45.50@45.75	8.35	8.50@9.00	7.85
Sept. 1	18.10@18.30	42.50	45.50@45.75	8.35	8.50@9.00	7.85

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point. All prices are in cents per pound.

Copper is commonly sold on terms "delivered" which means that the seller pays the freight from refinery to buyer's destination. The delivery cost varies, and it would be confusing to figure net prices on individual transactions. Consequently, an average deduction of 0.15c. is made from the "delivered" price, to arrive at the New York price. When copper is sold f.o.b. or f.a.s. New York, of course no deduction is made.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Aug.	Copper			Tin		Lead		Zinc	
	Standard		Electrolytic						
	Spot	3 M		Spot	3 M	Spot	3 M	Spot	3 M
26	93⅜	95¼	111	269½	278	35⅜	35⅞	39¾	41¼
27	94¼	95¾	111	274¾	282¼	35⅞	36	40	41½
28	....	....	....	....	....	....	....	....	....
30	94¾	96	111	273	281½	36½	36¾	40	41½
31	95	96½	111	272	279	36⅝	36¾	39½	41
Sept. 1	95	96½	111	269½	276	36½	36½	39¼	40½

The above table gives the closing quotations on the London Metal Exchange. All prices are in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Aug.	Sterling Exchange	Silver			Aug.	Sterling Exchange	Silver		
		New York, Domestic Origin	New York, Foreign Origin	London			New York, Domestic Origin	New York, Foreign Origin	London
26	357½	99½	98	61⅛	30	355	99½	94¼	59⅝
27	357½	99½	97¾	61	31	354½	99½	92⅝	58¾
28	356	99½	97½	60⅝	Sep 1	356	99½	91½	57⅝

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States. This quotation is retroactive to May 13.

Metal Markets

New York, Sept. 1, 1920

Price changes since last week have been of little importance. Sales of metal for August have generally been light, with the exception of lead, for which a good demand has existed. Low prices in London are acting as a brake on the metal market here.

Copper

No buying of importance is yet taking place at anything like the prices which the large producers are asking, viz. 18¾@19c. delivered. A few lots are being marketed at about 18¼c. delivered, but should the demand pick up this price is almost certain to increase. It is the general opinion that September will see a real buying movement, and that the average price will be at least ¼c. above that at which copper can now be had. Fundamental conditions are good.

Lead

A peculiar situation exists in the lead market. The A. S. & R. contract price continues at 9c., New York, and considerable metal is sold on this basis. On the other hand, lead can be imported from Europe and sold at a profit here at 8¼c. It is understood that 300 tons is on the dock here looking for a buyer at that price. This European lead is, in general, good Mexican and Australian brands. We quote prompt lead, New York, for the week at 8.25@8.50c., and forward delivery, 7.85@8.25c.

The dearth of lead in the Middle West and the fact that large quantities are being imported at New York for western delivery have caused the St. Louis price to rise above that quoted in the East. This is an unusual situation, which will continue until consumption slackens, or until domestic production is able to supply the demand. Small lots of favored brands for September shipment are commanding 9c. in St. Louis today, though some metal is being offered at ¼@⅜c. under this.

Zinc

Producers have been compelled to reduce their prices to 7.85c. to meet European competition. Even at this price some arguments have to be used to induce consumers to buy the domestic product, such as the fact that the brands are well known, as are the producers, and there will be no uncertainty as to shipment. Heretofore, we have quoted the New York price of zinc at 35 points above the St. Louis price, but in view of the abnormal conditions now existing, we quote, on Sept. 1, the New York price equal to the St. Louis price, 7.85c.

Tin

Some optimism was shown Thursday and Friday when the London market took a little spurt, but this week tin sellers are as doleful as ever, and report almost a total lack of business. The 99 per cent grade was depressed all of last month by the presence of about 1,300 tons of Chinese tin. Rarely has the tin market had a more quiet month.

Monthly Average Prices for August

Copper:	
New York Electrolytic	18.346
London Standard	93.935
London Electrolytic	111.143
Lead:	
New York	8.687
St. Louis	8.725
London	36.304
Silver:	
New York, foreign	96.168
New York, domestic	99.673
London	59.875
Sterling Exchange	360.404
Zinc:	
New York	8.185
St. Louis	7.835
London	41.220
Tin:	
99 per cent	43.856
Straits	47.620
London	274.048
Antimony	7.177
Quicksilver	83.806

Straits tin for future delivery: Aug. 26th, 46.75@47.25; 27th, 47.50@48.00; 28th, 47.50@48.00c.; 30th, 46.25@46.75c.; 31st, 45.75@46.00c.; Sept. 1st, 45.50@45.75c.

Arrivals of tin in long tons: Aug. 26th, China, 20; 27th, Liverpool, 75; 28th, Singapore, 200.

Silver

The silver market ruled steady and firm on China buying until Aug. 30. The London market was then demoralized by weakness in Indian exchange and continued sales by the bazaars. Supplies of foreign silver in our market continue limited and as the U. S. Treasury is buying all the Domestic output, exports to London are nil and only moderate amounts are available for China shipments.

Mexican Dollars—Aug. 26, 75; 27th, 74½; 28th, 74¼; 30th, 71⅞; 31st, 70¾; Sept. 1, 69½.

Gold

Gold in London on Aug. 26th, 115s.; 27th, 115s.; 30th, 115s. 5d.; 31st, 115s. 6d.; Sept. 1st, 115s. 1d.

Foreign Exchange

Yesterday francs were 6.97c.; lire, 4.67c.; and marks, 2.05c. New York funds in Montreal declined to 11⅝ per cent premium, probably due to the commencement of exportation of this year's grain. Only slight changes characterized the exchange market during the last week.

Other Metals

Aluminum—Ingot, 99 per cent and purer, 35.1c.; 98@99 per cent, 34.9c. Virgin metal still obtainable in open market at about 32.5c. for 98@99 grade.

Antimony—Market continues weak. Spot, 7c. per lb.; Cookson's "C" grade, 14@15c. Chinese and Japanese brands, 7c. W. C. C. brand, 9@9½c. [1]Chinese needle antimony, lump, firm at 8@9c. per lb. Standard powdered needle antimony (200 mesh), 10@12c. per lb.

Bismuth—$2.70 per lb., 500-lb. lots, and $2.72 per lb., 100-lb. lots. Market quiet.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady.

Cobalt—Metal, $3 per lb.; black oxide, $2 per lb.

Iridium—Nominal, $350 per oz. Heavy demand, but small supplies.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb., for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]Molybdenum Metal in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.; Monel metal, shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$100@$110 per oz.

Platinum—Firm at $115@$120 per oz. $105 per oz. in 100 oz. lots.

Quicksilver—Market quiet; $75 per 75-lb. flask. San Francisco wires $75. Barely steady.

Ruthenium—$200@$220 per troy oz.

[1]Selenium, black powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]Thallium Metal—Ingot, 99 per cent pure, $20 per lb.

Metallic Ores

Bauxite—About 52 per cent alumina content, less than 2 per cent iron oxide, up to 20 per cent silica and artificially dried to contain not more than 4 per cent free moisture, $10 per gross ton at mine; 54 per cent alumina and about 15 per cent silica, $11; averaging 57 per cent alumina, 8 to 12 per cent silica, less than 3 per cent iron oxide, $13 on basis of 8 per cent free moisture. Ores of very low silica content suitable for the manufacture of aluminum oxide and hydrate of alumina command a fancy price.

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a minimum of 6 per cent silica, 80@85c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 70@75c.

Iron Ores—Lake Superior ores, per ton, delivered at Lower Lake ports: Old Range bessemer, $7.45; Old Range non-bessemer, $6.70; Mesabi bessemer, $7.20; Mesabi non-bessemer, $6.55. Congestion at Lake Erie ports due to car shortage has resulted in decreased tonnage. The ore movement is better than at any previous time this season.

Manganese Ore—70@80c. per unit, 50 per cent Mn content, c.i.f. Atlantic seaport; chemical ore (MnO_2) $75@$85 per gross ton.

Molybdenum ore—85 per cent MoS_2, 75@80c. per lb. of contained sulphide, New York.

[1]Tantalum Ore, guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots, against recent price of 65@70c.

Titanium Ores—Ilmenite[1], 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $7 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $6@$7, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[1]Zircon—Washed, iron free, 5c. per lb.

[1]Zirkite—$90@$100 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Zinc and Lead Ore Markets

Joplin, Mo., Aug. 28—Zinc blende, per ton, high $52.70; basis 60 per cent zinc, premium $48.50; Prime Western, $47.50; fines and slimes, $45@$42.50. Calamine, basis 40 per cent zinc, $36. Average settling prices: Blende, $47.16, calamine, $38.18; all zinc ores, $47.12.

Lead, high, $110.25; basis 80 per cent lead, $110; average settling price, all grades of lead, $104 per ton.

Shipments for the week: Blende, 13,591; calamine, 33; lead, 2,121 tons. Value, all ores the week, $862,870.

A total of 295 carloads of blende were shipped at an average of 46.2 tons per car. The larger tonnage is being shipped in coal cars, as few box cars are provided.

Platteville, Wis., Aug. 28—Blende, basis 60 per cent zinc, $52.50 per ton for high grade. Lead ore, basis 80 per cent lead, $105@$110 per ton. Shipments for the week: blende, 1,373; lead, 60 tons. Shipments for the year: blende, 47,143; calamine, 2,330; lead, 3,900; sulphur ore, 1,209 tons. Shipped during week to separating plants, 2,107 tons blende.

Non-Metallic Minerals

Asbestos—Crude, No. 1, $2,400@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax. Freight rate from mines to Sherbrooke, Quebec, over Quebec Central R.R., 20c. per cwt.; from Sherbrooke to New York, 27½c., carload lots; freight to New York for crude No. 1, f.o.b. Thetford mines, $8.45 per ton, carload lots. Market very strong, owing to heavy demand and a production that is 25 per cent below normal. Higher prices for all grades of material are expected soon.

Barytes—Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $24@$30 in bags, carload lots; (off-color) $22@$26 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $12 per gross ton; ground (white) $23@$25; ground (off color) $16@$19 per net ton, f.o.b. Cartersville, Ga. Crude, 88 to 94 per cent, $23; ground (white) $40.50; ground (off color) $27 per net ton, less than carload lots, f.o.b. New York. Crude, not less than 98 per cent, $11@$11.25 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—Domestic, extra light, 5@6c. per lb.; light, 4½@5½c.; heavy, 4@5c; English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin)—Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground,

$15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@ $30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$18 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $25@$30 car lots, f.o.b. Baltimore; ground, $17@$20, f.o.b. North Carolina points; $17@$20 per ton, No. 1 ground, f.o.b. New York State; $21@ $23 per ton, ground, f.o.b. Maine.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Graphite—Crucible flake, 85 per cent carbon content, 8c. per lb.; 88 per cent, 9½c.; 90 per cent, 10½c., all f.o.b. New York. Crucible grades of Alabama graphite sell as follows, f.o.b. Ashland, Ala.: 80 per cent, 5c.; 90 per cent, 10c. Lubricating grades in increasing demand, with price ranging from 11c. for the 85 per cent guaranteed grade in car lots to 30 and 40c. for higher grades. Mexican, amorphous, $45@ $55 per short ton; Korean, 3½c. per lb.; Madagascar, 8c.; Ceylon, 4½@15½c.

Gypsum—Raw crushed rock, $3.50@ $4 per ton; raw ground fine, $4@$4.50; calcined stucco, $9, all f.o.b. works. Containers extra. The last price quoted for plaster of paris in carload lots was $4.25 per 250-lb. bbl., alongside dock, New York; but a new price, not yet made public, will soon be effective.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $65@$75 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—Imported block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20 @$1.40; No. 4, $2@$3; No. 3, $4.25@ $5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $4; No. 3, $5.75; No. 2, $7; No. 1, $9; A1, $14; extra large, $25, all f.o.b. New York; ground, $85@$100 per ton, Philadelphia.

[1]**Monazite** — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses.

Pumice Stone—Imported, lump, 4@ 50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish, fines, per unit 12c., c.i.f. Atlantic seaport; furnace size, 17½c.; run of mine, 12@14c.; domestic, fines, f.o.b. mines, 12@14c.

Quartz—(Acid tower) fist to head, $10; 1½ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines. F.o.b. Wausau, Wis., the price is $16 per ton in car lots, and $22 less quantities, including bags.

Sulphur—$18 per ton for domestic; $20 for export, f.o.b. Texas and Louisiana mines.

Talc — Paper making, $10@$20 per ton; roofing grades, $9@$15; rubber grades, $10@$15, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $15@$20 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60 @$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $2.25 @$2.50 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15-18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12 to $15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 17@18c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c. f.o.b. works.

Ferromanganese—For 76 to 80 per cent, prompt delivery, $200@$210, freight allowed; last half, $170; English, $190@200, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $80@$85, f.o.b. furnace.

Ferromolybdenum—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2.50@$3 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $80@$85; 75 per cent, $150 @$160.

Ferrotungsten—70 to 80 per cent W, $1.10@$1.15 per lb. of contained tungsten, f.o.b. works.

Ferro-uranium—35 to 50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium—Basis 30 to 40 per cent, $6.50@$9.50 per lb. of V contained, f.o.b. works.

Metal Products

Copper Sheets — Current New York price, 29½c. per lb.; wire quoted, 22½@ 23c.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver—Unchanged at 39½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 26¾c.; sheathing, 25¾c.; rods, ⅜ to 3 in., 23¾c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $160 per 1,000, f.o.b. Pittsburgh.

Chrome Brick—$100@$110 per net ton, carload lots, eastern shipping points.

Chrome Cement—40 to 45 per cent Cr_2O_3, $50 per net ton, and $55 in sacks, carload lots, eastern shipping points.

Clay Brick — First-quality fire clay, 9-in. shapes, $55@$60 per 1,000, Pennsylvania, Ohio, and Kentucky works; second quality, $50@$55. First quality, St. Louis, $45; New Jersey, $75.

Magnesite Brick—$110@$120 per ton, eastern shipping points; 9-in. straights, $90@$100; 9-in. arches, wedges and keys, $95@$105; soaps and splits, $110 @$120.

Silica Brick—9-in. per 1,000, $56@ $61, Birmingham, Ala.; $55@$60, Mount Union, Pa.; $65, Chicago district.

Iron Trade Review

Pittsburgh, Aug. 31, 1920

The continued stagnation in the steel market is having its effect on some producers, leading them to plan curtailments in production, but no effect upon prices, which are stiffly maintained. This is in line with pre-war experience, when sellers felt that to reduce prices would be to discourage buying. Such demand for steel products as exists is for early deliveries, and for such deliveries steel is still scarce. The practical ending of the midsummer period, normally dull, with the market grown still duller nevertheless, is regarded in some quarters as ominous.

Transportation conditions continue to improve and are likely to be practically normal within a few weeks.

Pig Iron—Actual market prices on bessemer and basic have been developed by a few transactions totaling only a few thousand tons, at $48 Valley, for both grades, previous market prices having been $47 and $46.50, respectively. Foundry remains at $50, Valley, to which level it recently advanced. Inquiry for all grades is very light and there is likely to be a deadlock for some time.

Steel—There is only occasional demand for billets, chiefly from brokers, and sheet bar demand has become light, but mills show relatively little disposition to shade prices. We quote billets at $60 and sheet bars at $67.50.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $20@$22; foundry, $23@$24.

COMPANY REPORTS

Alaska Gold Mines Co.

Gold; Alaska

The following is a comparative summary of results of mining and milling of the Alaska Gastineau Mining Co. for the periods indicated:

	Second Quarter 1920	First Quarter 1920
Tons milled	537,754	625,890
Gross value	$0.85	$0.84
Yield per ton	.68	.66
Tails per ton	.17	.18
Extraction	79.39%	79.16%
Value recovered	$0.68	$0.66
Operating expenses, less miscellaneous income	$0.79	$0.79
Loss per ton	$0.11	$0.13

During the quarter 646,327 tons of ore was broken in the mine and 535,874 tons trammed to the oreways, as compared with 561,358 tons broken and 627,451 tons trammed during the previous quarter. Of the amount trammed about 41.6 per cent represented excess ore drawn from the caved stopes. The transportation division operated satisfactorily throughout the quarter. A total of 537,754 tons of ore was milled, compared with 625,890 tons for the previous quarter.

The gross value of ore delivered to the mill during the quarter averaged $0.854 per ton, or an increase over the first quarter of $0.019. Operating expenses, less miscellaneous income, amounted to $0.79 per ton, as compared with $0.79 per ton for the previous period. The miscellaneous income showed a net loss of $10.67, the loss sustained in the operation of the company's boarding houses having been in excess of the amount received from the sale of power.

The following statement compares the operating results:

	Second Quarter 1920	First Quarter 1920
Revenue:		
Gross value of bullion and concentrates produced	$364,866.48	$413,246.04
Expenses:		
Ore production and transportation	$237,696.86	$285,406.01
Milling	150,980.00	172,441.33
Shipping and smelting charges	15,339.45	17,572.48
Administration and general expense	22,520.62	22,410.60
Total operating expenses	$426,536.95	$497,830.92
	$61,670.45*a*	$84,584.88*a*
Miscellaneous income	10.67*a*	2,966.94
Operating loss	$61,681.12	$81,617.94

(a) Loss.

Included in costs in the above statement are prepaid development items representing costs of breaking and preparing ore in previous periods, which have been carried on the books as deferred charges. Consequently, although the above operating statement shows a loss after including these charges, the actual cash receipts and disbursements for the period reflect a cash gain of $8,603.46.

International Nickel Co.

Nickel; U. S. and Canada

The consolidated general profit and loss statement of the International Nickel Co. for the three months ending June 30, 1920, follows:

Earnings		$2,172,097.06
Other income		272,208.32
Total income		$2,444,305.38
Administration and general expense	$160,651.38	
Reserved for U. S. and foreign taxes (estimated)	306,973.33	467,624.71
Net income		$1,976,680.67
Depreciation and mineral exhaustion		574,611.74
Profits		$1,402,068.93
Dividends		
Preferred No. 59, payable Aug. 2, 1920		133,689.00
Balance		$1,268,379.93

Union Miniere du Haut-Katanga

Copper; Congo Free State

The report of the Union Minière du Haut-Katanga for the year 1919 indicates that seven copper mines were regularly in operation during that year, producing 876,000 tons of ore suitable for direct smelting and 316,000 tons of ore unsuitable for that purpose. The output of smelted copper amounted to 23,028 tons, against 20,238 tons in 1918. The number of native workmen increased from 6,000 in 1918 to 12,000. The average producing price per metric ton c.i.f. European ports was 2,500 fr., not taking into account the charges arising through the transfer of the company's office from Antwerp to London during the war and its becoming liable to British income and other taxes thereby. The copper production during the first six months of 1920 was affected by strikes on the railways connecting Katanga with Beira, and only amounted to 10,251 tons.

New Jersey Zinc Co.

Zinc; New Jersey

A statement of the New Jersey Zinc Co. for the quarter ending June 30, 1920, follows:

Income (including dividends from subsidiary companies) after deductions for expenses, taxes, maintenance, repairs and renewals, betterments, depreciatioo aad contingencies		$3,341,576.98
Deduct interest on first mortgage bonds	$ 40,000.00	
Reserve for retirement of bonds	75,000.00	
Reserve for federal taxes	470,000.00	585,000 00
		$2,756,576.98
Dividends		
Quarterly, 4 per cent:		
Payable Aug. 10, 1920		1,680,000.00
Surplus for the quarter		$1,076,576.98

Cerro Gordo Mines Co.

Silver, Lead, Zinc; California

The fourth annual report of the Cerro Gordo Mines Co. for the year 1919 indicates that 357 tons of lead-silver ore, of a net smelter value of $26.21 per ton; 167 tons of zinc ore, with a net smelter value of $12.45 per ton; 159 tons of slag worth $3.92 per ton—a total of $12,060.66—were produced. Operations for the year resulted in a deficit of $26,481.27, and were abandoned in June, 1919.

August Mining Dividends

The following is a partial list of mining dividends paid during August, 1920:

U. S. Mining and Metallurgical Companies.	Situation.	Per Share.	Totals.
Am. Zn. Ld. & Sm., pfd.	U. S.	$1.50q	$120,810
Anaconda Copper Min., c, s, z	Mont.	1.00q	2,331,250
Barnes-King Develop., g	Mont.	1.65q	20,000
Gemini, g, s	Utah	6.00k	30,000
Internat. Nickel, pfd.	U. S.-Can.	1.50q	133,689
Miami Copper Co.	Ariz.	0.50q	373,557
Mohawk Mining Co., c	Mich.	1.50q	150,000
New Cornelia Copper Co.	Ariz.	1.25q	450,000
New Jersey Zinc Co.	U. S.	4.00q	1,680,000
United Verde Ext., c	Ariz.	0.50q	525,000
Canadian, Mexican, Central and and South American Companies			
Amparo Mining, g, s	Mex.	0.05qx	100,000
Coniagas Mines, Ltd., s	Ont.	0.12½q	100,000
Greene-Cananea Copper	Mex.	0.50	250,000
Hollinger Consol. Gold	Ont.	0.05bl-m	246,000
Ouro Preto Gold	Brazil	1sh., s-a	£1,358.05
Holding Companies.			
General Development Co.	U. S.	0.50k	60,000

m, monthly; q, quarterly; s-a, semi-annual; k, occasional; x, includes an extra dividend.

Greene-Cananea Copper Co. resumed dividends on Aug. 23, the first payment since February, 1919.

Bankers Trust Co., New York City, declared its readiness to pay the initial dividend of $1.35 on the "American shares" of Rand Mines, Ltd., on Aug. 27.

The Co-ordination of the Mining Industry

*By J. E. SPURR**

MR. STOUGHTON, I understand, was to have spoken of the Federated American Engineering Societies. I am glad to add my vote to the effect that this is a big idea. It means an organization that will make it possible for the great and powerful engineer class of the country to act as a unity and therefore effectively, instead of as individuals or scattered and separate societies, and therefore ineffectively. By all means we should support this enthusiastically. It will make engineers better citizens.

But there is another classification in which we fall, besides being engineers. We are also miners—that is, representatives of the mining industry; and I venture to say that we are as much wrapped up, heart and soul, in our business as miners as we are in our profession as engineers. Looking at this phase we find that other engineers have less in common with us than many groups who are not engineers: the civil engineers, the architects, the highway and sanitary engineers, ordinarily concern us less closely than do the various groups other than engineers that form an integral part of the mining industry—namely, all those who mine, mill, smelt, transport, sell and manufacture the products of the earth. Engineering is our profession, mining is our business; we should organize for efficiency along both lines, and they lead us in different directions. Organization as engineers will allow us to use our training and skill for the greatest general service as citizens: organization as miners will promote the scientific progress of the great basic industry for which we are so largely responsible.

That organization of the industry has already gone far is shown by the record of this society. There are also other organizations devoted to various phases of our industry. We have a Mining and Metallurgical Society of America and an American Mining Congress. We have in Washington the Bureau of Mines and the Geological Survey; and in many of the states Mining Bureaus and Geological Surveys; in the legislative branch in Washington we have standing Committees on Mines and Mining. We have various other societies, such as the Zinc Institute and the newly organized Society of Economic Geologists; and we have a press devoted to the various phases of mining, from engineering to marketing. These elements of the government of the mining industry are like the thirteen colonies before they cast around for a plan whereby they might work as a unit. At present they often work at cross purposes, thus neutralizing their strength.

Yet those who conduct the industry have a heavy responsibility. This country has been more than all other nations endowed with great deposits of minerals. But the wise use of this power is an opportunity that will come to us just once in all eternity. As the stock phrase goes, "these ores are wasting assets." Our responsibility is to so manage the industry, with the aid of science, technical skill, knowledge of political economy, and of national and international relations, that the greatest benefit shall be obtained for the greatest number for the longest time.

The American Institute of Mining and Metallurgical Engineers specializes on the sciences of mining, metallurgical and geological engineering; the Mining and Metallurgical Society on the philosophical problems of mining; the American Mining Congress represents the mining interests, as the United States Chamber of Commerce does the manufacturing and trading interests, and has special direct methods for influencing direct governmental action in favor of mining. The Bureau of Mines specializes largely in safety work and metallurgical research; the Geological Survey on mining geology and the condition of the mining industry.

There is much overlapping, and there are many gaps. No attempt at co-ordination or the invention of a central co-ordinating device is described. Indeed, I believe that no two of these are co-ordinated. Is it not plain that we could progress further and faster if it could be done?

Granted that this is desirable, how shall we go about it? First, perhaps, for each group to find out what the other groups are doing. Has the Institute made any critical study of the Bureau of Mines or of the Mining Congress? I know that Mr. Callbreath, secretary of the Mining Congress, who is here, has appointed a committee to consider the co-ordination of the Institute and the Congress. How many of these organizations have made a critical study of the various branches of executive control of the mining industry in Washington or the mechanics of mining legislation by Congress, or the machinery which imposes tariffs on ores or their products? It is very much their business to do so.

Investigation, therefore, should come first. Then, in any event, co-ordination. Possibly a central council could be devised, a central mining council, scientifically chosen from the principal mining groups. If any special program agreed on by such a council should be supported by all the groups they should represent, the effect would be instant and powerful. It is not too much to say that the mining industry could thus be steered in the general direction of the greatest good to the greatest number for the longest time.

*This address, on account of lack of time, was read only by title at the banquet of the American Institute of Mining Engineers in Minneapolis on Aug. 26, 1920.

There is no use in imagining that any one organization like the Institute can swing the whole thing itself. It won't do it, and it can't do it. These other units are solid facts, like itself; and they have originated from fundamental needs, though ever so clumsily expressed. Mining engineers cannot afford to be narrow and clannish in this respect. It only reacts against them and diminishes their influence and authority.

Who controls the representation of the mining industry in Washington? In the executive branch, a lawyer; in the legislature, a conclave of farmers, lawyers, doctors, and what not. There is not a mining engineer on the Mines' Committee of either house; nor have they even a consulting engineer. You may imagine that the Bureau of Mines and the Geological Survey act in this capacity; but they do not. When the engineers of these bureaus appear before the committees, the committee has the same defensive and offensive attitude as it has toward the engineers with axes to grind for special interests. Its members believe that the Government bureaus are primarily interested in their own expansion, or, more specifically, in appropriations.

When the exigencies of the war showed the necessity of a close study and control of the mining industry no attempt was made to consult the industry itself, nor any one of its representative bodies. The control was left uncertain and remained split among half a dozen departments and special war boards. Necessity developed gradually a sort of central informal council out of this confusion, which became more definite toward the close of the war; but all this strenuous effort vanished with the armistice. In England they were not so quick to forget what they had learned as to the close relation between mining, political economy, and statecraft. In this country, at least, we must organize the relations of the mining industry and the Government largely from without the Government, for the inevitable bureaucratic organizations at Washington are not so free to speak or to work for reform and progress. Without outside stimulus they tend to become crystallized, set, and sometimes reactionary. But they are, I believe, in general, thankful for the outside stimulus.

The theme of my story is therefore: First a liberal attitude of one mining organization toward the others; second, an interested and thorough investigation by each of all the rest; third, co-ordination among all; and fourth, the suggestion of the achievement of this co-ordination through a central council.

Contracting and Leasing

CHANGED economic and labor conditions have brought into prominence both the contracting and leasing systems in mining operations. It is unnecessary to dilate upon the broad conditions affecting the mining industry, but high labor costs, diminishing tons per man per shift, have stirred mine managements to the point where they find it necessary to make a considerable amount of change in procedure. How to secure co-operation of mine workers in an enterprise is a critical problem, which affects the worker's interests as well as the industry as a whole. Contracting development work and leasing a block of ground in a mine have long been established practice, but there is a preponderance of the day's pay system. The bonus system has been thoroughly tried out, and it is doubtful whether it has adequately met the situation. At best it is a modification of the contract system.

The contract system has the advantage of putting a contract crew upon its mettle and establishing a definite responsibility for results. By making it complete—that is, making the contractors responsible for tools, supplies and power used—the company supplying only the necessary timber for support of workings and the general equipment for hoisting and haulage, the system has the advantage of establishing a definite business relationship between the company and the men on a basis distinct from day's pay and putting the details up to the men themselves. There is a real opportunity for a man to make better than day's pay. Skill and foresight will bring an added reward. The result to the company is a greater stabilization of operating conditions.

In leasing operations with payment on a sliding scale of royalties based on the recoverable value in the ore mined, the lessee has a stake in the enterprise. He is under the incentive to practice selective mining and to keep his own costs at a minimum. He occupies a higher place in the community in which he lives. The leasing system operates to produce cleaner mining and the lessee is alive to the following of leads and stringers of ore, with the result that sometimes blocks of ground abandoned as unprofitable under regular company operation become once more remunerative. A mine with well-developed ore bodies cannot lease its ground to advantage, but where ore bodies are numerous, irregular, and uncertain in size, as well as distributed over a wide area, the conditions are much more favorable for the leasing system. It is in mines of this kind that leasing is successful, though in mines of the developed type stoping on a contract basis presents distinct advantages.

We believe that under existing conditions both the contract and leasing systems warrant extensive use.

The Public and Mining Information

NOWADAYS one has but to enter a drug store to satisfy a desire for about everything from drugs to books and furnishings. Similarly with the press. For example, to be properly informed on the copper situation, perusal of the pages of a periodical ordinarily devoted to society news, fashions, art, and the theater seems to be in order. We were surprised to see in the September *Vanity Fair* an article covering the copper situation—for the layman (and by one?). It was easy reading, but that is about all that can be said for it. Excepting obviously erroneous statements, as "the well-known public . . . is completely deprived of knowledge as to developments in copper," which the Government and the technical press have been providing for years; "as a result, the price quoted by the great producers is to an exceptional extent nominal, and *occasional sales are made by smaller dealers below the market*," and other conclusions of the writer requiring either qualification or elision, the article is commendable, if only as an attempt to clarify the situation for the benefit of the magazine's readers.

Oddly enough, comparatively little emphasis is placed by the popular press as a whole on the importance of the two great fundamental industries of the world—agriculture and mining. Considering humanity's su-

preme dependence upon these two activities, one would logically expect the conditions in farming or mining to be stressed more than they are by the general press. We have financial and class organs which make a specialty of covering particular fields, but, nevertheless, public ignorance concerning these two foundation piers to our commerce and prosperity needs much enlightenment.

We wish that knowledge of the copper industry's troubles were more generally disseminated, that information concerning our vanishing gold-mining industry were spread broadcast—by no means in a partizan sense—so that suggested remedies for the mining industries' ailments might be based on sound and fair premises through public understanding and co-operation; and that other phases of mining and metallurgy were better understood by the people at large.

Through its close contact with mines and minerals it is one of the functions of the technical mining press to inform the reading public of all phases of the industry. Necessarily, however, much of its published matter must be devoted to material that is intended for the specialist—the engineer—and hence will have only casual if any interest for other readers. Frequently articles are published, be they editorials, special contributions, or other matter, which are more general in appeal and purpose, but ordinarily they are only those embodying a broad economic discussion of some mining problem. But it is just these matters which the public should find of interest, and for which it should turn to the technical press for illumination. To keep pace with the expanding fund of human knowledge in all its branches is prima facie impossible, but to lose sight of the developments on the farms and in the mines means neglecting an inspection of the keystone of our prosperity.

"Salting"

IN A PREVIOUS editorial we touched upon the methods and ethics of dressing a mine for sale. The art of dressing progresses insensibly to that of salting. For the dresser may go further than putting his best foot foremost: he may so do this that it comes plainly under the category of sinful salting. An instance may be cited of a silver quartz vein, where the values were largely in streaks and spots of silver sulphides—argentite and tetrahedrite. This mine was sampled by many prominent engineers, who took every known precaution against salting. Their results varied widely, let us say from $16 to $23 average per ton; a final sampling gave, let us say, $12. The divergence was said to be due to the spotty nature of the ore, and the highest average was claimed to be as likely as the lowest. But the facts, as divulged by one on the inside, were that the moilers were miners from the vicinity, and that the owner of the mine rewarded them privately (in addition to their wages from the examining engineers) if they would simply hit the rich silver streaks a little harder and oftener in cutting the samples than they did the barren quartz. This was imperceptible to the watchful engineers who stood by; but if the mining costs were, say, $8, the difference between an average assay value of $12 and $16 doubled the net value of the mine.

The coarser and commoner tricks of salting are well known—as salting ore faces with a spray of gold or silver solution; or, more economically, salting samples, by inserting a syringe through canvas bags or in some other way—even through a keyhole a secondary enrichment may be accomplished. Salting of ore in place is expensive if the examining engineer takes large samples, and mill samples will exhaust the ammunition of a salter of this kind, and show a surprising discordance with the hand sampling. Therefore, salting the fluxes in the assayer's laboratory is a favorite trick, though easily detected if the assayer takes care to assay his materials continually.

We have seen samples, intended to promote investment or sale, that were salted in a cruder fashion. Dentist's gold, plugging the vesicles of a gray obsidian, caused a certain stampede in Nevada in the early days, and nearly procured for the enterprising prospectors the unloading of their claims; and a Colorado diamond-drill core of dioritic rock, with the softened feldspar neatly plugged with gold, caused an investment in the drilled ground by some noted mining engineers and financiers, and the plugger retired to the life of a country gentleman.

Placer ground is easily and, one might almost say, habitually salted. Fine placer gold mixed with tobacco and smoked as a cigarette eluded the vigilance of engineers who were examining placers in Santo Domingo. The natives washers had to smoke cigarettes, of course, and a little of the ash accidentally dropped in the pan separated some enterprising Americans from their roll. We have seen a very good "string of colors" in a gold pan which under the magnifying glass showed the shot-like form of assay buttons, instead of the familiar scales of placer gold.

There is no real safeguard against this dishonesty. A certain mine in the south showed excellent values on salting, but the shrewd purchaser insisted on a mill test, and a number of tons were run through. A little fine gold dropped by the owner at the head of the mill was recovered on the plates to the satisfaction of all; and the sale was made.

There are many engineers who will declare that they "cannot be salted." It is an unwise boast: any engineer can be salted. But a careful engineer can always discover it before it is too late. A system of duplicate and even triplicate samples, numbered variously by a secret system; occasional dead-head samples of known worthless material run in under the guise of ore samples; and a system of duplicate and even triplicate assays by independent and widely separated assayers, unknown to one another, form a precautionary armor which it is difficult for the swindler to pierce.

More Unemployment Problems

JUST when we are assured that the labor situation is becoming easier and that the cost of living is decreasing, another orgy of strikes has broken out in New York. First it was the baggage men, as a result of which it will now cost you 25c. more to have your trunk smashed in the metropolis. Now, the Brooklyn Rapid Transit is demoralized, and those who ride at all must do so in steel-caged cars, like the tigers in a circus parade. Moving-van men, painters, and plumbers have also quit work. From Pennsylvania comes word of 125,000 anthracite miners "on vacation." (A "vacation" is a strike not sanctioned by union officials.) British miners are likewise restless, and there are threats of a general walk-out. Striking metal workers in Rome, according to report, have seized several factories.

Unquestionably, the most pressing problem before executives is the cure of the existing industrial unrest.

The Economics of Copper Blast Furnace Charging

Analyses Not Alone To Be Considered—Method of Calculating Costs of Great Importance—Graphs, as for Slag Losses, Plotted From Experimental Data, Almost Indispensable—Degree of Sulphur Oxidation and How It May Be Varied

By C. A. GRABILL*
Written for *Engineering and Mining Journal*

TO DETERMINE what should go into a copper blast furnace requires common sense, a lead pencil, and a correct idea of the value of money; the only indispensable requirement is common sense, though often it seems more rare than might be expected. Chemical reactions, heats of combination, melting points, formation temperatures, trisilicates, and similar data, are merely aids to the understanding of the complex action going on within the four walls of the blast furnace, and the moment they fail to simplify the conception of conditions or subsequent calculations they should be dropped, temporarily or permanently, as the situation demands. Some are merely terms used as adjuncts to a theory which is not proved, nor of much importance if proved, and all such terms are but tools of the trade to be used when required, and only when required; otherwise, they are likely to be worse than useless.

Simplicity of Blast Furnace

To get away from much of the mystery of the blast furnace it is well to consider the process going on inside it as akin to that in the kitchen range, and a study of the kitchen fire will help to picture in the mind's eye the conditions that exist in the former. Blowholes, crusts, cold bottoms, and irregularities in the air supply are common to both, as is the blowing-in process with wood fuel.

As for formulas, such as given by Furman, I can only say that in twenty years' experience I have met only one metallurgist who used them in practice; the others, like myself, use the method of "cut and try, and add ten kilos." One reason for this is that conditions change so often that the preparation and application of a formula is more laborious than the direct calculation. Another is that one becomes so familiar with the situation and the materials available that often a correct guess can be made the first time, and in many instances one must be guided by conditions rather than by figures.

Practical Determinations Preferred

As for the terms bisilicate, trisilicate, and similar designations, I have found them merely ingenious terms for causing labor and befogging the issue. The use of percentage composition, plain and unadorned, is far simpler, more practical, and just as accurate, particularly because the idea underlying the terms mentioned is certainly disputable if not positively incorrect. Balling's very elaborate tables are a trap for the unwary. The metallurgist should learn to associate the properties of slags with their percentage composition and thus avoid the intermediate calculations. The assay office does not report in silicate ratios, and the furnace will not wait while the metallurgist hunts up a mislaid copy of the "Metallurgist's Handbook" to consult the tables.

To a somewhat similar category belong the type slags of the lead smelter. These type slags were postulated many years ago, and doubtless represented a condition due to the composition of certain ores; but the attempt to apply them to all ores is a failure because the genuine type slag does not exist. The attempt to adhere to one may be a costly hobby. By type slag I of course refer to that hypothesis which stated that in a few slags the silica, lime and iron bore a simple ratio to each other and were therefore superior to other slags of approximately the same composition.

The most practical conception of slags is that they are mutual solutions of a number of silicates containing dissolved substances, all of which are dissociated, and that naturally they follow the laws of mixed solutions, their properties varying gradually and not in units. Unfortunately, the physical data are lacking to permit much use of these laws, so the question arises, "What basis can be taken for metallurgical calculations?"

Fundamentals of Pyrometallurgy

Fundamentally, the pyrometallurgist considers two facts: The first is that gold and silver are soluble in lead and copper, either in metallic form or combined with sulphur, or dissolved in iron sulphide, and that the fused compounds or mixtures are only slightly soluble in, heavier than, and therefore separable from, the fused oxides, their mixtures, compounds and solutes known as slags. The second is the profit to be derived from making this separation.

The first part of this statement is necessarily broad, not for the reason that metallurgists are confined to the use of a bisilicate or a "quarter" slag because of a sharply defined limiting property of silicates, but owing to the balancing of the cost factors. The kind of slag used will change up and down, not because of a change in properties of matter, but in prices and costs. No physical reason is approved that would prevent the design and operation of a furnace that would run on a pure quartz slag with a matte product. The cost would be high; say, $30 per ton. Nor is there any fixed limit at the other end. It is the custom to think of silica as necessary because of its cheapness and universal occurrence. Silicate slags are almost universal, not because of pre-eminent qualities only, but because of their cheapness; otherwise it is conceivable that borates, aluminates and ferrites might be used.

The same may be said of iron and lime as fluxes. In Russia, barium has been used in place of both, and in common with most metallurgists I have used dolomite

*First of a series of three articles on this general subject.

instead of limestone. Alkalies would be satisfactory, and, indeed, have been used. The whole question is merely one of cost and by cost I do not mean the price of the article alone but the total effect on operating results.

Costs as Important as Analyses

The metallurgist must, therefore, calculate his charge with the costs as elements just as much as the chemical elements, but to know his costs he must have figured the charge. I once wasted several days developing a formula for the cost of smelting, and ultimately did succeed in getting one that was not outrageously inaccurate, but it was so cumbersome that the waste basket was the only suitable place for it. The only practicable plan of calculation is by approximations. Plotting the results of calculations made by varying one element at a time often gives valuable and unexpected aid.

Slags are usually classed as silica, iron, and lime compounds because of the greatly preponderating proportion of these oxides. Comparison of results at the various copper-smelting plants of the United States will show that the ordinary limiting figures are: SiO_2, 25 to 50 per cent; FeO, 15 to 65; and CaO, 0 to 30 per cent; and 38 per cent SiO_2, 30 per cent FeO, and 22 per cent CaO may be said to represent a fair average condition, and, although not ideal, is still an approximation to that condition. I consider 36 per cent Cu a representative matte, and therefore a fairly satisfactory one.

To obtain these mixtures the metallurgist has available: SiO_2 and its substitutes, acidic; FeO and its substitutes, basic; CaO and its substitutes, basic; S, matte forming, and acidic in effect on the others in removing a portion of the Fe; coke; air (the air must not be overlooked, as it weighs twice as much as the rest of the charge), and miscellaneous impurities. The products of the treatment of the mixture are: Gases, fume, flue dust, matte, and slag.

Now, if the ore contains the first four items in exactly the right amount to produce the ideal slag and matte when the proportion of the coke and air is at the point of maximum efficiency, the metallurgist has an easy task, but a change in the price of coke would throw the operation out of balance. If the coke increased in cost it would be more economical to reduce the amount on the charge, and that would probably imply slower running and a higher-grade matte, more slag loss and more iron oxide in the slag, and consequently a smaller percentage of silica and lime.

Preferred Method of Computation

The metallurgist is confronted by the question as to whether it will pay to buy a siliceous ore to utilize the excess ferrous oxide, and if so what he can afford to pay for extra silica. This question is not a simple one, yet it is the fundamental factor in making up the charge, and recourse must be had to the records of the cost of smelting operations either at the same plant or at similar plants, as a starting point. The oldest method is to base the costs of operation on the ton of ore, irrespective of its composition, and charge against it the cost of the fluxes actually used. Although this is an important figure, as a tool of the metallurgist it is of a decidedly antiquated pattern. The better method is to base all cost statistics of operations on the ton of charge, consisting of the ore and fluxes (but not including secondaries, i.e., foul slag, cleanings, and such materials), but with the original price paid for the fluxes omitted, they being considered exactly as an ore on which a loss is incurred. The price of the ore would not appear either in these figures.

The cost of treatment of a ton of any ore, commonly referred to as the cost of smelting, would then be the cost of smelting a ton of charge plus a correction for the lime, silica, and other fluxes, determined in the manner shown later. Owing to the prevalence of siliceous ores in custom practice, these corrections are usually based on the cost of fluxing a ton (or unit[1]) of silica, but if there are more basic ores than needed this will automatically change the basis to the cost of fluxing a unit of Fe or CaO, as the case may be; in special instances the basis might be on zinc, barium, or sulphur.

Calculations Incorrectly Made Very Misleading

To the metallurgist the manner in which these costs of operation are calculated is of great importance, and I regret to say that it is not often correctly done even by some of the large companies. At the moment of writing I have before me the smelting costs of several companies, and not one of the lot is in a form usable by the metallurgist. This is because most cost systems are devised by an office force, frequently without metallurgical experience, and situated far from the plant. They are designed to be used as a guide from the financial standpoint, or to form a basis of suppositious comparison of work at both mine and smelter, and are frequently very misleading. As above indicated, they should be based on the ton of charge smelted and grouped first by class of operation performed, so that, in considering any particular ore only the costs applicable would be charged against it. Obviously it would not be correct, ordinarily, to charge limestone with a smelting cost that included roasting.

In any ordinary work the costs might be classified as follows: Sampling and assaying; sintering; roasting; briquetting; bedding and recovery; smelting; converting; recovery of fume and flue dust; overhead and general expense; construction and any unusual expense.

The cross classification would be divided according to the effect on increased tonnage: Overhead and general expense; construction; special; fixed expense (those expenses in addition to general and overhead expense and construction which are independent of the tonnage smelted, such as foremen, lights, and like charges); variable expense (those which vary directly with the tonnage smelted, such as coke and ore shovelers); and semi-variable expense (those which vary with the tonnage but not directly, for example, slag motors and matte tappers).

These classification are of course only general; each case requires individual consideration and in any event each of the above classes will have many necessary subdivisions.

The next matter to be determined is the value of the recoverable metals at the works. There is of course expense in shipping, refining, and selling the product, and this should not appear as an expense of operation, although it may be handled in that way if kept separate from the other accounts. The most convenient system

[1] "Unit" as commonly used, is equivalent to 1 per cent of a ton, or 20 lb.

is to use it in the form of a deduction from the selling price stated in cents per pound or per ounce. Stated in this manner it may be called "marketing expense."

The laws that govern the metal losses are next in importance. "Very easy," says the amateur: "Gold, 100 per cent recovery; silver, 95 per cent recovery; and copper, 1 per cent of the copper contents of the matte equals the copper assay of the slag. Q. E. D. Only there *is* a gold loss, and 5 per cent silver loss is merely the average of a number of discrepancies, and the assay of the slag varies like sin. In these days of high costs and close competition the professional must make a lot better guess than that.

Several years ago I cal'ed attention to the fact that the losses of copper in copper smelting were dependent on several factors, of which the solubility of copper sulphide in silicates, the flotation of copper matte by small bubbles of gas, and the solubility of the metal or the oxides due to imperfect mixing of an overblown portion, were the principal causes; and that, in a well-

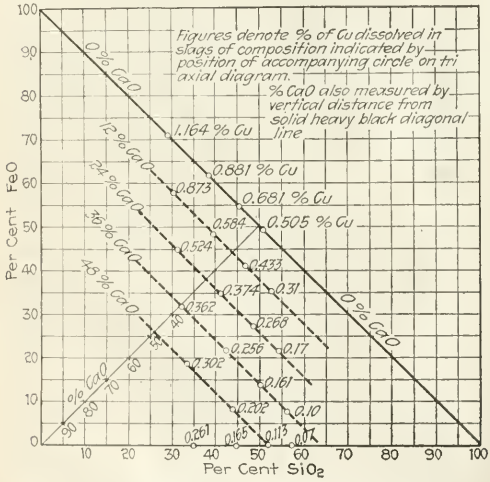

FIG. 1. COPPER CONTENTS OF SILICA-IRON-LIME SLAGS FOR MATTES WITH 30 PER CENT COPPER. FROM EXPERIMENTAL DATA

run plant, the first factor is decidedly the most important, the others coming into action only in case of furnace troubles.

Work of Wanjukov

Wanjukov published, in "Metallurgie," in 1912, the results of some experiments on this solubility, and from his data I have made Fig. 1. Comparison with actual results obtained is satisfactory, making due allowances. Wanjukov's results are usual'y higher than those found in practice, apparently because his figures are based on slags consisting of pure mixtures of silica, iron, and lime, whereas the ordinary slag contains a number of elements that have a favorable effect, such as magnesia. It should also be noted that the alumina must be calculated as silica. Wanjukov's own plotting of his results in accordance with the silicate degree fails to show this (Fig. 2), but recasting his figures on the percentage basis, with the curve showing the variations in the copper assay caused by the substitution of alumina for silica, unit for unit (Fig. 3), does do so. With the exception of two doubtful results, the maximum variation is about 0.05 per cent. This is, however, the least satisfactory part of his work, owing to the paucity of the data in the area practicable for smelting purposes.

As the result of a comparison of a good many years'

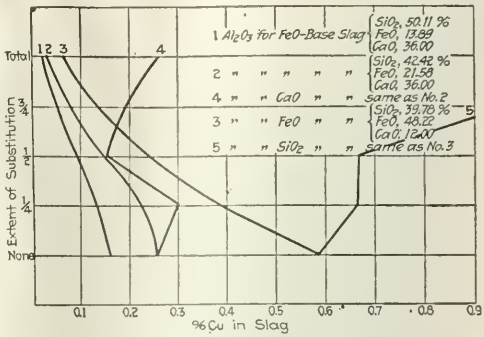

FIG. 2. WANJUKOV'S RESULTS. SUBSTITUTION OF CHEMICAL EQUIVALENTS OF ALUMINA FOR THE OTHER CONSTITUENTS OF VARIOUS SLAGS

work, involving the smelting of ores which have produced matte all the way from 4 to 79 per cent Cu and "black copper," I drew up the curve in Fig. 4.

These two diagrams have helped me immensely in my work, but, as Jeff says to Mutt, "Use discretion." In the first place, as Wanjukov points out, the solubility is dependent on the grade of matte; on the presence of small amounts of other substances than silica, iron and lime; on the temperature; and on the sulphur ions in the slag, the last factor being influenced by the others. I have found that calcium fluoride has a favorable effect, probably owing to reduction of the melting point, and, consequently, of the temperature. Reference to the beneficial effect of the fluoride is found in a Spanish work on smelting published in 1799, so the discovery is not new. The presence of small amounts

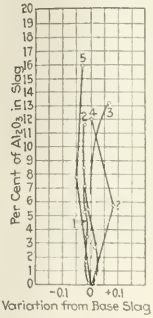

FIG. 3. WANJUKOV'S DATA FOR SUBSTITUTION OF Al_2O_3 FOR SILICA

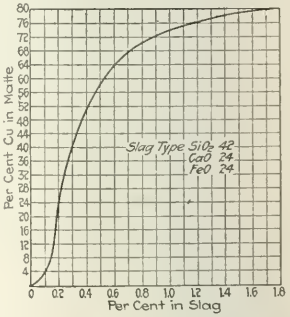

FIG. 4. APPROXIMATE RELATION BETWEEN THE COPPER CONTENTS OF SLAG AND THE ACCOMPANYING MATTE

of *any* base should lower the melting point and influence the solubility.

My own method is to tabulate all the slag assays available at the plant under consideration, plotting them against the grade of matte, silica, iron and lime, differ-

ent classes of ore, furnace speed, matte fall and the ratio between matte and slag to the same factors and to any other factor that might influence the loss, and thus determine the direction and extent to which the primary curve is modified.

Silver losses usually are found to follow the copper. I have never been able, however, to plot a general curve

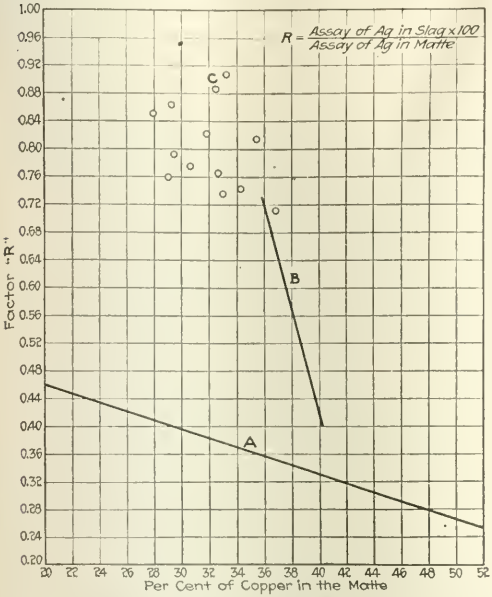

FIG. 5. RELATION BETWEEN SILVER IN SLAG AND COPPER IN MATTE

in the same way as for copper, apparently because the graphs which represent the effects of the various influences do not have a uniform curve; and the compound curve formed by a combination of the simple curves is therefore erratic.

Illustration of Curve Readings

In Fig. 5 I show a graph of the results obtained at three different plants. Curve *A* was drawn from results that harmonized well among themselves. Curve *B* was for a similar grade of matte, and the slag did not vary much from that in *A*, but there is no resemblance between the constants in the two cases. Curve *C* is merely a collection of points which have no resemblance to a curve, and it is apparent that any relationship that exists between the silver in the slag and the copper in the matte is masked by some much more important factor. *R* is simply the ratio, expressed in percentage, that the assay value of the slag was to the assay value of the matte. If, however, the points of *C* are plotted in accordance with the silver in the mattes, they fall into a regular curve, with two exceptions, as shown in Fig. 6. The dotted lines show the effect on the factor *R* caused by the minimum error of weighing in making the assays.

The differences between these curves were all explainable. When the amount of silver in the matte is small, variations in it have an important effect, but the collecting power of the copper in the matte is not of much effect. When the silver becomes a considerable part of the matte, as in *A* and *B*, the solvent effect of the copper overshadows changing amounts of silver.

The difference between *A* and *B* was due to certain constituents of one of the ores at the *B* plant, and other local conditions. These curves are inserted merely to show how easily incorrect conclusions may be reached and the care that must be taken in the use of these tools. Deductions from them always should be verified by direct experiment where possible, but with suitable precautions the use of curves in this manner is of more value than incomplete experiments, with the presumption, of course, that the curves represent the plotting of results obtained from much more work.

Consider the curve shown in Fig. 6 for example. The points on this curve represent about 800 samples taken during a year's work. The results and the deductions from them, therefore, are much more to be depended upon than conclusions reached from a few days' test. The curve could not be applied to the work of another plant without full knowledge of all the circumstances, but that fact does not destroy its value. Consider Curve *B* of Fig. 5. The fact that the steep pitch of this curve was due to strictly local conditions was of help in determining and controlling them, and although the steepness was apparently due to the collecting power of the copper, in reality it was attributable to certain influences which in this instance coincided with the grade of the matte. Impurities in the sulphide ore were one of the causes. The curve in Fig. 6 is shown as a straight line, but in reality is bowed slightly, with the concave side upward.

As far as my experience goes, the slag composition has more effect on the gold loss than do the copper or gold values in the matte.

The volatilization of silver must be remembered, but that of gold and copper is without importance except in the presence of chlorides. With baghouses and Cottrell plants the volatilization of silver may be neglected. Of course this refers to the fume and not to the flue dust question, which must always be watched.

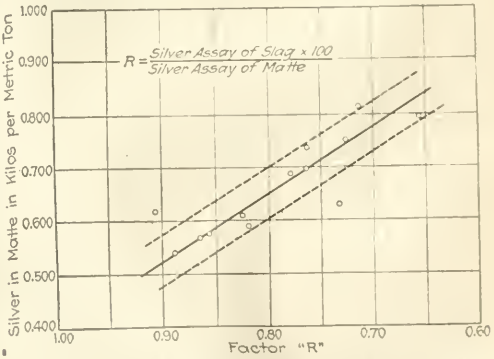

FIG. 6. RELATION BETWEEN SILVER IN SLAG AND SILVER IN MATTE

Limit of Error Must Be Watched

In plotting the assays of slags it should be remembered that the personal equation of the assayer, and the cupellation losses have a large percentage effect on the assays. Also, that a small flotation bubble of matte in

one sample will throw a number of assays out of balance, and yet these bubbles help to make up the average loss. Similarly, the limit of error in the ordinary slag assay is about 5 per cent, so that a close agreement with a theoretical formula is not to be expected. It is precisely for these reasons that the use of formulæ and curves is desirable. They do away with a constantly recurring error of judgment. It is easy to say that the slag from a certain 40 per cent matte will contain 0.3 per cent Cu, and so to calculate it, and the probable error is not large; but if it is found from tested curves that the true assay under the circumstances is 0.33, and that this extra 0.03 is due to the presence of a particular ore on the charge which comprises only 50 per cent of the total, then instead of an error of 0.03 per cent there is one of 0.6 per cent, or 12 lb. of copper for the offending ore, and $2.64 per ton with 20-cent copper, which is of importance.

Properly tested curves are simply tools corresponding to the vernier on the transit, and permit the metallurgist to read his calculations a decimal place further than he could otherwise.

Sulphur Oxidation an Important Consideration

Another important item is the percentage of sulphur recovered, but to make graphs for this factor is not of much use. Peters, I believe, says to assume the grade of matte that previous experience indicates will be produced. This is not much comfort for a new man, at a new plant, with a new ore. Sticht and Freeland are responsible for the doctrine that in pyritic smelting the oxidation of the sulphur, and, therefore, the amount recovered and the grade of matte produced, are controlled by the amount of free silica present. My own experience with pyritic smelting is limited, but with semi-pyritic smelting and straight matting, I must confess that I have not been able to identify that effect.

On the other hand I do believe that the metallurgist can control the sulphur recovery within wide limits by varying the quality and quantity of the coke, aided a little by changes in the air supply.

The first important factor is the quality of the coke. I recall an experience at one plant where the change from large, firm English coke, to small, brittle Connellsville, dropped the grade of matte, other things being equal, about 50 per cent. Pocahontas coke will permit the recovery of a much higher portion of the sulphur than will Dawson coke. I know of no definite method for grading coke on this basis, but an ocular examination coupled with analytical results will give a fair idea of the results to expect in practice. I think that the burning test in a tube, determining the relative amounts of CO and CO_2 formed under standard conditions, together with a crushing and sizing test, should give satisfactory results, but I have seen no comparative tests to substantiate this belief.

With smooth-running furnaces and average coke there is not as great a difference in the sulphur oxidized as is commonly believed. Most of the large differences reported are due to methods of calculation. One plant will base figures on sulphur volatilized, and count everything except the sulphur in the matte as volatile sulphur, neglecting the sulphur in the fume, dust, and slag; another will include the sulphur in returned matte and secondaries as part of the sulphur on the charge.

With a large coke charge the returned matte in the furnace will undergo little oxidation, but when the coke charge is reduced, as in concentration charges, the sulphur in the matte will be oxidized, though never to the extent that it is in the ore. Probably the correct way would be to assume a factor, based on experiment, for the oxidation of the returned matte, varying from nil at 16 per cent coke to, say, 40 at 6 per cent, but this factor would have to be varied with the quality of the coke. The sulphur oxidized is also influenced by the amount of copper on the charge, which has a protective influence when the ratio of copper to sulphur is large.

In a rough way, about 15 per cent of the sulphur in the crude ore will be recovered in the matte with 10 or 12 per cent of average coke on the charge. This figure will vary 5 per cent either way, depending on the quality of the coke, and another 5 per cent depending on the amount and manner of driving.

Metallurgist's Schedule Is Guide to Mining and Treatment

With the information indicated, and the cost and analysis of his base ore and fluxes (iron ore, sulphide flux, limestone, and quartz), the metallurgist is in position to make his calculations to see what price can be paid for the ores available in the district, whether they are from the company's own mine or purely custom ores, because, however carried in the cost system current at the smelting works, the metallurgist should prepare a schedule or tariff, from which the proper method of mining may be deduced. Otherwise the miner is working inefficiently and in the dark. This tariff should fix a treatment charge; a premium for all valuable elements, and a penalty for all harmful ones; premiums for increased tonnage, if desirable, and all so arranged as to promote the utmost economical development of the company's property.

The mine superintendent may say, "I can reduce mining costs per ton by including a little low-grade stuff from the walls. Shall I do it?" The metallurgist's tariff, combined with the mining costs, should answer the question definitely to the best interests of the company. With custom ores the question is different, in that provision must be made for a suitable profit. (The word suitable covers all requirements and is charitable.)

Discoveries of Copper Ore in Northern Finland

Two mining companies, the Finland Copper Co. and the Salla Mining Co., have bought some large deposits of copper ore, according to Consul L. A. Davis, which have been discovered in Kuolajarvi Parish, in the Oulanka River Valley, in northern Finland. Geological examinations have shown that the copper near the surface is rich, and if exploration and tests are made with the diamond drill it can probably be ascertained whether mining on a large scale will be profitable or not. The directors of the companies have applied for a government subsidy for this purpose, as security for which they offer shares of old stock at a nominal value of 200,000 Finnish marks.

They had planned diamond drilling last year, but contented themselves then by blasting with dynamite, which was carried on by a German engineer. In his opinion nineteen claims are so rich in copper that diamond drilling ought to be undertaken to ascertain if mining can be carried on profitably. There are also rich veins of iron glance and of sulphur pyrites in the same place, the latter amounting to several million tons.

Gold Dredging—Actual Recoveries Compared With Estimates

The Accuracy of Prospecting Drill Methods as Illustrated by Examples That Have Been Taken From Practice—Factors That May Be Used To Reduce Sampling Error—Churn Drilling a Satisfactory Method of Prospecting Gold Placers

By W. H. Gardiner

Written for *Engineering and Mining Journal*

DREDGING possibilities may easily be investigated and prospected—not only the value per cubic yard estimated with much accuracy, and the cost of operation predetermined with precision, but the extent of the deposit may be ascertained before recovery is begun. If the margin of profit is attractive, outside capital is not invited. If unfavorable, even the most plausible promoter has little to offer—which is why so little stock in dredging companies is offered to the general public.

With lode mining it is different: the element of speculation is much higher. A risk is to be shared, instead of a certainty jealously guarded. It may be said that the prospecting of a quartz mine is an investigation in three dimensions; a dredging property in two. A placer deposit covers a hundred or more acres and is 20 to 8 ft. in depth. The vein of ore would have to be exposed entirely on one side to be appraised with equal accuracy.

Sampling Dredging Gravel

The churn drill, steam or hand power, has been widely used in the last twenty years to determine the gold contents of dredging gravel. Heavy casing, fitted with a beveled-edge cutting shoe, is driven to bedrock. Every foot or two the sand, gravel, and boulders, loosened and broken by a heavy drill, are panned and the gold is recovered. Care is taken to keep the core to about the volume displaced—always maintaining a few inches of gravel between the bottom of the shoe and the pump to prevent the crowding out or forcing in of material not in the path of the pipe.

Vast acreages of gold-bearing gravels have been exploited throughout the world on the simple story of the drill. Even greater areas have been explored and "turned down." Sometimes check shafts were employed, but more often water would not permit them. For many years the prophesied returns have been checked closely by actual recovery.

Actual Recovery Estimates

Variable factors cannot be eliminated in making such comparisons—the personal equation and methods of estimating. Not all drilling has been done by the same engineer, with like crews or similar equipment. On one property the drilling yielding high assays was checked by more in the same locality, and the final results were enriched by averaging all these favored holes. On another the work was done in winter—the panner working in ice-cold water under inadequate cover. The figures given herewith, however, are generally from the records of conservative, experienced engineers and successful companies.

In drilling a level, extensive "blanket" deposit, holes are customarily put down at the corners of regularly plotted rectangles. The prospecting of a stream or channel, on the other hand, necessitates a line of holes close together, these lines being repeated at considerable distances apart—a cross-sectioning, so to speak. The final estimate must allow each hole to "govern" only the proper amount of area.

The conservative engineer figures 33⅓ cu.ft. of gravel to a hundred feet of pipe (7½ in. cutting shoe). The more optimistic prospector, on the other hand, has figured 27 cu.ft. Today it is not uncommon to figure 30 cu.ft. (there being 30.68 cu.ft. in a cylinder 100 ft. long and 7½ in. in diameter). A table follows showing a short-cut to drill-hole estimates, the factor being 33⅓.

TABLE FOR FINDING VALUE PER CU. YD. FROM TOTAL AMOUNT OF GOLD RECOVERED BY DRILL

Diameter cutting shoe 7½ in. Constant 33⅓. To find value in cents per cu. yd. multiply number of milligrams of gold recovered from drill hole by the number in table opposite depth to bedrock.

Depth to Bedrock in Feet	Factor	Depth to Bedrock in Feet	Factor	Depth to Bedrock in Feet	Factor
10	.4860	26 5	.1834	43	1130
10 5	.4629	27	.1800	43 5	1117

20 5	.2371	37	.1313	53 5	0909
21	.2314	37 5	.1296	54	0900
21 5	.2260	38	.1279	54 5	0892
22	.2209	38 5	.1262	55	0884
22 5	.2160	39	.1246	55 5	0876
23	.2113	39 5	.1230	56	0868
23 5	.2068	40	.1215	56 5	0860
24	.2025	40 5	.1200	57	0853
24 5	.1984	41	.1185	57 5	0845
25	.1944	41 5	.1171	58	0838
25 5	.1906	42	.1157	58 5	0831
26	.1869	42 5	.1143	59	0824

Bear in mind that the engineer is not so much concerned with the actual total gold content as with the amount that of a dredge will recover. There are no data available as to the percentage that escapes the riffles—certainly over 5 per cent but probably under 20 per cent, conditions being ordinarily favorable.

A carefully prospected property will have a hole to every two to five acres. Sometimes the actual returns of dredging along one side of an area will reduce the drilling necessary to forecast the value. Some deposits have been perforated with holes in a feverish endeavor for meticulous accuracy. With one or two notable exceptions, all drilling in excess of one hole to two acres was so much wasted energy.

The estimated returns of the long-continued operations of the Butte Dredging Co. and the El Oro Dredging Co. may be tabulated as follows:

Location	Company	Estimate	Recovery, Cents per Cu.Yd.
Oroville, Cal.	Butte Dredging Co.	25 0	13 69
Jenny Lind, Cal.	Butte Dredging Co.	22 0	18.30
Oroville, Cal.	El Oro Dredging Co.	47 0	16.50
Yuba, Cal.	El Oro Dredging Co.	15.0	15 44

It will be noted that actual returns at Oroville were much less than expected. The management accounts for this by the fact that the gravel was somewhat cemented—bound together by clay that interfered with complete washing. The tailings from other operations in this neighborhood have been reworked at a profit, the air-slacked chunks yielding up their gold to rewashing.

The Yosemite Dredging & Mining Co., at Snelling, used a factor of approximately .27, but discounted final figures by 20 per cent as a factor of safety. Unusually high assays were cast out. Ground was loose and gold was well distributed. One piece of thirty acres, carefully prospected, showed a recovery of 6.74c. per cu.yd., against an estimate of 4.44c. Final returns, after working some acreage of much more compact deposit, showed a recovery of approximately 15 per cent greater than drill results.

In somewhat similar ground, although located at the Calaveras River, the Isabel Dredging Co. reports a much greater recovery than expected. On one piece of twenty-three acres, covered by twenty-five holes, the estimate was 2.35c. and the recovery 8.8c. Here, as elsewhere, it has seemed that the drill fails to recover all gold in certain kinds of gravel.

Further Examples

The Yuba Consolidated Gold Fields, at Hammonton, Cal., with its fleet of huge dredges digging 80 ft. below water level—five of them individually handling 300,000 cu.yd. per month—have washed an enormous volume of gravel. Some of the operations were carried on with little exploration, it being known that it would be profitable to work certain acreages from results on bordering tracts. Results as a whole have checked estimates closely, although many times there has been a wide variance in individual blocks. For instance, recovery in one tract was within a tenth of 1 per cent of the forecast; in another only 60 per cent; in a third 195 per cent—the three tracts involving a total of over 500 acres.

Perhaps no stream deposit has been more carefully drilled than the ground of the Powder River Dredging Co., at Sumpter, Ore. Dredge No. 1, in the lower valley, worked in deeper ground—a field prospected by two different crews at different seasons, although under the same engineer. On the shallower up-stream areas Dredge No. 2 operated over a rough, hard bedrock. Dredge No. 1, in 369.5 acres, showed a gain of 39.8 per cent over the estimate. Dredge No. 2 failed by 7 per cent to yield to expected returns. Refiguring the latter property to a factor of .3068 would show an almost exact check of estimate and recovery.

The discrepancy of the results of Dredge No. 1 may be partly explained by the presence of a narrow but rich "pay streak" that meandered down the creek, dodging most drill holes, and failing to make itself apparent when tapped. The very irregular bench line caused a marked variation between estimated and workable *area*.

On the extensive properties of the National Companies, of California, on the American River, there occur many widely differing conditions—heavy wash and cemented gravel on the benches and broad acres of more shallow, softer ground down-stream. A check made four years ago on the operation of three dredges resulted as follows:

Dredge	Area, Acres	Time of Operation, Years	Per Ceot of Estimate Recovered
No. 5	180	10	86
No. 8	106	4	87
No. 9	135	6	101

These results are based on a factor of .30. During the last four years these dredges, as a total, have produced about 101 per cent of the expected recovery.

A KEYSTONE DRILL IN KOREA WITH A FENCE TO KEEP OUT PREDATORY NATIVES

"Old No. 1," worked in 25-ft. ground—loose and easy to dig—recovered 125 per cent of the drill returns, these being figured with a .27 factor. In a soft sandy deposit on the Sacramento Bar the actual dredging results fell far short of the estimate. It will be noted later that probably the pressure of underground water forced gold into the casing. On the benches, where clay was encountered, there have been notable instances of the failure of actual dredging to give estimated returns, fine gold having been lost in the muddy water. On the acreage worked by Natoma No. 7, the returns held up to the estimate as long as the gold

was reasonably coarse, but on the edges of the deposit, where there were areas of fine gold, returns would immediately drop below expectations. It was concluded that the drilling was accurate enough, but that the size of gold particles affected recovery in the unavoidably dirty water.

Other reports are available, but sufficient evidence has been produced to confirm important conclusions recently advanced by dredge engineers.

It may be observed that the accuracy of results gained by drilling is surprising, considering the comparatively small size of the sample. For example, one hole to two acres in 50-ft. ground would mean that $\frac{1}{328,000}$ part of the gravel was examined. Of course one hole by itself means nothing—it is only a carefully charted series that reliably represents actual conditions.

All available data seems to point to the following facts regarding the accuracy of drilling:

1. Drill results give high assays where gold is fine.
2. Estimates will tally with returns where gold is reasonably heavy, ground is compact with a little clay, and prospecting and dredging are intelligently done.
3. The drill will exaggerate the value of *very* loose ground where sand or water pressure crowd material into the bottom of the pipe.
4. The drill will signally fail to show recoverable gold in areas of moderately loose ground where gold is distributed and in comparatively small amount.

This fourth conclusion is of considerable importance. Dredging at Jenny Lind, at Natoma, at Yuba, on the Merced, at Cottonwood, and many other places has proved its truth.

DRILLING OUTFIT ON CHISTOCHINA RIVER, ALASKA

James W. Neill, in writing on the subject, says: "If the driller keeps his bit behind his shoe, and sees that he gets a correct amount of core, there should be little question of the correctness of a *large general average*, and the engineer can use such factors of safety as his experience and the character of the ground indicate. In very loose ground, I personally look for a recovery of full drill values where the gold is coarse and is entirely contained in the foot or two above bedrock. I think one will usually also overrun the drill, provided the bedrock can be dug. That is about the sum of our experience at Snelling."

In loose ground the drill churns up the gravel and crushes stones before pumping. Its jarring action induces the settling of the gold, making it most difficult to procure by pumping. On the other hand, very loose sandy ground with free water content may force gold into the pipe, even if pains are taken to keep the core within safe limits. This explanation partly accounts for the recovery of 8.79c. in a Colorado property where the drill sheets indicated 17.19c.

When a certain readjustment of economic conditions or legislative relief increases the value of gold in terms of commodities, there is destined to be a renewed interest in dredging. Most of the gold-bearing river gravels of Oregon, Montana, Idaho, Colorado, Arizona, New Mexico, and California have been drilled by dredge capitalists, and the vast majority of the possible fields rejected as too low in value or too difficult to dredge. The modern dredge man, with improved machinery and methods, fears the boulders, the clay, and the deep or hard bedrock much less than a half-dozen years ago. Engineers will review properties once rejected.

A DRILL OPERATING IN CALIFORNIA

The Huancavelica Mercury Deposits, Peru*

Geology of an Old South American Mining District Located at Great Altitudes in Sedimentary Formations of the Andes, and Difficult of Access — Attempts To Exploit Them Profitably With Modern Mining Methods Now Being Made

By Joseph T. Singewald, Jr.
Written for *Engineering and Mining Journal*

AMONG the notable mining districts of the Spanish colonial empire was Huancavelica. The mercury ores were known to the Incas before the Spanish conquest, and were utilized by them as a pigment. There is some uncertainty as to the exact date of their discovery by the Spaniards. In 1570 the Santa Barbara mine, which was already productive, was sold to the Spanish crown, and henceforth all mercury discoveries were declared crown property. Mismanagement on the part of the administrators sent out from Spain led to such poor financial results that subsequently the Huancavelica mines were turned over to the "Gremio de Mineros," a sort of miners' guild, which was required to sell the output to the crown at a fixed price.

The recorded output during the colonial period amounted to about 550,000 tons of metallic mercury. In those days the Santa Barbara mine was heralded as "the greatest wonder of the world." For some years after Peruvian independence the district lay idle, until in 1836 to 1839 an unsuccessful attempt was made to revive mining to supply the local consumption of mercury. Since that time there have been desultory operations resulting in a small annual production. In the early history of the district, mining was often carried on in a haphazard and unsystematic way; and, in the eagerness to extract the richer ore, pillars were robbed without regard to the safety of the mine, so that several disastrous cavings occurred, and a few years ago the old workings of the Santa Barbara mine were practically inaccessible.

Recent Development

About 1915 E. E. Fernandini, the well-known Peruvian mine operator, bought up a large part of the district, including nearly the whole of the old productive area about the Santa Barbara mine. Mr. Fernandini has had the old Belen Tunnel cleaned out, opened up a part of the workings at the Brocal, and has started a new crosscut tunnel to get under the main creshoot of the Santa Barbara mine. He has also erected experimental furnaces to work out an efficient method of treating the ore. The district gives promise, therefore, of once again becoming an important contributor to the mercury production of the world.

The city of Huancavelica is situated in the valley of the Huancavelica River, a branch of the Mantaro River, on the eastern side of the Western Cordillera, at an elevation of 3,792 meters. Its former importance is attested by the ruins of ancient buildings and by the eight churches which still try to eke out an existence at the expense of the diminished and impoverished population. Today it is a backward town of several thousand inhabitants, consisting almost entirely of Indians.

Formerly access to Huancavelica was by way of the port of Pisco. This necessitated a five-day muleback ride of 370 kilometers, involving crossing the Cordillera at an elevation of 4,900 meters. The completion of the railroad to Huancayo, made the district more accessible, but even the trip from Huancayo to Huancavelica requires a journey of 120 kilometers, or two days, on muleback over a highly accidented trail. A further extension of the railroad to Ayacucho is under construction and should soon be completed as far as Izcuchaca, at the mouth of the Huancavelica River. The district will then be only fifty kilometers from the railroad, and if the prospecting that is now being done is rewarded with the hoped-for success, doubtless the construction of a spur to Huancavelica will be the next step.

General Features of Region

The prevailing rock of the district is Cretaceous limestone, in which are intercalated zones of sandstone and shale. Outcropping over considerable areas are limestone conglomerates. The sediments are intruded by large masses of basalt and porphyrite, and along the mineralized zone are small andesite intrusions. A mineralized belt extends discontinuously from Chunamachay in a southeasterly direction through Huancavelica to beyond San Antonio, a distance of about sixty kilometers, and has a width of one to three kilometers. It follows a belt of sandstones in the limestone, and the ore usually impregnates the sandstones. Where they are compact and their texture is unfavorable, and when the limestone has been shattered, the ore enters the latter rock. Some mineralization of the igneous rock has also occurred.

Mercury ores have been worked at a number of points in the mineralized zone, but the great bulk of the production has come from the vicinity of the city, from the hills that overlook the town on the south. Extensive workings there, known as the Santa Barbara mine, are evidence of the former activity of the district, and the present explorations purpose reaching the continuation in depth of the old productive orebodies. This part of the district is, therefore, that of the greatest past and present interest.

The Santa Barbara Mine

The old Santa Barbara mine consisted of a group of outcrop workings on the top of the mountain directly south of the city of Huancavelica and extensive underground workings, of which the most important were those of the Belen Tunnel. Most productive seem to have been the vicinity of El Brocal and the Hundimiento Morroqui, two large open cuts, the size of which is due, however, largely to the collapse of underground workings. The Brocal is at an elevation of 730 meters (2,400 feet) above the level of the Huancavelica River.

The most elaborate work in the early history of the mine was the driving of the Belen Tunnel, which was begun between 1601 and 1617, and completed in 1642. It had a length of 600 meters, a width of three to four meters and in places was four meters (13 feet) high. The

*George Huntington Williams Memorial Publication No. 3.

entrance to the tunnel became the center of operations for the mine. It cut the orebody at a depth of 160 meters, beneath the Brocal. The ambition to reach the orebody at much greater depth is represented by the beginnings of the Pochcoco Tunnel at an elevation of fifty meters above the river, or 520 meters below the south of the city of Huancavelica. Rising precipitously above the city is a series of steep westerly dipping beds, which are called on the map the Grand Farallon limestones. They are characterized by wide and frequent variations in chemical composition. There are transitions from pure limestones, through increasing argil-

Belen Tunnel. This work was abandoned after penetrating only 60 meters. A new attempt to get beneath the Santa Barbara orebody is now being made by Mr. Fernandini, who is driving a tunnel at an elevation of 350 meters above the river, or 220 meters below the Belen Tunnel.

Fig. 1 is a geologic map of the area immediately

laceous content, into shales, and, through increasing silica content, into sandstones and quartzites. A well-marked horizon of cherty limestone characterized by bands and nodules of chert lies about 250 meters above the Grand Farallon sandstone. Most abundant in this series are beds of argillaceous and siliceous limestone.

A prominent feature of these beds is a great ledge of

massive and in many places remarkably porous sandstone. It extends across the river in a direction a little west of north at the town of Huancavelica. On the south side its outcrop is so prominent that it is called the Grand Farallon. In the mass of debris and old dumps about the cave-in of the Hundimiento Marroqui this prominent sandstone outcrop suddenly disappears. With like abruptness a similar sandstone with equally

FIG. 2. THE GRAND FARALLON SEEN FROM THE PLAZA DE INDEPENCIA, HUANCAVELICA. DIFFERENCE IN ELEVATION ABOUT 2,000 FT.

prominent outcrop appears 600 meters to the southeast and swings around to the northeast toward the Huancavelica River some distance below the city. On account of the mass of debris which covers the ground on each side of its outcrop the contact of the Grand Farallon sandstone with the adjacent beds is generally obscured. On top of it—that is, on its west side—is a horizon of shale nearly 100 meters thick, in which there are gray, red, and green zones. A similar series of shales overlies the heavy sandstone southeast of the Grand Farallon, but here the sandstone and the shales are much thicker than in the Grand Farallon. The great sandstone outcrops appear to belong to opposite limbs of an anticline, the axis of which pitches toward the southwest and the nose of which has been faulted out.

A second series of limestones extends from the southwest corner of the map in a southeasterly direction to the Belen Tunnel and the Hundimiento Morroqui. The upper part and the greater thickness of this series consists of a conglomerate, the pebbles, boulders, and cobbles of which are limestones. The fragments range in size from small pebbles to cobbles more than twenty centimeters in diameter, and in general are but little waterworn and rounded. The matrix of the conglomerate varies from fairly pure calcium carbonate to a reddish sand material. The lowest beds of the series are not conglomeratic.

The Conglomerate limestones have been regarded by some as late surficial deposits, but their strike and dip and their relation to the present topography are such as to indicate that their origin has no relation to the present surface. On the other hand, their relation to the Grand Farallon limestones is not known. Where the two series ceme in contact, at the Hundimiento Morroqui and to the south, the beds are much disturbed and outcrops very meager. The beds are older than the period of mineralization, as ore deposition has taken place within them.

Several igneous intrusions outcrop within the area of the map. For the most part the rocks are highly altered. In general character they appear to be of andesitic composition, and such differences as are noted are probably due mainly to minor variations in chemical composition and to variations in texture. The area in the southwest corner of the map is the edge of an extensive igneous mass. At its base, that is, between it and the Conglomerate limestones, in the canyon below the Belen Tunnel, is a horizon of stratified tuffs. A large intrusion also separates the two series of limestones over most of their outcrop. In addition to these, several smaller areas of volcanic rock occur.

FIG. 3. THE GRAND FARALLON AT THE BROCAL, ELEVATION 15,000 FT., SHOWS OLD MINE OPENINGS AND DEBRIS OF FORMER OPERATIONS

The Huancavelica valley is covered with alluvium and with extensive deposits of calcareous tufa. The latter deposits are still being formed in and about the city by warm springs, the temperature of the waters of which is about 30 to 35 deg. C. One group is utilized at the public baths on the north side of the city.

The areal geology and the observations in the tunnels show clearly that the district is one of tight folding, with much slipping along bedding planes and the development of jointing. The frequence of discordant strikes and dips and the separation of the two big sandstone outcrops indicate considerable faulting. It seems, therefore, that the principal mineralized area is coincident with an area of great disturbance.

Mineralization has been widespread, and the mineralizing solutions entered and deposited their mineral content in all of the rocks of the district. The center of mineralization, however, was at the south end of the Grand Farallon, from the vicinity of which almost all the production has come.

indicates, however, that the ore followed planes of bedding and jointing in the limestone.

Of least importance have been the ore occurrences in the igneous rocks. In fact, they are of interest chiefly in fixing the period of mineralization subsequent to their intrusion.

The mineralization of the district is, consequently, an impregnation by cinnabar and its associated minerals of porous and jointed rocks in an area of igneous intrusion and tectonic disturbance. In the absence of well-defined fissures the mineralizing waters were compelled to spread over a wide area and follow less pronounced openings.

The Grand Farallon limestones are of Upper Cretaceous age. The Conglomerate limestones are younger than these. The igneous rocks are of still later age. As mineralization has taken place in all of these rocks the period of mineralization would appear to be at least as late as Tertiary. There is no necessary connection between the present warm springs and the

FIG. 4. THE BOTIJA PUNCU MINE. MINE OPENINGS IN LIMESTONE. GRAND FARALLON OUTCROPS ON RIGHT. HUANCAVELICA VALLEY IN DISTANCE

Maximum ore deposition took place within the Grand Farallon sandstone itself, in the form of an impregnation of its porous parts. The cinnabar and its associated minerals occur chiefly as a filling of the interstices between the sand grains. Where the rock is more compact the minerals have been deposited in tiny cracks in the form of stringers and veinlets.

Next in importance to the ore deposition in the sandstone was that in the limestone. The most productive deposits were in the Botija Puncu, Trinidad, and Florida mines. The Botija Puncu orebodies occurred in the Grand Farallon limestones, and seem to have been quite large (Fig. 4). Somewhat less extensive are the workings of the Trinidad and Florida mines, which are in the Conglomerate limestones. As all visible ore has been removed from the accessible portions of these workings, knowledge of its mode of occurrence depends largely on second-hand information. The nature of the workings

mineralization, but they may represent the final stage of an igneous sequence of which the volcanic rocks represent the first and the cinnabar mineralization an intermediate stage. In that event the period of mineralization was probably late Tertiary.

MERCURY ORES ASSOCIATED WITH OTHER MINERALS

The condition of the workings of the Huancavelica mines is such that practically no ore in place can be seen. It is only in the sandstone of the Brocal that some lean pillars are accessible Here the ore is primarily an impregnation of a porous, clean sandstone, either by uniform impregnation of the rock, or along certain planes, giving the ore a banded appearance, or in veinlets and stringers. In places the cinnabar occurs alone, but it is usually associated with a black or dark bituminous substance, pyrite or marcasite, and some very fine-grained galena. Here and there is a little

realgar. No native mercury was seen, and it is said to have been very rare. Considerable quantities of native mercury are reported to have been found beneath the city in digging foundations for houses. As this may have come from various sources, it is of no particular significance in connection with the genesis of the ore deposits.

Reliable data concerning the mercury content of the ores that have been produced are impossible to secure. The average of several samples of the ore left in the mines, taken by Umlauff some years ago, was about 2 per cent mercury. Specially selected samples ran as high as 10 per cent. These figures are of little significance, however, as an aid in determining the metallic content of the ores formerly produced, or in attempting to estimate the probable content of ores that may be developed in the future. The only certain information that history affords is that this was a rich and important ore deposit in this old and geologically interesting Peruvian mercury field.

Present Operations Experimental

An inappreciable and desultory production of mercury is accomplished by small operators in outlying parts of the district. The center of interest and future promise lies in the result of the present attempt of Mr. Fernandini to get under the old Santa Barbara orebody, and thus again make this famous mine a producer. If these operations are successful, the Huancavelica district will once more become an important mercury producer. Fernandini's efforts are being centered in two major operations—one, the driving of a crosscut tunnel to get under the old oreshoot; the other, the operation of experimental furnaces at Santa Barbara with which to determine the best method of recovery of the mercury content and the limits of profitable mining and metallurgical operations.

The requisite length of the Nuevo tunnel will be at least 1,200 meters. Work on this is being pushed rapidly in two eleven-hour shifts daily, with a progress of about forty-six meters per month. Power is furnished by the hydro-electric plant, which is equipped with a Pelton wheel. A flow of three litres per second, with a fall of 140 meters, generates 106 hp. The power is stepped up to 4,800 volts for transmission to the compressors, where it is reduced to 480 volts. There are six 15-hp. compressors, all of which are run at 60-lb. pressure.

Trial Furnaces Recover Over 80 Per Cent of Mercury

Two small trial furnaces have been built at the Belen Tunnel, nine meters high and with a total charge capacity of seven tons. Ore is passed through the furnaces at the rate of 200 to 500 kilograms every three hours, and roasted at a temperature of 800 deg. C. Taquia, llama dung, is used for fuel, and the roasting requires 10 per cent more fuel than ore. The taquia costs $3 to $4 per ton. The sublimed gases are passed through a series of nine condensing chambers for the recovery of the metallic mercury. The ore for the trials is obtained from the old workings of the Brocal and averages 0.2 per cent mercury. Under the conditions of these experiments, the recovery is said to be 80 to 83 per cent. It is estimated that 0.5 per cent ore is necessary to meet expenses under the conditions that exist in the Huancavelica mercury district.

Resumption of Mining in Argentina

The mining activities of the Rosario district, Argentina, according to *Commerce Reports*, though never of prime importance, show a tendency to revive after the suspension due to the war. The Corporación Minera Famatina sent a representative, Bancroft Gore, to the United States to study the class of installation best suited to replace the water-jacket furnaces at their copper mine in Chilecito, Rioja. The company produced 733 metric tons of copper in seven months, which resulted in a financial loss, but the outlook for the future is said to be favorable and a production of 300 tons of metal per month thought possible.

The new company, known as the "Pumahuasi Industrial de Plomo," has under lease two lead properties in the Province of Jujuy, with a foundry located in Buenos Aires. The revival of the borax workings at Rosario de Lerma, in Salta, and at Santa Catalina, in Jujuy, has recently been discussed.

The beginning of a revival in building in the north is indicated by renewed activities of the marble and granite quarries and lime workings of northern Cordoba after six years of depression. By a system of co-operation the lime interests of northern Cordoba maintained themselves during the depression by pooling all orders and giving them to the concerns that most needed the business. Now that prosperity has returned, the producers prefer their independence, and this co-operative system has been discontinued.

The Japanese Iron Industry

The iron ore used in Japanese furnaces is obtained in part from domestic mines and in part from Korean, Manchurian, and Chinese mines. The iron ore produced in Japan comes mainly from the Kamaishi group of deposits in the northern part of the island of Honshu. The iron ore reserves of Japan are estimated at about sixty million tons.

The Korean iron ores used in Japan have come mainly from the surficial limonite deposits of Hoang-hai-do, about one hundred miles northwest of Seoul, which have been actively mined for ten years or more.

Chinese iron ore used in Japan has been obtained from the Tayeh mines of Hupeh Province. A part of the ore from these mines goes directly to Japan, and a part goes to the Han-Yang furnaces, near Hankow, to be manufactured into pig iron and steel products, which also go to Japan. The Han-Yeh-Ping Iron & Steel Co., which owns both the Tayeh mines and the Han-Yang furnaces, is a Chinese concern the capital of which is at present controlled largely by Japanese banking firms.

Two important Japanese-controlled iron and steel manufacturing projects are at present being developed in Manchuria.*

French Interests in Georgia

A French group, according to *The Ironmonger*, is reported to have applied to the government of the Caucasian Republic of Georgia for the concession to build a hydraulic station on the river Kur for supplying electric energy to the manganese mines at Tchiatury. The same group intends to take up the manufacture of ferromanganese on the spot.

A Picturesque Mining Experience—III

The Bucking Aërial Tram

BY HARRY J. WOLF
Written for *Engineering and Mining Journal*

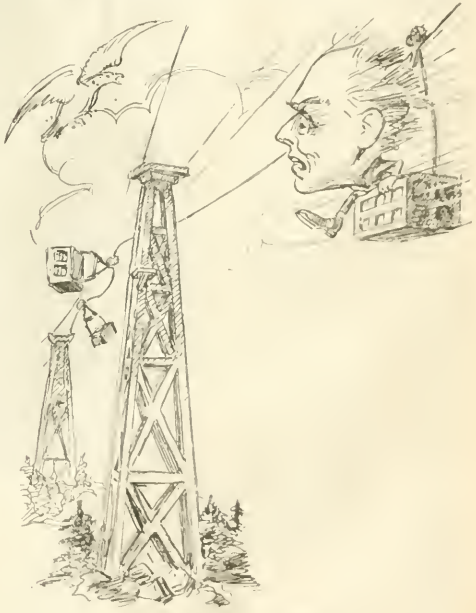
THE mining engineer's moving picture film of memory is almost sure to contain certain vivid sections which record particularly thrilling or unusual experiences. In throwing the following picture on the screen for the amusement of my friends I recall the serious state of mind of the photographer at the time the original exposure was made, and how thankful he was soon afterward when he found that the camera was not smashed.

The picture was made in the San Juan Mountains, in Ouray County, Colorado, in the gulch leading from the Camp Bird mine to the cliffs above the mill, in the winter season early in the year 1907. It was necessary for me to go from the mine to the mill. Much snow was on the ground; more was falling; the snowslides were getting ready to run; and the trail was slippery and uninviting. What could be easier than to take passage on the wire-rope tramway that carried down the $35 mill dirt that we were producing about that time? On that tramway was one special bucket that we called the "Pullman" because it was long enough for a man to lie down in and go to sleep, if he did not care to enjoy the scenery on the way. In anticipation of a possible "hang up" on the line in blustery weather, I put on a warm sweater, and a blizzard cap provided with a visor which could be pulled down over the face, and which contained two holes to look through. On reaching the upper tram terminal I learned that the special car was at the other end of the line, so I climbed into an ordinary ore bucket, in which I sat in a cramped position as the attendant clamped it to the traction cable, and we were launched out over the snow.

The first lap of the journey was uneventful. In about a quarter of an hour I reached the curve station, where I greeted the attendant as he unclamped my bucket from the upper section of the tram and pushed it along the curved rail past the bullwheel of the lower section. With a cheerful "all's well" and "good luck to you," he clamped my carrier to the traction cable and away we went on the second lap, and here is where the fun began.

I had scarcely left the curve station when I felt a slight pulsation on the cable, which I attributed to the clamping on of the bucket of ore which followed me, and thought nothing more of it. My bucket was about fifteen feet above the ground, and I experienced a pleasant sensation skimming along over the snow and listening to the click of the bucket pulleys over the saddle that supported the track cable at each tower along the line. In a drowsy state of mind, my imagination made of my bucket a rowboat drifting over the crest of a wave each time we passed a tower, for at this point towers were rather closely spaced because they were not very high.

I was awakened from my reverie by the realization that I had felt another pulsation on the cable. The first little jerk meant nothing to me, and I had disposed of it to my satisfaction, but a second, exactly like the first, might be significant. I waited for a third, and sure enough it came, and I imagined that it was just a little heavier than the first. Now I sat up and began to take a real interest in the phenomenon. I commenced a deliberate analysis of the situation by considering first the interval of time between jerks, and I was surprised and somewhat pleased at my conclusion that the period of time elapsed between the jerks was about the same. "Ping" went the cable for the fourth time, and I was sure the interval was uniform. Each jerk was a little more pronounced than the preceding one, so that my original explanation would no longer hold water. There was no time to lose. I must investigate hurriedly, or I might not be able to solve the mystery before the trip would be over. It was also necessary to decide at once whether I should hang over the side of the bucket and drop about fifteen feet into the snow, or go ahead and



'TIS A SAD TALE, MATES

see the trip through, for the cables were rapidly rising higher above the ground. My decision was that it would be more interesting to solve the mystery than to risk breaking a leg by dropping from the tram.

The next idea that occurred to me was to find out if the distance between buckets on the line bore any relationship to the interval between pulsations on the cable. At the very next jerk I noted the position of my bucket to be about ten feet past a tower. Then I kept my eyes on the next bucket following me until it reached the same position that my bucket had occupied a few moments before, and "bing!" went the cable. The problem was now almost solved. It was evident that each bucket on the loaded side of the line was hitting something, but the obstruction was not sufficient to stop

the tram, and apparently the attention of either of the tramway attendants on the section on which I was riding had not been attracted.

My bucket was now approaching a rise, beyond which there was a basin-like depression crossed by the tramway in a few long spans between high towers. The last of these high towers was at the top of the cliff above the mill, and below it was the big rock barrier which had been built to protect the mill against a repetition of the snowslide disaster of 1906. Beyond this tower was a group of smaller towers, arranged to let the cables curve gradually over the cliff on their dip into the mill terminal.

The last jerk on the cable had been an angry one, as if to warn me that fate was out of patience with my bravado, and that I had better be less theoretical and more practical in the solution of my difficulty. I looked ahead over the long spans between me and the tall tower at the rock barrier, and it was evident that there were interesting manifestations deserving of no light consideration. The sixth bucket ahead of me reached the tall tower. It did not rise as high as the bucket coming toward me on the other cable. Apparently the track cable had jumped out of its saddle on the tall tower, and was hanging against the side of it. The bucket seemed to grab the tower for an instant and then let go, at the same time executing the most fantastic contortions as it lunged for the next tower beyond.

I viewed the show grimly, but with some consternation. The pulleys on the bucket carriage were wider than the diameter of the cable, and as the track cable was against the side of the tower the pulley would go up against the timber and try to stop; but the traction cable kept right on going and made the bucket pulley lose its grip on the tower and move along with the procession.

The fifth bucket ahead of me now had its turn, and as it lost its grip on the tower it swung from side to side through an arc of more than 180 degrees, but stayed with the track cable, thanks to the downward pull of the traction cable at this point. Next came the fourth bucket ahead of mine. I watched it execute its "shimmy" and disappear with a wiggle over the cliff. The show was becoming exciting, I began to feel warm in spite of the cold weather, and as near as I can remember, I experienced an extreme sensation of exultation somewhat comparable to that of the small boy at the circus, just as the snare drum begins to roll, and the high diver begins to lean. As the third and second buckets ahead of me did their turn, I studied their positions at the tower. The last bucket's stunt was my cue, so I stood up on the edge of my bucket, and held on to the bail, prepared to jump for the leg of the tower just before my bucket should strike. It appeared to take my bucket an interminable length of time to reach the tower, but it finally arrived, and I jumped.

An engineer is supposed to be accurate in his calculations, but my time calculation was off by a fraction of a second: at any rate the bucket and I jumped at exactly the same time, and I was shot out into space where there seemed to be nothing to grab but the air. For an instant I seemed headed for the rock pile below, and everything turned black.

A thud awakened me, and I found myself clinging to one of the legs of the tower, at the same time supported by a small temporary platform less than two feet square, which a contractor who had recently painted the towers had neglected to remove. This was the only platform of its kind on the whole line. Fate had placed it directly in my trajectory. I had fallen six feet!

Mazapil Copper Co. Operation

The Mazapil Copper Co., an English corporation with main office in Saltillo, Mexico, has a three-furnace lead smelter on the outskirts of Saltillo, southwest on the mesa. This smelter has a capacity of 300 tons of ore per day and is now smelting 200 tons daily, with a monthly output of about 720 tons of lead-silver bullion. This is shipped to England via Tampico. About 200 natives are employed and 10 foreigners. The peon wage is 1.75 pesos per day.

The same company has a larger smelter at Concepcion del Oro, in northeastern Zacatecas. This smelter handles copper ore, having an equipment of four furnaces with blowers and a battery of six boilers. It has a capacity of 25,000 tons of ore per month and is now smelting about 15,000 tons, the present monthly output of copper matte being about 350 tons. This smelter employs 500 natives and 30 foreigners. The peon wage is 1.75 pesos per day.

In the region of Concepcion del Oro are the following mines belonging to the Mazapil Copper Co.: Aranzazu, producing 15,000 tons of copper ore per month and employing 1,500 men; San Eligio, producing 4,000 tons of lead-silver ore per month and employing 550 men, and Cata Arroyo, producing 4,000 tons of sulphur and iron flux and employing 250 men. The Mazapil Copper Co. is providing employment to approximately 3,000 men.

Manganese Industry in Japan

The expansion of the Japanese shipbuilding industry and other iron and steel manufacturing industries during the war brought about a greatly increased demand for manganese, according to Vice Consul H. C. Goodier, as is shown by the fact that 125,683,952 lb., valued at $973,153, was produced in 1918, a gain of 85,417,067 lb. in production over 1913. Of the 1918 output, Kyoto produced 24,422,317 lb., valued at $185,794; Hokkaido, 18,408,075 lb., valued at $143,060; and the remainder was produced by Gifu, Aomori, Oita, Tochigi, Nagano, and Shizuoka prefectures. No statistics are available for 1919, but it is estimated the production was small, owing to the marked decrease in domestic demand that has followed the cessation of hostilities.

In 1918, Japan proper consumed 106,235,000 lb. of manganese, two-thirds of which was used in the manufacture of iron and steel and the remainder for smelting and other purposes. It is believed the consumption in 1919 was not more than a third or a half of the 1918 amount.

Japan in 1918 imported ferromanganese to the amount of 1,697,280 lb., valued at $203,452, of which Australia furnished 1,132,800 lb., valued at $141,139, and Great Britain 564,480 lb., valued at $62,313. The principal countries to which Japanese manganese is exported are the United States, Great Britain, France, and China. In 1918 Japan's exports to these countries aggregated 5,229,864 lb., valued at $176,120, and in 1919 the exports amounted to 6,158,932, having a total value of $237,365.

Government Officials Influential in Mining

Frank J. Katz

In Charge of Mineral Statistics for the Census Bureau

TEN years ago the census reports on the mineral industries were done so poorly that their value frequently has been called into question. In an effort to improve on past performance arrangements were made for close co-operation with the Geological Survey and the Bureau of Mines during the taking of the present census. With the approval of the Bureau of Mines, F. J. Katz, a geologist long connected with the mineral resources division of the Survey, was appointed by the Superintendent of the Census to direct the gathering of the mineral statistics. He is now actively engaged in tabulating the vast amount of information which has been collected. The work has gone far enough to determine that 47 per cent of all mining and quarrying operations have as their object the securing of oil or gas. The remainder of such operations is divided as follows: Coal, 18 per cent; gold, silver, lead, copper and zinc, 21 per cent; quarries, 11 per cent; iron, 2 per cent; all others, 1 per cent. Mr. Katz has warned against a possible disappointment in the work of this census, owing to inadequacy of funds and to the policy of continuing tables so that they will be comparable with those of previous censuses.

FRANK J. KATZ

Mr. Katz was born in New York City. His early education, however, was obtained in the public schools of Milwaukee. After being graduated from the Milwaukee high school he entered the University of Wisconsin, where he completed the regular course in 1905. He did a year's post-graduate work at the institution and took further post-graduate work at the University of Chicago.

When Mr. Katz entered the University of Wisconsin he expected to do only a limited amount of work there, preparatory to entering a school specializing in metallurgy. Prof. C. K. Leith and the late Prof. C. R. Van Hise made the geology classes so interesting, however, that he gave up his idea of being a metallurgist and made geology his specialty. His first work was exploration of iron lands for a private company. Even then he devoted a portion of his time to the U. S. Geological Survey. In 1907 he abandoned private work and began giving his entire time to the Survey. He spent four years in the division of Alaskan mineral resources and later did general geologic field work, chiefly in New England. In 1912 he was assigned to the division of mineral resources, where he has specialized in abrasives, feldspar and silica. During the early war period he did emergency work on manganese in Virginia. With the formation of the Joint Information Board, early in 1918, he was assigned exclusively to its work. One of Mr. Katz's principal activities during the war was as an expert on the abrasive industry. This important industry was continually under investigation by the War Industries Board, the Bureau of Mines and the War Trade Board. The various kinds of abrasives of varying hardness, which are used in the finishing of all metal, were indispensable war necessities, and the minerals used as natural abrasives were produced both in the United States and elsewhere. In the vexing problems of securing a sufficient supply, coupled with economy of effort and conservation of shipping space, Mr. Katz's special knowledge made him an invaluable stabilizer of half-cock impulses; and at times also he lent his knowledge to preventing raids on the Treasury by politicians who seized the war as a cover for attemping to push through schemes to promote unnecessary abrasive mining in their home districts. Prior to his census assignment Mr. Katz had been promoted to the post of administrative assistant to the chief of the mineral resources division.

Those who know Mr. Katz best agree that the conferences among the Census Bureau, the Geological Survey, and the Bureau of Mines, which resulted in his appointment, picked a good man. The official in charge of mineral statistics for the last census was, according to tradition, the secretary of a cloakmakers' union; at any rate, some of the statistics were such that they were very much criticised by experts in the mining industry. However much Mr. Katz may be hampered by precedent, the results of his work are bound to be important in giving a more correct picture of the industry than was presented before.

HANDY KNOWLEDGE

Prolonging the Life of Elevator Belts

By DONALD M. LIDDELL

Written for *Engineering and Mining Journal*

The life of the elevator belts at the Butte-Kansas mill, near Waco, Mo., has been more than doubled by putting strips of belting between the cups and the belt.

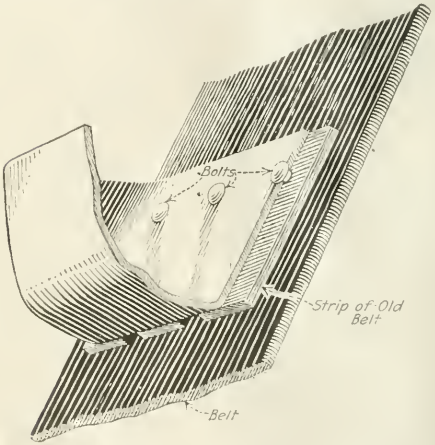


FIG. 1. METHOD OF ATTACHING ELEVATOR CUPS

Old belting is cut into strips about $1\frac{3}{4}$ in. broad and 5 in. long, and a hole punched at one end of the strip through which the cup bolt passes. Three or four

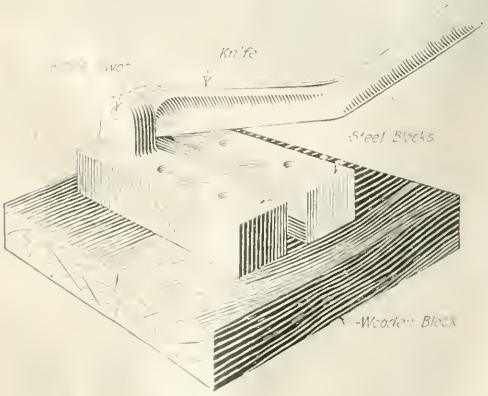

FIG. 2. KNIFE FOR CUTTING STRIPS OF BELTING

of these, depending on the number of cup bolts, are then used behind each cup. With these strips of old belt behind the cup the belt does not crack along the line of the upper cup edge. When the belt does begin to show wear, the cups are all set in new positions. Sometimes the cups can be reset three times.

A large knife (Fig. 2) has been made, with a lever handle, especially for cutting the old belt into strips. The knife blade comes down between the steel blocks, shown in the cut, which must be set not much further apart than the thickness of the knife blade.

The experiment has also been tried of crowning some of the elevator pulleys with old belting, which apparently saves both pulleys and elevator belts.

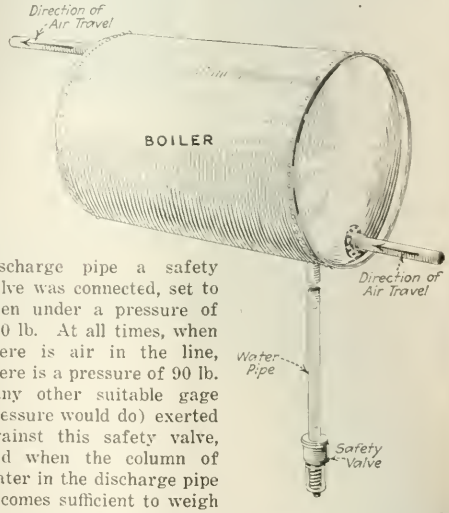
Water in Compressed Air

By G. L. SCHMUTZ

Written for *Engineering and Mining Journal*

The presence of water in compressed air is one of the principal causes of machine-drill repairs, owing to the fact that water in the air, in a few strokes of the machine, replaces the oil, leaving the drill to run without lubrication until the machine is again oiled; but even then, it is only a short time until the machine is again divested of its lubrication. This is a source of loss of time as well as money, and the obvious solution is to remove the water from the compressed air.

One method which has come to my attention consists in incorporating an old steam dome, or boiler, into the main air line leading away from the compressor, at a sufficient distance from the compressor to permit the precipitation of the humidity in the air. The air line enters the bottom of the boiler and passes out through the top at the other end, the boiler being used as a catch basin for the precipitated water. To dispose of this water automatically a 2-in. pipe leads away from the bottom of the boiler and down an old winze, or down the sides of a hill. On the end of this water-



discharge pipe a safety valve was connected, set to open under a pressure of 100 lb. At all times, when there is air in the line, there is a pressure of 90 lb. (any other suitable gage pressure would do) exerted against this safety valve, and when the column of water in the discharge pipe becomes sufficient to weigh 10 lb., making a total of 100 lb. exerted on the valve, it opens, thereby automatically releasing the water from the air line. Operation and maintenance involve no expense.

By The Way

Early Smelting in Nevada City

"In 1851 the people of Nevada City were led widely astray to their great cost and disgust by an individual, who called himself Dr. Rogers," runs a passage in Hittel's "History of California." "It cannot be affirmed that he was a fraud in the same sense that Captain Slater, of Downieville, was; he probably deceived himself as well as others; but the story of the excitement of the people of Nevada City at the time referred to, and the wild-goose chase that Rogers led them, illustrates another phase of early mining days, which was often exhibited. The discoveries there and in that neighborhood of extensive auriferous quartz veins attracted much attention to the nature of siliceous rock and the possibility of extracting gold from it. Dr. Rogers professed to know all about the subject; and as he made great pretensions and talked learnedly and glibly, almost everybody believed in him. He said that quartz was of a porous or cellular structure; but that the interstices between the crystals were not large enough in the ordinary state and at the common temperature to allow the particles of gold to drop out. By the expansion of heat, however, the pores would open and the metal have free egress either in form of minute grains or, if the heat was sufficient, as a melted current. All that was needed was the appliances for heating and giving it a complete shaking up. To the Nevada City people this looked reasonable enough; and there was no difficulty whatever in raising all the money needed, while everybody who had the opportunity of contributing reveled in the idea of soon rolling in gold. A capacious furnace and large chimney were built at great expense and a mammoth wheel erected on Deer Creek about a mile below the town. Wood, coal and ore in immense quantities having been brought to the place, a large iron reservoir at the bottom of the furnace was filled with water to receive and cool the precious metal as it loosened and fell or flowed from the rock. Everything being ready, the furnace was filled with alternate layers of fuel and auriferous quartz; the fire was kindled; and, as the mass burned down and lowered in the furnace, more and more wood and rock were added at the top. The great man, in whose capacious brain the whole process lay prefigured and who was receiving a salary commensurate with the magnitude of the undertaking, rode up occasionally, and with the air of a commander-in-chief gave orders, which were obsequiously obeyed, while the expectant millionaires stood around, eager for a sight of the first fruits of the princely harvest they were to reap. At length, after tons of rock had passed through the fiery ordeal and it was supposed that the iron reservoir must be about running over, a suggestion was made that it would be well to take out a few millions so as to give place for more. The cinders and ashes were accordingly scraped away and the cauldron was hauled forth; but it was as void of gold as when originally put in position. Not a pore of the burnt quartz had opened, or, if it had, not a particle of the rebellious gold had come out of it. The entire scheme, which had been based upon ignorance and presumption, instead of knowledge or experience, was a complete failure; and the prospective Midases reaped no harvest except the consciousness of having long ears. Rogers himself left in disgust; the quartz was pronounced a humbug, and property in Nevada City, which had gone up in the excitement, fell to a lower figure than it was before."

Versatility

An artesian flow of hot water was recently encountered in the Wheeler Oil Syndicate's well at Stillwater, Nev., which is said to have spouted to a height of 100 ft. and to have shown "unmistakable signs of oil." "The well is versatile," according to a local published account, which goes on to say:

> Not alone has hot water come from several stratas, but silver and gold were found at the 140-ft. level. This paystreak was found above the first flow of hot water, and it is asserted that a vein of sulphide ore was penetrated that is from four to five feet in thickness. The assayer made a determination of values of the samples released by the drill and found that they contained 7.29 oz. silver and $1.20 in gold—a total of $8.49. Three days later the drill released a small seepage of oil, which was followed by a vast and constant flow of hot water from the stratum reached Saturday. It must be seen that the Wheeler Oil Syndicate is at work exploring a wonderland that has never been understood, yet gives promise of yielding both metal and oil in paying quantities.

Some of the holes being drilled on the Comstock at present, which may not be dignified by being called "wells," will no doubt show just as much gold and silver and even more hot water, unless the Comstock has gone dry below as well as on top. And, perhaps, as a sweetener, there will be a dash or two of oil, to say nothing of acid and other things, the recital of which would make this sound like a recipe for something or other. But this is hardly versatility.

How To Be Poetical Though Practical

A correspondent sends us one of his mining reports, from which we quote an excerpt:

> Those snowfields and glaciers, those raging torrents and gentle streams and rolling rivers have come from afar from the sun-kissed waters of the Pacific, and they have been borne here on the wings of the wind and deposited on the hills and mountains to gladden the heart of man and give life and joy to the world. Their task being done they return to the great ocean whence they came.
>
> Keats, or Francis Thompson, or some other of the mystic poets, must have had this vision of the moving waters in mind when he wrote:
>
> "Henceforth live as becometh the God's elect,
> And though thy sins be countless as the seashore sands,
> Thy life as loathsome as the sulphurous pit,
> All shall be forgiven and forgot and thou, thyself,
> In time shall be dissolved,
> In the great ocean of God's unfathomable love."
>
> Looking down the Valley of the Sheep one sees two lofty and rugged ranges towering over it on the north and south. Torrents and slides and rivulets have worn deep in the sides of these mountains, and in the gorges and gulches, woods and groves are plentiful, save where avalanches and rock slides have played havoc. The ridge on the south is a formation of sandstone and shales in alternate layers, and in this formation are some thirty or forty layers or seams of coal. The coal seams dip to the south and west at an angle of 70 deg., being thus nearly vertical, and they vary from a few inches to forty or fifty feet wide.

What Color Is a Cape?

"A deputation representing the Cape-coloured Mine Workers waited on the Chamber in April and presented a petition setting out certain grievances."—Transvaal Chamber of Mines, Report of the Executive Committee, June 19, 1920.

CONSULTATION

Dollar Silver Payments

"In the *Engineering and Mining Journal*, issue of July 24, Vol. 110, p. 147, the first page, and also on page 188, you make some statements upon which I should like to have a little advice.

"1. Page 147, article entitled 'The Fixed Price of Silver': 'The silver so bought will be minted into coins or placed in the Treasury vaults as a reserve against the silver certificates outstanding or to be issued.' The 'outstanding' leaves me with the impression that our Government has issued silver certificates certifying that the silver has been deposited in the U. S. Treasury without its actually having been done so. I beg to inquire whether or not such is the fact.

"2. Page 188, 'On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States.' I beg to inquire whether or not there is any known method of determining whether the silver delivered has been mined, smelted, or refined in the United States or some other country. If it can be purchased cheaper in some other country, is not there considerable temptation to introduce some of this silver in that mined, smelted and refined in the United States?

"As far as I can see, the only thing which has maintained our silver dollar on a par with the gold dollar is that it was redeemable in gold, and its value consisted of the metal in it and the guarantee of the Government behind it. I have been told, and have no reason to question it, that on the Mexican frontier people have taken our United States silver dollar into Mexico, purchased a dollar's worth of goods there, and brought back a Mexican silver dollar having as much silver in it as ours. It, however, was different in this respect from ours: it was worth nothing more than the silver in it, whereas ours, upon being taken to the United States Treasury, could be exchanged for a gold dollar, with which you could buy twice as much silver as there was in our silver dollar, and take it to Mexico and get it coined into two silver dollars.

"3. I beg to inquire in what form is the payment made for silver which the Government purchased at $1 an ounce. Is it in silver certificate, silver dollar, or gold dollar? It is my understanding that in purchasing gold, it is paid for in gold or the free coinage."

1. We cannot answer for the Treasury Department, but believe that the Goverment has no silver certificates outstanding which are not fully protected by a metallic silver reserve in the Treasury vaults, particularly as a large quantity of silver remained from the stocks drawn upon during the Pittman Act. Silver certificates were retired during 1918 and an equivalent amount of silver bullion was issued in exchange.

2. Although there may be considerable temptation to perpetrate fraud upon the United States Government by disposing of foreign silver in introducing it into silver bullion of domestic origin, the authorities insist upon affidavits which will unquestionably indicate the origin, place of smelting, and refining of the metal. A few months ago, as the purchase provisions of the Pittman Act were put into effect, considerable difficulty was experienced by the smelters—particularly the ones smelting foreign ore in conjunction with domestic supplies—in segregating silver as regards origin. However, owing to an admirable spirit of co-operation between the Government officials and smelter operatives, these difficulties were gradually straightened out, chiefly through a modification of the original affidavits required. It is not so easy to palm off foreign silver as may be supposed, and no doubt there are just as stringent penalties covering this especial variety of fraud as any other brand. Besides, it is indirectly possible to obtain a check on the domestic production from past and present performances.

3. As to the form in which payment is made for silver purchased by the Government, we presume the settlement is usually concluded by a check or draft upon the Treasurer of the United States. This in turn can be exchanged into most any form of currency desired, with the great probability that Federal Reserve notes will be the currency ordinarily acquired—or at any rate negotiable paper. But the form at the present time has little if any significance, as the country is in a sound financial condition and all forms ultimately revert to a gold basis, which is the real foundation of settlement. For each ounce of bullion sold to the Government, one dollar in gold, or its equivalent, is paid. When the Government sold its silver at one dollar an ounce it also received payment on the same basis.

An Illogical Mineral Exploitation Agreement

"We have received an inquiry from one of our clients who has found traces of valuable minerals on some land in Tennessee and would like to get in touch with a mining company or promoter who would undertake to sink a shaft and make the necessary investigations to ascertain the value and desirability of extending operations. This work of investigation would have to be done by the company or promoters at their own expense, with the assurance, of course, that they may lease the ground at reasonable terms, should valuable mineral deposits be discovered. We would greatly appreciate your sending us the name or names of any individuals or organizations which you know of that would be likely to undertake work of this nature."

It is our impression that considerable difficulty would be found in obtaining a mining company or promoter to undertake the development of this property under the terms and conditions that you outline. In the first place, you say your client has only discovered traces of valuable minerals on his land. Surely, this alone is not enough to justify the sinking of a shaft and the expenditure of money in the hope that valuable and commercial deposits can be found at depth. Modern mining is not done upon this principle. Furthermore, you say that your client would require the promoting company to assume the expense of sinking the shaft and performing the development work, with the assurance that it may subsequently lease the ground at reasonable terms without specifying the reasonable terms. This is a rather loose and lop-sided proposition, and your client can consider himself fortunate if he secures any one to do this work on such terms, especially considering that no valuable ore has been found. The advertising pages of the *Engineering and Mining Journal* contain the names of companies which develop and exploit mineral deposits.

THE PETROLEUM INDUSTRY

Petroleum in Colombia

Proved Territory Limited to Three Square Miles, But Oil-Bearing Area Is Large—Development Expensive, Though Cheap Transportation of Product Is Possible—Tropical Petroleum Co. the Only Active Producer

BY ARTHUR H. REDFIELD*

THE oil-bearing formations of Colombia extend over about 34,000 square miles, of which only 618 square miles are believed to contain oil in commercial quantity, and only three square miles have been proved by drilling. The region may be divided into two principal districts, the Caribbean and the Pacific. The Caribbean district may be subdivided into the Caribbean fields, the Magdalena-Santander field, and the Tolima field.

Oil is now produced in the Magdalena-Santander field, but it has been found also in the Caribbean field, which, however, has not been commercially developed. The Tolima field and the Pacific district have been explored only.

The petroleum found in Colombia ranges from a heavy asphaltic oil to a light paraffine-base oil of 41 deg. Bé. (sp.gr. 0.8187).

THE CARIBBEAN FIELD

The Caribbean field extends from Hacha River, on the western edge of the Goajira Peninsula, southwestward along the Caribbean coast to the Gulf of Urabá (Darien) and inland to include the Tubará and Turbaco gas pools, up Magdalena River to a point thirty miles south of Chima and Mompos, and up Atrato River for ninety miles. It is about 300 miles long by 50 miles broad. In its 15,000 square miles are probably 300 square miles of productive territory, of which only one square mile has been proved by the drill.

The oil-bearing rocks of the Caribbean field are lower Tertiary (probably Oligocene). They are coal-bearing and consist of dark shales containing sandstones. Oil occurs in the sandstones and in the joints of the shales. The surface formations are either Miocene or Pliocene. The Miocene rocks of the coast are at least 8,000 ft. thick.

The beds in the region are broadly to sharply folded and are at places faulted. Nearly all the surface indications of oil are found in anticlinal areas. Most of the oil seeps occur in shattered fault zones or in the crushed cores of closely folded anticlines.

In weight, the petroleum of the Caribbean district ranges from 16 deg. to 41 deg. Bé. (sp.gr. 0.9587 to 0.8187), most of it being between 20 deg. and 30 deg. Bé. (sp.gr. 0.9333 to 0.9750).

A paraffine-base oil of good quality is found east of Sinu River. Its specific gravity is 0.858, its viscosity 0.98, and its flash point 101 deg. F. On analysis it gives: Naphtha, 2.92 per cent; kerosene, 31; lubricating oils, 30; paraffine, 3; and residuum, 27.08 per cent.

*Excerpt from a paper prepared by the Foreign Minerals Section of the U. S. Geological Survey.

Analyses of Colombian oils from the region of the Gulf of Urabá by the Engler method gave the following results:

ANALYSES OF MINERAL OILS FROM THE GULF OF URABÁ

Fractions	Percentages Arboletes	Pinar del Rio
Up to 150 deg. C. (benzine)	0	6
150 deg. to 300 deg. C. (kerosene)	25	64
Above 300 deg. C. (lubricating oils)	64	24
Carbonized residuum	11	6
	100	100

The oil from Arboletes is thick, reddish-brown by transmitted light, and dark green in reflected light. Its specific gravity is 0.9634; its flash point is 134 deg. C.; its point of combustion 149 deg. C. The residuum contains paraffine and 0.01 per cent of ash. It could be used in making lubricating oils.

The sample from Pinar del Rio is pure red in transmitted light and light green by reflected light. Its residuum contains very little paraffine. This can be used in making gasoline, kerosene, and lubricating oils.

Oil scum of good quality is found on the surface of the Hacha and other small Caribbean rivers. Sulphur springs occur at Usiacari, two miles southwest of Tubará, and seepages of oil are numerous in this region, especially near Tubará and near Arboletes. Indications of oil have been reported near Calamar, on Magdalena River; near Baranoa; south of Salgar, on the Puerto Colombia Ry.; and in the regions of Galera Zamba and Savana Larga. Sir Boverton Redwood reports no less than forty oil springs at places one to three miles from the Gulf of Darien. One seepage ten miles south of Punta Arenas and four miles east of the Gulf of Urabá yields seven barrels a day of a paraffine-base oil of 41 deg. Bé. (sp.gr. 0.8187). This high-grade oil is used in lamps by the natives.

HISTORY OF DEVELOPMENT

The first well drilled in Colombia for petroleum was sunk in 1909 at Tubará, six miles from Puerto Colombia. The Atlantic Oil Co., composed of capitalists from Toronto, Canada, after two unsuccessful tests, struck a high-grade paraffine-base oil at a depth between 700 and 800 ft. This well is still producing about a barrel a day, which is refined on the ground for use as automobile fuel. Gas was encountered in large quantities and at high pressure, and is used on the property as fuel. In 1912 the contract rights were transferred to the Three Seas Petroleum Co., of Chicago, which controls under lease about 400,000 acres in the vicinity and which purposes to continue operations.

Soon after work was begun on the Tubará lands a

well was drilled at Turbaco, ten miles from Cartagena, by Diego Martínez & Co., of Cartagena, to a depth of 2,000 ft. Showings of oil and gas were obtained, but work was not continued in that vicinity. The oil encountered was reported to be high in naphtha.

The same Diego Martinez, after having "denounced" (claimed) certain claims in the Lorica district, on Sinu River, in 1909 or 1910, contracted with the Standard Oil Co. of New York for their exploitation. This company sent down an outfit and began drilling in 1914. Three wells were drilled, in which showings of oil were encountered, but because of mechanical difficulties no oil was produced commercially, and work was abandoned in 1915. Diego Martínez & Co. are now operating in the region of the Gulf of Urabá.

In 1912 or 1913 William Plotz, of California, drilled to a depth of about 2,000 ft. at Baranoa, fifteen miles from Barranquilla, without result.

Magdalena-Santander Field

The Magdalena-Santander field includes the southern part of the Department of Magdalena, the Department of Santander, and the western edge of the Department of Boyacá, extending from Magdalena River to the eastern Cordilleras. It has an area of 10,000 square miles, of which only 200 square miles are believed to contain oil in commercial quantities. Only one square mile near Pamplona, and a similarly small area thirty-five miles from Barranca Bermeja, have been proved by drilling.

The petroleum is found in Cretaceous limestones and sandstone and in coal-bearing lower Tertiary (probably Oligocene) beds. In the Magdalena Valley and the eastern Cordilleras the oil is found in Cretaceous formations. The structural features in this district that are most favorable to the accumulation of petroleum in commercial quantities are long, well-defined anticlines (in places overturned) and fault zones in Cretaceous rocks.

The structure in the lower Magdalena Valley is of the fault-block mountain type, with downthrow on the west. The major structure is complicated by close folds, the axes of which lie parallel to the trend of the Andean ranges, and by more open cross folds. The lands where the petroliferous beds may be tested by the drill are confined to a narrow belt at the foot of the two mountain ranges. In the Department of Santander, on the east slope of the Andes, the structure is that of an asymmetric anticline.

Petroleum seepages occur along Magdalena River as far south as Girardot and along the Magdalena flank to the eastern Cordilleras from a point south of Girardot northward to Bucaramanga, in Santander. The strata are sharply folded and in many places fractured. Indications of oil are reported near Pamplona, on the Venezuelan boundary; near La Gloria, on Magdalena River; at Simiti, in the Department of Bolivar; in the valley of the Cesar River above Lake Zapatosa; in the valley of Lebrija River; near Ocana; on Carare River; near Zapatoca and Sogamosa River; near Bucaramanga; south of Honda; and near Chocontá, Ubaté, Chiquinquirá, and Tunja.

Petroleum is produced in Colombia only in the Magdalena-Santander field, on the celebrated De Mares concession. This concession, as originally granted in 1905, comprised 1,300,000 acres in the Department of Santander. It extended from the mouth of Sogamosa River up Magdalena River to the mouth of Carare River, up Carare River to the foot of the eastern Cordillera, thence along the foot of this range to Sogamosa River, and down that stream to its confluence with the Magdalena. The original concessionaire, Señor Roberto de Mares, enlisted the aid of a group of Pittsburgh capitalists, who organized the Tropical Oil Co., with a capital of $50,000,000, to exploit the concession. This company has drilled three deep wells at Infantas, which are said to produce daily 6,000 to 8,000 bbl. of an asphaltic oil testing from 35.5 deg. to 40 deg. Bé. This quantity is enough to supply all Colombia and leave a surplus for export. A 6-in. pipe line is being built to Barranca Bermeja, where a small refinery is to be erected. It is expected that the river steamers will soon burn native oil instead of wood, their present fuel. A railroad and a tractor road from Barranca Bermeja to the wells are among the projects under way.

It is reported that the International Petroleum Co., a subsidiary of the Imperial Oil Co. (Ltd.), which in turn is controlled by the Standard Oil Co. of New Jersey, has acquired control of the Tropical Oil Co.

Carib Syndicate Concession

The Barco concession, granted in 1905 to a citizen of Colombia, Virgilio Barco, includes 1,300,000 acres adjoining the Venezuelan frontier in the Department of Santander del Norte. The Carib Syndicate, of New York, was organized in 1916 to develop this concession, and formed, with the Cities Service Co., of New York (a subsidiary of H. L. Doherty & Co.), the Colombian Petroleum Co., in which the title to the concession was vested and in which the Carib Syndicate held 25 per cent of the stock and the Doherty interests the remaining 75 per cent. Drilling was started in the fall of 1919 but was necessarily slow, as all supplies had to be brought from the United States by way of Lake Maracaibo and Catatumbo River.

The petroleum of this concession is said to be an amber-colored oil of high grade, which seeps at the rate of 25 bbl. a day. It was reported in March, 1920, that the Carib Syndicate, of New York, had acquired from the Equatorial Oil Co. a block of 250,000 acres in the Honda district, adjoining the holdings of the Tropical Oil Co. The lands acquired lie on both sides of Sogamosa River, extending along that stream for about thirty miles. Practically all this area was acquired in fee simple, the fee including the oil rights subject to nominal tax by the Colombian government.

The Granada Oil Co. (formerly known as the Magdalena River & Coast Co.), of New York, has under long-term lease an area of 125,000 acres on Magdalena River near Ocano.

Tolima Field

The Tolima field consists of the upper basin of the Magdalena, including the departments of Cundinamarca and Tolima and the edge of the Llanos of San Martin and Casanare. Of a total area of 7,000 square miles in this region only 100 square miles are believed to be productive, and no part of it has been proved by the drill. The Tolima field consists principally of an elevated basin around Bogotá, which is surrounded by Carboniferous coal measures except where Magdalena River issues from the upland region.

The structure of the upper Magdalena Valley is of the fault-block mountain type, with the downthrow on the west, and is masked by late Tertiary tuffs or pyroclastics. Seepages of thick black asphaltic oil of 14 deg. Bé. and amber oil of 18 deg. Bé. are found along lines of faulting where black carbonaceous limestones and

shales of the Cretaceous system are brought to or nearly to the surface. Seepages of migratory oil are found in rocks of later age.

Six natural oil springs issue from fissures in sandstone near the village of Purificación, seventy miles south of Honda and three miles from Magdalena River. The oil is rich in lubricants and kerosene. Oil of a gravity of 22 deg. Bé. exudes from sandstones in the Plain of Medina, nine miles from Upia River, at the rate of two bbl. a minute. Seeps are abundant at the edge of the Plains of San Martin and Casanare, on the east side of the Andes. At a point 140 miles north of Nevea samples of an oil from 31 deg. to 38 deg. Bé. (sp.gr. 0.8696 to 0.8333), with a paraffine base, were collected. A seepage was found at Carmen, fourteen miles by road from Girardot, on Magdalena River. Oil taken from seeps in this district is used for lubricating the journals of car wheels on the Sabana railroad and on the railroad from Girardot to Bogotá.

Asphalt Deposits

Asphalt is found south of Ambalema; west and southwest of Honda; west of Magdalena River, especially near Saldama River; and at Natagaima, Yaguará, and Larida, in the Department of Tolima. Asphalt containing 99.5 per cent bitumen has been mined at Chaparral since 1903. Asphalt from Boyacá has been used to pave the streets of Bogotá. Gas has been noted at several places in the elevated plain of Bogotá.

The Pacific District

The Pacific district includes a belt in the Department of Cauca that extends sixty to seventy miles along the Pacific Coast from Buenaventura to Baudó River and thence inland to Atrato River at Quibdo and southward to Cali. It has an area of 1,800 square miles, of which eighteen square miles may be productive. None of this area has been proved.

The petroleum of Baudó River is connected with the "coal series" (lower Tertiary, probably Oligocene), which is perhaps a continuation of the petroliferous formation of the Caribbean coastal belt. The predominant rocks are shales that have been sharply folded. This oil ranges in gravity from 31 deg. to 37 deg. Bé. (sp.gr. between 0.8696 and 0.8383).

Oil has been seen floating on Andagusta River. A heavy petroleum has been found east of Quidbo, where the Quidbo-Medellin trail crosses Tutendnendo River. Other indications of oil occur along Baudó River, twenty miles from Santa Rosa, four miles north of Poree River, and south of Nechi River.

Colombia has certain geographic advantages as an oil-producing country. The Caribbean petroleum district is not more than 200 miles from the Panama Canal, where large quantities of fuel oil may be used. Magdalena River, if dredged and improved, would afford cheap transportation by water for the oil refined at Barranca Bermeja. The oil of Santander del Norte might be shipped on Catatumbo River.

Difficulties of Operation

Mineral oils have not been exploited in Colombia principally for three reasons: (1) Transportation is difficult and has been confined chiefly to the coast and to the immediate basins of the large rivers; (2) the local geology presents peculiar features, which have not all been adequately studied; and (3) certain practical difficulties of operation have not been fully overcome.

The cost of the preliminary work by the geologists in a country where the mode of travel and transportation are still in a primitive state is great. The work of prospecting requires heavy machinery, which is difficult and expensive to transport. Three hundred tons of machinery is required for a single well, and if the well has to be abandoned the machinery will be practically a dead loss, owing to the difficulty and expense of moving it. All experts, whether technologists or skilled workmen, must be brought into the country at high salaries or wages, and much of the food, especially canned goods, needed for the working force must be shipped from the United States. Practically all wood used in constructing buildings or bridges must be imported, for the native woods are unsuitable for this use. For lack of detailed geologic knowledge of the ground, the driller may not be able to determine the type of drill rig, rotary or standard, that is best adapted to the formations; and consequent accidents to the drilling apparatus may cause the loss of the well. Finally, after wells have been drilled, oil may not be found in sufficient quantities to warrant the construction of roads, bridges, pipe lines, tanks, refineries, and pumps. The cost in Colombia of laying a pipe line, which is considered the cheapest method of transporting the oil, was estimated in 1917 at $20,000 to $30,000 a mile.

Companies Participating in Development

The American companies that were working or prospecting in Colombia in the latter part of 1919 included the Tropical Oil Co., of Pittsburgh, exploiters of the De Mares concession and the only active producers of petroleum in Colombia; the Colombian Petroleum Co., of New York (in which the Doherty interests hold 75 per cent of the stock and the Carib Syndicate 25 per cent), owners of the Barco concession; the Three Seas Petroleum Co., of Chicago, which is operating at Tubará, near Puerto Colombia; the Bradford-Colombia Oil Co., of Bradford, Pa.; the South American Gulf Oil Co., of Pittsburgh; the Midco Co., of Tulsa, Okla.; the Island Oil & Transport Co., of New York; Guffey & Gillespie, of Pittsburgh, who have purchased 1,250,000 acres adjoining the De Mares concession; the Ohio Cities Gas Co., of Columbus, Ohio; the Sinclair Gulf Oil Corporation, of New York; the Carter Oil Co.; the Prudential Oil Co.; the International Petroleum Corporation, which is reported to have recently acquired control of the Tropical Oil Co.; the Magdalena Oil Corporation; the Granada Oil Corporation; the Caribbean Petroleum Co. (a subsidiary of the Barber Asphalt Co., of Philadelphia); the Emerald Oil Co., (A. J. Diescher); and the Transcontinental Oil Co., which is under the control of Benedum-Trees interests.

British Capital Also Interested

British capital is represented by the Lobitos Oil Co., of Peru; the Royal Dutch-Shell group; the Anglo-Persian Oil Co.; Balfour, Williamson & Co., of London; the Alvez group, of London; and the Jenks group, of London, all of whom are reported to be active in making contracts but about whose activities little definite information has been obtained.

Colombian capital has indicated its intention of participating in the development of the petroleum resources of the country by the formation of the National Petroleum Co., of Bogotá, announced Feb. 9, 1920. No details of the capitalization or activities of the company have been made public.

NEWS FROM THE OIL FIELDS

26,000-Bbl. Well a Record in Brazoria County, Tex.

From Our Special Correspondent

At West Columbia, Brazoria County, the Texas Co.'s No. 1 Abrams well is still flowing at the rate of 26,000 bbl. daily with the drill stem and bit still in the hole. The previous record producing well in this field is said to have made 1,000,000 bbl. in thirteen months. This record is practically surpassed already, with little if any abatement in flow.

The Texas Co.'s No. 16 Koehler well at Humble, Harris County, was worked over and deepened to 3,178 ft. recently, and it responded by flowing 5,000 bbl. per day.

An opinion has been given to the State Land Commissioner, J. T. Robinson, by the Attorney-General's office that any person leasing state land for oil or gas production purposes must pay the state $2 an acre per year in advance for such leased land.

It is reported that the well of the Capitol Petroleum Co., near Weatherford, Parker County, came in flowing a strong head of gas estimated at 500,000 cu.ft. The gas became ignited.

The test well on the Baggett lease, two miles south of Gunsight, Stephens County, was completed at 3,335 ft. after penetrating a considerable footage of oil-bearing limestone. Nitroglycerine was lowered into the well to shoot it, but when the casing was raised considerable ground caved upon the charge, and the well will not be disturbed for a few days.

Short Supply of Casing Will Limit Wyoming Drilling

From Our Special Correspondent

A meeting was held in Denver on Aug. 19 and 20 by representatives of several of the larger oil-producing companies of Wyoming, particularly those of the Salt Creek field, to discuss the problem of the shortage of casing caused by insufficient transportation facilities. It was resolved that it would be better to limit drilling, if necessary, rather than pay premiums or bonuses for casing or any other supplies above the usual list prices plus freight charges. The Salt Creek operators also agreed to limit the spacing of wells to one per acre, to protect the future production of the field.

A number of large oil-well supply houses have opened or are opening offices in Denver as a result of the extension of the Wyoming oil fields to the southern part of that state, and the large amount of prospecting which is under way or planned in Colorado. James Purcell, formerly with the Texas Co., has been appointed manager of the Denver office of the Continental Supply Co., with offices in the First National Bank Building. The National Supply Co. has opened offices in the Gas and Electric Building, with J. O. Ingram in charge. His supervision still extends over the Laramie, Wyo., district, where he formerly was situated.

Possible Legal Difficulties in Salt Creek Field, Wyoming

From Our Special Correspondent

Wednesday, Aug. 24, was the last day of the six months' period in which claimants to lands within withdrawn areas could relinquish their claims to the Government in order to apply for leases under the oil-land leasing act. The Salt Creek field in Wyoming is particularly affected by this act, as a large acreage is held by the Midwest companies under titles extending many years. Few applications for leases have been filed by the Midwest companies with the receiver of the General Land Office at Douglas, and it is believed an interesting legal battle for title to much of the land will result.

The well of the Trail Canyon Oil Co., recently completed in the Tisdale field, ten miles north and west of Salt Creek, will produce about 25 bbl. daily. The well is said to be 230 ft. deep and in the Dakota sand. About three years ago a test well which was drilled on this structure west of Salt Creek found only water.

Manitoulin Island, Ontario, Now Being Actively Developed

From Our Special Correspondent

Active oil development is in progress in the Manitoulin field by a number of companies and syndicates, and some good results have been obtained. The Standard Oil Co., which early in the century secured a lease of 30,000 acres in the Indian Peninsula and spent considerable money in exploration but afterward withdrew from the field, has resumed operations. An English syndicate headed by Sir Stopford Brunton has leased 25,000 acres. The Kyto Oil Co., of Dayton, Ohio, has brought in three wells at a depth of 456 ft., which have settled down to a steady daily production of 12, 15, and 18 bbl., respectively. Mr. Gordon, of Dayton, is drilling several wells near Manitowaning, and a Toronto syndicate has secured oil rights to a large tract in the southern part of the island. Interest in the Manitoulin field has been greatly stimulated by the work of M. Y. Williams, of the Canadian Geological Survey, which has materially increased the knowledge of its oil-bearing possibilities and has done much to encourage oil companies to develop the island.

Second Big Gas Well Brought in in Barren County, Ky.

From Our Special Correspondent

Another huge gas well is reported to have been brought in on the Smith lease near Temple Hill, Barren County. The first well, brought in two weeks ago, showed a production of 15,000,000 cu.ft. of gas daily, by the mercury test, and the second well is said to be even greater. It blew the tools, weighing 2,000 lb., far out of the hole. Four other wells are being drilled by Merry Brothers, who are responsible for bringing in the first two.

The Twin Lakes Petroleum Co., of St. Louis, brought in a 100-bbl. well on the Brawner lease in Simpson County on Aug. 25. It has a well started on the Ellis lease near Temperance, which will be shot soon. There is 45 ft. of pay sand at a depth of 570 ft. The company also has brought in a good well near the Reeder gusher in east Simpson County at 638 ft.

A 75-bbl. well was drilled in on Aug. 24 on the Davenport lease along the Barren River Pike, Warren County. The well on the T. K. Bohon farm, six miles west of Bowling Green, pumped 250 bbl. in twelve hours when it was brought in recently.

The Beech Bottom well, in Clinton County, eight miles west of Albany, is showing up well at 1,785 ft. The oil is standing 600 ft. in the hole. It probably will be drilled 20 ft. deeper. It will make 200 bbl. a day, according to estimates. This apparently opens a new deep field.

Australian Refinery Proposed—Crude From Papuan Fields?

Arrangements are being made to bring into effect the agreement entered into by the Australian government with the Anglo-Persian Oil Co. in accordance with which an oil refining company will be registered in Australia. The company will have a capital of £500,000 in £1 shares, of which 250,000 shares will be taken by the commonwealth government and 249,996 by the Anglo-Persian Oil Co., and three shares by nominees of that company. The company undertakes to work and equip a modern oil refinery in the commonwealth, and to control the sale and disposal of the products of the refining of mineral oil. Boring and developmental operations in the Papuan oil fields are proceeding, and if successful, the commonwealth will eventually supply 200,000 tons of oil per annum to the new refinery company for the purchase of which it holds an option. Meanwhile the Anglo-Persian Oil Co. will supply oil for the refining purposes up to the amount of approximately 200,000 tons.

ECHOES FROM THE FRATERNITY

Labor Emigration From Europe Checked and Controlled There

America Must Make Special Effort to Win and Hold Immigrants as Loyal Citizens—Few Laborers Coming Here

Frances A. Kellor, vice-chairman of the board of directors of Inter-Racial Council, has just returned from an industrial survey of Europe, and in the following paragraphs summarizes his observations and impressions concerning labor prospects of the near future:

"The time has passed," says Mr. Kellor, "when the American employer may count on an unlimited supply of labor from abroad. Emigration from Europe will be strictly regulated by the respective governments in the near future, and is already being directed in some of the Old World nations, which have begun to realize the value of their workers. The French government has offered Italy six tons of coal per month for each Italian miner induced to go to France, and Italy's Commissioner of Emigration is advising his people to emigrate to France. Greece is offering the inducement of farms to the people, and has passed an act requiring large land owners to surrender two-thirds of their estates to the peasants. Furthermore, emigration from Greece may be prohibited at any time by law. Similar conditions are found in Finland.

"These instances show the attitude of foreign governments toward their nationals. Emigration will be curtailed by many governments to the extent deemed expedient for their own interests. Furthermore, they will advise the emigrant where to go, and in some cases will retain him as a citizen with voting rights, even while living abroad.

"Immigrants who do come here will thus have less tendency to make America their permanent home and become citizens, and we shall have to make greater efforts than in the past to win over and assimilate them.

"Some of the foreign nations are planning to do the things which America should have done long ago: to protect immigrants from fraud, to establish official information bureaus, to take care of their savings through branch banks, and generally to look after their welfare.

"International agreements regarding immigration are being made between Old World countries. Hungary, Poland, Greece, Italy, France, Lithuania, Spain, Portugal, and the Balkan countries have taken the lead in such conferences, but the United States, which has so much at stake in the matter, has shown indifference. If our supply of coal, iron, oil, or cotton were threatened the whole nation would be aroused, but with the imminent curtailment of our labor supply, even at this time of acute labor shortage, the Government and the business men who should be interested are remaining apathetic. These are matters of direct immediate concern to the American business man. When the manifesto of a leader in Russia can react on the workers with greater force than the words of the plant executives —when a stream of literature in foreign languages can counteract utterances in the American press or in plant organs—it becomes essential to the self-interest of the American business man that he know about these things promptly and take adequate action in the light of his information on the facts.

"Meanwhile the tendency of the foreign-born workers to return to their old homes should be checked by every legitimate means. The most powerful inducement to them to remain is, of course, just and humane treatment, with no discrimination in wages, housing, and living and working conditions between them and the native born. Efforts should be made to establish closer relations with the foreign-born workers. If they have legitimate causes for discontent, the grievances should be understood and removed. The same spirit of co-operation that is being secured through enlightened employers and their English-speaking workers should be developed in relation to the foreign-born laborers. This is not 'coddling,' not philanthropy, but labor conservation.

"We should not be deceived by the temporary increase in immigration. The figures that indicate a large number of arrivals at Ellis Island fail to show the fact that the proportion of women, children, professional and clerical workers is so great as to afford little relief to our labor shortage. Of the manual laborers coming in, a large percentage are men who went abroad to fight, and are now only returning to their old jobs. Of new workers to do the essential work of America there is an exceedingly small percentage, and recent correspondence from all parts of the United States indicates serious shortage of labor in almost every section.

"The course of action for the employer is therefore, first, to conserve labor as carefully as he conserves his raw material; and, second, to regard immigration problems with the same interest that he gives to international commerce, realizing that America is no longer isolated and that what happens in the Old World today will be reflected in his own business tomorrow and the day after.

"An international conference on immigration is planned for 1921, in which the United States should play a leading part. Business men who are interested may obtain further details through the Inter-Racial Council, Woolworth Building, New York."

Organizations Invited To Join F. A. E. S.

The joint conference committee has been asked by one of the technical papers concerning the invitation to become a member of the Federated American Engineering Societies.

Pursuant to the request of the governing boards of the four founder societies, of the American Society for Testing Materials, of the United Engineering Society, and of the members of the Engineering Council, contained in the resolution unanimously adopted at their joint meeting on Jan. 23, 1920, the joint conference committee issued the call to the engineering and allied technical organizations of the country to attend the organizing conference in Washington, June 3-4, 1920, which was sent to engineering and allied technical organizations whose chief object is the advancement of the knowledge and practice of engineering and the allied technical arts and which were not organized for commercial purposes.

The organizing conference approved the list of organizations to whom the invitation was extended by the joint conference committee and no other organizations were added to this list by the conference. The joint conference committee is, therefore, extending invitations to these organizations to become members of the Federated American Engineering Societies under the authorization given it by the organizing conference on June 4, 1920. There may be other organizations which are eligible for membership. Such organizations may make application for membership to the American Engineering Council.

Montefiore Foundation Prize

The Association of Graduates in Electrical Engineering of the Montefiore Electrotechnical Institute announces under recent date that April 30, 1921, is the final date for receiving typewritten manuscripts or publications submitted in competition for the prize of 20,000 fr. offered by the George Montefiore Foundation. Memoirs must have been prepared during the three years preceding the meeting of the jury of award, must be in French or English and typed or printed. The award will go to "the best original work on scientific advance and progress in the technical applications of electricity in any field." Works of popularization compilations are barred.

The jury comprises ten electrical engineers, five from Belgium and five from other countries. Further details may be had by addressing L. Calmeau, secretaire général, Association des Ingenieurs Electriciens sortis de l'Institute, Etc., Rue Saint Cilles, 31, Liége, Belgium.

Dangers From Explosives Fumes in Metal Mining

Toxic Gases Always Present—Straight Nitroglycerine Never Permissible—Small Electric Fan-and-Pipe Units Needed

Two recent occurrences in Western metal mines, in each of which three men were killed, due to breathing fumes from explosives, have aroused keen interest among mining men not only as to the exact cause of such accidents, but also as to possible preventive measures. Both the accidents and their possible prevention are discussed as follows under the above title by D. Harrington and B. W. Dyer, engineers of the U. S. Bureau of Mines, in one of its recent reports of investigations:

In sinking the 45 deg. incline Marsh shaft near Burke, Idaho, on May 13, 1920, a round of holes containing about sixty pounds of 40 per cent gelatin explosive was blasted by the night shift on leaving at 11:30 p.m. It was customary for the night shift to leave compressed air blowers open at bottom of shaft until the compressor was shut down, slightly before midnight. Presumably this was not done on the night of the 13th, as the fumes were so heavy in the shaft bottom on the morning of the 14th that at about 8 o'clock, Superintendent Bergen and one of the shaft men, on reaching the shaft bottom, were overcome and fell from the bucket into the sump containing about six feet of water; and when two other men went down in the bucket a few minutes later to investigate, one also fell into the sump and the other was barely able to reach the shaft collar. The three bodies were later on recovered from the sump.

At 4:50 p.m., on June 10, 1920, at the Dominion Mine, Colville, Wash., a round of eleven holes containing about fifteen pounds of 60 per cent nitroglycerine explosive was blasted in a 50 deg. raise about fifty feet above the main tunnel level by the shift going off for the night. In this mine it was the practice not to try to blow out the fumes until just before the shift went to work the next morning. Although no work was being done on the night shift, one of the raise men, curious to ascertain the effect of the shots, about 7:45 p.m., wandered into the mine (which was a tunnel only a few hundred feet in length), and was missed by one of his companions about an hour later. When three men tried to remove the body of the inquisitive miner, two of them were also overcome; ultimately these two and the first man were removed from the point at which all were asphyxiated, which was practically at the foot of the raise.

In this case the explosive was seven-eighths *straight nitroglycerine*, used because the ordinary one-and-one-fourth gelatin was temporarily unobtainable, though the holes were drilled for the larger sized stick. The explosive, too, was about a year old. Though two of the eleven holes missed fire, there was no obtainable evidence of burning of explosive, but later on, after blasting these two missed holes, containing possibly three pounds of the explosive, an air sample taken a few minutes after blasting, and essentially at the point at which the three men had been asphyxiated, gave 0.79 per cent CO, or sufficient to cause death after having been breathed a comparatively few minutes. It was thought locally that the deaths were due to other gases, but analyses indicate strongly that CO was responsible.

These accidents indicate forcibly a danger daily confronting men working in metal mines and especially in small or prospecting mines. In one case, the dangerous fumes were in a shaft, in the other in a raise, the deaths in the latter being, however, practically on the tunnel level. Compressed air constituted the usual method for removal of dangerous gases, and in both cases it failed. In both accidents there is at present no obtainable evidence of defectiveness of explosive or of method of firing.

Dangerous Gases Always Present

Theoretically, there are in existence today explosives with constituents so chemically balanced that with complete detonation there should be no resultant gases of more potential danger than CO_2 which would be diluted to such an extent as to be practically harmless. Nevertheless numerous air samples at blasting faces in metal mines almost invariably reveal the presence of dangerous gases, due, generally, to incomplete combustion, these dangerous gases being usually CO and oxides of nitrogen. Dangerous percentages (upward of 1 per cent) of CO have been obtained at drift faces in metal mines after blasting with explosives of ammonium nitrate as well as gelatine base, detonated with No. 8 as well as with No. 6 caps, fired electrically as well as by fuse, tamped and untamped.

The most dangerous gas found in fumes of explosives is CO, of which quantities up to and over 1 per cent are frequently found in the general air around newly blasted faces in metal mines, and frequently as much as $\frac{1}{10}$ or $\frac{1}{5}$ of 1 per cent in air from muck piles several hours after blasting. This gas gives headache in air with proportions as low as 0.05 per cent; it is dangerous at 0.2 per cent and quickly fatal when over 0.50 per cent is present. Nitrous oxide is sometimes found, and its effect, though serious, is not likely to be so quickly fatal as that of CO. However, when dynamite burns instead of exploding, the nitrous oxide content of surrounding air may be sufficiently high to cause death. Other dangerous gases, such as H_2S and SO_2, may also be found in explosive fumes, but are rarely present in harmful proportions. However, straight nitroglycerine explosive dynamite gives off several times as much CO gas as gelatin or ammonium base explosive, hence *straight nitroglycerine should never be used in the confined places found in mining.* At present no explosive is applicable to metal mining in which there is any guarantee that formation of dangerous gases can be prevented in blasting; hence the one feasible preventive is effective ventilation.

Effective Ventilation Needed

It is significant that in 1919, the great coal mining industry of the United States had but three deaths from suffocation from explosives fumes among over 760,000 men, or about three times as many employees as in our metal mines. Metal mines only too frequently place entire reliance on natural ventilation or on compressed air, and both are likely to be inefficient, dangerous and, in the long run, costly. * * * For dead-end faces of drifts, crosscuts, raises, winzes and shafts, small electrically driven fans direct connected to one-half hp. to ten hp. motors force air through canvas tubing or galvanized pipe, and readily deliver 1,000 to 5,000 or more cubic feet of air per minute, or ten to fifty times as much air as can be obtained from compressed air blowers and at much less cost. These small fan and canvas pipe or galvanized pipe units not only remove explosive fumes from the face, but if operated as blowers will keep a stream of moving air at the point where the machine man or mucker works. In hot mines, especially, the worker's comfort and efficiency are greatly improved thereby and his health and safety assured at least as far as explosives fumes are concerned. Larger metal mines now recognize this and many new mechanical ventilation installations have been made in large metal mines, especially in the West, and the time will soon be at hand when laws will demand efficient ventilation providing circulation of ample currents of fresh air at all places where men work underground.

Dry Jackhammers Prohibited in Rand Mines

At a meeting held early in July in the offices of the Government Mining Engineer of the Union of South Africa, representatives of the Transvaal Chamber of Mines, the Mine Managers' Association, Underground Officials' Association, and of the South African Mine Workers' Union agreed that a new regulation should come into effect after March 31, 1921. This regulation, which is an amendment to No. 101 (1) (3) of "Mines, Works and Machinery Regulations," provides that "No person shall in the drilling of holes use or cause or permit to be used any machine drill in which only air is passed into the hole through the hollow jumper of the drill."

As the *South African Mining and Engineering Journal* says, the effect of this order on the mines remains to be seen. There are considerable numbers of dry jackhammers in use today on the Rand and also held in stock, and these will have to be scrapped or converted by the date mentioned. One estimate placed the cost of conversion at £9 per machine.

Book Reviews

Mica in the Eastern Transvaal—By A. L. Hall. Memoir No. 13, Geological Survey, Department of Mines and Industries, Union of South Africa; pp. 95; 17 plates, 8 text figures, 1 map; 6 x 9½; Johannesburgh, 1920.

As the first really comprehensive report on the Transvaal mica deposits, this memoir is a welcome addition to the literature on mica. The mica belt, approximately 300 square miles in extent, has been worked on a considerable scale since 1909, but until 1912 the nearest railway station was 120 miles distant. The opening in that year of the Selati railway, which crosses the belt, has given a great impetus to the industry. The muscovite occurs in coarse pegmatites in granites associated with basic rocks.

The deposits and workings of the six operating companies are described. An instructive feature of the report is the emphasis placed on the uncertainties of mica mining, and the practical importance of the physical condition of the product. Although some exceptionally large blocks of mica have been uncovered, on the whole the marketable mica is in comparatively small sizes. Data from two of the largest mines indicate that to procure one ton of mica, trimmed and ready for the market, it is necessary to mine from 850 to 1,700 tons of rock. A series of instructive tables are presented, giving prices of South African mica in the London market, dimensions and grades of sheet mica, chemical analyses, dielectric strength and percentage of various grades produced. At present the great waste in the mica fields is practically unused, and the author points out its possible successful utilization as ground mica. Transvaal mica compares favorably with that now used in Europe and America and with growing outside demand there is the prospect of a larger development.

A summary of conclusions condensed to half a page is a useful feature for the busy reader. Although less comprehensive than de Schmid's monograph on the Canadian deposits, the report is clear, instructive, and ranks favorably in the mica bibliography. O. B.

Retraining Canada's Disabled Soldiers.—By Walter E. Segsworth, M.E. Cloth; 7 x 10; pp. 193. Published by the Department of Soldiers' Civil Re-establishment, Ottawa.

Canada may be justly proud of the way she has handled this very human problem. The work was begun in 1915, and by the time the United States had the same problem to solve, our northern neighbors had much to tell us of their very satisfactory system, so well described in this book. Mr. Segsworth, a mining engineer, has been in charge of the work since July, 1917. The work has been centralized, and is perhaps being carried on more effectively in Canada than in any other country. Up to Jan. 1, 1920, over 33,000 returned men had availed themselves of the government's offer of training in a new occupation. Some were physically incapacitated from returning to their former occupations, others sincerely thought they were, and still others were not immediately able to take up the work to which they were accustomed, but might become so later. The government's interest in the men has continued after their graduation from training, so that accurate statistics are available as to the results secured.

This book will be of interest to all who have disabled men to take care of, whether caused by war or industrial accidents. Although devoting little space to mining and metallurgical work, many applicable ideas can be gained.

Technical Papers

Mica—"Mica in 1918" has been issued by the U. S. Geological Survey. Most of this substance comes from India, but the U. S. production in 1918, 822 tons, was the largest since 1913.

Smelting With Enriched Air—F. G. Cottrell and C. A. Meissner discussed the enrichment of air by oxygen, for metallurgical purposes, at the New York meeting of the American Iron and Steel Institute on May 28. The *Iron Trade Review* for July 29 republishes the papers, possibly in abbreviated form. With a cheap source of oxygen the practicability of the process is worthy of consideration, both in ferrous and non-ferrous metallurgy, though it is in its application to iron smelting that the authors are principally interested. Little practical work has been done, the papers being chiefly of suggestive value.

Gasoline—The July issue of *Reports of Investigations* (Department of the Interior, Washington, D. C., Serial Number 2,149) contains a motor gasoline survey. The quality of the gasoline supplied during the summer is ordinarily not as good as that marketed in winter, but that sold this summer seems to be worse than usual. Some samples were found diluted with kerosene. Of the seven cities in which samples were taken, San Francisco was found to have the most satisfactory gasolene, followed in order by New York, Chicago, Pittsburgh, Washington, New Orleans, and Salt Lake City, the poorest.

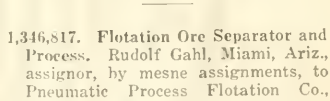
The Taylor System—In the August issue of *Industrial Management* (120 W. 32 St., New York, 35c.) is published the first of a series of articles on the application and practice of the Taylor system of management.

Geological Investigation—The Tennessee Geological Survey has again taken up the study of the Upper Cretaceous Series of West Tennessee, an illustrated report on which occupies fifteen pages in Bulletin 23 of the State Geological Survey (Nashville, Tenn.).

Recent Patents

1,316,817. Flotation Ore Separator and Process. Rudolf Gahl, Miami, Ariz., assignor, by mesne assignments, to Pneumatic Process Flotation Co., New York, N. Y. Filed June 26, 1915.

A flotation ore separator comprising a flotation tank divided into frothing compartments by partitions not reaching completely down to the bottom of



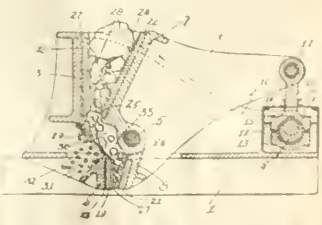
the tank, a concentrates delivery, and a whole-flow tailing discharge extending upwardly from the bottom of the tank beyond a frothing compartment.

1,316,939. Method of Sampling. Robert E. Carmichael, Damon, Tex. Filed Dec. 1, 1919.

A method of raising the cuttings from an earth-boring drill to the surface comprising forcing a stream of flushing liquid downwardly through the drill stem and through channels in the bit to the bottom of the hole, forcing downwardly outside of the drill stem a current of compressed air, forcing the same into the drill stem toward the lower end thereof and causing the air to pass downwardly through the bit to unite with the flushing liquid and lift the cuttings and flushing material to the surface outside said drill and drill stem.

1,316,871. Crusher. Herman P. Andresen, Chicago, Ill. Filed April 30, 1920.

A crusher embodying therein a double-action jaw member mounted for swinging movement, spaced crushing portions thereon, spaced stationary crushing portions with which they



coact, the crushing portions on the swinging jaw member and the stationary crushing portions forming spaced pairs of crushing portions, and a sizing device arranged intermediate said spaced pairs of crushing portions.

MEN YOU SHOULD KNOW ABOUT

G. R. Mansfield is engaged in geologic field work in southeastern Idaho for the Geological Survey.

Samuel W. Cohen, consulting mining engineer, of Montreal, is in Newfoundland on examination work.

Kirby Thomas, mining engineer, of New York City, is investigating kaolin deposits of the Eastern States.

C. M. Heron is examining mining properties in the Lordsburg and old Apache mining districts of New Mexico.

George C. Martin is making geologic surveys in the Kuskokwim region of Alaska for the U. S. Geological Survey.

A. E. Drucker, mining engineer, was visiting mines and reduction plants at Butte, Anaconda, and Great Falls, Mont., at the end of August.

Jack Welch, general manager of the Majuba Silver, Tin & Copper Mines Co., Nevada, has been sick for several months and leaves soon for San Francisco.

Y. Nakayama, a metallurgical engineer on the staff of the Furukawa Mining Co., Marunouchi, Tokyo, Japan, has been visiting some metallurgical plants in the United States.

George Rupp has returned from a two-months' trip to the Hudson Bay country, where he and **Dwight Woodbridge** examined large deposits of iron ore on islands in the bay.

D. Dale Condit and **Robert W. Howell** of Washington, D. C., who were in Singapore April 21, are engaged in geologic field work in southeastern Idaho for S. Pearson & Son, London.

Everett H. Parker, who was graduated from Columbia School of Mines last June, is now looking over mines in England, after visiting the Continent. Mr. Parker expects to return to the United States about Oct. 1, and will then go to Butte, Mont.

J. E. Healey, general manager of the Consolidated Main Reef Mine & Estates, Ltd., Johannesburg, Transvaal, is in Los Angeles, Cal., while visiting America. He will visit San Francisco, Denver and Chicago on his way East and will sail from New York for London about Oct. 15.

Henry M. Payne, assistant to the president of Bertha Coal Co., Pittsburgh, Pa., has resigned to become general manager of the Douglass Barnes Corporation, 53rd St. and 5th Ave., New York City. Mr. Payne, who is a member of several directorates and mining organizations, assumes his new duties Sept. 20.

Rienzi W. Macfarlane, assistant superintendent of the Arizona Copper Mining Co.'s Longfellow group of mines, left Morenci, Ariz., for Parral, Mexico, on Aug. 12, expecting to be absent several weeks. Before the troubles of recent years Mr. Macfarlane was engaged in mining in the Parral region.

C. M. Lazuire, of the mining department of the California State Mining Bureau, has been appointed district engineer in charge of the northern California field division of the bureau with headquarters at Redding, Cal. Mr. Lazuire succeeds **Emil Huguenin**, who has been transferred to the oil and gas department, with headquarters at Taft, Kern county.

OBITUARY

J. GEORGE LEYNER

J. George Leyner, pioneer in the development of rock drilling machinery, inventor of the piston-hammer drill and the water jet-hollow steel system, died at Littleton, Col., Aug. 5. It is not generally known that Mr. Leyner also built the original shredded-wheat machines.

Benjamin Smith Lyman, geologist and mining engineer, died on Aug. 30 at Cheltenham, Pa. He made the first geological survey of Japan and his work there from 1873 to 1879 revealing and surveying valuable coal and mineral deposit won high honors from the Mikado.

Mr. Lyman was born in Northampton, Mass., Dec. 1, 1835, and was graduated from Harvard in 1855, and the Ecole des Mines, Paris, in 1861. He studied at the Royal Academy of Mines, Freiberg, in 1862.

After several years in private geologic work and as a mining engineer, he was employed by the Public Works Department of India surveying oil fields. From 1873 to 1879 he was chief geologist and mining engineer for the Japanese government. From 1887 to 1895 he was assistant geologist of the State of Pennsylvania. He was a Fellow of the American Association for the Advancement of Science and the American Institute of Mining Engineers and an honorary member of the Mining Institute of Japan.

SOCIETY MEETINGS ANNOUNCED

American Society of Mechanical Engineers will hold its 1920 annual meeting in Engineering Societies Building, New York City, on Dec. 7 to 10, inclusive. Sessions will be held on Appraisal and Valuation, and the Application of Engineering to Woodworking. The professional sections on Management, Power, Fuels, Machine Shop, Railroads, and Textiles will also conduct sessions; and a number of valuable papers will be presented at general sessions.

A memorial session for Dr. Brashear is planned as a fitting tribute to his life and work.

The Canadian Institute of Mining and Metallurgy will hold its second annual western meeting in Winnipeg, Man., on Oct. 25, 26 and 27. Headquarters of the meeting will be at the Hotel Fort Garry, Winnipeg. The local secretary, W. W. Berridge, may be addressed at 905 Union Trust Building, Winnipeg, Man.

Institution of Mining & Metallurgy, No. 1, Finsbury Circus, London, E. C. 2, will hold a special general meeting of the members and associates, at the rooms of the Geological Society, on Oct. 21, 1920, at 5:30 p.m., to act on a proposed revision of the conditions of admission and of membership dues in the institution.

The American Society of Civil Engineers, at its regular business meeting at 33 West 39th St., New York City, on Sept. 1, 1920, considered proposed amendments to the society's constitution, and the question whether the society shall join the F. A. E. S. as a charter member. A questionnaire on the latter is being mailed to members.

The Association of Iron and Steel Electrical Engineers will hold its Fourteenth Annual Convention at the Hotel Pennsylvania, New York City, Sept. 20 to 24. The program includes papers on transmission for industrial plants and underground transmission for Sept. 21 morning session, and the report of the electric furnace committee for Sept. 23 afternoon session.

A. I. M. E. Petroleum and Gas Meeting will convene in St. Louis, Mo., Sept. 21 and 22, in conjunction with the American Society for Testing Materials and the Petroleum Fuel Section of A. S. M. E. It is expected that this meeting will crystallize into a petroleum and gas section of the A. I. M. E. An invitation to attend has been sent to the American Association of Petroleum Geologists, and many of its members are expected to be present.

The Institute of Metals, 36 Victoria St., London, S. W. 1, will hold its fall meeting at Barrow-in-Furness, on Sept. 15 and 16.

THE MINING NEWS

LEADING EVENTS

Mining Situation in Mexico Rapidly Improving

August Exports of Copper, Lead and Zinc Show Increase—Demand for Iron Forces Price Up

The beginning of September finds operators in Mexico in a more optimistic mood than for the last four years. Although the price of silver has wobbled a bit, costs of production have been more favorable and the steady demand for lead has been more than encouraging. It is stated that 25 per cent of the railway cars of the Mexican lines are hauling silver and lead ores and that the exports of lead during August were only approached in quantity by those of copper. With the resumption of work on scores of old properties that had been closed down because of bandit activity, the production of lead promises to beat all records for many years. Prices in the local market beginning in September range from 70 to 75c., Mexican, per kilo.

A fresh impetus has been given to zinc, also, during the last sixty days and according to mining department figures thirty-one zinc properties were in full or partial operation on Sept. 1 in the states of Coahuila, Zacatecas, Nuevo Leon, Durango, Chihuahua, Jalisco, Sonora and Tamaulipas. In addition, a number of denouncements were made during August. Zinc mine owners suffered more in proportion than any other class during the revolution, as most of the properties were in the main track of the storm. Quotations run from 80 to 85c. Mexican per kilo. Most of the output is being exported.

Notwithstanding the closing down of the Democrata and some copper properties of minor importance, the total copper output of Mexico is increasing rapidly and the export exceeds that of any other metal, this in spite of unfavorable prices. For the first ten days in August nearly 600,000 kilos of copper were sent to the United States through the port of Naco alone. Heavy shipments also went through Agua-Prieta, Topolobampo and from La Paz, in Lower California. The Boleo Company (French) is expecting to get back to its normal production of 400 tons daily, of which fully 85 per cent goes to the United States. The recent arrangement with Governor Cantu, of Lower California, enables the Federal government here to inaugurate a number of schemes looking to an extensive exploitation and development of the mineral resources of that back-woods section of the republic.

There has been a big jump in the local price of iron because of the demand for rebuilding the sugar plants, railways, mines and innumerable industrial concerns which were put completely out of business. The big iron and steel plant at Monterrey is breaking all records in way of output and the Consolidated and National iron and steel plants of Mexico City are practically taking no new orders. A few small furnaces are being opened throughout the country, but Mexico is depending largely on the United States for its iron.

Operations in antimony are light. Two small shipments arrived late in August from China by the way of Manzanillo. Both China and Japan are trying to break into the Mexican market.

WEEKLY RÉSUMÉ

The new so-called Mississippi Valley experiment station of the U. S. Bureau of Mines is to be established at Rolla, Mo., where work will be done in co-operation with the State School of Mines. The War Minerals Relief Commissioners are reported to have disagreed over the amount to be awarded on the Hanna Minerals Co.'s claim for over half a million dollars.

Steady improvement is reported in the mining situation in Mexico, as reflected in metal exports for August. The Cia de Minerals y Metales has been practically absorbed by the Penoles Mining Co. In Utah, the state public utilities commission has refused to allow the transportation rates on ore and coal to be increased. Hearings have been conducted in the suit of the Lone Pine-Surprise Mining Co. against the Northport Mining & Smelting Co. over extra-lateral rights on the Last Chance Black Tail vein. From Canada it is reported that the Belcher Islands, in Hudson Bay, have been visited by prospectors in an aeroplane.

Belcher Islands, in Hudson Bay, Visited by Prospectors in Airplane

For the first time in the history of northern Ontario airplanes have been used to assist prospectors. Within the past two weeks a large seaplane has taken geologists, prospectors and supplies from the railway to the Belcher Islands in Hudson Bay, where large deposits of iron ores are known to exist. The first leg of the journey was from the railway to Moose Factory on James Bay, and was made in about an hour and a half. This trip usually took about a week by canoe. The second leg was from Moose Factory to the islands and took about three hours. Several trips have been made from the railway base to the bay. Another plane, with a motion-picture outfit, is also operating in the same district. The iron deposits of the Belcher Islands were discussed by E. S. Moore in the *Engineering and Mining Journal* of Aug. 28, pp. 396-400.

Utah Commission Refuses Higher Freight Rates on Coal and Ore

Smelters Announce Increased Charges To Meet Increase on Bullion to Atlantic Seaboard

Increased freight rates as affecting the transportation of coal and ores within the State of Utah have been refused by the state public utilities commission, to which the Utah chapter of the American Mining Congress recently appealed, with especial reference to rates on low-grade ores. The Utah commission takes the ground that, provided state rates are fair and reasonable and proper in themselves, the interstate body has no authority to order them changed.

At present, rates on coal in Utah constitute 20 to 25 per cent of the price to consumers, and in refusing the proposed increase the commission stabilizes the price of coal to that extent. It was feared that higher rates on low-grade ores would cause many mines to close down. The smelters have announced increased charges to meet the increase in freight rates on bullion to the Atlantic seaboard. One notice says:

"We are advised that, effective Aug. 26, there will be an increase of 33⅓ per cent in the freight rates on lead bullion and blister copper to the Atlantic seaboard. In accordance with the clause in our contracts covering this matter, we are obliged to make deductions from the metal quotations to cover this increased cost. Metals received at our plant after this date will not be shipped out in bullion until after the freight advance has become effective, therefore on all ores or concentrates received at our Midvale plant on and after Aug. 26 we will make the following additions to our contract deductions from metal prices: Lead, 0.25c. per pound; silver, 1c. per ounce; copper, 0.25c. per lb. As was true of the previous deductions due to increased freight rates, an attempt at a fair division of the burdens between silver and lead producers has been made. We realize fully the many difficulties confronting the mining industries, difficulties in a like manner faced by the smelting industry, but we believe that these added costs should be absorbed and reflected in the market price of metals resulting from our related industries. An advance in metal prices can reasonably be expected to follow; we think this necessary in order that sufficient production of metals to supply demand may be encouraged. The shipper can be assured that in case freight advances announced should be modified by the railroads our deductions will be changed."

Reopening of Old De Lamar Mine Under Way

Property, Formerly Worked by Hand Methods Only, Now Being Modernly Equipped

By Robert N. Bell

The original De Lamar mine, which formed the basis of Captain De Lamar's fortune, is situated on the west slope of the Owyhee Range, sixty miles south of Boise, Idaho, and twenty-six miles from Murphy, the nearest railway point. It is in the Carson mining district, better known locally as the Silver City district, Silver City being seven miles away. The district is known for its production in the past of bonanza gold-silver ores.

A year and a half ago, the property was taken over by certain oil operators of Fort Worth, Tex., and Tulsa, Okla, who have since reopened the mill tunnel and the long and badly caved No. 8 level, and relaid the track. They have also put in over a mile of air line in these two levels, installed two compressors, and are refitting the mill and putting the property in shape for an aggressive development campaign.

DE LAMAR MINE, MILL AND DUMP AT PORTAL OF TUNNEL, CARSON MINING DISTRICT, SOUTHERN IDAHO

Fully 80 per cent of the $14,000,000 worth of gold and silver produced by the De Lamar mine was derived from a series of closely parallel fissure veins that strike northwest and dip southwest at an angle of 45 deg. All of these are cut off and terminate at what is locally called the Iron dike, which is 10 to 30 ft. thick. This dike is decidedly crooked but has a general east and west strike and low southerly dip and the veins terminating on the under side show a decided drag or bend of 30 or 40 ft. to the west, closely parallel to the fault before diverging on their true northwest course.

This dike was definitely classified by Lindgren as a thick gouge-filled fault plane, its clay filling having practically the same composition as the enclosing soft ryolite wall rocks. It has a flat dip at the surface of about 30 deg., gradually steepening to 40 deg. at the deepest point penetrated on the 8th level. It cuts both the vein system and the ryolite at a sharp angle. In my opinion it is a fault of more recent date than the rich mineralization of the old ore courses and those more recently developed. On the south slope of De Lamar Mountain on the hanging wall side of the fault, several distinct ore-bearing fissures have since been discovered and developed to a limited extent.

The surface on the upper side of the fault is deeply covered with débris, which makes investigation there expensive and unsatisfactory. From the position of the ore found on the hanging wall side of the fault, a horizontal displacement of several hundred feet is indicated.

The latter years of operation were sweetened by the discovery of a series of narrow fissures, also under the fault and 500 ft. west of the original veins and parallel to them. These produced a total yield of fully $1,000,000 of $15 to $30 ore. This was known as the Summercamp group of veins. Three hundred feet west of this system and still under the fault another system of parallel fissures having a different type of gangue was partially developed, and for whose treatment the mill was not adapted on account of the extreme hardness of the gangue and sulphide ore. These newer westerly ore courses offer at present one of the most attractive chances for new ore development.

Due to the easy ground and soft gangue this property was always worked by old fashioned hand tool methods. An air compressor was never employed, even for development purposes, except temporarily for driving the 3,800-ft. crosscut tunnel from the Mill level on Jordan Creek through the hard basalt country rock.

Ten miles north of De Lamar the King, Berg and Rooster Comb mines, opening on steep pitching fissures in the granite formation at comparatively shallow depth, exhibit massive sulphide mixturs of lead, zinc and iron, carrying $20 to $30 in gold and considerable silver. Recent development on the 1,400 level of the Trade Dollar mine, five miles east of De Lamar, has exhibited some interesting specimens of lead-zinc sulphide associated with silver and gold. Also the big quartz-filled fissures of the Demming Mines, 10 miles further southwest, are conspicuously mineralized with arsenical and antimonial sulphides associated with lead, zinc and iron. These conditions of mineralization in the granite point strongly to the probable existence of similar primary ore conditions in the De Lamar.

At the west end of the De Lamar property, 100 to 300 ft. west of the Summercamp stopes, the Idaho vein exhibits an ore shoot over 200 ft. long, stoped 80 ft. deep, with a maximum width of 25 ft., from which a quarter of a million dollars worth of ore was extracted, running $25 per ton, principally in gold. It was so extremely hard, however, and involved so much handling to get it through the mountain to the mill tramway on the north side that it proved unprofitable and very expensive to mine with hand tools. During this development there was discovered between this vein and the Summercamp stopes what is now known as the New silver vein, a distinct fissure, 3 to 15 ft. wide and with a reversed dip filled with very hard, blue silicious breccia carrying silver sulphides and pyrite, averaging 12 to 120 oz. silver and only $1 to $2 gold per ton, forming a new type of gangue. This vein has been opened at several points on the surface and down to the No. 4 level but its most important development is at the No. 8 level through the Summercamp crosscut from the old vein system where it shows its best size and values. It has been drifted on for 80 ft. and the face is still 150 ft. short of the fault. This ground has also proven too hard to work with hand tools. It indicates a reserve of ore aggregating several hundred thousand dollars in value above the 8 level, 400 ft. vertically under the surface.

Another vein on the south side of the fault is developed in the No. 4 Summercamp crosscut tunnel and is known as the "M" vein. It has been stoped for a distance of 100 ft. and has produced a small tonnage of pay ore carrying $15 to $20 in gold. Two hundred feet east of this point, also on the south side of the fault, the Cash vein, a vertical fissure was discovered by panning and trenching the deep surface débris that covers the mountain slope. These shallow developments south of the fault are indicative that the fault is a post-mineral movement.

The production of the Trade Dollar Consolidated Mines on Florida Mountain, five miles east of the De Lamar, came from a series of nearly vertical fissures. The two productive veins outcropped in a thick sheet of altered ryolite, passed through this into basalt and then into the underlying granite. Its orebodies extended for more than 1,000 ft. along the strike and were equally rich in all three formations but faded in the granite at 1,700 ft. At the 1,400-ft. level a parallel vein, known as

the Empire, that was never developed because of too low grade, has recently been picked up by the Florida Mountain Mines Co., now operating the property, and is exhibiting a shoot of high-grade milling ore. This enterprise is also being financed by oil men from Tulsa and Fort Worth and has recently shipped some high-grade concentrates.

Large Russian Iron Ore Deposits Thought To Exist

A large body of magnetic iron ore is reported to have been indicated in the neighborhood of Kursk in the boundary sphere between Russian and Ukraine territory. The discovery is stated to have been made by earth-magnetic observations and calculations. These had been in process, systematically, for the last 24 years, and had been carried out by Dr. Ernst Leyst, professor of geology at Moscow University. Professor Leyst died in 1918, but his papers on the subject, including a number of charts with data on his calculations, etc., have been preserved and sent to Sweden, where they are being examined by Prof. Dr. Valfrid Petersson at the High School of Mines, and H. J. H. Nathorst. Both have come to the conclusion that Leyst's data can scarcely be explained otherwise than that they indicate very large iron ore reserves. Nathorst maintains that they clearly have to do with two parallel bodies of ore striking northwest-southeast, and about 60 kilometers apart.

Melting Down War Scrap Found Dangerous

In the metal scrap shipped to Gäfle, Sweden, from the Baltic provinces during the early part of summer for smelting a quantity of live projectiles were found. After an exhaustive sorting of the scrap by order of the state explosives inspector a couple of thousand live shells were taken out to sea and sunk at a depth of 27 m.

Similar discoveries of live shells in consignments of scrap have been reported at other points in Sweden, in particular Stockholm and Värtan. This scrap is brought over for melting down at various iron works and several explosions have occurred through live grenades being placed in the furnaces.

Iron Mountain Project Deferred

The newly formed Iron Mountain Furnace Co. of Iron Mountain, Mich., on the Menominee Range, has decided to postpone the construction of a pig iron furnace and chemical plant until next spring. Several Michigan lumber concerns are to have an interest in the enterprise, in order to insure a market for part of their product, a great deal of wood being used in charcoal and chemical plants of the sort. The furnace will handle about 400 tons daily.

The new State School of Mines at Miami, Okla., will open on Sept. 13, according to Lloyd B. Drake, president. Classes will be held in the mining exchange building until the school building is completed.

Germany's Industrial Situation As Related to Coal Supply

Iron Ore and Coal Insufficient To Keep Industries Going

From Our Vienna Correspondent

German industry faces a triple problem. It must find work for the industrial population, which is 43 per cent of the total. Germany has lost 70 to 75 per cent of its iron ore supply and expects a delivery of only 6 to 7½ million tons (metric) of ore. This suffices to feed only three-fifths of the former number of smelters making pig iron and steel, and at the best can make but 12 million tons of iron or three-fifths of the amount formerly produced. For this there must be imported at least 12 million tons of high-grade foreign ore. In view of the high cost of getting out ore, however, at present one may count on a production of only 7 to 7½ million tons of pig iron. To work up this amount Germany will need about 2.6 million tons of Lorraine-Luxemburg minette, 2.7 million tons of Swedish, and 1.4 million tons of Spanish ore. With these amounts one can barely satisfy the minimum requirements of 600,000 tons monthly, or 7.2 million tons annually in iron wares. If the iron industry itself must pay for the imported ores then one-eighth to one-sixth of the manufactured product must be exported. Only such surplus as may remain after minimum demand and cost of ore are satisfied can be applied as payment for other imports or for reparation (reconstruction). There will not be available the quantity of iron and steel necessary for an actual reconstruction of Germany—shipyards alone require deliveries of 45,000 tons monthly. Thus the German iron industry will become, in great part, a refining business.

In 1919 the German coal production, including Upper Silesia, amounted to 108 million tons or but 57 per cent of the supply of 1913. This decrease will not be counterbalanced by the slight increase in brown coal from 87 to 94 million tons, since the poor condition of the mines and the inefficient workmen have reduced the quality of the bituminous coal 12 to 15 per cent. The calorific value of the total coal production, bituminous and brown, of Germany, aside from the Saar district, amounted to but 57 per cent of the pre-war value, and would have been but 47 per cent without the supply from Upper Silesia At the same time the mine consumption has risen, as has the amount assigned to the use of the personnel due to the increased number of mine workers.

The 1920 coal production may be estimated at 126 million tons, if no labor disturbances occur. Of this quantity, 70 million tons will be available for family, industrial and agricultural purposes. From October, 1919, to March, 1920, the limited total needs for all kinds of fuel for industry were met by only 57 per cent. Any further increase in coal production will be possible only if it is possible to restore the mines to their former technical level, and if sufferable accommodations are available for the newly employed workers. There is still needed, in all, about 150,000 more workmen.

Minerales y Metales Absorbed by Penoles Company

Former Gets 180,000 Shares of New Stock in Return for Holdings—Certain Oil Properties Not Included

An important operation in mining circles in Mexico is the practical absorption of the Cia. de Minerales y Metales by the Penoles Mining Co. At a specially called meeting of the stockholders of the latter concern at which 90,721 shares out of 129,000 shares were represented it was unanimously voted to increase the capital stock to 9,000,000 pesos, represented by 300,000 shares. Of this increase 180 000 shares were turned over to the Minerales y Metales stockholders in exchange for practically all the assets of the latter concern, with the exception of some oil properties, which remain with the M. & M.

Included in the transfer are the mining properties and smelter at Villadama, mines at Guanacevi, mines at Santa Eulalia and Avalos, mines and smelter at Cerralvo, smelter No. 2 at Monterrey, a large railway equipment and extensive holdings in real estate in various parts of the Republic The transfer also includes a controlling interest in the Paloma & Cabrillas Mining Co., 81 per cent of the stock of the Agujita Coal Co., Coahuila, 83 per cent in the Cia. Metalurgica of Torreon, 40 per cent of the stock of the famous Naica silver mines, and 50 per cent of the La Parrena group of mines. All these properties are in the north, mostly in the states of Chihuahua, Durango, Zacatecas and Coahuila. There will probably be no change in the management and policy of the Penoles, and the active work of development and exploration will be continued as at present.

Would Shut Down Zinc District for Week's Festival

The remarkable proposal that an entire mining district shut down its mines for a week to attend a "fall festival" was made at the Picher meeting of the Tri-state branch of the American Zinc Institute recently. It was argued that the shut down would be a good thing for the operators and a favor to the miners. No action was taken.

The festival is to be held at Baxter Springs, Kan., and will include the annual drilling contest. It has been announced that Carthage limestone will not be used this year for the drillers to work upon, but a special rock constructed of cement and "nigger head" boulders, which is expected to require more skill on the part of the drillers, and more time.

Lone Pine-Surprise Suit Begun in Spokane

Extra-lateral Rights Involved in Action Brought Against Northport M. & S. Company

The suit of the Lone Pine-Surprise Mining Co., of Republic, Wash., which has been brought to recover extra-lateral rights from the Northport M. & S. Co., began at Spokane recently. The plaintiff company is owned by the Day interests, of Wallace, Idaho. The property involved includes one of the prominent gold veins of the Republic camp. It is the contention of the Lone Pine-Surprise company that its Black Tail vein trends about half the length of the Lone Pine claim, then makes a sharp bend to the east and passes through the east side line of the Lone Pine claim into the Last Chance claim, where it is being worked as the Last Chance vein No. 2. The Northport company maintains that the Black Tail vein continues northward and that its vein No. 2 is a cross vein trending approximately at right angles to the Black Tail vein.

John Gray, of Coeur d'Alene, is attorney for the Lone Pine-Surprise company and W. E. Colby, of San Francisco, is handling the case for the Last Chance company. During the first two days of the hearing, Fred J. Searles, Jr., of Nevada City, Cal., and J. C. Ralston, of Spokane, appeared for the Lone Pine-Surprise company and William A. Simpkins, geologist, of San Francisco, for the Last Chance company. E. F. Babb and John Welty, original locators of the Black Tail vein, appeared and testified as to the continuity of that vein.

Recent Production Reports

Kennecott Copper produced 10,656,000 lb. copper in July (including Braden's output), compared with 10,120,000 in June.

Oriental Consolidated, Unsan, Chosen, reports its August cleanup as $75,500. The severe drought that had affected production is reported to be over.

NEWS FROM WASHINGTON

By PAUL WOOTON
Special Correspondent

Rolla, Mo., Gets Mississippi Valley Experiment Station

Will Co-operate With Missouri School of Mines in Studying Lead and Zinc Problems

Rolla, Mo., has been selected as the site of the U. S. Bureau of Mines experiment station, which will specialize in lead and zinc problems. The business office of the station will be located in St. Louis. The station will be known as the Mississippi Valley Experiment Station and will be conducted under a co-operative agreement with the Missouri School of Mines and Metallurgy at Rolla.

The exact problems which will be taken up at the new station will not be determined until the views of the lead and zinc operators are ascertained. Bureau officials will meet the zinc and lead interests of the Mississippi Valley in a conference at St. Louis on Oct. 9.

The statutory appropriation of $25,000 will be available for the new station. In addition, the Board of Curators of the University of Missouri will furnish, free, all the necessary office space at Rolla. Employees of the station will be given free use of the University's laboratories and libraries. The curators have agreed to include in their next legislative budget a sum sufficient to construct a new building especially designed to meet the requirements of the work of the station.

New Map of Arizona Offered for Sale

The Bureau of Mines of the University of Arizona at Tucson, in conjunction with the U. S. Geological Survey, has completed and is offering for sale a new map of Arizona. Special attention has been paid to designating the location of the several mining districts in making the map.

Relief Commissioners Disagree on Hanna Minerals Claim

Company Seeks Over Half Million—Pomeroy Would Award $229,603; Other Members Less

The feature of the work of the War Minerals Relief Commission during the week ended Aug. 28 was the disagreement of the Commission on the pyrites claim of the Hanna Minerals Co. This concern submitted a claim for $502,191.37. In the opinion of Commissioners Shaforth and Moore, the company is entitled to $140,397.48. Commissioner Pomeroy, however, considers that the company should have $229,603.21.

The Commission recommended an award of $600 on the $5,728 chrome claim of Gallagher & Grasselly. In addition, revised recommendations were made in several cases. The claim of Moore & Robinson had been disallowed, but on reconsideration, an award of $445 was recommended. This is 13 per cent of the amount claimed. The award of P. H. Bray was increased by $128.88, bringing the total award to $1,532.91, or 15 per cent of the amount claimed. Holbrook & McGuire were awarded $5,905.18 in July on their chrome claim. This has been increased to $7,216.85, or 46 per cent of the amount claimed. In June, a manganese claim by J. J. Cummings & Son was disallowed. On revision, $1,234.80 was allowed. The award was 15 per cent of the amount claimed.

The Commission continues to expect that its work will have been completed by Jan. 1. From present progress, however, it is believed that practically all of the important work will have been done by Dec. 1.

That the Relief Commission is a target for bouquets as well as for brickbats is indicated by the following letter from a claimant:

"As president and general manager of our company, I wish to express to you my thanks for the courteous treatment extended to our attorney and myself upon the several occasions of our meeting with you.

"The outcome of our claim has given relief without which our company would have been in a deplorable condition indeed. The amount received was less than the claim, but the ruling which eliminated the return of capital expended upon purchase of property and purchase of leases left you no alternative but to eliminate the large amount included in our claim. The latter we hope may be taken up at no distant date with the Secretary of the Interior as per his recent expressed willingness to do so.

"You expedited the settlement of our claim with all the speed at your disposal, and your departments throughout were most courteous and satisfactory to us."

Another letter received by the Commission in the last few days says:

"I received the registered letter from you recommending our award. I thank you very much for the recommendation, and even though we were out more than that, I feel that it is a liberal sum—a helping hand in time of need. There will be no objections. I write this as a letter of thanks and acceptance.

"Now, unless there is a certain rule and we must wait the twenty days, please have it sent me as soon as you can. The quicker I get it the more good I can do. I want to show some knockers around here that their Uncle Sam does treat us right, if we help in a pinch."

The Old Hickory powder plant near Nashville, Tenn., is to be sold. It was constructed during the war and is considered to be thoroughly equipped.

Mining Industry Needs More Aid From Government in Research

Knowing that plans are now being made for work during the next fiscal year, industries concerned with research and other functions of the Federal Government are calling attention to their particular needs. One of the insistent demands being made by the mining industry is for additional economic work on metal mining subjects. It is pointed out that the more easily obtained orebodies are being rapidly depleted and that future supplies must come from the poorer grades of ore.

The mines of the country are becoming so large that ventilation is demanding much more attention and, judging from correspondence reaching the capital, there is a very generally held opinion that the Federal Government is in a position to render valuable assistance in that particular.

No data are available on the exact effect of gases on the human system. It is known that the gases from explosives are poisonous but the degrees of poisonousness are not thoroughly understood. It is not even known in what concentration these gases may exist before they become dangerous to human beings. There is a determined demand for non-metals investigations, as well as for an enlargement of the Government's work on petroleum.

Rice Deplores Tendency To Increase State Taxes on Mines

A tendency to increase the state taxes which must be paid by the metal-mining industry is deplored by George S. Rice, chief mining engineer of the U. S. Bureau of Mines, who has just returned from a visit to the principal mining centers of the West. With the rise of agriculture in the metal-mining regions, the influence of that industry at some points has become predominant. As a result, the tendency has been to increase more and more the taxes which must be borne by the mining industry. It is Mr. Rice's opinion that, sooner or later, metal mining must receive every encouragement and the taxes levied should be, broadly, an output tax rather than one on potential reserves. It was Mr. Rice's observation that the gold-mining industry is placing very general reliance upon the passage of the McFadden bill, which provides a premium of $10 per oz. for the producers of newly mined gold.

One of the principal objects of Mr. Rice's trip was to explain the properties of liquid oxygen as a mine explosive. He believes that the metal-mining industry can effect important economies, under certain conditions, by substituting this explosive for dynamite. He calls attention to the observations of Dr. C. L. Parsons, the secretary of the American Chemical Society, who recently looked carefully into the use in Germany of liquid oxygen as an explosive. It is Dr. Parsons' belief that this explosive can be used to great advantage in this country. In Germany, Dr. Parsons found that it is being used successfully on small operations as well as in large mines. The Germans have developed machines for the making of liquid oxygen which can be placed on motor trucks and operated by the truck's engine. Machines of this character are made as small as seven liters an hour capacity.

Mr. Rice is very much impressed with the slime filling operations being used at Butte to extinguish the fire in the Leonard mine. He points with some pride to the fact that these operations are under the immediate direction of H. J. Rahilly, a former Bureau of Mines man. He also calls attention to the fact that the Anaconda company is making very effective use of the cement gun in combatting fire, a procedure recommended to the company by the Bureau of Mines. Mr. Rice predicts the successful outcome of the present campaign against the fire. He says the public does not take into consideration the many great expenditures on the part of the mining industry, of which this is an example. More than 200 men are constantly employed in this fire-fighting activity and the results obtained are considered satisfactory.

NEWS BY MINING DISTRICTS

MEXICO

Commission on Taxation Expected to Report This Month

Mexico City — There has been a marked improvement in mining conditions throughout the Republic during the last fortnight. The almost complete disappearance of brigandage, the advance in silver and the prices of various metals and the normalizing of the labor situation in most of the mining districts has brought a wave of optimism, rare for the last six years.

The increased consumption and advance in price of tin has resulted in the reopening of several properties in Jalisco, San Luis Potosí and Aguascalientes and by the end of the year a considerable export is expected. At the present there is a very slight import from the United States for home consumption.

The commission appointed by President de la Huerta to make a careful study into the mining situation with a view to reducing taxation along certain lines and suggesting minor changes in the mining laws is expected to make a final report early in September. The disposition of the government appears to lean toward any reasonable measures that will facilitate an early rehabilitation of the mining industry throughout the country. Already hundreds of small properties have begun work under the July decree cancelling fines and making special condition for back payments of taxes.

Zacatecas

Unusual Activity Noticeable in Zacatecas Camp

Zacatecas—The old camp of Zacatecas is waking from its Rip Van Winkle sleep and is taking on real activity for the first time in years. It is likely that hydro-electric power will shortly be brought into camp from the falls of Juanacatlan, in Jalisco. Local mine owners have guaranteed sufficient consumption to warrant the transmission and installation and the Federal government is also assisting the project, which means a great deal not only to Zacatecas district but to many intervening camps.

The San Cristobal is in process of reorganization preparatory to remodeling its mill and unwatering and operating its properties, which have been idle for eight years.

The Puerto Rico properties have been optioned and an examination is going on.

The San Andreas Panuco district, a short distance north of Zacatecas, has been sold to foreign interests, who are unwatering and shipping high-grade ore to Torreon.

The Penafiel property, also in the Panuco district, has erected a new hoisting plant and is preparing to work the mine with a large force.

The Providencia and Buena Suerte both erected new hoists and are taking out ore.

San Manuel is shipping high-grade ore to the Minerales y Metales at Torreon.

The old Veta Grande is at work again, mining above water in a strong silver and lead vein and shipping to the A. S. and R. Smelter at Aguascalientes.

The Parroquia mine, belonging to the estate of the late Frederick Palmer, now managed by Captain Barrett, is making a good production. The estate has also acquired the Magistral group and other adjacent properties.

The San Roberto, of which C. A. Bentley is manager and half owner, is making heavy shipments of zinc ore and also sinking a main shaft an additional hundred feet.

A. F. Main, of the Cia. de Inversions de El Oro, has taken an option on Los Campos properties east of the San Rafael and intends to unwater and

examine. Los Campos properties have been idle for over 30 years. Mr. Main has also taken options for his company on the Victoria and San Bernabe, within the city limits.

La Fe is making preparations to move its 300-ton mill about 15 leagues from its present property and has under consideration the erection of a large mill of 2,000-ton daily capacity to exploit their new purchases in that section.

Labor conditions have become practically normal throughout the entire district, and plentiful. There have been no strikes or unrest for several months. Railway facilities continue to be the principal drawback to extensive work and some of the important companies are attempting to acquire rolling stock of their own.

Oaxaca

San Juan Property Down Temporarily

The San Juan, which recently resumed work, has temporarily closed down because of its head frame collapsing.

The Natavidad Company, in the Sierra Juarez, is actively engaged in repairing its plant and expects to be in full blast by the end of October.

Several smaller mine owners in the Tavichi district have returned since the advent of the new government has restored peace and expect to begin operations before the end of the year.

CHILE

Santiago—A powdered-coal-fired reverberatory has recently been installed by Cia. de Minas de Cobre de Gatico. This furnace has a bed 80 ft. long by 18 ft. wide and is operating successfully on Chilean coal. About 200 tons of cold charge, it is said, is being smelted per day. One ton of coal is consumed for five tons of charge smelted.

Ontario

Kirkland Lake To Deepen Main Shaft. —Financing the Davidson

Porcupine—The success of the arrangement for financing the Davidson Consolidated in England depends upon the willingness of the shareholders to option 50 per cent of the stock now in their hands to the new English interests. There has been some misapprehension as to the effect of this proposition, some shareholders objecting to the idea of a pool under which they would be unable to take advantage of market fluctuation. President G. C. Crean has issued the following explanation of the proposed transaction.

"The offer which was made by the English interests and which was communicated to the shareholders was as follows: 'The English syndicate would purchase 1,500,000 shares of treasury stock at a price of 75c. per share net to the company, amounting in all to $1,125,000, on condition that they could secure an option on 2,000,000 shares at present in the shareholders' hands; the treasury stock to be paid for on or before March 31, 1921, and the option on the shareholders' stock to remain in force until nine months after the first 500-ton unit of the mill is completed, but in no case to exceed a period of two years.'" President Crean points out that every shareholder will have to option 50 per cent of his holdings, leaving him free to dispose of the remaining 50 per cent should he care to do so. A refusal on the part of the shareholders to option their stock would mean that the offer of the English interests to put money into the company could not be accepted. The company is dependent on the securing of this money, and failing the same would have no other alternative than to assess the shareholders to provide for building the mill and carrying on development.

The **Clifton** will be extensively diamond-drilled in order to ascertain the extent of the continuation of orebodies opened up in the workings.

Kirkland Lake—The Kirkland Lake plans to sink the main shaft situated in the center of the property down to the 700-ft. level, where connections will be made with No. 1 shaft now down 919 ft., making the drift on the 700 ft. level the main haulage way for all ore broken between the two shafts. Raises will be made from the 700 ft. level and ore mined on the upper levels passed down to be trammed to the main shaft. The rock formation at 900 ft. depth is similar to that occurring on the upper levels. Total operating costs have been reduced to $6.21 per ton.

Sesekinika Lake The Height of Land Gold Mining Syndicate has been formed to operate two groups of claims, one block of eight being on an island in Sesekinika Lake and another group of eight claims lying at the corner of Benoit, Melba and Maisonville townships. A force of men has been engaged and camps are being constructed.

Wolfe Lake—The Lakeview has finished the building of camps and done considerable surface work. A mining plant is being brought in and sinking will be undertaken in the hope of striking a continuation of the Murray Mogridge vein.

Gowganda—At the Trethewey a shaft is being sunk on the "office vein" which faulted at a depth of 34 ft. but was picked up by crosscutting and high-grade ore taken out. The main shaft has been carried down to the 150-ft. level where a crosscut has encountered three new veins.

British Columbia

Nelson Remodeled and with more equipment, the California-Athabasca mill, situated on Give Out Creek above Nelson, has started operations after three trial runs. The plant will treat the ore of the California now being developed by the California mining company, of which John Cassin, of Spokane, is head.

Trail—Ore shipments received at the Consolidated smelter during the week ended Aug. 31 were as given in the following table:

Mine	Location	Gross Tons
Bluebell,	Riondel	156
Canada Copper,	Greenwood	11
Iron Mask,	Kamloops	83
Josie,	Rossland	296
Mandy, Le Fas,	Man.	372
McKay & Erickson,	Mayo, Y. T.	3
Monarch,	Field	37
North Star,	Kimberly	251
Sally,	Beaverdell	45
Providence,	Greenwood	72
Skylark,	Greenwood	16
Silver Standard,	New Hazelton.	41
Venus,	Carcross, Y. T.	20
Company mines		9,854
Total		11,257

The gold receipts at the Dominion of Canada assay office, Vancouver, B. C., from January 1 to July 31, 1920, total at $1,073,451.17. From April 1 to July 31, 1920, they aggregated $819,216.72, or about $200,000 per month for the four months of the fiscal year 1920-21.

SMELTER AT CIA DE MINAS DE COBRE DE GATICO, CHILE. NEW COAL-FIRED REVERBERATORY IN FOREGROUND

CALIFORNIA

Lack of Power Hampers Mother Lode Operations—Paxton Discusses Conditions at Engels Copper

Sutter Creek—Mining operations along the Mother Lode are seriously hampered by lack of power. All the companies have been compelled to reduce their power consumption materially. At the Central Eureka mill only twenty stamps of the forty are dropping, and that number for only sixteen hours out of the twenty-four. Other electrically driven machines about the mine have also been put out of commission in whole or in part, until such time as additional power can be obtained. Without early rains this condition may exist for some time, and at those mines which are barely meeting expenses or running on assessments the situation seems serious.

Despite adverse conditions the Central Eureka is continuing development on the 3,900 level. A crosscut west from the shaft located a good orebody and indications are that it has both permanency and value.

Volcano—Work on the debris dam half a mile from this old mining camp, in preparation for extensive hydraulic operations by the H. L. Crocker Co. of San Francisco, is nearing completion. Besides the Elephant deep gravel mine, the company has options on several pieces of property in the district. The dam is being constructed of stone and earth and will be about 30 ft. high and 429 ft. long. The debris will be carried to the dam by a flume about 700 ft. long. A spillway 125 ft. long north of the dam has been completed.

Nevada City—Howard M. Black and associates are engaged in opening up a small gravel mine near the Parsons ranch in the Banner section. A tunnel has been driven and upraises are being put in to intersect the true channel. A form of gravel has been encountered and it is hoped to find the pay channel believed to exist there. Several years ago about $10,000 was taken from a small deposit of gravel discovered on the property.

Marysville—P. F. Roosa, of Washington, D. C., was in Yuba County recently obtaining records of chrome production during the war. When these reports are filed in Washington, action will be taken on reimbursing producers for the chrome ore they were unable to sell after the armistice.

Englemine—General Manager Paxton, of the Engels copper mine, has made the following report concerning operations and developments at the mine: "The Engels copper mine today has enough high-grade ore in one solid block, actually proven, above the 6th level in the Superior mine, to more than pay for, at the present market price, all the company's stock now in the hands of the public. In spite of the labor shortage, which has been acute, we have added half a million tons to our proven ore reserves, since January 1, and should operating conditions not improve, we confidently expect to add another million tons to our blocked out reserves before the end of the year. Development of the Engels is proceeding most successfully. We have sunk a shaft 200 ft. to level No. 7, and are developing the ore in this large body of high grade. It is between No. 6 and No. 7, that we propose to block out the extra 1,000,000 tons before the close of 1920. We have drilled 400 ft. below level No. 7 and have cut considerable orebodies at this depth."

There are now twenty copper mines and prospects being operated along the Plumas copper belt, with the Engels and the Walker as chief shippers.

Portola—The Gruss copper mine now has its mill in operation and developments are being pushed with increased efforts. H. W. Turner has just completed his report on the results of his examinations of the Gruss property, in the interest of local financial men. It runs in part as follows: "In the report no mention is made of the reserves of oxidized gold ore, which were not examined. Attention was given only to the sulphide ores of the underground levels, which are suitable to be treated in the present oil-flotation concentration plant. More recently a new shaft was sunk to the depth of 400 ft. Connection was made with the old 90-ft. shaft (70 ft. down in the new shaft) and levels were run at 200 and 400 ft. In all of this lower ground the ore is largely unoxidized and consists of copper sulphides, bornite, chalcopyrite, and chalcocite with gold and silver. Practically all of this ore is found in the footwall rock, a kind of porphyry, technically called meta-andesite. The main vein is known as the Contact vein, since it lies at the contact of porphyry and clay slate, the porphyry forming the footwall and the clay slate the hanging wall. The strike of this main vein is northwesterly and the dip southwesterly. No attempt was made to sample the mine as a whole, but sample of 400 sacks of mill-feed ore taken from the raise on the 20-ft. level gave the following assay per ton of ore: Copper 2.96 per cent; gold 0.05 oz.; silver 2.85 oz. The superintendent is of the opinion that he can extract sufficient mill-feed of about this grade to keep the mill in continuous operation."

Golden Gate—The Golden Gate mine in Mono County, Cal., nine miles from the Nevada line, has recently been taken over under bond and lease, with the usual cash payment, by Wade Armstrong for the Diamond Peak Mining Co. This is the twelfth time since 1901 that the Golden Gate has been "turned," a substantial cash payment having been made and considerable development done in every case by the intending purchaser, but eleven deals failed of consummation and the property reverted to the owner, Joe Brown. Development to the extent of a mile of tunnels, drifts, crosscuts and shafts have been done on the mine, and it is equipped with a 20-stamp mill. The ore carries gold values and is free milling.

Grass Valley—With the exception of the Empire, all of the mines here will be able to keep virtually their full forces employed, despite the power restriction, providing the period of curtailment is not too long. The North Star and Idaho-Maryland will use the extra labor at work not requiring power. The Empire has laid off about 150 men, but may be able to recall some of them later on. Partial assurances are given that the 20 per cent restriction will not extend beyond one month.

NEVADA

Rochester Plants Expected to Resume Soon—United Comstock Active at Gold Hill

Tonopah—The Tonopah Extension's work of sinking its Victor shaft to the 1,860 level has been delayed for the past several weeks on account of a lack of experienced miners, but work has now been resumed. Crosscutting from the McCane shaft, in the 1,200 level, to the No. 2 shaft workings has been started. About 500 ft. of work will be required and then shaft sinking will be started.

Development for August in the West End totaled about 600 ft. with no new discoveries of importance reported. Crosscutting in the Tonopah "76" ground is being done at the rate of about 120 ft. per month with no change in formation as yet, which is favorable. Profits of the West End for July are announced as $48,803.17 from 4,039 tons of West End mine ore and 526 tons of Jim Butler Lease ore.

In the Tonopah Belmont good ore is being followed in a foot-wall drift under the Belmont vein on the 1,200 level. Normal development work was accomplished on levels from the 700 to the 1,200, with no new discoveries satisfactory results.

The Tonopah Mining Co. shipped 1,450 tons of ore to the Millers mill last week, and 109 ft. of development work was performed last week in the Silver Top and Mizpah ground, mostly in the latter.

Active work is being performed in the California Tonopah, in the southeastern portion of the district, and considerable ore of good grade has been developed above the 700 level in narrow veins. A winze is being sunk from the 700 level and crosscutting will be done from the 900 under favorable conditions.

Divide—Recent developments in the Divide district have stimulated interest in the entire Divide district. Official statements are to the effect that drifting and crosscutting on the 165 level are producing very satisfactory results. The vein has been proven to have a width of 17 ft., with an average value of $25 per ton in these latest workings. The shaft is now 1,000 ft. deep and after sinking an additional 25 ft. or more for sump purposes crosscutting south to the vein is to be begun. The work from this level is of utmost importance to the Tonopah Divide mine and to the Divide district as a whole. With no deterring factors the crosscut should

reach the projected position of the vein, which is practically vertical and was reached at about 150 ft. from the shaft on the upper levels, in about two months. Regular shipments of about 30 tons per day are being made to the MacNamara mill at Tonopah, the ore averaging about $25 per ton.

The Brougher Divide, to the west of the Tonopah Divide, is doing work on the 500 level, and occasional bunches of ore have been encountered.

The Gold Zone, on the southeast extension of the Divide vein, are crosscutting on their 700 level to cut the downward extension of the ore shoot as followed downward in a winze from the 500 level.

Pioneer—The Consolidated Mayflower Mines Co. are sampling the Mayflower and Starlight orebodies with the idea of estimating ore reserves and as a basis for future development.

Gold Hill—The new boarding and bunk houses of the United Comstock Mines Co. are nearly completed. A large force is employed and Gold Hill, which is close to Virginia City on the Comstock lode, is assuming some of the old-time activity. A new headframe has been built and a new compressor house is going up at the Belcher shaft. At the Jacket, the company will house the compressor and is crosscutting from the shaft to the headings for the haulage tunnel. At the Imperial, it is planned to resume shaft sinking. Crosscutting is continuing here.

The Virginia & Truckee R.R. Co. is figuring on cementing the Yellow Jacket tunnel through which the road passes between Gold Hill and Virginia City. If this is decided upon a cement gun will be used, this being the most practicable method.

Ione—Work has been resumed by the Nevada Quicksilver Mines Co. near Ione, 60 miles south of Austin. This property, which has been idle two years, is said to have a production record of 5,000 flasks and to have ore sufficient to keep the 50-ton furnace busy for some time.

Rochester—The Lahontan reservoir is filling and water will soon be available for generating electric power. It is expected that the mines and mills at Rochester and Packard will be able to resume operations soon.

Jean—Important disclosures of vanadium are reported from the Christmas Consolidated mine, nine miles southwest of Jean. It is said that offers have been made both for the ore and for the property.

Eureka—A new orebody has been opened up in the Eureka Holly mine from which shipments at the rate of 200 to 300 tons per month are being made except when there is a shortage of railroad cars.

The Ruby Hill Development Co. has over 800 tons of ore in bins and plans to ship regularly if cars are provided. Unwatering of the Locan shaft is progressing.

Mina—Demonstrating the continuity of the hanging-wall orebody from the 6th to the 7th level in the Simon Silver-Lead mine and indicating that the present ore reserves of approximately 500,000 tons will be almost doubled, the recent strike of high-grade milling ore in that mine in the raise driven from the lowest level has aroused much interest in the district. Engineers estimate that there has now been added more than 150 ft. of backs available for stoping operations. Ore has been followed in the raise for approximately 100 ft. Work is under way on the plans for the new 100-ton flotation mill. The millsite has been surveyed and mapped and engineers are now examining the footwall territory adjacent to the mine with a view to selecting the spot for the new working shaft.

ARIZONA

Arizona Bisbee Offering New Stock—Little Activity in Empire District

Bisbee—The Arizona Bisbee Copper Mining Co. is continuing drifting on its 400 and 600 levels. Both drifts are in a hard blue limestone with occasional stringers of iron oxide. It is expected that the faults toward which these drifts are advancing will soon be cut. About 20,000 additional shares of stock are being offered to the public at 50c. per share. The property is located about two and one-half miles west of the Whitetail Deer country in which several lessees are operating.

The Wolverine & Arizona has temporarily shut down underground operations. Repairs are being made to its hoisting equipment and compressor.

The sulphide ore recently struck by the Boras Leasing Co. is continuing. The width of the ore is about 12 ft. Development work has not gone sufficiently far to determine its length.

Empire District—There is now practically no work going on in the Empire district, which is located in a spur of the Santa Rita Mountains about half way between Benson and Tucson. The Hilton brothers are producing a small amount of lead-silver ore from their property. The Forty-nine mine was closed down four weeks ago. The Total Wreck is the largest mine of the district with a production of about $450,000. It has not been worked for over ten years.

Phoenix—It is claimed locally that the "Lost Dutchman" mine of the Superstition Mountains has been rediscovered. A property thus dubbed has been located around an old shaft that was found covered with mesquite timber, this spread with rock and dirt to obliterate all evidences of mining. At 100 ft. depth, it is claimed, a ledge has been found showing ore worth $400 a ton. The ore, it is said, is to be packed on burros to the Roosevelt road and shipped from Mesa station.

Globe—The El Paso Iron & Bridge Co. is completing construction of a large head frame at the upper shaft of the Arizona Commercial.

New Dominion is said to have financial backing in New York and is to sink its shaft to 1,200 ft. from the present 800-ft. level.

Douglas—The Hilltop mine in the Chiricahuas has developed a large tonnage of shipping ore, but operation is hampered by a labor shortage.

Superior—Magma Copper has further increased its large local holdings by purchasing the Easton and Smock group on the west and the Superior-Safford group on the east.

Jerome—Cores from drillings from the 1,300 level of the Verde Combination at 450 ft. of depth are showing ore well shot with chalcopyrite.

Encouraged by the Shea strike, the directors of the Pittsburgh-Jerome have instructed Charles Arata, the superintendent, to resume diamond drilling. A hole from the lower workings is to be completed and then there will be started a 2,400-ft. hole from the surface.

Miami—At a sheriff's sale, on a single bid of $300,000, the Cactus copper property has been bid in by the Susquehanna Trust Co., which holds a mortgage claim upon it for $390,000. The group of four patented and many unpatented claims lies in the Pinto Creek section, west of Miami. It has had much development, including churn drilling, and it is understood some commercial ore has been found. At one time the stock was quoted at $10.

Gila Bend—The Rowley property on the Gila River northwest of this point, has been closed, pending installation of needed pumping equipment.

NEW MEXICO

Freight Increase Stops Manganese Ore Shipments from Stevens Property

Silver City—Shipments of low-grade manganiferous ores from the Stevens property have been stopped, the increase in freight, which amounted to $2.20 per ton, having absorbed all the profit. An effort will be made to have the old rates re-established. M. W. Porterfield, who has been in charge of operations, is in Chicago in an effort to get relief. Shipments had been running about 350 tons daily to the U. S. Steel Corp. in the Pittsburgh district.

The Silver Spot mine shipped a car of good-grade manganese ore on July 28 making 7 cars shipped in 60 days.

Work of installing the new cyanide mill at the Cora Miller mine in the Mangas Valley is progressing satisfactorily. Milling operations are expected to begin about Oct. 1. Two 60-ton redwood tanks, a number of smaller tanks, engine beds, buildings and residences are completed.

Torbernite ore is reported to have been found in the Lucky Bill mine of the Black Hawk Mines Co. at Bayard Station in the Central district.

Pinos Altos—The Mexarco Mining Co. have leased their Langston property to the Hecla Mining Co. a new organization, not to be confused with a company of the same name owning property in the Lordsburg district. Work will start at once.

Kingston—The Lady Franklin group is being operated by Minor C. Keith and associates of New York, under the direction of W. H. Paul. About 20 men are on development work. Some shipments of silver ore have been made recently to El Paso smelter.

Empire Zinc is working a large force on development work under C. T. Brown. New machinery has been installed recently.

On North Percha Creek, the Moffett Consolidated Mines are continuing their development with encouraging results. An air compressor, drills and 60-hp. gas engine are being installed. The same company owns a group of copper claims 15 miles north of Elephant Butte dam, where work will be started soon. A mill is planned.

Chloride—Silver Mountain Metals Co. claims to have shipped $10,000 silver ore to El Paso smelter recently. Old concentrator on the property has been repaired and will be put in operation soon. John H. McCutcheon is manager.

The old Colossal has been equipped with new machinery by Albuquerque parties who are figuring on a mill at an early date. Both the Midnight and the U. S. Treasury properties are working.

Lordsburg—The Ruby Silver Mining Co. has been reorganized with an authorized capital stock of 500,000 shares of a par value of $1. L. P. McHalffey, a local attorney, is president. The property has been paid for and work will again be pushed under the new management. Development to date consists of three shafts, 220, 150 and 40 ft. deep respectively, all showing some ore.

The main shaft of the C. & A. Mining Co.'s 85 mine is down 960 ft. It is locally reported that good ore has been cut with the diamond drill at 1,700 ft. from the surface. K. I. Mohler is superintendent.

The Octo Mining Co. is working 60 men and pushing the exploration cross cut, which at 70 ft. from the shaft has encountered ore and water. The main shaft is 325 ft. deep. New residence buildings are being erected.

COLORADO

Test Run To Be Made at Pony Express Mine at Ouray—Senorita Mine Sold

Ouray—The Eurades Mining Co. has built a large food cellar and is now doubling the capacity of the bunk house; they plan to carry on the active development work now in progress, throughout the winter, drifting and raising, and expect to employ forty men. Several carloads of food are on the way.

The Senorita mine, north of Ouray, has recently been sold to outside people represented here by Mr. Myers. A contract will be let for continuation of the lower tunnel to develop the main orebody. Meanwhile, the dump has been sampled and tests of a new process of treatment have been made in Denver; these tests are said to have yielded excellent results and it is Mr. Myers' intention to erect a treatment plant on the railroad below the mine in the near future. The new process involves roasting with reagents and cyaniding.

A test run is to be made on the Pony Express mine by C. R. Wilfley for Delta people. A hundred tons of ore is to be mined by hand, hauled to Ouray by wagon, and run through the Gold Crown flotation mill. This, while expensive on a small scale, will determine thoroughly the average value of the large low-grade orebody developed in the Pony Express mine, and at the same time give a fairly good idea of the possibility of treating the ore by flotation. If the test shows good results, a mine plant will be installed and milling undertaken at the Gold Crown mill. A mill will be erected at the mine if this venture proves successful. For the second stage, regular milling at the Gold Crown mill, it is expected that bids will be asked for hauling the ore by auto truck.

The Hidden Treasure mine continues to ship lead-silver ore to town for shipment to the smelters. Considerable ore was accumulated at the mine last winter while the roads were impassable and it was announced that this ore would be shipped rapidly when the roads opened, while plans were also made for erecting a small mill at the mine. Much of the shipping ore remains at the mine and nothing has been done in the way of a mill.

Davis & Hall, working a portion of the Bi-metallist, have opened up some excellent high-grade gold ore. This property yielded $50,000 very quickly and cheaply a few years ago, in high grade gold ore, and has excellent possibilities.

The new freight rates will work a great hardship on this district—in fact, some mines are already seriously considering a shut-down.

UTAH

Ophir Tunnel Face in Mineralized Ground—Silver King Coalition in Promising New Ground

Ophir—The tunnel of the Ophir Silver Mines is in 700 ft. This is being driven to cut at depth the ore-bearing limestone of the district. Silver mineralization is beginning to show as the work approaches the contact. Considerable water is coming in.

Park City—At the Silver King Coalition, exploration in new ground promises a productivity equal to that of the older portions of the property. Developments between the 1,300 and 1,500 levels would appear to indicate that the new shipping ore opened in the O'Brien fissure in the "Blood" drift on the 1,100 level is persistent. The showing in the "quartz" drift on the same level is equally promising, it is said. Ore has also been opened near the Brown raise between the 1,200 and 1,300 levels, which appears to be a continuation of the old "Copper stope" orebody, productive of a large tonnage of specially high grade copper-silver ore in early days.

Eureka—Shipments from the Tintic district for the week ended Aug. 28 amounted to 141 cars as compared with 121 cars the week preceding.

Silver City—The Tintic Milling is preparing to add to its present source of water, which is supplied by the Chief, by taking water from the Ruby Hill shaft of the Tintic drain tunnel also. The new system of sluicing instead of tramming the tailings on to the flat below the plant requires more water than formerly. About 200 gal. per minute is being used.

Alta—The Columbus-Rexall between June 4 and Aug. 31 shipped 44 cars of ore, amounting to about 1,500 tons dry weight. Present shipments amount to three cars a week, and could be considerably increased if more labor were available. The company reports two promising oreshoots opened recently, the development of which, however, is being held back by labor shortage.

MONTANA

Anaconda Adds Lead Stack at Great Falls Plant

Butte—The addition of a lead stack is one of the latest improvements at the Boston & Montana smelting works at Great Falls, one of the old copper reduction works' stacks being remodeled to effect a saving of the lead content had from the residue from the electrolytic zinc plant. The recovery of the lead will be confined to chiefly the company's own ores and will add considerable to the recovery of values from zinc ores, which are running fairly well up in lead, particularly the ores from the Nettie mine, in the western part of the Butte district and from the Hibernia of the Davis-Daly. This will be the first saving of lead in the Montana plants of the Anaconda.

The No. 2 shaft at the Black Rock mine is now well below the 2,300-ft. level and the sump will be completed within a short time. From the 2,300 level a crosscut will be driven to a point under the No. 3 and a raise then driven to connect with the latter, the principal working shaft of the mine. This will bring the No. 3 shaft to the 2,300-ft. level without any interference with the hoisting of ore or the maintenance of tonnage.

Ore is mined by East Butte Copper on practically all levels of the Pittsmont mine at present, with new ore being developed on the 1,800-ft. level in a satisfactory manner. It is expected to push development on this level within a short time, a heavy flow of water from the face of an ore-bearing vein opened some time ago interfering with work to such an extent that it was considered more economical to delay operations and permit it to drain itself. East Butte's Pittsmont smelter for the first seven months of the present year has turned out 10,446,700 lb. of copper as compared with 10,359,260 lb. in the corresponding period in 1919, with production costs reported to be a shade under those for the previous year, when they averaged 16.69c. per pound of metal.

Working force at North Butte's Sarsfield property on the east side is being increased and the showing bad on the 900-ft. level is said to warrant the continuation of development. Cross cut-

ting continues on the 3,600-ft. level of the Granite Mountain mine with the Edith May vein the objective. Completion of repairs to the Speculator shaft has enabled a resumption of development work on the 700-ft. level together with mining operations. The showing of the Adirondack vein on the 2,200-ft. level is proving somewhat of a disappointment, but there appears to be promise of some improvement with drifting. The North Croesus vein is showing an improvement with depth, a wider and higher grade orebody being found on the 2,800-ft. level as compared with the 2,200. Owing to the poor supply of experienced miners and the unsatisfactory condition of the market, work at the Bertha mine has been temporarily suspended.

Jardine District—Fifty stamps are dropping in the Jardine mill, treating daily about 250 tons of sulphide gold ore. This is the largest operating gold mill at the present time in Montana. Jardine is six miles from the north gateway of the Yellowstone National Park.

Cooke City—A fleet of 21 trucks is hauling ore from the Republic company's properties to Gardiner, Mont., where it is loaded on railway cars.

Neihart—An electric hoist has been ordered by the Flohart company. A good ore showing is reported.

Lump Gulch—Ore opened some time ago on the fifth level of the Free Coinage, showing high silver content, is reported to be widening both east and west with drifting operations.

WASHINGTON

Orient—A large oil engine is being installed at the Galena Hill mine to replace the steam equipment now used. A 5-drill compressor is also being added. A raise is being driven at 80 deg. from the 300 level to the surface and when completed will be used as a new central shaft for deeper development work.

ARKANSAS

Big Hurricane Near Pindall To Increase Output—Development To Be Resumed at Lonnie Boy

Rush—The McCargar Mining Co., under the management of D. J. McCargar, has started another opening on a carbonate outcrop on its lease at Rush. The new work is close to the White Eagle line.

Pindall—The Big Hurricane zinc mine near Pindall has been operating steadily this year. J. C. Shepard, the owner, is in charge. Tonnage has been curtailed owing to the low price of ore, but preparations are under way to run at full capacity.

Flippin—Nishwitz Bros. are pushing development work on their property on Bull Mountain, six miles northeast of Flippin, where there is a good face of jack in an open cut. Several thousand tons of mill ore are on the dump. A mill will not be built, however, until development has progressed further.

Rush — Development work at the Lonnie Boy will be resumed at once.

TENNESSEE

Tennessee Copper Experimenting With Underground Mechanical Loaders

Isabella — The Ducktown Sulphur Copper & Iron Co. has almost completed the first 300-ton unit of its new flotation plant at the Mary mine, at which differential flotation is to be used. It is anticipated that, if the grinding mills that have been ordered are received in time, the test run will be made during the autumn.

Copper Hill—The Tennessee Copper & Chemical Corp. has purchased two mechanical loaders for experimental purposes to be used in the Burra Burra mine. One of them, a Myers-Whaley shovel, has already been received and is now at work. The only difficulty noted so far has been that of getting a stope large enough to keep the shovel constantly employed. The other machine is a type O, full-circle-swing Thew shovel with a ¾-cu.yd. dipper. This has not been delivered yet. The existing shortage of labor is responsible for the company taking this step.

JOPLIN-MIAMI DISTRICT

Oklahoma-Missouri-Kansas

Laclede Lead & Zinc Co. Opens Another Lead Cave

Tar River, Okla.—At the Laclede Lead & Zinc Co.'s property north of Tar River, Okla, one of the largest and richest watercourse lead caves ever discovered in the Oklahoma field is now being worked. With only twenty-nine men the company turned out 100 tons of lead during the last week, virtually all of it coming from this cave. From a spectacular standpoint, the cave is not as beautiful as some others that have been discovered in the Oklahoma field, as the ore is quite generally covered with a sediment. But investigation reveals that the sides and roof are almost solid lead ore. The cavity is approximately 40 ft. wide, 70 ft. long, 8 or 10 ft. high.

MINNESOTA

Mesabi Range

Federal Consolidated Resumes at Ajax —Winston-Dear Stops 300-Ton Shovel Until Frost

Hibbing—Clement K. Quinn and associates have taken an option on five forties near Nashwauk and adjoining the Shada No. 2 now controlled by them. The property is understood to be a wash proposition owned by the Landon-Warren interests, of Minneapolis, and exploration is now going forward.

The 300-ton shovel operated by Winston-Dear in the Boeing pit of the Mesaba Cliffs Iron Co. has been forced to cease operations because of a pocket of very treacherous muskeg encountered. The shovel will remain in position and resume operation as soon as the frost has made firm footing.

Chisholm—The Billings mine of the Tod-Stambaugh Co. has reduced forces until but ten gangs are now at work. A small shovel is at work loading out last winter's stockpile.

Biwabik—The Federal Consolidated Mining Co. has started to resume operations at the Ajax mine. The Ajax has shipped 207,000 tons of high-grade non-bessemer ore during its career but has been idle for a number of years. A shipment of 25,000 tons is expected during the present season.

Cuyuna Range

Coates & Tweed Purchase Ida Mae Stockpile—Northland Mine Shut Down

Riverton—John A. Savage & Co. has resumed hydraulic stripping of overburden at its Sagamore mine, a manganiferous iron ore property. Following early experiments with the hydraulic giant on starting stripping operations last year this method was abandoned and a contract let for stripping by dragline shovels. A dragline shovel is now being used in loading ore. The overburden includes a heavy covering of muskeg. Plans are being made for erecting a drying plant to treat all ore from the pit.

Ironton—The Cuyuna-Duluth mine, operated by the American Manganese Manufacturing Co., is shipping 8 to 10 cars per day. Slicing above the 280-ft. level is rapidly being completed and drifting and raising on the new 340-ft. level is well advanced. The pump station has been completed and a triplex electric-driven pump installed. Operators are planning to use electric haulage on the new levels. At the instigation of the county mine inspector, G. A. Swanson, the Bonnie Belle mine, operating on the next forty west, is sinking a winze from its 193-ft. level, from which connection will be made to the Cuyuna-Duluth 280-ft. level, improving air and safety conditions.

It is reported that Coates & Tweed of Duluth have purchased the stockpile of the Cuyuna-Minneapolis Iron Co., at its Ida Mae mine and will ship same at once. There is in stock about 18,000 tons of 15-per cent grade manganiferous iron ore, low in moisture and silica. The property is not operating, having pulled its pumps July 17 after small scale operation last year through the past year.

Cuyuna—The Northern Minnesota Ore Co. has suspended operation at the Northland mine, having bulkheaded the drifts and pulled the pumps. The property, opened up for managanese during the war, has not been operated since last fall. The company has recently purchased a high-grade manganese property near Cushman, Ark., from Walter H. Denison and T. F. Snell, and will devote its efforts for the present to continuing hand mining and exploration with a view to possible larger scale operation of the new property. A. K. Knickerbocker, formerly superintendent at the Northland mine, will have charge of the operation of the Arkansas property.

Nearly all operators on the Cuyuna Range report a small shortage of labor, and several of the open pits are seriously handicapped in keeping up their production average.

THE MARKET REPORT

Daily Prices of Metals in New York

Sept	Copper	Tin		Lead		Zinc
	Electrolytic	99 Per Cent	Straits	N. Y.	St. L.	St. L.
2	18.00@18.35	42.50	45.25@45.50	8.50	8.50@9.00	7.75@7.80
3	18.00@18.35	42.50	45.00@45.50	8.75	8.50@9.00	7.75@7.80
4	18.00@18.35	42.50	45.00@45.50	8.90	8.50@9.00	7.75@7.80
6						
7	18.00@18.35	42.25	45.00@45.25	8.90	8.50@9.00	7.75
8	18.00@18.35	42.00	44.75@45.00	8.90	8.50@9.00	7.75

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point. All prices are in cents per pound.

Copper is commonly sold on terms "delivered," which means that the seller pays the freight from refinery to buyer's destination. The delivery cost varies, and it would be confusing to figure net prices on individual transactions. Consequently, an average deduction of 0.15c. is made from the "delivered" price, to arrive at the New York price. When copper is sold f.o.b. or f.a.s. New York, of course no deduction is made.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Sept.	Copper			Tin		Lead		Zinc	
	Standard		Electro-lytic						
	Spot	3 M		Spot	3 M	Spot	3 M	Spot	3 M
2	95⅛	96⅜	111	269	276	36½	36⅝	38½	40
3	95¾	97	111	267	274½	36½	36⅜	37¾	39½
4	....	....	....	....	....	....	....	....	....
6	95¼	96¼	111	267	272½	36¼	36¼	38¼	39¾
7	95	96	111	264½	270½	35⅝	35½	38⅛	39¾
8	96¼	97¼	111	266	272¾	36⅛	36	38¾	40⅛

The above table gives the closing quotations on the London Metal Exchange. All prices are in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Sept.	Sterling Exchange	Silver			Sept.	Sterling Exchange	Silver		
		New York, Domestic Origin	New York, Foreign Origin	London			New York, Domestic Origin	New York, Foreign Origin	London
2	356	99½	93½	58½	6	....	....	....	60⅜
3	355	99½	94	59	7	354	99½	94½	59½
4	355	99½	94⅞	60⅛	8	353½	99½	94	59

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States. This quotation is retroactive to May 13.

Metal Markets

New York, Sept. 8, 1920

Unusual quietness is the dominating characteristic of the metal market, all the metals apparently feeling the effect of a holiday week. Price changes from the preceding week have been small, and the unimproved London market is still depressing the metal market here. If any improvement is to be noted it was indicated by a slightly improved buying by the copper trade.

In general the buyers are now having their own way, and producers are unable to pass on the increased cost due to recent freight advances.

Just when conditions will improve is hard to say. By some, buying is expected to pick up considerably this month, whereas others feel that no great improvement can be expected until after the November election.

Copper

Sales during the week were recorded at bargain prices, although not in great volume. A somewhat greater interest was shown by the European market, some American copper being bought by Germany. Large tonnages would be hard to obtain under the 18¾@19c. delivered price of the producers, although some shading of prices is likely. Sales were made at 18@18½c. delivered. It is reported that 5,000 to 6,000 tons of copper shell bands are available in London and were offered here at 18½c. delivered. The sale of such metal in this market would be a depressive influence, which may retard the expected buying movement. The statistical position has not been seriously altered, although August sales were among the smallest of the year.

Lead

Practically all of the lead sold last week, except at our average price, was marketed by the A. S. & R at their contract price of 9c., New York, so that our quoted price, which is based on sales, approaches that figure. The market was exceedingly quiet, and lead could be obtained all week at 8c., New York. In fact, it was slightly weaker than last week. Importations of Tarnowitz and other grades of lead are being made from Germany. Despite the known shortage of supplies in Germany, the country is evidently pursuing the same tactics shown in the silver market several months ago, when large quantities of silver were unloaded upon the market at a time when there was a scarcity of metal.

Producers expect increased production by the gradual return of the miners from the farms, where they gravitated this summer, to the mines. Forward delivery is purely nominal.

Zinc

Prices have shown a slight drop in a dull market and the question of importation of cheaper foreign metal is still an important factor in the situation. The effect of the reduction in price in the American market to meet the lower London prices was to decrease importation. It was reported that only 25 tons of zinc has been imported. An inquiry for 500 tons from France developed during the week, but it was felt that this was merely to "try out" the market, for zinc can be obtained more reasonably in Europe than here.

Tin

The market is "deadly dull," as one consumer has put it. Some buying was recorded at the end of last week, but the decline in London stopped it. Quotations may even vary greatly throughout a single business day, and all out of proportion to the amount of business done. Spot Banca tin has been fairly well cleaned up, and producers of electrolytic report business somewhat better on that account, at fractional discounts over Straits.

Straits tin for future delivery: Sept. 2d, 45.50@46.00c.; 3d, 45.50@46.00c.; 4th, 45.50@46.00c.; 7th, 45.25@45.50c.; 8th, 45.00@45.25c.

Arrivals of tin in long tons: total for August, 5,075; Sept. 1st, London, 25; 2d, London, 25.

Silver

The London market on Sept. 8 declined to 59d., brought about by offerings from the Continent, with limited buying. Cables report sales at a concession under the fixed price of 59d. later in the day. Moderate buying for China, via San Francisco, continues at a small premium over London equivalent. The Mexican government, according to latest advices, continues to purchase silver bullion for coinage at the rate of a million to one and one-half million oz. per month.

Mexican Dollars—Sept. 2d, 71; 3d, 71⅞; 4th, 71⅞; 7th, 71⅞; 8th, 71⅞.

Gold

Gold in London on Sept. 2d, 115s. 1d.; 3d, 115s. 3d.; 6th, 115s. 6d.; 7th, 115s. 6d.; 8th, 115s. 11d.

Foreign Exchange

Foreign money in general declined slightly during the week. Yesterday francs were 6.79c.; lire, 4.29c.; and marks 1.93c. Argentine exchange has depreciated to 85.75c. New York funds in Montreal, 10⅞ per cent discount. Indian exchange has improved during the week, closing yesterday at 33.25c. per rupee. This should be a favorable influence on silver.

Other Metals

Aluminum—Ingot, 99 per cent and purer, 35.1c.; 98@99 per cent, 34.9c. Virgin metal still obtainable in open market at about 32.5c. for 98@99 grade.

Antimony—Market continues weak. Spot, 7c. per lb.; Cookson's "C" grade, 14@15c. Chinese and Japanese brands, 7c. W. C. C. brand, 9@9½c. [1]Chinese needle antimony, lump, firm at 8@9c. per lb. Standard powdered needle antimony (200 mesh), 10@12c. per lb.

Bismuth—$2.70 per lb., 500-lb. lots, and $2.72 per lb., 100-lb. lots. Market quiet.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady.

Cobalt—Metal, $3 per lb.; black oxide, $2 per lb.

Iridium—Nominal, $350@$400 per oz. Heavy demand, but small supplies.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb. for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]**Molybdenum Metal** in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.; Monel metal, shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$100@$110 per oz.

Platinum—Firm at $115@$120 per oz.; $105 per oz. in 100 oz. lots.

Quicksilver—Market quiet; $75 per 75-lb. flask. San Francisco wires $75. Barely steady.

Ruthenium—$200@$220 per troy oz.

[1]**Selenium**, black powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]**Thallium Metal**—Ingot, 99 per cent pure, $20 per lb.

[1]**Tungsten Metal**—$35@$60 per kilogram, according to purity and gage.

Metallic Ores

Bauxite—About 52 per cent alumina content, less than 2 per cent iron oxide, up to 20 per cent silica and artificially dried to contain not more than 4 per cent free moisture, $10 per gross ton at mine; 54 per cent alumina and about 15 per cent silica, $11; averaging 57 per cent alumina, 8 to 12 per cent silica, less than 3 per cent iron oxide, $13 on basis of 8 per cent free moisture. Ores of very low silica content suitable for the manufacture of aluminum oxide and hydrate of alumina command a fancy price.

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a minimum of 6 per cent silica, 70@80c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 70@75c. California production has fallen off, even since May, owing to the low price, which does not permit operation of mines that were worked in 1918 when prices were $1.50 a unit for 50 per cent. The market is strengthening, and should prices rise some abandoned properties will be reopened. There are considerable tonnages of 40 per cent ore at different points in California, which are being held for prices of 50@60c. a unit, f.o.b. cars, California.

Iron Ores—Lake Superior ores, per ton, delivered at Lower Lake ports: Old Range bessemer, $7.45; Old Range non-bessemer, $6.70; Mesabi bessemer, $7.20; Mesabi non-bessemer, $6.55. Congestion at Lake Erie ports due to car shortage has resulted in decreased tonnage. The ore movement is better than at any previous time this season.

Manganese Ore—65@75c. per unit, seaport; chemical ore (MnO_2) $70@$90 per gross ton, lump; $80@$100 per net ton, powdered.

Molybdenum ore—85 per cent MoS_2, 75@80c. per lb. of contained sulphide, New York.

[1]**Tantalum Ore**, guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots, against recent price of 65@70c.

[2]**Titanium Ores**—Ilmenite, 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $7 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $6@$7, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Vanadium Ore—$1.25 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[2]**Zircon**—Washed, iron free, 5c. per lb.

[2]**Zirkite**—$90@$100 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

Zinc and Lead Ore Markets

Joplin, Mo., Sept. 4.—Zinc blende, per ton, high, $52.90; basis 60 per cent zinc, premium, $48.50@$50; Prime Western, $47.50@$45; fines and slimes, $45@$42.50; calamine, basis 40 per cent zinc, $36. Average settling prices: Blende, $47@$31; calamine, $38.11; all zinc ores, $47.

Lead, high, $111.35; basis 60 per cent lead, $112.50@$110; average settling prices, all grades of lead, $104.90.

Shipments for the week: Blende, 12,040; calamine, 420; lead, 2,050 tons. Value, all ores the week, $800,580.

Platteville, Wis., Sept. 4—Blende, basis 60 per cent zinc, $52 to $52.50 base for high grade. Lead ore, basis 80 per cent lead, $110. Shipments for the week: Blende, 1,116; calamine, 30; lead, 21; sulphur ore, 32 tons. Shipments for the year: Blende, 48,259; calamine, 2,360; lead, 3,921; sulphur ore, 1,241 tons. Shipped during the week to separating plants, 1,910 tons blende.

Non-Metallic Minerals

Asbestos—Crude, No. 1, $2,400@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax. Freight rate from mines to Sherbrooke, Quebec, over Quebec Central R.R., 20c. per cwt.; from Sherbrooke to New York, 27½c., carload lots; freight to New York for crude No. 1, f.o.b. Thetford mines, $8.45 per ton, carload lots.

Barytes—Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $24@$30 in bags, carload lots; (off-color) $22@$26 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $12 per gross ton; ground (white) $23@$25; ground (off color) $16@$19 per net ton, f.o.b. Cartersville, Ga. Crude, 88 to 94 per cent, $23; ground (white) $40.50; ground (off color) $27 per net ton, less than carload lots, f.o.b. New York. Crude, not less than 98 per cent, $11@$11.25 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis.

Chalk—Domestic, extra light, 5@6c. per lb.; light, 4½@5½c.; heavy, 4@5c; English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin)—Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground,

$15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$18 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $25@$30 car lots, f.o.b. Baltimore; ground, $17@$20, f.o.b. North Carolina points; $17@$20 per ton, No. 1 ground, f.o.b. New York State; $21@$23 per ton, ground, f.o.b. Maine.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Graphite—Crucible flake, 85 per cent carbon content, 8c. per lb.; 88 per cent, 9½c.; 90 per cent, 10½c., all f.o.b. New York. Crucible grades of Alabama graphite sell as follows, f.o.b. Ashland, Ala.: 80 per cent, 5c.; 90 per cent, 10c. Lubricating grades in increasing demand, with price ranging from 11c. for the 85 per cent guaranteed grade in car lots to 30 and 40c. for higher grades. Mexican, amorphous, $45@$55 per short ton; Korean, 3¼c. per lb.; Madagascar, 8c.; Ceylon, 4¾@15½c.

Gypsum—Raw crushed rock, $3.50@$4 per ton; raw ground fine, $4@$4.50; calcined stucco, $9, all f.o.b. works. Containers extra. The last price quoted for plaster of paris in carload lots was $4.25 per 250-lb. bbl., f.o.b. mill, alongside dock, New York.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $75@$85 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—India block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20@$1.40; No. 4, $2@$3; No. 3, $4.25@$5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $4; No. 3, $5.75; No. 2, $7; No. 1, $9; A1, $14; extra large, $25, all f.o.b. New York; ground, $100@$150 per ton, Philadelphia. Domestic, uncut f.o.b. Franklin, N. C., as follows: Scrap, $45@$50 per ton; punch, 4@5c. per lb.; circle, 15@25c.; 1½ x 2 in., 75c.; 2 x 2 in., $1.15; 2 x 3 in., $1.65; 3 x 3 in., $2.10; 3 x 4 in., $2.50; 3 x 5 in., $2.75; 3 x 6 in., $3.75; ground 165 mesh, $240 per ton; ground roofing mica, $60; mica washers, 75c.@$2 per lb.; 1¾-in. disks, No. 1, $1.60 per lb.; No. 2, $1.30.

[1]**Monazite** — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses.

Pumice Stone—Imported, lump, 4@50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish, fines, per unit 12c., c.i.f. Atlantic seaport; furnace size, 17½c.; run of mine, 12@14c.; domestic, fines, f.o.b. mines, 12@14c.

Quartz—(Acid tower) fist to head, $10; 1¼ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines. F.o.b. Wausau, Wis., the price is $16 per ton in car lots, and $22 less quantities, including bags.

Sulphur—$18 per ton for domestic; $20 for export, f.o.b. Texas and Louisiana mines.

Talc — Paper making, $10@$20 per ton; roofing grades, $9@$15; rubber grades, $10@$15, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $15@$20 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60@$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $2.25@$2.50 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15 to 18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 17@18c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c. f.o.b. works.

Ferromanganese—For 76 to 80 per cent, prompt delivery, $200, freight allowed; last half, $170; English, $170@$175, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $80@$85, f.o.b. furnace. Conditions are a little better in California, owing to the opening of a ferromanganese plant there. This plant can, of course, afford to pay a higher price for California ore than can Eastern buyers.

Ferromolybdenum—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2.50@$3 per lb. of contained metal, f.o.b. works.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $82.50@$85; 75 per cent, $150@$160.

Ferrotungsten—70 to 80 per cent W, $1.10@$1.15 per lb. of contained tungsten, f.o.b. works.

Ferro-uranium—35 to 50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium—Basis 30 to 40 per cent, $6.50@$9.50 per lb. of V contained, f.o.b. works.

Metal Products

Copper Sheets — Current New York price, 29½c. per lb.; wire quoted, 22¾@23c.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver—Unchanged at 39½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 26¾c.; sheathing, 25¾c.; rods, ⅜ to 3 in., 23¾c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $160 per 1,000, f.o.b. Pittsburgh.

Chrome Brick—$100@$110 per net ton, carload lots, eastern points.

Chrome Cement—40 to 45 per cent Cr_2O_3, $50 per net ton, and $55 in sacks, carload lots, eastern shipping points.

Clay Brick — First-quality fire clay, 9-in. shapes, $55@$60 per 1,000, Pennsylvania, Ohio, and Kentucky works; second quality, $50@$55. First quality, St. Louis, $45; New Jersey, $75.

Magnesite Brick—$110@$120 per ton, eastern shipping points; 9-in. straights, $90@$100; 9-in. arches, wedges and keys, $95@$105; soaps and splits, $110@$120.

Silica Brick—9-in., per 1,000, $56@$61, Birmingham, Ala.; $55@$60, Mount Union, Pa.; $65, Chicago district.

Iron Trade Review

Pittsburgh, Sept. 7, 1920

Pig Iron—There is scarcely any inquiry, even for early deliveries. Furnaces are firm on prices and have well filled order books, at least for the time being. Southern furnaces have held their market to the basis of $42, Birmingham, attained at the end of last April, and thus there is the anomalous condition that, even with the advanced freight rates, Southern iron is cheaper delivered Pittsburgh than Valley iron, the new Birmingham-Pittsburgh rate being $7.60. Valley iron remains quotable at $50 for foundry and malleable and $48.50 for bessemer and basic, the new rate to Pittsburgh being $1.96.

Steel—Standard billets have sold at $60, Pittsburgh, which seems to be an established market. Sheet bars are $67.50@$70, Pittsburgh or Youngstown, both markets being quiet.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $17@$18; foundry, $18@$20.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

The Unusual Lead Situation

St. Louis Market Ruling Above New York, a Condition Duplicated in 1916—Domestic Production Failing To Increase To Relieve the Lead Shortage—France Developing Her Own Lead Resources

THE present abnormal relation between the St. Louis and New York lead market is due to exceptional circumstances and is a condition that rarely arises. In fact, the only similar occasion in recent years was recorded in the spring of 1916, when the St. Louis lead price ruled higher than the New York quotation. This instance, however, differed radically from the present one, and was due primarily to a very large demand for export lead from the Orient, buyers being willing to pay prices high enough to justify shipments of lead from Omaha and St. Louis to Pacific Coast points. Consequently the St. Louis market was placed on equal terms with New York, and to compete for the Asiatic export trade the New York price necessarily was lowered to allow for the freight differential from New York points to St. Louis.

The Difference Between the 1916 and 1920 Markets

The present situation is in marked contrast to the one prevailing in 1916 and is due to lead coming into the United States—not leaving it—plus an acute domestic shortage of prompt lead supplies. Expressed differently, the combination of demand and supply for spot lead is so strong, and has been for weeks, that domestic producers have been unable to fill requirements and have therefore had to allow foreign lead of Mexican, English, Spanish, and Australian brands to come into the country. This importation would have been unprofitable were it not for the low London metal market quotations by which lead can be laid down in New York, duty paid, from 8.00c. to 8.50c. per lb. to compete with domestic lead. Naturally, if there is a scarcity of lead in the Middle West, imported lead which is used for Western requirements must stand the freight charge to the West, and hence rule correspondingly higher in price, in Western districts.

Protection of the Lead Industry

Of all the major metals pig lead has the greatest tariff protection, with an ad valorem duty of 25 per cent. Raw copper is admitted free, and imported metallic zinc must shoulder a duty of 15 per cent. Yet in spite of the comparatively splendid protection rendered the domestic industry, it is paying importers to buy lead in London, and pay the commission, delivery, insurance, transatlantic freight, lighterage, loss of interest and miscellaneous charges. This condition is most unusual.

There can be no complaint about the price of lead. Compared with a pre-war price of 4.5c., which was considered satisfactory at the time, 9c. lead is highly remunerative, particularly when the price is considered in relation to the deflated prices of other metals.

Why the London Market Has Not Responded

The failure of the London market to rise only slightly to meet that of New York is a singular feature of the situation, and is ascribed to a number of conditions, but principally to the lack of demand in England and on the Continent—a direct contrast to the eagerness with which supplies of lead are utilized in this country. Also a little give-and-take element is introduced in the delivery of American lead to England on old contracts. Furthermore, there is the influx of Spanish lead in England, material which formerly found its way to France. The latter country is evidently trying to become independent of Spanish lead resources, and it is reported that the Escalette works are drawing raw material from Morocco in preference.

It should be noted in connection with the imported lead that about 75 per cent of the lead consumed in the United States is based on average-price and sliding-scale contracts and only the excess requirements are filled by imported lead, or contract requirements which cannot be met because of a shortage of domestic supplies.

Labor's Attitude

The summer and fall seasons are always trying upon the mining operations of the country, as labor has a tendency to migrate to the farms and harvest fields, where the wages are, in these days, better than in the mines and where a more healthful occupation can be followed. Practically all the lead producers are complaining about this attitude on the part of labor, and no doubt could speed up production greatly if they had a representative share of workers. A solution to this pressing problem of mine operation, which recurs yearly in periods of agricultural prosperity, would be most welcome.

The Lead Ore Reserves

In connection with the decreased production in the United States, it is pertinent to consider if there is not some basic reason underlying this broad trend in the industry other than labor and transportation embarrassments, and if it may not be that the domestic resources are smaller than has been assumed and whether a pinch of easily worked reserves is not actually being felt. Glancing at production figures for the last few years, it is noticeable that the great lead-producing centers in the United States, southeastern Missouri, Idaho, Utah, and Colorado, were easily able to meet the intense war demand, and, in fact, have readily responded to conditions in the industry, and give the impression of being highly flexible in productive capacity. It has only been in the last year that production has failed to keep pace with demands placed upon it.

Even though the figures indicate that nothing is inherently wrong with the lead reserves of the country, it is interesting to consider the contrasted position of the large copper deposits, with well-developed reserves, and those of lead. Lead deposits are not gigantic low-grade occurrences, and the success of a lead-mining enterprise often hinges upon a metallurgical ability to separate the closely related metal, zinc, from the ore. Flotation and improvements in the treatment of ores have worked wonders in increasing available lead and zinc reserves throughout the world. Furthermore the lead bonanzas have been worked out, and it is becoming increasingly more costly—leaving aside the question of present high labor and supply cost—to produce lead.

Australian and Spanish Difficulties

The settlement of the Broken Hill strike should soon bring increasing quantities of lead upon the market, but the full effect of Australian production will not be felt for some time.

The low level of the London market is undoubtedly working a hardship upon the producers in Australia and also in Spain, who find it difficult to lay down lead in London at a profit, when quotations around £36 per ton are ruling, especially when the serious labor troubles in these countries are considered. In the United States there is a shortage of lead supplies; in Europe there is more than enough to supply present requirements, and yet the London and New York markets have failed to strike a balance. It is a peculiar world situation.

Illustrating the great consumption of lead that is taking place in other than paint and storage-battery manufacture, it is interesting to note the lead consumption of the Western Electric Co. in telephone apparatus during the year ending June 30, 1920, which amounted to 100,000,000 lb. The Western Electric Co. produces practically 95 per cent of the world's transmission apparatus at one of its plants near Chicago.

COMPANY REPORTS

Consolidated Interstate-Callahan Mining Co. Preparing for Increased Output

Lead-Zinc; Idaho

The report of operations of the Consolidated Interstate-Callahan Mining Co. for the second quarter of 1920 follows:

Net value of shipments	$384,162 64
Miscellaneous receipts	2,234 76
Total income	$386,397 40
Production costs, expenses, taxes	341,650 54
Profits	$44,746 86
Cost of improvements	9 00
Surplus for the period	$44,737 86

The principal features of the mining and milling operations during the quarter were as follows:

Tonnage mined	51,074
Tons of mine ore milled	37,534
Average contents of ore milled:	
Zinc	14 67%
Lead	6 91%
Silver	2 27 oz.

Shipments	Tons	Zinc Assay, per Cent	Lb. Zinc	Lead Assay, per Cent	Lb. Lead
Zinc ore, crude	175	53 81	188,347	2 19	7,682
Zinc concentrates	8,037	52 13	8,379,539	3 36	539,938
Lead ore, crude	70	6 02	8,428	65 46	91,647
Lead concentrates	3,116	13 23	824,261	57 95	3,611,780
	11,398		9,400,575		4,251,047

Total recovery of zinc	38 85%
Total zinc in zinc crude and zinc concentrates shipped	8,567,886 lb
Total lead in lead crude and lead concentrates shipped	3,703,427 lb
Ounces of silver in lead crude and lead concentrates	61,825 oz
Cost of mining, crushing, and sorting, per ton mined	$4 456
Cost of milling and flotation royalties, per ton milled	$2 511

During the second quarter shipments of zinc and lead-silver ore and concentrates were 4,576 dry tons less than the preceding quarter. This falling off is accounted for by the scarcity of miners and by a lack of efficiency on the part of labor in general.

Since the last report, the company has consummated the purchase of a controlling interest in the Chicago-Boston Mining Co. and also in the Killbuck Mining Co., both of which are lead-silver properties; the former owning approximately 280 acres and the latter 100 acres, about 1½ miles from Wallace, in the Coeur d'Alene mining district, Idaho. The work of opening up the orebodies at depth in these properties is being actively prosecuted preparatory to shipments on a large scale. The acquisition of the above properties required a considerable outlay in cash, which has been appropriated from surplus funds, so that no new financing was necessary.

Mount Morgan Gold Mining Co. Reserves, 3,437,687 Tons

Gold; Queensland, Australia

The Mount Morgan Gold Mining Co., Queensland, Australia, raised 147,510 tons of ore during the half-year ended May 30, 1920. Of the total, 52,293 tons was smelting, 93,710 tons concentrating, and 1,507 tons leaching ore. Reserves were depleted by 100,517 tons, leaving the estimate as on May 30 at 3,437,687 tons containing 2.59 per cent copper and 6.11 dwt. of gold per ton. In addition to the ore 3,685 tons of fireclay, 2,410 tons of silica, 794 tons of siliceous ore containing 9.12 dwt. of gold per ton, 25,635 tons of limestone, and 8,594 tons of ironstone were raised by the company for its own use.

The mill treated 91,818 tons of ore, assaying 2.0 per cent Cu and 5.52 dwt. Au per ton, producing 8,522 tons jigged concentrates (2.31 per cent Cu; 4.65 dwt. Au); 19,427 tons table concentrates (2.62 per cent Cu; 8.82 dwt. Au); 7,023 tons flotation concentrates (14.49 per cent Cu; 25.98 dwt. Au); and 1,479 tons of leaching product (2.17 per cent Cu; 5.64 dwt. Au).

At the smelting works, 87,580 tons of ore and concentrates were treated, comprising 53,461 tons crude ore, 8,887 tons jigged concentrates, 21,459 tons table concentrates, 1,560 tons crude ore from Many Peaks, 2,016 tons calcines from Many Peaks, 159 tons purchased ore, and 38 tons of precipitates. From this material 3,130.55 tons copper (3.58 per cent), and 39,387 oz. gold (8.99 dwt. per ton) were recovered. The gold, however, included 181.68 oz. from silica linings, the tonnage of which was not included.

Blister copper sold during the term brought £503,357, and sundry income £1,458. Working expenses totaled £405,255, leaving £99,560 to be carried to profit-and-loss account. Of this, £38,482 remained as net profit after provision for the usual items, and the total available, after adding £153,710, brought forward from previous account, was £192,192. Two dividends absorbed £100,000 and the balance, £92,192, was carried to balance sheet. Liquid assets were £487,933 in excess of liabilities, as against £543,732 at the beginning of the term.

Barnes-King Development Co. Second-Quarter Earnings, $20,219

Gold-Silver; Montana

The records of the Barnes-King Development Co. show the following operating results for the quarter ending June 30, 1920:

Earnings		
Shannon property operations		$16,005 89
Piegan-Gloster property operations		7,901 07
Kendall property operations		699 70
Interest received		775 01
		$25,381 67
Deduct		
Loss on operations at North Moccasin property	$2,985 85	
Miscellaneous expense	1,824 60	
Capital stock tax	346 50	
Black Hawk option	5 00	
		5,161 95
Balance, being net profit on operations for quarter ending June 30, 1920		$20,219 72

The above figures include provisions for depreciation on the various plants of the company on the same basis as has been used heretofore.

Production from the North Moccasin property amounted to 336,469.33 from 3,768 tons of ore, or $9.68 per ton. Development work, 605 ft. The North Moccasin production has been decreasing for some time, owing to unsuccessful search for new orebodies, and the present outlook at this property is discouraging, with operations being continued at a heavy loss.

Production from the Piegan-Gloster property amounted to $35,447.85 from 2,661 tons of ore, or $13.32 per ton. During the latter part of May, a larger flow of water than anticipated from the bottom workings of this property made it necessary to take out the remaining pay ore in the winze as fast as possible and pull the pumps and equipment, or take the chance of drowning them by trying to continue work. The former plan was adopted, which practically closed the mine for the present, and future work has not been decided on.

Production from the Shannon property amounted to $69,084.07 from 7,009 tons of ore, or $9.86 per ton. Development work, 1,048 ft. The Kendall lessees paid in royalties $548.36 during the quarter.

Dividend No. 14, of $20,000, 5c. per share, was payable on Aug. 16, 1920, to stockholders of record July 26, 1920. This disbursement makes total dividend payments $440,000.

INDUSTRIAL NEWS

International Minerals & Metals Corporation is the new name under which Beer, Sondheimer & Co. Inc., 61 Broadway, N. Y., have recently incorporated. The management and relationship to affiliations and subsidiaries have not been affected and will continue as heretofore.

Pennsylvania Pump & Compressor Co., Easton, Pa., has opened additional sales offices at 788 Potomac Ave., Buffalo, N. Y.; 232 St. Clair Ave., N. E., Cleveland, Ohio; 1956 N. Broadway, St. Louis Mo.; 423 Fifth St., S., Minneapolis, Minn.; and 804 First Nat. Bank Building, Omaha, Neb.

W. A. Olen, president, with **D. J. Rohrer** and **C. F. Folkman**, members of the board of directors of the Four Wheel Drive Auto Co., Clintonville, Wis., sailed for England on Aug. 14. They will study the truck situation with a view to improving present facilities of the company for handling its increasing export trade.

Technical Advertising Service, 1133 Broadway, New York, announces the election of Raymond Hawley as vice-president. Mr. Hawley, who has had much experience as advertising, sales and production manager, was last with Keystone Motor Truck Corporation, of Philadelphia, Pa.

Uehling Instrument Co., 71 Broadway, New York, manufacturers of fuel economy equipment, announces that its New England States representative is the Smith Engineering & Supply Co., 89 State St., Boston, Mass.

H. K. Lidstone and **G. H. Van Dorp**, mining and metallurgical engineers, have opened an office at Texas and Yankie Sts., Silver City, N. M. Their postoffice address is Box 216.

The General Briquetting Co., 25 Broad Street, New York City, announces the appointment of Thomas F. Kelly, formerly with the Lackawanna Steel Co., as Sales Engineer in its flue dust, ore and byproducts department.

Worthington Pump & Machinery Corporation, 115 Broadway, New York City, announces that it is ready to furnish improved waterpower machinery of all capacities for low, medium, and high head service.

A. B. Way, recently secretary and general manager of Bridgeport Chain Co., has become New England District Sales Manager for Chain Products Co., of Cleveland, Ohio. His headquarters will be 150-152 Chambers St., New York City.

Julius Janes, former president of Standard Steel Castings Co., is sales representative of Farrell-Cheek Steel Foundry Co., Sandusky, in Cleveland and Cuyahoga County, Ohio.

Blaw-Knox Co., steel products, Pittsburgh, Pa., announces that DeWitt Clinton Grove, formerly in charge of the advertising for an Ingersoll-Rand subsidiary and past vice-president of the Technical Publicity Association, has become its advertising manager, vice George Land, resigned.

Industrial Information Bureau for China

Of interest to those who do, or desire to do, business in China is the announcement that beginning with February, 1921, the Government Institute of Technology at Shanghai, China, will open a bureau of information for alumni. The school is under Chinese government support and turns out engineer and railway administration men with a technical education equivalent to that of an American engineering school. These men often are situated away from the port cities, and find it difficult to obtain desired information regarding equipment. To meet this need the school is about to open this bureau. Manufacturers who are interested are invited to send catalogs, specifications, designing data, approximate costs, samples, or models. In case samples are sent an attempt will be made to place same in running order. No sales will be made nor attempted. Impartial information alone will be offered. A member of the faculty is now in America on leave, and he will be glad to communicate further with any who desire information regarding the China field. Address H. A. Vanderbeek, 5 Cammann Place, Somerville, N. J., until Dec. 1, 1920, and Box 951 United States Post Office, Shanghai, China, after that date.

American Welding Society Organizes a Chicago Section

At a meeting of members of the welding trade in Chicago, held in the rooms of the Western Society of Engineers, on Tuesday, Aug. 3, a Chicago Section of the American Welding Society was organized. About seventy-five were in attendance, representating many railroads terminating in Chicago and also many of the larger local industries. The following officers and directors were elected: Chairman, M. B. Osburn, assistant superintendent, Pullman Car Works; vice-chairman, O. T. Nelson, president, General Boilers Co.; secretary-treasurer, L. B. Mackenzie, president, *The Welding Engineer;* directors: three years, E. Wanamaker, H. B. Bently, Andrew Oliver, W. M. B. Brady; two years, Harold Cook, W. A. Slack, K. R. Hare, J. M. Jardine; one year, W. H. Bleecker, Jr., Oliver Mitchell, W. L. Senhert, Don B. McCloud.

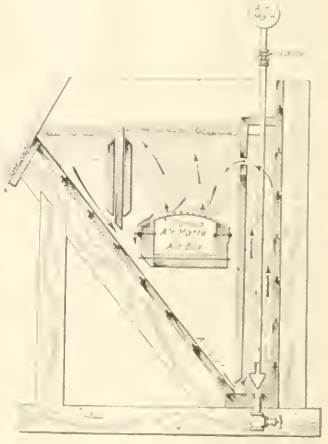
Meetings will be held on the second Tuesday of each month in the rooms of the Western Society of Engineers, and those interested in the subject of autogenous welding, by all methods, are invited to attend. The address of the secretary-treasurer is 608 South Dearborn St., Chicago.

The Simpson Flotation Cell

Has No Mechanical Parts—May Be Safely Shut Down Under Full Load —Will Not Clog

BY S. FORD EATON

The Standard pneumatic flotation cell, invented and manufactured by Gerald R. Simpson, of Kingman, Ariz., operates entirely on the pneumatic principle. Air lifts are employed to circulate the pulp, continually feeding it to an agitation compartment where compressed air, admitted through a porous medium or spray, is employed to produce the froth. The froth is under positive control by the adjustment of the volume and pressure of air admitted to the agitation compartment, and by adjustment of the baffle board. By means of these adjustments, a deep or a shallow froth can be carried, as may be desired. After passing over the



STANDARD PNEUMATIC FLOTATION CELL INVENTED BY G. R. SIMPSON

baffle board, the froth must cross a spitzkasten of quiet water before being discharged over the overflow lip into the concentrate launder, and thus much of the gangue matter which has been mechanically entangled in the froth is given an opportunity to settle, thereby securing a cleaner concentrate than otherwise. The control which is thus exercised over the depth and the rapidity of discharge, or overflow, of the froth, results in a high percentage of recovery and a high-grade concentrate.

By means of a series of vertical and inclined partitions, the bottom of the cell is converted into a number of hoppers, whose walls converge to a central point at the bottom of the air lifts. The pulp is thus conveyed progressively from one air lift to another, being submitted by each to the agitating compartment. The floating particles are thus given a number of opportunities to engage with an air bubble and be carried into the froth before reaching the discharge compartment.

Commercial machines of from 50 to 100 tons daily capacity are equipped with six to eight air lifts, each of which treats the entire pulp twice before it is discharged.

Clogging, which has been a serious drawback to other air machines, has been entirely eliminated by means of an improved air injector at the bottom of the air lift and the conical shape, or converging walls, of the respective hoppers or compartments. The machines may be closed down while containing a full charge of pulp for twenty-four hours or longer, and again placed in operation merely by turning on the air. From 2 to 3-lb. pressure is sufficient for the operation of these machines.

The discharging device, when once set, is automatic, and, working in conjunction with an overflow weir, maintains the water at a constant point, which is determined by the adjustable position of the weir.

The Standard pneumatic cell was developed at the property of the Standard Minerals Co., near Kingman, Ariz., where a molybdenite ore was being treated.

An interesting problem has also been solved at the Diamond Joe Silver mine, near Yucca, Ariz., by the use of Mr. Simpson's invention. A silver chloride and bromide ore containing some lead sulphide is being sulphidized and floated. Satisfactory extraction is being secured with concentrates carrying 500 oz. of silver and from 30 to 45 per cent of lead. The principal tailing loss occurs in the slime and can be somewhat reduced under more favorable grinding and sulphidizing conditions.

Mr. Simpson's invention was prompted by his desire to get away from the expensive shutdowns experienced at his mill on account of some of the parts of the mechanically-agitated machine that he was using becoming out of order. In departing from mechanical agitation entirely, he eliminated this difficulty, as the only part of his machine which could possibly cause a shutdown is the porous air mat. This seldom requires adjustment, but in any event can be changed in ten minutes.

Shop Workers Get Leave With Pay

Four thousand shop employees of the Western Electric Co. will receive a vacation with pay this summer for the first time in the history of the company. The board of directors has promulgated an order extending the vacation privilege to every department. Previously, factory workers did not receive the same benefit as the members of the sales, clerical, technical and executive branches, and any time off during the summer months was taken at their own expense. The fact that they received pay on an hourly basis with extra rewards for overtime always counted against granting them the same privileges as the weekly salaried body, the members of which get no remuneration for additional labor. The new ruling is a radical change in factory practice.

An American Gold Dredge for New Zealand Fields

An example of the far-reaching activities of American industry is to be found in a gold dredge that has been designed and constructed in New York State for the purpose of operating in New Zealand gold fields. This dredge is being built by the New York Engineering Co. and is along the type of dredge constructed for operations in Alaskan fields. The hull is 115 ft. 6 in. over all, beam 50 ft., depth 11 ft., and is built of kaurice pine. Power for dredging, pumping, and shifting position is furnished by Westinghouse electric motors. Twelve men, four men to a shift, constitute the crew. A winch motor is used to change the position of the dredge.

The digging ladder carrying the buckets is 100 ft. long and weighs 110,000 lb. There are 73 buckets, each bucket weighing 3,000 lb. empty and with a load capacity of about 10½ cwt. When in operation, dredging is at the rate of 18 buckets per minute, and a linear speed of 54 ft. per minute is obtained from a 200 hp. slip-ring motor with a magnetic controller for reversing and 50 per cent speed reduction.

The screen is 40 ft. long and 7 ft. in diameter and weighs approximately 6,500 lb. A 50-hp. slip-ring motor operates this screen at seven revolutions per minute.

About 8,000 gal. of water per minute are used in washing, and the three pumps (the high pressure, low pressure, and nozzle pump) are driven by Westinghouse squirrel-cage motors of 125, 60 and 25 hp., respectively.

The conveyor belt transferring dirt from the screen to the stacker is 42 in. wide and 130 ft. long, and the stacker is operated by a 40-hp. slip-ring motor. Winch drive is furnished by a 25-hp. slip-ring motor, and a 10-kw. transformer is used for lighting purposes. All motors are of the three-phase, 60-cycle, 2,200-volt alternating-current type, and have special impregnated windings to protect them from moisture.

Power will be furnished by a hydro-electric plant, and feeders are run along the ground to the dredge. As alternating current is used the dredge can be operated a considerable distance from the plant. Dredges of this type have operated on a cost basis of 6½c. per cu.yd., and in one instance where records are available 418,745 cu.yd. have been dug in a period of two years.

The General Engineering Co., Salt Lake City, Utah, is retained by the Utah Consolidated Mining Co. to design and erect the 1,000-ton flotation plant which the mining company is building at Tooele, Utah.

The Henry E. Wood Ore Testing Co. has removed its assay office and chemical laboratory to 1750 Arapahoe St., Denver, Col. A necessary increase in the rate of charges is also announced but the new rates continue moderate.

TRADE CATALOGS

Wire. — The Hazard Manufacturing Co., Wilkes-Barre, Pa., has issued an interesting booklet, "Rubber-Insulated Wire," which traces the story of the manufacture of rubber-insulated wire from the winning of the crude rubber to the finished lead or cloth incased cables of insulated wire used for aërial, submarine or underground transmission lines. The Hazard company produces standard brands of insulated wire for all conceivable purposes.

Carbon Dioxide Indicators—Uehling Instrument Co., 71 Broadway, New York City, has just issued their Bulletin 111, describing their Style U CO_2 equipment. This is a new design, built to serve any number of steam boilers simultaneously, up to six. Among the notable features of the new machine are speedy action, absence of chemical solutions, greater simplicity, and an auxiliary boiler front CO_2 indicator which guides the fireman, while the CO_2 recorder installed elsewhere makes a continuous record of all changes in boiler-adjustments.

Pipe Welding—The Metal & Thermit Corporation, New York, N. Y., has just issued and will distribute on request the third edition of its Thermit Pipe Welding Pamphlet No. 16. In this new edition the subject of Thermit pipe welding has been revised and brought up to date.

Drills—The Chicago Pneumatic Tool Co., 6 East 44th St., New York, announces that Bulletin 504, describing its Slogger Rock Drill, is now available, upon request, from its New York office or branches.

Melting Pots—"Metal Melting Pots" is the title of a new two-page 8½ x 11 illustrated leaflet descriptive of The Cutler-Hammer Manufacturing Co.'s melting pots, both portable and bench types. These heating pots are specially serviceable for melting lead, tin, solder, babbitt, and similar metals, and maintaining these metals at the proper temperature. The heat may be controlled by means of a rotary snap switch or an automatic control device which maintains the temperature at the desired point. The leaflet, known as Publication 826, may be had on application to the company at Milwaukee, Wis.

Crucibles—A new edition of the illustrated twenty-one-page catalog of its goods has been issued by the Ross-Tacony Crucible Co., Tacony, Pa. The pages illustrate the dimensions of the different types of general and special crucibles, retorts and accessories supplied by this company, and the pamphlet closes with two pages of hints on the proper handling of a crucible which will be appreciated by all users of this make.

The Divining Rod

THE visions of the Middle Ages are with us still. We dream of transmuting base metal into gold, and of finding by some mystic power the ores from which the metals are extracted. The belief in the divining rod dates back to dim and obscure times, and will doubtless yet endure in some form for ages. Most prevalent is the belief in its ability to find water; but also the metals. From this in specific instances we progress to buried treasure; and a recent correspondent writes in of his ability to locate not only all these, but "animal bodies," and concealed whisky as well. A private still would have to be very still and private indeed to elude him, as he claims.

It would be a bold man who nowadays proclaims the impossible. We hesitate to begin, because we do not know where to stop. It may be possible some day for a man to jump to the moon, to see to the center of the earth; but we do not believe these things will ever happen. Similarly, we hesitate to proclaim the impossibility of locating water or ore by some hitherto undiscovered delicate process; but (speaking editorially) we do not believe that such a power or process exists.

The operator of the divining rod cuts a forked twig of willow, and grasps the two ends in his hands, with the point of juncture upward. As he walks over the ground at a certain place the stick turns over and its point designates the earth; and he cannot prevent its doing so, no matter how much strength he expends.

We once saw a demonstration of a similar rod for finding minerals, except that the rod was of metal, with a little box in each handle into which different metals might be slipped, according to the mineral to be detected. If gold was to be discovered, gold was slipped into the handles, and then the instrument pointed out the gold ore, in the manner indicated above. If nickel was the object, or petroleum, the insertion of the corresponding metal or mineral in the handles tuned the rod for a corresponding discovery. Armed with this instrument, the operator walked over a pasture, in Delaware, disturbing the peaceful cows, and located and plotted a broad gold lode; at right angles to this, and traversing it, a wide vein of nickel; and running in various other directions, tin, copper, and "petroleum" lodes. The operator was in earnest, and there is no question that his intensest efforts failed to hold the rod when it started to turn. Of course, the net result was humbug. There was nothing in the field. For others, the instrument failed to perform—it would not perform for the son of the operator. Plainly it would work for only certain personalities, who possessed the mysterious sensibility (which, the operator confided, had to do with the ultra-violet rays). And herein lies, in our opinion, the secret of the phenomenon. As for the rod, there is nothing whatever in it. It might as well be a rabbit's foot or a ball of crystal.

The manifestations noted are exclusively psychological, and analogous to those of the ouija writer, and they deal with natural but little understood nervous or mental laws. The writing on the ouija board, and the manipulation of the divining rod, are due to the subconscious impulses of the operator, which control and direct the muscles far more powerfully than can the relaxed conscious mentality. In the familiar phenomena of hypnotism, the hypnotist tells the subject that he cannot rise from his chair, and, exert himself as he will, he cannot do so—not because of the power of the hypnotist, but because of the dominant inhibition imposed by his own subconscious self. No hypnotist is necessary to induce this state.

An incident was related to us recently of a Mexican boy who was accustomed to light dynamite sticks and throw them for amusement. One day he could not let go his lighted stick; and could only push his hand as far away from his body as possible before the explosion which blew off his hand. Many further illustrations of this state, when the will is unable to combat the suggestions or fears of the subconscious mentality, might be cited. The subconscious mentality is ordinarily an indispensable part of our equipment: invisible to ourselves and without a speaking acquaintanceship with our conscious mentality, it does much of our mental work for us. Does a name escape you? Do not worry about it. Forget it, and presently the faithful subconscious mind will hunt it out among the archives of your memory and fetch it to you. Is a problem perplexing? Do not decide it tonight. Sleep on it, and in the night your subconscious mind will rake over and sift out the problem, and have the best solution ready for you when you wake in the morning.

It is this subconscious mind that directs the muscles of the divining-rod performer, the ouija writer, and the sleep walker. It is a reasonable and logical-appearing part of our mentality, and its messages often appear intelligent and hence surprising, since they come from a source unknown and ignored by most; but it is really hardly, if any, wiser than the rest of us; indeed, by itself alone it becomes unhealthy. A man dominated unduly by his subconscious cerebration may become to all degrees unbalanced mentally: the nerve-taxing nature of divining-rod operation, ouija writing, sleep walking, psychic trance and other phenonoma of this state are well known. And in the end the subject can tell little or nothing that is not known before. The subconscious mind of an illiterate ouija operator will spell as badly as the conscious mentality; the spirit of the Indian maiden who takes possession of the New York medium will use Bowery idioms; and the subconscious mind of the divining-rod operator is controlled by his own delusion. In the case of the operator of the alleged wonder-working device cited above the delusion had been nursed by an unscrupulous assayer.

Community Problems In Mining Camps

IT IS surprising indeed how community problems have forced their attention on mine managements. In the case of the isolated mining community which had to be developed literally from the grassroots in order to provide living conditions, that the mine might be continuously operated, these problems have been presented to engineers and managers in such a form that they had to be solved. Throughout the history of mining operations there have been a goodly number of such cases. Fortunate is the mine which is so favorably situated that it can call upon a community already organized to supply its labor during the development stages and then during the larger-scale operation when greater numbers of workers are required. Even in such cases community conditions have sometimes reached a pass such that only by the strong and intelligent leadership of the mine management can conditions be righted. Beginning with a cook house and a few tents, there are all degrees of the mining camp up to a village of several hundred houses, with a school, hotel, and accompanying stores. As an example of a substantial and well-ordered kind we may mention Hammonton, Cal.

The extremes of opinion on the subject appear to be that, on the one hand, the mining company has no other obligations than those of affording employment under safe and hygienic conditions, and, on the other, that, in addition to these conditions, it must exercise a paternalistic oversight over all of the community, providing amusement, sanitation, and housing, and initiating and even paying for all of the inevitable charities and sociological activities that may be necessary.

We are not disposed to debate these extremes of opinion. Nor do we believe that any well-balanced formula can be worked out that will serve for all cases and be a guide for the harassed mine management. We do hold the view, however, that a mine management cannot afford not to be a part of whatever activity there is in a community looking toward better housing, better sanitation, better living, and more wholesome amusement. This is an obligation which rests upon every individual in the community as well as upon the individual manager and the various members of his executive staff.

Looking back over two decades of mining progress, anyone familiar with the facts will conclude that there has been a great improvement not only in working and safety conditions about mines and reduction plants but about mining communities as well. One has only to spend a few days in Grass Valley, Cal., or Kellogg, Idaho, or some other camp which has become established upon a producing basis, to realize that "times have changed," and for the better.

As in so many other things, it is organized effort intelligently directed which accomplishes most for the mining community. Just how far this effort can go or is willing to go is of considerable interest. A recent example comes from South Africa. A company embracing the head office of the principal mining companies and affiliated organizations, employees and others, to the number of 800, has been organized as the Rand Co-operative Stores, Ltd., for the purpose, primarily, of reducing living costs. The co-operative trading organization is not new; it has been tried out successfully in England. With good leadership and wise restraint upon the part of the members, success should attend its efforts.

In a statement of objectives of the company, the following paragraph is worth noting:

> To form and establish pension funds for employees and to promote and establish institutions, clubs, or societies, and to erect, lay out, plant, and maintain buildings, grounds, fences, and ornamental gardens with the object of providing pensions for employees, recreation, and means of social intercourse for members of the company, their families and their relations, and the furnishing of any such institutions, clubs, societies, buildings, or grounds with furniture, fixtures, games, billiard tables, libraries, books, or any other matters or things conducive to the recreation and the social requirements or benefit of members.

This is a novel addenda to the co-operative trading plan. Its inclusion is a distinct expression of the need for such things in the average mining community, and of correcting the haphazard lack of method often characteristic of the mining camp or town.

We doubt whether conditions in many of our mining communities will admit of extensive introduction of co-operative trading, although experiments have been started in Tonopah, Nev., and Grass Valley, Cal., on modifications of this plan; but many of the purposes given in the interesting paragraph quoted are possible of attainment. Mining engineers and managers can serve a useful end, apart from their company duties, by stimulating initiative along similar lines in every mining camp.

Our 40 Per Cent Gold Cover Dollars

PROFESSOR WILLIAM E. CHANCELLOR, writing in *The Annalist*, discusses the danger in our Federal Reserve currency, which is secured by only 40 per cent of gold, and the rest by nothing tangible. As to the interchangeability of this currency and gold, he remarks aptly:

"I submit as certain that no ordinary bank depositor and customer would consider it judicious to ask his local bankers regularly to honor his checks in gold. He knows that were he to do so he would soon cease to enjoy banking credit. He would be considered erratic and annoying. Any banker would assume that such a customer was engaged in trying to build up a private gold hoard. Of course, an occasional request for a small amount of gold is granted at this time, though it was not granted a few weeks ago by ordinary banks.

"Now, this raises a very important question—whether or not we are even upon the gold standard in fact, whatever may be the case technically. Is this present currency anything more than a convenient counter? Have we not, without recognizing the fact, given up the gold basis and adopted the paper currency that the radicals have long been arguing for? And is not a large measure of our present social disturbance due essentially to the fact that we are trying to accustom ourselves to something as money that in fact is not money, but a mere concrete computing system?"

He concludes that,

"Money is a medium of circulation, and a system of storage units of value. Paper, even 40 per cent gold cover paper, whose gold we never see, is not money. A currency consisting entirely of the shoddy part of a wool-and-shoddy financial clothing cannot retain the confidence of any people long. Out in the open country, far from the centers of banking, most of the millions of Americans live; and these millions do in fact control the Government and the nation. Most of these millions know nothing of the Federal Reserve System beyond seeing this new and relatively powerless paper money. They are taking the two as synonymous, knowing

nothing and understanding nothing of the larger values of the system in delaying and perhaps ending panics, in moving crops, and in harmoniously co-ordinating the entire industrial, commerical, and other business life of the country."

According to Professor Chancellor's opinion, the remedy for the popular discontent over paper money is contained in the following suggestions:

"First. The replacement upon the counters of all banks, of gold to be taken at sight by bona fide depositors, as of old. Otherwise, the hoarding of gold by the great banks will start the hoarding of free gold as fast as possible by every citizen who can get and keep his hands on it; and America will become another India or China, with an insatiable appetite for real money, to be hidden.

"Second. The restoration to ordinary circulation of gold certificates.

"Third. The substitution for the small issues of Federal Reserve banknotes, of similar silver certificate issues in which the people have more confidence.

"Fourth. More candid and more frequent publicity through the Treasury Department respecting the exact amounts of all kinds of currency in actual circulation.

"Fifth. Deflation until we are so far away from 40 per cent gold cover and so near to the 100 per cent gold cover as to reassure the minds of all citizens."

It will be noted that the gist of this writer's pertinent recommendations is the restoration of gold as real money; and, moreover, leaning heavily, as an auxiliary support, on silver as real money; for he truly says that people have more confidence in silver certificates than in Federal Reserve notes, which, as we have previously stated, are 40 per cent gold value and 60 per cent I O U's.

Our financiers and bankers must not forget the fundamental fact that money is metal, under the century-tried system of the world; and that there is no other real and valuable money. Even the most stable government fails to sustain the fictitious stamped value of its paper money unless this really represents accessible metal. The protection and encouragement of the gold industry, then, becomes clearly a matter of great material importance; and it is clearly the duty of Congress to assist this by passing the McFadden bill. Furthermore, it is necessary to intensify the conception of silver as true money, and for this a fixed ratio of value with gold should be established in all countries, by a world-wide agreement, as it has been fixed temporarily in the United States by the Pittman Act. The passing of India to a so-called gold basis has resulted in hoarding of gold there, as well as silver, and further limits the basis of real money on which the world is doing its enormous paper business, and going bankrupt on its "easy-money" system.

Vocational Training for Injured Workers

LITTLE note apparently has been taken of the bill providing for the vocational rehabilitation of workers injured in industry, which became law on June 2, when it received the President's signature. The seeming lack of public interest in it probably is because its purpose has been confounded with vocational training of disabled soldiers. By the provisions of this new bill, the expense of restoring to vocational usefulness those injured in industry or any legitimate pursuit is to be divided between the state and Federal governments.

This marks a new step forward. Workmen's compensation legislation is not sufficient. It compensates, to greater or less extent, the injured worker for his injury, but it may leave him incapable of producing further at his regular occupation. The necessary funds for the work have been provided. An appropriation of $750,000 for the current fiscal year, and of $1,000,000 for each of the three succeeding years, is to be divided among the states on a basis of population, no one state to receive less than $5,000 per year. Each state must contribute an amount equal to that which it receives and must submit its plans, its courses of study, and the qualifications of teachers and other officers employed, to the Federal Board for Vocational Education for the latter's approval. It must also report how its money is expended. Civil employees of the Federal Government disabled in the course of duty are to enjoy the benefit of the act.

The workman is told to produce and keep on producing; that thus only can reconstruction be achieved. It is not strange, then, though some will say it is paternal, that the Government should seek to render the incapacitated workman productive. Instead, it is quite logical. The principle is sound and thoroughly up to date. But the saying "Once stung, twice shy" is apt. "Vocational training" has recently come to have a disreputable significance through the maladministration of the work among injured soldiers. It will take time for the public to forget this. The popularity of the new statute will depend largely on the manner in which the work is conducted.

The Housing Shortage

THOSE who live in mining communities have one advantage over the populace of our cities, especially over those unfortunates who do not own their own homes. Most mining towns have at least enough houses to go around, even though they are not always everything that might be desired in luxuriousness. In many company towns, particularly, suitable and sufficient houses have been provided. Furthermore, the rents charged are often nominal, and in practically all cases considerably less than profiteering landlords are exacting in more populous centers. They are also fairly constant and permanent, and the lessee need not fear an advance whenever the owner feels that the time is ripe; or that he may be evicted on the fatal first of October. Often, electric power is supplied at a nominal figure and sometimes other benefits are derived which are not included in the ordinary lease.

The housing situation is acute in almost all of our cities, so that residents of mining communities would be wise to consider this fact before deciding to move. If one wishes to buy, the price asked is about three times the pre-war cost and the risk of a rapidly depreciating investment must be assumed. To rent or lease is almost impossible. Only last week a friend wrote us that he had rented the last house in Detroit. Here in New York we recently heard this story: After trying in vain for months to get a house, Brown wandered to the river, possibly with the thought of ending it all. Suddenly he heard a splash and saw his friend Green struggling hopelessly in the water. Without attempting to save him, he rushed off to his house agent. "Quick!" he gasped; "Green has fallen in the river. Can I have his house?" "Sorry," said the agent, "I've already let it to the man who pushed him in."

The Ophir Mining District, Utah

An Attempt To Correlate Ophir Sedimentaries With Those of Tintic District—Great Anticline, In Which Chief Ore Deposits Occur, and Ophir Fault Principal Geological Features—Locality a Steady Producer Since 1870

By F. M. Wichman
Mining Engineer, Salt Lake City, Utah
Written for *Engineering and Mining Journal*

THE history of the mining industry of Utah dates from 1863. From 1863 to 1869, activity was confined principally to the location of claims. Several small smelters were erected near Stockton, but these were not successful. The railroad entered Utah in 1869, and with it came the first real stimulus to mining. Branch lines were soon constructed from Salt Lake City, one south through the Salt Lake and Utah valleys and one west and southwest into Tooele Valley. The latter reached the Stockton district and immediately encouraged active development of the mines of Stockton and Ophir.

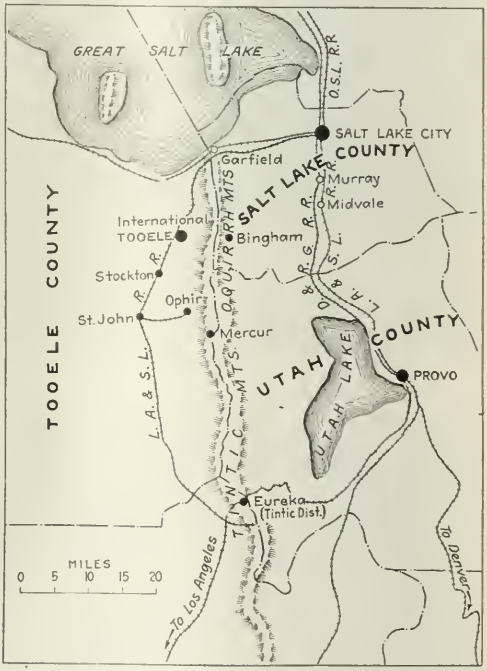
The Ophir mining district is situated on the west slope of the Oquirrh Mountains in Tooele County, eighteen miles south of Tooele City, the county seat, and fifty-seven miles by highway in a southwesterly direction from Salt Lake City. The first claim located in the district was the Silveropolis in 1870. As Ophir is but six miles from Stockton, it naturally followed that its rich outcrops of silver ores should receive early attention from the prospectors. The first shipment of forty tons of ore from this claim is said to have netted $24,000. The silver was in the form of chloride or hornsilver, and the surface ores are reported to have carried as high as 6,000 oz. to the ton. A stamp mill was erected in Ophir Canyon in 1871, and this was followed by several others as the mining industry progressed.

From 1870 to the present Ophir has been a steady producer. The rich surface ores were soon exhausted, but systematic development by organized mining companies soon brought to view rich carbonates and sulphide of lead accompanied by a high silver content and a small quantity of gold. In later years other metals have been profitably mined, copper, zinc, and manganese, but the lead-silver ores have always been the main source of revenue.

The district is credited with a gross production of from $35,000,000 to $50,000,000. Accurate records are not available, however, and it is probable that the lower figure is nearer correct. One mine alone, the Ophir Hill Consolidated, reported to the State Board of Equalization gross proceeds for 1918 of $840,668. This property, owned principally by Senator W. A. Clark, of Montana, has been a steady producer for a quarter of a century, and its claims under individual ownership yielded much rich silver ore in the earlier days. Among other mines in the district which have been highly productive are the Montana-Ophir, Hidden Treasure, Buckhorn, Lion Hill, Chloride Point, Northern Light, Buffalo, Jim Fisk, Kearsage, Eureka-Ophir, and Queen of the Hills. During recent years, consolidations have taken place, and the active mines at present are the Ophir Hill Consolidated, Montana-Ophir, Ophir Metals, and Hidden Treasure, together with a few of the older mines under lease.

With regard to smelters, Ophir is favorably situated. The International Smelting Co.'s lead and copper plant is only twenty-five miles by rail from Ophir; the Garfield smelter of the American Smelting & Refining Co. is forty miles distant. The American Smelting & Refining Co.'s Murray plant and the U. S. Smelting Co.'s Midvale plant are but sixty-five and seventy miles, by rail. A fair freight rate permits the mining of comparatively low-grade ore.

The Oquirrh Mountains form the most easterly of the series of north and south ridges lying in the Great



MAP SHOWING RELATIVE LOCATION OF OPHIR DISTRICT, UTAH, WITH RESPECT TO SALT LAKE VALLEY

Basin area between the Wasatch and the Sierra-Nevada ranges. They are separated from the Wasatch, about twenty miles distant, by the Salt Lake and Utah valleys. The Oquirrh Range extends from the south end of Great Salt Lake southerly for a distance of thirty miles. Here it is separated from the Tintic Range to the south by a broad pass. If the two ranges are considered as sections of a single range, which in reality they are, they will have a total length of seventy miles. The Oquirrh Range proper has a width of five to ten miles and its highest peaks reach an elevation of 11,000 ft.,

only 1,000 ft. less than the highest peaks in the Wasatch Mountains.

The Ophir district, unlike the Bingham district fifteen miles north, has developed practically no underground water. The mines are almost dry even to a vertical depth of 1,000 ft. As no development has taken place immediately under the floor of the canyon, it remains to be seen whether or not this area will develop water, but it is noteworthy that in diamond drilling to a vertical depth of over 1,200 ft., the holes appeared to be dry throughout and even the water that was pumped into the holes seldom reappeared at the surface.

Ophir Canyon is on the west side of the Oquirrh Range about six miles from its southern extremity. The general course of the canyon is southwest. Its floor is narrow, in some places scarcely the width of the wagon road and railroad track combined; in other places it is several hundred feet wide.

Ophir Hill rises on the north side of the canyon to a height of 2,500 ft. above the town. The south slope of this hill has the form of a great amphitheater with a semi-circular rim near the top of almost vertical cliffs. On the south side of the canyon Lion Hill rises as a great dome, nearly 2,000 ft. high. The north face of

LION HILL, OPHIR, UTAH

Lion Hill is very steep, owing to a series of vertical limestone cliffs 30 to 100 ft. high.

The Oquirrh Range is composed of Paleozoic quartzites, shales, and limestone, cut by stocks, dikes, and sills of various igneous rocks. The sedimentary rock has been subjected to intense folding and faulting. The average dip is northerly, but there are all variations from this, and it is difficult to follow any particular bed, even from one canyon to another. The limestones in some localities, notably in the Bingham district, have been considerably metamorphosed by contact with great masses of monzonite porphyry. In other localities, Ophir for example, much of the limestone is very pure. Other strata are either carbonaceous or dolomitic.

The rocks of the Ophir district consist almost entirely of limestone. The exceptions are two comparatively small exposures of Cambrian or pre-Cambrian quartzite on the south side of Ophir Canyon, several beds of shale at different horizons in the limestone, and a few intrusive dikes. The limestone consists of many varieties, ranging in color from white to black, in texture from very fine grain to very coarse grain; massive varieties, and thinly bedded varieties, beds of nearly pure calcium carbonate, and others running high in magnesium carbonate, but all differing materially in their paleontological character.

Unlike the Bingham district, Ophir exhibits only a scanty amount of igneous rock. Several narrow dikes, one of them outcropping prominently near the top of Ophir Hill, of a persilicic rock resembling rhyolite porphyry, and one narrow dike of subsilicic rock probably diabase, are the only intrusive rocks visible on Ophir Hill. The former stands nearly vertical and strikes north. It has no apparent genetic relationship to the orebodies. The basic dike follows one of the prominent northeast fissures and exhibits a small amount of ore along its walls. Owing to lack of development of this dike beyond a few shallow prospect holes, no conclusions can be reached as to the genetic relationship between the dike and the ore adjacent to it. Near the summit of Lion Hill, a broad dike accompanied by an intrusive sheet of porphyritic rock has caused a local silicification of the inclosing limestone. Some of the orebodies on Lion Hill are in this silicified zone, but they are likewise associated with northeast fissures. The basic dike noted on Ophir Hill crosses the canyon and is also found on Lion Hill.

The most striking geological feature of Ophir is the great anticlinal fold, which, on Lion Hill especially, is most remarkably developed. The axis of the anticline strikes N. 40 deg. W., and the two limbs dip to the northeast and southeast, respectively, in great sweeping curves. On Ophir Hill, the anticlinal axis dips at an average angle of 18 deg. to the northwest; on Lion Hill it is level for a short distance from the canyon, then gradually dips to the southeast. Thus, within an area two miles square, one may find dips in every direction, producing the structural feature called a quaquaversal fold. It is a noteworthy fact that nearly all the important mines of the Ophir district are on or close to the anticlinal axis. Folding has naturally caused considerable fracturing where the strain was greatest, but, as far as known, there are no deep-seated mineralized fissures conforming with the course of the axis; therefore, it is reasonable to conclude that the anticlinal axis, by virtue of its fractured and weakened condition, acted as a favorable receptacle for the deposition of ore brought to that region through other channels.

Only two unconformities of any importance exist in Ophir stratigraphy. One is at the contact of the quartzite and the overlying lime-shales and the other occurs at the top of the dolomite series. The former is the more interesting, inasmuch as it indicates that a long period of erosion occurred between the deposition of the quartzite and that of the shales. Before the latter were deposited, the quartzite had attained a very uneven surface. In some localities, the floors of the valleys were at least 300 ft. lower than the ridges. Consequently, as the shales were deposited, the valleys filled first, and some of the higher ridges still remained uncovered when the period of shale deposition gave place to that of the next higher formation. Owing to this uneven floor, there is a considerable variation in the thickness of the ore-bearing lime-shales.

Second in structural importance to the anticline is

the Ophir fault. This fault shows plainly near the base of Ophir Hill, and is the direct cause of the upthrow of that hill, exposing the Cambrian quartzite at the axis of the anticline. The fault strikes about N. 70 deg. E., and dips southerly at 65 to 70 deg. It is accompanied by several important and numerous unimportant sympathetic faults paralleling the main fault in a zone a thousand feet or more in width on either side. Until recently, it was thought that the displacement between Lion Hill and Ophir Hill was due to a single fault on which the displacement, represented by the difference in elevation between corresponding formations on the two hills, was 900 ft. However, recent diamond-drilling operations have proved the existence of other faults, and have shown that the maximum vertical displacement is nearer 1,700 ft., the most deeply faulted block being a narrow one, the top of which is completely covered by the gravel in the canyon. The fault can be traced for two miles in a westerly direction and nearly a mile to the east, but its point of maximum effect appears to be at the axis of the anticline.

Faulting Followed Ore Deposition

The consensus of opinion is that the entire fault system is post-mineral. The fault is unaccompanied by mineralization except in the vicinity of orebodies, and there it is much in the nature of drag ore. Diamond drilling by the Ophir Central Mines Co. on the south side of the canyon has proved the existence of ore deposits in the most deeply faulted block of ground in a lime-shale formation similar to that carrying ore on Ophir Hill, indicating that a continuity probably existed in the ore deposits under Ophir Hill and Lion Hill before the period of faulting.

The Ophir district is traversed by many northeast fissures. They strike from N. 20 deg. E. to N. 60 deg. E., and, with few exceptions, dip steeply west. A few of the important ones have yielded rich silver-lead ores, but in profitable quantity only where they cut certain limestone beds which have been more susceptible to replacement than other beds. These fissures are found at all depths, and are evidently the channels through which the metal-bearing solutions ascended. The typical gangue is calcite, although one prominent fissure has a quartz gangue. The fissures vary in width from a fraction of an inch in the hard formations to four or five feet in the softer ones. Faulting of considerable importance, in one case 200 ft., accompanies several of the fissures, though others show none whatever. In many places the gangue and ore of the fissures have been removed by the circulation of vadose waters, leaving open-air courses hundreds of feet in depth. Ore-bearing solutions passed from the fissures into the more "soluble" limestone beds, thus forming the bedded deposits which have been the source of 90 per cent of all the ore mined in this district.

Geology of District Given Scant Attention

The geological features of the Ophir district seem to have received scant attention from the U. S. Geological Survey. J. E. Spurr, in his valuable paper on the "Economic Geology of the Mercur Mining District," which appeared in the Sixteenth Annual Report of the U. S. Geological Survey, refers to the general geological features of the Ophir district. The Fortieth Parallel Survey, by Clarence King, also furnished some valuable information, but neither of these reports went into detail with regard to the various limestone formations. In recent years, greater importance has been attached to this phase of the subject in other mining districts, and the estimable report on the Tintic district by Lindgren and Loughlin, published a year ago, goes into great detail in this respect. These geologists have established a definite nomenclature to the more important formation represented in the Tintic district, comprising in the aggregate nearly 7,000 ft. of sedimentary rock.

In Ophir, however, no definite nomenclature has been established. The productive lime beds have been named after various mines and claims, but there seems to be

SURFACE WORKINGS IN OPHIR FORMATION. OPHIR, UTAH

a difference of opinion, even among local mining men, as to which is which. The "Henrietta limestone," for instance, is a name applied to a mass of limestone and shale having a stratigraphic thickness of 1,200 ft., and comprising several very distinct formations.

A geologist engaged in the study of the various sedimentary beds exposed in the mountain ranges of the Great Basin area is constantly impressed with the importance of having an established nomenclature with which to work. Of course, one would not expect to find every formation that is represented in one district also represented in another district 100 miles away, but if, as a basis of nomenclature, the various horizons in one locality, where the stratigraphic column is complete and definitely fixed, were accepted, investigators would be materially aided in their work elsewhere.

For my own convenience, I have attempted to correlate the Ophir sedimentaries with those in Tintic, applying the same names to similar formations. On close examination, a striking similarity appears. However, in the mineralized district of Ophir, that is, on Ophir Hill and Lion Hill and in the adjacent canyons, only 3,000 ft. of the Tintic sedimentaries above the quartzite are represented.

The oldest formation represented in Ophir is what I shall call the Tintic quartzite, about 400 ft. of which is exposed on the foot-wall side of the Ophir fault near the base of Ophir Hill. It has been correlated as a Cambrian formation by some geologists, and by others pre-Cambrian. Metamorphism has destroyed all fossils that the original sands may have contained. The quartzite has been brought to the surface by faulting and is exposed in only two places; namely, in two gulches located approximately in the axis of the anticline.

Lying unconformably upon the quartzite is the Ophir formation, consisting of an alternating series of shale

and limestone beds. The lower shale members are quite siliceous, whereas those near the top grade into an argillaceous limestone. The shale has a greenish tint on fresh fracture, due to the development by dynamic metamorphism of epidote and other aluminum silicates. The thickness of this formation varies widely from the narrowest trace to 300 ft.

Five Ore Horizons in Ophir Formation

The Ophir formation has furnished the bulk of the ore which has come from this district. It contains five ore horizons, which have been mined to a depth, on the incline, of nearly 2,000 ft. The ore is associated with northeast fissures cutting the formation. The superficial ores were rich in silver, but in depth they are principally in the form of argentiferous galena associated with sphalerite, chalcopyrite, and pyrite. The ratio of silver to lead varies from one-half to one to one to one. Copper sulphide ore, largely chalcopyrite, of excellent grade, is also mined in one horizon. Secondary enrichment is not particularly noticeable below the surface. It is probably the secondary zone that now shows at the surface, erosion having removed the original leached zone. Both chalcopyrite and galena, apparently in primary form, are found close to the surface.

There is no clear line of demarcation between the Ophir formation and the Teutonic Limestone. In a section taken at the anticlinal axis, the Teutonic has a thickness of 665 ft. It is bluish-gray, fine grained, thinly bedded argillaceous limestone. It is not known to be ore-bearing, but is a very distinct formation and is persistent in many localities in western Utah.

The Dagmar limestone rests conformably upon the Teutonic. In the section above referred to, it has a thickness of 125 ft. It can be distinguished readily from all other formations by its oölitic beds, of which there are several, varying from 3 to 8 ft. in thickness. They alternate with beds of an argillaceous limestone.

The Herkimer limestone which overlies the Dagmar includes at its base about 12 to 18 ft. of shale. The bulk of the formation, however, is a thin-bedded argillaceous limestone. The shale contains secondary silicates, and in a few localities a little pyrite and chalcopyrite. It is an excellent horizon marker. The Herkimer has a total thickness of 268 ft.

The next higher formation is the Blue Bird dolomite. One can never fail to identify this rock, as it is entirely different from anything else appearing in Ophir. The characteristic rock is of a dark gray, medium-grained crystalline texture, but interbedded with it are several layers of nearly pure white dolomite, having a sugar-like texture. A section of the Blue Bird dolomite on the anticlinal axis exhibits a total thickness of 690 ft., about 160 ft. of which is the aggregate thickness of three white dolomite beds occurring in the upper half of the formation. The Cole Canyon dolomite of the Tintic district is not represented in Ophir.

Above the Blue Bird there is a bed, 200 ft. thick, of gray, crystalline dolomite, above which lies a bed, 90 ft. thick, of dolomite similar in texture but darker in color. It resembles the lower part of the Opex dolomite in Tintic, but lacks the shale members of that formation.

A slight unconformity exists at the top of the dolomite series. It is more noticeable on Lion Hill, especially when viewed from a distance, than on Ophir Hill. None of the dolomites has been found ore-bearing.

Overlying the dolomites at Ophir is an important limestone bed which is apparently not represented in Tintic. It is locally called the Buckhorn. It is a fine to medium-grained rock, is nearly pure limestone, and has been the source of considerable ore. The average thickness is 30 ft.

Above the Buckhorn in Ophir appears the lowest of the cherty limestones. In Tintic the lowest of this type is called the Ajax, but aside from the cherty inclusions there is no similarity between them. I am inclined to place this formation in Ophir much higher in the series, correlating it with the Gardner dolomite of Tintic. In the southern part of the Ophir district, there occur siliceous beds at the base of this formation quite comparable to the Victoria quartzite which underlies the Gardner in Tintic. The lower part of the Gardner on Ophir Hill consists of a bed of magnesian limestone, 90 to 100 ft. thick, dark bluish-gray when fresh, but weathering a dirty brown. Higher in the Gardner formation the limestone becomes more massive. Fossils, including large brachiopods, are common at some horizons. The total thickness of the Gardner in Ophir is somewhat over 500 ft.

Overlying the Gardner, but with no distinct boundary separating them, lies what is called in Ophir the Hidden Treasure limestone. It might be considered as the upper part of the Gardner, but, on account of its value as an ore-bearing medium, it is advisable to give it a distinct name. It forms the summit of Ophir Hill, and several beds within the formation have been very productive of high-grade ore. It is a coarsely crystalline, rather soft, light gray to brownish limestone. The formation contains interbedded layers of thin dark-colored limestone similar to that in the Gardner and at least one bed of dense carbonaceous shale. The last is usually considered to be the hanging wall of the ore-bodies. Fossils of Mississippian age are abundant. Of this formation, 75 to 150 ft. is all that remains at the top of Ophir Hill.

Ophir and Tintic Columns Compared

The comparison of the Tintic column in the Lindgren and Loughlin memoir and the Ophir column from the author's notes shows a remarkable similarity for the first 2,300 ft. above the quartzite. Above that horizon, however, the Tintic column contains over 2,300 ft. of sedimentaries which are not represented in the Ophir column. The missing strata would indicate that there was either no deposition at Ophir between Upper Cambrian and Lower Carboniferous or else a long period of erosion preceded the sediments of the Lower Carboniferous.

The Ophir formation offers the greatest field for future development, but the upper productive limestones are of too great importance to be overlooked. It is possible that other ore zones will be found to the east of the developed anticlinal zone, just as in Tintic ore has been developed in depth several miles to the east of the synclinal trough. In fact, the existence of at least one mine, the old Jim Fisk, which produced very rich silver ore in the early days, is indicative of the fact that orebodies occur on the east limb of the anticline, nearly a mile from its axis. The ore in this mine occurred in fissures where they traversed one of the Hidden Treasure beds, and typifies how important certain limestone horizons are in the deposition of ore. Development work in this mine shows that where the same fissures passed into the underlying stratum they are insignificant.

Tin a Much-Maligned Metal

Some Elementary Facts for the Man Who Does Not Know What a "Tin Can" or a "Tin Lizzie" Is Made Of

By E. D. Ward
Written for *Engineering and Mining Journal*

OWING to the extremely loose use of the word there is probably no metal of which less is known by the man in the street than tin. Any metal container of food is referred to as a "tin" can, but the amount of actual tin in, say, "a tin" of sardines is about equal to a quarter of a dollar in weight. The "tin" popularly so-called is in reality made of thin sheet-iron coated with a solution of tin to prevent rust. "Tin" dishes and "tin" roofs are made of galvanized iron. Even the "tin" soldiers of our youth are made of lead. As a consequence of this mistaken nomenclature the word "tinny" has even been coined to signify a somewhat meretricious metal article.

Why tin should be maligned to this extent is difficult to understand: a "tin" can does not even closely resemble the metal whose name it has appropriated. Popular prejudice is admittedly a difficult matter to tilt against, but it is certainly due to a valuable and miscalled metal to give some account of its production and uses.

The chief tin-producing countries of the world are the Federated Malay States and the nearby Island of Banca, which annually export about one-half of the world's tin supply. Next in order come Bolivia and China, and among the smaller producing countries may be mentioned Siam, Nigeria, Australia and Great Britain. In the Federated Malay States tin is found as an ore in gravel, and all the workings are alluvial, with the exception of a few deep-cast mines. There are no underground workings. When the gravel has been washed thoroughly the resultant ore contains about 70 per cent pure tin, and the same percentage is, on the average, extracted when the ore is smelted, though exceptionally good lots may give 75 per cent or even higher.

Until comparatively recently the actual mining operations in the Federated Malay States were in the hands of the Chinese, the European merely acting as buyer of the ore. The primitive methods of washing adopted by the Chinaman naturally were wasteful. The mines are now gradually coming under British management, and are being worked and developed by more modern and scientific methods. In many places the old washings, or "tailings," as they are called, are being retreated for the recovery of the metal contained, with satisfactory results.

The actual mining of alluvial tin ore is simplicity itself. The ore-bearing gravel is mixed with water and led down a series of wooden troughs. In the bottom of these troughs are nailed slats of wood about an inch high. The ore, being heavier than the gravel, keeps to the bottom of the trough and is trapped by the slats, while the gravel is carried off by the water. The ore is then dried, placed in bags and sent off to be smelted. In some mines, particularly the more modern ones, the labor of digging the gravel is dispensed with by playing a powerful jet of water on to the face of the working, and guiding the wash thus obtained directly into the troughs.

Other minerals occur in tin ore, but rarely in sufficient quantities to be of commercial value: in fact, rather the reverse, for in that event the ore requires special treatment, such as roasting, to dispose of them. In this connection an illuminating story is told of a well-known smelting firm which before the war accidentally came into possession of a large quantity of wolfram ore. The firm reported the find to the British government and offered to sell at the market price of the day. The authorities loftily replied that they did not do business privately in that way and suggested that the ore be put up for public tender. It was, and was bought by a German firm at twice the market price!

At the smelting works the ore is mixed with anthracite and crushed slag and put through the furnaces. It is not possible to extract the full percentage of tin in one smelting, hence the addition of the slag—the residue of a previous smelting. When ready, the molten metal is run off into rough ingots, which are again smelted down in a refinery and ladled out into moulds for shipment, each block weighing about 130 lb.

If the metal containers of foodstuffs really were made of pure tin there would be reason indeed to complain of high prices. At present tin sells for about £269 per long ton; sheet iron for about £40. Tin plays a small but very important part in the composition of "tin" cans. It possesses the valuable property of being absolutely rustless and is therefore used as a barrier between the iron of which the container is made and the contents. When one thinks of the hundreds of millions of "tins" of bully beef, jam, pork and beans, M. & V. rations, and other necessaries and delicacies that were produced during the recent war it will be realized that tin "did its bit."

In the unenlightened past, before national economy became so essential, it was customary in Great Britain to throw away empty "tins," and special ships were employed to take large quantities out into the North Sea and dump them. Shortly before the war the Germans set up large foundries in England for dealing with this waste material. They perfected a process for recovering the actual tin, they melted off the solder and they pressed the iron into blocks, and then exported the whole lot to Germany! British enterprise is now at work, and the empty "tin" so carelessly thrown into the dustbin has by no means finished its usefulness.

Tin is also largely used in alloys. Stereos and type are composed of an alloy of tin, lead, and antimony. Pewter is an alloy of tin and lead, and most "white" metals usually have some proportion of tin in their composition.

As previously mentioned, tin is found in the British Isles, chiefly in Wales and Cornwall, but rarely in a free state, and its production is never likely to be a big commercial success in those districts, on account of the heavy working expenses. In the Federated Malay States, on the other hand, the industry has not yet been developed to anything like the fullest extent. In many places, particularly in the State of Perak, tin mining is superseding rubber planting. Labor is plentiful and cheap, the Chinaman is a good worker, water is abundant, and the smelting works are thoroughly up to date. In short, the industry has an assured and prosperous future.

The Cost of Mining as Influenced By Poor Development

Ultimate Expense Per Ton Increased by Hit-or-Miss Methods of Laying Out Workings — Money And Time Loss Through Unnecessary Footage of Drifts and Crosscuts Illustrated by a Concrete Example

BY A. G. WOLF

Written for *Engineering and Mining Journal*

MANY mines have been developed from small prospects into large properties, by the simple process of extending their workings in a hit-or-miss manner from the original discovery shaft or adit, resulting in a set of mine excavations that resemble in plan the labyrinthine openings of a big limestone cave. In some operations this is unavoidable, but where prospecting work and preliminary development have exposed the mineralized zone and the probable limits within which oreshoots are to be expected, the careful planning of development with the future operation of the mine in view may result in greatly increased profit. The best way to illustrate this is to give a concrete example.

In the mine used as an illustration, the ore had been formed by contact metamorphism. The oreshoots were of various sizes and irregularly spaced throughout a zone of fairly regular strike and dip. The strike of the zone was well marked on the surface, and, after certain preliminary development work and the completion of the main lower haulage tunnel, the dip was known. The major portion of the mine is now worked out, and produced say, 250,000 tons of ore during a period of thirty months. A study of the mine maps shows that instead of the winding, twisting and branching set of drifts and crosscuts that were driven, uniformly spaced parallel drifts along the zone and crosscuts at a certain regular interval would have exposed every pound of ore ultimately stoped, with a saving of 1,500 ft. in drifts and crosscuts.

The cost of this unnecessary development work applied to the tonnage of ore extracted amounted to about $0.065 per ton; not so serious taken alone, but many other factors affecting ultimate cost were involved. These are tabulated as follows:

FACTORS IN DEVELOPMENT AFFECTING ULTIMATE COST PER TON

1. Cost of extra footage driven.
2. Cost of extra equipment.
3. Cost of delay in supplying ore to reduction plant.

FACTORS IN ORE EXTRACTION AFFECTING ULTIMATE COST PER TON

4. Cost of straightening drifts and rounding turns.
5. Extra cost of inefficient tramming: Less tons per man-shift due to longer trams; interference; more wrecks; bad grades; more wear and tear on equipment; more lubrication.
6. Time lost by new men learning their way about crooked workings.
7. Cost of extra mine repairs.
8. Cost of lower efficiency due to poorer ventilation.
9. Extra overhead mine cost due to longer time to work out mine.
10. Extra overhead reduction-plant cost due to longer time to work out mine.

The factors listed above are discussed in detail as follows:

1. The cost of 1,500 ft. of excess drifts and crosscuts was estimated at $10 per ft., or $15,000. This included labor, general mine expense, and supplies except track, pipe, and lighting equipment.

2. The cost of equipment for extra footage is given in the following table:

COST OF EQUIPPING EXTRA DEVELOPMENT FOOTAGE

1,000 yd. 16-lb. tee rail at $3 per 100 lb	$480
1,500 ft. 2-in. air line at 20c. per ft.	300
1,500 ft. 1-in. water line at 10c. per ft.	150
750 ties at 12c.	90
Spikes, bolts, fishplates	50
Lighting equipment	30
Total	$1,100

3. As to delay in supplying ore to reduction plant, no loss of time in operation resulted in this particular instance, chargeable to the extra time required to do the unnecessary development work, because the reduction plant drew its ore supply from several mines. It can readily be seen, however, that any delay in operating the reduction plant would have increased greatly the interest, depreciation, and overhead charges, and hence the cost per ton of ore extracted and treated.

4. After the development work was done many drifts had to be strightened and sharp turns rounded to permit motor haulage and to make hand tramming reasonably efficient. No actual figures of the cost of this work are now at hand, but a conservative estimate based on intimate acquaintance with the mine operations is $1,000.

5. The actual cost of hand tramming is known. This could have been materially reduced by planning the drifts and crosscuts in the first place. The drifts should have been reasonably straight and the crosscuts parallel to each other and at such an angle with the drifts that an easy turn could have been made in going in one direction from the crosscuts into the drifts. This would have resulted in greater tonnage per trammer-shift, owing to shorter trams, less interference of cars going in opposite directions, better grades, fewer wrecks on account of fewer curves, frogs, and switches, and lower cost of materials, as there would have been less wear and tear on the cars and less lubrication would have been needed. There must also be taken into account an indefinite but important factor, namely, the difference in spirit with which a man works when he has an easy tram and when he has a hard one. What the total saving under this heading would have been can only be estimated. After a careful consideration of the various factors, it is my belief that 25 per cent could have been cut from the cost of hand tramming. The total cost of this operation from the stopes alone was $42,750; hence at least $10,687 would have been saved.

6. The labor turnover was high, machinemen, machinemen helpers, trammers, and shovelers having to be replaced about once a month. The average time lost or "killed" by new men in finding the working places in the crooked mine openings was easily one-half shift per man per month more than it would have been if the plan of the mine had looked less like a labyrinth of

classic antiquity. The total payroll represented by such labor, taking into account heading No. 5, was $138,370. There was incurred, then, a loss of one-sixtieth of $138,370 or $2,306.

7. The actual cost of mine repairs is known, and in this particular operation was quite low, especially as little timber was required. It is conservative to estimate, however, that $2 per day could have been cut from these repairs during the working time. As the tonnage under consideration was extracted in thirty months, there is an indicated saving of $1,800.

8. As all ventilation was by natural draft, aside from the blowing out of workings with compressed air from the drilling lines, no direct comparison of costs can be made, but it is certain that ventilation was poorer in the irregularly developed mine than it would have been had the mine been opened along the lines suggested. One set of drifts and raises could have been used for direct air courses and another set for return air courses. Poorer ventilation meant loss of efficiency, which actually influenced the cost of mining, although it cannot be shown here in dollars and cents.

9. To arrive at definite figures regarding the extra cost per ton of ore mined owing to slower operations, an assumption must first be made as to the percentage of the whole period of ore extraction that could have been saved by properly planned development work. After taking all factors into consideration, and knowing the mine, I believe that 10 per cent of the total time consumed in ore extraction could have been saved. There was, therefore, a loss amounting to 10 per cent of the overhead mine charges during this thirty-month period. Those monthly charges not already considered are given in the following table:

OVERHEAD MINE CHARGES PER MONTH

Superintendence	$250
Shift bossing	450
Engineering and clerical	300
Compressor operation	325
Tool sharpening and blacksmithing	440
Watching	90
Rock crushing	225
Nipping	90
Aerial tramway operation	900
Power	300
Total	$3,370

The 10 per cent loss, then, for the thirty-month period, expressed in dollars, was $10,110.

10. As to increased overhead cost of the reduction plant, it has already been stated that in this instance the plant did not depend upon this mine alone for its ore supply, so that no extra treatment charge per ton of ore would be made against the mine on account of the daily tonnage being smaller than that which could have been shipped. However, if the mine had been the only source of supply, this greater overhead charge at the reduction plant would have been serious.

The total extra cost of mining caused by the poorly planned development work follows:

TOTAL EXTRA COST OF MINING DUE TO POOR PLANNING

Extra development	$15,000
Extra equipment	1,100
Delay in supply of ore to plant	Nil
Straightening drifts	1,000
Cost of tramming	10,687
Time lost by new men	2,306
Extra mine repairs	1,800
Loss of efficiency due to poor ventilation	Not estimated
Greater mine overhead charges	10,110
Greater plant overhead charges	Nil
Total	$42,003

This is equivalent to $0.168 per ton, assuming the tonnage mined and treated to have been 250,000 during the thirty-month period.

It is realized that the above example is not applicable to the majority of mines, but there are many to which it will apply. With a present labor cost 50 per cent greater than that noted, and with a charge included for extra mill overhead costs due to slower production, the extra cost per ton of ore mined and treated as shown above might easily be doubled. A moderate exercise of foresight in planning mine development and in computing the overhead costs of administration and practical operation may be worth thousands of dollars. The success of the property may depend upon it.

Geology and Ore Deposits of Jerome District, Arizona*

Arizona stands pre-eminent as a copper-producing state. In 1918, it produced four-tenths of the total amount produced in the United States. The production of the Jerome district gives it the sixth place among the copper-producing camps of the United States and third among those of Arizona, being surpassed by Bisbee and Globe-Miami. Two mines furnish the entire output of the district—the United Verde and United Verde Extension. The United Verde is 2,500 ft. deep and has blocked out a large reserve of massive sulphides. The United Verde possesses one of the largest known bodies of high-grade chalcocite ore.

The oldest known rocks of the Jerome district are a series of pre-Cambrian volcanics, with later sedimentary beds. Subsequent to the formation of these rocks, they were squeezed into close folds, with strikes from east to north-northeast, and this deformation was followed by the intrusion of masses of quartz-porphyry. This porphyry was subsequently rendered schistose in limited zones; and masses of diorite were afterward intruded. Still later came the ore-deposition. In the later part of the mineralization diorite dikes were intruded along east-west lines.

All these events were pre-Cambrian, according to Dr. Reber. Later came Cambrian sandstone (100 ft.); then Devonian limestones, (300 to 500 ft.), Carboniferous limestones (300 to 500 ft.) and Permian red shale and sandstone (0 to 500 ft.). There was no further rock formation till the late Tertiary, when basaltic lavas were poured out. Still later came a period of profound normal faulting.

All the orebodies are highly pyritic, and pyrite predominates. Chalcopyrite and pyrite seems to have been the chief primary copper mineral. The primary sulphides carry also gold and silver. The orebodies have formed by replacement of schist. Among the other primary minerals are bornite, tetrahedrite, sphalerite, galena, and specularite; also calcite and dolomite, and quartz, especially of a jaspery variety.

Structurally, the United Verde mineralization has been determined by a steeply pitching inverted trough of relatively impervious rocks, indicating ascending solutions, which are assumed to be of magmatic origin. The igneous body most closely related to the mineralizing solutions is believed to be the Bradshaw granite, with which are associated similar schist-replacement copper orebodies south of Jerome. All the other pre-Cambrian intrusions mentioned, together with the Bradshaw granite, may be regarded as related to a single period of batholithic intrusion.

*Abstract of paper by Dr. L. E. Reber, Jr., presented at Lake Superior meeting of the A. I. M. E., August, 1920. Abstract by J. E. Spurr.

Ball-Mill Tests on Missouri Lead Ore*

Variations in Speed and Ball Load Found To Be of Comparatively Minor Importance — Open-Discharge Cylindrical Mill With Large Balls Found Best Adapted for Securing a Product With Minimum of Slime

SOME interesting crushing tests were made in the Bonne Terre mill of the St. Joseph Lead Co. in 1916. The ore occurs as widely scattered deposits of galena disseminated through limestone. For the tests, material through 9-mm. and on 2-mm. round hole screens was used, an average screen analysis being about as follows: On 3 mesh, 3 per cent; on 4 m., 12; on 6 m., 17; on 8 m., 26; on 10 m., 25; on 14-m., 12; and through 14 mesh, 4 per cent. The mills used were a 6-ft. x 22-in. Hardinge mill, and a 6 x 4-ft. Allis-Chalmers ball granulator, both with and without grates.

The capacity of the ball mills and the nature of the product were considered to be governed chiefly by the following factors: Speed of rotation, weight of ball charge, nature and size of balls, moisture in feed, and rate of feed. Slime in the product was not desired.

Speed and Ball Load

The speed and ball load directly determine the power consumed. Within certain limits, variations in speed did not give a marked difference in the work done, but the tests in this direction were not extensive, nor the results conclusive. Apparently, not much variation was experienced between the limits of 420 to 490 ft. per min. peripheral speed for the cylindrical mill, and between 450 and 550 ft. per min., for the Hardinge.

Variations in the ball load also were found to be of comparatively minor importance. A heavy ball load consumed more power, but gave higher capacity, up to the point where the balls discharged through the trunnion, and the amount of crushing done per horsepower remained practically the same. Table I shows the combinations of speed and ball load that were found to give the best results.

TABLE I. SPEEDS AND BALL CHARGES

	6 ft. by 22 in. Hardinge Mill	6 by 4 ft. Allis-Chalmers Peripheral-Discharge	6 by 4 ft. Allis-Chalmers, Open Trunnion
Speed, revolutions per minute	28	23	26
Weight of balls, pounds	10,000	12,000	12,000
Horsepower	51 6	62 5	69 0

Size of Balls

The size of balls is important in determining the nature of the product. Balls of 5-in. diameter are necessary to crush the coarse ore. Small balls increase the slime in the product. During the earlier tests, when cast-iron balls were used, considerable trouble was experienced by the breaking up of the balls, until the charge consisted largely of very small pieces of 1-in. diameter or less. Samples taken from day to day during this period showed a gradual increase of oversize and in the amount of slime. The cast-iron balls were therefore replaced by steel balls from 5 to 2 in. in diameter. Various combinations of these sizes were used, and the highest capacity and lowest slime were obtained with a charge containing a large proportion of 5-in. balls. The charge now used is calculated to give an equal area in each size, a 12,000-lb. charge being made up of 5,460 lb. 5-in. balls, 4,040 lb. 4-in. balls, and 2,500 lb. of 2½-in. balls. New balls to make up for normal consumption are added weekly in the same ratio of sizes as the original charge; this practice has given satisfactory results.

Moisture Content

The moisture content of the material crushed affected the results mainly in the very fine sizes. A low moisture content increased largely the amount of slime in the product, without materially decreasing the amount of 10-mesh oversize. In the case of the peripheral-discharge mill, the difference is not so marked, but in all cases it has been found better to sacrifice a little capacity in order to obtain a product with low slime content. An average of 60 per cent moisture is, therefore, maintained in regular operation.

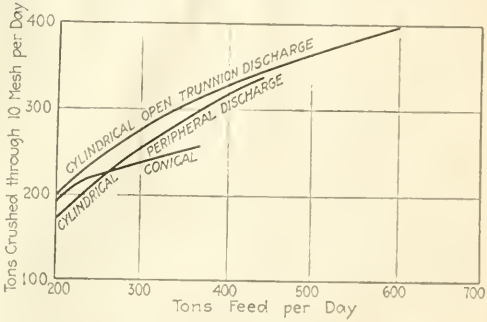


FIG. 1. EFFECT OF RATE OF FEED ON CAPACITY

TABLE II. MOISTURE TESTS ON HARDINGE MILL

	Test 1	Test 2
Tons feed per day	240 0	190 0
Per cent moisture	65 8	48 1
Horsepower	51 6	51 6
Capacity: Tons through 10 mesh	216 0	181 0
Tons through 10-mesh per hp.	4 18	3 51
Per cent slime in 10-mesh undersize	23 8	57 7

Rate of Feed

The effect of rate of feed is shown in Figs. 1 and 2, where the capacity and per cent of slime are plotted against the tons of feed per day, the moisture remaining constant at 60 per cent. The limits of the curves in each case represent the greatest tonnage that could be forced through the mills and maintained for any length of time. In the case of the peripheral-discharge mill, the tonnage was limited by the fact that when the 10-mesh oversize amounted to more than 25 per cent of the total, the mill began to fill and finally choked. With the open-end mills, a higher rate of feed was possible, giving a much greater capacity. This was one of the main factors that led to the adoption of the open-discharge cylindrical mill. Fig. 1 shows that the maximum capacity of this mill is 390 tons crushed to pass through a 10-mesh screen, against 340 tons for the peripheral-discharge mill, and 255 tons for the conical mill. By passing a very heavy tonnage through the mill,

*From a paper written for the Lake Superior meeting of the A. I. M. E., Aug. 23-28, 1920, "Application of Ball Mills in Southeast Missouri," by Lewis A. Delano and Harold Rabling.

the relative amount of slime is decreased considerably, as shown in Fig. 2; therefore, it is considered best to crowd the mill with a heavy tonnage having a high moisture content and to pass this through the mill rapidly, returning a large amount of oversize. This method of operation also decreases the ball and liner consumption by preventing undue wear of metal on metal.

Table III shows a comparison of the three types of ball mills, with the conditions under which best results were obtained, and the maximum capacity of each mill. The results shown were obtained under closer supervi-

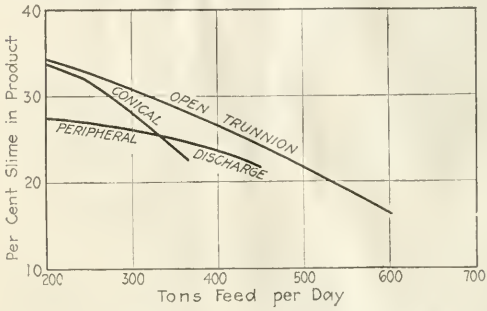

FIG. 2. EFFECT OF RATE OF FEED ON SLIME

sion than is possible in regular operation and which could not normally be maintained. In Table IV is shown an average condition at a normal operating rate, one that gives a product containing from 20 to 25 per cent of 10-mesh oversize for each mill, and has been found

TABLE III. OPERATING CONDITIONS AND MAXIMUM CAPACITY OF BALL MILLS

	Hardinge Mill	Allis-Chalmers Peripheral-Discharge Mill	Allis-Chalmers Open Trunnion Mill
Speed, revolutions per minute	28	23	26
Weight of balls, lb.	10,000	12,000	12,000
Size of balls, in.	4-2½	5-4-2½	5-4-2½
Material of balls	Steel	Steel	Steel
Tons of feed per day	320.0	450.0	600.0
Per cent moisture	59.3	59.5	60.0
Horsepower consumed	51.6	62.5	69.0
Delays, per cent time	1.41(*a*)	6.44	0.70(*b*)
Capacity, tons through 10 mesh	2.55	3.40	3.90
Tons through 10 mesh per hp.	4.93	5.45	5.65
Per cent slime in product	22.7	21.88	17.0

(*a*) Percentage delay on account of feeders breaking off, 1.35; other causes, 0.06.
(*b*) Percentage delay on account of gears, shafts, and countershaft bearings, 0.55; other causes, 0.15.

to be most satisfactory in every way. Under these conditions, the Allis-Chalmers open-discharge mill has the highest capacity, and shows the best ratio of tons crushed per horsepower. Examination of the products of each mill shows that the Hardinge mill produces more slime lead than the cylindrical type, and that the peripheral-discharge type gives a good product containing a larger amount of granular galena than either of

TABLE IV. NORMAL CAPACITY OF BALL MILLS

	Hardinge Mill	Allis-Chalmers Peripheral-Discharge Mill	Allis-Chalmers Open Trunnion Mill
Tons of feed per day	300.0	375.0	450.0
Per cent moisture	60.0	60.0	60.0
Horsepower	51.6	62.5	69.0
Capacity, tons through 10-mesh	237.0	305.0	345.0
Tons through 10-mesh per h.p.	4.60	4.88	5.00
Per cent slime in product	28.2	24.2	24.1

the others. However, mechanical troubles and delays were so great and the capacity was so limited by the grates that it was considered better to use the open-trunnion mills, which were installed in all sections of the Bonne Terre mill.

Krupp Mills vs. Rolls for 10-Mesh Grinding

Tests in Bolivia Showed Latter With Newaygo Screens To Be Preferred Equipment—Rolls Cut Costs But Product Not as Fine

FINE grinding is ordinarily done in the presence of water, but occasionally metallurgists are confronted with the problem of grinding to approximately 10-mesh in the dry condition. For this purpose, rolls or ball mills of the Krupp type are commonly used. In a paper prepared for the Lake Superior meeting of the A. I. M. E., entitled "Roasting and Chloridizing Bolivian Silver-Tin Ores," M. G. F. Söhnlein describes how the ore was ground for the chloridizing roast. Originally, Mr. Söhnlein says, No. 4 Krupp ball mills were used, but they were replaced by two pairs of 36 x 12-in. rolls. The rolls did the work for less than one-third of the cost of the ball mills, but gave a distinctly coarser product, which decreased the furnace capacity considerably. Therefore, a Toncap wire cloth of only 0.85-mm. opening was used on the finishing screen instead of one with 1.2-mm. opening on the ball mills, to obtain a product that was suitable for the furnaces. The first rolls were set with a ¾-in. opening, and their product went to a trommel with ⅜-in. openings, the oversize being returned to the coarse rolls and the undersize going to the finishing trommel, which was 42 in. in diameter and 12 ft. long. The last trommel was operated in closed circuit with the finishing roll.

Afterward, a ring-roll mill was installed to do the work of the fine rolls and a 6 x 8-ft. Newaygo screen was used instead of the trommel. Although with this arrangement the product was as fine as that from the ball mills and the capacity higher than from the roll plant, it was not found economical, on account of the high power and steel consumption of the ring-roll mill, which also showed other weak points in construction after having been used for some time. Now the rolls are again used, but with a Newaygo screen instead of the finishing trommel. Although the product is not quite as fine as that from either ball mills or ring-roll mill, it is sufficiently fine for the purpose. The cloth on the Newaygo screen, which is a No. 8 with 0.078-in. opening, lasts over two months, and the screw conveyor which distributes the ore evenly over the screen surface has a life of about seventy-five days. Power consumption is 11.8 hp.-hr. per ton ground from 2 in. maximum size to about 1 mm., and steel consumption is 0.38 lb. per ton.

SCREEN TESTS OF BALL-MILL AND ROLL PRODUCTS

Mesh	Krupp Ball Mill 1.2-Mm. Toncap Wire Cloth, per Cent	Rolls with 0.85-Mm. Trommel, per Cent	Rolls with Newaygo Separator, No. 8 Cloth, 1.9-Mm. Opening, Per Cent	Roughing Rolls and Ring-Roll Mill with Newaygo Separator No. 6 Cloth, 3.0-Mm. Opening, per Cent
On 10	3.0	0.0	1.5	4.0
On 20	17.0	19.0	16.0	24.5
On 40	24.0	31.5	19.5	20.0
On 60	8.5	11.0	23.0	5.5
On 80	7.0	10.0	8.0	4.0
On 100	5.0	5.5	5.5	6.5
On 150	3.5	4.5	4.5	9.0
Through 150	32.0	18.5	22.0	26.5
	100.0	100.0	100.0	100.0

Selecting a Slag and Apportioning Slag Losses

Detailed Method of Calculating Slag and Matte Composition From a Given Charge—Various Means of Charging for the Copper Loss—Advantages of Basing It on Iron Contents of Slag

By C. A. Grabill*
Written for *Engineering and Mining Journal*

THREE general conditions may exist in a given smelting works: That condition or circumstance in which the available ore will produce approximately an ideal slag, and under which, consequently, no fluxes will be required; that in which an excess of bases is present; and that in which there is an excess of siliceous ores, lime and iron fluxes being required. The last of these three is the most common, and as a schedule can be based on only one condition at a time, a definite example of that kind will be taken to make the method of cost calculation clear.

Assume that the materials available are: *A*, an oxidized siliceous ore from the smelting company's mine, forming the basis of operations; *B*, a sulphide flux available in the market at $9 per ton delivered at the smelter; *C*, limestone from a neighboring quarry costing $2 per ton delivered; *D*, an iron ore from a small near-by mine; and, *E*, a custom ore available if required.

The coke will be assumed as average quality with 20 per cent ash, the analysis of which is given below. Costs will be assumed to be as follows: Coke, $10 per ton; smelting, 10 per cent coke, $1; fixed expense, including overhead, $1; variable expense, $1; semi-variable expense, $1; total, $4. These figures are of course arbitrary.

The marketing expense of copper will be taken as 2.5c., made up of freight, 0.5c.; converting, 0.5c.; refining, 1.25c.; and selling commission and overhead, 0.25c. The market price will be assumed at 22.5c., leaving the works value 20c. per lb. of copper. The market price of silver will be assumed to be $1.26 per oz., with a marketing expense of 1c. per oz.

Obviously, no roasting or sintering will be required, and it is also assumed that all ores and fluxes will take the same treatment, so that the above smelting expense is applicable to all components of the charge in accordance with their tonnage.

The assumed analyses are as follows:

Ore	Silver, Oz. per Ton	Copper, per Cent	SiO_2, per Cent	Fe, per Cent	CaO, per Cent	Zn, per Cent	Al_2O_3, per Cent	S, per Cent
A	20 0	3 0	50 0	10 0	18 0	1 0	4 0	1 0
B	1.0	1 0	4 0	48 0		2 0		44 0
C			2 0		54 0		1 0	
D			4 0	65 0			2 0	
E	80.0		80 0	5 0		1 0	2 0	6 0
Coke ash			50 0	15 0	2 0		25 0	

To simplify calculations, gold assays have been omitted.

Because most of the smelters operating with excess silica use a slag containing about 42 per cent SiO_2, and find 36 per cent Cu in the matte a fairly satisfactory amount, it will be assumed that the copper losses will follow the curve in Fig. 4,[1] and 42 per cent SiO_2 will be taken for the standard slag. There is no particular reason for this, other than that it is convenient, and 41 or 43 would do just as well.

Slags do not vary by steps, as the theory of type slags would require, but gradually. Similarly, 36 per cent matte works well in the converters, is high enough to retain its collecting power, and low enough to prevent excessive losses. A slight variation each way does not make much difference, because of the compensating action of its diversified effects.

TABLE I. CALCULATION OF CHARGE

Material	Amount	Ag		Cu		SiO_2	Fe		CaO		Al_2O_3		S	
	Lb	Assay	Oz.	%	Lb.	%	Lb.	%	Lb.	%	Lb.	%	Lb.	%	Lb.
A	620	20.0	6.20	3.0	18 6	50.0	310.0	10 0	62 0	18 0	111.6	4 0	24 8	1 0	6 2
B	180	1.0	0.09	1.0	1.8	4.0	7.2	48 0	86.4					44 0	79 2
C	200					2.0	4 0			54 0	108 0	1 0	2 0		
Coke	(100)					10.0	10.0	3 0	3 0	0 4	0 4	5 0	5 0		
Total	1,000		6.29		20 4		331.2		151.4		220 0		31 8		85 4

85.4 × 0.15 ÷ 0.25 = 51.24 = Wt. of Matte
20.4 − 2.10 = 18.30 = Wt. of Cu in Matte
18.30 ÷ 51.24 = 35.6 = % of Cu in Matte
51.24 × 0.34 = 17.4 = Wt. of Fe in Matte
151.4 − 17.4 = 134.0 = Wt. of Fe in Slag
134.0 × 1.287 = 172.3 = Equivalent FeO

Slag Content:	Lb.	%
SiO_2	331.2	42.1
FeO	172.3	21.9
CaO	220.0	27.95
Al_2O_3	31.8	4.05
Miscellaneous	31.7	4.00
Total	787.0	100.00

20.4 − 18.3 = 2.1 lb. Cu in slag = 0.267%
Or, Cu in slag (from Fig. 2) = 0.267%
From Fig. 3, Ag in slag = 0.82 oz. per ton and Ag in matte = 2.33 oz. per ton

Slag loss: Ag, 5.1%; Cu, 10.3%
Cu loss per ton of charge, 4.2 lb.
Cu loss per ton of slag, 5.34 lb.
Cu loss per lb. FeO in slag, 0.01218 lb.
Cu loss per lb. Fe in slag, 0.01567 lb.
Cu loss per unit of Fe in slag, 0.3135 lb.
1 lb. Cu in matte requires 0.95 lb. Fe

Slag Ratios

$$\frac{FeO}{SiO_2} = 0.52 \qquad \frac{Fe}{SiO_2} = 0.4046$$

$$\frac{CaO}{SiO_2} = 0.664 \qquad \frac{FeO + CaO}{SiO_2} = 1.185$$

$$\frac{S \text{ in charge}}{Cu \text{ in matte}} = 4.66$$

Method of Calculating Furnace Products

The results of the calculation on this basis are shown in Table I. The procedure is to set down the weights of the proposed components of the charge and their constituents, and add up the total of each element as indicated. The total weight of sulphur is then multiplied by 0.15 (the assumed recovery of sulphur) and divided by 0.25 (the amount of sulphur in the ordinary

*The second of a series of three articles on the calculation of copper blast-furnace charges and costs. The first article was published in the Sept. 11, 1920, issue of *Engineering and Mining Journal*.

[1]See p. 512 in the Sept. 11, 1920, issue of *Engineering and Mining Journal*.

matte), and the result is the weight of matte that will be produced by the charge. Knowing this, and the amount of copper on the charge, it is easy to make a guess at the grade of matte and the slag loss. Deducting the copper lost in the slag from the copper charged, and dividing the result by the number of pounds of matte made, gives the grade of matte. Knowing this, the iron in the matte is calculated easily.

In this instance the sulphur, iron, and copper contents of the matte are assumed to total 95 per cent. In practice the iron would be determined from a plot showing the iron contents of average mattes of different grades under the works conditions, or else allowances would be made for the zinc and lead contents, if required.

The iron in the matte is deducted from the total iron charged and the remainder calculated to FeO. The silica plus FeO plus CaO plus Al_2O_3 are assumed to be 96 per cent of the total slag, or whatever experience dictates. If present in sufficient quantities, zinc, barium,

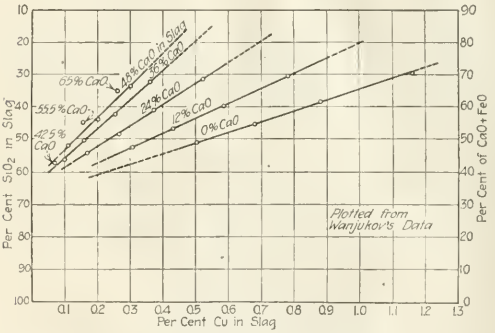

FIG. 7. RELATION BETWEEN SLAG COMPOSITION AND COPPER ASSAY OF SLAG FOR 30 PER CENT Cu MATTE

and magnesia would be included and suitable totals taken. These figures give the total weight of slag, and referring to Fig. 4 for the copper assay corresponding to the grade of matte, the slag loss is calculated. If the guesses have been good, nothing remains to be done, but if the results do not check, the calculation must be repeated. The second result should be correct. The silica, iron, and lime percentage is calculated; the silver loss, using Curve *A* of Fig. 5*, and all the other data are shown in the table.

For furnace work, many of these refinements would be omitted, because changes in ore and furnace conditions outweigh them. The course of procedure in 75 per cent of the charges put in the furnace is to look at the slag reports, the matte assays, the stockpile, and the furnaces, and, if necessary, add 10 kilos of sulphide flux and cut the limestone 20, or whatever seems to be required. But in working out the principles on which these short-cuts are based, the long elaborate procedure is usually strictly necessary, and all the refinements available should be considered, whether used or not.

The slag calculated is a little high in lime, and therefore its use is supposed to be somewhat dangerous. But it is similar to one I once used for several months, and, from the assumption, iron flux is expensive, and so the slag will be taken as a basis for the other calculations. In actual operation, the slag losses in both copper and silver did not conform to the curves in Fig. 4 and *A* of Fig. 5, owing to certain local conditions.

With this slag as a starting point it becomes possible to ascertain the value of its component fluxes and to calculate the cost of fluxing and smelting an ore of any given analysis, provided that this grade of matte, and a slag with this silica content, are used.

Because the capacity of the plant does not enter into the question at this point, the cost of smelting a ton of neutral ore will be assumed to be the total cost, that is, $4 per ton. The simplest method of calculating the cost of smelting a ton of ore *A* will be, taking the data from Table I:

Smelting 620 lb. ore *A* at $4 per ton	$1.24
200 lb. limestone, at $2 per ton	.20
180 lb. sulphide flux at $9 (less credit for 20 lb. Cu per ton at 20c., and 95 per cent of 1 oz. of Ag	.34
Smelting 380 lb. flux at $4	.76
Copper loss, 2.1 lb. at 20c	.42
Total for smelting and fluxing 620 lb.	$2 96
Cost of smelting and fluxing one ton	$9 55

This is entirely correct, so far as it goes, but it does not go far enough and will not enable one to calculate the cost of the ore, if the silica changes, without recasting the whole charge sheet. Neither does it permit of ready valuation of a new ore, or supply the basis of a tariff to guide the mine superintendent.

Apparently the cheapest source of flux is the limestone; so the first thing is to ascertain the cost of a unit of CaO.

Limestone, one ton	$2 00
Smelting, one ton	4.00
2 units of SiO_2 require 0.81 unit Fe at 24.39c.	.20
Fluxing coke ash (10 per cent coke, 20 per cent ash)	12
54 units CaO less 1.33 for the 2 per cent SiO_2 cost	$6 32
1 unit CaO costs	12.00c.

The use of iron for fluxing the SiO_2 in the limestone is assumed because the slag in this case is so high in lime that it would not be advisable to increase it; therefore, all silica must be charged with the corresponding amount of iron for fluxing.

The cost of the iron and fluxing the coke ash must be estimated until determined. If the guess is wrong, correction must be made. In practice, the cost of fluxing the coke ash would be charged to the cost of coke.

The cost of a unit of iron is determined in the same manner:

Cost of one ton of sulphide flux	$9 00	
Smelting one ton	4.00	
Fluxing coke ash for one ton	.12	
4 units of SiO_2 require 2.66 units CaO at 12	.32	
Copper loss of 0.3135 lb. per unit of Fe. 48 units Fe = 15.05 lb. (Cu at 20c.)	3.01	
Credit for 1 unit = 20 lb. (Cu at 20c.)		$4.00
Credit for 1 oz. silver, 95 per cent, at 1.25		1.19
Iron required for matte for 4.95 lb. Cu recovered at 24.39c. per unit Fe	.06	
Credit for overcharge for copper loss in last item		.01
	$16 51	$5 20
	5 20	
48 units Fe less 1.62 for 4 per cent of SiO_2 cost	$11 31	
1 unit of Fe costs	24 39c.	

The silver loss has been taken up in the conventional way, at 5 per cent, but this is not correct, as will be shown.

No credit has been allowed for sulphur, because its computation is a rather complicated matter and is generally considered separately. However, this value will be determined later and it will be shown that it has a big effect on the iron value, and that the method of calculating here indicated is correct only in instances where an oxidized iron ore is required for flux; it is,

*See page 513 of the Sept. 11, 1920, issue of *Engineering and Mining Journal*.

therefore, not correct in this instance. However, it would be correct if the sulphur were in ore *A* and not in *B*. I have used the method as shown so as to give an example in which sulphur does not enter the question, and then to show the big difference to be noted when it must be considered. If, in this case, the sulphur were in the ore *A* and not in *B*, still *B* would have to be used as a source of iron, and the above calculation would be correct. Therefore that assumption will be made for the present.

Methods of Charging for Copper Loss

The method used of charging for the copper loss is unusual, but is the nearest approach to accuracy that is practicable. Several methods may be suggested, but, if the results do not agree, not more than one can be correct; it is of importance to know which to use. The most obvious method is to consider all the copper in the slag as derived from the principal ore, and this would be reasonable in some instances; but suppose there are two principal ores, one silver-bearing without copper, and the other copper without silver? Another method is to apportion the loss, calculating it in pounds per ton of charge and distributing the loss to all ores and fluxes in accordance with their weight. This is a simple method, both in practice and thinking. (See *B*, Table II.)

Suppose that the company bought an old slag dump, and that the regular ore was a mixture of gypsum, hydrated ferrous carbonate, and silicates with combined water. In the first case a ton of charge would make a ton of slag, and in the other, a ton of charge might make less than half a ton of slag. I have before me the analysis of an ore containing only about 46 per cent of slag-forming elements. Nor is this question purely hypothetical. If the smelter slag contains 0.45 per cent Cu, which is not uncommon, the loss will be, at the present price of copper, about $1.80 per ton of slag, and it may be a question of getting or losing a contract whether the ore is charged with half or all of this, or the difference averaged.

Another method would be to apportion the losses on the percentage basis. (See *C*, Table II.) This does not allow for the effect of the ore on the slag losses. Or, the losses may be charged in proportion to the slag-forming constituents. The objection is that one ore might be a self-fluxing ferrous silicate which would have a very foul slag, and the other ore might be a garnet ore, high in lime, giving a clean slag. The use of silica as a base for the apportionment is open to the same objection. (See *D*, Table II.)

The method which I have adopted is to base the losses on the iron contents of the slag. This has its objections also, but they are less than those incident to the others, and the principle is of much broader application. (See *A*, Table II.) For example: It is common in smelter practice to keep the silica constant and to vary the proportions of iron and lime. There are many reasons for this. Reference to Fig. 1 will show that a great difference exists between the amounts of copper dissolved in iron slags and in lime slags; practice bears this out. The last method allows for this effect in calculating losses, not only qualitatively but quantitatively, with a fair degree of accuracy, at least within the range of ordinary smelting practice. The curves in Figs. 7 and 8 show this. Fig. 7 is plotted directly from the data given by Wanjukov. Fig. 8 is plotted from Fig. 7 by interpolation on the curves drawn to connect the points located by Wanjukov's data. The effect of the iron on the copper loss may seem to vary too much to use a fixed ratio, but if the line *AB* is drawn on Fig. 8, the composition of the slags lying below it will be found not practicable for actual use.

The amount of Cu loss per pound Fe is determined by dividing the copper loss as shown in Table I by the

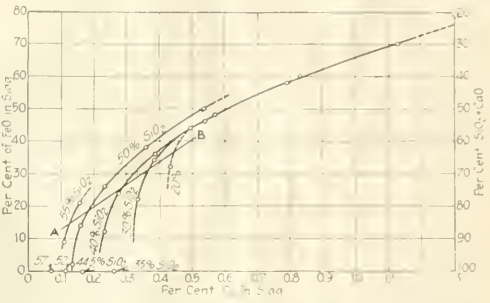

FIG. 8. INTERPOLATED CURVES FROM FIG. 7 SHOWING RELATION OF SLAG COMPOSITION TO COPPER CONTENT

Fe contents of the slag. Multiplying the result by 20 gives the loss per unit of Fe. Of course, this applies only within the definite limits.

Having determined the cost of the iron and lime the cost of fluxing a unit of silica is easily found.

1 unit of SiO_2 requires 0.664 unit CaO at 12.0c.	7 97c
1 unit of SiO_2 requires 0.4046 unit Fe at 24.39c	9 87c
Cost of fluxing 1 unit of SiO_2	17 84c

The cost of smelting a ton of pure quartz would be:

Cost of fluxing 1 ton of SiO_2 (100 units)	$17 84
Cost of smelting 1 ton	4 00
Fluxing ash in coke	12
Total	$21 96

The cost of fluxing the coke ash can also be determined:

50 units of SiO_2 at 17.84c	$8 92	
Copper loss due to Fe; 15 units at 0.3135 lb. per unit = 4.7 lb Cu at 20c	94	
Credit for 15 units of Fe at 24.39c		$3 66
Credit for 2 units of CaO at 12.0c		24
	$9 86	$3 90
	3 90	
Cost of fluxing 1 ton of ash	$5 96	

The cost per one ton of charge would be 20 per cent of 10 per cent of the $5.96, or 12c. The cost of smelting the ore would be:

Smelting 1 ton	$4 00	
Fluxing coke ash for one ton	12	
50 units of SiO_2 at 17.84c	8 92	
Cu loss due to 10 units of Fe at 0.3135 lb. = 3.135 lb. at 20c	63	
Credit for 10 units Fe at 24.39c		$2 44
Credit for 18 units CaO at 12c		2 16
Iron for the matte: 56.85 lb. Cu = 2.7 units Fe at 24.39c	66	
Credit for overcharge for copper loss in the Fe going into the matte		17
Total	$14 33	$4 77
	4 77	
Cost of smelting and fluxing 1 ton ore	$9 56	

That the importance of the correct apportionment of the losses be thoroughly understood, I have calculated the cost of silica, iron, and lime by the methods mentioned above and compared them in Table II.

TABLE II. COST BY DIFFERENT METHODS OF CALCULATION

Cost of	*A*	*B*	*C*	*D*
1 ton limestone	$6 32	$7 04	$6 27	$6 32
1 unit of CaO	12 0c	13 36c	11 90c	12 0c
1 ton of silicate flux	$11 31	$9 24	$8 83	$8 51
1 unit of Fe	24 39c	19 92	19 03c	18 83c
Fluxing 1 unit of SiO_2	17 84c	16 95c	15 61c	17 81
Smelting 1 ton of pure SiO_2	$21 96	$21 07	$19 73	$21 93

Method *A* is the method recommended above, charging the copper losses against the iron in the slag.

Method *B* is based on a uniform distribution of the loss in proportion to the tonnage, 4.2 lb. per ton in this case.

Method *C* proportions the copper loss on the percentage basis. In this case it is 10.4 per cent of the copper in the ore.

Method *D* is based on the distribution in accordance with the silica contents of the material charged, 12.68 lb. of copper per ton of silica.

The amounts are all taken from Table I.

It is obvious that something is wrong. A smelter operating on a profit of $1 per ton of ore would have a difficult time if the metallurgist could not calculate the costs within $2.80 per ton. A little consideration will aid in discarding the bad methods.

Substitution of Iron Ore for Limestone

Take method *B* first: So far the sulphur contents of these ores have been assumed to lie in ore *A*, not in the flux *B*. This can be done without throwing things out of balance. Assume, also, that the sulphide flux contains enough silver to make the cost of a unit of FeO equal to that of a unit of CaO. It is then clear that for fluxing purposes the iron ore may be substituted completely for the limestone without throwing the metal losses out of balance if method *B* be used. Doing this would produce an irony slag with much less lime and it would consequently be a fouler slag. The first method allows for this. The same reasoning would apply for the other two methods if the iron flux contained no copper. Method *A* covers the point in all cases.

A method which would be correct for every condition that may arise is, of course, impossible of conception or contrivance. Data are lacking, and the formula would be too cumbersome for general use. The best course is to follow medical practice and "diagnose by exclusion," until a method suited to the case is found, but it must constantly be borne in mind that all conclusions should be carefully tested. The lead pencil is a wonderful little instrument, but will lie like Ananias if not closely watched.

Exports of Mineral Products from Burma

The exports of minerals from Burma during the last three years were as follows:

Articles	1917 Tons	1918 Tons	1919 Tons
Wolfram:			
Foreign	4,542	4,744	4,799
Tin:			
Foreign	214	300	371
India	15	116	190
Pig lead:			
Foreign	10,351	10,569	9,223
India	2,813	5,824	8,708
Zinc:			
Foreign	3,198	2	.....
India	33	14	.....
Silver:			
India	(a)	(b) 1,653,000	(b) 1,973,00

a No statistics before 1917 18. b Ounces.

There was an increase in the quantity of nearly every kind of mineral exported, but the fall in the price of some minerals has prevented a corresponding increase in value. Since the close of the period covered by this report the price of wolfram has taken a great drop, and exports of this metal will undoubtedly be considerably smaller, both in quantity and in value, in the following year.

Phosphate Rock in the United States*

The principal deposits of phosphate rock in the United States are in Florida, South Carolina, Tennessee, Kentucky, Arkansas, Montana, Idaho, Wyoming, and Utah. Although by far the largest deposits are in the Western states, those deposits yield less than 1 per cent of the whole, because of the lack of a large near-by market and high freight rates on the crude rock. It is not a matter of common knowledge, but it is, nevertheless, a fact, that the Western rock-phosphate deposits are so extensive as to be practically inexhaustible, even if the entire world were dependent on them for its supply of phosphate.

The Florida phosphate deposits, which are the most extensively developed in the United States, comprise three classes of phosphate—hard rock, land pebble, and river pebble. The first is highest grade, the second is produced in largest quantity, and the third is not mined at present. The hard-rock deposits lie in a narrow strip along the western part of the Florida peninsula from Suwanee County to Pasco County, a distance of approximately 100 miles. The land-pebble phosphate area, just east of Tampa, is about 30 miles long and 10 miles wide. Sales of Florida phosphate declined tremendously after 1913 through the restriction on exports by the war. In 1913 the sales were 2,500,000 tons, valued at $9,500,000, and in 1915 the production was 1,350,000 tons, valued at $3,700,000.

South Carolina produces land-rock phosphate in the vicinity of Charleston. River-pebble phosphate occurs in the same area, but is not mined. Some of the South Carolina output has been exported annually. Sales decreased from 169,000 tons in 1911 to 83,000 in 1915, and the value in the same years decreased from $673,000 to $311,000.

RESERVES OF PHOSPHATE ROCK IN THE UNITED STATES

	Long Tons
Florida	227,000,000
Tennessee	88,000,000
South Carolina	9,000,000
Kentucky	1,000,000
Arkansas	20,000,000
	345,000,000
Western States:	
Montana, Idaho Utah and Wyoming	5,367,082,000
Total	5,712,082,000

Tennessee deposits of rock phosphate are in the west-central part and extreme northeast corner of the state. The latter have not been mined. Three types are recognized and known by their colors as brown, blue, and white rock. The last has not been mined recently. The brown rock is sold under guarantee of 70 to 80 per cent tricalcium phosphate. The blue rock varies considerably in its phosphatic content. Sales of Tennessee phosphate in 1914 were 483,000 tons, valued at $1,823,000; by 1915 they had fallen to 390,000, valued at $1,328,000.

Kentucky has been an insignificant producer of phosphate rock in recent years. Arkansas phosphate deposits are in the north-central part of the state. The output is small.

Four Western states possess enormous deposits of high-grade rock phosphate, but their output is as yet insignificant, being only 3,000 to 5,000 tons a year. The producing states are Idaho, Utah, and Wyoming. Montana is not a producer, although it contains extensive deposits easy of access and close to rail transportation.

*R. W. Stone in "Political and Commercial Geology," McGraw-Hill Book Co., 1920.

A Picturesque Mining Experience—IV

The Bear Facts

By CHARLES HALEY
Written for *Engineering and Mining Journal*

IN THE summer of 1916, Charles Janin, assisted by me, made a placer examination in the Little Delta region, in Alaska. The trip itself was mainly interesting on the Fairbanks end, so there is where my story begins.

After a delay of a tiresome week in Fairbanks, our deputed guide and conductor—who will have to be nameless, because most of the names we had for him would not look well in print—said that a car would be waiting for us in the morning. As matters turned out, he was wrong—we were waiting for it. About 10 o'clock it finally flivvered up on three lungs in front of the hotel. Besides the driver, there were four and a half of us in the car, one member of the party weighing over three hundred.

It had rained the night before, and the road was improbable before we were a mile out; beyond that it rapidly became impossible; and before we arrived at Eighteen Mile House it was beyond belief. We squattered past a team about two miles out; and later had to get it to pull us through. The flivver itself was a tribute to the great pacifist who designed it; like him, it was shy on power, but willing to take an awful lot of knocks. Whenever it stuck its nose in the road and refused to budge, we would pile out, hunt up a pole and a root for a fulcrum and our heavyweight friend with one foot would pry it up to a normal position. You could tell by the noise of the three operating cylinders when it was ready to die, and forestall the final agony most every time: "I think I can; I think—I can; I—think—I can; I—know—I—can't."

Anyway, we arrived at Eighteen Mile roadhouse about 3 o'clock and had lunch. From there on, the road was better, and we made Munson's roadhouse, on the Salchaket, in time for dinner, with Fairbanks forty miles away. We stopped and fought mosquitoes for about twelve hours, after which period of rest and refreshment we snorted forth again.

Arriving at the turn-off of the winter trail, the car gave up the ghost, and we had to pack our belongings to Martin's roadhouse, about two miles and two hundred million mosquitoes away. This roadhouse is on the wrong side of the Tanana, and we had to be ferried across by Archie. He, with the possible exception of our chaperon, was the most unusual institution of the entire trip. Before he made the landing, we were impressed by the fluency and weight of his verbiage; and as we stayed for nearly three days, we had a magnificent chance for observation. Two of his leading observations, "The cur-r-rse of Cain rest on yez all," and "be the bald-headed mother of Judas," were used as a foundation for a most startling structure of cusswords. When he locked horns over a small matter with our local Fremont, and woke us up at 3 o'clock in the morning to tell us about it, we thought him little short of sublime; it was worth being wakened for.

We finally managed to make our getaway to the property. The original idea, too original, as it proved, was to take a team and wagon all the way up the Delta River to the property, supposed to be a distance of about thirty miles. As it worked out, the trip was made by pack animal; but not until we had wasted the first day in attempting to cut through about half the stunted firs and young birch and alder growth in central Alaska. Our team unfortunately was not arboreal of habit, so we gave up the attempt after the first day and returned to Martin's with our faith in our self-appointed Nestor sadly shaken by this and other breaks too numerous to mention.

We managed to pick up a real guide—henceforth known as Frank—and decided to make the trip with what animals we had. This meant that one horse had to carry a pack, while the other was divided between us for riding purposes. A little providential inspection of the grub supply prevented us from setting forth with half a case of condensed milk and half a pound of bacon on what afterward proved to be a three-day journey; and, much to the disgruntlement of our pathfinder, we insisted on a few more of the luxuries of life. As the trip turned out to be about fifty miles, with very little trail and some 30 per cent grades to negotiate, our respect for his judgment was not enhanced from day to day.

We saw quite a bit of game—three moose, a caribou, and a black bear—on the way up, and were quite disgusted that none of them would pose for his picture. Arriving at Portage Creek on the morning of the third day, in the midst of a driving rain, our eyes were cheered by a collection of canvas doghouses wherein we lived until the examination was completed. This operation concluded, we decided to return under Frank's care, leaving our cicerone on the claim. He had the only gun of the party, so we set out weaponless.

About four or five miles on the homeward trail, we saw a bunch of mountain sheep; too far away to shoot even if we had had a weapon. And then came the main excitement, in fact, it might be called the big tent show of the entire trip. It was nearly lunch time, and we had both been discussing how hungry we were. We were traveling along the edge of a basin which we were due to cross within a couple of miles and into which the ground sloped precipitously off from the bluff on which we were. On the other side was a long gentle slope into a series of gullies at the head of Iowa Creek. Down one of these gullies we saw three animals which we at first took for caribou at the distance—about a mile.

Going over a little closer, with the idea of sizing them up for a picture, they caught sight of us. They immediately began running, not away, but toward us, with real speed, and we saw that they were either glacier bear or silvertip grizzly. We did not stop to ascertain which, but beat it for all we were worth. Clumsy and lumbering as they were, and bigger than all outdoors, they were gaining on us about four for one, and we knew pretty well what it meant if they ever caught up with us. We had one short knife and an axe in the pack, and those bear meant business. We forgot all about taking pictures and being hungry, and ran for our lives. Fortunately the horses did not see them, or they would have bolted.

The ground favored us; for while the bear were charging up the middle of the gully, we went out of sight over the top of the next draw. Coming to the top of the draw where we had been, they saw us again, and turned after us. By this time we had come to the top of the next bridge, and dropped down out of sight. Soon we came to where our trail went down into the basin, and we kept behind a ridge which hid us from them. We didn't stop for lunch until nearly 4 o'clock, and then we didn't feel so awfully hungry.

With the good start we had, we concluded to keep on going to Martin's, and we traveled the better part of the night, arriving early in the morning. After a couple of hours' sleep and a good breakfast, Archie ferried us across the river again. His usual string of objurgations was intensified, as the Tanana was rather high, and neither his rowlocks nor his steersman—who happened to be myself—was working to his fancy.

Followed two mosquito-ridden miles to Birch Lake roadhouse. Here we caught the stage in for Fairbanks, and bumped our beatific way toward civilization and the Arcade restaurant.

Copper a Hundred Years Ago

Price Range at That Time Not Essentially Different From That Obtaining Now—No American Market for Ore

RECENTLY we were asked as to the price of copper 100 years ago. This did not seem an unreasonable query, but the oldest member of our staff could not remember, and we were unable to find the information in any of the reference books to which we customarily resort in such cases. The inquirer has, however, rooted out the information, and we are publishing it as a matter of record. Our own copper production did not reach 100 tons yearly until 1845, so British prices for this period are standard.

PRICE OF COPPER IN ENGLAND FROM 1800 TO 1831*

Years	Average Standard Price per Long Ton £	s.	d.	Equivalent Cents per Lb. (£1 = $4.86)
1800	133	3	6	29
1801	117	5	0	25
1802	110	18	0	24
1803	122	0	0	26
1804	138	5	0	30
1805	169	16	0	37
1806	138	5	0	30
1807	120	0	0	26
1808	100	7	0	22
1809	143	12	0	31
1810	132	5	0	29
1811	120	12	0	26
1812	111	0	0	24
1813	115	7	0	25
1814	130	12	0	28
1815	117	16	0	26
1816	98	13	0	21
1817	108	10	0	23
1818	134	15	0	29
1819	127	10	0	28
1820	113	15	0	25
1821	103	0	0	22
1822	104	0	0	23
1823	109	18	0	24
1824	110	0	0	24
1825	124	4	0	27
1826	123	3	0	27
1827	106	1	0	23
1828	112	7	0	24
1829	109	14	0	24
1830	106	5	0	23
1831	100	0	0	22

The price in those days, it will be observed, was not much different from what it is now, although we presume that a dozen eggs could have been purchased for 5d; so copper probably seemed high. The mines in Cornwall gradually increased their ore production from about 56,000 long tons in 1800 to 144,000 in 1831. The ore was rich, too—7 to 10 per cent copper.

Some other statistics taken from "History of Money and Prices," 1896, by J. Schoenhof, go even further back:

PRICES OF IRON AND OTHER METALS FROM THE CLOSE OF THE SEVENTEENTH CENTURY

(In English Shillings)

	1693 to 1702	1784 to 1790	1791 to 1803	1804 to 1819	1821 to 1838	1848 to 1852
English pig iron, per long ton.	240	70 @ 120	103 @ 157	140 @ 180	114 @ 120	41 ...
Finished iron (in bond), per long ton.....	....	268	364	298 @ 380	308 @ 380	119 ....
Copper per 112 lb.....	99	80	93	143	91	87

More recent statistics covering copper prices from 1860 to 1912 were published in the *Engineering and Mining Journal* of Dec. 6, 1913.

Although saying little about prices, the following letter may prove of interest while our thoughts are in the dim and distant past:

Manchester, Eng. June 4th, 1788.

Dear Cousin John:—

We received your letter of inquiry about the mine north of Rockey Hill, N. J., U. S. A. We opened this mine in the year 1748. We worked it along up to the indepents war then Washington came to New Brunswick, then his soldiers came to the mine and ordered our men to surrender. I was there at the time our men all came out of the mine. there was a little fight between six solgers and eighteen of our miners of the solgers was killed and several of them hurt.

I will never return to America again.

I will give you a description of the mine.

The west shaft is over one hundred feet deep. We mined many hundred tons of copper ore and sent it home to Ingland, and we sold it for seventy dollars a ton on an average.

There is two large floors in this shaft. sometimes the vane is fore or five foot wide and again it narrows to one foot then widens out again to 4 or 5 foot. this is a very rich vane of copper, there is a shaft east a little north of the above shaft which is about one hundred and fifty feet distance which has a large vane of black copper in it. We worked both shafts. We left our tools in the mine. If you should get the mine will you let me know.

Yours Affectionately,

Good By (Signed) J. G. George

The account of the battle between the "solgers" and miners is no worse than a great many others which we have read.

Armenian Mineral Wealth

The Department of Mines of the Armenian Republic, in a report on the minerals of that country, states that Armenia was the cradle of metallurgy, and that there are hundreds of abandoned mines in the country, and numerous ruins of forges and foundries. The mining industry of Russian Armenia is represented by twenty-two copper-ore, rock-salt, and iron-pyrites enterprises, eighteen of which exploit old mine workings. There are seven copper smelters. The average annual production during the years 1911, 1912, and 1913 was 154,900 tons of copper ore, 10,000 tons of iron pyrites, and 6,614 tons of copper metal. The Russian-Armenian production of copper before the war was 26 per cent of the total production of Russia.

*From M'Cullock's "Practical, Theoretical and Historical Dictionary of Commerce and Commercial Navigation"; 1847. Vol. 1, p. 481.

Men of Note in the Mining Industry

Colonel William Boyce Thompson

A RECITAL of the achievements of William Boyce Thompson suggests a composite biography of several great men. How could one man do so much before his fifty-second year? The answer is simple—work. This explanation is like that of the prestidigitator who says, "Ladies and gentlemen, the quickness of the hand deceives the eye," and leaves his audience as mystified as before. "The outstanding characteristic of Colonel Thompson," said one of his intimates, "is his capacity for work. His evenings are usually spent on work of some kind." With this recipe, therefore, for reaching the top, the young aspirant may go his way, bearing in mind that what is meant is the kind of work that gets results of the right kind. There it is in a nutshell. And the results? Colonel Thompson is to be credited with the success of Inspiration, Magma, and Nevada Consolidated, of which no mining man need be told. Less well known is the fact that he was mainly responsible for daylight saving, having put Senator Calder up to this parsimonious piece of business in the first place. His title of colonel dates from the war, when he was commissioned a lieutenant colonel and sent to Russia as a member of the Red Cross Commission, of which he later became head. He had been actively backing the Belgian Relief work before this, and it was through his efforts that the Rocky Mountain Club, of which he was vice-president, postponed the erection of a costly clubhouse, that the funds might be used to aid war sufferers abroad.

COLONEL WILLIAM BOYCE THOMPSON

New York's prominent men, more often than not, were born outside of the city. Some of them came originally from Brooklyn and other Eastern points. Thompson comes from Montana. To go back to the beginning, he was born in Virginia City, in that state, in 1869, his father having followed prospecting, mining, and lumbering on his own account. His education was received at Phillips Exeter, in New Hampshire, and at the Columbia School of Mines. Then came a few years of knocking about his native state, in which he learned more of the ins and outs of mining. At the age of twenty-nine he headed again for the metropolis, determined to sit in the big game. He came with little cash and lots of nerve, and before long his ability as an organizer was evident. When the Utah Copper project was launched, Thompson, believing in D. C. Jackling, backed his faith with money and reaped a corresponding reward. His ability was signally recognized by the metropolitan business interests, when, in 1914, he was elected a director of the Federal Reserve Bank of New York. From this position he resigned last December, upon his appointment as chairman of the ways and means committee of the National Republican Committee. He is also president of the Roosevelt Memorial Association. Colonel Thompson's schemes are big. Nothing else seems to attract him. One of the more recent ones, of which comparatively little has been published, is the mineral exploration work in China which engineers representing him have undertaken. Another project, now under way, is the prospecting and development of the huge Flin Flon ore deposit, in northern Manitoba, in which he is engaged, together with his associates. In all his dealings he will have facts and not theories, and goes to heavy expense, if necessary, to determine them. On this trait undoubtedly rests his success. Two P's, patience and persistence, are said to be his mottoes, and in his successful handling of the Inspiration project these characteristics may readily be discerned.

Although Colonel Thompson has amassed great wealth, this has not been his object. Apparently it is the fun of playing the game, rather than the reward, that attracts him. Having brought Inspiration to successful production, he disposed of the property to Anaconda.

He has given largely. While in Russia he dug heavily into his own fortune to combat the German propaganda that was designed to draw that country from the war. His interests aside from business are varied. He is seen now as a collector of minerals, now as an exhibitor at the flower show. He belongs to several clubs. All things considered, Colonel Thompson gets a great deal out of life.

BY THE WAY

A Chance for the Reno Station

A map in process of being made, which shows the occurrences of minerals in the United States, has been submitted to the U. S. Geological Survey, with the request that it be criticized, particularly as to "the occurrences of alimony and manganese." At the Survey it is stated that neither its field researches nor statistical inquiries have been expanded to cover the subject of alimony, although during the war period they did considerable work in determining the extent of the nation's antimony deposits.

Anybody Lose This?

"Yellville, Ark.—Gus Young, an ore buyer and real estate man of this place, found the remains of a fragment of a meteror several days ago near the Winchester mine on the Buffalo River in Searcy County. He and Tobe Woods, a lawyer residing at Marshall, Ark., were going through the woods when his attention was attracted to a burned area some six feet in circumference. Upon examination he saw a strange stone lying buried to a depth of six inches in the center of this area, and upon picking it up found it to be a fragment of a meteror. The fragment resembles a big cinder, much the same as are taken from base burners, with the exception that it is highly glazed on the surface and some iron can still be seen in its composition. In bringing it home it became broken in three parts. When first discovered it was 18 in. long, 8 in. in circumference at the head, and tapered to a tail."

Put to the Test

C. C. Norton, president of the Jazz Cat Oil Co., is going to wash his hands completely of W. E. Stephens, according to the *Verde Copper News*, unless the latter immediately disproves the charge that his "vibratile motion instrument" is a fake when it comes to testing for the presence of oil. Unless he does this forthwith, Mr. Stephens is going to lose the golden opportunity of testing the Verde Valley, in Arizona, for oil for the Jazz Cat company. "Stephens must present some positive proofs or we shall have nothing to do with him," says Mr. Norton. So there, Mr. Stephens, get busy with that vibratile motion instrument of yours.

Why Boys Leave Home

Down in the Oklahoma and Kansas sections of the Joplin-Miami zinc and lead district many of the mining men live either in Joplin or Miami and, finding it inconvenient to go home every day, spend all but the week-end at the mine. Idle time in the evenings has naturally led to various diversions, including the indoor national game, mostly at a small limit. A stranger in the district, however, who had heard interesting tales about these evening games, had occasion not long ago to visit a mine office in the Kansas section, northwest of Picher, in the evening, and found seven of the boys seated around a table. Much to his astonishment, however, he found that they were playing pitch a nickel on the "corner." "First thing you know you boys will get to be gamblers," he commented, whereat there were protestations from the players that they were only passing the time away. About a week later the same visitor had occasion to visit the same office and again found the same boys gathered around the table, pasteboards in hand. He expected to find that the stakes had been raised decidedly, having had some experience in such things. Instead he found that the game of pitch and the regulation playing cards had been eliminated entirely, and the boys were playing "Rook" and entirely for the fun of it, not a cent being ventured. While he was there one of the leading players, the ground boss at the property, threw down his cards and quit, declaring: "I've got to cut this out; it's growing on me. First thing I know I won't want to do anything else." And he withdrew from the game.

Nothing But the Truth

This story looks too open-faced to be new, yet is told in sober earnestness by an Arizona mining engineer: A party of sightseers had been taken, of an evening, into one of the mines at Globe, Ariz. As the visitors were being hoisted, one of the ladies exclaimed: "It has been a wonderful trip. I feel that we should come again in daylight, when we can see things so much better."

It Is Hard To Please

The following letter was sent to us from Chile by a company that had received it from a disgruntled prospector. We find it quite idiomatic:

In regards to that telegram of 15th I thought i would receive somcthing of that sort, Because I dident like the way that Man you call an Engineer took Samples he dident go into the Earth he Scratched on top like a hen Now? you or any entelegant man ought to know when water hits gold it will part from anything but the solid rock on those Veines is exposed to the Sun the Rock will Powder he took only on the very top the *peones* or me was to take samples we would go at least one to two meters in depth, him no on the very top of the earth. As to my crosscut I wanted to go one meter in depth he said he dident have time nor money enough what do you think of that he took what I was cleaning off to find the *guier*[1] and said that was enough the *peones* laughed at him & said tbat wasant nothing atall but he was paying the men so I couldant say any thing we cleaned off the *guier* with a bar no wedges nor a hammer we just got the hole cleaned out that isant no time to take samples. You have to open up the work you cant pick up gold on the floor of the hole he was only 3 days on the mine where he ought to have been at least 15 days; I AM NOT AT TALL PLEASED WITH HIS WORK ATALL It isant Justes for you or me. I like Engineer tall slim man I dont know his name a man about 45 years of age that man knows his business; but this other has been in the air to much[2] to know much a bout Gold mines he says let me have the pan I am going to the river to get samples what do you think he brought back it was colores he said it was Pure Sand OXIDE OF IRON stain he calls it gold color the man must be simple Simon I can figuer the Compy Out. I am going out to the mine & get some samples for you that you will be proud of all that stoughf he took i would be a shamed to get souch stough i would expect to get fired at once; or say I dident get to the mine i took sick or something because he had good *guier* I will say that much But i gave him that myself when you find good *guier* you will find good Gold that is Rich *guier* but the gold you cant expect to get gold on the hanging wall do you no nor any body else I want Justes as you do neither one has yet got Justes, hoping to here from you soon.

Respectfully Yours, C. MURPHY.

[1]The word *"guier"* above should be spelled *"guia,"* which is Spanish for "stringer" or "veinlet."

[2]The reference to the engineer having been too much in the air probably is related to the fact that he was in the U. S. Air Service during the war.

CONSULTATION

U. S. Platinum Deposits and Production

"Are there any mines regularly producing platinum in the United States, or is the metal purely a byproduct in the recovery of other metals? I realize that the domestic production is very small."

Crude platinum in 1919 was produced mainly by the gold dredges operating along the foothills of the Sierra Nevada as a byproduct from gold recovery. The total United States production was estimated by the U. S. Geological Survey at 824 troy ounces, a record production in recent years, in spite of its relative smallness, and the largest output since 1906, which was 1,439 oz. Domestic production in 1913, 1914, 1915, 1916, 1917 and 1918, was 483, 570, 742, 750, 605, and 647 oz., respectively. Most of the 1919 output came from California, but Boss Mine, Clark County, Nev., produced some platinum- and palladium-bearing copper ore, which was shipped to Eastern refiners for treatment. The Rambler Mine, Albany County, Wyo., also made a recovery of platinum and palladium from similar ore. The Salt Chuck mine, in Kasaan, Alaska, described in a previous issue of the *Engineering and Mining Journal*, was a producer of very rich ore.

As to other localities which are potential platinum-producing areas and which have produced in the past, there might be mentioned the placer gold fields of Butte, Yuba, Calaveras, and Stanislaus counties, Cal., where the platinum is derived mainly from the Mother Lode country's serpentine areas. Other platiniferous localities are in Nevada County, and in the Klamath Mountains in Trinity, Siskiyou, Humboldt and Del Norte counties.

In southwestern Oregon, the stream placer deposits of Josephine, Curry and Coos counties have been known to carry platinum. Beach placers in Curry and Coos counties have produced some of this metal. The Blue Mountains of northeastern Oregon, in Grant and Baker counties, have been sources, particularly near Sumpter. Utah and Washington have also reported the discovery of platinum, but the production has been unimportant.

The Customs Tariff on Metals

"Will you please inform me what the duties on the metals copper, lead, zinc, nickel, quicksilver, and antimony are?"

The customs duties on these metals, according to the Customs Tariff Act of 1913, are as follows:

Copper in ores, matte, bars, ingots, pigs, regulus, plates, scrap and composition metal is admitted duty free. Manufactured copper forms carry a duty of from 5 to 20 per cent.

Lead ores command a duty of ¾c. per lb. of lead contained. Lead in bars, pigs, granules, bullion, alloys, iron, hard metal, old scrap lead, and refuse (lead content taxable) commands a duty of 25 per cent. Lead pipes, sheets, shot and wire, white lead (dry or in oil), and red lead also carry the same duty.

Zinc slabs, blocks or pigs and old zinc suitable only for remanufacture, 15 per cent duty; zinc-bearing ores (on zinc content) 15 per cent; zinc dust, sheets not polished or plated, 15 per cent; zinc oxide, 10 per cent.

Nickel in ore, matte, or other crude form, free; nickel in alloys, pigs, plates, ingots, bars, and oxide, 10 per cent; nickel in sheets and strips, 20 per cent.

Quicksilver commands a duty of 10 per cent.

Antimony ore is admitted free; metal and regulus, 10 per cent; antimonial type metal, 25 per cent; antimony containing 10 per cent lead, 10 per cent.

Lead Mining and Refining Companies

"I have been trying to secure the addresses of the lead companies in the United States that are both miners and refiners of lead, and have been referred to you for the information. I will be very grateful if you can have the addresses sent me or tell me where I will be able to secure them."

Lead companies in the United States that are both miners and refiners of lead are given in the following list:

American Smelting & Refining Co., 120 Broadway, New York. (Subsidiary companies all over the United States.)

American Metal Co., 61 Broadway, New York. (Has several subsidiary companies.)

Bunker Hill & Sullivan Mining & Concentrating Co., 1,022 Crocker Building, San Francisco. (Smelting company is a subsidiary.)

St. Joseph Lead Co., 61 Broadway, New York.

Anaconda Copper Mining Co., 42 Broadway, New York. (Controls subsidiary lead companies.)

U. S. Smelting & Refining Co., 120 Broadway, New York. (Controls subsidiary lead companies.)

Eagle-Picher Lead Co., Joplin, Mo.

American Zinc, Lead & Smelting Co., 55 Congress St., Boston, Mass. (Controls a subsidiary lead company.)

Northport Smelting & Refining Co., Northport, Wash. (Controlled by Hercules Mining Co., in Burke, Idaho, and Tamarack & Custer Mining Co., Wallace, Idaho. The bullion is refined by the Pennsylvania Smelting & Refining Co. at Pittsburgh.)

National Lead Co., 111 Broadway, New York. (Controls a subsidiary.)

Geophone Manufacturers

"In referring to your article "Military Mining in France," in *Engineering and Mining Journal* of March 6, 1920, showing in the frontispiece a soldier using the geophone, kindly let me know where in the United States I can get a geophone and what would be the price of it."

The instrument is finding increasing commercial application, which supplements its chief use in rescue work in underground mining operations. Thus the geophone has been successfully used in detecting leaks in water mains and locating underground water courses. The manufacturers claim that knocks in automobile valves and cylinders have also been located with the aid of the instrument. An important use in mining work for which the geophone is peculiarly adapted is checking underground surveys designed to connect drifts, raises, and other workings.

The Globe Phone Manufacturing Co., of Reading, Mass., manufactures the instrument and can furnish prices for the different styles.

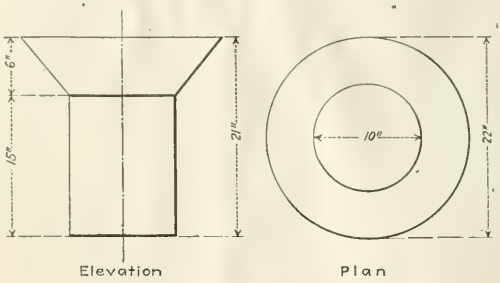
HANDY KNOWLEDGE

Another Method of "Holding the Sack"

By LEROY A. PALMER

Written for *Engineering and Mining Journal*

I was much interested in the description of a device for holding a sack while filling it with ore which appeared in a recent issue of the *Engineering and Mining Journal*, but the type of funnel shown in the accompanying sketch, which is the design of one used for sacking concentrate at the Plymouth Consolidated mine, in Amador County, Cal., in my opinion, has it beaten.



FUNNEL FOR FILLING SACKS

Dimensions may be varied, of course. Those shown give the cylindrical portion a capacity of 100 lb. of ore which weighs 4,000 lb. per cu.yd. when broken.

In use, the sack is slipped over the funnel and the latter is stood on the floor, when the sack naturally slips down over the cylindrical part and rests on the floor while the funnel is being filled to the proper point. When filled, the sack is held up with one hand while the funnel is lifted out and the ore runs into the sack as it is being removed. Or, the mouth of the sack is taken in both hands, grasping the lower end of the cylinder at the same time, so that sack and funnel may be lifted at the same time and the ore run from the funnel to the sack.

The funnel is made of moderately heavy sheet iron, which may or may not be galvanized, according to the conditions to be met.

Motor Haulage Switch Protection

By T. H. ARNOLD

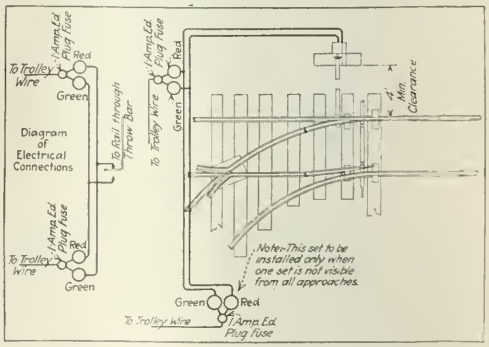
Written for *Engineering and Mining Journal*

The customary railroad switch stand lamp, turned with the operation of the switch, has not proved adaptable to underground mining conditions. A visible indication of the switch position is a necessity from a safety standpoint. This also expedites the handling of trains on the motor haulage. To meet these conditions, several electrical devices were tried out, all depending upon the operation of various forms of electric switches controlled by a bar attached to the movable switch points, this operation causing a red or green lamp to burn, depending upon the position of the switch.

The first form of lamp unit was simply two weatherproof sockets hanging from the mine timbers. The sockets were connected on one side directly to the trolley wire and the other side through the switch to the track. Thirty-five watt, 250-volt carbon lamps were used, the lamps being dipped in red or green lamp coloring. As the maintenance is rather high, and the lamp color faded rapidly, these have been superseded by a more satisfactory type, with three cleat receptacles mounted on a piece of 20-gage galvanized iron. The common wire of two receptacles carried through the third, which has a 3-amp. Edison plug fuse for protection. This wire then goes to the trolley. Two wires are carried through the switch to the track.

Twenty-five-watt, 250-volt mill type Mazda lamps have been substituted for the 35-watt carbon lamps, and color caps have been substituted for the dipped lamps with beneficial results, as the lamps are more visible and the color distinctions more positive. Also the color does not fade. A considerable saving is made in kw.-hr. consumption. As one lamp burns at each switch twenty-four hours a day, and thirty days per month, the saving on seventy-two switches will amount to 518 kw.-hr. a month. The life of the lamp is approximately double that of the carbon lamps, which will pay for the difference in cost of the two lamps.

The form of switch now being adopted is built up of two automatic door switches, one of the opening, and one of the closing, type. The plunger is spring-loaded to allow a possible movement of an inch and a half on the bar from the switch; the door switches require exactly ½-in. total movement. These switches are enclosed in a substantial iron box and can readily be mounted in place of the older types. They are safe from shock by accidental contact, and will withstand considerable moisture and rough handling.



WIRING DIAGRAM FOR MOTOR HAULAGE SWITCH PROTECTION

It is also customary to mount a 120-watt carbon lamp directly over each switch, on the lagging between the caps. In this way the caps cut off the direct light in the motorman's eyes. These lamps are being superseded by the 50-watt mill-type Mazda lamps with the tungsten filament.

THE PETROLEUM INDUSTRY

Physical and Chemical Data on Colorado Oil Shale

Results of Recent Work by Government Investigators on the Density, Heat of Combustion, Thermal Conductivity, Analyses, Specific Heat, and Oil Yield of a Representative Sample of Massive Rock

BY MARTIN J. GAVIN AND LESLIE H. SHARP*

Refinery Engineer, U. S. Bureau of Mines, and Chemical Engineer, State of Colorado, respectively

INVESTIGATIONS of the oil shales of Colorado were begun on Feb. 1, 1920, by the U. S. Bureau of Mines and the State of Colorado, under a co-operative agreement entered into by the Bureau and the state, funds for which were provided by the state. The investigations are for the purpose of determining, by large-scale laboratory retorting tests, those conditions which will produce optimum yield of best quality products from Colorado shales. (For an outline of the work and description of the apparatus, see Gavin, Martin J., and Sharp, Leslie H., "Investigations of the Fundamentals of Oil-Shale Retorting," Reports of Investigations, Bureau of Mines, July, 1920.)

In the preliminary work which is usually required when a new material is being dealt with, certain physical and chemical constants of the shales being investigated, and their products, were determined. These data will be of much value not only to the thorough retorting tests now under way at Boulder, but to engineers who will design and construct oil-shale plants. Although the figures presented in this report apply only to the shale used in the determinations, strictly speaking, the shale used was selected to represent, as well as possible, an average of the massive type of oil shale occurring in Colorado. The figures, therefore, can probably be applied with little danger of serious error to any massive Colorado oil shale which yields approximately a barrel (42 gal.) of oil to the ton.

SCOPE OF THE WORK

The following data were obtained on a representative Colorado oil shale:

1. Weight per cubic foot of different sizes of shale.
2. Apparent specific gravity.
3. Specific heat of raw and spent shale.
4. Heat of combustion of raw and spent shale.
5. Thermal conductivity of raw shale.
6. General analyses.
7. Oil yield.
8. Heat of combustion of crude shale oil.

The above-noted factors were determined for the oil shale obtained from De Beque, Col., which is being used in the retorting investigations. This shale is of the massive variety, and on laboratory tests yields oil of 0.905 specific gravity at the rate of 42.7 gal. to the ton (2,000 lb.). In addition, the specific heat was determined on a sample of oil shale from the Parachute Creek district, Col., as an indication of the order of variation of this factor in shales of the same approximate richness from different localities.

*Excerpt from U. S. Bureau of Mines, "Reports of Investigations."

DATA OBTAINED

The following data were obtained as a result of the work:

1. Oil yield, 42.7 gal. per ton.
   (Method, Bureau of Mines assay retort.)
2. Specific gravity of oil, 0.905 (24.7 deg. Bé.) at 15.56 deg. C. (60 deg. F.)
3. Weight per cubic foot (Method, direct weighing)

Size	Weight, Lb. per Cu. Ft.
Run of mine	53.775
Plus 1 in.	54.775
Minus 1 in.	56.015
Minus ¼ in.	58.200

4. Apparent specific gravity of raw shale, 1.92 to 2.06
   (Several specimens from large sample.)
   (Method, weight in air divided by loss of weight when immersed in water.)
5. Specific heat, (average of several closely agreeing determinations.)
   (Method, method of mixtures, Studentia calorimeter.)
   Specific heat, raw De Beque shale . . . 0.265 mean 20-90 deg. C.
   Specific heat, raw Parachute Creek shale . . . 0.242 mean 20-90 deg. C.
   Specific heat, spent De Beque shale . . . 0.223 mean 20-90 deg. C.
6. Heat of combustion
   (Method, combustion in oxygen in Emerson calorimeter.)
   Heat of combustion, raw De Beque shale, about 2,460 calories per gram.
   Heat of combustion, spent De Beque shale, about 600 calories per gram.

The determination of the heat of combustion of raw and spent shales cannot be considered entirely satisfactory. Except in one or two determinations with the raw shale, it was impossible to obtain complete combustion even when using oxygen at 500-lb. pressure in the calorimeter bomb. In no test was it possible to obtain complete combustion of the spent shale in the bomb. Both the physical appearance of the ash taken from the bomb and the fact that various residues lost 2 to 6 per cent, in the case of the raw shale, and 13 to 15 per cent in that of the spent shale, indicate that combustion was incomplete.

In two instances samples of raw shale were completely burned in the bomb, and showed no further loss on subsequent ignition. These two determinations indicated the heat of combustion of the shale to be 2,432 and 2,486 calories per gram, respectively. As regards the spent shale, the heat of combustion was calculated by making a rather arbitrary correction on the basis of the loss on ignition of the residue after combustion in the calorimeter. There is little scientific justification for making such a correction, but the fact that the figures obtained on several determinations agree so closely probably makes it worth while to present the results obtained. Indications are that the heat of combustion varies somewhat even between carefully taken

samples of the same lot of shale. It was not considered advisable to spend any additional time on more carefully determining these figures at present, as it was intended merely to show that spent shale and even raw shale probably could not be considered satisfactory fuel for direct combustion. Later it is hoped that modifications in the method can be worked out which will permit the practical operator to obtain accurate and trustworthy results in this regard.

7 Thermal conductivity
Thermal conductivity, De Beque raw shale, range 25 to 75 deg. C., 0.00382. (Method, Forbes' method, giving absolute conductivity.)

8 Analytical data

De Beque Raw Shale	Sample 1 Per Cent	Sample 2 Per Cent
Loss at 110 deg. C. (moisture)	0 60	0 59
Loss on ignition	40 00	39 70
Ash or residue	59 40	59 71
Totals	100 00	100 00
Ash Analysis		
Silica (SiO_2)	44 70	45 10
Iron and alumina (Fe_2O_3 and Al_2O_3)	25 60	26 35
Lime (CaO)	17 65	18 35
Magnesium (MgO)	5 28	5 35
Undetermined	6 77	4 85
Totals	100 00	100 00

9 Heat of combustion.
Heat of combustion, crude shale oil, 10,215 calories per gram. (Method, combustion with oxygen in Emerson calorimeter.)

Comparative Values

The following tables are presented for the purpose of comparing various physical and chemical data on oil shale obtained in the present investigation with similar data on other more familiar substances.

TABLE I DENSITY AND WEIGHT PER CUBIC FOOT OF VARIOUS SUBSTANCES

Material	Grams per Cu. Centimeter (Density) *c*	Pounds per Cubic Foot (in Place) *d*	Authority
Massive Colorado oil shale	1 92–2 06 *a*	119 8–128 5	Present work
Anthracite coal	1 4 –1 8	87 112	Smithsonian Inst
Bituminous coal	1 2 –1 5	75 – 94	Smithsonian Inst
Clay	1 8 –2 6	122 –162	Smithsonian Inst.
Coke	1 0 –1 7	62 –105	Smithsonian Inst.
Limestone	2 68–2 76	167 –171	Smithsonian Inst
Peat	0 84	52	Smithsonian Inst
Sandstone	2 14–2 36	134 –147	Smithsonian Inst.
Petroleum	*a* 878–9 65 *b*	a54 8 60 *2b*	Smithsonian Inst.

a At 16 deg. *b* At 0 deg. C. *c* The determined density of a material depends on its state (especially if porous), and its previous treatment, i. e., whether air dried, how long, and at what temperature. The method used in this work gives apparent density (grams per cubic centimeter), but, from the nature of the material used, this figure is undoubtedly close to the true density. *d* Obtained by multiplying density by 62 4 *e* Ordinary atmospheric temperature is understood.

Table II presents specific heats of raw and spent oil shales as determined in the present investigation, compared with specific heats of other materials.

Specific heat of a substance is the ratio of the amount of heat measured in calories required to raise the temperature of one gram of the substance 1 deg., to the amount of heat required to raise the temperature of 1 gram of water 1 deg C., at a specified temperature. The specific heat of a substance varies with the temperature of the substance.

TABLE II. SPECIFIC HEATS OF VARIOUS MATERIALS

Material	Specific Heat	Mean Temp., Deg. C. *a*	Authority
Massive De Beque, Col., oil shale	0 265	20–90	Present work
Massive Parachute Creek, Col., oil shale	0 242	20–90	Present work
Spent De Beque, Col., oil shale	0 223	20–90	Present work
Sandstone	0 22		Smithsonian Inst.
Limestone	0 216	15 100	Morano
Granite	0 192	12–100	Joly
Asbestos	0 195	20 98	Ulrich
Clay, dry	0 22	20–100	Mean of several
Wood	0 42		
Gas coal	0 3145	20–1040	Smithsonian Inst.

a At 16 deg. C.

Table III presents the heats of combustion of the raw and spent shale and crude shale oil in comparison with average figures for well-known fuel materials.

TABLE III HEATS OF COMBUSTION OF VARIOUS SUBSTANCES

Material	Heat of Combustion — Calories per Gram	B.t.u. per Pound	Authority
Massive De Beque, Col., oil shale	2,460 *a*	4,428 *a*	Present work
Spent De Beque, Col., oil shale	600 *a*	1,080 *a*	Present work
Bituminous coals	6,088– 7,852	10,958–14,134	Smithsonian Inst
Anthracite coals	6,987– 7,417	12,577–13,351	Smithsonian Inst
Lignite coals	3,526– 3,994	6,347– 7,189	Smithsonian Inst

a Approximate values as already mentioned.

Table IV presents the thermal conductivity of De Beque, Col., massive oil shale, and various other good and poor heat conductors.

Thermal conductivity, "*k*," is the heat in gram calories flowing in one second through a plate 1 centimeter thick, per square centimeter, for 1 deg. C. temperature difference between faces of the plate. "*K*" is found to vary with the absolute temperature of the plate.

TABLE IV HEAT CONDUCTIVITIES FOR VARIOUS SUBSTANCES

Material	K	Temp., Deg. C.	Authority
Copper	0 918	18	Jaeger & Diesselhorst
Copper	0 908	100	Jaeger & Diesselhorst
Iron, cast	0 108	18	Jaeger & Diesselhorst

Oil shale (De Beque, Col.)	0 00518	Mean 25–40	Present work
Oil shale (De Beque, Col.)	0 00314	Mean 40–75	Present work

General chemical analyses of oil shales ordinarily have little value except in comparison with other shales. Analytical figures may serve to indicate the fusibility of the shale ash and its possible utilization for brick or cement making and the like. In comparison with analyses of other oil shales, the Bureau of Mines is attempting to use analytical data, especially data having to do with loss on ignition (volatile and fixed carbon), as an indication of possible oil yield and the analyses of shale ashes as a means of classifying shales by districts and as possibly influencing the quality of oils recovered from the various shales.

Table V shows the difference in composition of mineral matter (ash) of shales from different localities. It also indicates the relationships between volatile and fixed carbon and oil yield.

TABLE V. ANALYSES OF OIL SHALES FROM VARIOUS LOCALITIES

Source of Shale	Ash Analysis — SiO_2	Fe_2O_3 and Al_2O_3	CaO	MgO	Volatile and Fixed Carbon	Oil Yield, Gallons per Ton *c*

NEWS FROM THE OIL FIELDS

Deepest Gulf Coast Well Produces From 3,700 Ft.

From Our Special Correspondent

Several important completions have been made recently in the Gulf Coast fields. At West Columbia, in Brazoria County, Tex., the No. 1 Hogg well of the Gulf Production Co. came in, making 700 bbl. from a depth of 3,700 ft. This is probably the deepest producing Gulf Coast well. At Humble, the Sun Co. has struck oil on Lot 11 of Block 2, Riverside addition, at 3,200 ft. In the old Barber's Hill field, Chambers County, the joint well of the United Petroleum Co. and G. C. Smith et al. came in, making about 700 bbl. from 1,900 ft. Previously, the production from this field had been gradually decreasing. Now there is considerable leasing, and at least two other companies will drill again. Two good wells were also completed at Hull, Liberty County, one a 1,500-bbl. well of the Republic Production Co. and the other a 300-bbl. well of the Phoenix Development Co. The production of the Hull field has been increasing gradually for the last few months. The famous No. 1 Abrams well of the Texas Co. at West Columbia, which has been decreasing in its former rate of flow, suddenly stopped flowing for five hours early Sept. 5th. It was sanded, and the insertion of a flow pipe caused the flow to resume. The rate was not given.

Gas was turned into the mains from the Amarillo gas field on Sept. 4th. It is stated this field can supply 500,000,000 cu ft. of gas daily.

It is believed a large gas field will be opened south of Burkburnett and adjoining the Texhoma field. Recently, J. I. Staley completed a well at 1,450 ft. having a gas flow of 7,000,000 cu.ft. This is the third large gas well completed in an area of four or five square miles.

In Eastland County a development of importance in the southern part is the discovery of oil in quantity in the Caddo lime. Previously this formation was considered dry in most places, and wells were drilled right on through it. The Pittsburgh Western Oil Co., however, shot its Pruett well, south of Carbon, at about 2,300 ft. and obtained a good producer. Later the Atlantic Oil & Refining Co. developed a flow of 1,000 bbl. in one of its wells to the southwest of the Pruett well by shooting at 2,400 ft. Many wells that were drilled through this stratum may be plugged back and shot in an effort to get production from this lime.

Two gas blowouts are reported in the Pettus well of the Goliad Oil Co., near Goliad, Goliad County. These occurred at 2,700 ft. Whether this will be an oil producer cannot be determined until casing is set.

Market Arranged for Louisiana Natural Gas

From Our Special Correspondent

According to a recent report at a special session of the New Orleans commission council held on Sept. 1, 1920, a fifty-year lease to supply that city with natural gas was granted certain interests, not named, represented by W. E. Wren, of Minden, La., and W. A. Trimpe, of Houston, Tex. The franchise grants to the new company the right to lay gas mains and distributing pipes under the streets, but does not exclude the present company now supplying artificial gas. Work of installing mains must begin within twelve months from the time of acceptance of the franchise, and six miles of mains must be laid within a year from that date. The price of gas is fixed at 65c. per 1,000 cu.ft. for domestic use up to 6,000,000 cu.ft. daily, and when the consumption exceeds that figure, 50c. per 1,000 cu.ft. Other clauses limit the minimum of B.t.u. contained in the gas and provide for artificial gas in case of failure of the natural-gas supply, and payments to the city for the franchise based upon the consumption. The supply of natural gas, it is stated, has been acquired, but its source is not yet made public. It is probable, however, that it will come from the big gas field a few miles south of Houma, Terrebonne Parish.

The American Oil & Drilling Co. has started drilling on the J. J. Thompson plantation two miles from Opelousas, St. Landry Parish. An area of 8,000 acres has been leased.

Drilling will be done near Church Point, Acadia Parish, where W. G. Morgan has a mineral lease on 9,000 acres. In 1903 the Crowley Oil & Development Co. brought in a small oil well near here.

The Detroit Oil & Gas Co. will drill for oil on its recently acquired lease in Iberia Parish about four miles west of New Iberia. The rig for this work has been received.

Gas Coming Through Salt Water at Holbrook, Ariz.

From Our Special Correspondent

Rising through 700 ft. of salt water, gas that will burn is coming from the Adamana well in Arizona. The bore has been stopped at 2,140 ft. for casing, in fear that a big gasser will be developed. For several hundred feet the drill has been passing through alternating strata of sandstone, limestone, and rock salt, the log being similar to that of the Hopi well, now blocked by lost tools at 2,500 ft. depth. The Holbrook well, now down 1,600 ft., is to be driven to 3,000. Zuni is down 400 ft.

Warren County, Kentucky, Has Another Gusher

From Our Special Correspondent

A gusher was brought in at 225 ft. on Sept. 3 on the farm of Mrs. J. W. Stone, Warren County, Ky., adjoining the General W. L. Sibert gusher. It is estimated at 1,800 bbl. daily production.

The Richpond Oil Co., operating in Warren County, reports two good wells on the John W. Phelps lease, estimated at 140 bbl. each. They were brought in at 395 and 450 ft. The company has started No. 3 and 4 on the Frank Holland lease. A 100-bbl. well is reported on the Skiles lease situated along the Smallhouse Pike. This is considered a new pool. The oil was of a light grade.

The Hugh Potter well on the Bailey lease, Warren County, owned by the Whittle Oil Syndicate, is pumping 150 bbl. a day.

Butler County, northwest of Warren, is looked upon as a possible extension of the oil fields, following the recent discovery of oil at Gilstrup. A company of farmers and business men, after drilling 1,250 ft. without success, struck oil sand with a flow of gas. The well will be sunk deeper. Another wildcat test will be made soon.

Several good wells have been brought in in the Merba pool, Menifee County. No. 1, on the Shelby Palmer lease, has been completed. A location for No. 2 of the same operator has been staked out on the Edgar Smallwood farm. Several companies are resuming operations in this field. Indications are that it will equal Lee and Wolfe, other central-eastern counties of Kentucky.

Oil men are giving attention to Clinton County following a strike at Beach Bottom. This well reached a showing of oil at 1,735 ft., with small quantities of oil for 40 ft. The driller estimates it as good for about 50 bbl.

Montana Has 2,000-Bbl. Gusher

From Our Special Correspondent

Well No. 2 of the Frantz Corporation, a subsidiary of the Elk Basin Consolidated, was brought under control recently after it had spouted unrestrained for more than a week at the rate of around 2,000 bbl. daily, with a flush production of 3,000 bbl. at one time, it was estimated. As many men as could be obtained were busily engaged in throwing up dirt dams to impound the oil. For the grade of oil, which runs up to 50 per cent gasoline, the Frantz well is said by oil men to stand out for volume among the foremost producers in the country. Piping of the oil from the well to Winnett, Mont., a distance of about twenty miles, began last week, the oil being shipped to the Elk Basin refineries in Wyoming.

COURT DECISIONS IN MINING CASES

By Wellington Gustin

Federal Title to Mining Claim Confirmed

North American Transportation & Trading Co. Loses Appeal Against the United States—Was Awarded Value of Claim at Time of Taking by Government

The Supreme Court of the United States has affirmed the judgment of the U. S. Court of Claims in the suit brought by the North American Transportation & Trading Co. in the Court of Claims in 1906 to recover the value of a placer mining claim situated on the public land near Nome, Alaska. It was alleged this mining claim was taken by the United States in 1900. General Randall, of the United States Army, commanding the Department of Alaska, took possession, as a site for an army post, of a large tract of public land which included the mining claim. The tract has been used as an army post continuously since possession was first taken by General Randall. The buildings erected thereon are situated on that portion of the land which had been the company's placer claim, so that the company has not been able to operate.

The court said that when the government, without instituting condemnation proceedings, appropriates for a public use, under legislative authority, private property to which it asserts no title, it impliedly promises to pay for same.

The company claimed $100,000 from the United States, alleged to be the value of the mining claim, and the further sum of $7,500 per annum for the use and occupancy of said claim from 1900. The court of claims found the value of the mining claim when it was taken to have been $23,800, and an award therefor was given the company. The loss of this use for nearly twenty years was due to the company's delay in prosecuting its suit, the Court of Claims having no power from Congress to allow interest. This award was sustained as correct.

"Unless Lease" Valid

An "unless lease" for oil and gas exploration and development purposes was the subject of a suit in equity brought by E. L. Brunson and others against the Carter Oil Co. in the United States District Court for the Eastern District of Oklahoma.

Judge Williams, in deciding the case for the oil company, held that such an exploration "unless lease" for oil and gas, for which the lessee paid a substantial bonus, with a privilege of renewal of the lease by payment of a substantial sum annually, was a valid mutual contract based on a valuable consideration, and not subject to forfeiture because of failure to make an annual payment in time to a grantee of lessor, where it was in fact made before due, but through mistake of a clerk in failing to make proper entry of transfer of title on the records of the lessee the payment was sent to lessor, instead of to his assignees.

An "unless lease" was considered in another case where the court said: "It would seem to me that a lease of this character, the lessor receiving valuable consideration for the privilege of exploration for oil, would confer a valid right of exploration for the time and on the terms spoken of in it. Such would seem to be the intent of the parties and the justice of the matter, notwithstanding the contract imposed no obligation on the lessee to drill or pay. The lessor has been paid his price for giving such privilege."

Must Consummate Transaction To Earn Commission

Broker Loses Suit Against the Esperanza Mining Co. and Guggenheim Exploration Co. for Sale of Mexican Mining Property

In the suit of Dennis B. Harris against the Esperanza Mining Co. and the Guggenheim Exploration Co. to recover commissions amounting to $202,500, alleged to have been earned by Brad Barnar by procuring the sale of a Mexican mining property, the New Jersey Court of Chancery dismissed claimant's bill, upholding defendant's contention that Barnar was not the "procuring cause of any sale" of the property in question.

The defendant Guggenheim Exploration Co. alleged that it never purchased the mines of the Mexican company, but that a syndicate composed of the said defendant, an English corporation known as the Venture Co., Ltd., and a firm of brokers of London, England, known as L. Hirsch & Co., as the transferees of an option held by one E. A. Wiltsee, purchased from various individuals a majority of the capital stock of the Mexican corporation, in good faith and for a valuable consideration, namely $3,000 in Mexican currency for each share of stock, and that this price was paid without the knowledge that Brad Barnar or his assignee had any claim for commissions.

The court said that where negotiations between the parties introduced by a broker had terminated without a sale, the fact that the prospective purchaser subsequently acquired an interest in the mines by employing as its manager one who had acquired an option on the property, as the result of negotiations independent of the broker does not entitle the broker to a commission.

Washington Statute Does Not Authorize Use of Second-Class Tidelands

In Seattle, Wash., Warren Stetson applied for a writ of mandamus to require the Commissioner of Public Lands to execute to him a lease for mining and extracting petroleum and natural gas from certain tidelands belonging to the State of Washington. The commissioner had refused to execute the lease on the ground that tidelands are not lands within the meaning of the state statute, Sections 6,791 and 6,792.

Though the Supreme Court of Washington held that tidelands are "lands belonging to the state," it would not interfere with the action of the commissioner in refusing to execute lease of unsurveyed tidelands for extraction of petroleum and natural gas under the above sections of the law authorizing the leasing of such lands, "not to exceed one section," though the application for a lease described the land affected as "containing 640 acres," as the area of the described land has not been ascertained and cannot be determined by any mathematical process from the description contained in the application. This results from the fact that there was no official or state survey of second-class tidelands in the State of Washington.

Mineral Reservation Exempts Operator From Negligence in Mining

In the action taken by Atherton against the Clearview Coal Co. for negligence in the mining of coal, the property of the company, underneath the surface of land owned by the complainant, the Supreme Court of Pennsylvania held that the mineral reservations in the deed exempted the owner of minerals from liability for negligence in mining.

The exception, or reservation, contained in the deed of the surface of the land to Atherton, reserved the right to mine and remove all coal and minerals beneath the surface, with the right to mine and remove the same by any subterranean process, without liability under any circumstances for damages done to the surface or improvements erected thereon.

The court said such reservation was sufficiently broad to include liability for negligent mining, and there could be no recoveries for injuries to buildings from improper blasting, for the intention of the parties to the deed of conveyance, as shown by the language used, must govern in the interpretation of the written instruments, and it is apparent all liability was excluded.

ECHOES FROM THE FRATERNITY

Super-Power Survey Committee To Report June 30, 1921

W. S. Murray and Assistant Engineers Making Critical Examination of Country's Power Resources and Conservation

A committee representing the engineers of the United States appeared before the Appropriations Committee of the House of Representatives last April to urge the necessity of a careful survey of our natural-power resources, with a view to securing more efficient generation, transmission, and use of electricity. W. S. Murray, consulting electrical engineer of New York City, who had charge of the electrification of the N. Y., N. H. & H. R.R., had outlined a Super-Power System which offered definite plans for eliminating the economic waste of our present power arrangements, and Congress was urged to contribute to the necessary expenses of a proper preliminary power survey of the country.

Public interest and opinion were sufficiently strong to secure favorable action from both houses of Congress, and $125,000 was appropriated to finance an administrative and engineering force that will show clearly in its report (a) the points where present wastes are occurring and (b) the design of a regional system which would eliminate these wastes, for a zone 150 miles deep along the Atlantic seaboard between Boston, Mass., and Washington, D. C. W. S. Murray is naturally chairman of the engineering staff of the Super-Power Survey, as this organization is called, and its headquarters are at 709 Sixth Avenue, New York City.

As organized, this investigation under W. S. Murray's chairmanship is divided into the three departments of power and transmission under L. E. Imlay; railways under Cary T. Hutchinson; and other industries under Henry W. Butler; all three assisted by the engineer-secretary, Henry Flood, Jr., who will collaborate in the collection of field data and preparing the data for the report. N. C. Grover, chief hydraulic engineer of the U. S. Geological Survey, and O. P. Hood, chief mechanical engineer, U. S. Bureau of Mines, are also collaborating with the staff of the survey.

Every two months from now until April 30, 1921, the chairman of the engineering staff meets an advisory board under the chairmanship of Prof. L. P. Breckenridge, of Yale, presents the progress of the work and discusses with the board his program for the next two months. This advisory board is designed to secure the counsel of men representative of power producers, consumers and the interests of the people in a national power policy, and properly embraces eminent representatives from all these classes, such as E. G. Buckland, vice-president N. Y., N. H. & H. R.R.; Magnus W. Alexander, National Industrial Conference; Henry W. Butler, consulting engineer, New York City; the Secretary of the Interior; the Director of U. S. Geological Survey; and others.

The final report of the Survey will be made June 30, 1921, and the responsibility for taking further action will rest on the Congress. As a recent editorial in *Power* very truly said:

"This undertaking is not alone of particular interest to those living along the North Atlantic seaboard, but to the entire country. Railway congestions in this district did not alone affect the industries located in this region but practically the entire nation. Consequently, the Super-Power Survey, at present under way, merits national support."

Iron Trade Control Association of Germany

Acting Commercial Attaché Henry F. Grady reports from The Hague, Netherlands, that by a decree of the German National Government, dated April 1, 1920, there was established for the control of the iron trade an autonomous body with legal standing called the "Eisenwirtschaftsbund" (Iron Trade Control Association) with headquarters at Duesseldorf. A translation of this decree may be consulted at the Bureau of Foreign and Domestic Commerce, Washington, D. C., on referring to file No. 42075.—*U. S Commerce Reports.*

Ontario Mining Association held its first annual meeting at Sudbury, Ont., Aug. 17 to 19. Among the important matters considered was the position of iron-ore mining in Canada. The association appointed R. W. Leonard, A. J. Young and G. S. Cowie as a commission to assist the provincial and dominion governments in any possible study of Canada's iron-ore industry.

The South African Institution of Engineers awarded its gold medal for 1918-1919 to Henry S. Potter, member of the institution, for his paper, "Hammer Drills: Their History, Design and Operation," published in the Journal of the Institution, Vol. 17, Nos. 4, 5 and 6. The Central Mining-Rand Mines award for the same season was made to T. H. Bayldon, also a member of the institution, for his "Notes on Experiments Made With a View to Reducing the Consumption of Explosives and Increasing the Fathoms Broken Per Machine Shift in Machine Stoping," published in the same journal, Vol. 16, No. 12.

Mining Standards Committee Urged by Mining Congress

Would Not Compete With Existing Bodies, Says W. R. Roberts—Invitations Being Issued to Denver Conference

The American Mining Congress has undertaken to organize a nation-wide movement for the standardization and improvement of mining practice as it pertains to mining machinery and equipment, cost accounting, safety codes, life- and time-saving devices, and co-operative methods.

At an informal conference in Chicago on Aug. 30 between officers of the congress and representatives of the American Engineering Standards Committee, the National Safety Council, the American Institute of Mining Engineers, and the U. S. Bureau of Mines, a resolution was adopted requesting the American Engineering Standards Committee to at once organize a mining standards committee composed of members selected by the bodies represented in the informal conference.

"It is not the intention of this committee to in any way duplicate the work of existing bodies," said Col. Warren R. Roberts after the meeting "There will be no competition and no friction. The American Mining Congress represents the industry because it is composed entirely of operators, and hence, is the industry. We intend to take up and consider all of the standards that have been or may be suggested or adopted by either the Government or by voluntary organizations, and to make these standards operative and profitable. We will also propose such changes and new standards as our committee, by experience and contact with the actual conditions in the mines, believes would be of value or necessity. The standardization conference in Denver during the annual meeting of the American Mining Congress in November will be, I believe, one of the most important meetings ever held, and its influence will be felt permanently in both mining and manufacturing. Among the most necessary things to be developed is to show how standardization has made possible wonderful progress in other lines; and how the coal men have materially strengthened their business standing by recent adoption of standardized accounting, without which they might have suffered many embarrassments during the strikes and wage conferences."

The official invitation now being prepared is signed by Colonel Roberts, chairman of the general committee on the standardization of coal-mining machinery; Charles A. Mitke, of Bisbee, Ariz., and Richard A. Parker.

Engineering Council Experience Guided F. A. E. S.

Organizing Conference Recognized Successes and Limitations of the Council—Plans a Broader and More Effective Body

In connection with the Federated American Engineering Societies two questions have arisen:

1. "If Engineering Council is a success why should the proposed federation supplant it?" and

2. "If Engineering Council is a failure why should the Federation be organized along lines so nearly parallel?"

These are basic questions and worthy the serious consideration they have received, not only from the joint conference committee when it was preparing its report, but also from the committee on constitution and by-laws of the Washington organizing conference.

When the joint conference committee, composed of conferees of four of the then five member societies of Engineering Council, considered the question of co-operation of these societies in matters of common concern to the engineer, the functions and accomplishments of Engineering Council naturally came under review. There were present as conferees three members of Engineering Council, and by invitation of the committee Council also had an official representative present.

The committee decided that some form of comprehensive organization was necessary to provide a medium that could speak for the engineering and allied technical professions on matters of common concern to them. The committee also decided, which decision was concurred in by the official representative of Engineering Council and the members of the committee who were also representatives on Engineering Council, that

"If desired, Engineering Council can be moulded into this organization by making it more democratic and founding it on direct representation of all engineers, rather than by appointment as at present."

It was agreed that Engineering Council is at present not properly constituted to carry on efficiently the work which it has undertaken; its organization is from the top downward, rather than from the bottom upward, which the committee deemed desirable if a thoroughly representative and efficient organization was to be established.

It has been admitted by Engineering Council, and it was so pointed out to the members of the joint conference committee, that Engineering Council has been handicapped from the beginning in regard to funds for its operations, in freedom of action on the matters that came before it, by reason of the necessity for reference to the member societies and to the United Engineering Society, and the great difficulty in electing additional member societies. The annual contributions of the member societies never exceeded $22,000; which amount was wholly inadequate for meeting the demands for service which Council has been desirous of rendering.

Despite these difficulties, Engineering Council has been able to accomplish a great deal, as was pointed out by the joint conference committee in Bulletin No. 3, and particularly has it been successful in its work of developing among its member societies the habit of united effort in matters of common concern to the engineer and the allied technical professions. Engineering Council may be said to be a success, and considering the conditions under which it has operated, to be a commendable success. It is evident, however, that basic defects in its organization prevent Engineering Council fulfilling the real functions of a comprehensive body representing the engineering profession, and these defects are not remedial through reorganization.

Engineering Council has six member societies. At the organizing conference in Washington 71 societies were represented, with an aggregate membership of over 80 per cent of all the individuals represented by the 110 societies invited.

Engineering Council Approved Action of Conference

The action of the organizing conference in creating the Federated American Engineering Societies and its governing board, American Engineering Council, was unanimous. This action has received the unanimous approval and support of Engineering Council. The affirmative consideration that is being accorded the invitation to become members of the Federated American Engineering Societies insures that American Engineering Council will have a far greater number of member societies at its initial meeting in November than Engineering Council, based on its present rate of growth, could possibly have had under existing conditions at the end of many years.

The work of Engineering Council is not to be abandoned, but is to be carried on and extended under a more comprehensive program made possible by the more representative American Engineering Council.

The deficiencies of Engineering Council are not in the quality of the work that it has accomplished, but rather have been due to its organic limitations and to the fact that it is not sufficiently representative of the local, state and regional organizations and affiliations. The organizing conference in Washington laid the foundation for a more democratic organization in which the local, state, regional engineering, and allied technical organizations and affiliations will be represented and have a real voice in its management.

The organizing conference in its wisdom recognized the successes and limitations of Engineering Council and has evolved an organization in which all of these successes will be utilized and a broader opportunity afforded for more effective work on behalf of the engineering and allied technical professions.

Harding and Cox Answer Queries Put by A. A. E.

Candidates State Positions Concerning Department of Public Works, Conservation and the Budget System

In reply to the following questions, drafted at the recent annual convention of the American Association of Engineers,

1. Are you in favor of a National Department of Public Works, for the purpose of reducing and co-ordinating the present number of bureaus and commissions, and reducing the useless expenditures of money incident thereto?

2. Are you in favor of assembling and co-ordinating all the engineering and construction enterprises of the Government (excepting the purely military works) in a department such as the National Department of Public Works, to the end that economy and efficiency will be obtained?

3. Do you favor the appointment of an engineer of recognized ability and unimpeachable character as a member of the Interstate Commerce Commission?

4. Do you favor a progressive and constructive program of conservation and development of our natural resources?

5. Do you favor the budget system of appropriation of public funds?

6. Do you favor the reclamation of waste lands by drainage, irrigation, flood control or other methods?

Do you favor giving the settler the advantage of procuring the land by a sound financial system such as is provided by a rotating fund?

the following letters have been received:

State of Ohio,
Executive Department,
Columbus
August 13, 1920.

Mr. L. K. Sherman, President,
American Association of Engineers,
63 East Adams St., Chicago, Ill.

My dear Mr. Sherman:

My reply to every one of the questions you ask is unequivocally "Yes."

Time will not permit, nor do I consider it proper, that I answer the ordinary questionnaire. My past record and public utterances must be sufficient. However, as in the case of your letter, the reply to questions asked and my record and public announcements are one and the same. I therefore take great pleasure in making this statement.

With every good wish, I am,
Very truly yours, JAMES M. COX.

Marion, Ohio,
August 9, 1920.

Mr. C. E. Drayer, Secretary,
American Association of Engineers,
63 East Adams St., Chicago, Ill.

My dear Mr. Drayer:

Your letter to Mr. Christian of Aug. 4 has been brought to my attention.

It is not an easy matter for me to make a detailed reply to the inquiries conveyed in your letter, and I do not care to enter into a categorical reply to questionnaires, no matter how friendly they may be and no matter how reputable and high-standing is the source from which they come.

My theory of a campaign is, that a man's candidacy ought to be based on the formal and public utterances, though, of course, we are all of us informal enough to discuss informally many of the problems which are in the minds of various groups of our American citizenship.

I have had up the matter of the Department of Public Works in some personal interviews, and quite agree with you that the question is an exceedingly interesting and important one. I fear I should be unworthy of public confidence if I ventured to decide so important and far-reaching a question without the very fullest study. It involves the reorganization of several departments. Undoubtedly, there is necessity for this, but I should be very reluctant to unalterably commit myself to it without the very fullest of understanding.

You may be interested to know that I have already sent for the Congressional hearings on this particular question.

I may say, in a general way, that I think very well of the appointment of an engineer on the Interstate Commerce Commission and I have always spoken heartily in favor of a progressive and constructive program of conservation. I am sure you know that I favor the budget system and a very forward policy relating to reclamation and irrigation.

Very sincerely yours, W. G. HARDING.

Book Reviews

South African Engineers' Directory. Compiled and published by *The South African Mining and Engineering Journal*, 176-180, Stock Exchange Building, Johannesburg. Cloth, 6 x 10, pp. 422. First edition, 1920. Price, 30s.

This directory is the only one of its kind covering that part of the world, and embraces every branch of the engineering, electrical, iron, steel, machinery, hardware, and allied trades throughout the Union, Rhodesia, and Mozambique. One section gives an alphabetical list of all firms, with such data as postal and telegraphic addresses, names of the partners or directors, agencies represented, capital, and other details. Another section gives the names arranged geographically. Another is a list of about 1,000 overseas manufacturers and their South African representatives. A buyer's index of factories and firms selling various classes of merchandise is followed by what will probably be of most interest to our readers, a list of the mining and industrial companies, with the names and addresses of both major and minor officials. An alphabetical classified list of engineers and mining officials is also given. The book is very complete, and those who know South Africa tell us that it is also exceptionally accurate.

Statistical Abstract of the United States, 1919. Cloth; 6 x 9; pp. 864. For sale by the Superintendent of Documents, Washington, D. C., for 50c.

There is an old saying to the effect that figures don't lie but liars can figure. This book affords plenty of material, as it contains nothing but statistics, although a volume of almost 900 pages. For those whose requirements extend beyond such tomes as the "World Almanac," this should be a very valuable book.

Technical Papers

Clay.—Bulletin 58 of the Iowa State College Engineering Experiment Station, Ames, Iowa, tells of the possibilities of pottery manufacture from Iowa clays. Those who have clay deposits in other parts of the country can get from this bulletin information as to the uses of various kinds of clay and methods of testing.

Fuel Oil.—Oil fuel is cheaper per heat unit than coal in most parts of the United States. It also has many advantages. How to change over to oil, in boilers previously equipped to burn coal, is described in a three-page article in the Aug. 14 *Electrical World* (New York, 25c.).

Magnesite.—The U. S. Tariff Commission (Washington, D. C.) has issued a twenty-eight-page pamphlet entitled "Information Concerning the Magnesite Industry," which gives data on the grades and uses, sources of supply, mining and calcining methods, costs, and competitive marketing conditions. This country consumes normally one-half of the world's output, and before the war 90 per cent of the domestic supply was imported, chiefly from Austria and Greece. A slightly ferruginous magnesite is required for metallurgical purposes. Pure domestic ores are satisfactory only if iron is added, which has been generally done.

Pulverized Coal.—Joseph F. Shadgen has a four-page article in the Aug. 19 *Iron Age* on the science of powdered-fuel combustion, including reference to thermic fundamentals, effects of various air quantities on temperature and gases produced, the ash problem, and burner essentials. Previous articles by the same author were, "The Status of the Powdered-Fuel Problem," in the Jan. 1 issue of *The Iron Age*; "Methods of Pulverizing Coal," in the issue of Feb. 5; and "Pulverized Coal Distributing Systems," in the issue of May 20.

Mining in Quebec.—"The Report on Mining Operations in the Province of Quebec During 1919" (free, from the Department of Colonization, Mines and Fisheries, Quebec, Que.) will be of especial interest to those engaged in the asbestos and magnesite industry, for those minerals, along with copper and sulphur ore, are Quebec's chief mineral products. The asbestos industry flourished during the last year, but the value of magnesite produced was only about one-quarter that of 1918.

Selling a Prospect.—The editor of the *Arizona Mining Journal* has a four-page article in the August number (price 20c., Phœnix, Ariz.) on how a prospector or owner should go about interesting capital in his property. Some of the things the exploration engineer wants to know are outlined.

Graphite.—In the *Canadian Mining Journal* (Gardenvale, Que., 15c.) for Aug. 20 is a four-page article on the past and present methods of concentrating graphite ore. Flotation is now commonly used, but the problem is rather one of proper grinding. The "perfect process" of M. J. Paterson, mentioned on the page preceding the article, seems to have received scant attention.

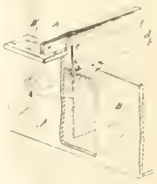
Porphyry Copper.—A history of the past activities and an illustrated description of present conditions at the mines of the Copper Canyon Mining Co. cover six pages in the Aug. 15 issue of the *Salt Lake Mining Review* (Salt Lake, Utah, 15c.). This property is seven miles southwest of Battle Mountain, Nev., and promises to be a large producer of the "porphyry" type.

Clay.—The Bureau of Mines has issued Technical Paper 233, "The Properties of Some Stoneware Clays" (pp. 41). This gives the results of a study of the properties of some Ohio and Pennsylvania clays. Obtainable from the Superintendent of Documents, Washington, D. C., for 10c.

Recent Patents

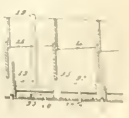
1,347,189. Recovery of Zinc by Electrolysis. Royale Hillman Stevens, assignor to Electrolytic Zinc Co. of Australasia Proprietary, Ltd., Melbourne, Victoria, Australia. Filed Nov. 11, 1919.

In the electrolytic process for the recovery of zinc, providing a protective coating for the cathode above the normal solution level by first carrying out a preliminary electrolysis with the cathode immersed to substantially a line immediately below the supporting bars, the cathodes having wooden strips affixed at or about the normal solution level which prevent the deposition of zinc under them, and then removing the said strips and proceeding with the electrolysis in the ordinary way in cells with the solution at normal level, whereby the subsequently deposited zinc strips along the line of weakness at or about the solution level.



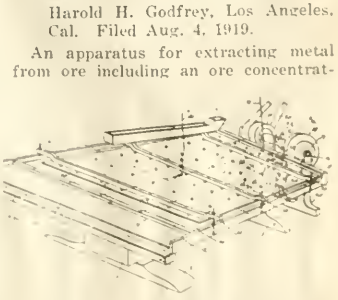
1,346,818. Flotation Ore Separator. Rudolf Gahl, Miami, Ariz., assignor, my mesne assignments, to Pneumatic Process Flotation Co., New York, N. Y. Filed Jan. 31, 1916.

A flotation ore separator comprising a receptacle having an impervious bottom, means for supplying ore to be treated to said receptacle, and means for removing concentrates therefrom, said receptacle having located near the bottom thereof a series of independently removable foraminous air chambers having longitudinally extending upper surfaces, said air chambers being arranged for travel of substantially the whole of the pulp over the series.



1,347,026. Apparatus for Extracting Metal From Ores and the Like. Harold H. Godfrey, Los Angeles, Cal. Filed Aug. 4, 1919.

An apparatus for extracting metal from ore including an ore concentrating shaking table inclined longitudinally and transversely, said table being covered with a cathode, and an anode spaced above said cathode.



MEN YOU SHOULD KNOW ABOUT

J. B. Tyrrell, of Toronto, Ont., has gone to Newfoundland on professional business.

C. W. Cooke has completed several months' geological work in Colombia, and is again in the United States.

J. B. Harper, of Jerome, Ariz., who was recently visiting New York on professional business, has returned to Jerome.

D. E. Winchester has completed an extended field study of oil shales, and now is engaged in writing his report thereon.

John Sterling, chief inspector of mines for Alberta, is in Scotland for a rest after his serious illness during the summer.

Harry J. Wolf, of New York City, has completed mine examinations in southeastern Arizona and has gone to Denver, Col.

Harold Kingsmill, of New York, stopped in Salt Lake City Aug. 25 for a short stay while returning East from Eureka, Nev.

Robert N. Bell, retiring state mine inspector of Idaho, will take over and operate the Clayton mine in Custer County, Wash.

K. C. Heald, of the staff of the U. S. Geological Survey, is inspecting the work being done by Survey geologists in Western oil fields.

Paul Liver, of Wallace, Idaho, was elected president and manager of the Giant Mining & Development Co. at the annual meeting.

Roy L. Barns, of the Solvay Process Co., sailed for France on Sept. 9. He will study alkaline deposits in Belgium, France, and England.

W. W. Risdon, of Albuquerque, N. M., has been appointed as the New Mexico state inspector of coal mines, to succeed the late J. E. Sheridan.

Y. Fukihara, mining engineer, of Tokyo, Japan, is visiting mines in the United States on his way home from an extended visit to England.

J. Carlton Bray recently made a professional examination of the Nevada Western Gold & Silver Mining Co. property near Pyramid Lake, Nev.

F. M. Manson and **Morris P. Kirk** are inspecting mining properties in the Lordsburg, N. M., district, and also in the Chiricahuas, in Cochise County, Ariz.

K. S. Twitchell, mining engineer of San Francisco, Cal., sailed this week for a trip of several months in Europe. Most of the time Mr. Twitchell will devote to France.

William H. Crague, metals specialist, and **Raymond Richards**, oil specialist, have been appointed tax-valuation engineers in the income-tax unit of the Bureau of Internal Revenue.

Charles E. Knox, president of the Montana-Tonopah Mining Co., Tonopah, Nev., was among those present at the beginning of operations of the Gold Canyon Dredging Co., of Dayton, Nev.

S. F. Shaw, of Charcas, San Luis Potosi, Mexico, has resigned from the American Smelting & Refining Co., to become manager of Cia. Minera La Constancia, at Sierra Mojada, Coahuila.

W. A. Funk has recently returned from Colombia, South America, where he was in charge of the Chicago mine in the Guamoco district. Mr. Funk will resume his practice as a mining engineer, at Idaho Springs, Col.

Angus W. Macdonald, employment agent of the companies of Dominion Steel Corporation, and recently superintendent of Black Diamond Coal Co. at Lethbridge, Alberta, has been appointed superintendent of industrial relations by the corporation.

WILLIAM SPENCER MURRAY

William Spencer Murray, consulting engineer of New York City, author of the Super-Power System, chairman of the Super-Power Committee and of its engineering staff, was born in Annapolis, Md., in 1873, and was graduated in electrical engineering from Lehigh University in 1895. After seven years of practical training with the Westinghouse Electric & Manufacturing Co., he engaged in four years of consulting practice in Boston. After this Mr. Murray, in 1905, became chief electrical engineer of the N. Y., N. H. & H. R.R., and took full charge of the great task of carrying out the electrification of the New Haven. He was president of the Housatonic Power Co. in 1917-18, and a member of the electrical engineering firm of McHenry & Murray from 1913 to 1917, and vice-president of the A. I. E. E. from 1913 to 1914. His experience in large-scale electrical engineering undertakings has logically led to his conception of a nation-wide survey of our power system and to his selection, by Secretary Payne, to execute the restricted survey as authorized by the last Congress.

Walter H. Wiley, of Los Angeles; **Fred Searls, Jr.**, of Berkeley, and **Albert Burch**, of San Francisco, Cal., all retained by the Hecla Mining Co. in the pending apex litigation with the Federal Mining & Smelting Co., were recently in Wallace, Idaho, in connection with that case. They were accompanied by John P. Gray, chief attorney for the Hecla.

Recent visitors to New York included the following engineers and mining men: Emilio Mosonyi, Salvador Deep Well Boring Co., San Salvador, C. A.; P. R. Hines, Allis-Chalmers Manufacturing Co., Milwaukee, Wis.; L. A. Barton, Shreveport, La.; Everett W. Smith, Roasting & Magnetic Concentrator Zinc Co., Ltd., Montauban, Que.; F. F. Kett, San Francisco, Cal.; Courtenay de Kalb, Baltimore, Md.; William F. Jahn, El Salvador silver mine, Gilman, Mont.; Charles C. Selbie, of Pasadena, Cal., and Dundu, Caixa 347, Loanda, Angola, Africa; F. J. S. Sur, San Antonio, Tex.; Dr. E. Barth, Roswell, N. M.; A. Matsuhara, Kyoto, Japan; K. S. Twitchell, Los Angeles, Cal.; H. C. Anchor, Dome Extension Mines, South Porcupine, Ont.

SOCIETIES

American Mining Congress, holding its twenty-third annual convention at Denver, Col., Nov. 15 to 20, invites all manufacturers of mining machinery, all engineers, all mine operators, their officials, and all others interested to the **First National Standardization Conference**. This conference, meeting on the dates mentioned in the Albany Hotel, Denver, will discuss the improvement and standardization of mine practice as applied to mining equipment, machinery, labor- and life-saving devices, safety codes, costs accounting, government and state co-operation, and related subjects. The first annual joint meeting was at St. Louis in 1919, and the standardization committees have now divided their work into two general divisions, Metals and Coal. Address all inquiries to John T. Burns, assistant secretary, American Mining Congress, Albany Hotel, Denver, Col.

National Safety Council has issued the preliminary edition of the program of the **Ninth Annual Safety Congress** to be held in the Auditorium, Milwaukee, Wis., Sept. 27 to Oct. 1, inclusive. That week is also to be "No Accident Week" for Milwaukee. The Mining Section begins its sessions on Sept. 28 at 2:30 p.m. and includes papers on Vocational Training, Industrial Nurses, Safety Devices on Hoisting Engines, Handling Mine Cars, Gas Explosion Prevention, Hazards in Open-Cut Mining, by C. A. Mitke, L. F. Mitten, D. E. A. Charlton, and others. Headquarters will be at Hotel Wisconsin, 3d St. near Grand Ave. J. C. Pinney, 108 Mason St., Milwaukee, Wis., will attend to requests for hotel reservations.

LEADING EVENTS

National Tax Association Meets in Salt Lake City

Various Plans of Taxation Discussed by Delegates—Utah Copper Workings at Bingham Visited

The National Tax Association recently met in Salt Lake City, the place of meeting being the Hotel Utah. The question of a plan of taxation to take the place of the tax on stock dividends under the head of excess profits tax refused by the supreme court was discussed on Wednesday, Sept. 9, when it was announced that treasury officials are seriously considering the imposition of a tax on undivided earnings. John E. Walker, special attorney for the Internal Revenue Bureau, speaking for his chief, T. S. Adams, who was unable to be present, said that Mr. Adams was giving much thought to this form of taxation, combined with an extension of special excise taxes on commodities sufficiently in common use to yield a considerable revenue to take the place of that which the supreme court decision placed out of the reach of the Federal officials.

At the close of the evening session, Prof. Charles M. Bullock, of Harvard, at the round table discussion spoke in opposition to the proposed form of taxation, saying that it would place larger corporations in a more favorable position and work hardship on newer and smaller enterprises. Meyer D. Rothschild of New York, chairman of the business men's national tax committee, speaking for the proposed plan, held that the little business men would be in rather a better position than at present. Thomas W. Page, chairman of the U. S. tariff commission, opened the evening session by giving an outline of the history and work of the commission, now four years old, describing also the chaotic condition of commercial relations between countries following the world war.

A paper by Prof. R. M. Haig, of Columbia University, was then read by A. E. Holcomb on "The Exemption of Mortgage Interest as a Solution of the Housing Problem," stating that real estate stands to lose more through such a policy than any other interest, as any breakdown in income taxation would throw the burden back on realty. A report adopted unanimously by the committee on exemptions was read by Prof. Carl C. Plehn, of the University of California. This report urged "that there should be no privileged class free from bearing their share of the cost of the institutions upon which their well-being, if not their lives, depended."

Douglas Sutherland, of the Illinois constitutional convention, gave an account of taxation problems in his state. On the afternoon of Sept. 9 members, after a morning session given over to round table discussion, were taken to Bingham as the guests of the Utah Copper Co., where they were shown about by John M. Hayes, treasurer of the company, who explained the pioneer work of D. C. Jackling in bringing to commercial use low-grade porphyry ores.

WEEKLY RÉSUMÉ

It is reported from California that the Rising Sun Mining Co., at Colfax, has found the rich ore shoot lost years ago. At Salt Lake City the National Tax Association convened during the week. In Nevada, the Gold Canyon Dredging Co. has begun its operations. Virginia City, on the Comstock, has experienced a strike of miners. Word is received from Melbourne that the Electrolytic Zinc Co. has acquired the Mount Reed and Roseberry mines, in Tasmania. At Hill City, S. D., the National Tin Corporation has suspended operations. Little of note is reported from Washington. Work is to be undertaken by the Bureau of Mines looking to the improvement of drill steel.

Lake Ore Shipments in August Pass Last Year's Figures

Iron-ore shipments from the head of Lake Superior are now 3,200,000 tons greater than at a similar date in 1919, shipments during August, 1920, having exceeded those of August, 1919, by 2,500,000 tons because of the coal dock strike which so seriously curtailed ore shipments during that period last year. At this writing shipments have practically ceased over the D. M. & N. on account of a strike of wipers and hostlers at the Proctor shops. The men are not employees of the railroad, but are hired by a contractor to whom the railroad company sub-lets that phase of its work. The men are now paid 50c. an hour for a twelve-hour day and are striking for 60c. an hour and time and one-half for over eight hours. A compromise of 55c. has been offered, but has not been accepted. Below are detailed figures of 1919 and 1920 shipments:

	August, 1919	August, 1920
D. M. & N., Duluth	1,645,788	2,351,918
D. & I. R., Two Harbors	847,944	1,444,926
C. & N. W., Ashland	302,305	1,101,991
Soo, Ashland	72,940	225,303
Soo, Superior	171,743	251,596
N. P., Superior	67,644	93,895
G. N., Superior	700,710	1,921,023

Unloading and loading ore carriers at lower lake ports have greatly improved and fleet capacity in the ore trade has been more than maintained in spite of increased coal shipments which have been made.

Comstock Miners Walk Out

Strike Unauthorized by Unions—I.W.W. Control Apparent—Seek Dollar Per Day Increase

Underground workers at Virginia City and Gold Hill, Nevada, walked out on Sept. 5. The strike was not authorized by the unions but was apparently organized and directed by an I.W.W. element. A mass meeting of miners was called for Sunday, Sept. 5, and on that day, at the meeting, all miners who approved the disregarding of the secret ballot and the demand for a dollar per day increase were asked to step to the right and those against to step to the left. The result was apparent approval on the part of the underground men. The "hybrid organization" then attempted to serve notice on the operators but the operators refused to recognize such notices and on Sept. 6 issued the following statement which clearly indicates the situation:

"In view of the walkout of miners of the Comstock district and their subsequent demand for a general increase of $1 per day, together with the elimination of the secret ballot, we, the undersigned operators, make the following statement of our position:

"Owing to the increased prices of mine supplies and equipment, and increased freight rates, the cost of mining has, during the past few months, been steadily climbing. On this account, and believing that a reduction in cost might be expected in the near future, many of us have been considering seriously the advisability of suspending operations in the hope of such a decrease. We have been unwilling to do this on account of the large number of men who would be thrown out of employment. By reason of this unannounced walkout the miners have settled this question for us.

"This action of the miners was taken in spite of the existence of several contracts, some of which were effective until Jan. 1, 1921, and all of which were subject to 30 days' notice before they could be nullified. In view of the absolute proof that the cost of living has already decreased and will continue to decrease, we do not feel that a raise in wages is at all warranted at this time We are ready and willing to resume operations under the old scale of wages.

"None of the organizations represented by the undersigned operators is opposed to unionism on the Comstock.

"(Signed)

"R. A. Hardy,
"George H. Drysdale,
"H. B. Bulmer,
"H. L. Slosson, Jr.,
"Alex. Wise."

Operations at Virginia have been con-

tinued under difficulties which are not appreciated by the miners. In spite of increasing costs, efficiency has not increased and as a consequence unit costs have risen greatly. If pumps have to be pulled, as intimated, the added cost of unwatering and repairing later may operate to prevent some mines from resuming. From 300 to 350 miners are involved. Governor Emmet D. Boyle is using every effort to clear up the situation in a way that will be equitable to both parties.

Rising Sun Mine at Colfax, Cal., Finds Lost Vein

An important strike has been made by the Rising Sun Consolidated Mines Co., near Colfax, Cal. The property, which was famous about forty years ago for its rich ore, has been closed down until recently. The rich ore streak was lost years ago and much development work has been done in an effort to find the vein. Although good ore has been found it was not until Sept. 6 that the main orebody was uncovered. Crews on the 6th, 7th, 8th and 9th levels all cut the lost vein at about the same time, it is stated. The ore is free milling gold quartz, about 4 ft. wide. Some assays are said to run several thousand dollars per ton.

Mackay School of Mines Expects Good Year

The number of inquiries received from prospective students before registration day indicates that the Mackay School of Mines, connected with the University of Nevada at Reno, will have a larger attendance than ever before. It is the expressed opinion of the director, F. C. Lincoln, that the coming year will be the most successful in its history.

Mining schools at various camps in the state have been affiliated with the Mackay School of Mines, but the ones at Goldfield and Ely have been discontinued, and it is probable that the one at McGill will be also. Those at Virginia City and Tonopah will continue. A rearrangement of the mineral exhibits at the museum has been made recently and many gifts of fine mineral collections have been received recently.

The contract is expected to be let at once for the new building to house the Rare and Precious Metals Station of the U. S. Bureau of Mines, which will be in line with the east wing of the Mackay School. It will have two stories and basement and cost $30,000. The first carload of machinery to be used at the station has been shipped from Golden, Col., the former location. Charles E. Davis, of the Bureau of Mines, is now in Reno but the balance of the staff is not expected until the building is finished.

The staff of the Mackay School of Mines consists of F. C. Lincoln, director and professor of mining; J. C. Jones, professor of geology and mineralogy; and Walter S. Palmer, professor of metallurgy.

Midvale Smelter Seeks Platinum Stolen From Laboratory

166 Grams Taken Recently—Sheriff's Office of Salt Lake County, Utah, Hunting Thieves

The recovery of 166 grams of platinum stolen the night of Aug. 30 from the chemical laboratory of the U. S. Smelting, Refining & Mining Co. at Midvale, Utah, is being sought by the sheriff's office of Salt Lake County. These pieces have been listed as follows by the company:

Clyinders[1]	Numbers on Cylinders	Size of Nos. on Cylinders
1	6	$\frac{1}{4}$ in.
1	31	$\frac{1}{4}$ in.
1	25	$\frac{1}{4}$ in.
1	29	$\frac{1}{4}$ in.
1	1	$\frac{1}{16}$ in.
1	3	$\frac{1}{16}$ in.
1	5	$\frac{1}{16}$ in.
1	6	$\frac{1}{16}$ in.
1	7	$\frac{1}{16}$ in.
1	9	$\frac{1}{16}$ in.
9 Spirals		
2 Crucibles		
2 Crucible covers		
3 Filtering cones		

[1] All cylinders have "B & Co." on stem.

The superintendent, E. H. Hamilton, will be glad to receive any information relating to the stolen platinum.

Joplin Zinc Producers Expected Higher Price on Slab Zinc

Zinc producers of the Joplin-Miami district have been interested in the effect of the recent freight rate increase on offerings for zinc ore and have been surprised to note that slab zinc is not quoted higher on account of it. Figures showing just what the rate increases mean for smelters buying ore in the Joplin field were recently prepared by Ross A. Blanchard, traffic manager for the American Zinc Lead & Smelting Co., and were presented by him to the Tri-state branch of the American Zinc Institute at the weekly meeting at Picher. They were as follows:

INCREASE ON ORE PER TON FROM JOPLIN DISTRICT TO VARIOUS SMELTING POINTS

	Old rate.	New rate.	Increase per ton
To St. Louis	$3.70	$5.00	$1.30
To La Salle	4.60	6.13	1.53
To Cleveland and Donora	6.10	8.35	2.25
To Fort Smith	2.40	3.25	.85
To Bartlesville	1.90	2.55	.65

INCREASE ON SLAB ZINC PER TON FROM SMELTER TO SELLING MARKET

	Old rate.	New rate.	Increase
From Bartlesville and Fort Smith	$3.53	$4.79	$1.26
From East St. Louis to Boston	7.40	0.15	2.75

When it is considered that smelters must first pay the freight on the ore and then again on the slab zinc to East St. Louis or to New York, the increased rates are decidedly important.

The Utah Power & Light Co. has been granted permission to extend its power lines through the town of Morgan in Morgan County, Utah, in order to supply power to the district beyond that place. Morgan itself is supplied by a private company, which buys the power at wholesale from the Utah power company.

New Cornelia Co-operative Store Described

Profits Distributed Among Company's Employees in Proportion to Amount of Their Purchases

E. D. Gardner, mining engineer of the U. S. Bureau of Mines, describes the New Cornelia co-operative store at Ajo, Ariz., as follows:

"The town of Ajo is built in the desert and consisted of but a few houses when the New Cornelia Copper Co. started operations. Since there were no stores at Ajo or vicinity the New Cornelia Co-operative Mercantile Co. was established to serve the needs of the employees of the New Cornelia and allied companies.

Weight of Platinum, grams	Size of Cylinders
17.0002	$4\frac{1}{2}$ x 2 in.—$5\frac{5}{8}$-in. stem
15.6973	$4\frac{1}{2}$ x 2 in.—$5\frac{5}{8}$-in. stem
15.4663	$4\frac{1}{2}$ x 2 in.—$5\frac{5}{8}$-in. stem
15.6608	$4\frac{1}{2}$ x 2 in.—$5\frac{5}{8}$-in. stem
11.50	$3\frac{7}{8}$ x 2 in.—4 -in. stem
11.50	$3\frac{7}{8}$ x 2 in.—4 -in. stem
11.50	$3\frac{7}{8}$ x 2 in.—4 -in. stem
11.50	$3\frac{7}{8}$ x 2 in.—4 -in. stem
11.50	$3\frac{7}{8}$ x 2 in.—4 -in. stem
11.50	$3\frac{7}{8}$ x 2 in.—4 -in. stem
about 6 gm.	$4\frac{1}{2}$ in. long—$\frac{1}{4}$-in. flat coil
about 20 gm.	$4\frac{1}{2}$ in. long—$\frac{1}{4}$-in. flat coil
about 5 gm.	$4\frac{1}{2}$ in. long—$\frac{1}{4}$-in. flat coil
about 2 gm.	$4\frac{1}{2}$ in. long—$\frac{1}{4}$-in. flat coil

"The New Cornelia Copper Co. advanced the money to erect the store building and to buy the stock, and assumes all risks. In all, $85,000 has been advanced, representing the capital stock of the enterprise.

"The store is run by a store manager appointed by the copper company and who reports only to the general superintendent. A committee of seven workmen, representing the various departments, meet with the store manager monthly and make suggestions for the betterment of the service and present complaints which have been brought to their attention.

"The store is well managed, carries a large and well assorted stock and is modern in every respect. Prices are at the same level as in the other southwestern mining camps. The copper company does not participate in the profits of the store but does receive 6 per cent interest on the capital advanced. At the end of the year, after making proper deductions for interest on capital account, depreciation of store equipment and fixtures, and for a proper sum to the surplus account, the rest of the profits is distributed among the employees of the company in proportion to the amount of their purchases.

"To participate in the store profits employees must be in the company's employ at Christmas, when the dividend or rebate is paid, and must have worked four months previous to Dec. 20, when the books are made up.

"When a man quits he forfeits any interest in the dividend fund which he may have acquired, and it has been found that this rule promotes the stability of the working force beside reducing the cost of living of the regular employees.

"The following profits have been distributed by the store to date: 1917 (9 months) $12,052.60 to 472 employees; 1918, $32,777.71 to 773 employees; 1919, $40,825.05 to 618 employees. The average discount has been 15 per cent and about 70 per cent of the men have benefited.

"Employees, to receive the rebate, must make purchases on credit and all store accounts are deducted from pay checks. Thereby no bad debts are accumulated. The store does considerable cash business with others than employees and the profit from these purchases as well as from the business by the men who have quit the company's service, all goes into the general dividend fund.

Mine-Rescue Car Visits Engelmine, Cal.

The U. S. Bureau of Mines' rescue car No. 1, stationed at Reno, Nev., has just completed a two weeks' stay at Engelmine, Plumas County, Cal. E. D. Gardner and R. Hicox conducted classes in first aid and mine rescue for miners, foremen and superintendents of the district. The classes were held in the evening both at Engelmine and the upper mine of the Engels Copper Co.

Operations in St. Louis County, Minn., Compared

The mine inspector of St. Louis County, Minn., has submitted his annual report as of June 30, 1920. Below is a summary of the report together with a comparison with the preceding year:

	1919	1920
Number of mines operated	117	114
Number of mines idle	49	58
Total number of mines	166	172
Number of inspections	299	305
Number of men employed underground	6,552	5,898
Number of men employed in open pits	2,692	2,795
Number of men employed in stripping	2,470	2,624
Number of men employed on surface	2,498	2,804
Total number of men employed	14,212	14,121
Tons ore shipped from underground	9,575,514	7,850,590
Tons ore shipped from open pits	22,253,295	17,499,334
Total shipments	31,828,809	25,349,924
Cubic yards stripping removed	14,124,832	11,699,279
Fatal accidents underground	18	26
Fatal accidents open pit, stripping and surface	15	10
Total fatal accidents	33	36
Accident factor per 1,000 men employed	2 39	2 59
Tons ore per fatal accident	964,509	704,164
Number serious non-fatal accidents	21	36
Average wage	$5 55	$6 93

The greater part of the Mesabi Range, in the iron country, is included in St. Louis County.

Electrolytic Zinc Co. Acquires Read-Roseberry Mines

Reserves of Zinc Ore in Properties Taken Over Exceed 1,000,000 Tons —Gets Option To Buy Zeehan Smelters

From Our Melbourne Correspondent

An agreement has been executed whereby the Electrolytic Zinc Co. of Australasia Proprietary Ltd. will take over as from July 31 the mines and other assets of the Mount Read & Roseberry Mines Ltd., Tasmania. The consideration for the sale is the issue to the Mount Read & Roseberry Mines of 350,000 ordinary shares of £1 each fully paid in the capital of the Electrolytic Zinc Co.; the right to the Mount Read & Roseberry mines to take up 150,000 cumulative participating preference shares of £1 each in the Electrolytic Zinc Co.; and the right of the Mount Lyell Mining & Railway Co. to appoint two directors to the board of the Electrolytic Zinc Co.

The authorized capital of the Electrolytic Zinc Co. is £1,000,000 in 1,000,000 shares of £1 each, with power to increase from time to time. The issued capital at date is 600,000 ordinary shares of £1 each, fully paid, which are held by the undermentioned companies in the following proportions: Amalgamated Zinc (De Bavay's), 240,000 shares; Broken Hill South, 120,000; North Broken Hill, 120,000; Zinc Corporation, 120,000; total 600,000.

It is intended to increase forthwith the subscribed capital by a further issue of ordinary shares, which will be offered to the shareholding companies pro rata to the respective holdings at this date. Steps will then be taken to increase the authorized capital to £2,500,000, divided as follows: 1,250,000 8 per cent cumulative participating preferential as to capital and dividends, and ranking *paripassu* with the ordinary shares in any dividend distribution over and above 8 per cent on such ordinary shares; and to issue as rights to the individual shareholders in the constituent companies 1,050,000 of such preference shares. Of the 1,250,000 ordinary capital, 350,000 shares of £1 each fully paid will be issued to the Mount Read & Roseberry Mines Ltd. in terms of the agreement. These shares will be deferred as to dividends until July 31, 1925, after which date they will rank with the other ordinary shares issued in any distribution of profits.

The assets acquired under the agreement comprise the Hercules and Roseberry groups of mines, with ore reserves estimated at over 1,000,000 tons of the following average: 27.40 per cent zinc, 7.30 per cent lead, 9.57 oz. silver per ton, 0.127 oz. gold per ton. In addition the interest is acquired in an option to purchase the Zeehan smelters from the Government of Tasmania.

In a circular to shareholders, the directors of the Mount Read & Roseberry Mines point out that the issued capital of that company is 256,503 shares, and the company is under obligation to issue 97,500 shares to the Tasmanian Copper Co., making a total of 354,003 shares. The company is indebted to the Mount Lyell company for advances made for working capital to a total of £180,000. An arrangement has been made for the discharge of this indebtedness by an allotment of 180,000 of the deferred ordinary shares in the Electrolytic Zinc Co. In consideration of the Mount Lyell company being released from any further obligation under its agreement with the Mount Read & Roseberry Mines it will accept an allotment of 30,000 deferred ordinary shares in the Electrolytic Zinc Co. in full settlement of its rights as the holder of 100,000 shares in the Mount Read & Roseberry Mines. On a proportional basis, the Mount Lyell company would have been entitled to approximately 48,000 shares. Should it be decided to distribute the remaining 140,000 deferred ordinary shares in the Electrolytic Zinc Co., shareholders would receive approximately fifty-five such shares for each 100 shares held by them, but the distribution will be slightly reduced by the number of shares required to meet the company's expenses after June 30, 1920. The Mount Lyell company will have the right to apply for 90,000 out of the 150,000 participating cumulative preference shares in the Electrolytic Zinc company, which the Mount Read & Roseberry company is entitled to subscribe for at par. It is the intention of the board to give shareholders the opportunity of taking up the remaining 60,000 shares when the issue is made by the Electrolytic Zinc Co.

MINE RESCUE CAR NO. 1 OF U. S. BUREAU OF MINES

The Lake Rolleston scheme, like the King River scheme, will be held in abeyance for the time being. It will be possible to concentrate upon the Great Lake scheme. All mining, smelting and concentrating will be done at Roseberry and Zeehan. At the same time power will be carried to Launceston.

Gold Canyon Dredging Co.'s Start A Gala Occasion

Large Crowd Sees New Dredge Begin Work—Governor Emmet D. Boyle Addresses Gathering

The intense interest which has been manifested in the operations of the Gold Canyon Dredging Co., at its immense holdings of gold placer ground but a few miles from the historic Comstock lode in Nevada, culminated on Sunday, Sept. 5, when not less than 1,200 people came to see the big steel dredge begin its work. Men prominent in the mining world were present, many Californians being among them, though Bulkeley Wells, president of the company, and Harry Payne Whitney, one of the principal stockholders, were unable to come.

The interest in the occasion felt by most of the visitors was expressed by George L. Hurst, manager of the dredging department of the Bethlehem Shipbuilding Corporation, of San Francisco, who said: "This is a great gala occasion. I have never seen anything like it. You would think we were launching one of Uncle Sam's battleships. This is even better, for not one of our sixteen launchings in 1918 drew such a crowd as this."

Among those who addressed the crowd before the current was turned on and the dredge put in operation were: Roy H. Elliott, assistant manager of the Gold Canyon Dredging Co., who acted as master of ceremonies in the absence of President Bulkeley Wells and General Manager Fred G. Farish; Walter E. Clark, president of the University of Nevada; Dr. Aurelia Rhinehart, president of Mills College, California; Emmet D. Boyle, Governor of Nevada; and Edwin Higgins, consulting engineer for the company. The latter gave many interesting facts regarding the history of gold dredging in general, as well as the particular dredge on which he was standing.

Program Committee Named for Mining Congress

The advisory program committee for the convention of the American Mining Congress to be held at Denver, Col., in November has been appointed with the following membership: Bulkeley Wells, ex-officio chairman; D. W. Brunton, Albert Burch, James F. Callbreath, John C. Howard, E. W. Parker, Col. Warren W. Roberts, Carl Scholz, George Otis Smith, J. E. Spurr, and Francis A. Thompson.

Civil Service Examinations

Those interested in the following should apply to the Civil Service Commission, Washington, D. C., for form 1,312, stating the title of examination desired:

Ore-dressing engineer, $2,400-$3,600; both sexes; male eligibles preferred. An open competitive examination. Applications received up to Oct. 12. A vacancy in the Bureau of Mines, for duty at Moscow, Ida., may be filled from results of examination.

Recent Production Reports

Shattuck-Arizona in August produced 194,003 lb. copper, 563,452 lb. lead, 34,661 oz. silver and 406.71 oz. gold. Production of copper in July was 166,938 lb.

Sons of Gwalia, Kalgoorlie, crushed 11,120 tons of ore in July yielding £15,919 in gold, this value being based on the normal price of gold.

Cerro de Pasco produced 4,444,000 lb. copper in August, compared with 3,652,000 in July.

Phelps Dodge produced 8,365,000 lb. copper in August compared with 8,357,000 in July. Of the August output the Copper Queen Branch produced 5,054,000 lb.; Moctezuma Copper, 2,490,000; Burro Mountain Branch, 92,000; and custom ores yielded 729,000.

North Butte produced 1,286,137 lb. copper in August.

U. V. Extension's August production was 5,805,568 lb. copper against 3,304,878 in July.

Calumet & Arizona produced 5,200,000 lb. copper in August, of which 3,650,000 lb. was available for the company. The figure corresponding to the latter in July was 3,528,000.

New Cornelia's August output was 3,842,000 lb. copper, as compared with 3,522,000 in July.

Miami Copper produced 4,630,720 lb. copper in August against 4,459,298 in July.

Arizona Copper's output of copper in August was 3,000,000 lb., unchanged from recent months.

Inspiration produced 7,200,000 lb. copper in August against 6,500,000 in July.

East Butte's smelter produced 1,566,800 lb. copper in August against 1,537,880 in July.

Utah Copper's August production was 8,820,000 lb. copper against 8,500,000 in July.

Chino Copper produced 4,000,148 lb. copper in August compared with 4,360,932 in July.

Ray Consolidated's output in August was 4,505,000 lb. copper compared with 4,500,000 in July.

Nevada Consolidated's August production was 4,650,000 lb. copper, unchanged from June and July.

Greene-Cananea's August output was 3,500,000 lb. copper unchanged from July.

Butte & Superior's August output was 7,800,000 lb. zinc and 140,000 oz. silver against 7,914,024 lb. zinc and 159,778 oz. silver in July.

Interstate Callahan produced in August 4,452,000 lb. of zinc concentrates carrying 52-53 per cent zinc, 2,014,000 lb. of lead concentrates (including some lead ore) running 60 per cent lead, and 20,140 oz. silver. Zinc concentrates produced in July totaled 4,400,000 lb., the grade being the same as that given above.

NEWS FROM WASHINGTON

By PAUL WOOTON
Special Correspondent

Bureau of Mines To Study Drill Steel

More work will be done by the U. S. Bureau of Mines in the near future on problems looking to the improvement of drill steel. Some work has been done on this subject by the Bureau, but in view of the revelations at the recent meeting of the American Institute of Mining Engineers more attention will be given the matter. It was pointed out very clearly at the meeting that, while there has been great development in drills during the past two decades, there has been little if any improvement in drill steel. If a steel is developed which will stand up longer, it will mean the saving of considerable losses of time in changing drills.

Officials of the U. S. Bureau of Mines have been surprised by the number of companies that are directly interested in the lead and zinc industry in the Mississippi Valley. A list of such companies was compiled so that invitations could be issued to their representatives to attend the meeting in St. Louis on Oct. 9. On Sept. 11, there were 137 companies on the list, with prospects that others would be added.

Before the nature of the mining and the metallurgical work, which is to be undertaken at the new experiment station at Rolla, Mo., is determined the Bureau wants to hear from the industry itself as to what problems are most pressing. The appropriation for the work is $25,000, which is too small to permit the study of all of the problems.

With the development of sources of aluminum in certain clay deposits, there has come an insistent demand that the Government undertake some work on that subject. Some are of the opinion that aluminum-bearing clays which could be worked profitably are much more widely distributed than is generally supposed. This carries with it the possibility of using these clays as a source of aluminum oxide.

It is also claimed that the small operators, who are trying to get a foothold in the aluminum industry, are entitled to the results of Government research in such matters as cheap methods of manufacturing aluminum oxide and the losses in re-melting. The highly organized concerns in the industry are able to carry on their own research but it is argued that it would be in the public interest for the government to undertake work on such problems as would be of benefit to the entire industry, especially to the smaller interests.

In addition, it is requested that research be done on the alloys of aluminum. It was pointed out that the Germans developed duralumin for their Zeppelin construction, an alloy at once light and of great strength. It is believed that aluminum alloys alone offer a great field for development.

It is also pointed out that there is great need for research in the whole matter of non-ferrous alloys. The demand for alloys with special properties has been augmented greatly by the development of automobile and aeroplane industries. Even in an alloy as well understood as is brass, the full possibilities of varying the percentages of copper and zinc have not been realized.

War Minerals Awards

Awards recommended by the War Minerals Relief Commission, for the week ended Sept. 4, are as follows (the name of the claimant, the mineral, the amount recommended and its percentage relationship to the amount claimed are shown): G. L. Sledge, manganese, $100, 23 per cent; Bulkeley Wells, chrome, $7,098.95, 45 per cent; Ozark Manganese Co., manganese, $4,290.76, 39 per cent; the Hillside mine, chrome, $10,642.27, 63 per cent; Floyd Brown, manganese, $132, 4 per cent; E. K. Hoy, chrome, $845.50, 14 per cent.

In the pyrites claim of the Kelsey Mines Co., the Commission previously awarded $1,961.21. A further allowance of $918.84 has been made. In the chrome claim of Byrnes Bros., which was disallowed, the sum of $400.96 has been awarded on a re-examination of the claim. On a previous award, J. J. Cummings, Jr., was allowed $120 on a manganese claim. An additional $487.50 has been allowed. To date the Commission has acted on 994 claims.

Building materials have soared to such a point that the Government bureaus interested are studying every possible economy. It is believed that great economies can be effected in the mining of the non-minerals which are used so extensively in the building trades. During 1920, it is estimated that $400,000,000 worth of non-minerals and mineral products were used for those purposes. It is claimed that the average efficiency is low in the recovery of talc, soapstone, slate, limestone, granite, building stone and gypsum.

NEWS BY MINING DISTRICTS

SOUTH AFRICA

American Vanadium & Lead Mines, Ltd., Organized

Johannesburg—An important flotation has recently been announced under the name of the African Vanadium & Lead Mines, Ltd. The nominal capital is £200,000, of which £105,000 is to be issued. The chief object of the company is to take over and continue the working of the Doornhoek vanadium and lead mines in the Zeerust district. It is intended to supplement and improve the existing plant by the installation of a new haulage system, a concentrator, water supply, and power and lighting equipment for the production of high-grade lead and vanadium concentrates for shipment overseas or for local realization, and to acquire the existing stocks of ore.

The operations at the mine have hitherto been confined to recovery of galena nodules containing 80 per cent of lead and 6 oz. of silver per ton, which occur with great frequency. In the course of recovering these nodules, large quantities of lead ore, finely disseminated in the gangue, were recovered, and in the absence of any means of concentration were dumped on the surface. The masses thus dumped and available for immediate shipment are stated in the company's prospectus to be approximately 100,000 tons. Samples of these dumps show value varying from 5.83 per cent to 23.35 per cent lead after removing all visible galena.

It is also planned by the company to erect a plant for smelting and reducing vanadium and lead ores and concentrates, if this be found necessary. The remaining area may also be explored and prospected.

CANADA

Ontario

Government Not To Build Branch of T. & N. O. Ry. to Kirkland Lake—Dome Shareholders Ratify Dome Ex. Proposal

Porcupine—At a special meeting of the shareholders of the Dome Mines on Sept. 4 the proposal of the directors to purchase the property of the Dome Extension Co. was unanimously ratified. The shareholders of the Dome Extension will receive one share of Dome stock for each thirty shares of their Dome Extension holdings.

The new hospital of the Hollinger Consolidated, constructed on the most modern design, is almost completed. The main building is 113 x 37 ft. with a westerly wing 37 x 39 ft. The normal capacity is 35 patients, but in case of emergency twice that number could be accommodated.

At the North Davidson an orebody, reported to be 4 ft. wide, has been encountered in the shaft at a depth of 60 ft.

Boston Creek—The Miller Independence has cut several promising stringers conveying iron and copper sulphides on the 500-ft. level. The inclined shaft which opened up rich ore at a depth of 200 ft. has been dewatered for the purpose of further exploration

The Patricia mine, which has been closed down since the plant was destroyed by a bush fire last fall, has been optioned to T. J. Flynn.

Kirkland Lake—The mine managers of Kirkland Lake have been officially advised by the Ontario government that they do not intend to construct a branch line of the Timiskaming & Northern Ontario Ry. to the camp at present. This change of plan is due to the attitude of the Associated Goldfields of Larder Lake in refusing to submit its property to inspection by government engineers. In the first instance the government declared its intention to build the railway to Kirkland Lake, a distance of four or five miles. The mining interests stated that a good macadam road would be preferable, and the government acceded to their request and constructed a motor road at a cost of $100,000. Then the railway proposition was renewed in connection with the opening up of new mining territory lying between the proved up Kirkland Lake area and Larder Lake, and was favorably considered, the government promising to build the road, provided the property owners interested would permit government engineers to report on their resources and that their finding warranted the construction of a railway. Now the government announces that inasmuch as the Associated Goldfields, the only operating company at Larder Lake, has not accepted the provision for an examination of its property, and that as it has complied with the wishes of the Kirkland Lake operators in regard to the motor road, it would not feel justified in proceeding with the construction of a railway at the present time.

The Ontario government has begun the building of a wagon road from the Tough-Oakes mine east through Level township to Mud Lake.

At the Hunton Kirkland sinking operations have been begun, to carry the shaft down from its present depth of 40 ft. to the 200-ft. level.

Cobalt—New equipment, including a

shoveling machine and crushing machinery, is being installed at the Kerr Lake to handle a large tonnage of low-grade ore on the dumps, which will be shipped by aerial tram for treatment at the Dominion Reduction plant. Production is being maintained at upward of 50,000 oz. of silver per month.

ARIZONA

Ash Peak Extension Under Development

Duncan—The Ash Peak Extension is being developed and operated under the management of John Horrigan. The shaft has been sunk to the 500-ft. level, and drifting is in progress on the vein, which is 9 ft. wide and assays 25 to 30 oz. silver per ton. Eighteen to twenty tons per day is produced from development work, and transported by motor truck a distance of 10 miles to Duncan, whence it is shipped to the smelter at El Paso. This development is on the northwesterly extension of the Ash Peak vein, which outcrops prominently for a continuous distance of about two miles.

The Ash Peak Mining Co. has developed its property by the 800-ft. Shamrock shaft and the 500-ft. Commerce shaft, together with about 7,500 ft. of drifting on the vein. Much of this development work is in payable ore averaging about 14 oz. silver and $1 gold per ton. The company plans extensive surface improvements in the near future. The new equipment will include a 100-ton cyanide mill, compressor plant and new hoisting machinery at the Shamrock shaft. Arthur Murphy, Jr., is manager.

CALIFORNIA

Rich Strike Made at Spanish Dry Diggings—La Grange Hydraulic Mine Stripped of Equipment

Placerville—A rich vein of ore has been cut in the old Grit Consolidated mine at Spanish Dry Diggings. The strike was made by going below the old tunnel with the development work. The mine was formerly owned by William Buckman, who sold out his interests to the Grit Con. Mining Co. for $30,000. The property was one of the richest mines in the early days, but the vein was lost and has been sought continually until it was recently relocated by the present owners.

Grass Valley—The power shortage has seriously affected the employment conditions in this country and the latest result of the curtailment of power is that the Idaho-Maryland has let out thirty-five of its men until power conditions improve. Although the period of unemployment is known to be only temporary, many of the miners are leaving for other places, and the prospects are that when power is again normal there will be a dearth of miners.

The recent strike at the Alcalde mine is said to be fully as good as at first reported. Much ore has been taken out, and a large body of very rich ore uncovered.

Redding—The Yankee John Development Co., operating four miles west of Redding, has purchased the Simmons ranch, including the Reese reservoir and water rights. The deal was made principally because of the water rights, which will enable the new owners to obtain ample water supply for operations at the Yankee John gold mine.

The last lot of machinery has been removed from the famous La Grange hydraulic mine near Weaverville, and will be shipped to China. The noted old producer, for many years the largest hydraulic property in the world, was closed a few years ago, and at present indications are that it will never again be worked.

Sutter Creek—The Central Eureka Mines Co. has cut its main orebody on the 3,900-ft. level. Because of the shortage of electric power the output for last month was greatly curtailed, and only twenty stamps could operate. Instead of the usual three shifts, only two were able to work.

The Argonaut has been unwatered to the 3,300-ft. level, and plans are being made for renewing development at this point, for it was here that the rich orebody was first encountered and was afterwards traced and mined to the 4,800-ft. level. Unwatering is continuing at the rate of about 150,000 gal. daily.

Bakersfield—The Rand Silver mine reports that it has $3,000,000 worth of ore in sight and is paying dividends amounting to $25,000 per month.

NEVADA

Nevada Con. Opens Large Orebody at 700 Level—Gold Pen Mines Co. Shuts Down

Ely—A large body of high-grade ore is said to have been opened up by Nevada Consolidated on the 700-ft. level of the Ruth mine which is said to be getting richer as development proceeds. When this orebody was examined several weeks ago by Louis Ross, it was figured that it would run "better than 7 per cent copper," but late reports indicate that the values are much in excess of the figure given. It has been drifted on for a distance of 100 ft. and crosscutting is in progress to see if the width is as great as on the levels above. Great significance lies in the fact that this same orebody averages but 2½ per cent copper on the 500 and 600 levels above. A saving of 20c. per ton in treatment costs is expected as a result of rearranging the company's mill at McGill so as to use flotation, also an increase in extraction by five per cent. At full capacity the mill treats 14,000 tons daily.

Rand—The property of the Gold Pen Mines Co. at the camp of Rand, near Rawhide, has been shut down. A disagreement of the principal stockholders as to future operations is said to have been the cause.

Pioche—The Burke mine, one of the principal producers in the Pioche district in the early 70's, is being opened under lease from the Amalgamated Pioche Mines & Smelters Corp. to Charles Stindt and associates of Pioche. Preliminary examination disclosed the impracticability of utilizing the old two-compartment Burke shaft, through which the mine has been developed in the past, and it was decided to sink a new incline shaft at a point about 1,000 ft. easterly on the Burke fissure. This incline is now down 75 ft. and is following the well-defined Burke fissure, which has a dip of 50 deg.

Ore shipments from the Pioche district for the week ended Sept. 3 were as follows: Prince Consolidated, 1,900 tons; Virginia-Louise, 800 tons; Black Metals, 100 tons; Bristol Mines, 250 tons; Combined Metals, 150 tons; Con. Nevada Utah, 40 tons; total, 3,240 tons.

IDAHO

Coeur d'Alene District

Amazon Dixie To Resume Development Soon; Will Deepen Shaft—Big Creek Co.'s Flume Completed

Wallace — The installation of new electrical equipment by the Amazon-Dixie Mining Co. is nearing completion and development will be resumed at once. An electric transmission line has been completed to the mine and a large transformer is being placed at the point of diversion from the main line of the Montana Power Co. A large station on the main tunnel level has been cut to accommodate a new electric hoist, a new compressor is in position. new dry room completed, and various other additions are in preparation for operations on a larger scale. Considerable ore is exposed in the main tunnel for a distance of 600 ft. From this level a shaft has been sunk 400 ft., from which the vein has been explored 350 ft., showing more and better ore than in the tunnel. The plan now is to sink 400 ft. further with the expectation of developing sufficient ore to justify the construction of a mill. The ore is lead-silver. Wesley Everett is manager of the company. The control is owned by Cleveland men of large means.

An important strike of copper-silver ore is reported by the Lookout Mountain Mining Co., operating on Pine Creek. Driving on the vein has exposed two and a half feet of ore which carries high values in both metals, and work on the surface indicates that it is the beginning of a long ore shoot. The company is also driving a tunnel to a very promising lead-silver vein. Control of the company is owned in Kellogg.

The Big Creek Mining Co. will resume operations at once. The company was restrained from permitting the mill water and tailings from entering the creek on complaint of the Kellogg Power & Water Co., which alleged contamination of the water, which is used for domestic purposes in Kellogg. The company has now completed a flume

which will convey the water from the mill to a point far removed from the creek. The management states that the mine and mill are now in position to insure steady operation.

The Montana-Standard, a silver-lead property that has been idle for many years, situated in Montana near the Idaho line, twelve miles from Thompson Falls, has been taken under bond and lease by Mahoney Brothers, of Spokane (until recently of Wallace). It is announced that development and probably shipments will begin at once.

L. W. Stedman, manager of the Paragon Mining Co., which holds a large group of claims about five miles above Murray, states that he expects to begin shipping soon. The company has a 100-ton mill which has been completely overhauled and repaired. The product of the company is both lead-silver and zinc. The ore will be moved to the railroad at Prichard or Delta by motor trucks. F. O. Hammer, of St. Paul, secretary of the company, recently spent several days at the mine.

UTAH

Eagle & Blue Bell's Operations Normal —Tintic Standard Building Mill Foundations

Eureka—Ore shipments from the Tintic district for the week ended Sept. 3 amounted to 141 cars. The Eagle & Blue Bell is keeping up its regular output of about 100 tons daily, the ore coming from levels between the 1,000 and 1,800 levels. The disaffection of a few radicals was unable to impair the working force and the company has the usual number of men at work. Development work, suspended for a time, has been resumed.

The Pinion Queen is working three shifts and sinking its shaft as rapidly as possible. E. J. Raddatz of the Tintic Standard is president.

The Mammoth is disposing of its 250,000 tons of dump ore, said to be worth about $7 a ton, at the rate of two cars a day. The mine is also sending out first class ore from its workings.

The Tintic Standard has a large force at work on the foundations of the mill which it is building at Warm Springs Creek. The boarding house, pump house, machine shop and other buildings have already been constructed.

In the Plutus, small stringers of ore have been opened on the 1,700 level, and prospects of ore in commercial amount soon are considered good.

Bingham Canyon — The Montana-Bingham is now under the same direction as the Bingham Mines. Imer Pett is manager.

Salt Lake City—The Woodlawn property in Big Cottonwood is being developed and a shipment is expected soon. Ore is reported in three places.

Park City—Shipments of ore and concentrates for the week ended Sept. 3 amounted to 2,186 tons, the Ontario and the Silver King Coalition with 600 and 582 tons, respectively, heading the list.

MONTANA

Davis-Daly Makes Rich Strike on 2,700 Level

Butte—On Sept. 11 the Davis-Daly company opened 27 ft. of ore running 6½ per cent copper and 5 oz. silver on the 2,700 level of the Colorado mine. The strike was made in drifting on an orebody already opened. It is said that this development is one of the most important of the year in the Butte district.

SOUTH DAKOTA

National Tin Corporation Suspends Operations—Cutting Mine Closed Down

Hill City—The operations of the National Tin Corporation have been suspended. It is not stated when work will again be resumed. Alexander Roy, manager, has gone to New York City to attend a meeting of company officials, after which a statement will probably be made as to what will be done in the future.

Deadwood—The Cutting mine has closed down. The large amount of water encountered within the last few months has made this advisable. It is not stated as to just when operations will be resumed but it is certain that no work will be done until suitable pumps can be installed.

Lead — The electrification of the Homestake company's Ellison hoist is being pushed. Some of the machinery has arrived and is being placed in position. When completed this shaft will be equipped with skips and together with the B. & M. hoist will raise all the ore from the mine.

JOPLIN-MIAMI DISTRICT

Oklahoma-Kansas-Missouri

Federal Company Takes Option on Acme Mill and Lease—Much Activity Near Baxter; 20 Prospect Drills Running

Commerce, Okla. — Otis W. White started up two mines in the Oklahoma field on Aug. 11 that have been idle for several months. One was the Otis L., formerly known as the Sullivan, at Commerce, and the other the Miami Metals, at Picher, which has been down since a tornado destroyed its hopper and derrick last spring. Part of the dirt at the Otis L. will be taken from the old Queen City lease, hoisted from a shaft on the Emma Gordon lease and milled at the Otis L. mill on the Sullivan lease. The office for both mines will be at Commerce. White is manager for both properties, with Edward Depee holding the contract for hoisting the dirt at the Otis L. and L. E. Cartwright superintendent for the Miami Metals.

Joplin, Mo.—Creech & Baker have taken a lease on the Fifteenth Street mine in Joplin. They have pumped the water out and are making a good production from four drifts in ore.

Picher, Okla.—The St. Louis S. & R. Co. has completed a new shaft a quarter mile southeast of the mill shaft at its No. 1 mill and has started operation of that property once more after idleness of several months. The dirt is being carried to the mill over a surface railroad. The company has been operating its No. 2 mill steadily. Its mill on the Kropp land, about a mile to the southeast, gave a recovery of 11 per cent (in local parlance) for August. Charles E. Schwarz is manager for the St. Louis.

Hockerville, Okla.—The Federal M. & S. Co. has taken a thirty-day option on the Acme Mining Co.'s mill and lease southeast of Picher and is drilling the ground. The option is on the lease and the No. 1 mill, the No. 2 mill being reserved by the Acme company for treating tailings. The Federal's Lucky O. K. company is having success with the Farmington property, located across the Oklahoma-Kansas state line to the south, and seems to have a good mine there although it had been virtually condemned by other operators. P. W. George is district manager for the company.

Baxter, Kan.—Continued production is being made by Chanute Spelter Co., a subsidiary of American Metal Co. At its Hartley mine west of Baxter it produced 1,905 tons of zinc and lead concentrates in August. The recovery for the month averaged 19 per cent (locally speaking). The company is sinking a shaft on its Brewster land lease one mile north of the Hartley and has it down to 175 ft. It expects to encounter water at 195 ft. and will go to 230 ft. for ore. The company is not expecting any such head of water as at Hartley, where company officials say one million dollars was spent before a pound of ore was produced, most of it being for pumping. About 2,500 gal. per min. still being pumped at this property.

General activity continues in the vicinity of Baxter on account of the rich ground found in the Chanute Hartley mine, and twenty prospect drills were working on Saturday, Sept. 11, on leases in this territory. Two shafts were also going down, one by the Victor Rakowsky interests on a lease just north of the Hartley and another by Messe and associates, one mile west of the Hartley.

LOUISIANA

Myles and Avery Island Companies Shipping Salt Steadily — Jefferson Island's Deposit Being Developed

Weeks Island—The Myles Salt Co., operating at Weeks Island, Iberia Parish, is making regular shipments of sized salt and of compressed salt bricks. Shipments are reported to be anywhere from 500 to 1,000 tons daily. The mine and breaker are completely electrified, and electric haulage and electric shoveling machines are used underground.

Avery Island—The Avery Island Salt

Mining Co., at Avery Island, Iberia Parish, is shipping a large tonnage of salt daily, some of it in the form of high-grade rock salt. Considerable new work is planned at this property including the sinking of an air shaft and the complete electrification of the plant.

Jefferson Island — The Jefferson Island Salt Co. started work about eight months ago to develop the salt body on Jefferson Island. This is on the line between Iberia and Vermilion parishes and about three miles north of the Abbeville branch of the Southern Pacific R.R. To date only development work has been done. Considerable difficulty is being experienced in making a watertight seal between the overlying strata and the salt. A three-mile railroad spur is under construction from the main line to the mine.

ALABAMA

Secondary vs. Primary Iron Ore Tonnage Discussed

Birmingham—The estimated tonnage of secondary ores in the South has materially increased in the last few years against a decrease in that of the primary ores. The possible exhaustion of the ores of the northern ranges is being discussed while to the fore comes the fact that development in the secondary ores is showing greater possibilities than have ever been considered and attention is bound to be attracted to the South, to the Alabama fields and to adjacent states. Investigations have been made recently as to secondary ores and interesting conclusions have been arrived at. Y. A. Dyer, mining and consulting engineer of Birmingham, who has just returned from a trip through the iron ore lands of Alabama, Georgia and other Southern districts, was asked for an opinion on the subject by the correspondent of the *Engineering and Mining Journal*. He made the following statement:

"With pig iron production in the United States proceeding at the rate of 32,000,000 to 35,000,000 tons per annum, requiring an average ore consumption of 65,000,000 to 75,000,000 tons, there is little wonder that the iron and steel interests of this country are ever on the alert for prospects which may lead to augmenting their ore supply—more particularly the reserve supply of what is commonly termed merchantable or primary ore.

"There is no discounting the fact that the United States has from 75,000,000,000 to 80,000,000,000 tons of non-merchantable or secondary ores, but the 'eternal trend' in the past and at present has been and is to woefully disregard secondary ores and vigilantly seek to mine, at maximum production, the primary ores. Thus far the universal policy has been to sidestep even the blending of primary and secondary ores in furnace mixtures, except in extreme cases of necessity. According to the Eckel estimate (which I consider a thorough and practical one) of 1912, the United States is conservatively and rationally credited with possessing 7,550,000,000 tons of "available" or primary ores. Since that period, to the present date, there has been mined approximately 531,000,000 tons with approximately 400,000,000 tons credited to Lake ore operations. This would leave 7,019,000,000 tons of primary ores now credited to the United States.

"At the time the Eckel estimate was made, the Lake district was credited with maximum reserves of 2,500,000,000 tons and Southern red ores 2,000,000,000 tons. Since that time approximately 400,000,000 tons of Lake ores have been exhausted and approximately 50,000,000 tons of Southern red ores, bringing the Lake reserves to 2,100,000,000 tons and Southern red ores to 1,950,000,000 tons. However, since 1912 there have been no new developments which have raised the Lake ore estimates, while in the Birmingham district the Shades Valley deposit of self-fluxing ore has been proven up by drill-holes, shaft and slope at depths ranging from 1,100 ft. to 2,000 ft. This proven area of basin ore practically doubles the tonnage estimate of self-fluxing red ore and very materially increases the secondary ore tonnage estimate outside of the self-fluxing area. One company alone, which has put a twin slope into operation, estimates its tonnage of self-fluxing ore in Shades Valley to be 10,000,000 to 15,000,000 tons. The district's ore production rate of 6,000,000 to 7,000,000 tons annually seems to cause no immediate concern, even among large producers, with reference to the exhaustion time of primary ores. Two hundred to 300 years' supply of primary ores, at present mining rate, seems a long time in the future, compared with thirty to thirty-five years' supply, at the present rate of exhaustion, of primary Lake ores. To the trained engineed this is a powerfully appealing factor, for it means that furnace practice from the standpoint of raw materials in the Birmingham district is fixed for many years hence and practically the only mining methods which are likely to change are slope to shaft and haulage conditions. The character of deposit, analysis of ore and thickness of vein have been proven persistent. In fact thickness of vein has increased with depth from the outerop to basin.

"Except in the case of foundry iron producers, the large deposits of rich brown ores seem to have been temporarily forgotten. The above tonnage estimate of red ores does not take into consideration the 75,000,000 tons of 'available' brown ores credited to Alabama by Eckel. At present these deposits are only worked sporadically for the reason that attention seems to be riveted, for the time at least, on low-cost self-fluxing ore. There has been no decrease in the quality of brown hematite ores. In fact, thus far only the rich wash deposits have been worked to any extent in the Warrior drainage area, Tennessee drainage area and the Appalachian deposits extending from the Shelby deposits on the south to the Rock Run-Piedmont area on the east. The term 'non-merchantable or secondary brown ore' is only applicable in the sense of 'availability' either from the standpoint of mining cost or transportation conditions. In time either will be met by rational mining and washing methods, for the richness of the ore is practically the same whether the washing ratio be 1:20 or 1:2. It simply involves the flushing of much or little earthy matter in which the ore is imbedded. The conglomerate boulder, or mountain ore, is not taken into consideration in tonnage estimates. There are many million tons of this type ore in Alabama. Only the valley or gentle sloping hill ore constitutes the brown ore tonnage of Alabama and the South. What may be termed 'inaccessible,' for the time being, brown ore in the state of Alabama will constitute many million tons, and throughout the distance from Shelby, Ala., on the south to Canton, Ga., on the east the total tonnage will reach well up into the nine-figure column. Prospect work is being done constantly on the brown ores of Alabama and Georgia, and I have covered the ground through the entire area inspecting, prospecting and reporting on various properties within the past four years."

CHRONOLOGY OF MINING

August, 1920

Aug. 2.—Burro Mountain branch of Phelps Dodge Corporation started first unit of new mill.

Aug. 7.—Rochester Combined Mines property in Nevada advertised for sale. —New mine-rescue car of Bureau of Mines destroyed by fire in shops of New York Central R.R.

Aug. 17.—Ontario Mining Association held first general meeting, at Sudbury, Ont.—Change house at Cliffs Shaft mine, Ishpeming, Mich., damaged by fire.

Aug. 20.—Steamer "Superior City" of the U. S. Steel Corporation, sank in Lake Superior in collision with the "Willis L. King" of Jones & Laughlin; 29 lives lost.—Gruss Copper Co., Portola, Cal., started new 15-stamp mill.

Aug. 23.—Lake Superior Meeting of A. I. M. E. formally opened at Houghton, Mich.; closed at Duluth, Minn., on Aug. 28.—Pedro Zamora, Mexican bandit, released Charles Hoyle and five other American and English engineers, retaining for ransom W. A. Gardiner and W. B. Johnson.

Aug. 24.—Case of Northport Mining & Smelting Co. vs. Lone Pine-Surprise Consolidated Mining Co., opened at Spokane, Wash., before Judge Rudkin. —Public Utilities Commission of Utah refused to allow increase in freight charges on shipments of coal and ore. —Manganese ore shipment from Brazil reached Mobile, Ala., for consumers in Birmingham district.

Aug. 26.—Freight rates on lead bullion and blister copper from Salt Lake smelters to Atlantic seaboard raised ¾ per cent.

THE MARKET REPORT

Daily Prices of Metals in New York

Sept.	Copper	Tin		Lead		Zinc
	Electrolytic	99 Per Cent	Straits	N. Y.	St. L.	St. L.
9	18.10@18.50	41.75	44.75@45.25	8.75	8.40@8.80	7.70@7.75
10	18.10@18.50	41.75	44.75@45.00	8.65	8.30@8.70	7.65@7.70
11	18.10@18.50	41.75	45.00@45.25	8.50	8.20@8.60	7.65
13	18.10@18.50	41.75	44.75@45.00	8.50	8.30	7.65
14	18.10@18.50	42.00	44.75@45.00	8.45	8.25	7.65
15	18.10@18.50	42.00	44.75@45.00	8.40	8.20	7.65

The above quotations are our appraisal of the average of the major markets based generally on sales as made and reported by producers and agencies, and represent to the best of our judgment the prevailing values of the metals for deliveries constituting the major markets, reduced to the basis of New York, cash, except where St. Louis is the normal basing point. All prices are in cents per pound.

Copper is commonly sold on terms "delivered," which means that the seller pays the freight from refinery to buyer's destination. The delivery cost varies, and it would be confusing to figure net prices on individual transactions. Consequently, an average deduction of 0.15c. is made from the "delivered" price, to arrive at the New York price. When copper is sold f.o.b. or f.a.s. New York, of course no deduction is made.

Quotations for copper are for ordinary forms of wire bars, ingot bars and cakes. For ingots an extra of 0.05c. per lb. is charged and there are other extras for other shapes. Cathodes are sold at a discount of 0.125c. per lb.

Quotations for zinc are for ordinary Prime Western brands. Tin is quoted on the basis of spot American tin, 99 per cent grade, and spot Straits tin.

London

Sept.	Copper			Tin		Lead		Zinc	
	Standard		Electrolytic						
	Spot	3 M		Spot	3 M	Spot	3 M	Spot	M
9	97 1/8	97 1/8	112	267	273 3/4	35 3/4	35 1/2	39	40 1/4
10	97	97 1/8	112	269 1/2	275 1/2	35 1/2	35	39 3/4	41
11	.	....	.	....	....	....	....	....	....
13	97 3/8	98	112	272 3/4	279	35 1/4	34 3/4	39 1/2	40 1/2
14	99 3/4	99 1/2	112	274 1/2	279 1/2	35	34 3/4	39 1/2	40 1/2
15	100	99 1/2	112	273 3/4	279 3/4	34 3/4	34 1/2	39 1/2	40 1/2

The above table gives the closing quotations on the London Metal Exchange. All prices are in pounds sterling per ton of 2,240 lb.

Silver and Sterling Exchange

Sept.	Sterling Exchange	Silver			Sept.	Sterling Exchange	Silver		
		New York, Domestic Origin	New York, Foreign Origin	London			New York, Domestic Origin	New York, Foreign Origin	London
9	352 3/4	99 1/2	93 1/2	58 1/2	13	348	99 1/2	94	59 3/8
10	351	99 1/2	94 1/4	59	14	344	99 1/2	94 1/2	60 1/8
11	349 1/2	99 1/2	93 1/2	59	15	345	99 1/2	95	60 3/4

New York quotations are as reported by Handy & Harman and are in cents per troy ounce of bar silver, 999 fine. London quotations are in pence per troy ounce of sterling silver, 925 fine.

On the authority of the Secretary of the Treasury, we quote 100c. per oz. for silver, 1,000 fine, delivered at the option of the Director of the Mint to the New York Assay Office or to the mints in Philadelphia, Denver, or San Francisco, and proved to the satisfaction of the Treasury Department to have been mined, smelted, and refined in the United States. This quotation is retroactive to May 13.

Metal Markets

New York, Sept. 15, 1920

There has been no substantial improvement in the metal market. Buying of the major metals took place in slightly larger quantities this week, but not in such an amount as to disturb the generally dull condition prevailing. This stagnant business in the metal market has now continued for many weeks, particularly in the copper market, but it is the consensus of opinion of those in close touch with the metal trade that improvement will soon set in to raise the position of metals such as copper and zinc. The London market showed a slightly upward trend on Monday, Tuesday and Wednesday of this week.

Copper

The purchases of copper improved slightly during the week, and consumers in general are still refraining from purchasing large quantities. It is naturally to their advantage to be able to obtain copper at the low market prices, and they realize that they can purchase sufficient copper for their current needs at attractive quotations. However, producers are satisfied that a better sentiment is developing among copper consumers and that it will take but a small impetus to raise the market out of the depths and place it on a higher level. Little interest is manifested in futures.

Lead

On Monday, the A. S. & R. Co., reflecting the downward tendency in the market, lowered their official price of 9c. New York, to 8½c. Our quotation, based upon sales, still reflects the larger tonnages disposed of by the A. S. & R. at their official price, as stated last week, but the metal could be obtained for prices around 7⅞@8c. Lead inquiries are slacking, and the importations of lead which have been made during the last few weeks have partly succeeded in neutralizing the shortage of lead in this country. Consumers are holding off in the anticipation of a further decline, and those importers who expected the market to stay at the recent high level have already had to take unlooked for losses by the recent decline. Consumption of lead is still good. Future delivery is nominal.

Zinc

Prices again showed a slight drop and the market is still quiet. Importations of cheap re-shipment American zinc are being made. All such zinc which can be satisfactorily proven to the authorities to be of American origin is entitled to be admitted duty free, but it is doubtful if in every case the necessary evidence is procurable. Smelters working on bonded and domestic ores are in a position similar to the silver smelters, who are compelled to satisfy the Government as to the origin of all silver proffered at $1 per oz. to the Treasury Department.

Tin

There was a small improvement in the London market during the first three days of this week, but the market is still erratic and quiet. Last Spring, when tin first exhibited a declining tendency, many consumers, not anticipating a further decline, filled their future requirements, to their own detriment, as tin subsequently dropped much further in price. Hence the reluctance of consumers to enter into the market at present. They prefer to wait and watch the market and exchange. Tin consumption is still good, but the production of electrolytic is decreasing.

Straits tin for future delivery: Sept 9th, 44.75@45.00c.; 10th, 45.00@45.50c.; 11th, 45.50@46.00c.; 13th, 45.00@45.50c.; 14th, 45.00@45.50c.; 15th, 45.25@45.50c.

Arrivals of tin in long tons: Sept. 1st, Penang, 375; 7th, Australia, 100; 9th, Batavia, 100; London, 25; 10th, Straits, 925; China, 175; London, 75; Penang, 200; 13th, China, 175; Singapore, 375; Penang, 400.

Silver

The silver market for the last week has been steady, with a tendency toward higher prices. Business, however, has been done on a moderate scale only, owing to the reluctance of holders to sell at current figures, and a rather limited buying market from the East. There seems to be good reason to look for more activity in the export trade from the Orient. Shanghai rates close at about 106 and Hongkong at 76. Generally speaking, the feeling is that there is room for improvement in the price of silver.

Mexican Dollars—Sept. 9, 71⅛; 10th, 71¼; 11th, 71; 13th, 71⅜; 14th, 71⅛; 15th, 72⅛.

Gold

Gold in London on Sept. 9th, 115s. 9d.; 10th, 116s. 6d.; 13th 117s. 3d.; 14th, 119s. 0d.; 15th, 117s. 4d. Transvaal gold is continuing to come to this country, and it is said that this week's receipts will make the total over $40,000,000.

Foreign Exchange

Social and political unrest in Europe and a heavy supply of grain and cotton bills have further depressed foreign exchange. Sterling, $3.45, is the lowest since last March. Yesterday, francs were 6.43c.; lire, 4.24c.; and marks, 1.66c. New York funds in Montreal, per cent premium, 9.

Other Metals

Aluminum—Ingot, 99 per cent and purer, 35.1c.; 98@99 per cent, 34.9c. Virgin metal still obtainable in open market at about 32.5c. for 98@99 grade.

Antimony—Market continues weak. Spot, 7c. per lb.; Cookson's "C" grade, 14@15c. Chinese and Japanese brands, 7c. W. C. C. brand, 9@9½c. [1]Chinese needle antimony, lump, firm at 8@9c. per lb. Standard powdered needle antimony (200 mesh), 10@12c. per lb.

Bismuth—$2.70 per lb., 500-lb. lots, and $2.72 per lb., 100-lb. lots. Market quiet.

Cadmium—Nominal, $1.40@$1.50 per lb. Market steady.

Cobalt—Metal, $3 per lb.; black oxide, $2 per lb.

Iridium—Nominal, $350@$400 per oz. Heavy demand, but small supplies.

Magnesium—Crude, 99 per cent or over pure, $1.75 per lb. for the metal in 100 lb. lots and over, f.o.b. Niagara Falls.

[1]**Molybdenum Metal** in rod or wire form, 99.9 per cent pure, $32@$40 per lb., according to gage.

Nickel—Ingot, 43c.; shot, 43c.; electrolytic, 45c., f.o.b. Bayonne, N. J.

Monel Metal—Shot, 35c.; blocks, 35c., and ingots, 38c. per lb., f.o.b. Bayonne.

Osmium—Open market, $50@$75 per troy oz.

Palladium—$100@$110 per oz.

Platinum—Firm at $115 per oz.; $105 per oz. in 100 oz. lots.

Quicksilver—Market quiet; $75 per 75-lb. flask. San Francisco wires $75. Weak.

Ruthenium—$200@$220 per troy oz.

[1]**Selenium**, black powdered, amorphous, 99.5 per cent pure, $2@$2.25 per lb. Demand strong.

[1]**Thallium Metal**—Ingot, 99 per cent pure, $20 per lb.

[1]**Tungsten Metal**—$35@$60 per kilogram, according to purity and gage.

Metallic Ores

Bauxite—About 52 per cent alumina content, less than 2 per cent iron oxide, up to 20 per cent silica and artificially dried to contain not more than 4 per cent free moisture, $10 per gross ton at mine; 54 per cent alumina and about 15 per cent silica, $11; averaging 57 per cent alumina, 8 to 12 per cent silica, less than 3 per cent iron oxide, $13 on basis of 8 per cent free moisture. Ores of very low silica content suitable for the manufacture of aluminum oxide and hydrate of alumina command a fancy price.

Chrome Ore—Guaranteed 50 per cent Cr_2O_3 foreign ore with a minimum of 6 per cent silica, 70@80c. per unit, New York. California concentrates, 50 per cent Cr_2O_3 and upward, 70@75c. California production has fallen off, even since May, owing to the low price, which does not permit operation of mines that were worked in 1918 when prices were $1.50 a unit for 50 per cent. The market is strengthening, and should prices rise some abandoned properties will be reopened. There are considerable tonnages of 40 per cent ore at different points in California, which are being held for prices of 50@60c. a unit, f.o.b. cars, California.

Iron Ores—Lake Superior ores, per ton, delivered at Lower Lake ports: Old Range bessemer, $7.45; Old Range nonbessemer, $6.70; Mesabi bessemer, $7.20; Mesabi non-bessemer, $6.55.

Manganese Ore—65@75c. per unit, seaport; chemical ore (MnO_2) $70@$90 per gross ton, lump; $80@$100 per net ton, powdered.

Molybdenum Ore—85 per cent MoS_2, 75@80c. per lb. of contained sulphide, New York.

[1]**Tantalum Ore**, guaranteed minimum 60 per cent tantalic acid, 55@65c. per lb. in ton lots, against recent price of 65@70c.

[1]**Titanium Ores**—Ilmenite, 52 per cent TiO_2, 1½@2c. per lb. for ore. Rutile, 95 per cent TiO_2, 15c. per lb. for ore, with concessions on large lots or running contracts.

Tungsten Ore—Scheelite, 60 per cent WO_3 and over, per unit of WO_3, $7 f.o.b. mines; wolframite, 60 per cent WO_3 and over, per unit of WO_3, $6@$7, in New York.

Uranium Ore (Carnotite)—$2.75@$3 per lb. for 96 per cent of the contained oxide (U_3O_8). Ores must contain a minimum of 2 per cent U_3O_8.

Vanadium Ore—$1.25 per lb. of V_2O_5 (guaranteed minimum of 11 per cent V_2O_5), New York.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

[1]**Zircon**—Washed, iron free, 5c. per lb.

[1]**Zirkite**—$90@$100 per ton, carload lots. Pure white oxide, 99 per cent, is quoted at $1.15 per lb. in ton lots.

Zinc and Lead Ore Markets

Joplin, Mo., Sept. 11—Zinc blende, per ton, high, $49.70; basis 60 per cent zinc, premium, $47; Prime Western, $46; fines and slimes, $45@$42.50. Calamine, basis 40 per cent zinc, $36. Average settling prices: Blende, $47.16; calamine, $38.20; all zinc ores, $46.99.

Lead, high, $108.15; basis 80 per cent lead, $100. Average settling prices, all grades of lead, $103.88 per ton.

Shipments for the week: Blende, 13,102; calamine, 250; lead, 1,565 tons. Value, all ores the week, $790,080.

Platteville, Wis., Sept. 11—Blende, basis 60 per cent zinc, $53 base for one choice lot of 180 tons down to $50.50 contract price for high-grade. Lead ore, basis 80 per cent lead, reduced to $100 per ton. Shipments for the week: Blende, 787; lead, 194 tons. Shipments for the year: Blende, 49,046; calamine, 2,360; lead, 4,115; sulphur ore, 1,241 tons. Shipped during week to separating plants, 1,511 tons blende.

Non-Metallic Minerals

Asbestos—Crude, No. 1, $2,400@$3,000; No. 2, $1,400@$1,700; spinning fibres, $400@$800; magnesia and compressed sheet fibres, $325@$400; shingle stock, $110@$150; paper stock, $60@$75; cement stock, $17.50@$30; floats, $8.50@$15, all per short ton, f.o.b. Thetford, Broughton, and Black Lake mines, Quebec, Canada; 5 per cent to be added as Canadian royalty export sales tax. Freight rate from mines to Sherbrooke, Quebec, over Quebec Central R.R., 20c. per cwt.; from Sherbrooke to New York, 27½c., carload lots; freight to New York for crude No. 1, f.o.b. Thetford mines, $8.45 per ton, carload lots. Car scarcity worse than ever before.

Barytes—Crude, 88 to 94 per cent barium content, $10@$12 per net ton; ground (white) $24@$30 in bags, carload lots; (off-color) $22@$26 in bags, carload lots; all f.o.b. Kings Creek, S. C. Crude, 88 to 94 per cent, $12 per gross ton; ground (white) $23@$25; ground (off color) $16@$19 per net ton, f.o.b. Cartersville, Ga. Crude, 88 to 94 per cent, $23; ground (white) $45; ground (off color) $30@$32 per net ton, less than carload lots, f.o.b. New York. Crude, not less than 98 per cent, $11@$11.25 per ton, f.o.b. cars, Missouri; floated, $28 per ton in bbls.; $26.50 per ton in 100-lb. bags; extra charge for bags, f.o.b. St. Louis. Business quiet; manufacturers not putting in much stock.

Chalk—Domestic, extra light, 5@6c. per lb.; light, 4½@5½c.; heavy, 4@5c; English, extra light, 5@7c.; light, 5@6c.; dense, 4½@5c. per lb., all f.o.b. New York.

China Clay (Kaolin)—Crude, $9@$12; washed, $12@$15; powdered, $18@$22; bags extra, per net ton, f.o.b. mines, Georgia; crude, $8@$12; ground,

$15@$40, f.o.b. Virginia points. Domestic lump, $10@$20; powdered, $25@$30; imported lump, $25@$35; powdered, $30@$60, f.o.b. New York.

Feldspar—Crude, $8@$18 per gross ton, f.o.b. Maryland and North Carolina points; $7.50@$10, f.o.b. Maine; ground, $25@$30 car lots, f.o.b. Baltimore; ground, $17@$21, f.o.b. North Carolina points; $17@$21 per ton, No. 1 ground, f.o.b. New York State; $21@$23 per ton, ground, f.o.b. Maine.

Fluorspar — Gravel, guaranteed 85 per cent calcium fluoride and not over 6 per cent silica, $25 per ton, f.o.b. Illinois mines, and $27.50, f.o.b. Kentucky; ground, suitable for acid, chemical or enameling purposes, $60; lump, $17.50, f.o.b. Tonuco, N. M.

Graphite—Crucible flake, 85 per cent carbon content, 8c. per lb.; 88 per cent, 9½c.; 90 per cent, 10½c., all f.o.b. New York. Crucible grades of Alabama graphite sell as follows, f.o.b. Ashland, Ala.: 80 per cent, 5c.; 90 per cent, 10c. Lubricating grades in increasing demand, with price ranging from 11c. for the 85 per cent guaranteed grade in car lots to 30 and 40c. for higher grades. Mexican, amorphous, $45@$55 per short ton; Korean, 3½c. per lb.; Madagascar, 8c.; Ceylon, 4½@15½c.

Gypsum—Raw crushed rock, $3.50@$4 per ton; raw ground fine, $4@$4.50; calcined stucco, $9, all f.o.b. works. Containers extra. The last price quoted for plaster of paris in carload lots was $4.25 per 250-lb. bbl., f.o.b. mill, alongside dock, New York.

Kaolin—See China Clay.

Limestone—Dolomite, 1@2 man size, $1.60@$1.65; 2@8 in., $1.55@$1.65 per net ton, f.o.b. Plymouth Meeting, Pa.; fluxing, $1.65@$1.75 per net ton, f.o.b. Howellville, Pa.

Magnesite, Calcined — High-grade caustic calcined, lump form, $35@$40 per ton, carload lots, f.o.b. California points. Freshly ground calcined, suitable for flooring trade, $75@$85 per ton, f.o.b. Eastern points.

Dead-Burned — $32.50 per net ton, Chewelah, Wash.; $52@$58, Chester, Pa. Austrian grade, $52@$55 per ton, f.o.b. Baltimore. (Magnesite brick—See Refractories.)

Mica—India block mica slightly stained, per lb.: No. 6, 50c.; No. 5, $1.20 @$1.40; No. 4, $2@$3; No. 3, $4.25@ $5; No. 2, $5.50@$7; No. 1, $8. Clear block: No. 6, 55c.; No. 5, $2; No. 4, $4; No. 3, $5.75; No. 2, $7; No. 1, $9; A1, $14; extra large, $25, all f.o.b. New York; ground, $100@$150 per ton, Philadelphia. Domestic, uncut f.o.b. Franklin, N. C., as follows: Scrap, $45 @$50 per ton; punch, 4@5c. per lb.; circle, 15@25c.; 1½ x 2 in., 75c.; 2 x 2 in., $1.15; 2 x 3 in., $1.65; 3 x 3 in., $2.10; 3 x 4 in., $2.50; 3 x 5 in., $2.75; 3 x 6 in., $3.75; ground 165 mesh, $240 per ton; ground roofing mica, $60; mica washers, 75c.@$2 per lb.; 1¼-in. disks, No. 1, $1.60 per lb.; No. 2, $1.30.

[1]**Monazite** — Minimum of 6 per cent thorium oxide, $35 per unit, duty paid.

Phosphate Rock—Per long ton, Florida ports: 77 per cent tricalcium phosphate, $13; 75 per cent, $11.50; 75@74 per cent, $11; 70 per cent, $8.35; 68 per cent, $7.85; 68@66 per cent, $7.60. There is no price schedule for spot for domestic uses.

Pumice Stone—Imported, lump, 4@ 50c. per lb.; domestic lump, 6c.; ground, 4@7c., all f.o.b. New York.

Pyrites—Spanish fines, per unit, 12c., c.i.f. Atlantic seaport; furnace size, 17c.; Spanish lump, 14@16c.; domestic fines, f.o.b. mines, Georgia, 12@14c.

Quartz—(Acid tower) fist to head, $10; 1¼ to 2 in., $14; rice, $17, all net ton, f.o.b. Baltimore; lump, carload lots, $5@$7.50 net ton, f.o.b. North Carolina mines. F.o.b. Wausau, Wis., the price is $16 per ton in car lots, and $22 less quantities, including bags.

Sand (Glass)—Dry glass sand, $4 per net ton, f.o.b. cars Mapleton, Pa. Sand, f.o.b. Ottawa, Ill., is $3 per ton; $2.50 on annual contracts. Sand or Klondike, Gray Summit and Pacific, all in Missouri, is $2.50 on contract; some outside sales have been made at $4.

Sulphur—$18 per ton for domestic; $20 for export, f.o.b. Texas and Louisiana mines.

Talc — Paper making, $10@$20 per ton; roofing grades, $9@$15; rubber grades, $10@$15, all f.o.b. Vermont. California talc, $20@$45, talcum powder grade. Southern talc, powdered, carload lots, $12@$15 per ton; less than carload, $25, f.o.b. cars; freight to New York $5.25 per ton, carload lots; less than carload lots, $9.25. Imported, $60 @$70; Canadian, $20@$40 per ton.

Mineral Products

Arsenic—White arsenic, 15½c. per lb.; sulphide, powdered, 20@21c. per lb., f.o.b. works, carload lots.

Nitrate—Soda, $3.85 per cwt., ex vessel, Atlantic ports. Market quiet.

Potassium Sulphate—Domestic, $2.25 @$2.50 per net ton, basis 90 per cent, f.o.b. New York.

Ferro Alloys

Ferrocarbontitanium—For 15 to 18 per cent material, $200@$250 per ton, f.o.b. Niagara Falls, N. Y.

Ferrocerium—Per lb., $12@$15. Foreign conditions as affecting the price of American goods remain unchanged.

Ferrochrome—Carload lots, spot and contract, 60 to 70 per cent chromium, 6 to 8 per cent carbon, 17@18c. per lb. of chromium contained; 4 to 6 per cent carbon, 19@20c. f.o.b. works.

Ferromanganese—For 76 to 80 per cent, prompt delivery, $200, freight allowed; last half, $170; English, $170 @$175, c.i.f. Atlantic seaports. Spiegeleisen, 18@22 per cent, $80@$85, f.o.b. furnace.

Ferromolybdenum—Standard grades, carrying from 50 to 60 per cent molybdenum metal, with low sulphur, phosphorus, and arsenic, $2.50@$3 per lb. of contained metal, f.o.b. works.

[1]Furnished by Foote Mineral Co., Philadelphia, Pa.

Ferrosilicon—For 10 to 15 per cent, per gross ton, f.o.b. works, $60@$65; 50 per cent, $82.50@$85; 75 per cent, $150@$160.

Ferrotungsten—70 to 80 per cent W, $1.10@$1.15 per lb. of contained tungsten, f.o.b. works.

Ferro-uranium—35 to 50 per cent U, $7 per lb. of U contained, f.o.b. works.

Ferrovanadium—Basis 30 to 40 per cent, $6.50@$9.50 per lb. of V contained, f.o.b. works.

Metal Products

Copper Sheets — Current New York price, 29½c. per lb.; wire quoted, 22½@ 23c.

Lead Sheets—Full lead sheets, 11c.; cut lead sheets, 12½c. in quantity, mill lots.

Nickel Silver—Unchanged at 39½c. per lb. for 18 per cent nickel.

Yellow Metal — Dimension sheets, 26¾c.; sheathing, 25¾c.; rods, ⅜ to 3 in., 23¾c.

Zinc Sheets—$12.50 per 100 lb., less 8 per cent on carload lots, f.o.b. smelter; zinc plates, 12c. per lb.

Refractories

Bauxite Brick—56 per cent alumina, $160 per 1,000, f.o.b. Pittsburgh.

Chrome Brick—$100@$110 per net ton, carload lots, eastern points.

Chrome Cement—40 to 45 per cent Cr_2O_3, $50 per net ton, and $55 in sacks, carload lots, eastern shipping points.

Clay Brick — First-quality fire clay, 9-in. shapes, $55@$60 per 1,000, Pennsylvania, Ohio, and Kentucky works; second quality, $50@$55. First quality, St. Louis, $45; New Jersey, $75.

Magnesite Brick—$110@$120 per ton, eastern shipping points; 9-in. straights, $90@$100; 9-in. arches, wedges and keys, $95@$105; soaps and splits, $110 @$120.

Silica Brick—9-in., per 1,000, $56@ $61, Birmingham, Ala.; $55@$60, Mount Union, Pa.; $65, Chicago district.

Iron Trade Review

Pittsburgh, Sept. 14, 1920

Pig Iron—The deadlock in pig iron is clearly marked, consumers being content with present commitments and regarding prices as at their peak. From July to August production of merchant pig iron increased 6 or 7 per cent, and further increases are to be expected, though consumption seems clearly to be declining. The refusal of Chicago and Birmingham district furnacemen to follow the recent advances in other markets is considered significant. We quote the Valley market unchanged at $50 for foundry and malleable and $48.50 for bessemer and basic, freight to Pittsburgh being $1.96.

Steel—Billets remain stagnant, with the $60 quotation almost nominal. Sheet bars are quotable at $67.50@$70 on the basis of last sales, with demand light. Forging billets are down to $75.

Charcoal and Coke

Charcoal—Willow, 7c. per lb. in bbls.; hardwood, 6c. per lb., in 250-lb. bbls.

Connellsville — Furnace, $17@$18; foundry, $18@$20.

Europe's Zinc Activities

Both London and United States Markets Dull—Germany Entering the Market, Great Britain's Industry Partly Closed, and Belgium Strenuously Attempting To Regain Her Important Pre-War Position

THE zinc market is still in the same inactive condition that has characterized it for many weeks. Quotations do not vary widely, and the average price for August, 8.185c. per lb., New York, showed but a small gain over the July average of 8.070c. The June average, 7.815c., was the lowest recorded so far this year, and although it would appear that the market has been given an upward impetus, a tendency is exhibited at present to lose a part of the gain made, mainly owing to the depressing influence of the London market.

In pre-war years the United States was accustomed to be content with a mediocre foreign trade in zinc, for domestic consumption almost balanced domestic zinc production. The war seriously disturbed this relation, and there is a desire on the part of the industry to retain the support and beneficent effect of the foreign market; but little if any success has attended the efforts of the industry, since the armistice, to become a factor of major importance in the foreign market, a circumstance that has been due to the evident present inability of Europe to consume large quantities of spelter. Plentiful supplies of European and American zinc seem to be available in the London market. In fact, with the present condition of the United States and London markets, foreign zinc (mainly of American origin) is freely offered here. Not only that, but German zinc is also being offered in London, and is the present contributory cause to the decline in zinc. Considering the greater post-war importance of the foreign market, any light on conditions in Europe, Australia, or other zinc-producing countries is especially valuable and suggestive.

German Zinc a Factor in the Market

Germany, so it is reported, has raised the allowable percentage of zinc production which can be exported, from a former maximum of 25 per cent to a maximum of September-October production of 50 per cent—a 100 per cent increase in allowable exports. The pressure to sell German zinc is an indication that the output of Germany is increasing, but the condition of the industry there is still uncertain. The political developments which will be disclosed by Silesia's vote in the plebiscite, soon to be taken, will do much to make Germany's future position in the zinc trade of the world apparent. It is clearly to Germany's advantage under present low foreign exchange to sell all zinc possible.

Belgium is endeavoring rapidly to regain her former importance in the zinc trade. The directors of the Société Anonyme des Mines et Fonderies de Zinc de la Vielle Montagne, the most important Belgian producers, recently gave an estimate of European zinc production during 1919 as 100,000 metric tons, against 680,000 tons in 1913, of which amounts Belgium produced over 200,000 tons in 1913 and but 18,000 tons in 1919, chiefly on account of dearth of raw materials. Production in 1919 should be close to 85,000 tons. The directors call attention to the fact that Japan greatly curtailed her zinc industry in 1919, which had been greatly stimulated in war time, and from other sources it is learned that Japanese production dropped 50 per cent, from 44,500 metric tons in 1918 to 10,000 metric tons in 1919, and that zinc exports decreased at an even greater rate, or from a value of 9,067,000 yen in 1918 to a value of 2,931,000 yen in 1919.

Belgium's Efforts at Reconstruction

During 1919 efforts were directed to the reorganization of the French and Belgian works of the Société Anonyme. In Belgium the foundries at Valentin-Cocq, Angleur, and Flone only partially resumed activity during the latter part of 1919. The works at Baelen-Wezel (Campine) have been almost exclusively engaged in repairing the destruction incident to the war. The rolling mills at Haumont are being rebuilt. Owing to the production of the company's own mines at Moresnet, and in England, Sweden, Algeria, Italy, and Sardinia, and stocks of raw materials at hand, the company was able to supply its reduction works with zinc ore after the armistice, but an acute fuel shortage interfered with operations.

Belgium is now having a trying time producing zinc with the London prices as they are. It is reported that the cost of production varies between £43 and £48 per ton. (Coal at 100 fr. per ton).

English Zinc Industry in a Parlous State

The zinc-smelting industry in England is still handicapped by labor troubles, which have compelled the industry to partly shut down. Some of the smaller plants are entirely closed. The London correspondent of the American Zinc Institute estimates the cost of zinc production in England at over £50 per ton, whereas the market is around £38 per ton. However, the explanation is vouchsafed that the London price is artificial, as 90 per cent of the zinc delivered against contracts is American, and with zinc in the United States at 8c. it cannot be laid down at less than £50 per ton. The forced liquidation of large stocks of speculative zinc and the large available supplies account for the low quotation.

The imports of refined and G. O. B. zinc into England during May, June, and July, in tons, are given as follows, by the London Metal Exchange:

From	July	June	May
U. S. A.	11,556	6,117	9,421
Belgium	148	409	966
Scandinavia	225	464	525
Rest of Europe	317	484	808
Canada	125	50	101
Other countries	319	1	84
Totals	12,690	7,525	11,905
Delivered from warehouse during July	1,299	946	923

Zinc stocks on hand in Great Britain on July 31 totaled 25,828 tons, compared with 26,828 tons on June 30 and 23,411 tons on May 31.

The absence of demand in London and the large liquidated stocks have induced dealers to offer metal on the Atlantic seaboard at the attractive prices of 7.70 to 7.80c., duty paid. Domestic producers cannot compete with such prices and must wait until surplus supplies are consumed before they can again enter the market. In many cases the freight rate from the Atlantic seaboard to interior consuming points is lower than the rate from East St. Louis; hence the advantage to the consumer of using reshipment imported zinc of American origin.

Latest Rand Gold Production

During July, the gold production of the Rand, in South Africa, amounted to 736,000 oz., an increase in output over the June figure, 715,957 oz. A table summarizing production since 1917 follows:

RAND GOLD OUTPUT 1917-1920

(Fine Ounces)

	1920	1919	1918	1917
January	670,503	676,059	714,182	782,634
February	625,330	636,728	659,750	721,321
March	707,036	712,379	696,281	787,094
April	686,979	694,944	717,099	742,778
May	699,041	724,995	741,217	729,385
June	715,957	702,379	727,696	759,724

December	.....	650,191	641,245	722,419

COMPANY REPORTS

Butte & Superior Mining Co. Resumes Normal Operation

Zinc; Montana

The following comparative statement shows the principal operating features of the Butte & Superior Mining Co. for the second quarter of 1920:

	Second Quarter, 1920	First Quarter, 1920
Dry tons of ore milled	81,619	130,204
Average zinc content (per cent)	13 339	14 164
Average silver content (oz. per ton)	5 340	5 530
Tons zinc concentrates produced	19,281	32,535
Average zinc in zinc concentrates (per cent)	52 774	53 859
Total zinc in zinc concentrates (lb.)	20,350,566	35,045,757
Average silver in zinc concentrates (oz. per ton)	19 429	19 499
Mill recovery (per cent zinc recovered in zinc concentrates)	93 457	95 018
Direct mining cost per ton	$7 000	$5 521
Direct milling cost per ton	$3 456	$2 610
Total direct cost mining and milling (per ton)	$10 456	$8 131
Indirect or general costs (per ton), exclusive of freight	$1 066	$0 497
Total costs (per ton)	$11 522	$8.628

The decrease in tonnage treated, with the resulting increase in costs, was due to the unsettled labor conditions during the entire quarter, which materially affected both mining and milling operations.

A strike called on April 19 resulted in a shutdown until May 5, when operations were resumed on a limited scale. Operations were being conducted on nearly a normal basis toward the end of the quarter.

The financial results for this quarter, as compared with the first quarter of 1920, are as follows:

	Second Quarter, 1920	First Quarter, 1920
Net value of zinc concentrates at mill	$587,957 25	$1,224,548 17
Net value of lead concentrates at mill and residual values	177,854 27	506,301 96
Miscellaneous	27,619 63	19,920 18
	$793,431 15	$1,750,770 31
Operating costs, depreciation, shutdown expense	940,432.97	1,123,514 36
Profit	(a) $147,001.82	$627,255 95
(a) Loss.		

The above statement includes charges for depreciation and shutdown expenses, but no allowance has been made for depletion or taxes.

The average price used in estimating the income for the period was 7.6487c. per pound.

Mond Nickel Co., Ltd., Shows Comfortable Profits

The annual report of the Mond Nickel Co., Ltd., for 1919 says that sundry credits stood at £750,232, showing a decrease of over £250.000, which was chiefly accounted for by the settlement of the amounts due to the government for taxation. The profits of the company were subject to taxation in England and in Canada, and it was to be hoped that by the end of the current financial year this tax would be entirely withdrawn. The substantial amount of £97,230, of "Additions in the United Kingdom," was made up of additions to the refining works at Clydach, and also to the new rolling mill which the company had acquired in Birmingham.

Since the end of the financial year the company had completed the purchase of the whole of the shares of Messrs. Henry Wiggin & Co., of Birmingham—the oldest established firm of nickel and nickel-silver manufacturers in England. Messrs. Wiggin owned three works in Birmingham, well equipped with rolling mills, wire-drawing plant, refining plant, and other machinery for the manufacture of their various products. The shares and debentures in associated companies stood at £316,501, and investments at £116,592. There had been no change since the previous year's report in the former item, but investments showed a reduction of about £560,000, owing to the sale of war bonds.

Stocks showed an increase of over £100,000, as compared with those of 1918, at which time, as large stocks of nickel had accumulated in the hands of the government and at the company's works at the end of the war, it was necessary to curtail production. These stocks had been substantially reduced, so much so that the company had begun producing on a larger scale at the refinery. The increase in the present stock was due to the increase in the stock of matte, which, during the year, was produced at a larger rate than was warranted by the amount refined. This the directors decided to do to keep the organization together in Canada, and to have a reserve of matte for contingencies.

The balance brought forward from 1918 was £168,058, and the balance at credit of profit-and-loss account was £382,354, making a total of £550,412, less directors' fees of £19,117, leaving a balance for distribution of £531,294, as compared with £422,658 in 1918. The total amount of dividend proposed to be paid was £332,500. In addition to the dividends the directors had also had to provide out of the profits £84,000 for income tax, which was the result of the change introduced in the previous year, of paying the dividends on the ordinary shares free of tax. This made a total of £416,500, leaving a balance of £114,794 to be carried forward to next year's accounts.

Davis-Daly Copper Co.

Copper; Montana

The report of the Davis-Daly Copper Co. for the second quarter of 1920 shows that tonnage hoisted amounted to 17,414 tons, producing 2,197,936 lb. of copper and 91,238.5 oz. of silver. The average assay of ore shipped for the period was 7.07 per cent copper and 5.88 oz. of silver to the ton.

Cash and quick assets on June 30, 1920, amounted to $580,176.99.

Receipts and disbursements follow:

RECEIPTS

	Ore Returns	Misc. Revenues
April	$105,759 35	$26,702 68
May	64,616 40	14,197.51
June	78,085 46	20,671.64
Total receipts, $311,034 04	$249,462 21	$61,571 83

DISBURSEMENTS

	Development	Mining Cost	Equipment	Butte Gen. Exp	Boston Exp.
April	$11,869 38	$62,791 82	$5,189 26	$13,869 14	$10,802 82 (a)
May	11,977 65	51,576 38	4,242 89	13,537 19	6,254 74
June	21,528 64	74,993 62	5,830 20	19,859 77	10,711 73 (a)
	$45,375 67	$189,361 82	$15,262 35	$47,266 10	$27,769 29

Total disbursements, as above, $325,035 23.
(a) Including U. S. Income Tax.

Chief Consolidated Mining Co.

Silver-Lead; Utah

The report of the Chief Consolidated Mining Co. for the second quarter of 1920 shows that 2,919,902 lb. of lead was contained in the ore mined, together with 513,285.4 oz. of silver, 100,935 lb. of zinc, 1,032.184 oz. of gold, and 471 lb. of copper. The average per ton of all ores was $39.44. Smelting, freight, and sampling was $19.12 per ton, giving a net value of $20.32 per ton. A total of 20,071 dry tons of ore was mined.

The net profit after payment of all charges was $18,073.09. A dividend of 10c. per share on the 884,232 shares of outstanding stock of par value $1 was paid on May 1.

The Directorship of the Bureau of Mines

IT IS NO SECRET that the present gifted and deservedly popular Director of the Bureau of Mines accepted the position only with a desire to do temporary service; and that he is desirous to quit it at an early date to take up again the research work to which he has devoted himself with such remarkable results. The question as to who is to be his successor is therefore an imminent one. As he will probably be reasonably permanent, there is a strong feeling in the mining industry that the new director should represent that industry, by reason of his experience, in the broadest and most understanding way.

The Geological Survey, the complement and sometimes the rival of the Bureau of Mines, has always had at its head able and distinguished geologists—Powell, Wolcott, and the present Director, George Otis Smith. The Bureau of Mines, on the other hand, has never had at its head a man personally familiar with mining; and we believe that the program and history of the Bureau has reflected this unfamiliar and purely academic quality.

The problems of the mining industry are manifold, broad, and increasingly significant; and the man who, as the head of the Bureau of Mines, weighs them and determines the policy and program of the Bureau should be a super-mining-engineer, just as the head of the Department of Justice must be a super-jurist, and by no chance a physician. We, therefore, recommend to our mining societies, such as the Institute of Mining Engineers, the Mining and Metallurgical Society, and the American Mining Congress, that they carefully investigate this matter and formally advise the Secretary of the Interior of their conclusions. Hitherto the succession has been purely bureaucratic: the second Director had been Chief Clerk of the first administration; and the present Director was Chief Metallurgist of the second administration. A clear perspective demands a new and independent point of view from without, such as can be brought only by a man who has behind him another background than that given by years of academic and government service. The Director's experience, should, moreover, be varied. He should not be a specialized metallurgist, because this will not have given him the desired oversight of the industry. This is the opinion of the present Director—himself a metallurgist. And the Director should not, in our opinion, be a specialized geologist, and for similar reasons, and because of the complementary and adequate nature of the U. S. Geological Survey. He should be a seasoned type of man, for example, like Pope Yeatman, and to instance the type will save us a great deal of further definition.

The office is not remunerative, as we count remuneration nowadays; but neither is the post of Congressman or Senator; and the representative of the mining industry in Washington has more power, with the corresponding influence for good, than a member of either house of Congress. Therefore, our best men should be glad to make the financial sacrifice in order to serve.

Hoover as Secretary of the Interior

THERE is a strong expectation in all parts of the country that if the Republican candidate is elected to the Presidency he will reverse the recent practice and appoint to his Cabinet the strongest and most upstanding men that are available. His own expressed policy is to do this, and beyond question the sentiment of the country demands it. Among the strong men that are included in the provisional slate made up for the Cabinet is Hoover; and he is mentioned as the future Secretary of the Interior.

Anyone who has followed the trend of the master mining engineer's thought as expressed in recent writings and speeches—as in that at the Institute of Mining Engineers banquet at Minneapolis—cannot fail to be struck with his conspicuous fitness for that post. The Department of the Interior is concerned, more than anything else, with engineering problems. Hence the proposal to convert it into a new Department of Public Works, and to gather under it, so far as possible, the various engineering activities which are now sheltered under other departments. Hoover is in favor of this change; but whether or not this proposal materializes, it would be epochal for the Department of the Interior to be presided over by a man who understood the work and the functions of the bureau under his control, and it would be an excellent and sane precedent for all government activities. For the mining industry, of course, it would be a boon greatly to be desired, for the sympathy and understanding of the important mining bureaus in the department, which the Secretary would have, would reinvigorate them, and through their reinvigoration would give new impetus to mining.

The Engineers' Chance

THAT the abilities and capacities of engineers are underrated by the man in the street is still true, though not to the same extent as formerly. For this, we may thank Herbert Hoover and others who have shown the public that we really can do something besides build locomotives, mine ore, plan a sewer, or install a lighting system. Still, however, we know that most people think that a good lawyer or a good doctor is a more desirable citizen than a good engineer. That this is a myth, all of us engineers know full well. We know we have a right to cross the street uninjured, but does the chauffeur of the big speeding truck know it?

Things are being done nowadays by organization. The voice of one hundred thousand all saying the same

thing will carry considerably farther than the effort of any individual or small group. At last the opportunity of the engineer is here.

Has the organization to which you belong made application to become a member of the Federated American Engineering Societies? This organization already has an aggregate membership greater than that of any other engineering body in the world. Most of the national societies have already joined or will do so soon. But the local societies and the smaller groups are needed too. Turn to page 633. Write for more information. *You*, personally, bring the subject up at your next meeting. It rests with you, and if you do nothing, blame only yourself for the position of the engineer as a citizen.

Oxygen Breathing Apparatus

THE limitations of the practical utilization of oxygen breathing apparatus have attracted the attention of mining men generally. The necessity for careful examination and thorough upkeep is now universally recognized, and, in most installations of this equipment, testing apparatus is provided and the training of the men in the proper conditioning of the apparatus is not neglected. Given, however, an apparatus in perfect condition, the human factor, or a thorough understanding of its value and method of use on the part of the human being who is to wear it into a dangerous place, is equally vital. The quantity of oxygen is limited. On there being sufficient for the complete round trip proposed depends the life of the wearer.

George S. Rice, of the Bureau of Mines, in a recent publication of the Bureau, calls emphatic attention to the danger of making trips which are beyond the capacity of the apparatus or the physical strength of the wearer. The specific incident that brought about this warning was the death of three men in the Black Diamond coal mine, near Seattle, Wash., recently. These men, equipped with oxygen breathing apparatus, attempted to make a trip 1,200 ft. down a twenty-five-degree slope which was filled with black damp. The supply of oxygen in the tanks was sufficient for only forty-five minutes. Mr. Rice points out that:

> To go 1,200 ft. down a twenty-five degree slope, make observations, rest, and then return 1,200 ft., thus making a total distance of at least 2,400 ft. in forty-five minutes, is a quick trip when a man is not encumbered with a heavy load; but to attempt it cumbered by an apparatus weighing about forty pounds makes it more than a hazardous undertaking.

Mr. Rice says, further:

> Modern apparatus when fully charged will furnish oxygen for two to two and one-half hours when used with moderate exertion or with periods of rest, but a person uses four to five times as much oxygen in climbing a steep slope with a load of forty pounds as he would when walking at a moderate gait along a level road. It is quite probable, therefore, that the forty-five minute charge indicated by the dial will not last forty-five minutes with the violent exertion necessary. The Bureau of Mines, in its handbook on "Rescue and Recovery Operation in Mines After Fire and Explosions," on page 49, makes the following statement:
>
> "The rescue crews should observe every known precaution for their own safety while traveling in after-damp or other noxious gases. Each crew should be composed of at least five men, including the captain, and the members of the crew should not become separated. If any one member complains of feeling unwell or is observed to be staggering or breathing unnaturally the entire crew should immediately return to fresh air. In view of the liability of a member receiving some injury or his apparatus being damaged a crew should never advance such a distance nor travel over such faults or wrecks as would prevent the crew from carrying one of its members back to fresh air. With the types of breathing apparatus now in service the maximum straightaway unobstructed course should not exceed 5,000 ft. with a reserve crew at the fresh-air base."

While in the foregoing it is to be noted that the maximum distance to be traversed is 5,000 ft., this is for a level, unobstructed road, and, as previously indicated, a trip of 2,400 ft. down a steep incline would be more than equivalent to a 5,000-ft. trip on the level and which maximum distance calls for a fully charged apparatus; that is, with at least three times the amount of oxygen which it was alleged the three men had who made the disastrous trip in the Black Diamond mine. While all of the details of the affair are not known, at least enough has been indicated to send out a caution against men making such a foolhardy attempt, and it is desirable that full facts shall be known, so that the public shall not be prejudiced against an apparatus which has greatest value when it is carefully used and used in accordance with well-established rules.

Bisbee an American Camp

THOSE who have predicted that Bisbee, Ariz., was fated to become a Mexican camp by reason of its proximity to the border, as well as because of the labor situation, will be interested to hear that Grant H. Dowell, manager of the Copper Queen branch of the Phelps Dodge Corporation, recently said that his company would continue to employ English-speaking men underground as far as possible. This has long been the policy of the company, and at present most of its underground employees are American. According to Mr. Dowell, it has been necessary to employ much Mexican labor on the Sacramento Hill project, but this, in Mr. Dowell's opinion, would be only a temporary condition.

American labor has never taken kindly to the idea of a great influx of low-paid Mexican workmen from across the border, and for obvious reasons. It is equally obvious, however, that when American workmen are scarce, a great corporation, on whose continued operation depends the welfare of thousands, will employ such men as it can get, rather than shut down. With the so-called American standard of living in view, the workman in this country has demanded good wages and living conditions, and expects as his right that he be given a square deal in his relations with his employer. All these are to be had in the Bisbee district, where the large operators have gone to much expense to make the community attractive. The companies in this part of the Southwest will seek to keep their camps American, but in this they must be met halfway by labor, organized and unorganized. Only through co-operation can American standards be maintained.

Mining Engineering as a Liberal Education

MANY young men who are not entirely settled as to their future life calling desire to acquire a liberal education to expand their horizon and form a solid foundation for any future activities. Surely this is a wise motive. The question arises as to what education will most fundamentally broaden and develop and inform.

Fifty years ago the answer would have been decidedly "Latin and Greek"—the study of the languages and literature of the Greeks and Romans. The arguments

in favor of this were clever and insistent—in fact, there was no out-arguing the supporters of this, the only "true culture"; yet the notion was only an inherited one, passed down from the Middle Ages, when it held good; and modern progress has dropped it into the background. The daring "new culture" consisted in modern language and literature; in history, philosophy, political economy, and the like. Encroaching on these, again, came the newer claims of science; and last and freshest, the combination of science and engineering. This last is believed by many to afford a broader and sounder culture (as nowadays we must choose) than any of the others. Much that was formerly confined to the university is now outlined in our preparatory schools, so that the developing individual can swiftly record, as in the stages of evolution, the progress of knowledge in outlines of history, Latin, modern languages, mathematics and the like, before the college or university training begins.

If engineering is the soundest foundation of general culture (and the proposition is worth cogitation), mining engineering should be the preferred department, for it covers many special types of engineering—civil, mechanical, geological, electrical, and human. One mine may depend mainly for its success on industrial management, another on mechanical engineering, a third on geological engineering, a fourth on metallurgical engineering, and so on.

Concerning Communism

IN THE Chronicles of the immortal Froissart, among a thousand other interesting pictures, a glimpse of the condition of Ireland toward the end of the fourteenth century is given. The king of England, having finally induced four of the kings of Ireland to signify their allegiance, sent an English squire to instruct them in the refinements of civilization. "When these kings were seated at table, and the first dish was served, they would make their minstrels and principal servants sit beside them, eat from their plates and drink from their cups. They told me this was a praiseworthy custom in their country, *where everything was in common but their bed.*"

We perceive from this that the theory of communism, so incessantly preached in various queer corners even up to the present day, was in practice in Ireland at the period mentioned. The result was what must be inevitable when perfect equality of environment is established—the common standards were those of the lowest, just as the standards of a class at school which must all move forward together will be set by the mentality of the most backward. Froissart relates that the English tutor had difficulty in teaching the Irish kings to wear breeches, and to induce them to ride with saddle and stirrups, which was contrary to their custom.

Indeed, the instinct toward communism is age old, and has been experimented with in countless groups and colonies both here in the United States and elsewhere. The French touched lightly on communism immediately after the revolution, and abandoned it; and it was even tried by the Pilgrims of Plymouth for a brief period after their arrival.

The Eskimos of Alaska, when their country was first explored, were living in communistic villages. The sovereign merit for an Eskimo was giving, not getting; and he who had given away the most was the most honored. An Eskimo would work hard for a year, that he might give a great feast, and distribute his accumulation in presents. Contests were held between neighboring communities or villages in giving, and the side which gave away most to the other was the victor, and the community which had received the most went home humiliated in pride and reputation. Still, the level of the Eskimo in habits and intelligence was as low as the lowest: they were clothed in skins and used the few tools and weapons of the stone age. In the forests of Nicaragua certain groups of Indians live also on the communistic principle; indeed, this seems to have been the general principle of most of the Indian tribes whom the Europeans found in America; and their level of intelligence and manners was such as to merit the common appelation of "savages."

In the froth and turmoil of our present social condition, clusters of the light-headed are gathered together like ships in certain vortexes in the current, as in certain sections of New York, there to indulge in fads and theories which they fondly believe to be advanced. These are strange, vaporous, and unprofitable folk, who live idly on the interest of capital while they attack the institution of capital; or preach the doctrine that only the manual laborer should be fed while they themselves live by soap-box oratory, worthless literature and art, or organizing discontent. Were their theories put into practice, they would starve the first. Among these theories is communism, and bolshevism, which is a step further than communism, since it inverts the natural social fabric, and proclaims that the most advanced and productive shall get least, and those at the bottom of the scale in civilization and mental attainments shall get the lion's share. Such theories, however, it will be seen from the examples cited, are not advanced but ancient, and natural to the savage.

In a different school of thought is the opinion of Darwin, who argued at some length that the life and advance of civilization depend on a leisure class who can pursue the arts and sciences without the handicap of the daily work and worry as to the means of eating, drinking, and sleeping. Huxley was also of the same opinion. Evolution depends upon differentiation, and the permission of the development of irregularity; and this is as true with men as with race- or draft-horses.

Somewhere between these two schools of thought—the elementary and savage conception of communism, or the still more barbarous one of bolshevism, and the school which justifies an aristocracy—will doubtless be found the practical adjustments of the future. It will be remembered that the glory of English art and letters has not resulted appreciably from her professional leisure class, but rather from those geniuses who have come from all classes of the population.

We shall doubtless settle finally on the conception suggested, among others, by Herbert Hoover, on *equality of opportunity*: a fair and equal start, with no inherited advantage or disadvantage, for every new-born babe. But after that, we shall be careful concerning levelings that are too repressive, and too injurious to the common welfare. Shall Edison, Root, and Kipling, Marconi, Coolidge, and Wells daily hoe the necessary corn and draw the household water; and thereby establish their equality with the honest bullet-heads who understand nothing else? Such men are sprung from the people, who will find it more profitable for the welfare and advancement of the whole commonwealth if their corn and water is provided for them.

Laboratory Practice in the Southwest

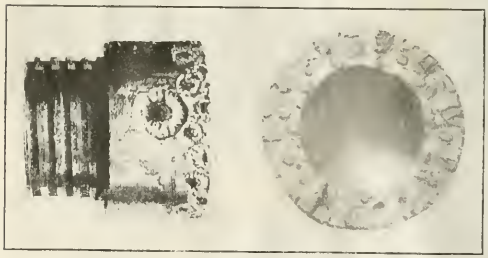
Diamond Drilling as a Means of Intensive Development

Output of Josie Mine, in British Columbia, Long Maintained at Moderate Cost by This Method of Exploration — Development of Several Veins Cut by Numerous Dikes Otherwise Costly

By Paul S. Couldrey and E. H. S. Sampson
Rossland, B. C.

Written for *Engineering and Mining Journal*

FEW mining camps owe as much to the diamond drill as Rossland, B. C. It would be no exaggeration to say that without this method of exploration anything in the nature of regular shipments would have been impossible, and it is extremely doubtful whether at present there would be any shipments at all. Continuance of operations has not been due, for the most part, to spectacular discoveries of new large orebodies, though such discoveries have been made, but rather to the continuous every-day use of the diamond drill in tracing out dislocated portions of known veins and in locating pay shoots or pay horizons in these veins.



CHIP BITS IN USE AT ROSSLAND CAMP

Previous to the detailed geological examination of this camp by Professor Brock, and more recently by Dr. Drysdale, at the instance of the Canadian Department of Mines, exploration work of all kinds was necessarily much more haphazard than at present, but the importance of diamond drilling was recognized even in the early days. It was felt that as diamond drill holes could be put in at a cost of $2 per ft., and at a rate of 20 to 30 ft. per double shift, as compared with ordinary crosscuts at $12 to $16 per ft., and at the rate of only 5 to 6 ft. per double shift, the advantage lay with the former method (in spite of its many inherent defects) in something like a proportion of 25 to 1 for exploratory work, even for comparatively short crosscuts. Taking into account, also, the complex geological structure of the camp, the adoption of what might be called intensive diamond drill methods followed as a natural sequence.

In the Josie mine of the Le Roi No. 2 Co. the diamond drill has been in almost constant use for nearly twenty years, and the experience gained in maintaining an output by this means may be of interest to others similarly placed. The characteristic ore of Rossland is a gold- and silver-bearing pyrrhotite associated with chalcopyrite. The gold content of the ore has always been the principal value, in fact of late years the copper percentage has dropped so low that direct smelting is very difficult. This ore occurs in veins more or less nearly parallel to one another, running roughly east and west. There are several veins in the Josie mine, but those referred to in this article are known as the Annie, North Annie, Hamilton and No. 1.

Numerous Dikes Cut Veins in Josie Mine

The formation in this section of the camp is, for the most part, a very hard augite-porphyrite, with patches of diorite-porphyrite and grano-diorite, giving place at the north end in depth to a silicified stratified rock, and at the south end to a porphyrite-monzonite. Numerous dikes running approximately north and south cut across this formation at frequent intervals, interrupting and in some cases faulting the orebodies. These dikes are roughly divisible into two classes, micaceous and non-micaceous. The former are distinguishable by the prevalence of biotite mica associated with orthoclase or plagioclase feldspar (minettes and kersantites). The largest and most important of the micaceous dikes is known as the Josie (kersantite). This varies from 60 to 100 ft. in width. It faults the ore a distance of 350 ft. horizontally and probably about 200 ft. vertically,

PARALLEL OR "FOLLOWING" DIKES IN HANGING WALL OF STOPE. A—MICACEOUS. B—NON-MICACEOUS

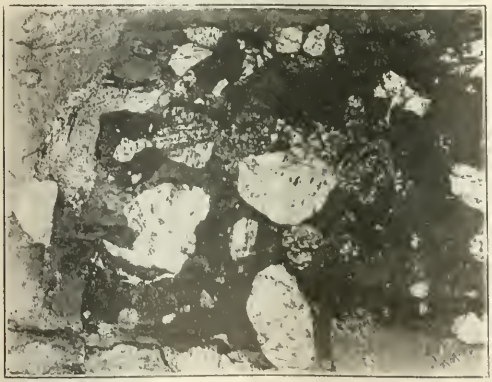
though the amount of vertical throw is not yet clearly established. Mineralized zones frequently occur at planes of contact of the various formations.

The non-micaceous dikes are usually hornblende associated either with orthoclase or plagioclase feldspar, and as a rule are much harder than the micaceous variety. An exception to this rule is the dike locally known as the Porphyry dike (pulaskite), which is traceable from the surface to the 1,300-ft. level, splitting into four or five branches as it goes downward and northward. Accompanying this dike is another one known as the Vitreous dike. Where these two dikes cut across the Annie and North Annie veins the values immediately west of the intersection are invariably poor as compared with those to the east, but with the other veins no such change is noticeable, although an enrichment between the forks of the dike has been observed on the Hamilton vein. The Porphyry dike interrupts all veins without faulting any.

"White" Dike an Underground Landmark

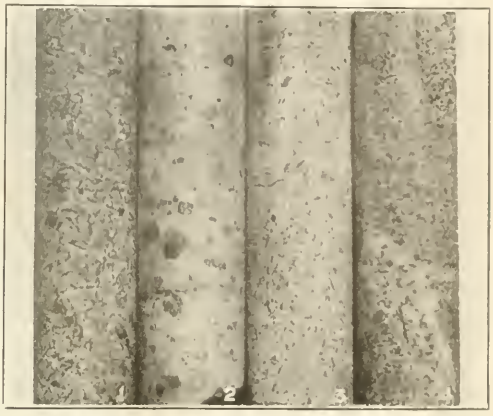
A very interesting dike of the non-micaceous variety, and one which forms a veritable underground landmark, is locally known as the White dike (conglomerate). This has very much the appearance at first sight of a brecciated vein running north and south. It is traceable from the surface to the 900-ft. level, and it is noticeable that large boulders of the same material have been found several miles away. It consists of characteristic angular fragments of white quartz associated with other rocks (such as quartzite, gneiss, and syenite, many of which are entirely foreign to the neighborhood), embedded in a dark olive-green or almost black matrix of spessartite in which large crystals of hornblende are often apparent.

In addition to the north and south dikes proper there are tongues of apparently altered diorite-porphyrite



"WHITE" DIKE, 500 LEVEL, SHOWING SPESSARTITE MATRIX

paralleling certain of the veins. These are usually spoken of as "following dikes," though this may be, geologically speaking, a misnomer. Two such "dikes" (one micaceous and the other non-micaceous) are found interlaced with the ore in the No. 1 vein, and though they are easily distinguishable the result is somewhat confusing, as the ore is found not only under or over but in both positions, and even between them. At the contact of the following dikes with the regular pyritic vein matter exceptionally high values in free gold are sometimes found, usually in the presence of crystals of arsenopyrite, antimonite, and, most noticeable of all, molybdenite. Precisely how this enrichment occurred, and whether of primary or secondary origin, is a matter for conjecture. Good gold values are sometimes found also near north and south mica dikes, for example, under the Tramway dike, in the under or western side of which both the Annie and North Annie veins have "bunched up" and widened out considerably.



DIAMOND-DRILL CORES FROM JOSIE MINE

1. Porphyritic monzonite, showing characteristic crystals of biotite and pyroxene. 2. Augite-porphyrite, showing prisms of augite. 3. Diorite-porphyrite, showing acicular crystals of hornblende. 4. Grano-diorite, showing granular, crystalline structure

The north and south dikes almost invariably dip at steep angles, sometimes being quite vertical, an exception to this being the "H" dike, which dips flatly to the west, interrupting all veins without faulting, but being itself faulted at certain points. The veins themselves dip in a northerly direction at angles varying from 50 to 80 deg.

Complex Formation Favors Diamond Drilling

Such a complex formation as the above therefore produces at once the opportunity and necessity for rapid exploratory methods. In drifting along any of the above veins a dike will be encountered and crossed. Provided pay ore is not immediately found at the crossing point, diamond drilling can at once be employed to discover either the faulted portion of the same vein, or in the case of a non-faulting dike, to explore for pay ore in the parallel vein. If this is successful the exploratory drifting can be transferred to the second vein, and when this work has advanced sufficiently far ahead a second hole can be put back across the track of the first vein, and *vice versa*. In this way the shortest distance to pay ore can be ascertained, and by inclining the holes upward and downward, and "fanning" them out horizontally, the extent of the shoots can be anticipated within reasonable limits. The majority of the holes drilled in the Josie are horizontal or nearly so, and very little drilling is done in the dikes themselves, as this would be both non-productive and difficult, on account of the broken nature of the ground. The augite-porphyrite, on the other hand, though hard, gives excellent cores.

For the flat holes an "E" Sullivan drill equipped with a Stone core barrel is used, the outside diameter of the bit being 1⅞ in. and the diameter of the core ⅞ in. This machine is not recommended by the makers for depths of more than 450 ft., but here it has drilled five holes over 1,000 ft. and at least a score over 600 ft.

For down holes an "S" Sullivan drill, also with a Stone core barrel, is used, the same sized hole being drilled as with the "E" machine. In both flat and down holes chip bits are used extensively, more particularly for short holes. These chip bits, however, are not suitable for broken ground.

The advantages of the above system of exploratory work would not be nearly so apparent in mines with a simple vein structure, but some such system, modified, for "spotty" mines having parallel veins might be well worth considering, provided, first, that the geological conditions are known, and, second, that the ground is not too soft or broken for rapid and cheap drilling operations.

COST OF DIAMOND DRILLING AT JOSIE MINE

Year	Feet Drilled	Total Cost per Ft. (Labor, Air and Supplies)	Year	Feet Drilled	Total Cost per Ft. (Labor, Air and Supplies)
1902	2,148	$2 37	1911	14,932	$1 65
1903	3,748	2 64	1912	14,185	1 69
1904	3,617	2 22	1913	15,075	1 60
1905	3,121	2 70	1914	12,249	1 63
1906	4,505	1 86	1915	2,799	1 73
1907	5,088	2 61	1916	5,065	2 23
1908	7,439	2 39	1917	807	1 84
1909	9,820	1 96	1918	3,995	1 66
1910	11,508	1 89	1919	3,535	2 04

The total footage is 120,762 and the average cost per foot $1.92 over a period of eighteen years. Of the above footage, 4,831 ft., or 4 per cent of the total, were down holes. The proportion of diamond drilling done to ordinary development is about 2 to 1. In 1904, a double-tube return water (Stone) core barrel was first used. During the last five years covered by the above table detailed costs per foot have been as follows: Labor, $0.99, being 51 per cent of the total; air, $0.28, being 14 per cent of the total; and supplies, $0.68, being 35 per cent of the total, which is $1.95.

The total cost will now probably be higher, on account of increased labor costs. All of the above work was done on day's pay.

Mineral Production of Former German Southwest Africa

The mineral output of Southern Africa, in 1913, according to *The Ironmonger*, was valued at £3,517,351. Of this sum, however, no less than £3,084,581 represented the value of the output of diamonds. The balance of £432,770 was made up mainly of copper ore and matte (including also lead ore) to the value of £396,436, tin ore to the value of £31,568, and other ores and minerals with an aggregate value of £3,316. Copper ranks second to diamonds in importance among the minerals of the Protectorate, the principal concern engaged in the copper-mining industry being the Otavi Mining & Railways Co., which was registered in Germany in 1888, with a capital of £200,000, in 200,000 shares of £1 each, all issued and fully paid up. Copper mining is conducted by this company at Tsumeb, Guchab, Great Otavi, Asis, and in the Otavi Valley, the principal mine being at Tsumeb.

Particulars of the total mineral output for the year 1918 are not available, but the Otavi Co. exported 7,358 tons of ore, with an assay value of 12 to 33 per cent of copper and 12 to 22 per cent of lead. On Dec. 31, 1917, the company had on hand 139,322 tons of ore, with an assay value of 2 to 41 per cent of copper. The Otavi Exploring Syndicate for the year 1918 reported exports of 100 tons of ore, with an assay value of 43.5 per cent of copper.

The export of tin from the Protectorate began in 1911 with consignments of nine tons, valued at £470. By 1913 the exports had risen to 200 tons, valued at £34,500. Ninety per cent of the best tin claims have now been acquired by British companies. German prospectors were first in the field, but they appear to have found no support, either locally or in Germany. A considerable number of the claims in British hands appear to be payable, but the distribution of the ore is for the most part over the surface, with little depth. The development has, on the whole, been slow, and the companies will not erect their final plants until they have proved the capacity of their claims to their satisfaction. The output of tin in 1918 amounted to 65 tons, assaying on the average at 68 per cent. The quantity on hand at the end of the year, however, amounted to only 33 tons.

The following figures, however, relating to the chief exports of minerals for the years 1913 and 1918, and for the nine months ended Sept. 30, 1919, serve to indicate some of the recent effects of the war upon the export trade:

	Exports		
	1913	1918	Jan.-Sept. 30 1919
	£	£	£
Diamonds ..	2,945,475	652,628	395,955
Copper	10,002		
Copper ore	381,434	55,981	5,278
Tin	34,500	12,800	5,256
Lead	17,293		
Other ores	2,958	...	

Activities of Ontario's Nickel-Copper Refineries

During the half year Jan. 1-July 1, 1920, a total of 627,681 tons of ore was raised, and 520,705 tons smelted in Ontario, the total output of nickel-copper matte being 28,365 tons, containing 15,030 tons of nickel and 7,705 tons of copper, according to the Ontario Department of Mines. The British America Nickel Corporation and the International Nickel Co. of Canada worked the Murray and Creighton mines respectively, and the Mond Nickel Co. raised ore from the Garson, Levack, Bruce, Worthington, and Victoria No. 1.

As regards shipments of matte, 7,944 tons went to Canadian refineries at Port Colborne, Ont., and Deschenes, Que.; 16,323 tons to the United States; and 1,123 tons to Wales. During the period the new electrolytic refinery at Deschenes began operations and had 1,185 tons of matte in process on June 30, although no refined metals were ready for market at that date. The new plant, which permits recovery of metals of the platinum group in pure form, is reported to be working satisfactorily, as is also the smelter at Nickelton, one mile from the Murray mine, where the ore is smelted direct without preliminary roasting. In addition to metallic nickel, nickel oxide and blister copper, there was a byproduct recovery at Port Colborne of the precious metals, gold, silver, platinum, palladium, rhodium, ruthenium, osmium, and iridium. There was also a small recovery of copper in the United States from Ontario silver ores.

Gold Mining in British Guiana

Gold Production Has Been Decreasing Since 1895 and Is Now Only About One-Eighth the Maximum Recorded—A Few Companies Are Still Operating, but Mining Is Hampered by Lack of Transportation and High Costs

Written for *Engineering and Mining Journal*

IN 1595 Sir Walter Raleigh touched the coast of the Guianas and ascended several rivers in his search for El Dorado the mythical city, whose houses were supposed to be roofed with gold. The publication by him of "The Discovery of Guiana," with its descriptions of enormous serpents, one-legged men, and other freaks of nature, undoubtedly led other adventurous spirits to visit the region. Permanent colonization followed, with the usual changes of control from Spanish, French, and Dutch to English which was so common in the days of buccaneers in the West Indies.

LOW RIVER STAGE. HAULING A BOAT UP A SMALL RAPID

The first recorded instance of an organized search for gold was an expedition in 1720, which ascended the Berbice River. In 1740 the directors of the Dutch West India Co. sent an expedition under an engineer named Hildebrand to explore the Mazaruni, Cuyuni, and Essequibo rivers. These first attempts were failures, and it was not until 1863 that a well organized effort was made to find gold in paying quantities, when a company was formed consisting of local and English capitalists called the British Guiana Gold Co. Gold-bearing quartz was found at Wariri, on the Cuyuni River and work was started, including the erecting of a small stamp mill. The project was, however, abandoned, owing to a boundary dispute between Venezuela and British Guiana, which arose over the territory in question. In the early eighties, interest was again aroused in the possibilities of successful gold mining, and in 1884 a production of 250 oz. is recorded.

PICKING THE WAY BETWEEN SUBMERGED ROCKS

Until 1890 only placer mining was carried on. The Omai placers, on the Essequibo River were one of the most successful operations, about 24,000 oz. of gold, being obtained from claims in the first two and one-quarter years of work. In 1890 the numerous outcrops of auriferous quartz reefs in the gold-bearing areas began to excite interest. Engineers and gold miners from other parts of the world were attracted to British Guiana, and an era of promotion started. Numerous companies were organized, and several large mills for crushing quartz were erected. The most notable among these operations were Kanaimapoo, on the Demerara River; Arakaka on the Barima River; Peter's mine, on the Puruni River (fifteen-stamp mill), and Aremu, on the Cuyuni. None of these mills are now operating. The total amount of gold produced by milling to date is 69,430 oz. The yearly production of gold since 1884 is given in the following table, which is taken from the annual reports of the Department of Lands and Mines:

THE LANDING PLACE AT ROCKSTONE, FROM WHICH THE START TO THE GOLD FIELDS AT THE ESSEQUIBO RIVER IS MADE

Year	Ounces	Year	Ounces
1884	250	1904–1905	95,864
1885	939	1905–1906	94,363
1886	6,518	1906–1907	85,504
1887	10,986	1907–1908	67,209
1888–1889	20,216	1908–1909	73,624
1889–1890	32,332	1909–1910	64,825
1890–1891	66,864	1910–1911	54,988
1891–1892	110,555	1911–1912	50,273
1892–1893	134,124	1912–1913	51,765
1893–1894	138,527	1913–1914	82,706
1894–1895	132,994	1914–1915	64,982
1895–1896	121,285	1915 Apr. to Dec.	39,793
1896–1897	127,479	1916	37,129
1897–1898	121,490	1917	29,538
1898–1899	113,114	1918	24,546
1899–1900	112,789	1919	16,216
1900–1901	114,102	1920, Jan. to Mar. 31	2,315
1901–1902	101,332		
1902–1903	104,526	Total	2,596,448
1903–1904	90,336		

It will be noted that the peak of production was reached in the year 1893-94 with an output of 138,527 oz., but that the industry has steadily declined, with little reaction, and lately, in common with gold mining all over the world. Production for 1919 was only about one-ninth of what it was in 1893. The gold mined in 1919 came from the following districts:

	Ounces
Barima River	1,321
Barima River	118
Cuyuni River	394
Puruni River	564
Mazaruni River	5,982
Potaro River	7,714
Essequibo River	71
Wani River	48
Total	16,216

HYDRAULIC MINING IN BRITISH GUIANA

The value of the 1919 production was $287,044.

The production to Dec. 31, 1918, was distributed according to sources as follows:

	Ounces
Quartz milling	69,430
Dredging	107,622
Hydraulic operations	38,367
Placer, by hand mining	2,362,498
Total	2,577,917

The following large nuggets have been found in the districts given:

	Ounces
Jumbo, Barima River, one weighing	333
Kanawaruk Creek, Potaro River, one weighing	274
Tiger Creek, Potaro River, one weighing	106
Puruni River, one weighing	90
Omai Placers, Essequibo River, one weighing	84

At present, two companies, the Guiana Gold Co., Ltd., and the Minnehaha Developing Co., Ltd., have six small dredges on creeks running into the Essequibo and Potaro rivers. These companies have been much hampered for the last few years by the increase in the cost of provisions and labor and the difficulty in getting supplies and renewals; so much so, that the government saw fit to remove the royalty of 70c. per oz. on Jan. 1, 1919, and charge, instead, a tax of 5 per cent on the profits.

The last hydraulicking outfit, that of the Tassawini Mining Co., on the Barima River, shut down in 1914 after reporting a production of 243 oz. for that year. Quartz milling in the colony stopped with the closing down of the Peter's mine in 1916.

By far the largest part of the production has been from small placer operations. In the balmy days of the industry, large, well-organized parties carried on the work. At present, however, most of the gold comes from what are known as "pork-knockers." These are negro or colored men, who are grubstaked by claim owners or shop-keepers, and who go up to the "bush" for six or eight months on a trip, dividing the profits on their return. They band together for mutual protection and help in getting boats up the rapids. Several Chinese firms maintain shops or trading posts in the interior, but the supplies from them are uncertain and expensive.

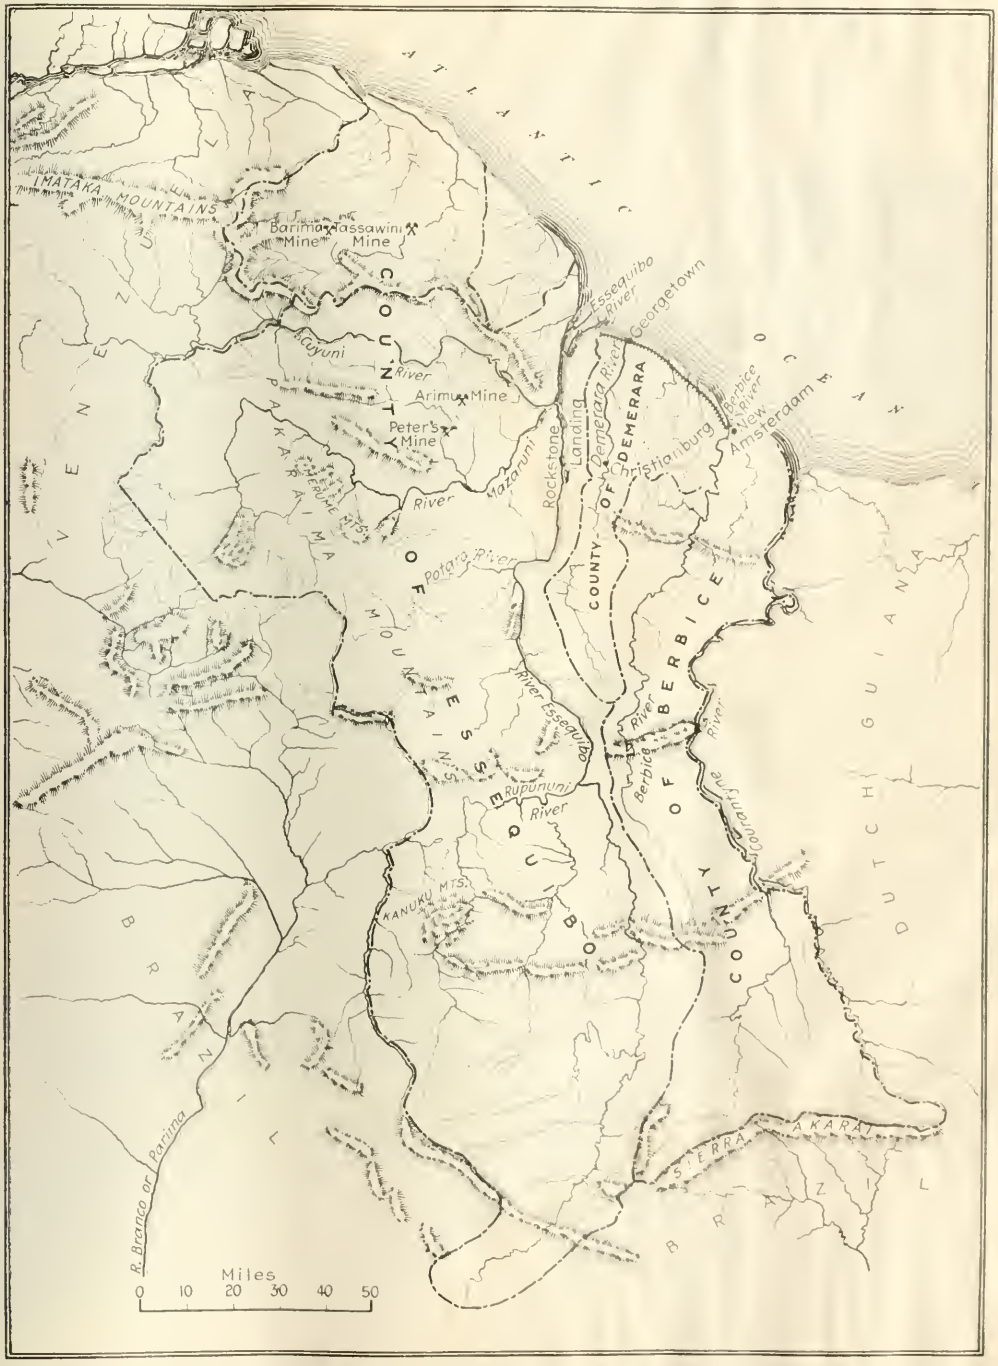
Practically all of the interior is still crown land. A prospecting license, costing $5 per year, allows a prospector to operate anywhere on government land not already leased in locating a claim. Claims measuring 1,500 ft. x 800 ft. for gold and 500 acres for diamonds pay an annual rental of $5 each, plus a royalty of 50c. per oz. on gold and a royalty of about 10 per cent on diamonds.

Mining concessions or leases for ninety-nine years can be obtained on any area by payment of $10 on application, and an annual rental of 20c. per acre. Dredging concessions on rivers or creeks pay 10c. per acre.

The decline of the gold-mining industry does not seem to be due to the working out of the field, as large areas are scarcely touched, but to the high cost of provisions compared to the more or less fixed price of gold and the diversion of the labor to the bauxite fields and the sugar plantations.

Prospecting is difficult, owing to lack of transportation and the denseness of the tropical jungle. Trails when cut are quickly overgrown and disappear in a few weeks. No railroads have been built into the interior, and the only two roads that have been cut have never been kept in condition to be of use, so the only method of getting into the interior is up the rivers. As soon as one leaves the alluvial belt along the coast the rivers are a series of rapids and low cataracts. Dragging boats up these is slow and laborious work. When the rivers are in flood they overflow into the jungle, and there is no shore on which to land or from which to work. In the dry season the reverse is true—a small volume of water is spread out in trickles over a large area and boats have to be dragged over sand and between boulders. The change from one condition to another is often quite rapid and a boat starting down with a flood may

WASHING FOR GOLD IN TIGER CREEK, POTARO



A MAP OF BRITISH GUIANA, SHOWING PRINCIPAL TOPOGRAPHICAL FEATURES

ground before reaching tidewater. The failure of the large companies seems to be due to poor organization, expensive transportation, and tropical diseases.

In a number of instances, companies that have tried to take machinery to the interior have expended their entire capital on transportation, and at several plant sites equipment is now rusting in the original crates.

LUNCH TIME ON AN ISLAND

It would seem that the transportation problem could be solved only with government aid.

With modern knowledge of tropical sanitation developed in Cuba, Panama, and elsewhere, there should be no great difficulty in combating the two principal diseases, malaria and dysentery.

Comparison of High- and Low-Grade Cyanide

Equally Good Metallurgical Results Follow Use of Product Containing 37 Per Cent NaCN By Tonopah Extension

By JOHN G. KIRCHEN

General Manager, Tonopah Extension Mining Co., Tonopah, Nev.

Written for *Engineering and Mining Journal*

UNTIL recently, the Tonopah Extension Mining Co. has used the ordinary cyanide, containing 97 per cent NaCN, in its mill at Tonopah, Nev. Calculation showed, however, that the low-grade cyanide now on the market could be delivered at a less cost per unit of NaCN, so it was decided to make some experiments to determinate the relative efficiency of the two products.

In preliminary laboratory tests, equal quantities of the same grade of silver-gold sulphide ore were agitated under parallel conditions with solutions of the same cyanide content, one using "Aero Brand" cyanide containing 37 per cent NaCN and the other solution using the 97 per cent NaCN product. One-half pound of lead oxide per ton of ore was added in each test to precipitate the sulphide ion liberated in the solution by the dissolving of the silver with NaCN. The gold and silver extractions after 60 hours of agitation were the same—93 per cent—and the consumption of NaCN and CaO was the same in both tests.

In a following test, the lead oxide was not added. Again, the extractions in both tests were the same, although 1 per cent lower than when the lead oxide was added; the NaCN consumption was higher but practically the same in both tests. After some additional work, which confirmed these results, it was decided to use the low-grade cyanide in the mill.

For the last seven months "Aero Brand" cyanide has been used exclusively. It has proved satisfactory as a dissolving agent for silver and gold contained in the company's sulphide ore and "reducing" matter has apparently not accumulated in the solution.

An analysis of this product, as furnished by the manufacturers, shows: CN, 19.10 per cent; Cl, 25.13 per cent; Ca, 28.13 per cent; Na, 16.40 per cent; SiO_2, 0.80 per cent; R_2O_3, 0.91 per cent; Graphitic C, 3.94 per cent; Carbide C, 0.36 per cent; S, 0.55 per cent; N (?), 1.14 per cent; Mg, 0.15 per cent; O & Undet., 2.80 per cent.

This cyanide is shipped in cylindrical steel drums weighing 380 lb. gross and containing about 360 lb. of cyanide product, which contains about 37 per cent NaCN. The material is in the form of small, brittle flakes of dark gray color, about $\frac{1}{32}$ of an inch thick and from $\frac{1}{4}$- to $\frac{1}{2}$-in. in diameter. The soluble portion dissolves readily, leaving a light, flocculent, black residue.

In mill practice solution is effected in a tank in which a mechanical agitator is installed. Agitation promotes the more rapid dissolving of the soluble constituents. On account of the CaC_2 present, acetylene gas is immediately generated, so it is advisable that good ventilation be maintained over the dissolving tank. Ammonia is also frequently liberated from the solution. The small amount of soluble sulphide present apparently oxidizes rapidly. The alkalinity (not including that of the NaCN) is about 12 per cent, in terms of NaOH, so it is of service in neutralizing acidity and consequently saves lime, where lime is used to promote alkalinity of the solution.

The following table gives a comparison of results covering one month's operation at the mill of the Tonopah Extension Mining Co., using 97 per cent NaCN exclusively; also one month's run at the mill, using the 37 per cent NaCN "Aero Brand" cyanide. The two months selected were July, 1919, and March, 1920, and were taken for comparison because the average silver content of the ore treated during each of these months was about the same. The solutions used were also of the same NaCN content.

COMPARISON OF RESULTS WITH HIGH- AND LOW-GRADE CYANIDE

Cyanide Content of Product, per Cent	Feed Assay, Oz	Tailing Assay, Oz.	Per Cent Extraction	Consumption NaCN per ton, Lb	Consumption NaCN per Oz. Bullion, Lb
97	1 1 63	0 90	92 26	1 64	0.142
37	1 1 34	0 82	92 77	1 71	0 160

The "reducer" in solution, in terms of N 10 $KMnO_4$ (Clennel test), was 4.2 cc. and 4.0 cc. respectively.

Ancient Rumanian Copper Deposits

The iron and copper deposits of the Oltenic region, Rumania, were known to the Romans, and traces of their workings are still found. Owing to the low percentage (2 to 4 per cent) of copper which the ore gave, the experiments recently made to re-establish the working of these deposits have ceased, according to *Commerce Reports;* but pyrites rich in sulphur (40 per cent) were being extracted as a means of continuing the manufacture of sulphuric acid.

Copper ore (5 to 7 per cent) has been found in the Dobrudja. In this area deposits of ore amounting to 250,000 tons are estimated.

SLAG composition has been discussed in a previous article, but so far nothing has been said about what consideration should be given to sulphur in calculating a furnace charge and product. The question is by no means simple. In the first place, sulphur has three different effects causing a variation in its value. They are: fuel value, reducing value, and matting value, though the first two may be considered as one. This combined value for the first two properties may be considered separately from the third without interfering with the conclusions reached. It is difficult to give any formula representing the combined value, because it is dependent on many factors, but the subject may be considered in this way:

A good black-copper charge would smelt with 17 per cent of coke and 1 per cent of sulphur. With each added unit of sulphur, one unit of coke could be deducted until 10 per cent of sulphur is reached. From that point the value of the sulphur as fuel would decline rapidly until the sulphur becomes a source of expense. The reducing value is a part of the above effect, and I think most of the ferric oxide is reduced by sulphur. These interchanges represent merely a certain balance attained in actual practice. A change in the quality of the coke or its cost would alter the relative amounts involved.

The matting value and the fuel value are both recorded in the statistics covering the smelting cost. That is, if conditions are such that it pays to run with the lowest possible fuel, the amount of coke in the table of smelting costs will decrease, and at the same time and in proportion, the figure representing the recovery of sulphur in the matte will decrease.

MATTING VALUE INDETERMINATE

From an absolute standpoint, the matting value is indeterminate. Take a low-grade oxidized copper ore as an example. The first unit of sulphur is absolutely necessary to the smelting operation; the second not quite so important, and so on, in constantly decreasing value, until sulphur becomes an annoyance and source of expense.

The subject is complicated by the fact that the sulphur atom is bound to an iron atom with a fluxing value, but causing a copper loss in the slag. In any given operation, however, this is determinable, but it is necessary to avoid misconceptions.

Take the instance considered in the last article[1] with the sulphur in ore *B* as shown. It is clear that if the ore *D* can be purchased at a price at which the cost of a unit of Fe would be the same as that in the ore *B*, still, operations could not be maintained with *D* in place of *B*. The sulphur is the cause of the difference and must therefore have some definite value.

Now, 28 per cent CaO in the slag has been assumed as the most favorable amount; it will be assumed further that for the furnace operation it is immaterial whether the lime varies a few per cent or not, the injurious effect on the losses being protected by the charge against the iron. This being so, the fluxing value of the iron is limited by its equivalence to CaO, and is less than the value of CaO by the amount of copper loss caused by the equivalent of Fe.

What would happen if the lime limit were 28 per cent, making it necessary, in case of increased silica, to purchase sufficient iron to hold the CaO down to this amount is another matter, and does not enter at this point. It may be said, however, that the relative values would have to be determined for both iron and sulphur from the savings or losses incurred by unit changes in the charge.

Applying the reasoning stated above, and taking the data from Table I[2], the following quantities are obtained:

Cost of 1 ton of limestone	$2 00
Cost of smelting 1 ton and fluxing coke ash	4 12
2 units of SiO_2 require 1.185 units of base each, and 54 units CaO less 2.37 units leaves 51.63 units available, costing	$6 12
1 unit CaO costs	11.84c.
1 unit of SiO_2 requires 1.185 unit CaO at 11.84c	14.04c.
1 unit Fe = 9.7 unit FeO, and, therefore, of CaO, and is worth for fluxing, not allowing for the effect on slag loss	15.21c.
1 unit of copper in matte requires sulphur in the charge for matting purposes	4.665 units

With this data the cost of the sulphur in the sulphide flux may be calculated.

COST OF SULPHUR

Cost of 1 ton of sulphide flux	$9 00	
Smelting and ash of coke	4 12	
4 units of SiO_2 at 14.04c	56	
Cu loss, .48 units Fe at 0.3135 lb. 15.05 lb	3 01	
Credit 20 lb. Cu at 20c		$4 00
Credit 95 per cent of 1 oz. Ag		1 19
Credit 48 units Fe @ 15.21c		7 31
Fe for 4.95 lb. Cu in matte	04	
Credit for overcharge of Cu loss		.01
	$16 73	$12 51
	12 51	
44 units S, less 1.15 for matte for Cu recovered	$4 22	
Cost of 1 unit of sulphur	9.85c.	

The price of 15.21c. per unit for Fe denotes its equivalence to CaO in fluxing value, and to get its real value the copper carried into the slag by it must be deducted. Thus, 0.3135 lb. Cu at 20c. is 6.27c. Deducting this from 15.21c. leaves 8.94c., and correcting for iron and sulphur not carried into the matte, makes the cost of Fe 9.81c. per unit.

Much calculating may be saved by determining the value of the iron and sulphur in the matte per pound of copper and deducting the result from the works value, and also using the above cost as given for the iron contents.

4.665 lb. S per lb. Cu = 0.23325 unit S =	2.30c.
0.95 lb. Fe @ 9.81 =	4.6
Total deduction per lb. Cu	2.76c.

[1] Last of a series of three articles on the calculation of blast-furnace charges and costs. The first article was published Sept. 11, and the second Sept. 18, 1920.

[2] See our issue of Sept. 18, 1920, page 371.

[3] See our issue of Sept. 18, 1920, page 569.

Returning to the original ore

Smelting, etc.	$4 12	
50 units SiO_2 at 14.04c. per unit	7 02	
10 units Fe at 9.81c. per unit		$0 98
18 units CaO at 11.84c. per unit		2 13
1 unit of sulphur at 9.85c. per unit		10
2.7oc. deduction on 60 lb. Cu (not otherwise charged)	1 66	
	$12 80	$3 21
	3 21	
Cost of smelting one ton of A ore	$9 59	

The tools being obtained and tested it is possible to use them not only on the regular ores but also on others. Consider *D* ore:

SiO_2, 4 units at 14.04c. per unit	$0 56	
Smelting and ash	4 12	
Credit 65 units Fe at 9.81c. per unit		$6.37
	$4 68	$6 37
		4 68
Value of 1 ton		$1 69

Form for a Smelter Tariff

The metallurgist is now in position to make up a tariff for the mine superintendent:

Silver—Pay 95 per cent.
Copper—Market price less 5.26c. (2.5 marketing expenses plus 2.76).
Iron—Pay 9.81c. per unit.
Lime—Pay 11.84c. per unit.
Sulphur—Pay 9.85c. per unit.
Silica—Deduct 14.04c. per unit.
Treatment—$4.12 per ton.

All taxes and duties of whatever nature in force at the time of, or within sixty days subsequent to the receipt of the ore, and levied by Federal, state, or municipal government or other authority on the ore, substances contained therein or products thereof, whether levied on the production, extraction treatment, shipment, or sale, or on the documents covering these transactions, are for the account of the shipper.

This tariff may be suspended on due notice, or without notice, in case of force majeure.

conditions constant, such as percentage of coke on the charge, and sulphur recovery, the calculations are shown in Table III. It can, of course, be said that the higher silica slag would increase the requirement for coke, but my own experience leads to the belief that the demand for more heat is met largely by the increased percentage of sulphur oxidized on the charge, and that the practical effect is slower furnace running. That always tempts one to the use of more coke to speed up the smelting.

Taking the data from Table III, the cost of smelting a ton of ore would be:

Smelting 620 lb. ore at $4 00	$1 24
180 lb. sulphide flux	34
Smelting 180 lb.	36
Copper loss: 1.71 lb. at 20c	34
Total for 620 lb.	$2 28
Total for 1 ton of ore	7 36
Saving on silver in the slag	20
Net cost	$7 16

The saving over the other method in this operation would amount to $2.33 per ton of ore, which would seem to offer ample opportunity to pay interest on an extra furnace, or the cost of a little extra coke or compensation for considerable furnace trouble.

In the case mentioned, the extra furnace capacity was available and the effect of the higher silica showed in slower running and a little extra furnace trouble. The conditions demanding the higher silica lasted only a few weeks, and the practice was discontinued.

The difference in the character of the slag is to be noted. In the former case the lime almost reached the upper limit, whereas in the latter it is about the average and the Fe has increased but slightly. The copper lost per unit of Fe has decreased, as is forecast by the curve in Fig. 8.[1]

TABLE III. CALCULATION OF CHARGE

Material	Amount, Lb.	Ag — Assay	Ag — Oz.	Cu — %	Cu — Lb.	SiO_2 — %	SiO_2 — Lb.	Fe — %	Fe — Lb.	CaO — %	CaO — Lb.	Al_2O_3 — %	Al_2O_3 — Lb.	%	Lb
A	620	20.0	6.20	3.0	18.6	50.0	310.0	10.0	62.0	18.0	111.6	4.0	24.8	1.0	6.2
B	180	1.0	0.09	1.0	1.8	4.0	7.2	48.0	86.4					44.0	79.2
Coke	(80)	....	....	....	....	10.0	8.0	3.0	2.4	0.4	0.3	5.0	4.0	....	....
Total	800		6.29		20.4		325.2		150.8		111.9		28.8		85.4
Slag	664	0.82	0.27	0.257	1.71										

85.4 × 0.15 + 0.25 = 51.24 = Wt. of Matte
20.4 − 1.71 = 18.69 = Wt. of Cu in Matte
18.69 ÷ 51.24 = 36.5 = % of Cu in Matte
51.24 × 0.34 = 17.4 = Wt. of Fe in Matte
150.8 − 17.4 = 133.4 = Wt. of Fe in Slag
133.4 × 1.287 = 171.5 = FeO equivalent

Slag Content:	Lb.	%
SiO_2	325.2	49.1
FeO	171.5	25.8
CaO	111.9	16.8
Al_2O_3	28.8	4.3
Miscellaneous	26.6	4.0
Total	664.0	100.0

Slag: Base ÷ SiO_2 = 0.872
Silver:
Matte assay, oz 235
Slag loss, per cent 4.3

Copper:
Matte assay, per cent 36.5
Slag loss, per cent 8.38
Slag loss, lb. per ton of charge 4.275
Slag loss, lb. per unit of Fe in slag, 0.2563
Slag loss, lb. per lb. of Fe in slag, 0.01281

N. B.—Slag assay calculated from Fig. 6 and corrected for miscellaneous constituents to correspond with Fig. 2 and Table I, by deducting 0.035 from amount in Fig. 6.

Returning to the last article[1], the question naturally arises as to whether the assumed slag is the best possible one to use under the circumstances. The answer depends largely on local conditions; off-hand, I should say not. I think that in this case the silica should be increased to at least 45 per cent, though in one instance under nearly the same circumstances I was not able to run a slag containing more than 40 per cent silica, because of conditions not considered in this calculation. On the other hand, I once successfully used a slag containing over 49 per cent SiO_2, having very much the same analysis as will result in this case, by dropping the limestone from the charge. Keeping all the other

With iron and lime contents of the slag both in the middle of their range, it is proper, on the assumptions so far made, to consider the cost of fluxing a ton of silica as if the fluxing could be done with limestone alone: in this example it would cost 10.21c. per unit, because any moderate variation in the iron-lime ratio is taken up in the constants used.

If, however, the case as shown by Table I and the schedule offered to the mine is considered, and it is assumed that practical considerations limit the slag to 42 per cent SiO_2 and 28 per cent CaO, the situation is one of unstable equilibrium. Suppose ore *E* is offered. In this example it cannot be assumed that it can be

[1] See our issue of Sept. 18, 1920.

[1] See our issue of Sept. 18, 1920, page 571.

fluxed entirely with limestone, because doing so would raise the total lime in the slag to a prohibitive amount. Iron must be provided, either from *B* or *D*. To provide it from *B* would be to disarrange entirely the system which has been assumed to represent ideal conditions. If it is provided from *D*, then the cost of fluxing the silica in *E* must be determined on the basis of combining limestone, ore *D*, and ore *E* to form the standard slag, and not by recasting the standard slag and charge and recalculating the unit costs. This latter act is a mistake often made.

The figure correctly obtained should be checked by recasting the charge and calculating the increased cost, charging the whole of the increase to ore *E* and in that manner calculating the cost per ton of *E*. At this point the use of the curves becomes important, because a small inaccuracy in estimating the slag loss is greatly magnified, and individual assays are unreliable, or, rather, the demand for accuracy is greater than that attainable in practical work, and must be reached by following the laws that govern the averages.

It will be apparent that a rise in the silica contents of the mine ore will have the same effect as the purchase of outside siliceous ores; that is, *D* ore will have to be purchased for fluxing if the grade of matte is to be retained and the lime kept below 28 per cent.

The matter would have to be considered in several ways before deciding how to handle it. If *D* ore is expensive, it might pay to alter the base slag and matte. If the rise in silica is due to the mining of too much wall rock, for example, and the contract for the sale of the matte penalizes a drop in grade severely, then perhaps the best way would be to penalize the excess silica in the mine ore by an added charge, say, 14.04c. per unit up to 50 per cent SiO_2 and 20c. for all above that. This is the excess penalty clause seen so often in contracts. The exact method of handling the situation would depend largely on the mine and the mining methods.

Silver Loss Variation

That the copper loss is dependent on the silica in the slag, the grade of the matte, and the iron in the slag has been shown, and the tariff devised covers these points, but does not cover the silver loss. It has been indicated, also, that under certain circumstances the ratio between the silver assay of the slag and the silver assay of the matte is constant if the percentage of copper in the matte is constant, and for convenience in calculation it has been assumed that this is the case. In Table I, 18.3 lb. of copper is calculated as recovered, and the resulting matte assays 233 oz. per ton. If the copper assay of the ore *A* rises to the point at which the recovery of copper is doubled, the silver assay of the matte will drop to 116.5 oz. per ton, the slag assay will drop proportionately, and the loss will be halved. In this case, therefore, the silver loss is not a constant percentage loss, but varies inversely as the copper on the charge.

If *D* ore and *E* ore may be purchased in such amounts that it becomes desirable to add to a thousand pounds of the regular charge another thousand pounds of a mixture of *D*, limestone, and *E*, in proper proportions to form the standard slag, then, roughly speaking, the amount of slag produced on the total charge will be doubled. If ore *E* is a gold ore and contains no silver, the extra slag will be saturated with silver from ore *A*, and the silver loss will be approximately doubled.

The extra copper loss is taken care of by the charge against the iron of the new ores, but the percentage basis of calculating the silver loss again fails. It might be well to make a charge against the iron for part of the silver loss, and a credit to the copper for silver recovery, but this is not common in practice.

Several years ago a series of articles was published in the magazines on what constitutes an ore. Suppose the limestone contains silver. When does it become an ore? The answer is easy from the viewpoint of the metallurgist. As the amount of silver increases, the cost of a unit of CaO decreases until it reaches zero. The moment it passes this point the limestone ceases to be a flux and becomes an ore and will be smelted for its silver value rather than for its fluxing value.

Then, if it be understood that the supply of limestone is greater than the demand by the smelter (which has been understood to be the case, otherwise it would be the price of the limestone that did govern the costs), the situation has fundamentally changed.

The Importance of a Definite Nomenclature

In making these calculations it is essential to think definitely and to be careful not to apply the conclusions to situations to which they are not applicable. This is likely through the lack of a definite nomenclature for the quantities used by the metallurgist, and is particularly so with the words "cost" and "value." The terms "price," "cost," and "value" must be carefully distinguished.

Price per unit of an element, say, CaO, is the number of monetary units paid for the customary mercantile unit, divided by the number of metallurgical units of the element in the mercantile unit.

Cost is the price, plus all the other expenses that are incurred in the utilization of the unit.

Value is the monetary measure of the results obtained by the use of the element in question.

This is simple enough, but these three measures have negative quantities for which there are no adequate differentiating terms. In metallurgical slang it is customary to speak of a negative value as a "red" value, because in bookkeeping negative profits are often entered with red ink. Negative profits are losses, but a negative value is not necessarily a cost, nor a negative cost a value. This is where a misconception is likely to occur.

In Table I and the schedule based on it the cost of a unit of CaO is calculated to be 11.84c. This is the measure of the marginal value of the same unit under these conditions, because it was assumed that the standard slag was the most economical. If the cost were less than the value, another unit would have been added, or vice-versa, but the cost is not a measure of the average value, because then there would be no profits. Or, another small deposit of limestone costing less might be utilized for a part of the requirements and the difference between cost and value would be profit.

What term, then, represents the potential cost of the silica in the ore? What is the correct term for the monetary quantity attached to a unit of lime from a limestone with silver values in excess of the cost? What is the term of these same units when they are in excess of requirements? The terms unit, cost, and value are overworked, and it is necessary to keep in mind exactly what is meant each time they are used, or confusion results.

To return to the silver-bearing limestone. If it be assumed that the cost of a unit of CaO is zero, then the cost of fluxing a unit of silica becomes zero (basis of interchangeability of Fe and CaO), and the cost of a unit of sulphur under the conditions is as follows:

Cost of one ton of sulphide flux	$9 00	
Smelting	4 00	
Fluxing coke ash (Cu for Fe)	03	
Cost of fluxing SiO_2		
Value of Fe as flux		
Copper loss due to Fe at 0.3135 lb. per unit	3 01	
Credit for 20 lb. copper at 20c. per lb		$4 00
Credit for 95 per cent of 1 oz. of silver		1 19
Fe for matte		
Credit for overcharge for copper loss in Fe in the matte		01
	$16 04	$5 20
	5 20	
44 units of sulphur, less 1.15 in matte	$10 84	
Cost of 1 unit of sulphur	25 3c	

One pound of copper requires 4.665 lb. of sulphur, costing at the above rate 5.9c. It also requires 0.95 lb. Fe to make matte, and as the Fe so used does not drag any copper with it into the slag, there will be a credit to the 5.9c. equal to the penalty on the 0.95 lb. Fe. Estimating this penalty per unit of Fe at 4.5c., makes the credit per pound of Cu 0.21c., leaving the net deduction per pound of copper 5.69c. Adding this to the 2.5c. marketing expense, makes a total deduction per pound of copper of 8.19c., and a net value of 14.31c. (market price, 22.5c.).

The iron going into the slag has no fluxing value, but drags 0.3135 lb. Cu with it per unit of Fe. This, at 14.31c. per lb., is equal to 4.49c. per unit of Fe, which is the amount it should be penalized. The schedule would then be:

CaO, fluxing value	Nil
Fe, penalty per unit	4 49c
SiO_2	Nil
Sulphur, value per unit	25 3c
Copper, market price, less	8 19c
Treatment, per ton	$4 03

This is all based on the assumption that the 36 per cent matte is the most economical to use, and that FeO and CaO may be substituted for each other in the slag without inconvenience.

At first it may appear strange that the cost of sulphur has been increased by the presence of silver in the limestone, but a moment's consideration will show that such is actually the fact. The existence of cheap flux has taken away the fluxing value of the sulphide flux, leaving the whole expense to be borne by the sulphur. Although the price of sulphur has risen, the cost of treatment of the ore *A* has decreased. Also, as the cost of fluxing the silica has disappeared, most of the cost of treatment is directly referable to the pound of copper.

If it be assumed that 28 per cent CaO in the slag is the maximum permissible, the question of iron corresponding to the silica enters, and the costs must be calculated on that basis.

Practically, the sulphur usually brings the accompanying iron in sufficient quantity, although in practice I once met the problem just mentioned. The main supply was a siliceous ore, 60 per cent SiO_2, 20 per cent Al_2O_3, 10 per cent BaSO, and very little iron. The sulphide flux did not furnish enough iron, and the standard slag contained 25 to 28 per cent CaO and 3 to 5 per cent BaO; and to get even this it was necessary to buy oxidized iron flux. The marginal unit of cost was therefore regulated by the cost of a unit of Fe in the oxidized iron flux.

Practical considerations usually eliminate enough factors so that the problem is capable of solution.

Returning to the silver-bearing limestone: If the silver values are so great that the value of a unit of CaO is no longer a charge but is a credit, then the limestone is an ore, and the effect would be to change the standard slag so as to run with as great a percentage of CaO in the slag as possible, and presumably costs would be based on a unit of CaO rather than of SiO_2. Owing to the predominating amount of siliceous and irony ores, this is an improbable situation, though an entirely possible one, so the treatment of an ore with excess iron will be considered instead.

Assume ore *F* with 3 per cent Cu, 4 per cent SiO_2, 40 per cent Fe, 12 per cent S, 6 per cent CaO, 4 per cent Zn, and 2 per cent Al_2O_3. Quartz can be purchased at $2 per ton, delivered, and assume that it contains 100 per cent SiO_2.

Table IV shows a charge calculated from these materials. The slag loss has been calculated by interpolation from Fig. 4 and by using 80 per cent of the results so obtained after correcting for grade of matte by Fig. 2. Owing to the presence of bases other than FeO and CaO, results in practice will be lower than those shown in Fig. 6, and 80 per cent is merely an arbitrary figure. In actual cases, curves would be drawn to suit the results obtained, with due consideration to the source of the additional bases.

If it be assumed that the most advantageous slag is

TABLE IV. CALCULATION OF CHARGE

	Amount,	Ag		Cu		SiO_2		Fe		CaO		Al_2O_3		Zn		S	
Material	Lb.	Assay	Oz.	%	Lb.	%	Lb.	%	Lb.	%	Lb.	%	Lb.	%	Lb.	%	Lb.
F	1,000	1.0	0.5	3.0	30.0	4.0	40.0	40.0	400.0	6.0	60.0	2.0	20.0	4.0	40.0	12.0	120.0
Quartz	240					100.0	240.0										
Coke	(124)					10.0	12.4	3.0	3.7	0.4	0.5	5.0	6.2				
Total	1,240		0.5		30.0		292.4		403.7		60.5		26.2		40.0		120.0
Slag	933			0.597	5.56												

$120 \times 0.15 \div 0.25 = 72.0$ = Wt. of Matte
$30 - 5.56 = 24.44$ = Wt. of Cu in Matte
$24.44 \div 72 = 34.0$ = % of Cu in Matte
$72 \times 0.36 = 25.92$ = Wt. of Fe in Matte
$403.7 - 25.9 = 377.8$ = Wt. of Fe in Slag
$377.8 \times 1.287 = 485.7$ = Wt. of equivalent FeO

Slag Content:	Lb.	%
SiO_2	292.4	31.4
FeO	485.7	52.1
CaO	60.5	6.5
Al_2O_3	26.2	2.8
ZnO	30.0	3.2
Miscellaneous	38.2	4.0
Total	933.0	100.0

Copper:	
Matte assay, per cent	34.0
Cu loss, per cent	18.5
Cu loss, lb. per ton of charge	8.96
Cu loss, lb. per lb. of Fe in charge	0.01472
Cu loss lb. per unit of Fe in charge	0.2945

N.B.—The slag loss is calculated from Fig. 6, but only 80 per cent of the tabular values are taken to allow for effect of elements not shown in curves. See text.

The cost of treating a ton of *F* ore as in Table IV would be:

Smelting 1,000 lb. ore at $4 00	$2 00
Smelting 240 lb. quartz	48
Cost of 240 lb. quartz at $2.00	24
Copper loss, 5.56 lb. Cu at 20c	1.11
Total cost of treatment of 1,000 lb	$3 83
Total cost of treatment of 1 ton *F* ore	7 66

The cost of a unit of SiO_2 would be 6c.

that shown in Table IV, containing 31.4 per cent SiO_2, the cost of a unit of silica is its value under these conditions.

If another calculation be made using 1,000 lb. of *F* ore and 500 lb. of quartz, it will be found that under the same conditions as to sulphur recovery and other factors, the slag will contain 45.9 per cent SiO_2 and the cost of treatment of a ton of *F* ore, calculated in the same manner, will be $8.86. The difference of $1.20 is due to the addition of 520 lb. (two charges), of quartz, and measures the loss resulting from that addition, which amounts to $4.61 per ton of quartz. Then the value of a ton of quartz for raising the silica in the slag from 31.4 to 45.9 per cent would be negative in amount to $4.61 per ton if the cost price is included. Omitting the price paid it would have a negative value of $2.61 per ton; that is, the company would have to charge $2.61 per ton for smelting it to come out even.

I have shown the manner in which these figures are obtained, but the conditions which may exist at any given plant are infinite in their possibilities, and each case must be decided after a study of the whole situation.

In the examples cited conditions have been simplified by certain assumptions, because it is impossible in an article of this nature to allow for many of the important influences, such as furnace design, efficiency of the power plant, and general conditions, which affect the choice of a standard slag. In practice there are always conditions that permit of similar assumptions; otherwise there would be many indeterminate equations.

When Ores Are Purchased on Flat Rates

Take the case of a custom smelter operating on purchased ores which are available in such kinds and quantities that no fluxes are required, and which are purchased on flat rates, with no allowance for fluxing values. Here (as in all cases) the value of the marginal unit of each element will be determined by its effect on the metal recoveries or treatment expense and not by the cost of obtaining it. The fact that the smelter is not paying for the iron and lime does not affect their value (or vice-versa), but is merely a matter of business policy, which in this case is probably, but not necessarily, incorrect. Another plant may be buying ores on an elaborate schedule that has developed a similarly satisfactory ore supply, and yet the prices and deductions may bear no direct relation to the values, though entirely correct as to business policy.

The determination of the value of the marginal unit is no easy matter, and depends on both theory and practice. Furnace conditions vary so much from day to day that it is impracticable actually to test the effect of the addition of the marginal unit. The only way is to test the effect of substantial changes, so as to give points for plotting a curve from which the effect of minor changes may be deduced. This applies to theoretical calculations as well as to practical work, because few of these curves lie in straight lines, that is, ten units probably do not have ten times the effect of one unit.

Constant use of slide rules and approximate assays tend to make one a little careless in the use of such things as coke ash and 0.01 per cent in slag losses. In the calculations for daily furnace control they are of little importance, but in the determination of values they are very important if correct conclusions are desired. A rightly used graph is the micrometer which enables one to measure the value of the marginal unit and obtain results that are correct beyond the accuracy of the daily control samples and assays.

That these schedules of costs and values may be determined in more than one way has been demonstrated. They may be calculated to suit a general condition already existing, or for a prospective change in conditions. In either case, they are the means of measuring the cost of treating any ore the analysis of which is known. By their aid a company buying custom ores, or smelting ores from a number of different mines of its own, or a number of different ores from the same mine, is able, as a matter of routine, to calculate the profit and loss on each ore and thus find leaks that otherwise would escape notice. The mine superintendent will be able to recognize the exact value of each element, and so avoid those ores, or grades of ore, that do not yield adequate returns and to accomplish the mining so that the total profits from mining and smelting will be a maximum.

The schedule offers opportunity for graduating the charges and profits in accordance with the work done. Smelting a ton of neutral ore means just what it says, but smelting a ton of quartz when silica is in excess implies that three tons of limestone also must be smelted, or the treatment of four tons. The schedule also helps the ore buyer to develop and bring to the smelter at the most favorable terms the material required for operation. A miner may have an ore with 50 per cent excess SiO_2. The smelter, to cover treatment cost, adds to the treatment charge of a neutral ore a penalty of 15c. per unit excess SiO_2, a total penalty of $7.50 more than the charge on a neutral ore. If the smelter made a flat rate, this amount would have to be included in it, and there would be no recourse.

With the treatment charge in the penalty form, the miner may be able to sort out half of this excess silica at a cost to him of, say, 5c. per unit and save the difference. The world is better off because the cost of recovering the valuable elements from the ore has been reduced.

The schedule also enables two or more competing companies to go into a mining district and sort out the ores automatically in accordance with the cheapest total cost of smelting all the ores, and the greatest profit to the mining industry.

How To Apportion Fixed Expense

One phase of the matter is important and has not been mentioned; that is the fixed expense. Certain expenses at every plant will be incurred, whether the amount smelted is one ton per day or one thousand. These are the fixed expenses. The remainder for the sake of convenience may be called operating expense. Let it be assumed that the operating expense is $3 per ton and the fixed expense $1,000 per day and that there are no intermediate semi-variable expenses. The cost of smelting one ton per day would then be $1,003 per ton; the cost of smelting two tons per day would be $503 per ton, and for ten tons per day the cost would be $103 per ton, and so on until for 1,000 tons per day the cost would be $4 per ton. If the works are operating on a basis of one ton per day it is clear that the cost is $1,003, but the additional cost of smelting another ton is not $1,003, nor even $503, but only $3, and any price collected for the smelting of the second ton, if more than $3, will reduce the amount of loss in the $1,000.

Coming down to reasonable figures, if the works are

operating on a basis of 1,000 tons per day, and receiving $4,000 for the work, the company is neither losing nor gaining; it is costing it $4 per ton to smelt, and it is receiving $4 per ton. If, however, a contract for an additional thousand tons at $4 per ton is made, it receives $8,000 for the work done on the two thousand tons, and the cost is only $7,000; so it makes a profit of $1,000. This additional ore can be smelted, without loss, at $3 per ton, although the smelting cost is $4 per ton at the moment. It is to take care of this difference in effects between operating costs and overhead expenses that the various divisions of cost on this basis are required, and because the costs cannot be as sharply defined as in the example, the classification must be more extensive.

Therefore, in making up the schedules, charges, costs, and values of the different elements, it is evidently necessary to consider the purpose and manner in which they are to be used, before deciding on the bases to be taken in the calculations. It is the bank balance at the end of all the operations that is the final criterion of the correctness of the calculations.

Japan's Control of Chinese Iron Ores

The total known reserve of China's ores of such character and situation as makes them available for modern development amounts to about 416,000,000 tons, according to *North China Commerce*. Of this Japanese or Sino-Japanese companies own about 200,000,000 tons. The Chinese government retains its title to about 130,000,000 tons, including the Molingkwan ores.

The principal deposits owned or controlled by the Japanese are as follows:

Penshihu in Manchuria. Two grades of ore are found here, one containing 68 to 71 per cent iron and the other 35 to 40 per cent. No figures are available as to how much of the ore is high grade and how much of low grade, but the total tonnage is estimated at 80,000,000 tons.

Anshanshan. The tonnage here is estimated at 30,000,000, and the grade varies from 31 to 66 per cent.

Chinlingchen, in Shantung, where there are 37,000,000 tons and probably more of ore averaging 65 to 70 per cent iron. The Japanese government is retaining this deposit to supply the imperial steel works in Japan and seems to be planning to ship ore only.

Tayeh, nominally a Chinese company and actually dominated by Japan. The reserve is about 30,000,000 to 35,000,000 tons, which has already been contracted for delivery in Japan.

Tungkuanshan, at one time in possession of the British, now owned through the Sino-Japanese Development Co. by Japanese. This is an overrated deposit, having only about 2,500,000 tons of probable ore, but being well situated near the Yangtze.

Fangchanghsien, in Anhuei on the Yangtze, with 15,000,000 tons of ore containing 58-63 per cent iron. This is the main reliance of the new Oriental Steel Co., recently floated in Japan.

There is not one important deposit of iron ore in China controlled by foreigners except Japanese, and they now control about one-half the known reserve and are reaching for more. Much of the 86,000,000 tons in the hands of private Chinese firms may be expected to pass into Japanese hands.

The Molingkwan deposits are important because of their grade and situation. A steel works supplied by them would be in position to undersell any other works in China. The ore reserve is 30,000,000 to 40,000,000 tons and the grade is good. The deposits are situated about twenty miles south of Nanking.

China is not as rich in iron as was formerly supposed. The per capita reserve is less than one-seventieth of that of the United States, and the whole Chinese reserve, including that granted to Japan, amounts to only about six years' output from the Lake Superior region.

All these figures take no account of such deposits as those of Shansi for the reason that they are not available for modern industry. The individual bodies of ore there are so small that it is not feasible to mine enough ore in one day to keep a modern furnace running. These deposits are only available to feed small native furnaces which supply a limited local demand for pots and similar articles. From the point of view of modern industry they do not exist.

Gold in the Appalachians

As early as the sixteenth century, the Appalachian Mountains were known to contain deposits of gold, according to the U. S. Geological Survey. When the Spanish explorers came to southeastern North America the Indians showed them some rich nuggets and ornaments of gold that had been mined in the southern Appalachian region. In the seventeenth century the Spaniards mined for gold in Georgia. During the eighteenth century little gold mining was done anywhere in the Appalachians, although some writers have supposed that gold was found in North Carolina before the Revolutionary War.

Just at the close of the eighteenth century placer gold was discovered in Cabarrus County, N. C., and considerable prospecting was done in that region. The output of gold from South Carolina in 1829 was reported to be worth $3,500. From that time until the Civil War gold mining was a considerable industry in the southern Appalachians, and although the rich fields of California lured many miners from these lower-grade eastern deposits, the fever in California really stimulated gold mining in the East.

During the Civil War and for several years after it little gold was mined in this region, but in the seventies, eighties, and nineties gold mining there was more active. The gold-mining industry in the central Carolinas is not now flourishing, because the supply of free-milling ore is decreasing and because the gold cannot be extracted from the lower-grade sulphide ore at a profit.

"With Pitfall and With Gin"

"The oil-flotation process is to the mining industry of Yavapai County what the gin mill is to the great cotton business of the Salt River Valley in Maricopa County," says an article in the *Salt Lake Mining Review*. The gin mills of Arizona must then be more prosperous than those of New York and surrounding parts east, north, west, and south. At 75c. and up per "shot," the local mills doubtless make a considerable individual profit, but the overhead and underground are said to be high, and customers are not always what they seem. Neither are the beverages that the vintners sell (we hear). Curiosity as to the mysterious + habit + plain human cussedness are making the wake of Old John Barleycorn "some occasion"!

Geologists of Note

George Davis Louderback

AN ORDERLY MIND, imagination, and initiative, with an appreciation and love for humanity and nature, are basal elements in the make-up of a scientist. George Davis Louderback has, step by step, reached an eminent position as a geologist. The qualities which have contributed to this successful outcome have also endeared him to his associates and his students. At present he is professor of geology and dean of the College of Letters and Science of the University of California. His parents were pioneer residents of San Francisco, and he received his education in the California schools and University. On graduation he became an instructor in the University of California under Dr. Andrew C. Lawson. Soon after he became professor of geology in the University of Nevada. An incident will show the conditions that a new and, in this case, a youthful instructor has to face when installed in a strange place. On Dr. Louderback's arrival at the University of Nevada, and after meeting the president, he was turned over to the superintendent of buildings and grounds, to be shown his classrooms and facilities for instruction. The superintendent was gruff and direct. "Here's your place," he said, as he ushered the worthy professor into a small room. The walls of the room were the worse for wear, and the windows were covered with scratches where students had tested out minerals on the glass. In the center of the room was a heap of all the minerals of the department. It looked liked a sample ready for flattening and quartering. There was a battered table and four broken chairs. Dr. Louderback looked around at the superintendent—and smiled, to be met by an answering smile.

GEORGE DAVIS LOUDERBACK

After serving two years as research assistant of the Carnegie Institution of Washington, Dr. Louderback returned to the University of California in 1906, and was rapidly promoted until he attained the professorship of geology in 1917. The value of sound preparation in fundamentals rather than a high degree of specialization was demonstrated by his selection to take charge of a geological expedition into China for the Standard Oil Co. of New York. On the completion of his work in North China he conducted geological work for the Chinese government in Szechuan, and finished his Far East experience by three months investigations in the Philippines.

When the United States entered the war in 1917 the State Council of Defense for California organized a series of scientific investigations. Dr. Louderback was made chairman of the committee on geology and mineral resources. Under his direction a survey of the chrome and manganese resources of California was organized, with a corps of volunteer assistants, for the purpose of encouraging the mining of these minerals. In 1918, the U. S. Geological Survey placed him in charge of the investigation of chrome and manganese resources of California and the U. S. Bureau of Mines secured his services for similar work on the manganese resources of the same states. Dr. Louderback has marked organizing ability and possesses the faculty of getting others to work with him. His most effective work is in geological research and in the instruction of geological students. He made studies of Basin Range structure, the Truckee sedimentaries, and the oil-bearing formations and stratigraphy of the Pacific Coast. He discovered the gem-mineral benitoite. His methods are thorough, and mining and geological students from the University of California are well grounded in fundamental geology.

A wide field is covered by Dr. Louderback's activities. He served as secretary for the Cordilleran section of the Geological Society of America for a long time, and in this capacity stimulated research work on Pacific Coast geological problems. He assisted in founding the Seismological Society of America. He was secretary and later chairman of the Pacific Association of Scientific Societies. He is a fellow of the American Association for the Advancement of Science, member of the Washington Academy of Science, California Academy of Sciences, American Institute of Mining and Metallurgical Engineers, American Geographical Society, Geological Society of America, Mineralogical Society of America, the Committee on Sedimentation of the National Research Council, and many clubs.

Classifier Efficiency

Improvement Over Former Methods of Determination Suggested — Elutriation Preferable to Screening Tests

BY R. T. HANCOCK
Written for *Engineering and Mining Journal*

IN HIS recently published "Handbook of Ore Dressing," p. 214, A. W. Allen gives the following formula:

$$\textit{Efficiency of Classification} = \frac{100\,(t + t')}{F}$$

where t = tonnage of oversize in the coarse product, t' = tonnage of undersize in the fine product, and F = total feed tonnage. He gives an example of the performance of a Dorr classifier treating 1,100 tons, and producing a coarse-product discharge having 84.9 per cent of plus-65 mesh and 15.1 per cent of minus-65 mesh, the fine-product discharge consisting of 5.8 per cent of plus-65 mesh and 94.2 per cent of minus-65 mesh, the tonnage of coarse-product discharge being 790 and fine-product 310. The efficiency is given as 87.5 per cent.

The efficiency of a classifier cannot be obtained in this way. The problem is exactly similar to the obtaining of the efficiency of an operation of ore-dressing where what is desired is the separation of two substances of different nature, ore and waste, whereas in classifying the separation desired is of substances differing in size —coarse and fine. Therefore the same type of formula is applicable to both cases.

The formula which I have evolved for obtaining the necessary information (*Mining Magazine*, September, 1918, and *E. & M. J.*, April 10, 1920), may be written:

$$\textit{Percentage metallurgical efficiency} = \frac{\%\ \textit{recovery} - \%\ \textit{concentration}}{\%\ \textit{of waste in feed}}$$

or,

$$= \frac{\%\ \textit{concentration} \times (\textit{enrichment ratio} - 1)}{\%\ \textit{of waste in feed}}$$

In applying the formula to the classifier the percentage recovery is the weight of the plus-65-mesh material in the spigot or coarse products, expressed as a percentage of the weight of the plus-65-mesh material in the original feed, assuming that 65 mesh is the size at which it is desired to divide. The percentage concentration is the weight of the spigot or coarse product expressed as a percentage of the weight of the original feed. The enrichment ratio is the ratio of the percentage of plus-65-mesh material in the spigot or coarse product to the percentage of plus-65-mesh material in the original feed. The percentage of waste in the feed becomes the difference between 100 and the percentage of plus-65-mesh material in the original feed.

Calculated in this way the efficiency in the instance given by Allen is shown to be 68.1 per cent, and not 87.5 per cent, and it can further be shown that Allen's formula would give positive values of efficiency in cases where no segregation of the coarse sizes into the spigot product took place, but where the classifier merely split the feed into two parts of similar nature, in which case it would, of course, be operating with zero efficiency as a classifier.

In a classifier making only two products, spigot discharge and overflow, or in classifiers of the Dorr type, it is not necessary to know the weight of the products made, or of the feed. The efficiency can be calculated from the screening assays alone. In multiple-spigot classifiers it is necessary to know what percentage the weight delivered by each spigot is of the original feed. It is necessary, of course, to know the screening assays of feed, spigot discharge, and overflow in the former instance. A mere statement of the screen assays of the final products is useless, as Allen states.

Complete statements of the performance of multiple-spigot classifiers appear to be rare in technical literature. The only one I have seen is given in Richards' "Textbook of Ore Dressing" on p. 228. Where this table is reproduced in "Peele" (p. 1,662) the percentages which each spigot product and the overflow form of the original feed are omitted, as though the importance of this information had not been realized.

The data which Richards gives are as follows:

SIZING TEST OF FEED AND PRODUCTS FROM RICHARDS, DEEP-POCKET FREE-SETTLING CLASSIFIER

Size, mm.	Feed	1 Spigot	2 Spigot	3 Spigot	Overflow
On 0 907	0 41	0 0	1 49	0 0	0 0
0 566	20 55	52 5	17 90	0 40	0 12
0 427	14 84	24 62	19 90	1 50	0 31
0 351	12 39	14 30	23 60	3 70	0 43
0 277	9 87	5 22	18 19	6.90	0 81
0 206	9 05	2 61	9 60	12 09	0 43
0 137	10 03	1 00	8 20	29 50	3 67
0 130	3 59		0 79	8 21	0 62
0 107	4 08	0.38	1 81	37 75	0 31
Through	15 25				93 50
Totals	100 05	100 18	100 48	100 05	100 20
Weights	99 77	26 10	40 297	129	16.09

These figures require emendation, which has been attempted below, the figures being weights of sizes in each product.

ADJUSTED REPORT OF SIZING TEST

Size, mm.	Feed	1 Spigot	2 Spigot	3 Spigot	Overflow
On 0.907	50	0	50	0	0
0 566	2,064	1,339	716	7	2
0 427	1,477	644	802	26	5
0 351	1,314	352	895	60	7
0 277	991	134	726	118	13
0 206	786	70	454	244	9
0 137	962	27	343	531	61
0 130	271		47	209	15
0 107	573	8	57	504	4
Through	1,512				1,512
Totals	10,000	2,583	4,090	1,699	1,628

The result obtained will vary according to the particular mesh selected as a standard for the performance of the classifier, and to bring this difference out I have calculated the efficiencies for each size for all the products, as follows:

PER CENT EFFICIENCIES

Dividing on	1 Spigot	2 Spigot	3 Spigot
+ 0 907 mm		not computed	
+ 0 566	47 3	48 7	26 6
0 427	46 0	54 0	31 8
0 351	42 7	62 7	37 1
0 277	39 2	71 0	40 5
0 206	37 4	74 7	48 7
0 137	33 5	74 2	58 7
0 130	32 1	70 4	67 9
0 107	31 1	68 1	93 5

In calculating the efficiencies for the second spigot it must be remembered that its feed is the overflow from the first compartment, and not the original feed, and this overflow must first be calculated. The whole calculation is, in fact, exceedingly tedious, and anyone who thinks that the result obtained is of service in adjusting the classifier is welcome to that conclusion.

Taking the results as they stand, it is apparent that the maximum efficiency of the first spigot is associated with division on a comparatively coarse size; of the second spigot on a medium size; and of the third spigot on a fine size, which is as it should be. The high value obtained for the third spigot by dividing on plus 0.107 mm. mesh is unreliable, as much adjustment of the original figures was necessary here. The values obtained for the first spigot appear low.

In my opinion the grading assay of classifier products is best obtained by elutriation, and not by screening. By the latter what is found is the efficiency of the classifier as a screen, which it is not. Flaky particles present in the feed will be carried over to the later spigots, whereas by virtue of their size, as determined by screening, they should be found in the earlier spigot product. Perhaps this fact may be the cause of the poor showing made by the first spigot in this instance. The feed is stated to have been crushed by rolls through a 1-mm. screen.

Efficiencies for the overflow have not been calculated. Like the tailings of an ore, they would show the same efficiencies as the concentrate (here the third spigot product), but of minus sign.

Ice Formations Underground

By C. M. CAMPBELL

Written for *Engineering and Mining Journal*

FEW minerals crystallize in such beautiful forms as ice. The first illustration shows a view in an abandoned manway in the Granby mines at Phœnix, B. C. The manway is on an incline and contains a stairway. Along the roof run the electric wires, with drop lights where required. The upper part of the manway became blocked with ice, and, in the perfectly

FIG. 1. AN ICE CRYSTAL CLINGING TO AN ELECTRIC LIGHT GLOBE

quiet area below, crystals of large size have developed thickly along the walls and roof such as shown clinging to the light globe. Crystals almost a foot in diameter and of wafer thinness are quite common in the Granby mine.

Similar conditions prevail along old drifts, and in passing through abandoned stopes one occasionally comes among a congregation of ghost-like figures such as are shown in the second picture. These usually gradually disappear with the arrival of warm weather. Owing, however, to the working out of the deposit in recent years, the lower levels have been connected with the surface of large openings and permanent ice has gradually formed in the winter in the abandoned parts of the different levels, filling up, partially or completely, the drifts and stopes. The air currents in the summer take on the temperature of the ice, and one can now stand at the mouth of one of the tunnels,

FIG. 2. ICE STALAGMITES IN AN ABANDONED STOPE

on the hottest summer day, and face a blast of freezing temperature. No. 3 tunnel has an unobstructed opening 9 x 15 ft. in size; the ice on the floor is still dry 15 ft. from the portal, and has furnished a supply for the citizens all summer. Though the temperature may be 80 deg. F. outside, icicles are still forming on the timbers, and the tunnel is a veritable region of winter.

Ensenada's Mineral Resources

The Ensenada Consular District, Mexico, according to *Commerce Reports*, is rich in gold, silver, copper, lead, zinc, and iron. Magnesite is shipped from Magdalena Bay. The Mexican onyx quarries near Santa Catarina are the largest in the world. An immense surface deposit of iron ore at San Isidro gives much promise. Since 1911 mining has been on a decided decline, the one exception being the El Boleo copper mine, at Santa Rosalia, where a French company has produced steadily and successfully for a number of years. The company has its own smelter and operates its own ships, important considerations under the recent political conditions.

With the return of normal conditions and proper guarantees this will be a most attractive region for mining investments, for there are abundant surface showings and other indications that in Lower California important ore deposits await the pick of the prospector.

By the Way

Camille Industrielle

While conducting a research in polyglot technical literature, the consulting engineer observed that a report on the Alsatian potash field, by Monsieur Camille Binder, would soon be published by the *Societé de Chimie Industrielle*. Hastily jotting down the information on the back of an envelope, he continued on his special assignment. Late that night, Mrs. Babel conducted a little research of another character; technical only in its thoroughness. Being of a jealous disposition, next day she prevailed upon an ex-canteen-worker to assist her in a bit of translation. "H'm'm; let's see—*Industrielle* certainly means 'working girl.' Well! An affair of that kind may be all right for a Camille; but I tell you *we* never had such goin's on around *our* canteen!"

Some Salt

Under the heading "Some Salt" the U. S. Geological Survey informs the public, in Press Bulletin No. 455, that the volume of salt in the ocean is enough to cover the entire surface of the United States to a depth of 8,500 ft. Authorities on technical writing will agree that this use of the word "some" is not to be tolerated. It really looks as if the Survey wanted more people to read the bulletin and was descending to the use of levity to achieve its end. It would be, indeed, a whale of a lot of salt. This, we presume, is what the Survey would intimate. Besides "whale" is quite befitting a fish story and "lot" has been associated with sodium chloride ever since the days of Sodom and Gomorrah.

Quien Sabe?

A seeker after truth asks concerning a hypothetical zinc mine in the Joplin district: "What should be the average daily production of a vein, 3 x 5 ft., in a tunnel mine?" An open non-competitive examination will be held on this subject beginning at once. Both sexes may enter, but male eligibles will be preferred. A vacancy may be filled at a local sanitorium from the results of the examination.

Florida Water Preferred

The *Financial Times* of London recently published the prospectus, here given in full, of the Chemical Research Association, of Berlin, which purposes to extract gold from sea water. Unfortunately for us the term of subscription expired on Aug. 20. The announcement reads as follows:

THE CHEMICAL RESEARCH ASSOCIATION
Treasurer: O. A. SCHUESSLER
Berlin SW 19 (Germany).

BERLIN, April 20, 1920.

Dear Sir,

It is quite a well known fact, that the formerly richest gold mines of Transvaal and Alaska have become less productive and threaten to exhaust in time, as has already been the case with the goldfields of Australia and California. If no new goldfields are discovered, we shall surely steer into a gold famine.

In fact a scarcity of gold would certainly make its appearance, if it would not have been succeeded to discover new sources, the enormous abundance of which overshadows all previous wealth of gold and will cover the whole worlds demand for gold for ever!

This vast source of gold is—the ocean—the sea-water!

Careful chemical research of the sea-water brought forward the result, that it contains per ton about a grain of gold in solution. Conclusively there exists dissolved in the ocean a quantity of gold equal to 800,000 millions tons, that is to say 500,000 times as much as gold has been produced ever since the beginning of our chronology until this day!

THE CHEMICAL RESEARCH ASSOCIATION has set herself the task to secure these treasures from the ocean by a special extracting process. For technical and hydrographical reasons the South-East-Coast of U.S.A. would best serve the purpose. As soon as the preparatory work is done the works for the extraction of gold from the sea-water will be erected. In view to this THE AMERICAN GOLD EXTRACTING COMPANY with a share-capital of $1,000,000, divided into 10,000 shares, each to be $100 nominal, will be founded. The privilege to purchasing these shares will be reserved firstly to members of The Chemical Research Association. By subscription instalments of not less than 50% are to be made.

How lucrative the produce of gold is, show the gigantic profits of the gold producing concerns. The California Consolidated Virginia Mines for instance paid out in 1877 not less than $22,680,000 dividends to their shareholders.

With regards to the calculation drawn The American Gold Extracting Co. will be in a position to pour out a dividend of about $100 on each share by a years produce of only 4 tons gold already, i.e. 100%. As far as experience goes the rate of exchange of the share must then rise to at least the 15-fold. Each $100 share will then fetch $1,500 or more on exchange. As the raw-material—the sea-water—in any quantity is free of charge at our disposal, nothing can prevent us from extracting the ten-fold amount of gold and pouring out the ten-fold dividends, whereby the shares will rise to an unimaginable height!

The works of the American Gold Extracting Company will be erected on American soil and therefore is it important to get the American public interested in this enterprise and to admit English & American citizens into the Board of the concern.

From this point we beg to apply to you with the request to join the membership of The Chemical Research Association. The annual contribution for membership amounts to $10 only; by this means the membership entitles you to the privilege of purchasing 10 shares of The American Gold Extracting Company at par. Further shares are to be had at the rate of $130, whereby the Funds for International Scientific Research of our Association will be benefited with the residues and the members' fees. You will thus have the satisfaction to aid science and to increase your money as you can easily make at least $1,500 to $2,000 out of $100.

But the less wealthy who could not even afford to secure $100 for a share, shall have the opportunity to become patron of science and to earn money at the same time. He needs only become member of The Chemical Research Association and subscribe a sum divisible by 10 (at least $10). He will then receive the amount of dividend corresponding to his share.

Do not let this never returning opportunity slip by without securing a membership and shares and thus increasing your fortune! Please fill up and sign the enclosed form and kindly return it to the Treasurer of The Chemical Research Association.

Speedy dispatch is entirely in your own interest as the term of subscription expires on Aug. 20, 1920.

Warning

We warn our readers that one of these days they are going to read something like this in the *Engineering and Mining Journal:* "The limestones lie uncomfortably on the quartzite beds." Our compositors are not geologists and they have not yet learned that there is such a word as "unconformably." So far, we believe, we have always caught the error but we feel it in our bones that sometime it is going to slip in.

CONSULTATION

A Mining Agreement

"What share of profit is it customary to receive from a mining company when the ore fields belong to one party who locates the ore, and is sole owner, and the other party being a company who furnish the equipment, machinery and attend to the operating, mining, handling, treatment and commercial disposition of the product; the owner party acting as superintendent and actively engaged in directing the enterprise?

"This is identified in two classes:

"A—Owner party who owns the ore and works in any capacity.

"B—Equipping and operating party, who furnishes the money for machinery and labor, but none of this party does any actual labor and only supplies necessary money for equipment and operating.

"I believe the profit divided equally between A and B would be commensurate until B receives the amount of B's investment and 20 per cent annually for the time it took to return B's amount in half the entire profit. If B invested $10,000 and it was paid back to him in his share of profit in two years, then he would receive 20 per cent on the $10,000 for two years. Time being specified as that in which the mine is in operation, Sundays and legal holidays considered same as working days if in a time when the mine is in operation, but if operation should be suspended for a specified time, winter months, or indefinitely, interest to discontinue.

"Individual conditions vary according to the circumstances to be taken into consideration, but A having valuable copper bearing ore, is located near railroad with labor and supplies convenient, is favorable to B's operations.

"I would like your opinion here, and to learn if I can, what is generally customary."

The sum and substance of your statement indicates that one party is to be sole owner of the property and is to be actively engaged as superintendent directing the enterprise, while the other party is to furnish the equipment and attend to the financing of the operation, for which arrangement profits are to be equally divided between the two parties with interest at the rate of 20 per cent annually paid to B, the party contributing the finances.

This strikes us as an unusual arrangement. In the first place all A is virtually doing is raising a certain amount of money to operate the property, paying an unusually high interest rate *until all of B's money is returned* and hoping to pay back the principal in short order. All business connections between A and B will presumably be severed when this condition has been fulfilled. The provision that the interest discontinue during the time that the mine operations are suspended is a peculiar restriction, as an unsuccessful attempt to work the property, followed by a shutdown, would free party A from paying interest on the borrowed funds. Although this arrangement is unfair to B there are other considerations manifestly unjust to A's share in the agreement.

It should not be forgotten that in the proposed development of the property A has nothing to lose financially and everything to gain, but B's position is just the reverse. No provision has been made for a possible failure in the enterprise, something which is the rule more than the exception in the run of mining ventures.

As to what arrangement is generally customary in working mineral deposits, no hard and fast rule can be laid down. Frequently a bond and lease are taken upon the property with the intent of working, and paying for the land at regular intervals. Such a plan ordinarily contemplates complete purchase of the prospect or mine. If the owner desires to retain an interest in his property an agreement whereby he is to retain part possession in return for privileges granted to the operating parties might be consummated, but a plan such as you have outlined provides that one party act purely as a financier and does not become part owner of the property.

An important consideration and one which is not included in your statement is the condition of the mine. Its prospective value depends chiefly upon the profits to be won from ore exposed and the possible profits to be obtained from the extension of ore beyond exposures disclosed by development.

Is it assured beyond a shadow of a doubt that the enterprise will be successful? Have the risks incident to mining operations been carefully considered? The unwisdom and impracticability of laying down any general rule to follow is due to the difference between mining and other business ventures.

Ability to raise sufficient capital to work a mine alone would depend upon the owner's credit and a showing of the property sufficiently satisfactory to induce capital to finance the operation.

The arrangements that can be made are largely dependent upon individual circumstances and no generalization can be made. There should be concessions on both sides, and a willingness for both parties to cooperate in deciding upon what are fair and business-like terms.

The sale of a mining property or a prospect and a mutally satisfactory arrangement to purchaser and seller has been a bone of contention in the mining industry ever since mines were first operated. The vendor frequently lets his imagination picture the value of his property and its possibilities unduly great whereas the purchaser ordinarily adopts a Missourian attitude. An inability to reach an agreement has hindered the development of many promising mining prospects.

With the thought that perhaps some of our readers may care to contribute their experiences in arrangements for purchasing, selling, or operating mining properties, we are publishing your letter and our reply in these columns.

Highest Quicksilver Average Price

"What was the highest monthly average price of quicksilver during the war?"

The highest monthly average price of quicksilver during the war as indicated by *Engineering and Mining Journal* quotations was attained in February, 1916, with an average quotation of $283.50 per flask of 75 lb, which is almost four times the current quotation of about $75 per flask.

THE PETROLEUM INDUSTRY

Financial Record of Scotch Oil-Shale Companies

Details of the Amalgamation, Effective in November, 1919, by Which Practically All the Going Companies Were Merged Under the Control of the Anglo-Persian Oil Co., Ltd. Attractive Dividends Heretofore Paid

Written for *Engineering and Mining Journal*

IN VIEW of the serious endeavors now being made to inaugurate in the United States commercial operations in oil-shale treatment, the financial records and results of the companies which have been engaged in this special industry in Scotland for more than half a century become of special interest. Data on the subject have been accorded critical consideration abroad, incidental to a large merger plan which has just been effected, in which practically all of the going Scotch companies have been amalgamated and united to the interests of the Anglo-Persian Oil Co., Ltd., a world-wide organization in which the British government has a large financial interest and a dominating control.

The records indicate that the Scotch operators in oil shale have not always had clear sailing financially, even in recent years. Financial data of the early stages of the business are not available, but records of corporate readjustments, and the fact of the practical merging of a large number of small companies into five large companies reflect the earlier financial history of this Scotch industry. Even in recent years, after the technical difficulties incident to the infancy of any industry have been overcome, all of the companies except one, the Pumpherston, experienced financial embarrassments, as is evidenced by the varying and in some cases consistently low dividends declared. In fact, some of the companies report "nil" dividends as late as 1910 to 1914. The dividend record of the Pumpherston company, the premier of the Scotch oil-shale companies, is, however, as satisfactory as anyone could reasonably expect, and the general valuation placed on all of the securities of these companies in the financial plan of the new merger, which was only effective late in 1919, is evidence of the substantial soundness and large potentialities of the business.

In May, 1919, the Anglo-Persian Oil Co., Ltd., after a long and thorough investigation, submitted a proposition to form and adequately finance a merger of the Scotch oil-shale companies. This plan was obviously in pursuance of the expansion program of that powerful organization in the oil industry, but it was also opportune for the oil-shale companies, for they were having some difficulty in maintaining sufficient production to keep the refinery installations, incident to the development, going at full capacity. Trouble was also threatened because of the demand of the miners for increased wages equal to the greatly ascending scale of the British coal miners, and general conditions rendered it unlikely that the Scotch shale oil companies could maintain separately the large earnings made during the war. The proposal of the Anglo-Persian company was duly accepted by the requisite number of shareholders, and the change in control and policy and the unification of the shale-oil companies became effectual in November of 1919.

SHARE DISTRIBUTION OF THE NEW COMPANY

The new company, known as the Scottish Oils, Ltd., has a capital of £4,000,000; shares, £1. Of the total shares 3,000,000 are 7 per cent (non-cumulative) participating preference shares and 1,000,000 are ordinary shares. After the payment of 7 per cent on the participating preference shares the ordinary shares will be entitled to receive 7 per cent, and of the remaining distributable profits, the participating preference shares will receive 25 per cent before further distribution of profits to all shares alike are made. It is expected that the new company will be able to pay 7 per cent on the preference and ordinary shares and to leave a surplus for both classes of shares equivalent to at least a like dividend return.

The basis of the acquisition of the several unit companies and a record of their capital and of their dividends follows:

THE PUMPHERSTON THE LEADING COMPANY

The principal of the Scotch companies, the Pumpherston Oil Co., Ltd., registered 1883, capital £450,000, shares £1, has a very good dividend record. In addition to paying 6 per cent on £150,000 first and second preference shares, the distributions on the ordinary shares, of which £285,000 were issued, have been as follows: For 1900, 20 per cent; 1901, 15 per cent; 1902, 7½ per cent; 1903, 20 per cent; 1904 and 1905, 30 per cent; 1906 to 1910, inclusive, 50 per cent annually; 1911, 30 per cent; 1912, 35 per cent; 1913, 35 per cent and a bonus of £1 3s.; 1914, 25 per cent; 1915, 10 per cent; 1916, 25 per cent; 1917, 40 per cent; 1918, 40 per cent; 1919, 40 per cent; 1920, 30 per cent. In the report of April, 1919, a credit balance of £221,324 is shown, which, after deducting dividends on preference and ordinary shares, and transferring £14,000 to new plant account, and writing off £3,064 for improved plant and £3,000 for reserve fund, left £36,059 carried forward. The reserve is given as £110,000.

The £1 shares have the following recent market quotations: 1917, highest, £4 25/32; lowest, 79s.; 1918, highest, £5⅜; lowest, £4¼; 1919, highest, 98s.; lowest, 81s. 9d.

This company was taken into the merger on the basis of £5 for the ordinary shares, payable in fully paid 7 per cent (non-cumulative) participating preference

shares of a par value of £1 each in Scottish Oils, Ltd.

Young's Paraffin Light & Mineral Oil Co., Ltd., registered in 1886, had a capital of £700,000, made up of 175,000 shares of £4 each, and 113,202 shares were issued. In addition, the company had an issue of first and secured bonds totaling £300,000. The issue of £150,000 of second-charge bonds, in addition to 6 per cent, carried a right to interest at twice the dividends payable on the ordinary shares. The dividends on ordinary shares from 1919 average about 4 per cent only. The data are somewhat complicated by the preference interest payments made on the second-charge bonds of £150,000. The financial showing is not good, a fact which is mirrored in the offer of the merger to purchase the whole issued capital at 63s. per share, payable in preference shares in Scottish Oils, Ltd.

The Broxburn Oil Co., Ltd., registered in 1877, had a capital of £335,000, of which £100,000 was represented by preference shares, entitled to a cumulative dividend of 6 per cent. The dividends on the ordinary shares since 1900 have averaged better than 10 per cent (free of tax). The merger paid £2 each for the whole of the ordinary shares, the £2 being payable in preference shares in Scottish Oils, Ltd.

The Oakbank Oil Co., Ltd., registered in 1886, had a capital of £300,000—£100,000 preferred and £200,000 ordinary shares. The dividends from 1900 have ranged from 7½ to 15 per cent; since 1915 they have been 15 per cent (free of tax). The company had reserve funds of £61,940. This company was taken into the Scottish Oils, Ltd., at 37s. 6d. for the ordinary shares, payable in preference shares.

James Ross & Co. (Phillipstown Oil Works, Ltd.), which had a capital of £135,000 in £1 shares, was taken over by the Scottish Oils, Ltd., at 25s. per share.

In the same financial program, the Scottish Oils, Ltd. purchased for £150,000 cash the British Petroleum Co. and the Homelight Oil Co. Both of these companies were oil-distributing organizations, the latter already controlled by the Anglo-Persian Co. The inclusion of these companies in the merger is significant of the general program to broaden the Scottish Oils by finding facilities to distribute not only the products from the shale but crude oil products as well.

Will Get Crude from Anglo-Persian Company

The Anglo-Persian Co. has made a contract, effective January, 1923, to supply the Scottish Oils, Ltd., with crude oil to keep its refineries going to full capacity, a factor which will tend greatly to insure maintenance of dividends for the new company by removing one of the drawbacks, which was inherent under the plan of independent companies, of depending principally on oil from shale for the refinery supplies. It is expected that a shale will also be made from the unification of management and of equipment and facilities. The marketing organization and facilities of the strong parent company will also be of great advantage to the new operations.

It has long been known that the Scotch shale companies found it advisable and profitable to mix part of their oil product with refined oil bought in the market from the producers and refiners of crude oil. It is presumed that this practice will be continued with increased advantage under the new close financial relation with a strong producer and refiner of crude oil.

The plans of the new company, or its parent organization, the Anglo-Persian Co., with regard to the extension of the engagements in the oil shale business are not yet known. The Anglo-Persian Co. recently has made investigations of the oil shale of New Brunswick, and an agent of the company has been negotiating with some of the owners of oil-shale land in the Colorado-Utah field. It is not likely that the Scotch operations can be largely expanded because of the limits of the shale deposits which are available for cheap mining. Other deposits in the British islands have been investigated, and it is reported that they will be made the basis of new operations soon, but whether by the interests allied with the Scottish merger or not is not disclosed. It is expected that extensive improvements in equipment will be installed at the Scotch plants at an early date.

Polish Oil Industry Important, But Faces Many Difficulties

Oil is, at present, the chief reliance of Polish export and the principal means by which the Minister of Finance hopes to bring about a real stabilization of the valuta (exchange). Just now there is a crisis in the Polish oil industry according to *Commerce Reports*.

When the Polish administration of Eastern Galicia began, foreign capital rushed into the oil fields. Before the war British (chiefly Canadian), French, Belgian, German, and Dutch capital was invested, although the majority control was in Austrian hands. After the close of the conflict more British, French, and Belgian money was brought in so rapidly that during the last year practically the entire industry has changed hands, refineries as well as oil fields. French capital now predominates. One of the largest French companies is the Mugeot, which acquired its lands by direct purchase from the proprietors. There is very little American capital, only one company being recorded.

The oil situation in Galicia has developed rapidly. New wells are being constantly discovered and brought in. By June 15 the owners of oil-bearing lands in Galicia would no longer give options. They would consent only to sell outright.

The crisis in Polish oil dates back to 1909. It was accentuated during the war, particularly after the Russion invasion of Eastern Galicia. For several years no search was made for new wells and no oil extracted from the old ones, and only recently has the oil business been revived. The industry was greatly in need of organization and equipment. Former Austrian restrictions had to be removed, and war devastation repaired. A peculiarly irritating difficulty arose because, before the war, practically all technical materials used in the Polish oil industry were imported from Bohemia, Upper Silesia, and Sweden. Independent Poland found all these sources of supply closed, which occasioned great delay in production.

For the year 1919 the total production of oil in all Poland was slightly over 83,000 tanks of a capacity of 10,000 kg. each. These figures do not compare favorably with the total of 107,000 tanks produced in 1913 (the last pre-war year) and the 205,000 tanks produced in 1909.

The Panstwowe Urzad Naftowy (State Bureau of Oil Control) has had many labor, production, and price troubles. For instance, the coal supply of Upper Silesia, which is necessary to the full development of the Galician oil wells, is as yet not assured to Poland.

Relation of the Bureau of Mines to the Oil Shale Industry

Activities Should Be Devoted to Technologic Rather Than to Economic Factors—Problems Include Standardization of Testing Methods and Retorts as Well as the Securing of Much Fundamental Data

By J. O. Lewis
Chief Petroleum Technologist, U. S. Bureau of Mines
Written for the *Engineering and Mining Journal*

IN THE opinion of the United States Geological Survey, with which opinion the Bureau of Mines is in accord, the future petroleum needs of the United States cannot be supplied from domestic oil fields. Three alternatives are possible: Curtailing the consumption, going abroad for petroleum supplies, or developing other home resources for petroleum and its products.

The first choice is obviously not acceptable. The second is not the most desirable, in that the United States would no longer be self-sustaining, and might be forced to face unpleasant possibilities of foreign complications. Furthermore, there is no assurance of continued adequacy of such supplies. Although the country is now drawing upon importations, and must continue to depend upon that source of supply, it is highly desirable that the development of every possible domestic resource be promoted; and of the home resources, the oil shales constitute the most promising potential reserve of raw material from which petroleum products or substitutes can be derived. It seems inevitable that this latent resource must be drawn upon for at least a large part of the future needs of this country.

At present the oil-shale industry can be termed an "industry" by courtesy only. It is struggling to establish itself, but as yet is not on a demonstrated commercial basis. It is endeavoring to work out the technique of mining the shale, of recovering the oil, and of refining the products almost without precedent or example as a guide, for the Scotch shale industry can hardly be considered a satisfactory source of technical methods and practice, because of dissimilar conditions, particularly economic, and shale oil cannot be refined in precisely the same way as petroleum.

Promoters' Methods Hamper Development

The industry is faced with a host of problems, both technical and economic, which demand solution. Much of the money now being spent in endeavoring to prove the commercial feasibility of oil shale is being wasted because of the lack of fundamental data. The pioneers in the industry, upon whom falls the brunt of the struggle, are largely groping blindly, duplicating efforts or spending money in unproductive experiments. The larger and more conservative interests, although fully believing in the future of the oil-shale industry, are for the most part hanging back before risking their money, until the data necessary for the engineering appraisal and development of the industry become available. The industry, moreover, is beset with a plague of promoters who are mulcting the public and who threaten to discredit the future of the business by their extravagant claims or dishonest methods. Both the public and the legitimate interests should be protected by the Federal Government's making available reliable and impartial technical information from which correct opinions of the possibilities of the industry may be formed.

The Bureau of Mines has given much thought as to what part it should take in this development, and has sought the opinions and advice of most of the responsible engineers and men concerned. There are two broad phases, one the economic and the other the technologic. Under the economic may be grouped the cost factors, which include the cost of mining, of crushing, of extracting the oil from the shale, and of refining the oil products or recovering the byproducts. The other economic factors are the value of the products and byproducts and their present and future markets. Upon the favorable balance of cost against sales value of the products is dependent the profit, and this, of course, is the key to the situation, for the industry will attract capital only when it can be demonstrated that a reasonable probability exists that it can be put on a profitable basis. The margin between costs and values of products is the most important factor to be learned in the oil-shale industry.

Government Financing of Commercial Operations Not Recommended

The technologic factors include the richness and extent of shale deposits, methods of mining, methods of crushing, methods of extracting the oil to get the largest yield of the best quality oils at the least cost, how to refine the oil, and how to recover byproducts. Obviously, the economic and technologic factors are intimately associated, one controlling the other, but the main concern of the Bureau of Mines must be with the technologic rather than with the economic factors. This is particularly true of the strictly commercial aspects, for although estimates may be made of the various costs, and of the values of the products, only commercial operations will establish these factors definitely.

The Bureau of Mines holds that it must concern itself mostly with the technologic factors, and that the industry, through private enterprise, must answer the commercial questions. The Bureau therefore does not recommend that the Government finance commercial operations, because it believes private interests rather than the Government should make such a commercial test, but believes that investigations by the Bureau of Mines of the technologic factors will yield information of the utmost value to private enterprises in working out the economic factors.

What experimental and investigational work the Bureau undertakes must necessarily be controlled by the means at its disposal. At present its means are meager, and it has been unable to take up the many opportunities for service which await its attention. What it does in future is largely contingent upon the

appropriations it receives. The Bureau has plans prepared which are outlined in a general way in the paragraphs following. All of its plans are predicated upon the central idea that the chief asset and the greatest faculty for service of such a Federal agency as the Bureau of Mines is its disinterested position, which enables it to perform functions which no private concern, no matter how wealthy, can fulfill. It is in position to get information which a private concern would hold as a trade secret. Thus it can become a clearing house of information for the industry.

Much data of a fundamental nature should be supplied by the Bureau. This information will be necessary before the design and operation of retorting and refining plants can be undertaken intelligently. These fundamentals include such factors as the rate of heating of the oil shale, transmission of heat through oil shale, the effect of size of particles of shale, the effect of vacuum or reduced pressures, the effect of high pressures, the effect of steam atmospheres under various conditions of temperature, and the effect of atmospheres of other gases, such as carbon dioxide, carbon monoxide, hydrogen, and illuminating gas. Better ways even than retorting the oils from the shales may be found, such as the use of hot solvents.

Some of the Refining Problems to Be Solved

Investigations should also be conducted on the quality of products. An important problem is how to refine shale oils with the least loss and expense, for it is not generally appreciated that in the Scotch shale industry, which produces an oil superior to any so far examined from American shale retorts, there is a refining loss, including the coke, of 25 per cent. Unsaturated hydrocarbons, olefines and diolefines, are formed in retorting the shale, which are removed in ordinary refining processes. Investigation should be made as to how to minimize the formation of such undesirable compounds, or how best to treat them in refining.

Promotion literature emphasizes the large values in lubricants derived from shale oil. The information of the Bureau of Mines is to the effect that the lubricating values are likely to be very disappointing, as all lubricants examined so far indicate a quality of small value. It is possibly inherent in the breaking down of the organic materials in oil shale that only lubricants of low viscosity will be formed, and therefore they will be of small value, but the conditions under which these compounds are broken down will have an important influence on the final products, and a way to make good lubricants may possibly be discovered.

Testing Methods Should Be Standardized

The Bureau of Mines can serve a useful purpose by standardizing testing methods. Test methods which are reproducible, so that one can obtain comparable results, are always needed; otherwise there is no way of fitting together the odds and ends of information gained from all sources. These should go further than mere laboratory testing methods, and the Bureau of Mines contemplates the acquisition of a shale deposit of approximately average constitution, which will be used as a standard shale so that such shale can be sent to various plants to be tried out or to be tried out under various conditions, or to be used in research, that results, wherever obtained, will be comparable, inasmuch as all will be conducted on the same material. This will permit of a comparison of various methods, of differing conditions, and of many types of retorts; also it will provide a basis of comparison of different varieties of shale.

The standard shale should be supplemented by a standard retort which can be established at some convenient point by the Bureau of Mines. Such a standard retort should be a one-unit Scotch retort, not because the Scotch retort is believed necessarily to be the retort ultimately to be adopted by the American industry, but because it is one well understood, both as to design and operation, and in which reproducible results can be obtained. It is therefore the most suitable for establishing a present standard.

Byproduct problems are sure to be an important feature of investigation. One of the big questions today is whether to construct and operate the retorts to treat the maximum tonnage of shale, or to reduce the tonnage in order to recover ammonia. Prevalent opinion in the United States is that it will not be profitable to recover ammonia. The Bureau of Mines has seen no convincing facts supporting this contention, and it is one of the subjects which should be investigated.

Other byproducts have been mentioned. Not only should study be made of possible byproducts, but of prospective markets for them. Such markets may be already established, or they may be established by substituting oil-shale products for other materials.

Materials of construction should also be studied. For example, the capacity of the byproduct coke oven has been increased by two or three fold since its adoption in the United States, largely through the employment of silica brick, with a high rate of heat transmission, to replace the firebrick used in Europe, which has a much lower rate of heat transmission.

Although mining does not lend itself readily to investigations, the Bureau of Mines can be of great service on this subject also. The Bureau publications contain no data that can serve as a precedent for mining American oil shales, as shale is not entirely similar to any other material. In open works it is perhaps most similar to the handling of cement rock, limestones, and like substances. In drift mining it is more similar to mining coal, yet with certain differences. The Bureau investigations might well include the best kinds of powder to use, the best system of mining and breaking down the rock, safety devices, mine timbering, and all allied and complementary subjects.

Oil Shale in Esthonia

The use of oil shale in Esthonia is increasing rapidly, according to a bulletin of the Guaranty Trust Co. The Esthonian Ministry of Commerce sells several thousand poods every day, and receives about 500 orders of about 225 poods each. The small purchasers burn the shale in their dwellings, and several large factories also have adopted this fuel. Experiments in heating ships' boilers with oil shale are planned.

Oil Exploration in Ensenada, Mexico
