No. 1.

ADDRESS.

MATERIA MEDICA AND PHARMACY.

ADDRESS OF THE CHAIRMAN.

Read in the Section on Materia Medica and Pharmacy, at the Forty-fourth Annual Meeting of the American Medical Association.

BY FRANK WOODBURY, A.M., M.D.

PROFESSOR OF CLINICAL MEDICINE IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

The members of the Section on Materia Medica and Pharmacy are to be congratulated upon having with them to-day, as upon our two preceding annual meetings, delegates from the American Pharmaceutical Association, who at great personal inconvenience have come from widely different parts of the country, and who, by special invitation of the AMERICAN MEDICAL ASSOCIATION, are present in the double capacity of guests and active members of this Section. Upon many questions requiring technical knowledge and skill we shall hope to obtain their views, and may have reason to be grateful for the presence with us of those who can speak with the voice of acknowledged authority on all topics pertaining to their special department of medical science. If it should appear to some that on the present occasion we have unduly depended upon their valuable aid, it is hoped that they will construe it as a high mark of personal appreciation and as a compliment to their representative position in this special field of work. I think that I may just here be permitted to briefly refer to the many recent evidences of growth and development of pharmacy, and the wider diffusion of a professional spirit among pharmacists, especially in this country. A very appropriate illustration of the increased appreciation by the medical profession of the work of the pharmaceutical specialist, is furnished by the present existence of this Section of the AMERICAN MEDICAL ASSOCIATION.

Pharmacy apparently is now fully prepared to take its proper place as a specialty in medicine; it only remains for those who practice pharmacy to strive to govern their conduct upon professional lines, and for them to accept the regulations imposed upon all medical practitioners who wish to restrict their practice to recognized specialties. It would be well, in my opinion at least, if all pharmacists should aspire to be graduates in medicine as well as in pharmacy. Here it seems to me is the true solution of the twin problems, how to abolish counter-prescribing and to prevent the dispensing of their own drugs by physicians. Progress in the arts and sciences demands a division of labor, and specialism is the natural result; the important condition of further advancement is that each one shall loyally respect the chosen field of labor of the other, and faithfully adhere to his own. This, indeed, would be a consummation devoutly to be wished, and affords a practical solution of some existing difficulties, that are rather

encouraged by the current fiction that medicine and pharmacy are distinct professions, a fiction which stimulates a spirit of rivalry which is scarcely, if at all, appeased by prefixing the mollifying adjective of "sister" professions.

With circumstances as they are at present, it is to be expected that some friction would occasionally be experienced between physicians and pharmacists, each accusing the other of encroachment, rivalry and unfair competition. It seems as if many disputes and complaints might be obviated, even now, if physicians and pharmacists generally would become better acquainted with each other and endeavor to establish more friendly relations. In fact, I consider it a duty that every physician owes to his patient for him to assure himself of the qualifications of the pharmacist who is to dispense his prescriptions, and physicians should not hesitate to direct patients to pharmacists known to be competent. The greatest care in diagnosis and the highest therapeutic skill may come to naught, owing to carelessness or criminality of some unprincipled druggist—for I hold it to be a breach of trust amounting to crime, for a dispenser to use inferior drugs or to substitute cheap articles for better and more costly ones in filling a prescription. To the honor of American pharmacy, I would say here that substitution is rarely practiced, and as the rule to which there are only a few exceptions, pharmacists are faithful and conscientious in their work, and fully deserving of the confidence reposed in them by the medical profession and the general public.

This leads me to the thought which I wished especially to express in this brief address, the subject being "Scientifically Prepared Remedies Essential to Rational Therapeutics." The daily use of instruments of precision in clinical medicine, makes the demand an imperative one, at the present time, for the greatest attainable precision in our therapeutic methods. Hap-hazard prescribing and routine practice must yield before scientific pharmacy and rational therapeutics. These depend, however, not only upon accuracy of dosage of skilfully selected remedies, but also upon uniformity in composition and in physiologic action of such remedial agents; for it is impossible to prescribe intelligently unless active remedies shall in the same measured quantities, always produce proportionate results or, in other words, possess the power of causing equivalent physiologic effects. The standardization of pharmaceutical preparations, therefore, becomes as important to the practicing physician as is the reliability and uniformity in composition of his test solutions to the chemist.

In the choice and application of remedies, the modern physician is independent of the dictum of school or dogma. The ancient assumed laws of cure have been outgrown and rendered obsolete by modern methods of investigating the true nature of disease

and of tracing effects back to their natural causes. The microscope, the culture tube, and the chemic test, have in our day removed the old scholastic barriers, and they can never again be of sufficient importance to divide physicians into sects or schools of practice. It is true that names often survive the things and circumstances which called them into being, and among the laity there may still be found those who will ask the question: "To what school of practice do you belong?" It is possibly true that certain physicians may find it to their interest to foster such a belief; but it is well known that they use the same text-books and medical journals, and often resort to the same remedies as non-sectarian physicians, while their patients are led to believe that their methods are entirely and radically distinct from those of the "dominant school," which they lose no opportunity of denouncing. Theoretically, I have great respect for an honest sectarian physician; but must condemn him, nevertheless, for wilful ignorance; for honest sectarianism could scarcely survive the revelations of modern biology, which teaches that diseased processes are merely normal functions under abnormal conditions, which it is our task to remove. Such conditions are physical and natural and not spiritual or supernatural. "There is no sacred disease, and all diseases are equally sacred."

There can only be one best way of treating a patient suffering with a given disease, and it is the aim of scientific medicine to discover and to apply that method in the case, without reference to any hypothetical law of cure. Independence of the voice of authority other than that supported by clinical experience, and freedom to apply any discovered scientific fact to the alleviation of human suffering, are the boasts of modern medicine, and their consistent application in practice is the criterion of the truly scientific physician. Having asserted the right to the most perfect freedom in the selection of remedies in the light of modern science, we should next direct attention to the necessity of their having the quality of absolute genuineness. This requires uniformity both in chemical composition and in methods of preparation, so that the same dose under exactly similar conditions may be implicitly relied upon to produce precisely the same measure of effect. This is best illustrated in modern pharmacy by the hypodermic tablet. It has recently been successfully attempted to extend this principle to many of the commonly used remedies, by putting them up in tablet form, each tablet representing an average dose of the medicament. This is not identical with Dr. Burggrave's so-called "Dosimetric Method," which was principally based upon the use of alkaloids and other extremely toxic agents to be administered with metric dosage in the form of minute granules—but it may be regarded as an outgrowth of that method which never came into vogue probably because it appears to be restricted to the use of the products of a certain Parisian pharmacist, who prepared them "under the personal direction of Dr. Burggrave." While I acknowledge the pharmaceutical skill displayed in the manufacture of the modern compressed tablets, and their great convenience to the physician, especially when he is remote from any competent pharmacist, or on occasions of emergency, yet I must point out the dangers to both medicine and pharmacy from any attempt to the exclusive reliance upon

these tablets in practice. The very fact of uniformity of dosage is opposed to the highest skill in prescribing, and those who depend upon them will inevitably fall into routine practice and lose interest in therapeutics. There is danger that such a practitioner may follow the stereotyped formulæ until he loses his power of combining remedies *secundem artem*, so as to nicely suit the needs of the individual case. If it should also lead him to form the habit of administering powerful alkaloids, whose actions upon the human system are imperfectly comprehended, in place of the more simple and relatively harmless remedies of a former generation and of established value, I fear that such a change of practice would not be devoid of risk to the patient. The use of such remedies by the physician, brings up again the serious objection that in case of untoward result, where suit is threatened for malpractice, the physician is without any documentary evidences as to the character or identity of the remedies administered to the patient, such as he would have if the written prescription were preserved on the file of some neighboring pharmacist. Under such circumstances the original prescription would prove a safeguard which the persecuted physician would be glad to possess.

The mutual advantages accruing to physicians and pharmacists from the separation of pharmacy are so obvious that the arguments of Dr. George B. Wood in favor of pharmacy as a distinct vocation have never been refuted, and are even more valid to-day than when first uttered half a century and more ago. The physicians of this country, especially those practicing in our large cities, have for such a length of time accustomed themselves to rely upon the skilled assistance of the accomplished pharmacist, that they can hardly realize in their imagination, the methods of practice a century ago, when doctors spread their own plasters and made their own pills; or collected their simples in the fields and made their own tinctures and fluid extracts. I am sure that scientific medicine has been the gainer by the change, and that no one wishes to return to the good old times of medical practice. It remains for the practicing pharmacist to demonstrate by the reliability of his preparations and their scientific and esthetic qualities, that he is the loyal ally of the physician.

Our great manufacturing houses of established reputation have gained the confidence of the profession by the standard quality and pharmaceutical elegance of their preparations, so that it is necessary occasionally for the prescriber to specify certain manufacturers' products; and although it is acknowledged that this practice may be abused, yet it must be admitted to be within the right of the physician to require a particular brand of preparation, and this liberty of choice will be respected by all reputable pharmacists. On the other hand, no prescriber who values his reputation as a skilful therapist, will ever be guilty of ordering the use of proprietary articles of secret composition commonly known as "patent medicines;" and their use by the public should be discouraged on moral and scientific grounds, both by physician and pharmacist.

In connection with what has just been expressed, I think it well at this time to call the attention of both physicians and pharmacists throughout the country to the new revision of the "United States Pharmacopeia," which will soon be issued, and to urge them to at once employ it in prescribing and dispensing,

so as to avoid uncertainty and confusion both in clinical therapeutics and in current medical literature. To physicians who desire an extra pharmacopeia containing valuable formulæ not contained in the text, I would recommend the "Formulary" of the American Pharmaceutical Association; which contains efficient substitutes for many of the most prominent proprietary remedies, and thus offers a means of avoiding those of secret composition, the use of which the Code of Ethics condemns as unscientific and unworthy of educated physicians. It seems to me, if persistent effort were made by both physicians and pharmacists to instruct the community as to the dangers to the public health resulting from the constant use of patent medicines, that the business might be made less profitable than it now is, and the consumption of such articles very much curtailed.

In these brief introductory remarks, I have purposely refrained from discussing exhaustively any single topic, and have been content to indicate a few directions in which advancement may be made in the departments of medicine represented in this Section. Improvements might also be introduced in the work of this Section so as to make it more popular and attractive, and I believe that some recommendations will be made to this end at the present session, by the Business Committee.

FIBROID TUMORS OF THE UTERUS.

Address of the President, read before the Mississippi Valley Medical Society, Oct. 4-6, 1893.

BY R. STANSBURY SUTTON, M.D.

PITTSBURG, PA.

Definition.—The familiar terms, fibroid tumor, fibro-cystic tumor, and fibroid polypi of the uterus, every medical man recognizes as belonging to the same class of neoplasms. We all understand by the fibro-cystic tumor that a solid fibroid tumor has undergone a cystic degeneration. Notwithstanding our familiarity with these terms, they are objectionable, because they do not convey to the mind a comprehensive idea of the pathology of the neoplastic growths to which they are applied. The term fibroid (fibrosus and eidos), and the term fibrous mean fiber-like, and are only applicable to a tumor composed entirely of fibrous tissue.

The fibrous or fibroid tumor found in various localities is always situated in connective tissue; it contains only occasionally a few yellow elastic fibers, is often quite vascular, and must be dissected out.

But the so-called uterine fibroid contains a variable quantity of muscular tissue as well as of fibrous tissue, both of which are derived from the parenchyma of the uterus in which the tumor grows. By reason of the presence of muscular tissue, Virchow proposed that these tumors be called myomata. This term designates only their muscular element, and is as objectionable as the term, fibroid. The term, myofibromata or fibro-myomata, fully designates the solid tumor, and the prefix cystic, that variety in which cystic degeneration has occurred.

Etiology.—The etiology of these tumors is still a mystery. They are more frequent in the black than in the white race. In both races they are more frequent in the body than in the neck of the uterus, and more frequently situated in the posterior than in the anterior wall. Prior to puberty they present no positive symptoms of their existence.

From a careful analysis of cases under my care, I suspect the neoplasm does sometimes exist prior to puberty. After the menopause is established these tumors occasionally disappear, unless they have undergone cystic degeneration.

If, prior to the establishment of the menopause, the fibro-myomata has undergone cystic degeneration, it will continue to grow. The removal of the ovaries and Fallopian tubes in such cases has proved insufficient to stop the growth of the cystic or very soft fibro-myoma. Months after removal of both ovaries and tubes I have seen it necessary to make a supra-vaginal hysterectomy. Concerning the causes which produce these tumors nothing is known. By reason of their existence a woman may be sterile, but it is not yet proved that sterility favors their origin or growth.

Pathology.—The tumor always has its origin in the substance of the uterine wall or subperitoneal connective tissue. It begins as a hard nodule, involving in its further development both the muscular and fibrous tissues. Later it becomes invested with a thick layer of fibrous tissue, which, with the superimposed uterine tissue, constitutes its envelope or capsule. Within this capsule the blood vessels ramify and form a network, sending prolongations to feed the inclosed growth, which now lies like a foreign body in or attached to the wall of the uterus. Rarely, large blood vessels penetrate the substance of the tumor. Such tumors have, however, been observed by Virchow, Leopold and Schröder, in which large blood-sinuses existed, the walls of the sinuses being composed of the muscular fiber of the uterus involved in the growth of the tumor.

Klebs has proved the existence of lymphatics, and Lorey of nerves in this class of growths. The presence of lymphatics often determines the variety of future cystic degeneration. As the tumor enlarges it separates the tissues composing the uterine wall, or compresses it as it pushes the peritoneum outward. The consequent irritation invites a greater blood supply, and hyperplasia of the walls begins. As the tumor excites more and more irritation, and the muscular tissues of the uterus grow stronger, the neoplasm, if developing within the walls, may begin to migrate either toward the peritoneal covering of the uterus or toward the endometrium. Should, however, its location favor, it may separate wider and wider the uterine tissues, keeping its relative position from either surface. Thus the tumor is finally fixed in the uterine walls, and is designated as interstitial or intramural; or if it is developed or forced toward the peritoneum, carrying the latter with it as an investment, it is then designated as submucous. The tumor may consist of a single nodule or center of formation, or it may consist of a number of nodules or centers of formation interlaced closely and invested by a common capsule. This fact suggested to Mr. Lawson Tait a new nomenclature for these growths—namely, uninodular and multinodular fibro-myomata. As the tumor grows, either the fibrous tissue or the muscular tissue will preponderate.

When the fibrous tissue is bountiful, the tumor will be hard, even as hard as cartilage; when the muscular tissue is most bountiful the tumor will be softer, even sufficiently so as to merit the name, fleshy tumor or myoma. A tumor largely composed of fibrous tissue will usually be of moderate size and of

very slow growth, but the reverse is apt to occur in those tumors in which the muscular tissue preponderates; and these tumors are especially liable to cystic degeneration. On the other hand, the latter class, if cystic degeneration does not occur, are liable to rapid disappearance after the establishment of the menopause. Not infrequently several separate and distinct fibro-myomata are found in the same uterus. Dr. Thomas exhibited to the New York Pathological Society a uterus containing thirty-five tumors of various sizes, and Schröder of Berlin, cites a case by Schultz, in which at least fifty tumors existed in the uterus. A remarkable feature of Schultz's case was that the woman was 83 years of age. The uterus was obtained postmortem. In cases of multiple myomata, the growths may be so distributed in the uterus as to present the subperitoneal, the intramural, submucous, and polypoid varieties.

The changes occurring in the uterus itself are not constant. The muscular tissues hypertrophy to a greater or less extent in all cases, and while hypertrophy is going on in one direction, atrophy of the muscular tissue on the side toward which the tumor is advancing may be in progress. After the tumor has become subperitoneal, the uterus may atrophy to a very marked degree—a condition not infrequent in old subjects.

The cavity of the uterus is usually increased in depth, while in the submucous and intramural variety it may also be obstructed. The lining membrane of the uterus, by reason of the constant hyperemia, is more vascular, bleeds more readily upon the introduction of the sound, than in cases of normal condition, while in cases of submucous fibro-myomata or polypoid fibro-myomata, menstruation is almost always profuse, and between the regular periods blood is frequently lost or even constantly. In addition to this, a serous discharge, intermingled with the vaginal and uterine secretion and having an unpleasant odor, is not always wanting. The uterus in no instance occupies its normal position, but is either pulled or pushed into an abnormal one, dependent on the size and position of the tumor. The cut section of fibro-myoma will vary in appearance according to the preponderance of its constituents. If the fibrous tissue be very abundant, the section will cut like cartilage, and have a gray color and satin-like glossy appearance. If the muscular tissue exists to a marked degree, the consistency of the section will be softer and the color will vary from pink to red.

The lymphatic spaces of Klebs are sometimes seen between the bundles of muscular tissue. When but little muscular tissue is present the section will be smooth, but if the reverse is the case the surface is uneven as the contracting fibrous bands force the softer muscular tissue above the surface. At the margin of the section and surrounding it is found a layer of condensed, fibrous, muscular tissue forming the capsule. This is sometimes closely, at other times loosely, attached to the tumor. Frequently it is easy with the thumbnail to detach it entirely, a process we shall yet learn to be that of enucleation. On microscopic examination of the harder variety are seen wavy bundles of fibrous tissue with a small amount of unstriped muscular tissue. The softer variety presents, in addition to the fibrous tissue, a greater amount of unstriped muscular fibers in twisted bundles, the muscular fiber being identical

with the muscular fiber of the uterus. If the specimen be stained in carmine solution and washed in a solution of acetic acid, the rod-shaped nuclei of the spindle-shaped cells will be brought into view.

The important practical point in this is to establish a positive differential diagnosis between the fibro-myoma and sarcoma. The latter, when removed from the uterus, as elsewhere, is almost sure to return, and constitutes what has been erroneously called the recurrent fibroid tumor.

The nuclei of the spindle-shaped sarcoma cells are round or oval; of the fibro-myomata, they are rod-shaped. The limit of growth for the myomata is difficult to determine. They have, after removal, been found to weigh fifty or sixty pounds. Until expelled from the walls of the uterus they maintain a globular form. After extrusion into the cavity of the peritoneum they are free from the pressure of the uterine muscular tissue, and generally lose the globular form. After extrusion into the cavity of the uterus they usually become pear-shaped—a fact probably due to the lateral pressure exerted upon them in the expulsive efforts of the uterus. Their density varies with the amount of fibrous tissue in their composition, and is a determining element in the shape of their future growth, when they become subperitoneal. The globular form is not, however, infrequently retained in very solid tumors after they have become polypoid tumors, either upon the exterior or interior surface of the uterine walls. The irregularity of surface occasionally seen is due often to the multinodular composition of the neoplasm, some nodules growing faster than others by reason of obtaining a better blood supply. Another element in determining the shape of the subperitoneal tumor is the pressure against the walls of the pelvis; regularity of contour is more apt to exist when the tumor has become too large to enter the small pelvis. Occasionally, in addition to the mass in the pelvis, a prolongation of the tumor upward, cone-like, is felt through the abdominal wall. I have seen the tumor pear-shaped, the big end up, and the other end filling the pelvis completely.

Frequently the tumor, when subperitoneal, may be felt extending above Poupart's ligament, dragging the uterus with it, side by side, it being difficult or even impossible to decide, when the os is almost or entirely out of reach, which is tumor and which is uterus. The sound may determine. If the cervix can be seized with a volsellum forceps and the uterus be thus moved, while the free hand over the abdomen takes cognizance of the movements, it may also be determined.

The changes which occur in the fibro-myomata are as follows—varieties of softening:

Edema.—At the time of the menstrual period, they occasionally become swollen or edematous, this condition disappearing again a few days later. But this condition may continue to such a degree that a spurious fluctuation may exist. Such tumors have been tapped for ovarian cysts, and a few drops of yellow, slimy mucus escaping told of the error of diagnosis, or the tapping has been dry. Such tumors may give apparently real and distinct fluctuation after being extirpated and laid on the table. The tumors when cut through may be completely infiltrated; in the meshes of fibrous tissue hundreds of very small cysts exist, and the muscular tissues of the growth may have wellnigh disappeared. Such

tumors have been found by many operators. The edema is sometimes intermittent, returning after entire subsidence.

Fatty Degeneration.—After the menopause, and occasionally after pregnancy, complicated with intramural fibro-myoma, fatty degeneration occurs in the muscular element of the growth; this is absorbed and the fibrous tissue alone left. In very old subjects the remains of prior fibro-myomata are simply nodules of the concentrated fibrous tissue.

Myxomatous Degeneration.—Occasionally, in the tissues comprising the growth, there exists mucoid tissue which secretes mucus, and forms often cavities of considerable size; this condition of the tumor is known as myxomatous degeneration. (Virchow.)

Suppuration.—Should the blood supply be entirely cut off from the growth, as in twisting of the pedicle in the subperitoneal variety or of the polypoid submucous variety, or if the capsule be widely detached in an effort at enucleation per vaginam, the tumor may die and soften. This change has been designated erroneously as suppuration. True inflammatory softening and suppuration of a fibro-myoma is rarely seen.

Gangrene.—The submucous variety is especially liable to necrosis and spontaneous expulsion. An inflammation of the capsule resulting in interference with the nutrition of the growth, or inducing an ulceration on the surface of the capsule, is the usual cause. The resistance of the capsule being impaired by the opening, the tumor is expelled by uterine contractions entire or piecemeal. This fact led to the treatment of this variety by means intended to open the capsule through the cavity of the uterus. Atlee and Brown gouged holes in the capsule or divided it with the knife. Greenhalgh attacked the capsule with the cautery-iron. Byford induced rupture of the capsule with ergot. Cures have been obtained by all of these methods, none of which were free from danger.

Cases of inflammation of the capsule, adhesion to and perforation of the abdominal wall, followed by the escape of the gangrenous neoplasm, have been reported by Soir, Dumesnil, Gutierrez, Hofmohl and Schmidt.

Varieties of Induration.—After fatty degeneration of the muscular elements, their absorption follows, but the fibrous tissue is left behind and contracts to form a very hard but small tumor. When the tumor contains very little muscular tissue it is nearly as hard as cartilage.

Calcification.—Chalky or phosphatic degeneration of these tumors has long been known. Hippocrates relates such a case, a Thessalian woman aged 60 years; and Salins the case of a nun who had such a tumor. Schröder refers to such cases by Louis, Velpeau, Jaffe and Saxinger.

Years ago I removed a calcified subperitoneal fibro-myoma, which was larger than a goose egg and as hard as a stone. It was reached through the posterior vaginal wall. The cretaceous matter appears first, says Schröder, in streaks through the interior of the tumor. It may finally become so dense as to produce a stone of sufficient solidity to require to be cut through with a saw. The small tumors, especially the subperitoneal and intramural, are most liable to this change. When the blood vessels are cut off, the nutrition ceases. The tumor is now a foreign body, and is apt to act as such. It

may cause an inflammation of the adjoining tissues, and when these are softened it may escape into the peritoneal cavity, causing fatal peritonitis, or, escaping into the uterine cavity, be expelled, leaving the patient to recover. True suppuration of a fibro-myoma must be rare, yet authors authenticate it after traumatic injury to the growths, and also in association with cretaceous degeneration beyond the changes referred to; these tumors, by various processes of degeneration, become cystic, and occasionally are apparently attacked with that most malignant of diseases, sarcoma.

Cystic Degeneration.—A solid fibro-myoma may become cystic through fatty degeneration, mucous degeneration, suppuration, serous infiltration, the formation of lymph-cavities filling with a clear fluid coagulating on exposure to the air, or from breaking down of clots in large blood cavities already existing in the tumor. In the multinodular tumors one or more of the nodules may break down, while others maintain their original solid condition, and a mixed tumor results. As already observed, these growths take largely to themselves the connective fibrous tissue of the uterus. Connective tissue is that in which alone we find sarcoma developing in the body. The fibro-myoma and sarcoma are first cousins as to origin, and when the sarcoma begins, with its spindle cell and oval or round nucleus, to invade the myoma, it finds the natural tissue of its selection to work upon. Myomata thus invaded grow softer, and may even undergo cystic degeneration, and give rise to a tumor properly designated sarcomatous cystic fibro-myoma.

The termination of the cystic fibro-myoma is widely different from that of the simple fibro-myoma; while the latter occasionally destroys the woman, the former always tends to terminate fatally. Fibro-cystic tumors grow more slowly than ovarian cystomata, but by mechanical interference with respiration, circulation and nutrition, and by producing nervous exhaustion and organic diseases of the heart, and also occasionally by causing a great loss of blood from the uterus, they tend with equal certainty to the destruction, sooner or later, of the life of the patient. The location of simple fibro-myomata has everything to do with their importance; it is therefore excusable to make the arbitrary division of subperitoneal, interstitial, or intramural, and submucous; also to consider each variety separately.

Description. Subperitoneal Fibro-myomata.—Virchow termed this variety the peritoneal polyp, and there is no difference of structure between it and the fibro-myomatous polyp found in the uterine cavity. When the tumor is forced out of the uterine wall into the cavity of the peritoneum, it carries with it the peritoneum investing the uterus, except in those cases where it projects from the side of the uterus and is pressed out between the layers of the broad ligament, which subsequently forms a serous covering for it. The tumor may remain closely adherent to the wall of the uterus, or gradually leaving it, develop a pedicle which may, after a time, remain thick or become so attenuated as to consist of nothing but two layers of peritoneum, the intervening cellular tissue and blood vessels, some lymphatics, and nerves. The tumor continues to grow in the cavity of the pelvis, toward which it gravitates, retroverting the uterus early if attached to the pos-

terior wall, until finally it reaches such a size that it can not enter the superior strait of the pelvis. When the tumor projects from the top or anterior wall of the uterus, the latter is retroverted as soon as the growth has attained any considerable size. The growing of these tumors thus in the pelvis gives rise to distressing vesical and rectal irritation, and often to retention of urine, to the narrowing of the caliber of the rectum, to constipation, and to hemorrhoids. Besides this, there is often pain in the course of the sciatic or crural nerves of either side. The irritation and obstruction to the circulation, both from the mechanical presence of the growth and the malposition of the uterus, produces profuse bleeding at and between the menstrual epochs. That such is the pathology is proved by putting the patient in the knee-chest position, pushing the incarcerated tumor and uterus up, and draining the vaginal tissues with pledgets of cotton saturated with glycerid and by the free use of large quantities of hot water thrown against the vault of the vagina after the replacement is effected. Thus long-continued hemorrhages are abated.

Once the tumor has become subperitoneal it may contract adhesions to the viscera against which it rests, and thus it often happens in abdominal section that we find these tumors nourished by large blood vessels entering them through adhesions which, when the tumor is large and projecting into the cavity of the abdomen, frequently contain veins of enormous size. Twisting of the pedicle, when long, in these tumors may occur as in the ovarian tumor. If a new blood supply has been established, the tumor will not die, even though it may be eventually separated entirely from the uterus. When this variety of tumor drags the uterus upward, or when the base of the pedicle is broad and the tumor falls backward, bending the uterus, the cavity is increased in depth; as the pedicle becomes elongated the uterine cavity shortens whether the tumor decreases in size or not. The uterus may be flattened out completely and adherent to the side of the tumor. After it has contracted adhesions to the intestine, any rotary motion of the tumor is liable to produce intestinal obstruction and to demand immediate operative interference to save the life of the patient. Frequently I have removed fibroid tumors from which it was necessary to detach several loops of the small intestine. This variety of tumor is frequently accompanied by others of the same variety, either also expelled from, or still existing in the walls of the uterus. The greatest limit of growth as a rule for this variety is the size of an adult head, but they have been met with having a weight of fifty to sixty pounds.

Submucous Fibro-myomata.—As already stated, at least two varieties originate in the walls of the uterus as round tumors; when forced toward the lining membrane of the uterus they become submucous. As they project into the uterine cavity they carry the lining membrane before them. The pedicle of this, the polypoid variety of the tumor, may be thick, containing muscular tissue, the lining membrane of the uterus, and very small blood vessels. As long as the tumor lies beneath the unupheaved uterine lining it is round, but after it enters the cavity of the uterus and is macerated in constant discharge, and pressed upon by the contracting uterine walls, it becomes pear shaped, or if nipped near the center by the

fiber of Bandle's ring it may resemble a dumb-bell or hour-glass. This variety of myomata does not undergo cretaceous degeneration and is usually expelled too soon to undergo cystic degeneration, which occurs rarely in this variety. Nevertheless, it is probable that lives are as often lost from hemorrhages occasioned by this variety as by either of the other varieties of the myomata. This variety drags down the uterus when of moderate size, and after expulsion from the uterus, may by its weight as it descends drag the fundus uteri down and invert the uterus. Women often hide these growths, even after they appear at the vulva.

The size of the growth is determined mainly by the length of time it remains in the uterus or vagina. When in the vagina the tumor may be mistaken for an inverted uterus.

The Intramural or Interstitial Fibro-myoma.—This variety simply remains and grows within the uterine walls. Surrounded on all sides by uterine tissue, it receives a greater blood supply than either of the other varieties. It consequently grows with greater rapidity, and often to an enormous size, enlarging a patient like a full term pregnancy, and weighing ten pounds and upward. The great weight stretches the anterior wall of the belly, and the tumor overhangs, while it rests upon the pelvic brim. The abdominal walls grow very thin from pressure, the recti muscles atrophy and separate, and the tumor lies immediately under the superficial tissues of the belly wall. These tumors, bulging out the uterus laterally, spread apart the layers of the broad ligament, and the hypertrophied tubes are spread out high up on the tumor; the uterus and the tumor develop in such a way as to entirely alter the relative position of the uterine appendages. In these cases the cavity of the uterus is deepened or shortened and often rendered crooked, while at the same time it is very difficult to find the os uteri in the vagina. These externally large tumors are usually single, and the walls of the uterus may be found either greatly hypertrophied, or much atrophied. These tumors occasionally undergo cystic degeneration, and grow to an enormous size.

Fibro-myoma of the Cervix Uteri.—These tumors follow the same law as to location and development that they do in the body of the uterus. They may be subperitoneal when developed in the supra-vaginal portion; when developed too low down, they very rarely appear upon the outer surface of the cervix, namely, the outer surface of the vaginal portion. The growth is much more rare in the cervix than in the body. In the twenty-eight years I have been in practice I have met with but five or six cases where the growth was in the cervix. In one the growth was submucous, and in another, interstitial and as large as a lemon; in another, the tumor was as large as a fetal head. Where they become submucous, they are gradually forced into the vagina, retaining their uterine connection through a pedicle of varying density. When interstitial and large they pack the pelvis to a great extent. The lip of the cervix invaded is spread out over the growth, while the opposite lip is thinned and stretched as a band along the circumference of its enlarged neighbor. The uterus is dragged down until the growth has become large, when its fundus is deviated, at first in a direction corresponding to the lip of the cervix invaded. When the tumor is expelled from the cervix it will be oval

or round-ended, and when pouting between the labia may readily be mistaken for the fundus of the inverted uterus. On the other hand, the uterus has been mistaken for this variety of fibro-myoma, and been cut off with the ecraseur. Large growths in the cervix are more liable to produce vesical and rectal symptoms than those growing either from the posterior wall or fundus of the uterus.

Symptoms.—The symptoms which accompany the presence of these tumors in their various localities and stages of growth are widely different, as we shall learn in considering the diagnosis. However, a class of indications are patent as found in a vast majority of the cases, and may be tabulated as follows:

- A. Vague pain in the pelvic region;
- B. Pain referred to the front or back of the leg;
- C. Irritability of the bladder or rectum;
- D. Uterine tenesmus;
- E. Menorrhagia or metorrhagia;
- F. Dysmenorrhœa;
- G. Profuse leucorrhœa;
- H. Serous discharge from the uterus;

The disorders of menstruation, the tenesmus, the leucorrhœa and the serous discharge are typical, within the menstruating age, of the existence of the submucous fibro-myoma, and in a less marked degree in the interstitial variety. They may be entirely absent in the subperitoneal variety. It may be inferred as a rule in diagnosis that tumors producing these symptoms to a marked degree are situated immediately beneath or close to the lining membrane of the uterus. Exceptions to the rule do occur, and hemorrhages may accompany the existence of a subperitoneal fibro-myoma incarcerated in the pelvis. Progressive anemia from loss of blood, feeling of weight, depression of spirits, the development of unusual nervous conditions, irritability, loss of cheerfulness and gloomy apprehensions are frequent. When the tumor rises out of the pelvis it may be easily felt through the abdominal wall. If cystic degeneration has occurred, spurious or true fluctuation may be present; but absence of the symptoms will not be proof that cystic degeneration has not occurred,

Diagnosis.—Scarcely is it possible to name anything more difficult than the diagnosis of the very small fibro-myomata, when many of the leading symptoms are absent. This is sure to be the case with subperitoneal growths, and the surgeon is left entirely to exploratory skill. If the tumor has retroverted or anteverted the uterus, and become at all prominent upon either surface, bimanual palpation with a finger in the vagina or rectum will usually determine its existence. If the patient be fat, it will be necessary with the volsellum forceps to pull down the uterus, so that the finger in the rectum may be swept over the posterior surface of the uterus, or the sound may be well curved and made to drag the uterus well forward against the finger in the vagina. The tumor, if at all defined, will present an outline within which the tissue is harder than that of the normal uterus; if well defined, it will be easily recognized. Even at so early a date the uterine cavity is often found deeper than normal, and the uterus congested and abnormally heavy. When the tumor springs from the supra-vaginal portion of the cervix, it is readily felt through the vagina. But if it be from the posterior wall of the fundus, and of considerable size and firmly adherent in the cul-de-sac, a sound in the uterus may or may not enable the

examiner to determine that the growth is or is not attached to the uterus, or, if it is so attached, that it is a myoma. The direction taken by the sound and the consistency of the growth are the questions to be considered. The round form and solid feel of the myoma will aid in differentiating it from a hœmatocele or ovarian cyst, but it is not possible to differentiate it from a solid tumor of the ovary which is adherent to the uterus. Twice I have seen the abdomen opened, once by Billroth and once by Mr. Lawson Tait, for supposed myoma of the uterus, to find the tumor a solid one of the ovary. The differentiation from a cyst is less difficult; its elasticity, its rare close connection with the uterus, and its softer feel, are suggestive points. But if doubt exist, the aspirator-needle may be used.

When the tumor is interstitial and very small it will be very difficult, if not impossible, to determine its presence. The existence of some of the symptoms, alphabetically tabulated, may give good presumptive evidence; in addition, the uterus may be deeper than normal, or it may be possible for one of unusual skill to determine, by the aid of the sound, that one wall of the uterus is thicker than the opposite wall; or that a portion of the wall is more solid or thicker. If the tumor is small and in the anterior wall of the uterus, the canal will be so displaced backward that the direction taken by the sound will suggest that the body felt forward is not alone the fundus of the anteflexed uterus.

When the tumor has attained a considerable size and other symptoms are present, and the possibility of enlargement from pregnancy, chronic metritis and subinvolution are differentiated, the case is not so difficult to determine. But given a small interstitial fibro-myoma associated with chronic metritis or pregnancy, and the diagnosis may be impossible. Time alone will solve it. Should, however, in early pregnancy the fetus be dead and the woman present an enlarged uterus, with irregular periods of bleeding, a constant leucorrhœa, or flow of disagreeable odor, the case may be mistaken for a fibro-myoma, interstitial or submucous, and nothing except dilatation of the cervix and exploration with the finger will make a diagnosis possible. In chronic metritis the uterus is more or less tender; its walls are flat and soft, the os open, and frequently nausea exists. In cases of fibro-myoma, the uterus is rarely sensitive, and especially when the growth is interstitial or subperitoneal, the body as well as the cervix is hard, and the os normal. If chronic cellulitis with extensive deposits be encountered, the uterus is fixed, while the reverse is usually the fact when the symptoms depend on a neoplasm.

In early pregnancy the cervix and lower segment of the uterus are softer and the os occasionally more patent than normal; while in cases of fibro-myoma the cervix and os usually remain unchanged and the tumor is hard. In pregnancy the color of the vagina is bluish. Further, in bimanual palpation the pregnant uterus will be found soft or elastic, symmetrical, rhythmical, and nearly in the central line; in cases of even small fibro-myoma it will be hard, inelastic and usually misplaced. In small submucous neoplasms the bleeding is usually so prominent a symptom that the introduction of a sound or dilatation of the cervix and introduction of a finger will suggest themselves as the speediest way to decide the diagnosis. In a submucous growth, with the cervix

dilated sufficiently to admit the finger, the diagnosis is not difficult. When the tumor grows from the intravaginal portion of the cervix, if interstitial its early symptom is simply an enlarged lip; but later its solidity, freedom from tenderness, its circumscribed hardness, and the absence of the evidence of malignant disease will warrant an incision into the lip and an enucleation of the growth at the same time that the diagnosis is made. When the small interstitial fibroid is low down, its development toward the os externum enlarges the lip beneath it and protrudes it forward into the vagina. The opposite lip is spread out and the os loses its form, becomes a slit, and may be very difficult to find. When the neoplasm is entirely in the cervix the same difficulty will occur. The liability of mistaking such cases for inversion of the uterus is to be guarded against. A retroflexed or anteflexed uterus has frequently been taken for a fibro-myoma. The groove presenting to the examining finger between the neck and the fundus misleads; but the sound and bimanual examination will determine whether the round body felt is the fundus or a fibro-myoma. If the neoplasm arise from the posterior wall the uterus is retroverted, and the bimanual method of examination will enable us to trace its close connection with the uterus unless the pedicle be unusually long. If, however, the uterus and tumor fill the pelvis, the patient should be placed in the knee-chest position, or, better, in Sims' position, with the side of the table elevated. The uterus and tumor may now be pushed upward and forward out of the pelvis. A sound may then be introduced into the uterus and held with the thumb and forefinger of the right hand; the left hand passing over the patient's hip can grasp both uterus and tumor, and their connection may be determined by the movements of the sound. If the tumor can be grasped separately and moved without affecting the position of the uterus, it can not be uterine; but if its movements, as determined by the sound, do affect the position of the uterus, it is attached to the uterus and probably of uterine origin.

In thin subjects, especially, the sound may not be required; but bimanual examination with one or two fingers behind the cervix will enable the examiner to determine a close connection between the tumor and the uterus, or decide whether or not the tumor and uterus move together. But as it is the early development of fibro-myomata that will always give the case most difficult of diagnosis, a more lengthy examination of this subject will be required. A case or cases presenting, in which no change in the os or cervix has occurred, with no displacement, either retro- or anteversion or prolapsus, with or without much increase of the depth of the uterine cavity, with no marked elevation of either uterine wall to be felt bimanually, but with disordered and painful menstruation, or irregular discharges of mucus or blood, or the watery discharge of serum, will try the skill of the best diagnostician, and frequently compel him to summon time to his assistance. These symptoms, however, should always put us on the alert.

All growths of this nature are at first supposed to be interstitial, but if they are not, or become submucous, the leading clinical features of the case will be disordered menstruation, bloody discharges at irregular periods, and the presence of leucorrhœa consisting of mucus more or less watery. If, however, the tumor be developing toward the peritoneal coat of the

uterus, these symptoms may be entirely wanting, and pain usually present between the periods, and especially severe at the periods, may be the only symptom present. Meadows has observed that the location of the pain is much determined by the location of the growth: "If the pain is felt in the lower dorsal or upper lumbar region, then it is probable that the tumor is growing on the fundus uteri. If, on the other hand, the tumor is more confined to the body of the uterus, then the pain will be felt in the lumbar region above; and lastly, if the cervix be the seat of the disease, the pain will be felt mostly over the sacral region."

Pain due to ovarian disease, like the neoplasm of the ovary, is to one or the other side of the central line; due to uterine neoplasm, it is usually in the central line. Small ovarian neoplasms are not always accompanied by menstrual disorders and irregular discharges. Where the little tumor is subperitoneal, and pain and displacement alone point out a suspicion of its presence, we must wait until further development occurs. Later, the tumor may be made out, and the differential diagnosis from chronic metritis and pelvic cellulitis may be at once determined by the absence of sensitiveness to the touch of the finger; hœmatocele may be ruled out by the absence from the history of its sudden invasion with symptoms of shock. The slow growth of the tumor, its irregularity and solidity, are characteristic of fibro-myomata. Should, however, amenorrhœa be present, the density of the growing tumor, and possibly its irregularity, the asymmetrical condition of the tumor and the uterus together, the deviation of the uterus from the central line, the absence of changes in the mammary glands or vaginal mucous coat, the presence of a serous leucorrhœa of a peculiar odor, will usually lead to a correct diagnosis. Supposing the tumor and the uterus to be still in the pelvis, the uterus may be crowded to one side; or, if pulled down by the descending tumor, it will be retroverted, while the cervix is crowded forward; or, if the tumor proceed from the anterior wall, the uterus will lie retroverted beneath or to one side of the tumor. If the tumor has become so large as to lie above the pelvis in the cavity of the abdomen, the uterus will be dragged up and its cavity lengthened. While the tumor occupies the pelvis the pressure is extended to the bladder and rectum, and both retention of urine and difficult defecation are frequent. The ureters may also be so interfered with by the pressure of the tumor and uterus as to convey a diminished amount of urine to the bladder: with this condition almost complete suppression of urine may occur, but after the tumor is lifted out of the pelvis the flow of urine becomes greater than normal for a day or two. The presence of free fluid in the cavity of the abdomen is not very frequent, but when it does occur by reason of the presence of the tumor, it may come from irritation of the peritoneum, but usually from the covering of the tumor itself, the soft or edematous variety. Adhesions are the result of patchy or general peritonitis, usually the former.

The mechanical irritation of the tumor produces peritonitis, which may involve that portion of peritoneum covering the tubes, and the adhesions which follow may shut off the canal of the tube; or the pressure of the tumor may shut off the uterine canal and sterility result; or the irritation of the tumor may produce so much congestion of the uterus as to

set up the condition known as chronic metritis, viz.: congestion with hyperplasia. When this is the case the symptom of pain is much increased, and bleeding will occur.

It is not uncommon at the menstrual period to find the tumors and uterus more enlarged than ordinarily, and in some cases at these times there is frequently retention of urine requiring the use of the catheter. We may recapitulate the symptoms of the solid, subserous fibro-myomata thus:

- A. Uterine displacement;
- B. Pressure upon or irritability of the bladder and rectum;
- C. Bearing-down pain and backache;
- D. Uterine tenesmus at the menstrual period;
- E. Serous leucorrhœa with or without peculiar odor;
- F. Pressure on the nerves and blood vessels;
- G. Increased depth of the uterine canal;
- H. Occasional retention of urine;
- I. Sterility;
- J. A solid, non-sensitive tumor,
- K. Mobility of the tumor and uterus together;
- L. Ascitic fluid in the abdominal cavity.

Of these symptoms, nearly all will be found in those cases where the growth nearly fills the pelvis, and nearly all of them will be wanting if the growth is too large to enter the pelvis, and therefore lies above it. In one case the patient may be suffering from nervous irritability and a disorder of all her functions to a considerable extent; she may be confined to her room, locomotion being painful. In another case, the pelvis being but little encroached upon or entirely empty, the patient may have no symptom of suffering, and may enjoy good health.

When the tumor and uterus are above the true pelvis in the cavity of the abdomen, their connection is usually determined by bimanual examination without the aid of the sound. If cystic degeneration has occurred, palpation may detect it, and aspiration will produce a fluid having in it the fiber-cell or a fluid coagulating on exposure to the air, or blood alone may be drawn. The cavity of the uterus will likely be found lengthened, and the connection between the tumor and the uterus may be determined by seizing the latter with a volsellum forceps, while an assistant seizes the tumor; alternate pulls by each other will determine a connection with the uterus, but it will not determine positively that the tumor has not had another origin and formed a uterine attachment. In such cases the proper method of diagnosis is by an exploratory incision, the operation for removal of the growth following immediately.

Interstitial Fibro-Myoma, Solid Variety.—As in the case of the subserous variety, the earliest symptoms will be uterine displacement with vague symptoms of but little certainty. As the tumor increases, first in the anterior wall, anteflexion at first, and later retroflexion, will occur. If in the posterior wall or at the fundus, retroversion will soon follow. The uterus in all varieties, by increased weight, partly due to the growth and partly to increased blood supply, will descend to some extent. As the tumor grows, dysmenorrhœa, menorrhagia and leucorrhœa develop. The irritation of the growth hastens uterine tenesmus, and that organ, becoming congested and heavy, sags down in the pelvis. As the tumor is increased the uterine canal is pressed upon; the symptoms of pelvic engorgement spoken of in the

last section occur, and continue until the tumor and uterus, by reason of their size, are lifted up out of the pelvis. The introduction of a sound, or, better, bimanual examination, proves the growth to be the uterus enlarged by the tumor. Disordered blood flows from the uterus and leucorrhœa more or less serous are the other symptoms most generally encountered.

Fibro-Myoma of the Cervix.—Here the symptoms differ from the others in this, that menorrhagia is not so frequent, endocervicitis is more common, and the enlarging lip of the uterus is in sight if a speculum be used, and within easy reach of the finger. The differential diagnosis involves the malignant growths of the cervix, hyperplasia of the cervix following laceration, and inversion of the uterus. The tumor, if pedunculated, may be traced to its connection with the uterus. The consistency of the growth, its want of sensibility, the inability to separate it from the uterus by bimanual examination, the inability or difficulty of finding the os, the fact that it has lost its normal or usual contour, the slow growth of the tumor, the presence of the uterine fundus beyond, the absence of all cachexia, the fact that the growth is of sufficient size to impact the pelvis, will clear up the case. Should it be deemed necessary, however, an incision into the growth can be safely made and its nature fully diagnosed. Even should the tumor prove to be the inverted uterus, in the hands of a good surgeon no injury would result.

Submucous Fibro-Myoma.—The inception of this variety may be early followed by dysmenorrhœa, menorrhagia, metrorrhagia, leucorrhœa and serous discharge, uterine tenesmus and displacement, the symptoms steadily increasing with the growth of the tumor. Occasionally, menorrhagia and metrorrhagia are wanting. The uterus enlarges, its cavity increases in depth, its walls become heavier, and because of increasing weight it sinks in the pelvis. Anemia, neurasthenia, dyspepsia, great depression of spirits and prostration often rapidly follow, and unless the patient is relieved of the tumor, either by nature or her physician, she will die. Should the patient not get rid of the tumor early, it may so enlarge the uterus by its growth that the former is lifted out of the true pelvis.

General Remarks.—Solid fibro-myomata are differentiated from ovarian cystomata and fluid accumulations in the cellular tissue of the pelvis by the entire absence of fluctuation, their slow growth, their connection with the uterus, and the marked derangements of the functions of that organ. From solid tumors of the ovary it is not always possible to differentiate them, and as already noted, I have seen both Billoth and Lawson Tait open the abdomen for a supposed uterine tumor, and find instead a solid ovarian tumor. The moving about of the solid ovarian growth may move the uterus, and give the idea of a uterine tumor with a pedicle.

The most difficult diagnosis is encountered in very small subserous and interstitial tumors. But time or the bimanual method of examination carefully employed, or pulling down the uterus with a volsellum and retroverting it toward the examining finger in the vagina or rectum, will sooner or later discover the small growth. If it be subperitoneal and located on the anterior wall, and producing symptoms of stone in the bladder, I see no objection to dilating the urethra, dragging down the uterus, passing the

finger into the bladder and examining both bladder and the anterior wall at the same time. The interior of the uterus may be reached with the finger only after thorough dilatation, which may be accomplished with Molesworth's dilator or the metallic dilator of Marion-Sims, or Gooddell, either after or before division of the vaginal portion of the cervix.

Previous to entering upon either of the above-described processes, the bowels should be completely cleaned out, and all pelvic congestion further relieved with antiseptic hot water douches, and the last may be continued as a safeguard after the procedure. Both antelexion and retroflexion of the uterus have been mistaken for fibro-myoma. The uterine probe will locate the position of the fundus in either case, and careful manual palpation will further solve the problem. Fecal accumulations in the caput coli or sigmoid flexure would not follow the movements of the uterus, and would be affected by enemata and cathartics. Pelvic hematocele is of sudden appearance, accompanied by evidence of loss of blood; the tumor is fixed and painful to the touch.

Pelvic cellulitis produces a painful swelling which soon fixes the uterus, rendering efforts to move it painful; the temperature rises and examinations are painful; the vagina is hot and the pulse beats perceptibly in the vaginal arteries. These constitute the main clinical features, differential and otherwise, of solid fibro-myomata of the uterus.

Caution.—The uterine sound as an aid to diagnosis is beyond doubt valuable. Its use is entirely precluded in case pregnancy exists. It should be used with the utmost care and without the exercise of any force. The direction of the uterine canal should be first determined by means of a flexible probe, which may also be used as a substitute for the sound. An extensive experience in bimanual examination will enable any one to dispense with the constant use of this instrument with advantage.

(To be Continued.)

SICKNESS AND PAUPERISM.

Read before the Cambridge Society for Medical Improvement,
Nov. 23 1893.

BY L. L. BRYANT, M.D.

ASSISTANT CITY PHYSICIAN OF CAMBRIDGE, MASS.

There are over eight thousand histories of families who have applied for public aid on file in the office of the overseers of the poor of this city. This represents twenty-four thousand names, in round numbers which appear on the pauper books of Cambridge. To this list, names are continually being added at the rate of fifteen hundred a year. What are we, as a Society, doing to prevent this? The question has often been asked me: "What are you doing?" and I have many times propounded the same question to myself. This paper is written in the effort to reply. In the month of May, 1883, ten years ago, I was elected to the office of Assistant City Physician. The said office was created Dec. 1, 1880, to enable the local Board of Health to conform to statutory law and yet retain the incumbent City Physician, Dr. Henry P. Walcott, a man occupying an honored position in the State Board of Health, and standing deservedly high in the respect and esteem of the people, and of this Society, of which he is a member.

My predecessor, Dr. O. C. Turner, a most estimable

man, died in October, 1892, of typhus fever, contracted while in harness; and during his illness, and subsequently until my election the affairs pertaining to the office were satisfactorily conducted by my friend, Dr. Wetherbee.

With a nervous organization particularly susceptible to external influences, and with absolutely no knowledge of the refinements of modern economics as applied to the poor, I sought and found the office which I still occupy; and my only qualifications were a fair knowledge of general medicine, and that experience which usually follows the first few years of practice subsequent to graduation.

The gaunt, hollow-eyed, cadaverous poor, having nothing and wanting everything, I knew nothing about, and as little what to do for, or with. Entering the service of the city under the circumstances, and in the condition mentioned, I first made myself acquainted with the duties prescribed by the city ordinances.

I found the office of the overseers of the poor to be the abiding place of one of the most perfect systems with which I had ever been made acquainted, with its thousands of histories of individuals, each one necessary to the proper registration of an applicant for aid and the establishment of a legal settlement, numbered, indexed, and filed away in bound volumes. I found in this office all the usual machinery and labor-saving devices necessary to the conduction of a large business, and presided over by a Secretary, D. P. Muzzey, devoted to his work; and apparently constantly employed. I found that all appeals for assistance must be made to this Secretary, who was empowered by the Board to dispense the city funds at its command as it deemed for the best interests of the applicants, and then to so manipulate the official machinery in the interest of the city as to secure from the various cities and towns wherein they had resided long enough to acquire a settlement, a monetary equivalent for everything paid out and for all services rendered. I found that the fixing of a settlement on some other city or town was one of the most important duties of the office, and required the services of a so-called "Visitor," who, likewise, was apparently constantly employed. This labor necessitated calling on the applicant, asking for, and recording various personal questions, searching city and town records to prove the truth or falsity of his or her statements, and, in general, the making of such a return to the office as would enable it to form as accurate an idea as possible of what he had been, what he was, what he wanted, and "how we are to get anything back?" I found that the Secretary was the confidential clerk and advisor of the Board, the disburser of supplies, and came into more intimate relationship with the Board, the poor, and the general public than any one else, and conscientiously performed his duties.

The Visitor, Vespasian Danforth, enjoyed the distinction of being considered one of the best versed men in pauper law in the State. Both of these public servants were ever on the watch for fraud, and worked the machine, seldom allowing sentiment to change the order of its working. Not but they were susceptible, but experience continually taught them that yielding to it was an unprofitable indulgence save as a reflection from the Board. I found as a working formula that the overseers of the poor expected me to visit such of the poor of the city as the

Secretary should direct, prescribe for them as my judgment dictated, and to suggest to the office anything which I might consider it to be the policy of the city to do in the direction of relieving their sufferings and distresses, or tending towards making them better law-abiding and self-supporting citizens.

Of all classes, the poor seem to be the one easiest to prescribe for, their wants being few and simple, and one's mistakes are so easily buried. I went into the work largely for the salary I was to get. I did not love the poor, that I can remember, except in an offhand sort of way, and I am not certain just how much I have acquired; but I soon found that there was something more for me to do than to issue dogmatic instructions as to medicine and diet. These must often be furnished; and not alone diet and medicine, but everything that my patient's condition sets up within me the want for him to have, but there was more than this.

The labors of the Board, with which I was connected, were not only directed toward relieving paupers, but toward the prevention of pauperism. The more I became acquainted with the office and with its efforts in this direction, the more apparent became the responsibilities which I had assumed; and often, as the magnitude of the efforts of others in charitable work have become known to me, my own have seemed so futile, that a morbid sense of my unfitness for the work that was gradually unfolding itself oppressed me. To-day, all the Utopias of which I may have dreamed, are vanished. I feel that I have acquired what the boys call a "crust," from off which smiles, tears or curses alike glide, and if ever unpleasant reminiscences assail me I pull myself up out of the pessimistic slough, with the comforting thought that I have done my duty as I have seen it, and have earned my salary.

The man in private practice has his pensioners to whom he gives or withholds according as his emotional centers are affected. Nowhere have I found such tenderness, devotion, sacrifice, and forgetfulness of self, as that exhibited by the members of the medical profession, particularly for the worthy poor; those unaggressive individuals whose morals, or "rules of conduct considered essential to social existence," appear like ours and have not altered under poverty's pressure; those who suffer and are still, and who practice virtues we do not ourselves possess. This is often, however, but the chrysalitic or transition stage preceding their development or degeneration into the unworthy class.

The unworthy poor are those who do not approach or appeal to the average medical man as he fondly imagines that he would, were he in the same financial condition. There is an aggressiveness and an insolence about them that is repellant, and which gives one the impression that the same force economically applied would make them independent of others' assistance. But the law knows no such distinction; sickness levels both to the same plane, and as the medical officer of the city the fact that I am to care for any one being established, I have nothing to do with his morals except where their defection is the cause of his disease, and must use the same circumspection for all alike.

Upon going out into the homes of the poor, I found there the hard, coarse, hell-side of life. I found as types, the nice old lady who wouldn't for the world have her friends know that she felt obliged

to have the city doctor; the tired-out, exhausted, poorly fed, discouraged laborer; the thin, hatchet-faced mother, daily rubbing her very life into the washboard, while the father stays at home and minds the babies; the broken-down beat and bummer, with his trembling muscles and his protestations of sobriety; the sick infant, left to the care of one scarcely older than herself; the dirty, lousy syphilitic; the consumptive and chronic rheumatic, waiting for, and looking forward only to death; the criminal imbecile, fool and insane man; and the little children prematurely aged and kept at home at scullion's duties. Seldom I found the square, honest, upward energetic look, but oftener, the inert, downward, sneaking, leering glance, with the light reflected from the white of the eye. Here a woman asserts that she is sick, that her husband has rheumatism, or that her child has a contagious disease, that I may be induced to request of the office, fuel or groceries. Here is an intelligent man of the genus tramp. I met the same man last year, and the year before that. The nights are getting quite cool now, and he concludes that it is about time to go into winter quarters. Leisurely he makes his way to the office and informs the officer there that he would like to go to the almshouse. Asked why he does not go to work he replies with an injured air that he has a pain in his back and can not work. The officer demurs. The man grows persistent, and is finally referred to the doctor. The injected superficial veins and his general tremulousness tell their own story; but what about that pain in his back? Is there one of you here who is able to tell whether he has, or has not, a pain in the back? You are morally sure that he is a fraud; but who of you, having the power has the courage of his convictions, and will say to that man, "No." No; public sentiment has not reached that stage where it will support any such decision, and we think again, and we find that it is true that he is not quite "up to concert pitch"; that he does need a little straightening out; and a doubt begins to frame itself that we have all the factors relating to that pain clearly before us, and the man goes to the almshouse.

Here the best that the house affords is his: food, clothing, bedding, pipes, tobacco, and that luxury of the modern hotel, a smoking room. Here in this steam-heated shelter, he whiles away the short winter days, sleeps through the long restful nights, grows fat, and perhaps, when the snows have gone, and the spring is well advanced, he ties up clothes in a bundle that he did not fetch with him, tells us that he has found work, and bids us adieu.

It is no state secret that public officers are largely at the mercy of a class of persons made sharp, keen and desperate by their fancied necessities, who are more difficult to manage than criminals because they are not under the ban of public censure but, hiding under the wings of public sympathy are in the position to dictate and the officers must obey. That this is true abroad as well, is asserted by Josiah Flynt in the *October Century*, who says of Germany, the home of the most advanced public efforts relating to pauperism to-day: "With all its groans under taxes, military and otherwise, it nevertheless takes upon itself voluntarily the burden of the voluntary vagrant—the man who will not work," and after giving a resumé of the various methods and institutions employed he adds: "But the man who will not work

passes through these institutions as freely as the man who will."

And now, what shall I do with my patient? The therapeutics of pauperism, complicated with sickness, is somewhat different from that employed where treatment is confined to sickness alone. Both are morbid conditions, and either or both may be inherited, or acquired, or contagious. Both must often be treated at the same time, because if the treatment be limited to one, fatal results may accrue from an aggravation of the other. Together they make up a combination that in spite of the prayers, labors, study and money used and continually being used, is frightfully on the increase. When I do not know what to do I fall back on the machine. When I can care for my patient at home, I do so. When it is a question of hospital or almshouse, I send him to the almshouse. Why? Because it is cheaper. Surgical cases go to the hospitals, because there they have the appliances and can command the skill which I do not possess.

As the years have gone by, I have been led to look into the "springs of man's action," in search of the causes of pauperism, and for additions to my armamentarium. I have found the truth of Bastiat's observation, that all economic movement may be resolved into "wants, efforts and satisfactions," terms correlative of those of the reflex process of ideation; perception, comparison and action. Want, according to Gunton is "such conscious need of an object that its absence will cause sufficient pain to induce the effort and sacrifice necessary to its attainment." "Want is the sole motive and the only measure of effort, for no more effort is ever put forth than is necessary to secure satisfaction. Until a desire becomes so intense that more pain is produced by its non-satisfaction than will result from the labor and sacrifice involved in its gratification, it is not an economic force of want, the need to consume being too weak to impel sufficient effort to produce."

I found that a man's efforts tended toward the achievement of satisfactions that are "customary, and therefore demanded" by the best livers among those with whom he associates, the sum of which constituted his "standard of living."

I found that perceptible advancement in one's standard of living was not a matter of days or months, but of years; and that any attempt to force its growth met with waste.

I found that the standard of living of the poor with whom I came in contact was not mine, was best ascertained by comparison—not with mine—but with those of a social equality with them, and that their efforts were then more intelligently directed along economic lines.

I found that history teaches that public aid does not strengthen but weakens, and breeds the disease called pauperism.

I found that it was not expected that this people should remain paupers, but that their necessities should force them to continue their efforts to keep up in the race.

I found, as Stoddard puts it, that "not what we would, but what we must, makes up the sum of living," and that sickness, sighs, tears and groans were not economic forces, but media through which one's ineffectual desires and efforts were communicated to others.

Physical disease is a common foe, without senti-

ment, smiting alike the rich and the poor who disobey the inexorable laws of health. Money will not propitiate it, years of penitence and years of prayer have not stopped its devastating onward march, and it is only when we add the sick man's ineffectual desires to our economic wants, and let our strength compensate for his weakness in a common struggle for a common satisfaction that sentiment is of value as a therapeutic agent. It is not the empirical sentimentality that gives birth to flowers, ice cream or religious tracts, but the kind that reaches down, grabs you by the hand and stands shoulder to shoulder with you in a *fight* with a common enemy.

I have found that the same is true in the treatment of pauperism. It is not pity that comes in with tears, sighs and groans with which to fight tears, sighs and groans, but that coming with the trumpet call to arms. There is a sentimentality, and affectation born of ignorance, money and fadism with which we all are acquainted. It looks right, but it rings flat. It takes a man up, toys with him until he ceases to be a plaything and refuses to be wound up, or to run right when he is, then it tires of him, and he is told that if he wants any more assistance to apply to the overseers of the poor. What can the poor devil do? Go to work? Where? What is the incentive to work? No, he has eaten of the tree of knowledge, his ambition and energy are sapped, his moral tone lowered, he cries inertly: "God help me, what can I do?" and he lets his wife and children work. He applies to the overseers of the poor and contracts pauperism. His children are taken sick. He is informed that he can have free medical attendance by application to the city doctor. Is his condition improved? Is the material condition of his family improved? Not as I see it. Down he sinks, lower and still lower in the social scale until, as the years come and go and his children reach the age when they should be self-sustaining, they too think and act along the same lines, and have an incapacity for economic effort. A glance at the histories on file in the office of any board of overseers of the poor will show this to be true, as will also a perusal of the history of the notorious Jukes family.

And now, what can be done to prevent a continuance of this state of affairs? Make no distinction as to worthiness or unworthiness, and keep the people from going to the overseers of the poor. That the men of some sections of the city are doing this I know, from the few calls I get in their locality.

As physicians we can not afford to shirk the responsibility which is clearly ours, by every law of scientific and human right.

We are scientists, striving to look through the maze of error and to discover the truth.

We are philanthropists by virtue of our profession, intrusted with the lives and the material happiness of our fellows, poorly paid for our services even by the wealthiest, and looking forward to the close of life, not with the expectation of leaving a large account to our descendants, but an example for their emulation.

We are optimists, too, ever looking for the best principles that move mankind. We come into closer relationship with humanity than pastor, priest or lawyer. Ours is the opportunity possessed by no other body of men, to inculcate those principles of thrift and independence which are the essence of true manhood, womanhood and American citizenship.

The individual study and applied efforts of each in a few instances will produce better results and more lasting satisfactions than with many.

In my own case I aim at quality and not quantity. I am not at all anxious to present a list of a large number of patients in my annual report.

When a man comes to me to be inoculated with pauperism and informs me that such a doctor always attended his family, but that he owes him a bill and is ashamed to ask him for further assistance, I send him at once to his physician; and I instruct him to tell his doctor his whole story, concealing nothing; and then to say to him: "Doctor I have no money, but just as soon as I can get work I will pay you a little at a time until my bill is paid." I have never known such an effort to fail.

A little story of Marshall Wilder's I sometimes use as a therapeutic agent: "Two frogs fell into a pail of milk. One exclaimed: 'Help! Help! I sink! I drown!' The other answered gruffly: 'Kick! Kick! you little devil! Something will surely happen.' The first one continued to gasp and moan, and finally sank out of sight. The other kicked and kicked until nearly morning, when the milk having been churned to butter, he walked out onto dry land."

DISCUSSION.

DR. MORRILL WYMAN said he had not seen as much pauperism as the reader, yet he had had considerable experience with it. He told of one case rather remarkable, where the father a miserable fellow, became a pauper and the succeeding children, making three generations, followed his example. In the early days of his practice there were few foreigners in Cambridge as compared with the present time and there was less pauperism.

Seeing a number of lazy looking fellows loafing about a corner, only a short time ago, he accosted one who was smoking and asked how these men obtained a living; when he received the reply that their parents went out to work and their mother took in washing. When asked what was to become of these men the fellow replied: "They will bring up in jail if they are lucky enough to escape hanging."

DR. HORACE MARION said the reader had presented in a forcible and illustrative manner many stubborn and stony facts. The subject is a broad one to grasp, on which little literature has been published, and with foreign countries pouring in a constant supply of paupers, one of great moment for the welfare of this country.

It is difficult to say what is best to be done, but it is certainly sure and important that patients should be kept away from the overseers of the poor.

The emergency societies are doing much to prevent the development of pauperism. Their method is to practically give them the articles they require, but at the same time to make them work and think they thereby earn them. A great part of the work of the Overseers of the Poor consists of the investigation of settlements; by this means a certain amount of money is refunded from the township whence the pauper came.

DR. TAYLOR said in a few instances he had sent patients to the Overseers of the Poor, and thought it had a stimulating action, effecting the patient to do something for himself. He did not like to attend non-paying patients who live at a distance, neither did he think it right to send such patients for care to other physicians, although he knew instances where such cases paid something to the other doctor.

DR. CLARKE said when he came across long tedious cases that required much care and medicine he usually referred them to the city physician. With poor patients who can not

pay, he is in the habit of making them do service of some kind in exchange for his advice, and thinks in many instances it has a good effect. Certain cases are too lazy to work. In Boston, certain institutions are in the habit of making applicants for meals work—sawing a quantity of wood, in compensation for the food given them. Some men will work hard and others prefer to go without a meal, rather than work and earn it. He thought a similar line of action to this might be taken in Cambridge, and is of the opinion that most of the foreigners imported here are of an industrious nature and not inclined toward pauperism. The West is largely built up of this class of people. The greater number of paupers are American born and they form the worst class. Most foreigners come over here with higher motives than pauperism; they come to better their condition, and many instances might be quoted where they become prominent citizens, such as one he had encountered this summer at Chicago.

DR. NORRIS differed from this latter view; he thought "the microbes were imported," and that paupers originated, at least, from the foreign element.

DR. H. P. WALCOTT said his relations with the Government did not give him the intimate knowledge of the poor which Dr. Bryant possessed. He thought Dr. Clarke's statement worth consideration; it is certainly true that the worst class of paupers are those educated in pauperism, and that we have educated many of our citizens in this respect. We do not import many paupers now because our ports are guarded against the landing of this class, and a large number who come over are recognized as paupers and sent back. State and municipal aid are unfortunate for the poor as such aid tends to make paupers of them.

DR. VAUGHAN.—Municipal and State charity is an irremediable evil. Brooklyn has cut off all outside aid; the burden is carried by voluntary organization. Public relief is not charity; it is compulsory to meet an evil that can not be helped. The taxpayer supports it. The associated charities and Overseers of Poor work so closely together that the latter turn all cases over to the former for investigation. With more or less help from organizations to substitute the work of the Overseers of Poor, he thought the public would be relieved of much of its pauperism; and he hoped the time would come when by the combined effort of the associated charities and other similar associations, the work would be entirely removed from the Overseers of the Poor.

The medical work of the poor must be done in a similar manner, and by giving such advice free as may be required physicians will avoid making many patients paupers. There is an uncertainty about the effect of the associated charities, due to an imperfect knowledge of the after history of many of the cases, and a want of tact on the part of the visitor.

It is now arranged so that a person can have his or her name erased from the books of the Overseers of the Poor, by paying back such sums as have been given.

At one time there was no restriction in Cambridge against administering to the poor, and as a result this class flocked here for help. The evil of placing children in almshouses is recognized, and at present there is practically no department for children in this institution. All except the imbecile and the like are boarded out in families.

DR. DOW rarely sends a patient to the city physician; he explains that it makes paupers of them and usually they wish to avoid this condition, preferring to pay him something for his services. He questions the wisdom of sending a visitor to the poor, because they are received as a distinguished visitor and not as a friend. The associated charities makes the poor reform without giving them much.

DR. LLOYD thought the consideration of the poor at this meeting is in their relation to sickness, a complication of

pauperism, and a very proper subject to be brought before the medical profession. The pauper is a person in a chronic condition of mental and physical weakness, and requires to be carefully studied, like crime or other diseases. The sick poor must suffer until means are found to obviate the condition of pauperism. This is an evil of civilization and increases in ratio to the wealth and intelligence of the people. The condition may have come from the mental state, of antecedents which have been introduced into this country but not found among the early settlers. This foreign element diseased with crime, immorality, etc., give issue that are dealt with as American born citizens, live in and infect cities, cause crime, poverty and pauperism. All good citizens should act in conjunction to prevent the imposition of these people. The best way of dealing with this class is to make each individual believe he must be self-supporting; the poor man must be taught that he can and must do something for a living unless physically diseased.

DR. MAHECNIÉ thought it did harm to help poor families; we are guilty of doing them an injustice when we do not make them pay their debts. There are few paupers in West Somerville, because the physicians there render such aid as is required of them.

DR. HENRY O. MARCY considered intemperance a great cause of poverty. He asked if the hard times had not increased the work of the overseers of the poor among the worthy poor. There are many Italians at the North End, Boston, who have less comfort than cattle. He considered "educated men expensive animals."

DR. C. C. FOSTER thought that *children's homes* contributed to the list of paupers, because the children were not taught how to work and earn a living.

DR. MORRILL WYMAN asked if children that had been placed in the almshouse had any desire to return home?

DR. FOSTER.—No; they want to stay, and while there they hear the talk of the older paupers, which is vile and perfectly horrible for the ears of children.

DR. BRYANT in closing the discussion said that children in the almshouse were associated with old women and bums; do not get the care or instruction which they should, and become and remain paupers. The education of these poor children should be looked after. He considers the medical profession should be responsible for the well-being and morals of all homes into which it is brought.

A district nurse is of great value, to instruct and make homes brighter and cleaner.

Seventy-five per cent. of paupers are of Irish descent; next come the Western Islanders and Portuguese. Poverty comes from intemperance and intemperance often comes from poverty; the poor wish to drown their care and sorrow in drink.

ENEMIES OF THE HUMAN TEETH.

Read in the Section on Dental and Oral Surgery, at the Forty-fourth Annual Meeting of the American Medical Association.

BY A. M. BENSON, M.D., D.D.S.

LA CROSSE, WIS.

In the same mail with Dr. Talbot's letter of invitation to prepare a paper for this meeting, came a circular from a member of our profession announcing that he had discovered a new local anesthetic, making the extraction of teeth harmless and painless; the greater part of it being devoted to testimonials from doctors and dentists who had used it; and telling how they had removed from six to twenty teeth from the mouth of one person at a time, thereby very much increasing their business; the

author closing with urgent advice to all dentists to avail themselves of this great boon offered to the profession at the very low price of one dollar a bottle, or six for five dollars. During the past year I have received perhaps half a dozen similar advertisements, and nearly all of them signed by a D. D. S. Many of you have had no doubt a like experience.

Chagrined at this impudence and unprofessional proceeding, and believing that such practice ought not to go uncondemned and under professional protection, I have accepted the invitation, and the enemies I wish to direct your attention to are not those about which so much has been written, which it takes a scientist with a microscope to discover, and against whom the evidence is mostly circumstantial, but those conspicuous and more dangerous ones whom we have all seen with the naked eye and many of us felt upon our naked jaw; who plume themselves with professional titles and dwell mostly in "dental parlors," though they are sometimes found in the country doctor's office; who shed innocent blood and mutilate the human body in the guise of saviors, and claim special social recognition and honor; who write articles for the journals and are often found in college faculties, where they are conspicuous for their zeal in elevating the standard of the profession; whose interesting portraits so often confront us in the advertising columns of the public press along with the rest of the medicine humbugs.

Perhaps some one murmurs, This is a slander. Let me relate what I witnessed in one of the high grade schools:

A local dentist, not a member of the faculty, was invited to give a clinique for the benefit of the class, the operation to be the extracting of a number of teeth under an anesthetic, ether being the one administered. The victim, an ignorant servant girl, whose mouth was indeed in great need of renovation, affording the students a splendid opportunity to take a lesson in the highest achievement of the dentist, "the restoration to usefulness of diseased teeth." But what was done under the direction of the professor? The frightened girl was placed in the chair, pulled into the recumbent position, and the inhaler placed over her face, against all of which she frantically struggled, but the odds being against her, she finally succumbed. Then began a scene worthy of a place in the Spanish Inquisition, and which properly described and illustrated would form a fitting canto in Dante's "Hell." The chief operator, after removing his coat and cuffs, seized a forceps and with trembling hand thrust it into the spongy gums as near a tooth and collection of tartar as his shaky condition would permit. Successive quick jerks, accompanied by the sounds of crushing bones and low groans, followed by a swaying among the pressing crowd, trying to dodge flying pieces of haggled humanity continued for some time, when, owing to exhaustion of the operator or the overflowing of blood and ingesta which threatened to strangle to death the patient, active operations were for a moment suspended; but there still remaining some roots deep in the gaping wounds of her jaws, others present knowing themselves experts volunteered to kindly assist the tired scientist and cover themselves with blood and glory. The former was easily accomplished, but the opportunities for glory seemed wanting, and after bringing away a few chunks of gum and process, they retired, declaring those were the

most obstinate roots they had ever encountered. The patient having again collapsed, a sympathetic looker-on, realizing if this poor creature should any longer serve the ends of science she must die, suggested that the clinique cease for the present, and the remaining roots be removed at a future time, when the gums were not so swollen. The hour, too, now having passed, the class, evidently satisfied that their alma mater had provided them a fine clinique, hurried away to the amphitheater to listen to a lecture on remote disorders in the body caused by carious teeth, leaving the patient to the care of the janitors, who, considering her from the human rather than scientific standpoint, kindly cared for her until she was somewhat restored, and some hours later, though still dazed and bleeding conducted her out from this woeful place.

I have never been able to conceive of any excuse for such an outrage within a dental college. As evidence that such teaching bears abundant fruit in practice, I quote verbatim, articles from a popular dental journal, the first headed: "A Large Tooth."

"About a month ago a lady from our town introduced herself to me with the intention of having some teeth extracted to make room for an artificial set. I removed eight of them with great difficulty, though I had administered first a soothing preparation invented by me for this purpose. A few days ago the lady returned to have the remaining teeth removed. In examining the mouth, I found a perfectly sound upper cuspid on the right side, and I advised her to let it remain. The lady, however, insisted on having it removed, in doing which I succeeded, after two unsuccessful attempts with safety forceps. The tooth is one and one-eighth inches long, and shows a circumference of one inch. The lady weighs at the present time 110 pounds. Has any one extracted a larger tooth? We should like to compare notes."

In the next issue appeared the following answers:

"About five years ago I was practicing in the town of —. One day a cadaverous-looking man came into my office to have several teeth extracted. After removing two or three, I tackled the right upper cuspid, and after some little difficulty it gave way. I thought I had pulled the whole jaw off, for a large piece of process and the first bicuspid came with it. This bicuspid is one and seven-sixteenths inches long and one and one-sixteenths inches in circumference."

"Last June I extracted seven superior teeth for a lady. I found four very difficult to remove, viz.: two canines and two first bicuspids. One canine is one and five-sixteenths inches long and fifteen-sixteenths of an inch in circumference. The bicuspids were bayonet-shaped. One is one and one-sixteenths inches long and one inch in circumference. The lady weighs about one hundred and twenty pounds."

"About three weeks ago I extracted six teeth for a lady, among which were two upper cuspids, both largely decayed. The larger of the two measured one inch and five-sixteenths in length and almost one inch in circumference. The smaller is one and a quarter inches long by fifteen-sixteenths of an inch in circumference. I preserved these monsters and have them in my possession."

I avoid names, as my desire is not to point out individual shortcomings, but to direct attention to a too common practice. I believe the venerable Dr. Holmes is credited with saying, that if all the drugs

used as medicine had been sunk in the bottom of the sea, it would have been better for humanity in general. I think the same might be said, if not of the entire dental profession up to date, at least of all the instruments invented for the extraction of teeth.

I venture the statement that at the present time, though in the vanguard of the profession are many noble men who can truly be called dental doctors, a large number of so-called dentists are truly "enemies of the human teeth," destroying more than they save.

I knew a dentist, now deceased, who during the twenty-five years he was in practice extracted, it is safe to say, enough teeth to fill an old-fashioned farm cart. Imagine, for a moment, what this represents in blood, tears and trepidation, to say nothing of the leering deformity, crippled condition, and many deaths directly due to this malpractice. The best men in the profession are agreed that 99 out of 100 of all the teeth and roots presented for treatment can be saved and made comparatively useful and with less pain to the patient.

It has also been demonstrated by implantation—though I hope this operation will not become popular—that teeth long out of the mouth and strangers to the new organism can be accepted and become firmly held in the jaw; then how much better must it be to retain roots which have the advantage of natural position and long-established attachment. This being true, what shall we say of those who extract sound teeth to make room for an artificial set, or because some people ignorantly desire it?

As mentioned in the beginning of my paper, this has all been said before, and the majority of dentists have a vague idea that it is wrong. Then why is it? I think the chief reason may be given in one word, "Business."

O, Business! what crimes are committed in thy name!

The public has so long been educated by the quack in all the departments of life, that it is easy for men without moral character, but possessed of some cunning, to get money by preying upon them. Every day thousands of people freely give hard-earned money to have teeth extracted which should be saved, and thousands of dentists daily serve them, conscious of the wrong, simply because they want the money. Alas, that cash should be so dear and flesh and blood so cheap!

A dealer in dental materials informed me that one manufactory of artificial teeth sent out 5,000,000 sets each year, and there are a number of such enterprises in our country whose prosperity depends mostly upon the efforts of those dentists who extract teeth to make room for their products. Unfortunately this weakness for money does not belong to the dental specialty alone. If from all the learned professions were taken those who practice for revenue only, the number in each would probably be very much diminished.

Theoretically this is an age of high ideals, but practically we have something yet to reach; and though I have called attention to evils common in our profession, and am convinced that for many of us it were well to examine ourselves if we are worthy the title we bear, yet I believe that our specialty has made greater progress than any other department of medical science, having accomplished the successful treatment of nearly all the diseases of the mouth, and making the preservation of teeth in the hands

of the intelligent and conscientious dentist a certainty. In my opinion what is needed is not so much higher knowledge, but a better use of that already possessed.

While at college I was often edified with encouraging lectures by members of the faculty who never failed to inform us that there was plenty of room at the top of the ladder, seldom mentioning that there was anything needful or honorable to do at the bottom.

This may be well, but I have discovered in practice that if the glory of the dentist be the salvation of the natural teeth, for the dentist true to the noblest impulses of his nature who values the approval of his own better judgment above all things, and will succeed by honorable means or else retire, there is an extensive field for labor at the bottom of our professional ladder. Probably less than one-fourth of our population take proper care of their teeth.

I have thought that if, as in the clerical profession, we had different degrees or orders in our specialty, so that the ambitious youth who now seeks admission to the college, but owing to its high requirements fails to enter; for such there might be a sort of preparatory department where, if bringing evidence of having learned their catechism (especially our duty to our neighbor) they might be admitted and instructed in that branch of our work which does not necessarily require an extensive knowledge in science and literature, but rather mechanical skill, which having learned, they might be ordained and licensed like Fourier's Sacred Band to do such duties as are distasteful and likely to be neglected by the D. D. S.—missionaries, as it were, to a benighted public, who now under the flickering gasoline light sit and allow these devils who go up and down our country, seeking whom they may devour, to scatter their teeth about the public market-places while the band plays, "Annie Rooney"—saving them from this quack and his brethren, the vitalized-air and local-anesthetic fiends, by teaching the use of the tooth-brush and the saving power of amalgam filling, and after thus having served humanity for some time, and honestly earned some money by only asking the same fee for saving teeth as is now willingly paid for destroying them, might take a further course at college.

Three hundred years before Christ, Erasistratus, a dentist of ancient Greece, is said to have deposited in the temple of the Delphine Apollo, a leaden tooth-forceps, to impress upon all beholders that only those teeth should be extracted which could be removed with such an instrument. Might not, in our day, such an emblem be profitably suspended in every church and public school-house, or at least in every medical college and dental office?

But let me bring this paper to an end, confessing that its only redeeming feature is the object for which it was written, and if it shall be the means of saving a single tooth which otherwise would have been destroyed, I shall believe it was not written in vain.

DR. EDGAR PALMER said that the indiscriminate use of these secret compounds for local anesthesia should be absolutely and sternly discountenanced. He had never used any such. He had very carefully and rarely used a formula which had been recommended to him by one he could trust. He knew of cases where septicemia had been caused by

hypodermic injections of such a preparation by one who was exhibiting it for advertising purposes, causing one death and severe trouble to several.

DR. TAFT said that every dentist should stamp his disapproval on everything which is brought out as a nostrum, and never lose an opportunity to warn people of the dangers of the traveling quack who goes from town to town, and either from the gaudy chariot or in the "dental parlor" extracts teeth without pain. The danger of operating on one patient right after another, using the same syringe and the same forceps is so serious that if it were understood their occupation would be gone. Besides the danger of infection, is the necessity of having the nostrum strong enough to be effective in every case; this means that for those who would be easily influenced it is dangerously strong. People should be intelligent enough to know that they should not sacrifice teeth except when they can not be saved, and that one whose business is only to extract is not working for the good of the patients, but of his own pocket. The profession should set its face, as a flint, against such practices, and treat such operators as the Irishman treated the crowd in the fight, "whenever you see a head, hit it," and crush it if possible.

DR. S. SAXESPOKE of a man who came to his town, and, with a grand flourish of advertisements, announced himself as a famous dentist, and agreed to extract all teeth painlessly, and to refund the money unless he did so. The quack referred to, who really was a graduate and sported the D.D.S. after his name, pocketed over \$300 a week, while the conscientious dentists in the town were helpless to hinder the harm he did. The only way the dentists can stop such disastrous proceedings is to educate the people as to the value of the natural teeth, and the means necessary to preserve their usefulness.

DR. BROWN said he knew of one of these painless-extracting fiends, who, having guaranteed to extract with absolutely no pain, had been sued for damages by several sufferers upon whom the anesthetic had not had the desired effect, and he had had to pay the damages and seek new fields for practice.

DR. EDGAR PALMER said, on account of his position in the State Society, he always heard of these cases as soon as they advertised, and that he had taken pains to discover that this man was a graduate of the University of Pennsylvania. Upon learning this, he had written to Dr. Darby, sending him a copy of the advertisement. Dr. Darby had replied that he had communicated with the fellow, and would let him know what he said when he received his reply.

DR. TAFT said we can not hold the institution which graduates a man responsible for his future acts, and after a man has graduated the institution can exercise very little control over him. In some States the law will take hold, but in most States we can do nothing.

DR. BENSON thought that in cities the boards of health should prevent such practices. The ignorant public should be protected from the loss of their teeth, which loss will surely result in danger or injury to their future health.

DR. V. A. LAPHAM thought that the diploma should contain an agreement that advertising or other grossly unprofessional conduct would work a revocation of the diploma. This was the case in Great Britain, where a dentist who had received a diploma from any of the institutions which issued them, and who should be convicted of unprofessional conduct, would have his diploma annulled, his name stricken from the register, and would be fined or imprisoned should he describe himself as dentist, or use the initials of his degree after his name.

PRACTICAL ORAL THERAPEUTICS.

Read in the Section on Dental and Oral Surgery, at the Forty-fourth Annual Meeting of the American Medical Association.

BY GEO. V. BROWN, M.D.
DULUTH, MINN.

Genius has been defined by Carlyle as "an immense capacity for taking trouble," and the methods of oral therapeutics require genius in just that sense for their administration.

Having in charge the natural gateway of the whole wonderfully complex system of human mechanism, we are familiar through experience and the frequent statements in medical and dental literature, with the fact that inflammations having their exciting irritation in the mouth often cause by reflex action severe neuralgic pain in the eye, ear, different parts of the head, face and neck, or whenever connection can be found through the many ramifications of the fifth nerve and its ganglionic associates, that in the same manner also sometimes originate diseased conditions of a very serious nature in the eye and ear, as well as spasmodic affections of the muscles, lockjaw, convulsions, epileptic attacks, paralysis, nervousness and indigestion, and that too there are in contra-distinction to these, another class to which belong the infectious diseases of the oral cavity itself, and those that are caused by the migration of pathogenic microorganisms from the mouth to other parts of the body.

Miller in his "Microorganisms of the Human Mouth," considers the diseases caused by the pathogenic bacteria of the mouth under six heads according to the point of entrance of the infection, and it is this classification which I shall follow in discussing their treatment:

1. Infections caused by a breach in the continuity of the mucous membrane by mechanical injuries (wounds).

2. Infections through the medium of gangrenous tooth pulps and from alveolar abscess.

3. Disturbances conditioned by the resorption of poisonous waste products formed by bacteria.

4. Pulmonary diseases caused by the inspiration of particles of slime, small pieces of tartar, etc., containing bacteria.

5. Excessive fermentative processes, and other complaints of the digestive tract, caused by the continued swallowing of microbes and their poisonous products.

6. Infections of the intact soft tissues of the oral and pharyngeal cavities whose power of resistance has been impaired by debilitating diseases, mechanical irritation, etc., considering in this connection also the possibilities of infection by the accumulation in the mouth of the excitants of diphtheria, typho-syphilis and diseases of like nature.

Of the affections not caused by pathogenic bacteria, by far the greater number are the result of an inflammation of the tooth pulp, discussion of the treatment of which in all the variety of opinions so frequently brought forward by the enthusiastic adherents of each, would, of course, be quite beyond the possibilities of this paper. Therefore, I will simply state that in this opinion, while fully recognizing the important value of the pulp in a healthful condition, once it had been irritated by exposure to external influences and afterward covered by a capping, it must always afterward be looked upon as a source of danger and a menace to the associated parts,

unless the circumstances be so favorable that success is assured.

By the careful destruction and removal of the contents of the pulp chamber and canals, the thorough cleansing with antiseptic measures, and the filling of the roots with gutta-percha, inflammations of this character may be promptly and efficiently relieved. Once the exciting cause has been discovered and removed, usually nothing further is necessary in this class of inflammatory processes unless it might be the use of an astringent, a counter-irritant, or better still where practicable, the lance.

In taking up the treatment of diseases caused by pathogenic bacteria of the oral cavity, a rapid glance at the possibilities in this direction seems to be demanded.

The toxic properties of the human saliva have been noticed by observers since the earliest times, and the experiments of modern biologists have fully borne out the truth of their reports.

Fatal results, attendant upon the bite of persons, and the death of animals injected with human saliva, for the purpose of experimentation, have been explained, as we all know, by the transmission into the circulation of the omnipresent pathogenic bacteria, finding as they do in the mouth, a home easy of access, and possessing all of the little conveniences in suitable temperature, moisture and proper nourishment that go to make the microbe's lot a happy one.

Of primary importance, then, must be the care of our hands and instruments. Fatal septicemia, pyemia, and the transmission of syphilis through accidental wounding of the mouth with infected instruments are too well understood to need more than a passing reference here.

In my own practice it is my custom to keep a small jar of 1000 preparation of bichlorid of mercury upon the operating table, and I have given myself the habit of dipping my mouth mirror and every instrument that I use into it before putting it into the mouth. One has the comfortable feeling that an instrument subjected to the corroding influence of bichlorid, and then wiped so thoroughly that it does not corrode is at least mechanically cleaned, even if the action of the germicide might be questionable in so short a period of time.

In using instruments upon the soft tissues, and upon the bony structures I take the additional precaution of an open flame, because even if there be damage to the temper of the instrument it does not seriously unfit it for use in this manner.

The care of the necks of the teeth and that most obstinate affection at the gingival margin known under the various names of pyorrhea alveolaris, Rigg's disease, phagedemic pericementritis, etc., on through a variety of different appellations, each, however, signifying a chronic suppurative inflammation of the periosteum accompanied by an inflamed condition of the gums, and more or less affection of the alveolar process.

Undoubtedly there are constitutional predisposing conditions which are largely responsible for the frequency and obstinacy of this trouble, but there seems to be such a diversity of opinion and so many different constitutional disorders are given as predisposing causes that we are forced to the conclusion that the subject is but little understood; for instance, some writers put it in the category of bone diseases,

others ascribe its cause to wasting diseases, while rheumatism, gout, scrofula, malaria, tuberculosis, rachitis and a host of others have each been brought forward as the cause. Some investigators claim to have proven it to be the result of a specific bacterium, and to have separated pure cultures which in turn would produce a similar affection in animals, from which again pure cultures of the same bacteria were obtained; but biologists do not agree upon this point, notably, Miller who has been unable to get the same result with his experiments and who questions the correctness of others' claims in this direction; therefore, in view of its doubtful origin, we can only be safe in recommending for general treatment any constitutional defect that may be present as a precautionary measure, and then apply ourselves to the local sources of irritation.

Tartar about the necks of the teeth is the first step; then a careful following down of the denuded portions of the roots, and as thorough a cleaning as possible of the rough little deposits of sanguinary calculus nearly always present.

This is a matter of great difficulty, and its failure is probably the most common cause of recurrence of the disease.

Many instruments have been devised for the purpose, but none that I have used has given me such thorough satisfaction as small excavators ground flat. They can be prepared in a moment with a corundum disk in the engine, so that we have always at hand a scaler so small that it can be passed along the side of the root to the very end of the pocket with the least possible pain and laceration of the gum, besides being so sharp that the slightest sensation of roughness would be recognized by the fingers of the operator in a manner that would not be possible with a less delicate instrument.

In the application of local remedies three properties are necessary; antiseptic, acid and astringent.

Antiseptic because bacteria are always present, and to dissolve the particles of lime salts that may have and always do escape the mechanical cleansing; astringent, to reduce the inflammation and constrict the relaxed gum tissues. Hydrogen peroxid is a valuable wash for the purpose of syringing out the pockets; it destroys the pus, and at the same time acts upon the limy deposits in a most cleansing manner by reason no doubt, of the hydrochloric acid, which the preparations on the market have been found to contain. Dilute sulphuric acid, the aromatic preparation of sulphuric acid, the essential oils, and other remedies of a like nature are recommended. Pyrozone is also very highly spoken of.

Unfortunately my supply of rabbits and guinea pigs has been somewhat limited, and I have therefore been obliged to confine my experiments to the pig in a higher state of development, according to the idea of the comparative anatomist.

During the last four years, since my residence in Duluth, a great deal of this trouble has come under my care for treatment; either because it is of a catarrhal nature and the situation at the head of Lake Superior is particularly favorable to its development as to all catarrhal affections, or because having been constantly looking for it, more cases have come to my notice; but whatever the reason it has appeared in every stage of development, apparently in much larger proportion than in my practice in other local-

ities. The conclusions which I have to offer are therefore of an entirely practical nature.

First, in regard to its so-called incurability by reason of its relation to so-called constitutional causes.

My most obstinate cases have been almost invariably persons of robust stature in whom apparently all of the predisposing constitutional affections were wanting, whose teeth gave little trouble from caries, every indication pointing to good structural development, and a healthful general condition.

A typical illustration of this class is a patient who came under my care in January 1889, age 44 years; temperament a combination of bilious and sanguine; well developed chest, good circulation, good digestion, regular habits, a vigorous active business man; never had been seriously ill in his life, no catarrh of nose or throat, no rheumatic tendency, no skin disease, nor did a history of his case develop that any of his family had ever been, to his knowledge, affected by rheumatism, syphilis, scrofula, rachitis, or tuberculosis; and a most thorough examination of his urine failed to show any normal condition pointing to Bright's disease or anything of that nature. Constitutional search abandoned, the examination of the arch gave but little better promise; the teeth were large with perfectly developed crowns, each as nearly in its proper position as possible, the occlusion of the jaws correct, except where the affected teeth had elongated as a result of the disease; not a carious tooth among the number; all in place except the left superior third molar that had fallen a first victim to the disease; there was some accumulation of tartar, and its usual accompaniment of other deposits; the buccal roots of the right superior second molar were denuded their entire length as shown in Fig. 1. A loose flap of gum remained upon the buccal side of the first molar, as in Fig. 2, but examination showed that the pus filled pockets extended almost to the end of the root. The gums about the necks of the other teeth showed more or less pus upon pressure.

Treatment was continued at regular intervals for a period of two years, an antiseptic mouth wash prescribed and used regularly one or more times each day; the pulp canals of the two molars were cleaned and filled, for the continued formation of pus had finally reached the ends of the roots and destroyed the connection there; the pockets and necks of the teeth syringed with antiseptics, the loose gum removed by use of the lance, and by absorption, until both molars had buccal roots denuded.

The first sign of improvement was a cessation of the discharge from about the necks of all the other teeth, and finally it was checked about the molars, and all around the edge of the gum at the line next to the affected molar roots there appeared what seemed to be a line of brighter colored new granulations.

I still see the patient every five or six months, and he continues the use of the wash, but apparently there is no return of the pyorrhea.

We have all of us had many such cases, and I have only gone into detail at the risk of wearying you, because it particularly illustrated some points I desire to call attention to.

We have seen that all ordinary methods of discovering constitutional predisposition failed, and the fact that the case yielded finally to local treatment would seem to indicate the cause as a local one. We know that the contagion theory is not borne out by

the transmission by contact from one person to another, for if it were, undoubtedly husbands and wives would both be affected commonly instead of very seldom as reported, and yet, notwithstanding all this, I have under my care the two daughters of this patient, aged respectively twelve and fourteen years; they have each had quite severe inflammation of the gums, and quite recently I cleansed a pus filled pocket at the neck and palatal root of a first molar in the mouth of the younger one.

Pyorrhea can undoubtedly be held in check and with continued proper care be prevented from reappearing, but whether or no it can be entirely cured as is claimed by many, is a question not easily answered, because once severely attacked, even though the discharge be stopped, the parts never again regain that normal condition which should make them impervious to their destructive surroundings, and it is certainly a questionable difference whether a recurrence of the trouble be from the original infection or a fresh one; therefore I hold that just so far as a condition of self-cleansing surfaces can be restored, in that proportion only can the cure be estimated; to this end, therefore, I recommend (notwithstanding instruction from high sources to save the gum margins) the removal of loose flaps of gum covering the pockets as in Fig. 3, for I do not believe that they can ever be made to attach themselves to the separated surfaces again, and must of necessity afford a lodgment for infective influences.

The loose teeth should be banded to firm ones, and the irritation of their movement in the sockets thus removed; also the occluding surfaces ground down until the excessive strain due to elongation be obviated.

The one final injunction before passing the subject, is to urge the importance of going to meet this trouble—not waiting until the pus filled pockets are thrust upon us. Part of my regular examination is a pressure of my finger upon the gums inside and out all around the mouth, and it has been a matter of surprise to me how many of the apparently unaffected cases showed that light colored exudation, not pus but its almost certain forerunner.

This is the stage at which pyorrhea may certainly be cured, and to use a little Hibernian mode of expression, the best time to cure it is before it has begun.

In taking up the subject of infections from gangrenous tooth pulps, and alveolar abscess, one is confronted by a most appalling array of dangerous possibilities; however, as the subject of this paper was suggested to my mind by a point raised in conversation with a prominent physician, I will quote his remark and then discuss from that standpoint. He said: "I believe in saving teeth and all that sort of thing, but it seems to me that dentists are too anxious to save teeth, and put on crowns to preserve roots that afterwards cause serious trouble and are an injury to health instead of a benefit."

The undeniable force of this statement as generally applied struck me, and a perusal of medical literature showed, in almost every instance, wherever the general practitioner entered upon a discussion of diseases associated with the teeth the same idea governed his reference to the treatment of the mouth.

My answer to the above, was a messenger next day who brought the doctor in to see abscessed teeth treated, and some carious bone removed. I think he

left convinced that correct surgical principles were applied in the mouth as elsewhere, and now my answer to general writers is the bringing forward of well-known methods here urging their general distribution, that our best efforts may not be so often impeded by the suffering endured, and the serious complications that so frequently ensue before the dental practitioner is finally sought for relief.

Miller speaks quite bitterly of the custom of many physicians to disregard dental diseases altogether as a factor in pathology, and says it is as unjust to their patients as it is "discreditable to their profession," but I do not agree with censure of the physician; the fault lies among dentists, and there is where it would please me to apply the spur.

A gangrenous tooth pulp may be removed, the tooth canals disinfected by thorough drying with hot air, or a heated wire, and the use of antiseptics, preferably one that is not a coagulant (I use oil of cassia) and the danger of further infection removed, but when an apical abscess has formed such as is shown in Fig. 4, the destruction of the pus sac and the removal of the surrounding alveolar process as well becomes necessary.

An incision through the gum, followed by free use of a bur in the dental engine, quite readily effects the removal of the diseased tissues, then by enlarging the opening through the end of the root from the inside, medicaments injected into the opening in the crown can be freely forced through the end of the roots, and forced out through the gum, thus washing the entire affected surface perfectly clean.

A tooth thus treated is almost quite as completely under control as if it were extracted and in the hands of the operator, so far as cleaning it is concerned, and if the roots be immediately filled the wounded surface will heal up as readily as a simple cut.

Even the most chronic cases that have resisted other methods for years will yield to this treatment, provided however, there be enough of the periosteum alive, but of course the destructive processes sometimes include also the entire surface of the periosteum, and the root being entirely dead, nature will not tolerate it, and her efforts to get rid of its annoyance will be continued.

A few fragments of necrosed bone are all that was left of that portion of the superior maxilla on the right side, extending from the central incisor to the tubercle, including the floor and part of the outer wall of the antrum, as well as part of the palatal process from the mouth of a young woman who suffered some three weeks before I saw her.

Removal of the necrosed bone, and the teeth in that region with it, the application of the engine, and a large bur over all the roughened edges, washing with peroxid of hydrogen, oil of cassia, and equal parts of peroxid and bichlorid of mercury 1-1000 gave almost immediate relief. A tonic was prescribed (for a slight formation of pus upon one of her thumbs gave reason to fear, as did also her color, that there was danger of pyemia), and also an antiseptic mouth wash, with instructions to use the latter freely. A rapid healing of the parts followed.

For three months a poor unfortunate was kept in one of our hospitals with a fracture of the lower maxillary that refused to unite. When he came to me there were three fistulous openings in his neck, just below the angle of the jaw, into which the Sister

of Charity packed cotton in masses as large around as my fingers.

The fracture had occurred by reason of a blow from some heavy instrument—the man had been slugged and robbed—and search proved at the same time the pulp of a lower molar had been destroyed. Its removal, together with a portion of necrosed bone, syringing as in the last case, and in a few days the patient was discharged as cured.

Of very common occurrence is the infection of the maxillary sinus from apical abscess.

Many cases of so-called catarrh of the nose, throat and ear passages have had their origin from this cause, and have been cured by treatment from the mouth in the following manner, viz: removal of the source of infection by extraction, or treatment of the tooth, and a free opening made through the floor of outer wall of the sinus, as low down as possible, to give better drainage and to allow therapeutic cleansing by forcing medicaments out through the communicating opening into the nose, and with the head thrown back let them run down the throat until they thus reach almost every portion of the exposed surface of the mucous membrane.

I believe it will soon be considered the correct method to open into, and treat through the sinus, every case of chronic catarrh of the nose.

The same lining membrane must and does transmit the infection to the antrum; the offensive secretions thus formed are held as in a pocket where the usual treatment through the nasal passages can not reach them; what more natural, then, than the treatment described above?

No need to cite cases from practice of diseased antrum, we have all had too many of them, but I have given great relief in a number of instances where no purulent suppurative condition of the antrum was present, simply by the direct effect upon nasal catarrh that seemed to be otherwise incurable. One of my patients recently came to me in an extreme state of exhaustion, the constant presence in his throat and stomach of the discharges from his nose had prevented his eating or sleeping for some days and nights; relief was immediate, in fact, while he was still in the chair; and he made a business of eating and sleeping for some days afterward to make up (as he said) for lost time.

Peroxid of hydrogen I use until the passage into the nose is opened up and after it a strong solution of salt and water is quite sufficient and very safe. Thorough drainage, however, is the most important step.

Syphilitic necrosis and lesions of the soft parts of the mouth require in addition to the surgical and antiseptic local treatment, the internal administration of iodid of potassium, and mercuric bichlorid for which, together with a proper general treatment, I always recommend them to the physician, knowing full well that we can each of us do better for the assistance of the other.

The presence of bacteria in such great variety and number in the mouth at all times must be looked upon as a menace, not only to the teeth in their relation to dental caries, but through their action as well upon the mucous membrane, in rendering it more susceptible to the germs of specific diseases, fevers, etc., upon the digestive tract, for many complaints of the stomach and intestines have been found to be caused by mouth bacteria and their

waste products. Even the lungs are subject to this influence from the mouth, therefore its thorough disinfection becomes at once a matter of first importance.

Recognizing this fact, Miller, Black and others have prepared most carefully comparative statements of the strength of the various antiseptics used.

Miller particularly, has demonstrated that the rapid use of the ordinary antiseptic wash, unless accompanied by thorough cleansing is of comparatively little benefit, because at least several minutes are necessary to sterilize particles of food lodged between the teeth.

He recommends the following formula as one having the most rapid action:

R	Acid thymic25	grams.
	Acid benzoic	3.	grams.
	Hydrargium bichlorid80	grams.
	Tinct. eucalyptus	15.	grams.
	Alcohol absolute	100.	grams.
	Oilgaultheria	qt. xxv.	

℞.

Black's one, two, three mixture is:

R	Acid carbolie	i.
	Oil cassia	ii.
	Oil wintergreen	iii.

The wash that I have for some time past given to my patients is:

R	Listerin.
	Glycerin.
	Acid carbolie.

℞. Sig.: Dilute one-half teaspoonful in one-third glass of water, brush on the teeth and gums; hold in mouth and use on silk between teeth at night.

I give instructions to use full strength on the silk; in cleansing the mouth to hold it, and continue its use for several minutes consecutively.

This wash and the manner of using it has given my patients great satisfaction, not only as a means of checking tendency to caries, but also in fevers such as typhoid, by relieving the unpleasant accumulations of mucus, and I believe has exerted an influence toward obviating the deteriorated condition of teeth, which almost invariably follows this class of diseases.

A physician who had noted its effect upon one of his patients got the prescription from me, and now uses it regularly in his practice.

The day is fast approaching when the treatment of the oral cavity will be a battle with therapeutic remedies rather than one of mere mechanical skill, and if I have seemed to give undue emphasis or wearied you with too careful note of little things, let me excuse myself with the honest statement that nothing in my professional experience has given me so much encouragement, so lifted me above the daily grind of bread-winning, or made me feel the great possibilities that are before us so keenly, as the bringing to light of some hidden source of trouble that perhaps for years had caused pain and distress, and being the instrument for its relief, and this can only be accomplished by looking for the little signs that have escaped notice by reason of their deceiving insignificance.

Surely 'tis an honest payment upon the indebtedness of our creation, and after all makes life seem worth the living.

DR. EDGAR PALMER spoke of a new tooth powder recommended to him by a physician for morbid conditions of the mouth, such as spongy conditions of the gums and fungus

growths. The powder was quinin and Dr. Palmer asked those present if they thought there was anything in it.

DR. TALBOT said there were three distinct conditions which were called pyorrhoea alveolaris, and properly so-called too, as each was shown by the flow of the pus from the alveolaris. The first was Riggs' disease, which results from deposition of tartar upon the teeth below the margin of the gums. The second is the condition described by Dr. Ingersoll, characterized by the deposit of sanguinary or serumal tartar and the third, of which variety I have cases at present, is a disease of the gums only, with no particle of deposit. I wish to bring out the necessity for systemic treatment for these cases. Unless the condition is good the disease will not be cured, and if the general system after the cure of the local disease is attacked by gouty, rheumatic or renal trouble the condition of the teeth will return.

We, as dentists, do not pay the attention to the mouths of our patients which we should. It should be the rule to always examine thoroughly every mouth in which we have to do anything and treat and clean it, putting it in a thoroughly healthy condition. This is a very important part of our work and we should get paid for it, otherwise we can not afford to do it. When a patient comes to me, where pockets are observed along the margin of the gums, I remove the tartar from the teeth and saturate the gums with clear tincture of iodine. After the second day, I thoroughly overhaul the mouth and proceed with the treatment as recommended by the essayist. If, however, the teeth are loose, I can not treat successfully, except by removing the teeth. With the teeth extracted, it is a simple matter to heal up the gums and keep them in a healthy condition.

DA. A. M. BENSON asked how the iodine healed the gums?

DR. TALBOT said he did not know how, but knew that it did. He said that it was generally known that iodine would reduce tumors and swellings in all tissues, but we do not know how it acts.

DR. BENSON thought that if the teeth and gums were freed from all foreign substances the healing would come without medication.

DR. TALBOT said that in cases where there was no tartar on the teeth it was often possible to cure by systemic treatment, and spoke of cases in his own practice which he had successfully treated by building up the system, omitting all local treatment.

DR. W. A. GUDEX said that Riggs' disease was perhaps the most puzzling and least promising of the troubles which dentists were called upon to treat. It might be described as an ulcerative pericementitis; sometimes the result of mechanical irritation, sometimes he thought the result of lead poisoning. He had noticed it in painters who had suffered from lead poisoning. He could not boast of much success in treating it. The only radical treatment was to remove the tooth or teeth affected.

DR. J. TAFT said that the treatment of diseased gums was very difficult, but he thought the treatment pointed out in the paper was suitable for a majority of cases. In many cases the general system is in such a state that it is impossible to cure the local disease without systemic treatment; the system must be toned up. In other cases the general condition is so hopelessly poor and defective that it can not be brought up to a state in which there would be hope of success. In such cases the only thing to do is to extract. Then there are cases where the general system is so good, is so well nourished, and has such recuperative power that if the irritant be removed the part will cure itself. Remove all necrotic tissues either by an instrument, or by an escharotic, or by some other remedy such as iodine or peptin; these seem to break down the necrotic substance and to stimulate the circulation which carries off the broken down,

useless tissue. It is necessary to remove everything which will be an injury or an irritant. Simply pressing the finger on the part several times a day will be beneficial, as the pressure drives the blood away, and upon relieving the pressure there is an influx of new blood and an increased circulation which will help to carry off the diseased matter.

Robinson's remedy acts well as an escharotic, and if used as directed will prove efficacious in a large majority of cases. A dentist should always know just what effect he should expect from every remedy he uses, and why he uses the particular substance to effect the purpose.

DR. VIDA A. LATHAM spoke of the structure of the peridental membrane, and said that it had never been properly described. She denied that there was such a membrane, but said that it was the same as the periosteum, and said that there was no reason, just because it ran over the root of the tooth that its name should be changed. The description in the text-books of this membrane vary; some say that it is an elastic membrane and others describe it as a ligament; she thought it showed careless writing in the books when they varied so. She thought a good name for pyorrhoea alveolaris would be osteo-periostitis, meaning an inflammation of the bone and tissues surrounding the bone. These affections do not differ from similar inflammations in other parts of the body. Whenever found they are very hard to treat, as they usually occur in persons of poor organization, whose vital force is low and recuperative power almost nothing. In such cases the very structure of the bone is poor.

DR. G. V. I. BROWN said that his purpose in describing the case in his paper was to bring out discussion, as the case was one of perfect physical health, and he also wished to call the attention of the members of the Section to the fact that the daughter of the patient was troubled with the same disease, showing or appearing to show, that heredity was a factor in some cases.

SHALL THE PRACTICE OF MEDICINE AND THE PRACTICE OF PHARMACY CON- TINUE DISTINCT AND SEPARATE?

Read in the Section on Materia Medica and Pharmacy at the Forty-fourth Annual Meeting of the American Medical Association.

BY J. M. GOOD, PH.G.

ST. LOUIS, MO.

By giving a place for the discussion of problems in pharmacy in this organization, the intimate association of the two callings and their mutual dependence upon each other is emphasized. Yet it is scarcely to be expected that our sessions will be the ones most numerously attended. Those in both professions whom we delight to honor are they who confine themselves strictly to pharmacy, pure and simple, or to the practice of medicine, general and special. Nearly every physician has been made painfully aware, some time in his career, of his lack of pharmaceutical knowledge; hence we hope none will feel the time spent here has been wholly unprofitable.

Materia medica, as the pharmacist studies it, is different from that which is taught in the medical schools, and while we are likely to get hints here as to the therapeutic actions of drugs, they will serve simply as a warning for us to confine ourselves to compounding, and let those better able to judge and discriminate take the responsibility for the effects of drugs. In discussing some problems in which our two professions are interested, I am not unmindful of the fact that those whom I am about to criti-

cise do not attend conventions and to a great extent they are indifferent as to our opinions of them.

In this Section we, physicians and pharmacists, meet on common ground, and we can be mutually helpful. We may criticise each other, but always in a friendly way, I hope, and we may ask and answer questions to the edification of all.

It is too frequently the case that a man's readiness to give advice on any subject is inversely to the amount of knowledge which he possesses in regard to it. This seems to apply particularly to persons who are ready to give information about the action of remedies and the treatment and care of the sick.

Just now there is in the professions of medicine and pharmacy a disposition on the part of each to usurp the functions of the other. This is not the case, however, with the busy or successful man in either calling. He whose time is fully occupied is not likely to suspect any one of invading his field.

The exhibition of remedies is attended with a considerable degree of uncertainty at best. To know definitely the therapeutic action of drugs requires clinical experience with careful and intelligent observation at the bedside of the sick.

Accurate diagnosis must precede these. It is a weighty responsibility which rests upon the physician. Fortunately for him, as his stock of experience increases and his years multiply, he realizes these facts more forcibly than in the beginning.

For the druggist who recklessly and ignorantly assumes these responsibilities he has ill-concealed contempt. To his credit be it said he is willing to concede to the druggist all that he asks for himself, and he is just as prompt to condemn that foolish and dangerous legislation which assumes that the holder of a medical diploma is necessarily a person who, if not an expert and skilful manipulator of drugs, may safely be intrusted in compounding and dispensing them. The absurdity of such a claim is so apparent as generally not to admit of argument. Aside from the injustice of this to the entire business and profession of pharmacy, there is the additional damage to the colleges of pharmacy. They should be strengthened, not weakened. It is the duty of each profession to uphold its educational institutions. We can not, then, with complacency see the right to legally conduct a drug store conferred upon a man who has never served a day's apprenticeship in the business, when a period of four years of active service is required before a diploma from a reputable college of pharmacy will be granted. The easiest and shortest way to legal recognition is the one which will be adopted by the majority; the acquisition of knowledge is not a controlling influence with them.

Shall there continue to be the two professions, medicine and pharmacy, or only one?

If physicians convert their offices into dispensaries, and druggists, seeing their trade melt away, qualify as practitioners and add consulting rooms to their places of business, the dividing line will be obliterated in a generation.

This is retrogression; it is degeneracy. It is opposed to the natural tendency toward the division and distribution of labor and the segregation of all classes of workers into specialists. It is discouraging, it is demoralizing; and it seems to me some action by this Section calling attention to the situation, would be timely and in order. I do not forget

that this is the AMERICAN MEDICAL ASSOCIATION, and any steps taken should be such as would be approved by the conservative members.

Shall physicians dispense their own remedies; or shall the practice which has prevailed now for several generations of having the compounding done on order outside of the office, continue?

As I have already said, the busy practitioner is most likely to call the druggist to his aid. It will probably be said that the labor from which the old-time doctor was so glad to be relieved has been overcome by the modern methods in the manufacture of pharmaceuticals. How dainty, delightful, convenient and *cheap* are the tablet triturates for instance. Let the disciples of Hahnemann beware. Their occupation will soon be gone. *Similia similibus curantur* has ceased to be their strongest card. Sydenham, in his enthusiasm over what might be expected from the potency and convenience of the alkaloids, predicted that the time would come when a physician could carry around with him, in the head of his cane, all the remedies that he needed. His dream is not likely to be realized, for we have long since learned that the therapeutic action of a drug is very different from that of any one or several of its alkaloids.

Seeing this tendency on the part of physicians to do their own dispensing, it might be said that the wide-awake druggist will rise to the occasion and advertise his store as a "physicians' supply house." In time that may be all that will be left for him. At present, however, he is likely to have his triturates left on his hands, a perpetual reminder of mistaken enterprise.

It is impossible, as yet, to "meet all the indications" with these little tablets, and Dr. Saccharum Lactis, so long as he is obliged to send me an occasional prescription, will obtain his supplies through some other channel. But I am told that the triturates alone do not occupy the field. Hypnotics, alteratives, emmenagogues and rejuvenators multiply almost indefinitely. The habit of studying cases and selecting single remedies is becoming impracticable and polypharmacy again prevails.

"Physicians' supply" houses may or they may not turn out products which are accurate and reliable. The dispensing physician, unless he be a druggist, will naturally use the "ready-made" prescriptions.

Many who do not dispense justify the habit of ordering them on the plea that they are more skilfully prepared than will be the extemporaneous prescription in the average drug store. It is in order for pharmacists to question this. The "manufacturing pharmacist" can not monopolize either knowledge or skill. The manager of the establishment is seldom a manipulator of drugs, and often the assistants have placed upon their services a very low pecuniary value. I do not say this in a spirit of condemnation, but to show that in the use of such preparations there is not the universal safety which some suppose. For the most part they are not dangerous, since in the manufacture of the so-called "elegant" pharmaceuticals there has not yet been discovered any way of disguising disagreeable drugs that is so successful as omitting a large part from the mixture. To any one having the best interests of medicine and pharmacy at heart this state of things is not gratifying. Druggists who by years of faithful labor

have established a reputation will not be seriously affected, but the inducements for others to come forward and take their places are growing small by degrees and beautifully less. The following, quoted from a circular recently received, is a good example of the claims of superior skill which are often made by the mixers of proprietary remedies:

An elegant preparation, in powder form, resulting from the union of salol and acetanilid, skillfully combined with an alkali, which, with the *peculiar method of compounding*, greatly modifies and positively improves the therapeutic effects.

In point of quality, as a *fine and scientific* pharmaceutical product, this preparation is surpassed by none. The *chemist* properly *apportions the ingredients* and the elements are combined by *positive chemic* laws, that always produce perfect and uniform results. This careful method is observed that the greatest possible therapeutic benefits may be derived from the union of the composing elements, and a *peculiar* and entirely *new*, therapeutic agent is the result. The proprietors spared no *time, labor nor expense* that they might present to the medical profession a *perfect remedy* in its class, uniform in strength and action.

In comparing the claims of this with similar preparations in the market, we invite the particular attention of the profession to this fact: we state positively what it is made of. We do not refer to coal tar derivatives in any mysterious or indefinite way, but state plainly that acetanilid and salol furnish the active elements.

Will the physicians who prescribe these remedies, and the patients who afterward recommend them to their friends and purchase them without prescriptions, never learn that it was to make money and not to benefit mankind or alleviate their sufferings that actuated their originators?

By the aid of these conveniences in the shape of ready-made prescriptions, triturates and mixtures of various antipyretics the labors of the advertising specialists are made easy and, much to the injury of both physicians and druggists, the free dispensaries multiply.

It will be maintained by some, perhaps, that the druggist has only himself to blame for his vanishing business, they claiming that either by his practices or his incompetency he has forfeited the confidence of the medical profession. We must ask for a "stay of judgment" in this matter. Do not condemn all or any considerable part. It is allowable to discriminate against dishonorable, dishonest and incompetent men wherever we find them; they are as likely to be found in the pharmaceutical profession as elsewhere, and no more so. According to my observation, pharmacists are as a class, careful, painstaking and well qualified to stand where they are often needed, between the prescriber and the patient.

We are all fallible, and every man, some time in his life, will probably be obliged to acknowledge his responsibility for errors. The blunderer and the possible victim are alike fortunate when some one stands between them. This is possible only when the prescriber and the dispenser are two persons.

SELECTIONS.

Too Many Medical Societies.—We are suffering in this country from too many medical societies. The recent meeting of the Northeastern Ohio Medical Association in this city was a good illustration of the amusing phenomenon of the city specialists reading papers to the country practitioners without the presence of the county practitioners. While

many of the district medical societies in Ohio are doing good work and are most creditably conducted, yet it must be conceded that these societies are conducted and supported to the detriment of the county and State societies. It is also a lamentable fact that some of these societies are directly and openly antagonistic to the local and county societies, and thus do great harm. Another phase of this tendency to create innumerable medical societies was the recent second annual meeting of the Ohio State Railroad Surgeons, in this city. The meeting was announced with a great flourishing of trumpets and a most formidable appearing program covering three days. Notwithstanding all the newspaper notoriety and other advertising, only a handful of railroad surgeons was present, and all the business of the meeting was transacted and papers read in two short sessions. But this is only an example of the tendency to form district, State, tri-State, National, and every other possible excuse that can be thought of to organize new societies. The men who organize and run and get all the eclat and offices and free advertising from these societies, are not as a rule, the men of real scientific ability, and not usually the men who are respected by their fellow-workers at home. In fact, they are too often the men who are in bad odor and who do not hold the esteem and respect of those who know them best, and consequently are obliged to go away from home, where they are not known, in order to secure these positions of honor. Not infrequently these men manipulate the State and National organizations for their own purposes, as long as possible; and when they are found out and turned down, they go off and organize a new society. And the pity of it is that the respectable, well-meaning, intelligent, scientific practitioners will go into these new organizations and lend to them a certain respectability; and, in fact, without the labors of these unselfish members of the profession, they could not and would not exist.

Consequently it is of great importance for every one to carefully investigate the claims for existence which every new society has upon the profession, before lending it support. If properly conducted, the county, State and American medical associations would fulfill all the requirements of medical organizations of a State or National character; and in larger towns, one or more local societies would meet all the necessities of the case. By dividing the work into sections, as is done in the large Eastern cities, many of the local societies might be dispensed with. As a matter of fact, the great bulk of the work will be done by a limited number of individuals, no matter whether there is one or a dozen local organizations. The same is true of district, State, tri-State and National organizations; but the disadvantage of having a multiplicity of societies is much greater in the larger bodies. It is becoming impossible for a man to attend all the medical societies he might wish to, as at present organized.—*Cleveland Medical Gazette.*

Georgia and Boards of Health.—We regret to perceive a spirit of opposition to a State Board of Health in Georgia, which is being manifested by some of the medical profession in our sister State. The line of arguments used in opposing the measure seems to be that it is the "duty" of the general Government to take charge of and defray the expenses attendant on an epidemic of any disease, thus relieving the tax-payers of the State. The *Notes* concedes this privilege to the general Government, and if we should get into a "tight fix" again, which we do not apprehend, we will have no backwardness in coming forward promptly to ask assistance. The statute law creating the State Board of Health of Florida provides for this emergency. But when the Marine Hospital Service assumes charge or assists the State or local authorities in the management of epidemic diseases

its work and aid is confined to the locality or localities attacked. The authority of the Government does not extend over the whole State, and we do not understand that it was even proposed that it should. As a sequence local quarantines, under diverse management and more generally than otherwise, with unreasonable restrictions, very seriously damage the commercial interests of the State and neighboring States, and at the same time do not render the slightest assistance in health protection. The benefits to be derived and which Florida has enjoyed from a State Board of Health have been those arising from a central control in health matters, covering every part of the State. Instead of a hydra-headed health government, as used to prevail—each town for itself—with power to produce, by irrational quarantines, incalculable damage to the neighbors through local jealousies, Florida has now one central guiding power in health matters—the State Board of Health, through which instruction in sanitation is distributed to the people and under whose authority alone can surveillance measures over travel be instituted. It is not alone in matters connected with epidemic disease that the State Board of Health of Florida limits or confines its operations. Vital statistics, the movement of the "life wave" of the State claims a large share of attention and close study. As yet no direct good results can be seen, but this will be better realized and more profitably enjoyed in a few years more, particularly as each twelve months sees additional improvement in the method of securing the desired data.

The *Notes* trusts that Georgia may be fortunate enough to secure from her Legislature the needed legislation for a State Board of Health.

We invite attention in this connection to the following remarks made by a distinguished member of the medical profession:

"Both in preventive measures that are going on at all times and in the management of an epidemic, a State Board of Health is essential; and the time is not far distant when a State without a State Board of Health will be as anomalous as a State without a system of schools or militia."—*Florida Health Notes*.

Larvae of *Lucilia* in the Human Ear.—The *Insect Life*, November, publishes two instances of reported larvae occupation of the ear, from the State of Washington. As the *locale* is rather unusual, being so far to the Northward, the correspondent takes pains to state that "both stories are well authenticated." The following are the chief points of medical interest in these two cases:

"A. B., a rancher and logger, while driving home from town one evening last week felt a bug or fly of some kind strike his ear and crawl in. He endeavored to remove it and supposed he had done so. A few days later his ear began to pain him, and he thought he could feel something crawling within. It became unbearably painful so he prevailed on a friend to pour the ear full of *turpentine*. The effect was magical. Twenty maggots came from the ear. A number of persons witnessed the exit of the maggots. Dr. Green was called and concluded that the fly had remained in the ear long enough to 'blow,' possibly, a score into the ear, though the man thought the ear perfectly well. The victim is recovering, and the hearing appears not to be affected."

The insect was probably the *lucilia macellaria*.

The second case, that of a lad working on a farm, is noteworthy on account of the alleged enormous larval colonization in his ear, and of the apparent efficiency of a very mild remedy.

"B. C. had been troubled with a painful ear for several days. After much persuasion on the part of his employer,

the young man permitted the latter to examine his ear. He poured in some sweet oil, then took a straw and made a careful examination, after which he laid the boy on his side, and much to his astonishment about 150 maggots came out of his head and dropped onto the bench. The supposition is that a blow-fly had gotten into the boy's ear some time while he was asleep and the maggots had hatched out and crawled into his head out of sight, thus causing him much pain. The boy had worked hard during the hay harvest, and was not willing to consult a doctor, although after the above discovery he was persuaded to do so."

The pseudo-parasitic invasion in this case was probably by the *lucilia*. In earlier numbers of the same journal there have been reports of cases of a similar character, the treatment of which has been successful by the use of an infusion of tobacco and by instillation with chloroform. Failures, also, have been recorded there and elsewhere when any other than mechanical means have been used. Much must depend on the integrity of the drum membrane, whether the remedial agents can be satisfactorily applied or not, but this is a condition that is seldom made a part of the reported cases that come to us from the West and Southwest, where by far the greater number of cases occur in recent years. The use of oil of turpentine has been reported before, but we do not remember to have seen it recently. We would, a priori, judge that it would be a strong antagonist to larval life.

Mental Disorders in Diabetes.—The disorders occurring during diabetes in the centers of motion, feeling, and nutrition are well recognized, but mental disorders are hardly known. French authors principally have written concerning them Stanislaus Ierzykowski cites three cases of diabetes complicated with mental disturbances. In the first case there was melancholia with suicidal ideas, lasting about a year and disappearing when the patient became very weak, toward the end of the disease; in the second case there was mental debility, which temporarily improved in proportion with the decrease of the quantity of sugar in the urine; in the third there was considerable pruritus vulvæ with general uneasiness. In all three cases there was no hereditary influence. He also quotes a previously-observed case of epilepsy, which occurred suddenly, together with diabetes, at the sight of an epileptic fit; both the epilepsy and diabetes disappeared after one year's duration. The author also mentions one other case in which the quantity of sugar suddenly increased greatly under the influence of disagreeable emotion. Mental disorders in diabetes generally bear the character of intellectual depression or debility, and the cause of their development is not known.—*Nowing Lekarskie*, July and August, 1893.—*Universal Medical Journal*.

Four Cases of Trismus Neonatorum Treated by Tizzoni's Antitoxin.—Of four cases of tetanus neonatorum treated by Tizzoni's antitoxin, one was saved. In two of the cases the changes in the lungs (septic pneumonia) were such that they were properly considered as the cause of death alone. The fourth case presented such violent symptoms and such a high grade of infection that the injections were useless. In the first case treated, the dose of the antitoxin was much too small. The third case (the one which recovered) as well as the other three cases, there were evidences of septic infection. Antitoxin was twice injected in doses of 0.3 gm.

On the day after the second injection, the contractions ceased, the child was again able to nurse. There still remained, however, for several weeks spasms, and a moderate degree of trismus.—SEIFERT of Wurzburg, in *Centralblatt für Klinische Medizin*, November, 1893.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, JANUARY 6, 1894.

THE SPELLING REFORM.

At the Annual Meeting of the American Medical Editors held in Milwaukee, the Annual Orator took up with enthusiasm the subject of the spelling reform. The orator was forcible in his expression, happy in his manner and persuasive in his style. The American Medical Editors present agreed then and there, that each would begin the use of the reformed spelling on his return to the editorial tripod. The vote by which this conclusion was reached was unanimous, a sure sign that it was taken without much reflection. That this view is the correct one there is much evidence, because the new spelling is seldom adhered to, and in many instances the practice has been made the subject of direct attack.

One of our valued contemporaries, from whom to differ is painful, says in an outburst of ridicule that the new spelling makes the English language "hideous," and that it is an attempt to make an American language, and he fully convinces himself that the Association of American Medical Editors were wrong, hasty and ill advised. This article has been copied into the columns of several journals, whose editors, if we mistake not, were represented at the meeting. The English language has always advanced by excision, and in the present movement we only hasten changes that our English brethren are sure to adopt sooner or later. To prove this, we need only to open some of the volumes on our shelves.

About the earliest elaborate book on surgery in English, is in black letter:

"The most excellent worckes of chirurgery, made and set forth by Maister John Vigon, head chirurgen of oure tyme in Italy, translated into Englishe. Whereunto is added an exposition of straunge termes and unknowen symples belongynge unto the arte.

"Imprynted by Edwarde Whytchurch wyth the Kynge's most gracions priuelege for seven yeres. A. D. 1550."

In writing of furuncles, he says, among other things:

"When ye chaunge this playster, laye upon the sore this liquid cataplasma $\frac{1}{2}$ of the foresayde decoction ii-iii of the floure of barley and wheate *ana* ʒi. Of comune oyle, of buttyre, of swyne's grece melted *ana* ʒij wyth the yolkes of foure egges, let them seeth all together except the yolkes of the egges," etc.

He then gives a long discourse on furuncles, and concludes the chapter with the following:

"This is our short curation of froncles whyche we haue oft prosued with good lucke. Thus we end the fyrst parte of the second booke; for which God be prayed and thanked."

Of Apostemes whyche chaunceth in the corners of the eyes: "It chaunceth often if a catharous matter descendethe from the brayne to the corners of the eyes and tarryeth there by reason of the concavite of the place, and it is sone healed. But if it be not taken awaye quyckely, by pressynge the outwarde parte of the eye, it wyl come to a flegmatyke Aposteme." And again: "When ye perceyve that the Aposteme commeth to rypenesse (whyche thyng ye maye knowe by the reddenesse and beatynge whyche continueth wyth elevation of the parte, by reason of the quytture multiplied in the place, and lykewyse by the redormdyng and rysynge agayne, whan a man presseth thereon hys fyngers, lyftynge by one and thrustyng downe another) than it is conveniente in the rypest place wyth a sharpe lancette to open the sayde Aposteme."

"Nevertheless, wee wyl adde one thyng whyche is that in the tyme of mundification the place may be mundified wythoute perturbation of the eye, putting in thre tymes in the weke a lyttle of oure powder of mercurye whyche taketh awaye superfluous flesh wythoute payne, and is written in our Antidotarye."

We also notice that arm is spelled "arme;" egg, "egge;" first, "fyrste;" third, "thirde." We doubt if those who are so shocked at the modern changes, would be willing to return to the primitive English spelling or even to restore "u" to the words "color" and "honor," or the final "k" to the word "music," as most of our English contemporaries now do. Only a few years ago somebody proposed dropping the final "me" from the word "programme," and although the change was bitterly opposed it was made.

If, as our contemporary suggests, the outcome of the spelling reform movement will result in an "American Language" let it come. It will be clearer, stronger and freer from incongruities than the composite language from which it sprung. It will be easier for the remainder of the world to read and understand, when its superfluous letters shall have been eliminated.

TAXING PROPRIETARY MEDICINES.

The Ways and Means Committee, of the House of Representatives, has recommended the restoration of

the tax on proprietary medicines. If to the tax, the printing of the ingredients on the label would be required, much could be accomplished in the interest of the people and the profession. In this way this subject is regulated in European countries. Some of the preparations have value, and can be used by the public with safety, while many of them are not alone dangerous, but worthless, and their sale is dependent entirely upon the fraudulent claims to cure everything, in their advertisements. In fact, if this advertising was stopped, they would find no sale, and just in proportion as it is pushed, are they sold. They appeal to the hopes and fears of the sick and afflicted, and it is the obtaining of money under the worst kind of false pretenses, and is really nothing more nor less than robbery. While Congress is engaged in this business, would it not be well to tax the itinerant practitioner and vender of nostrums, with show accompaniments? They go from one State to the other, and the question naturally arises whether this is not one of inter-state commerce, and should be regulated by Congress. It is the policy of this class of frauds not to stay too long at one place, or to return at too short intervals to the same place, for the reason that it takes time to secure a fresh crop of dupes.

THE HERZ CASE.

DR. CORNELIUS HERZ, the Panama briber, who has been wanted by the French Government, has been sick at Bournemouth in England for the last five months. It was claimed that his removal would result in death. The French Government pressed so hard for his extradition, that an English commission was appointed to examine into his condition, and a report was made to the effect that his removal might endanger life. Later, a French Commission, one of the members of which was BROUARDEL, was sent to Bournemouth to examine him. This Commission came to the same conclusion. A report of the results of this investigation was made to the Academy of Medicine of Paris, causing quite a sensation. Many of the members denounced the report, and to quiet matters it had to be withdrawn. Since, the French Government has given up the idea of extradition. Take it all together it is one of the most extraordinary cases on record.

DR. HERZ for a short time in 1870 was connected with the Chicago Board of Health as Sanitary Inspector. He was well qualified, of agreeable and insinuating manners; prompt and very aggressive in the discharge of his duties, with, however, too exalted an idea of himself and his position. He did not remain long, as the sphere for him was too limited. From Chicago he went to San Francisco, where he cut a wide swathe in his peculiar way. He was not satisfied with small things, and next we hear of him as one of the most prominent characters in Paris,

and one of the prime movers in the Panama frauds. When exposure occurred, he fled to England where he has been since, a fugitive from justice, while some of his confederates have been punished. How soon he will now recover remains to be seen, as the French Government has evidently abandoned the further prosecution of the Panama suits. His career has been unique.

THE JOURNAL.

The JOURNAL this week is sent to very many who are neither subscribers or members, with the hope that upon careful comparison with other weekly medical journals they will conclude that however valuable those publications may be, and however admirable they may be in many, very many particulars, yet the JOURNAL OF THE ASSOCIATION owing allegiance to no publisher, to no manufacturer, owned only by the profession itself, and managed on that basis, is surpassed by none.

Whatever it is, the profession alone has the credit or the blame.

The following table gives the comparative statistics of the volume which closed with the last issue:

July 1, to December 30, 1893.	Journal Am. Medical Association.	N. Y. Medical Record.	N. Y. Medical Journal.	Boston Medical Journal.	Philadelphia Medical News.
Number of Original Articles . .	240	176	158	132	175
Number pages Original Articles,	665	334	380	300	397
Total number pages	1,024	860	816	660	756

“Comparisons,” says MRS. MALAPROP, “are odorous,” and we have no desire to use this table for any other purpose than to show our medical men what has been accomplished by their own JOURNAL, and to put a stop to the everlasting cry of inferiority, and covert attacks on our advertising business. The JOURNAL has come to stay. The members of the ASSOCIATION who were instrumental in founding it, are proud of it, for they have seen with pleasure its steady and regular growth from its rather slender foundation.

We by no means wish to imply that the JOURNAL is a finished production.

Quite the contrary. We believe that with the ASSOCIATION now fully awakened to the excellence of the JOURNAL, there has been created an interest that will cause it to begin a new and more extended sphere of usefulness. With the increase of membership will come the sifting process that has been asserted to be the chief need of the ASSOCIATION.

But, dear reader, look at the vast table of contents printed last week, and ask yourself which of the ASSOCIATION papers you would have omitted and which you would have abstracted. No! We assert

plainly and fearlessly, that the ASSOCIATION papers have never been better than those of this year, and that the Section officers have never been more thorough in their supervision.

That there is still room for improvement every one knows, but in this world there is room for improvement in almost everything, as the era of perfection has not yet been attained.

Let the members of the ASSOCIATION therefore, with renewed vigor apply themselves individually to the task of increasing the membership, conscious that in union there is strength and power, and that their reward is certain and not far distant.

RIGHTS AND LIABILITIES OF BOARDS OF HEALTH.

Boards of health and other like boards act summarily, and it has not been usual anywhere to require them to give a hearing to any person before they can exercise their jurisdiction for the public welfare. The reason for this is that the public health might suffer or be imperiled, if their action could be delayed until a protracted hearing could be brought to a termination. This, however, gives rise to certain very interesting questions. The Court of Appeals of New York, in the case of *People v. Board of Health of City of Yonkers*, decided Nov. 28, 1893, has carefully considered the subject, both with reference to the interests of the public and the rights of property owners. The conclusions reached by the court are very instructive, and are said to have the support of the best reasons and of ample authority.

First, the court says the question may be asked, How can statutes conferring powers upon boards of health to interfere with and destroy property, and to impose penalties and create crimes, stand with the Constitution, securing to every person due process of law before his property or personal rights or liberty can be interfered with? The answer must be that they could not stand if it were necessary to hold that the acts referred to made the determinations of the board of health, as to the existence of nuisances, final and conclusive upon the owners of the premises where they are alleged to exist. Before such a final and conclusive determination could be made, resulting in the destruction of property, the imposition of penalties and criminal punishments, the party proceeded against must have a hearing, not as matter of favor, but as matter of right; and the right to a hearing must be found in the statutes themselves.

Boards of health, under such statutes, can not, as to any existing state of facts, by their determination make that a nuisance which is not in fact a nuisance. They have no jurisdiction to make any order or ordinance abating an alleged nuisance unless there be in fact a nuisance. It is the actual existence of a nuisance which gives them jurisdiction to act. Their acts declaring nuisances may be presumptively valid

until questioned or assailed, for the same reasons which give presumptive legality to the acts of official persons.

What operation, then, does an order or ordinance of a board of health have under these statutes? The nuisance actually existing, and the jurisdiction having been regularly exercised, the order or ordinance has all the operation and effect provided in the statute, and the persons who abate the nuisance have the protection which they would not have as private persons abating, not a private nuisance especially injurious to them, but a public nuisance injurious to the general public.

It may be said that if the determination of a board of health as to a nuisance be not final and conclusive, then the members of the board and all persons acting under their authority in abating the alleged nuisance, act at their peril; and so they do, and no other view of the law would give adequate protection to private rights. They should not destroy property as a nuisance unless they know it to be such, and, if there be doubt whether it be a nuisance or not, the board should proceed by action to restrain or abate the nuisance, and thus have the protection of a judgment for what it may do.

It may further be asked, What, under this view of the law, is the remedy of the owner of property threatened with destruction or actually destroyed as a nuisance? He may have his action in equity to restrain the destruction of his property if the case be one where a court of equity under equitable rules has jurisdiction, or he may bring a common law action against all the persons engaged in the abatement of the nuisance to recover his damages, and thus he will have due process of law; and, if he can show that the alleged nuisance does not in fact exist, he will recover judgment, notwithstanding the ordinance of the board of health.

THE PROVINCE OF EXPERT TESTIMONY.

A clear exposition of the province of expert testimony is made by the Supreme Court of New Jersey in *Koccis v. State*, just reported. In this case, attempt was made to prove that a foreigner who spoke broken English could not use certain English words attributed to him, nor words of the same purport and meaning. This, it was held, was not a subject for expert testimony. The testimony offered, if admitted at all, the court said, would be received not as an expert's opinion, but because it came within that class of cases in which a witness may state the inference drawn by him from facts within ordinary knowledge occurring in his presence.

Familiar instances in which testimony of this kind may be given, the court says, are: whether two people were in love; whether a man was sick, or dazed, or despondent, or drunk; whether a dog was

savage, or a horse gentle,—and, in general, any matter touching physical or mental manifestations or appearances, as well as all questions of identity, resemblance, duration, distance, dimension, velocity, noises, smells and many other matters where the inference drawn by an observer is commonly recognized and received as an equivalent for the congeries of facts that produce it. But testimony of this class, however, so far from being related to expert proof, rests upon diametrically opposite grounds.

The expert witness is one whose possession of special knowledge renders his opinion admissible upon a state of facts within his specialty, without regard to the manner in which the facts are established, and without requiring that they should have come, in whole or in part, under the personal observation of the witness; whereas, the sole ground upon which a witness may give an opinion as to matters of ordinary knowledge is that they not only came within his personal observation, but that they come into proof so blended with the opinion to which they give rise that it is receivable in proof as a substitute for a specification of the host of circumstances that called it forth.

A failure to observe this distinction results, at times, in the offer of an ordinary witness to give an opinion calling for special knowledge, merely because he has had actual observation of the facts, and at other times in the offer to prove an opinion upon a matter of ordinary knowledge arising from assumed facts, by a witness who has not himself observed them, upon the ground that he is expert upon the special subject. In either of these classes of cases the proof must be rejected; the rule being that mere opportunity will not change an ordinary observer into an expert, and that special skill will not entitle a witness to give an expert opinion when the subject is one where the opinion of an ordinary observer is admissible, or where the jury is capable of forming its own conclusion from facts susceptible of proof in common form.

PHYSICIANS CAN NOT TESTIFY.

The policy of the law is to make the relation of physician and patient confidential and sacred. Only the patient himself, or, in case of his death, his legal representative, may waive the seal of secrecy and confidence. Thus holds the Supreme Court of Indiana, in the case of *Gurley v. Park*, decided Nov. 23, 1893. The application given to this doctrine here is to the effect that in a case where there is no legal representative, as administrator or executor of a deceased person to make waiver, the physician who attended her can not testify in an action to set aside her will as to her mental condition at the time she made the will, he being present in his professional capacity. The law, this court says, forbids the phy-

sician from disclosing what he learns in the sick-room, no matter by what method he acquires his knowledge.

CHOLERA.

Cholera seems to be again on the increase at St. Petersburg. The average number of cases for the past week have been 150, and the deaths 20 daily. On December 23, the British steamer *Eton*, from Sovlina, at the Danube's mouth, for Rotterdam, was detained at Gravesend for twenty-four hours for fumigation and examination. There have been three cases of cholera aboard her. The man who was stricken last had recovered on December 13. Cholera has again broken out at Liege, where it was supposed to have been stamped out.

SICKNESS AND PAUPERISM.

We invite our readers' special attention to the paper of Dr. BRYANT of Cambridge, which appears elsewhere in this issue, and to the discussion thereon.

No topic could be more timely, and the experience of the writer is such as to invest his utterances with great weight. Every city physician should read this paper of Dr. BRYANT's and do what he can to act on its precepts for the prevention of pauperism.

DR. PAUL GIBIER read a paper "On a New Agent in the Treatment of Epilepsy," before the New York County Medical Society, on December 25. The material used was the nervous substance of the sheep, great care being exercised in securing absolute purity in the matter employed. He cited nine cases in which there were beneficial results, and in four of these there were positive cures. "To sum up my results," he said, "in the treatment of epilepsy by injections of extract of nervous substance, I shall conclude by repeating, as in my first communication, that this method is especially beneficial in adding to the favorable effects derivable from other therapeutic agents, and by its application in the majority of instances the improvement is most satisfactory."

CORRESPONDENCE.

An Open Letter on Inoculation as a Preventive of Yellow Fever.

ATLANTA, GA., Dec. 15, 1893.

To the Editor:—As you are aware, I have taken great interest in the matter of preventive inoculation against yellow fever since the publication of the experience of Dr. Domingos Freire appeared in Brazil, more than ten years ago. My efforts were first directed to enlisting the influence of Dr. Joseph Holt of New Orleans, in support of a thorough investigation of this subject, under the impression that the people of that city ought to feel an interest in the results of such an inquiry. As a sequel of the agitation of this question by him before the American Public Health Association, and through the public prints, it was deemed proper by the

United States Government to send Surgeon G. M. Sternberg, U. S. A., to Rio de Janeiro to observe the working of yellow fever inoculation and report upon the same. Being impressed with the great difficulties likely to be encountered by one individual in getting a proper understanding of the facts presented in connection with the use of inoculation in a foreign land, I sought to secure the coöperation of others in this undertaking.

Resolutions were adopted at the meeting of the AMERICAN MEDICAL ASSOCIATION at Chicago in 1887, upon a motion by me, requesting the President of the United States to send two other competent members of the medical profession to assist in getting the data requisite for a proper comprehension of what had been accomplished by Dr. Freire.

Upon your motion, this action was rescinded, after a vote of a large majority of the ASSOCIATION against a motion for reconsideration. This was clearly without the sanction of parliamentary usage, and yet availed to arrest any further steps in that direction.

The unfavorable verdict of the special commissioner is well known to all who are conversant with this matter, and was such as might have been expected from his mode of conducting the investigation.

Only upon one occasion since that time have I made any effort to bring this subject to the attention of the profession or the people of this country.

But had I been present at the meeting of the AMERICAN MEDICAL ASSOCIATION at Nashville, when the President in his annual address undertook to commiserate the shortcomings of Freire, I should have met him with facts. In like manner, your comments upon yellow fever inoculation in your address as Chairman of the Section on State Medicine would most assuredly have received my attention, appreciating fully the complimentary terms in which you were pleased to refer to me.

I suppose the snap judgment of the committee who passed upon the claims of yellow fever inoculation at that time may have been considered final by the Section, and that you may have written its epitaph with *requiescat in pace* inscribed upon the mausoleum. But the stone placed upon the tomb and the seals affixed are destined earlier or later to be removed, and it will be verified that "truth crushed to earth will rise again."

I am in possession of facts confirmatory of all that has been alleged in favor of the results of inoculation against yellow fever, as put in practice by Domingos Freire in Brazil, and expect to present them before the medical profession at an early day.

It has not been from any diminution of my faith in the efficacy of inoculation in modifying materially or preventing entirely the access of yellow fever, that I have kept quiet during the past five years in regard to it.

My time and attention have been too much occupied latterly with matters which were of more importance to me personally and professionally, than the attempt to convince people against their will of the reality of the exemption secured by yellow fever inoculation. But some of the problems, which I have been working out, are now solved; and I am disposed to take up again the investigation of the claims of inoculation to the adoption of our people in the South.

I was pleased to learn from Dr. Holt during my attendance at the meeting of the Southern Surgical and Gynecological Association in New Orleans, that he has not despaired of realizing the benefits of inoculation as a prophylactic against yellow fever.

Notwithstanding the diatribe against Freire's methods in an editorial of the *New Orleans Medical Journal* of January, 1886, and the soft impeachment against Dr. Holt and myself

as having acted precipitately and without due consideration in advocating his claims to recognition, we are very far from giving up the fight in behalf of inoculation as a prophylactic measure against yellow fever.

The attitude of experts in regard to the immunity afforded by an attack of yellow fever comes to the support of what has been demonstrated by the very small fatality of persons not acclimated, who have been inoculated in Brazil. I am aware that bacteriologists of repute claim that no such microbe as the cryptococcus xanthogenicus, which Freire has described, can be discovered by a scientific investigation. But let it be denied that such a representative element exists in the form he has delineated it, this fact does not set aside the positive results obtained with his attenuated virus as a preventive against the dreaded disease.

I am not aware that the microbe of smallpox or that of cowpox has been definitely determined by bacteriologists. Dr. Eugene Foster, in his article on smallpox for the "Reference Hand-Book of the Medical Sciences," says: "We have no satisfactory proof that either vegetable germs or bacteria constitute the essential elements of the disease." Yet no scientific investigator at present hesitates to accept the plan of vaccination introduced by Jenner for preventing or modifying materially the access of variola. Neither has the microbe of rabies been ascertained with certainty in the investigations of Pasteur, but he continues to record the prophylactic virtues of the rabic virus obtained from the desiccated medulla of infected rabbits. His last report of the treatment of persons bitten by rabid animals in the Pasteur Institute at Paris, shows a fatality of less than one-fourth of 1 per cent., and the reports from the Chicago Institute and the New York Institute indicate like favorable results, in this class of cases.

It is evident, therefore, that past experience in this prophylactic mode of dealing with such disorders has proved eminently satisfactory without a recognition of microbiology in using an attenuated virus. Call it empirical, but the efficacy can not be questioned.

I have an abiding conviction that you would magnanimously admit the claims of this great prophylactic measure for the protection of our Southern ports, if you could see this matter in its true light. Your energetic administration of the sanitary work of the Marine Service in former years must have impressed our people with your discretion and zeal in adopting efficient measures against the spread of yellow fever. Should your mind be directed to a thorough comprehension of the details of the practical working of yellow fever inoculation, disconnected with any scientific investigation of the microbial element, I should expect you to be so impressed with its benefits, that at least you would be disposed to test this process in places where yellow fever may occur in future years. If this is done, I shall yet realize my fondest hopes in the adoption of this process among us. Yours sincerely,

J. McFADDEN GASTON.

How to Encourage Crimnals.

CHICAGO, Dec. 26, 1893.

To the Editor:—In THE JOURNAL of Dec. 23, 1893, Dr. W. P. Howle writes on "How to Manage Criminals." I approve of the publication of such articles by medical men to the end of becoming versed in sociology. Students of medicine are better prepared to give an opinion which approaches to accuracy concerning the health of a given criminal than is the ordinary layman.

Perhaps it was for want of space that the Doctor did not define crime, so that we might know who to brand as being wicked and deserving of punishment. Crime is the violation of a statute.¹ A criminal is one who knowingly violates a statute.

Since crime is by virtue of statutory enactments, it is pertinent to inquire whether the framers of our laws possessed more of virtue than they who violate them. In the case of William Lloyd Garrison and Wendell Phillips, it is

¹ The traditional decrees of judges, though unwritten, and called common law, are included in the term, statute.

now generally conceded that they were more justified in violating certain sectional laws than they would have been in keeping them. Other instances are of ready citation.

Laws are made in this country by majorities. These are operative against all alike when the majorities are humane, just, equitable. But these qualities are about as often lacking as they are present in modern legislators, who are products of majorities.

A child up to the age of 7 is not regarded as a person—only an attaché to its parents. Hence, notably, Judges Earle and Keating, declared that up to this age crime could not be committed, and I think all will agree also, that a criminal act committed by an insane person would not be answerable to the law.

The following is accredited to Rousseau: "The riot which ends in the deposition or death of a Sultan is as lawful as the acts by which he could, the day before, dispose of the fortunes and lives of his subjects. As his position was only maintained by force, so by force only was he overthrown." This is now as then, in accordance with everyday observation; and so is also the further fact, that in the absence of all human laws there would be a total absence of force. I am not oblivious to the fact that this imagined condition of society is spoken of as one of chaos, of confusion, of general rapine. That this last is not, however, a proper definition of the absence of majority-force is only too evident. Take, for instance, the encroachment on one's known personal rights. Whether the encroachment is by a stronger person or by a community through its laws, such encroachment would be injustice and its enforcement would produce confusion. Plainly, the presence, not the absence of law, engenders riot and justifies pillage. The individual who was being deprived of his rights was peaceable; the others were the marauders. As an instance of this latter mode of force, I will mention only the granting special privileges to private corporations to engage in business to a greater or less extent on our streets, alleys and highways. These in theory, and should in fact, belong to each and every one of the community in a manner and degree alike.

The Doctor says that "philanthropy and charity are well enough in their place, but to treat criminals on the theory that they are only sick people is a dangerous and an unholy *fad*." With this I am inclined to agree, excepting that I would speak of criminals of the class he seems to point out, not as being sick, but as being of imperfect organization and training. About uprightness, especially of the average modern legislator, I think I have the right to claim the Doctor's agreement with himself that to put him (legislator) on the list of sick people and treat him as such, would impoverish any nation on the globe.

Modern penology is being developed along two very prominent lines. The one, which is the old, is sufficiently clear when expressed in the Doctor's own language: "The way to manage a criminal is to punish him for his crimes, and this is the right and only safe way to manage him," and is known as the revenge method. While the new, a method advocated by another class of penologists, regards the criminal as being short to a lesser or greater degree in the substance or form of one or more of the convolutions of the cerebral cortex or nerve trunks. Hence they assume that his ideas and opinions of society and of laws are different from those who have their brains in substance and memory-images adjusted to what is more commonly believed to be on a normal line. To be a criminal according to this school does not require that he shall be in a state of ill-health, but that there is in him a failure of adjustment to environment in accordance with a societary standard, or requisite, of gray matter and axis-cylinder tissue. Hence to fully and markedly distinguish the work of this school from the former it is given the fast-running name, "*fad*." If this name is not appropriate to represent the work of a school of penologists it is wholly owing to the poverty of philology.

Upon the other hand, we, of the medical profession should labor to make more intimate the relations that all hold to each, and each member of the human species holds to every other; or, as it is more commonly expressed but seldom comprehended, the universal brotherhood of man. This racial relationship is more effectively furthered by kindly tutoring such of our species as are physically delinquent, to so round out character in whomsoever it is found lacking, which rounding out is essential to membership in the households of equity, far more than by driving them away from our presence by an emotional outburst of fury, by a drastic wave of judicial revenge.

CHARLES J. LEWIS, M.D.

733 Carroll Avenue.

Objectionable Photographs.

CHICAGO, ILL., Dec. 29, 1893.

To the Editor:—I have this day received a copy of a calendar for 1894, in six sheets hitched together by a string, purporting to have been issued by or in commendation of *Maltine and its combinations*. On each sheet is the picture of some well-known physician, underneath it a paragraph highly commendatory of the Maltine, and below that the calendar of two months of the year 1894. On one page is what purports to be a copy of some photograph of myself. As I have never prescribed an ounce of Maltine, nor written a line concerning it in my life, I presume the manufacturers have taken this method to inflict punishment. And certainly they could not have devised a more contemptible or meaner method if they had searched the records of meanness for half a century. If you will give this a place in the

JOURNAL as early as practicable you will greatly oblige
Yours respectfully, N. S. DAVIS.

65 Randolph Street.

The Chicago Health Department—Typhoid Fever.

To the Editor:—In looking over the Reports of the Chicago Health Department for the months of September, October and November, no mention is made of the number of cases of typhoid fever reported. During these months 210 deaths are given as having been caused by that disease. The number of cases of diphtheria and scarlet fever are reported, but nothing is said about the typhoid fever cases. Is there not an ordinance requiring the notification of the Health Department of every case? Does the Department exercise any sanitary supervision over the cases and their surroundings, or do anything to prevent the spread of the disease? Does it know whether the dejecta of the patients are thoroughly disinfected or not, a matter of vital import to Chicago? How can any care be taken of the cases unless they are reported?

TYPHOID FEVER.

Eleventh International Medical Congress.

1230 OLIVE ST., ST. LOUIS, DEC. 26, 1893.

To the Editor:—Referring to the item in the JOURNAL of December 23, regarding the International Congress, can you tell what arrangements for transportation and otherwise have been made as to visitors from this country?

Yours fraternally, FRANK RING.

Ans:—Address Dr. A. Jacobi, 110 W. Thirty-Fourth Street, New York.

Medical Department University of Minnesota.

ST. PAUL, DEC. 30, 1893.

To the Editor:—Please announce that the Board of Regents of the University of Minnesota have extended the course of instruction in the College of Medicine and Surgery from three, to four years, of eight and one-half months each course. The new rule will become operative commencing in 1895.

PERRY H. MILLARD, Dean.

NECROLOGY.

Dr. Samuel Baughman, Sibley, Ohio, Dec. 27, 1893.

Dr. P. M. Parker, Barry, Pike Co., Ill., Dec. 26, 1893.

Dr. M. J. Paulding of Daretown, N. J., was killed by a "West Jersey" railroad train, Dec. 26, 1893.

Dr. A. W. Edis, formerly lecturer on obstetrics at the Middlesex Hospital Medical School, London.

Dr. George Liggett, who went to Wooster, Ohio, a few months ago from Chicago, where he was connected with different hospitals, died December 24, of pneumonia. He was 60 years old and leaves a widow and daughter.

Dr. Willard C. Marsellus of Albany, N. Y., died of appendicitis, Dec. 24, 1893. He was a native of Scotia, N. Y., and a graduate of the Albany Medical College, 1884. He was in his thirty-seventh year.

M. Dupre, Honorary Professor in the Faculty of Medicine and formerly Dean of the Faculty at Marsailles, formerly Senator from the Hautes-Pyrénées died recently at the age of 85.—*L' Union Medicale*.

Dr. A. W. Armstrong of Kirkwood, Ill., died of bronchitis, Nov. 19, 1893. He was a pupil of Dr. McIntosh of Knoxville, Tenn., and was graduated at Rush Medical College, class of 1849. He had practiced in this State over forty-four years.

Dr. William M. Griffiths of Louisville, Ky., Dec. 24. He was the son of the late Dr. Thos. J. Griffiths of Louisville, and was an A.A. Surgeon in the United States Marine Hospital at that place. He was a young man of much promise, and had a large circle of friends in Louisville and throughout the Marine Hospital service.

Dr. Horace Hollister died at Scranton, Pa., December 29, aged 71 years from paralysis. He was an antiquarian, and made a very interesting collection of Indian relics throughout the Wyoming and Lackawanna Valleys. Dr. Hollister also wrote "The History of the Lackawanna Valley," which passed through five editions and is notable for the vast amount of information which it gives and the patient research that its pages reveal.

Dr Samuel Hawley Olmstead of Brooklyn, New York, died Dec. 22, 1893, in his sixty-first year. He was a native of Connecticut and a Yale College alumnus, graduating in medicine from that school in the class of 1861. He served as surgeon during the late civil war, acquitting himself with credit and having at the close of the contest attained to the rank of brigade surgeon. He made his professional home in Brooklyn, soon after leaving the service, and very speedily obtained a strong position in the community where he lived. He was favorably known as an operating surgeon and held a place on the staff of the Long Island College Hospital for several years. He was an officer in the Loyal Legion; a member of the Physicians' Mutual Aid Society. The cause of his death was cerebral hemorrhage.

Dr. Robert C. MacEwen of Saratoga Springs, died on the 26th of December, 1893, by paralysis from cerebral hemorrhage. He was a graduate in arts from Williams College, and from the New York College of Physicians, the latter in 1857. He was an interne of Bellevue Hospital. He became a resident of Saratoga in 1866. He was 60 years of age.

He was one of the founder members of the Medical Association of New York State, and an office-bearer therein; and was an ex-president of the Saratoga County Medical Society. During the late war, his services as surgeon in the 17th Regiment of Connecticut Volunteers extended over a period of four years, and for a time his field of practice was

at Stratford, Conn. Prior to that his home was at Springfield, Mass. He was known as a faithful doctor and friend, anxious to keep abreast of the march of his profession.

Dr. Charles T. Palmer died at Pottsville, Pa., December 11. He was born on Sept. 8, 1843, and was in his fifty-first year. He was the son of the late Robert M. Palmer, lawyer and statesman, who served as United States Minister to the Argentine Confederation under President Lincoln. He graduated from Pennsylvania University in 1864, and served as Resident Physician of the Wills Eye Hospital for the following two years. At the expiration of this time he opened an office in Pottsville and continued the practice of his profession. Dr. Palmer, when the late war broke out, enlisted, and served during the three months' campaign. After the war he identified himself with Gowen Post, No. 27, G. A. R. He was also a Mason and a member of the Pottsville Club. In 1870 he was elected Coroner of Schuylkill County on the Labor Reform ticket.

Dr. Solon P. Sackett, the oldest physician of Ithaca, N. Y. died at his residence, December 18, of Bright's disease. Dr. Sackett was born in 1818 and practiced medicine in Ithaca for nearly thirty-seven years. He came of an old Colonial and Revolutionary family; one of his ancestors was among the earliest settlers of Rhode Island with Roger Williams; his grandfather, Major Buel Sackett, was an officer in the Revolutionary army, and his father, Philo Sackett, saw active service in the War of 1812 as a captain of militia.

He was graduated from the Geneva Medical College when that was among the foremost medical institutions of the country. After a few years of practice in a country village, he removed to Ithaca in 1857. As Health Officer of Ithaca, a position to which he was repeatedly chosen, he instituted and indorsed a sewerage system that, although incomplete because of inadequate public funds, probably did much to make the place for a long time among the healthiest in the State. He was Coroner for several terms, and held the office of Secretary of the Tompkins County Medical Society for many years. He was a frequent contributor to the medical periodicals.

Dr. P. G. Barrett died at Scranton, Pa., December 8, after a week's illness of pneumonia. He was 47 years old.

Dr. Barrett was born in Ballycastle, County Mayo, Ireland, in 1846. Early in his teens he went to England and while there met a physician in the English army who inspired in him a desire to adopt the profession of medicine. He read with this physician for a time and then returned to his home in Ireland. In 1862, when sixteen years old he came to this country and settled in White Haven. He taught school there for a few years and then entered the College of Physicians and Surgeons in Baltimore. Before completing his course he left college and went to New York, where he was employed in a drug store. About twenty years ago he moved to Carbondale and opened a store which he successfully conducted for several years. He sold his property in that city and went to Pittston, where he also conducted business for a short time. Then he bought a tract of several acres in Priceburg and erected thereon a large hotel. After profitably disposing of this property, he again entered the College of Physicians and Surgeons in Baltimore and graduated from that institution ten years ago. He immediately opened an office on South Washington Avenue in Scranton and commenced an active practice, which he continued up to the time of his fatal illness.

Dr. Charles M. Cresson of Philadelphia, died December 27 in the 66th year of his age.

He was born Feb. 3, 1828, in Cheltenham township, Montgomery County, Pa. At an early age he was sent to Gummere's School, Burlington, N. J., and at the age of 10 years he was admitted to the Central High School at its opening, October, 1838.

He was a graduate of the University of Pennsylvania and graduated in medicine from the Jefferson Medical College

in 1849. He was manager and chemist of the Philadelphia Gas Works from 1849 until 1864, and for fifteen years chemist to the Philadelphia Board of Health, and also to the Fairmount Park Commission. He had been an active and prominent member of the Franklin Institute since 1849, and of the American Philosophical Society since 1857. Dr. Cresson opened the scientific departments of the Pennsylvania Railroad and of the Philadelphia & Reading Railroad in 1868 and 1869, and that of the Baltimore & Ohio Railroad in 1883. During his early youth a considerable part of his time was devoted to mechanical and architectural drawings for the Philadelphia Gas Works and in work in its chemical laboratory. Later he was elected first assistant engineer of these Works, his duties being the construction of new work, until 1855, when the whole of the new management of the mechanical department and the manufacturing devolved upon him.

Among other branches of chemical science that of photography early attracted his attention and from the exhibition of the first daguerreotype up to the present time he has maintained his familiarity with current improvements in that art. He has published from time to time a number of pamphlets upon "The Manufacture of Gas," "Explosion of Steam Boilers," "The Effects of Electricity Upon the Tensile Strength of Iron," "Wood Preservation," "Paper Manufacture," "Water Supplies of Cities," etc. He was connected with many Masonic bodies, having been at times E. C. of Philadelphia Commandery, No. 2, K. T., also E. C. of St. Albans Commandery, past master of Pennsylvania Lodge, No. 380, Girard Mark and various other bodies.

Added to the rest of his accomplishments he was a skilful musician, having mastered the study of music at an early age, and having for many years given his services as organist to the Church of the Atonement.

ASSOCIATION NEWS.

The American Medical Association.—Let it not be forgotten that this National body is to meet at San Francisco on June 5, 1894, for the first time since 1871, which was its first meeting on the Pacific Coast. The above date will occur during our Midwinter Fair, whose success is now assured, and which is certain to attract a large influx from the States east of the Rocky Mountains. There is no doubt that this concurrence is favorable to a large attendance of medical men, but it must not be presumed that our local committee can safely rely on the Fair without special action on their part, and we trust that they will spare no pains. Their efforts are needed for two special and chief objects: first, to secure concessions in railway fares and hotel charges; second, to raise money for the necessary local expenses of the meeting, including the usual courtesies and hospitalities. Physicians who attend the meeting will, at least, have all the concessions granted to those coming to the Fair; possibly the committee may be able to obtain more favorable terms, especially in hotel rates. On the second count, California can ill afford to be outdone in hospitality.—*Pacific Medical Journal*, January.

Our Association Treasurer, Dr. Duglison, has been ill with Ia grippe for the past three weeks, and for the past week confined to bed. His many friends wish for his speedy recovery.

SOCIETY NEWS.

American Medical Publishers' Association.—The first annual meeting of this Association was held in the Grand Hotel Cincinnati, Dec. 4, 1893, and steps were taken in the direction of active, routine work. The by-laws and rules were revised and amended, while the name was modified in accordance with a demand from medical publishers of a general nature who desired to become members of the Association. The active coöperation of every medical publisher is earnestly solicited. Next meeting in Washington, D. C., September, 1894. Officers: President, Dr. Landon B. Edwards, Richmond, Va.; Vice-President, Dr. J. C. Culbertson, Cincinnati, Ohio; Treasurer, J. MacDonald, Jr., New York city. For application blanks and copies of the Articles of Association, address CHARLES WOOD FASSETT, Secretary, Corner Sixth and Charles, St. Joseph, Mo.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 1020).

W. J. HERDMAN, M.D. of Ann Arbor, Mich., read a paper on

THE ACTION OF THE CONTINUOUS CURRENT WITHIN THE LIVING TISSUES AS DISTINGUISHED FROM THE LOCAL POLAR ACTION.

I find that certain electro-therapeutists who are making daily use of continuous currents are in doubt as to whether any beneficial influence can be brought to bear upon tissues that are not in immediate contact with either one or the other pole, their expectations as to beneficial effects being confined wholly to such as can be brought about by this local action. But while the known effects of one or the other pole have a very wide range of therapeutic action and can be employed to advantage in a great variety of local disorders,—a still larger proportion of morbid conditions are too remote from the surface of the body to be affected by modifying conditions in the immediate vicinity of the poles but must depend upon such changes, if any, as can be created interpolary. This is true of the majority of affections of deep-seated nerve trunks and nerve centers, and of derangements of the internal viscera generally.

Now what evidence have we that the flow of a continuous current of a strength such as is ordinarily employed in treatments by electro-therapeutists (from 5 to 20 ma.) has any interpolary effects upon living tissues through which it is made to pass? Let us see how far this question can be answered, by recalling the conditions existing within these tissues when subjected to such currents. We have in the interval, between two opposite electrodes placed at separate points upon the body, a variety of tissues differing in conductivity, lying in juxtaposition; the intervals between them and the interspaces within them filled with liquids holding in solution chemie elements, in simple or complex combinations, which are either the products of the destructive metabolism of cells, or are nutritive material awaiting the constructive action of the cells which they bathe and encompass.

These liquids, whether within or about the tissues, serve the purpose of an electrolyte and are capable of being resolved into their *ions* at any point where the density of a current traversing them is sufficient to overcome their chemie affinities. The fluids, themselves, in which these salts are dissolved, serve as ready conveyors of such currents, but they lie in contact with fibrous, areolar, muscular, nervous and other tissues of varying conductivities, dependent upon their arrangement and structure, so that the current is frequently subjected in the course of its transmission interpolary, to convection and *different degrees* of conduction, creating conditions in density which result in electrolytic decomposition of the constituents of the fluids at many points.

What influence *living cells*, in the presence of such electrolytes and the current traversing them, may have in preventing the separation into *ions* and what influence such *ions* when formed, may have upon the living cells with which they are in contact is a matter for present speculation, perhaps for future demonstration. But that a continuous current, and that a very mild one, can cause such interpolary electrolysis and the formation of *ions* remote from the points of surface application of the electrodes, is no longer a matter for doubt for it is readily demonstrated.

A simple illustration in proof of this statement is one that I often make use of in my class work. I partly fill a series of small glass receptacles with a neutral solution of sodium sulphate to which is added a few crystals of phenol-phthalein, which as you know is a ready detector of alkalinity—giving a red or violet color in the presence of an alkali; by connecting the fluid, thus constituted, in these receptacles by means of bits of copper wire and making a continuous current traverse it, even though the current be but a fraction of a milliampere, the violet color will soon appear about that end of the copper wire in each glass which corresponds to the negative pole showing that electrolysis has taken place and that soda has been set free at this point and acted upon the phenol-phthalein. The experiments that have been recorded by Davy, Dubois-Reymond, Hermann, Martin and others gave similar testimony and from such well-known facts I believe we are justified in concluding that whenever a continuous current, capable of being measured, is conveyed through the tissues of the body and

in its course utilizes for its progress the compound fluids of the body which everywhere surround and bathe these tissues, there must of necessity be a disruption of the constituents of such fluids, at each and every point in the current where such fluids are separated by a partition wall of greater or less conducting capacity than the fluids themselves. The result, then, of such application of electricity is to disengage to a greater or less extent from their combinations the chemie elements contained in such fluids, and thereby admit of new and perhaps quite different combinations. If the current of electricity is feeble, the disruptive tendency may be correspondingly weak, and when the current ceases the original combination may be resumed unchanged, but even a feeble current, while it is in action must render the existing chemie combinations less stable, and subject the atoms of the molecules to a possible rearrangement by reason of this instability, other forces or affinities that are present as there residing in living cells taking advantage of this period of instability to assert their peculiar influence.

The transmission of continuous currents of moderate degree through healthy living tissue, while they may have the effect above indicated upon all electrolytes that exist in such tissues may not prove injurious, if not prolonged or too frequently repeated, since the resulting *ions* would either at once resume their former combinations, as being the only ones possible to them when all else is harmoniously adjusted, or the cells in their normal action are capable of disposing of such *ions* in the natural processes of nutrition without detriment to themselves or other tissue structure.

It has been observed by several experimenters—myself among the number—that by subjecting healthy living animal and vegetable tissues to a gentle continuous current for a few minutes daily, their growth can be accelerated beyond the normal, and that a somewhat more prolonged application of the same current retards their growth. But let it be presumed that such currents are made to traverse a region where either morbid materials have been deposited in the tissues or where the electrolyte itself is charged with morbid or effete products whose presence is injurious to cell-life, and which in the chemie combinations they have assumed are not amenable to the laws governing cell action, and can neither be utilized nor removed. Or, again, and this is quite as probable, let it be assumed that by reason of the presence of such obstructing and irritating substances, the vitality of the cells deriving their nutriment from this pabulum surrounding them has been so far reduced by reason of its unsuitableness that they are incapable of performing their functions with their customary vigor and, while in their normal condition they were able to wrest apart certain molecules and reconstruct their elements in the combinations necessary for tissue growth, in their present feeble state they must needs have their nutriment presented to them in a much more elementary form in order that they may utilize it. Under such circumstances, it is reasonable to suppose, that the introduction of a force which is known to be capable of resolving the complex chemie combinations through which it passes into simpler ones might, at times, prove helpful in aiding eliminating cells to cast out unnecessary substances, and feeble constructing cells to more readily build up the tissues. When we consider how large a proportion of bodily disorders are dependent upon this feeble action of some blood-making or blood-purifying organ in which the cell activities are below the normal and need but a little additional assistance to aid them in their work of constructive metabolism, and when we recall that the imperfect action of such organs can give rise to innumerable secondary disorders, by loading the fluid of the body with waste products, which should under normal action find egress from the body; but which, not being properly prepared for elimination, are deposited in places where they cause obstruction or irritation, and may even occasion inflammatory action as is the case in gout and rheumatism; we can conceive in what manner the electrolytic action of the continuous current might prove serviceable in correcting such faulty action, either at its source in the offending organ, or by the removal of the products that have resulted from such faulty action.

Many disorders of the nervous system, both central and peripheral, are directly traceable to the imperfect work done by that series of organs termed by Michael Foster, "tissues of digestion," as well as by those which come under the category of "tissues of excretion," and by a little attention given to correcting this primary cause of disorder the normal action of the nervous tissues may be restored, provided, the secondary causes, such as the deposits of waste

products, or inflammations accompanied by their peculiar exudates and destructive action, have not worked irreparable damage. But do not the phenomena attending the passage of a continuous current through a series of minut receptacles containing an electrolyte, the partition walls of which vary in conductivity, and where both the electrolytic fluid and partition walls contain living cells, endowee with peculiar capacities for appropriating or rejecting the constituents of such electrolyte, justify us in assuming that some marked change in conditions, presumably for the better, would follow the persistent daily application of such current, to deposits of foreign material or the debris remaining at inflammatory foci in the spinal cord; along the course of nerve trunks, or even within the brain itself? That beneficial effects have followed such use of electricity, and that the electric action has been an essential factor in the treatment of lesions of the central nervous system of both focal and systemic character, to my mind, admits of no possible doubt. Pareses and paralysees of the spinal cord, dependent upon focal and systemic lesions resulting from traumatic, specific or constitutional causes have yielded more promptly and surely, when they have improved at all, by accompanying other means of treatment with the daily application of the continuous current carried through the part diseased. I can readily see how others might, with equal care and perseverance in the use of such means arrive at quite opposite conclusions as to the value of continuous current treatment in spinal cord lesions, for many such cases receive no benefit from any method of treatment whatever; and we all have our list of failures. In order that electricity or any other measures may do good in this class of cases the injured part must of necessity still contain sufficient nerve nuclei and other essential cells capable, when freed by the electrolytic action from the substances throttling and obstructing them, of recovering their normal action and regenerating the affected part. Unless this is the case all treatment will fail, and when measures which help in some cases fail in others, *ceteris paribus*—it would be rational to attribute the failure to this one thing lacking.

It has been long claimed by certain advanced electrotherapists and physiologists that electrolysis occurs throughout the entire area of tissues that are brought within the pathway of a continuous current. These considerations leave no doubt, in my mind, that this is the case, and the clinical facts that are reported to us on every hand from reliable observers, of the removal of inflammatory exudates, the removal and diminution of fibrous tumors, and of cicatricial bands causing strictures of various channels, as well as the disappearance of gouty, rheumatic and specific deposits under the action of the continuous electric current finds its explanation in the fact that such currents serve to set free living cells from their imprisonment as well as to furnish them with nutriment in elementary form, enabling them thereby to recover their lost vitality, and resume their normal functions.

DISCUSSION.

DR. WOOLSEY of California, asked what current direction had to do with nutrition.

DR. HERDMAN replied that he had not entered into the question of polarity, for this depends much upon the individual case. If, for instance, there is an inflammatory focus in the liver, where it can not be easily reached, unless one desires a distinct polar action in addition to the general action, the direction of the current is a matter of no importance. Cicatricial tissue is connective tissue which is firmer than normal, and contains only a few active cells, but many cells which have reached their highest stage of evolution. Cicatricial tissue contains very few inter-spaces; the lacunæ in which the fluids of the body accumulate in normal tissue are not present in this tissue. When you wish to resolve such a tissue you employ the negative pole, by which you get not only electrolytic action, but an accumulation of fluids, and the cells remaining there not only get more nutriment, but they are softened, and are therefore brought in a very favorable condition for absorption. Hence, he thought in deep-seated tissues, he would not consider the polarity at all essential in most cases.

DR. WOOLSEY of California, said the matter of the nutrition of the spinal cord had been alluded to, and the vaso-motor dilatation produced by statical electricity. Now, is increased nutrition not based largely upon this vaso-motor action, and upon the direction of the current? Allusion had been made to increased body weight as an evidence of improved nutrition, but no statement had been made as to the effect on fat people.

Dr. MASSEY said he had observed in a number of instances that the body weight of fleshy people had been increased by electrical treatment. As Apostoli had pointed out, patients undergoing his treatment frequently have an increased deposit of fat in the abdominal walls because the treatment has improved the general health of a woman approaching the menopause. The patient, however, thinks the abdomen is really smaller—probably as a result of the increased tonicity.

Intra-polar action was recently demonstrated in a case where very powerful currents were applied to the surface of the body by very large poles. Profound effects were experienced by the patient, which he thought were clearly attributable to the intra-polar action.

Dr. WOOLSEY said the explanation given by Dr. Herdman was satisfactory as regards cicatricial tissue and tumors, but he wished to know what would be the physiologic effect on nutrition when the positive pole was over the spine and the negative on some indifferent part; and if the current were reversed, what would be the effect on the spinal cord and membranes.

Dr. HERDMAN replied that every physicist knows that if a current goes through, there must be decomposition. If there were no living cells there, they would be the end of the effect, but there are certain molecules having complex combinations, perhaps containing a poison to the system, e. g., urea; and the cell has not done its duty probably because of cell insufficiency. If the electrical current passes through such a tissue, there will be a difference of potential where there is a difference of density, and hence, there will be a current. Now, by sending through the continuous current, we divide up these complex molecules, and so present them to the cell in such a form that the cell can act; in other words, the cell is freed from its thralldom. For the time being it is an infant, and it is therefore fed with milk.

Again, physicists long ago discovered that the negative pole is exciting, probably because it brings irritating material to that pole. The action of this pole is liquifying, and if this action obtains in a small area, why should it not do it on a larger scale? The spinal cord lies very deeply, and for a general degeneration he did not think it mattered which pole was used.

Dr. HAYES referred to a case in which during an electrolytic treatment the indifferent pole used was a basin of water, into which the patient's feet were immersed to a point just above the ankles. He complained of pain at this point, and an examination showed that electrolysis had taken place in the hair follicles at the level of the water. He mentioned this observation, as it showed that the electrolysis not only took place along the electrode, but at the point of contact of the surface of the water with the patient's skin.

Dr. HERDMAN, in closing the discussion, said that he had used the term, "convection," in his paper in the same sense as the more common expression, "progression of the atoms." There are many electro-therapeutists who do not believe in the intra-polar action, yet he considered it most important.

(To be Continued.)

MISCELLANY.

Change of Address.—Dr. R. Harvey Reed from Mansfield to Columbus, Ohio.

New Year's Gift for the Children.—Children's Hospital was opened at Columbus, Ohio, New Year's Eve.

Dr. Myers of the Philadelphia Board of Health, recently made a report to that body in which he claimed to have prevented diphtheria by inoculation.

Woman Physician in Japan.—Dr. Mary A. Sukanuma, an American lady, married to a native of Japan, has recently received a license from the Japanese Government to practice medicine at Nagasaki.

Board of Health Appointments.—Gov. Flower of New York, on December 28, announced the following appointments to the State Board of Health: Henry G. Wolcott of Matteawan, to succeed Thomas Newbold; Dr. John Edwards of Gloversville to succeed Dr. Dawes of Saugerties; Dr. Murray M. Adams of Watertown, in the place of Prof. Perkins.

College Appointments.—Dr. A. H. Ferguson of Winnipeg, has been appointed a Professor of Surgery in the Post Graduate Medical School of Chicago. The *Winnipeg Tribune* of December 27 says: "the practice of medical gentlemen holding similar positions is worth from \$50,000 to \$100,000 a year." We sincerely hope the amount is correct, but there are always drawbacks to rainbow chasing.

Professor Verneuil.—At the opening of the session of the Société de Chirurgie de Paris held Nov. 28, 1893, the President of the Society, M. Périer, presented the illustrious master his best wishes on the occasion of the 70th anniversary of his birth.

He recalled amid the applause of his colleagues, the numerous works of the learned Professor contributed to the progress of surgery, and which at the same time had placed M. Verneuil in the first rank of the surgeons of our epoch.—*Revue de Chirurgie*, Dec. 10, 1893.

A Native Sanitary Measure in Ceylon. "Horn Pulling."—We find in the *Wesleyan Notices* for December, 1893, notes on some of the strange habits of the Jaffna district of Ceylon. As an anti-cholera measure the people there have a ceremony, called "horn pulling." The people of the village are divided into two parties or sections; one belonging to Siva, and the other to his consort, Mariammal. These two companies try to pull asunder the horns of a deer, or two forked sticks which are substituted usually for the horns. When the break takes place in the fork, if it is on the Siva side the omen is favorable. The people expect that the affliction will be withdrawn from the land, or the periodical return of epidemic disease will be averted. This is effected through the appeasing, by the horn pulling ceremonial, of Mariammal, the cruel Kali, called the "mother of evil." During the recent epidemic of cholera, in Batticaloa on the eastern coast of Ceylon, this ceremony was frequently performed in the villages.

THE PUBLIC SERVICE.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from December 23, 1893, to December 29, 1893.

Lieut. JOHN S. KULP, Asst. Surgeon U. S. A., is relieved from further duty at Jackson Park, Chicago, Ill., from Dec. 23, 1893.

Major JOHN D. HALL, Surgeon, is granted leave of absence for two months, to take effect on or about Jan. 15, 1894, with permission to apply for an extension of one month. By direction of the Secretary of War.

LETTERS RECEIVED.

(A) Alma Sanitarium, Alma, Mich.; Anderson, A. H., Des Moines, Iowa; Alderson, J. A., Benton, Wis.; Ayer, N. W. & Son, Philadelphia, Pa.

(B) Bates & Morse Adv. Agency, New York City; Bories, Emil, Seattle, Wash.; Bacon, C. S., Chicago, Ill.; Brown, M. R., Chicago, Ill.

No. 2.

ADDRESS.

FIBROID TUMORS OF THE UTERUS.

Address of the President, read before the Mississippi Valley Medical Society, Oct. 4-6, 1893.

BY R. STANSBURY SUTTON, M.D.
PITTSBURG, PA.

(Continued from page 10).

Prognosis.—These tumors frequently cause death. Relatively, they are innocuous in the following order: subperitoneal, interstitial, cervical, and submucous. The last is especially dangerous, for it is almost always accompanied with great loss of blood; a very small tumor may cause fatal bleeding. Yet, although many of these tumors are not dangerous to life, they are liable at any time to cystic degeneration and to set up a train of evils demanding an entirely different consideration. These tumors occasionally disappear, as already stated, after the menopause or pregnancy. When submucous they are frequently expelled through the vagina as polypi. When the capsule ruptures under expulsive effort, they escape in mass or break down and are expelled piecemeal; ulceration of the capsule from any cause favors such a result. Nevertheless, these tumors occasionally destroy the patient through the advent of suppuration or necrosis of the tumor, producing septic poisoning, or, uremic poisoning may occur from pressure on the ureters; fatal peritonitis may result from the irritation of the tumor; or a fatal hemorrhage may ensue; or the long continuance of the discharges may exhaust the patient; or their continued pressure upon the nerves and ganglia may finally wear out the stoutest nervous system. The symptoms are so liable to change from year to year that a guarded prognosis is wise.

FIBRO-CYSTIC MYOMA.

As already intimated, the foundation of every fibro-cystic myoma is a solid fibro-myoma, either unilocular or multilocular. The latter undergoes cystic degeneration to produce the former. The fluids formed in these tumors consist largely of serum, mucus, blood, fat, or lymph, and occasionally pus, and are not confined to true cyst-cavities. The tumor may be infiltrated with serum to such an extent as to give a palpation so like fluctuation that even after the tumor is removed it is difficult to believe that it is not an ovarian cyst. The serum is contained in innumerable small spaces formed by spreading the meshes inclosed in the fibrous tissue. When the lymphatics entering the tumor or passing between the centers of the multilocular variety, dilate, the fluid accumulates often in a large quantity ("fibro-myoma lymphangiectodes" of Virchow). This fluid coagulates on exposure to the air. The formation of mucus in these tumors is more difficult to account for. This form of degeneration does occur and a fluid rich in

mucin accumulates. No mucous glands are found, and it is possible that the fluid is the result of a "mucous metamorphosis" of the protoplasm or a separation of the fluid by independent cell action.

The presence of blood in the tumor is not so difficult to understand when we remember that occasionally large vascular sinuses penetrate these tumors and an apoplectic condition, with subsequent clot, disintegration and softening of the adjoining structure may occur. Fatty degeneration and consequent softening have already been spoken of at length. Suppuration in these tumors, though rare, does occur. The subperitoneal and interstitial varieties are most prone to softening, while the submucous variety is not exempt from it. The tendency in these tumors, where the softening arises from infiltration with serum, fat, or blood, is toward enlargement, but subsequent absorption of fatty softening occurs and tends to recovery.

The enlargement from serous or apoplectic infiltration is not of definite limit. The enlargement from mucous degeneration and the accumulation of lymph seems to produce the tumors, which advance steadily in growth until the life of the patient is jeopardized. The rule, however, may be laid down that any fibro-myoma which gives evidence of fluctuation and progression should be removed without delay.

Diagnosis.—The diagnosis of these tumors presents always a question of origin. It also involves the rules of differentiation to be observed in the diagnosis of ovarian cysts. In the latter the uterus is found displaced downward and backward or forward; in the fibro-cystic uterine myomata, if large, the uterus is dragged upward; often the uterine cavity is lengthened, and a sound introduced into it will, when the tumor is moved about, move also, proving the connection between the tumor and the uterus. The tumor must be differentiated from pregnancy.

The shape, size, consistency and duration of the tumor, and effect on the health of the patient are important points. The history of the case pointing to the prior existence of a uterine tumor, and the age of the patient are to be considered. The question may be positively settled by the aspirator needle, which will emit fluid having microscopically characteristics entirely different from those found in ovarian cysts. Free fluid in the cavity of the abdomen is more frequently found than in the case of ovarian cysts, and by reason of the greater solidity aortic pulsation is probably more frequently observed. Even if the patient be within the menstruating age, menorrhagia would not likely be met with in ovarian tumors. Unlike ovarian tumors, the fibro-cysts are not met with in patients under thirty-five years of age. They grow very slowly, and the general health of the patient sympathizes with their presence at a later date. The expression of countenance and the emaciation seen in

large ovarian tumors are quite different. The face is often florid even when the tumor is large, and does not betoken the great danger of the patient. The emaciation comes on later than in ovarian tumor. Elasticity in the tumor may precede fluctuation. The varicose condition of the abdominal veins is rare in these cases, but frequent in ovarian cystomata. Aspiration of these tumors, in which the cysts are supposed to arise from obstruction of the lymphatic vessels, gives a fluid, limpid, yellow, and fibrinous as lymph, which coagulates as it flows into the basin. But when aspirated, the cysts produced by edematous infiltration give a fluid yellow and serous which does not coagulate when exposed to the air. The fluid of this variety may be tinged with blood; if, however, much blood is drawn from such a tumor, it may be from having opened a blood sinus, such as Virchow describes as having met within them.

Coagulability of the fluid was long ago described by Dr. W. L. Atlee as diagnostic of the fibro-cystic myoma. In the fluid drawn from the edematous variety the fluid microscopically presents nothing more than the ordinary constituents of fibrinous serum. The walls of a uterine fibro-cystic myoma are darker and more vascular than those of ovarian cysts. The uterine muscular fiber in the interstitial variety compose the cyst wall or capsule. The adhesions formed by these tumors are often immense—broad bands of tissue, often very vascular. Large plexuses of immensely dilated mesenteric veins are often seen adhering to the tumor, and occasionally the broad ligaments and tubes are spread out upon their walls like great vascular wings. The bladder is often adherent to the front of the tumor and dragged high up on the abdominal wall.

Medical Treatment.—Medically, but little, curative in character, can be done for the relief of patients suffering from fibro-myomata, and nothing for those suffering from those tumors which have undergone cystic degeneration. Many remedies have been given for the cure of solid tumors of the uterus. Prominent among these is ergot and its preparations. Hildebrandt established its use hyperdemically, and reported favorable results. Given by the mouth, rectum, or hypodermically in large doses, it is an excellent remedy for the relief of hemorrhages. Few patients can endure a sufficiently large number of injections to do them any good. The deeper into the cellular tissue and fat the fluid is injected, the less pain and danger of subsequent inflammation and suppuration. The late Prof. Byford of Chicago, relied on it in very large and frequent doses to expel the submucous and polypoid variety of the tumor. In addition to ergot, bromid and iodid of potassium, chlorid of calcium, arsenic, and phosphorus have been largely used: the same may be said of chlorid of ammonium. If the physician can keep the tumor out of the pelvis, relieve rectal and vesical irritation and congestion by resorting to elevation of the tumor and uterus by the knee-chest position daily and by copious douches of hot water, in some cases he will afford great relief, diminish the hemorrhage, and nurse his patient beyond the menopause or put her in better condition to bear surgical treatment.

Surgical Means.—As Ephraim McDowell of Kentucky, secured for American surgery the honor of establishing ovariectomy, so the late Washington L. Atlee inaugurated, by the publication of a paper entitled, "The Surgical Treatment of Certain Fibrous

Tumors of the Uterus" in 1853, a pioneer movement in the treatment of fibro-myomata. Thomas wrote in 1880: "With the means at present at our command all the variety of fibroids, the submucous, interstitial, and subserous, are amenable to extirpation."

There are but two routes by which these uterine tumors can be removed—either through the vagina or by abdominal section; with the exception of small submucous tumors, all fibro-myomata are reached now by section of the abdominal wall. The tumors properly removed through the vagina are polypoid and submucous. If the cervix has been dilated from within out by the pressure of the tumor, and it remains only to dilate the os externum, the avenue to the tumor is easily made patent. But if the cervix is undilated in its entire length, means must be employed with proper precautions and care to dilate it. The bowels should be cleared out and local congestion relieved by frequent antiseptic hot douches. The cervix may now be divided as far as the vaginal junction, with the scissors, as Meadows has advised, or with the Paquelin cautery-knife still higher as Prof. Thomas advises. Immediately, or after a week of delay, the patient's condition having been still further improved by appropriate treatment, we may proceed to dilate the now shortened and weakened cervix. If the growth seems free to advance, ergot may be given until the canal is sufficiently open to admit an instrument, with which the growth is seized, and traction should be made to assist the uterus to expel it. The importance of traction in the delivery of these tumors was insisted on by Dr. Thomas Addis Emmet years ago. If, however, the tumor is not free in the uterine cavity, it may project sufficiently to enable the operator after dividing its capsule to sink a double tenaculum into it, and still assist its final delivery by traction. If, however, it is necessary to provide for easier access to the cavity of the uterus, we must select means to effect it. If the tissues are tolerably soft, we may proceed at once, under an anesthetic, with Marion-Sims', Gooddell's or Dr. Wilson's large metallic dilator or Molesworth's hydrostatic dilator, with a fair prospect of success. The avenue once open, it should be thoroughly disinfected; the subsequent steps will depend on the location of the growth and its attachment to the uterus. If it be pedunculate, it should be seized with strong forceps and an attempt made to secure its pedicle with the wire loop of the ecraseur, or the galvanocauteric wire, with the former of which it may be crushed off or with the latter burnt off; with the polyptome of Aveling or Sims, the pedicle may be divided. Or it may be twisted off if the pedicle be slender. Once the pedicle is divided, it is delivered by traction. If it be too large, it must be reduced by cutting pieces out of it, or, as Emmet has advised, by making incisions into it in a spiral direction as the tumor is pulled down, the pedicle being reached last. If in the effort the uterus be inverted, reposition should be made immediately after removing the tumor. If by traction upon the tumor with its uterine attachments unsevered, the uterus is inverted, care should be taken not to cut off the pedicle with a sharp instrument, but with blunt scissors or with Paquelin's cautery, or if possible, to separate the growth by enucleation. This precaution should be observed as a guard against subsequent bleeding after reposition of the uterus has been made.

To be more precise, after dilatation of the cervix, polypoid growths may be twisted off, or if their pedicles be sufficiently long to permit, the tumor may be dragged into the vagina, where the pedicle may be dealt with by means of the wire ecraseur, blunt curved scissors, or the galvano-caustic wire; and in case of multipara it may be easy to secure the pedicle with a ligature, and below it cut off the growth with any sharp instrument convenient. When the polypus is in the vagina, if not too large, a Sims speculum may be slipped in and greatly expedite its removal. In cases of short pedicle, in addition to the means already spoken of, the polyptome of Aveling may be used to divide it, or the pedicle may be torn across with a stout curette or spoon saw, if it can be reached. Or the capsule may be nicked with curved scissors in its circumference as high up as possible, and strong torsion be applied to the presenting end of the polyp.

When the cervix is dilated and the tumor found to have a broad attachment to the uterus or to be well imbedded, none of these procedures may avail, and the operator will now meet with real difficulty. The object he must now attain is a method to open the capsule of the tumor. Before proceeding to this, however, he should weigh well the propriety of abandoning the attempt by the vagina for a subsequent removal of the ovaries and tubes after the method of Mr. Lawson Tait, or hysterectomy.

If, however, he elects the more difficult and scarcely less dangerous method of enucleation, he will proceed somewhat as follows: the patient well anesthetized, is placed on her back and an assistant forces the uterus well down toward the vaginal outlet. The operator now passes a finger into the uterus and locates the growth. Having done this, guiding a knife, a probe pointed bistoury, or a pair of scissors on his fingers to a point selected, he cuts through the capsule by as free an incision as possible. With the finger, the point of the scissors and enucleator of Simpson or of Sims, or with Thomas' spoon-saw he peels back the capsule, separating the tumor from its attachments as far as possible. At this juncture he may desist and give ergot—a dangerous experiment for the tumor, now largely cut off from its base of supplies, will probably slough and poison his patient. It is better to proceed, with strong volsellum forceps or Sims' large tumor hook drag the tumor into the vagina, or, if it be too large, cut pieces out of it or cut into spiral incisions as it comes into the open cervix under strong traction. The fact that it is not every fibro-myoma that can be shelled out of its capsule makes it possible to leave behind, either in avulsion or enucleation, pieces of the tumor; these may subsequently slough and poison the patient. The dangers by this method are sometimes scarcely less than by hysterectomy. When the tumors are of moderate size this method promises best, but if the tumor and uterus reach quite to the umbilicus, I would certainly prefer hysterectomy. Notwithstanding I have succeeded thus in enucleating very large tumors.

Simple division of the capsule or capsule and cervix with the guarded knife or Paquelin's cautery-knife, and the subsequent free administration of ergot, may be tried in almost any case, and if the growth is once started from its bed, traction will give great aid. Prompt delivery is the only safeguard against septic poisoning. In skilful hands,

the spoon-saw of Thomas is the most effective of all instruments for the immediate enucleation of the tumor. After the removal of the growth, the uterus should be frequently washed out with hot water containing a disinfectant in solution. The surgical treatment of hemorrhage occurring in cases of interstitial and submucous fibro-myomata, prior to the removal of the ovaries and Fallopian tubes, by Mr. Lawson Tait, was confined to division of the cervix uteri and division of both capsule and cervix at the same time. In division of the capsule, the divided blood vessels retract and become occluded. Why division of the cervix sometimes controls the hemorrhage I can not explain, but from personal experience I know it does it.

In many cases removal of the ovaries or ovaries and tubes holds out the greatest promise. After the establishment of the menopause, these tumors frequently atrophy by reason of fatty degeneration. The removal of the ovaries or ovaries and tubes usually establishes the menopause. Possibly it does more. Removal of the ovaries and tubes is now the established procedure. Mr. Lawson Tait found a monthly bleeding persist after Battey's operation, oöphorectomy, and subsequently included, when possible, the tubes in his operation. His experience and that of others is that the operation not only arrests the hemorrhage, but that the growth is also arrested, and in many cases disappears in from six to twenty-four months. He considers the time to get the full effect of the operation to be two years. If cystic degeneration has occurred, or the growth is malignant the operation does no good. It is to cases of small non-cystic fibro-myomata that the operation is applicable. The operation is now thoroughly established.

Tait's Operation.—The removal of ovaries and tubes. His manner of doing his operation is as follows: the abdominal wall is opened by an incision in the median line above the pelvic symphysis. When the peritoneum is reached, he controls all bleeding in the wound with ordinary hemostatic forceps. Picking up the peritoneum with a pair of forceps, he makes a small opening in it. Through this he introduces one finger, dilates or tears the peritoneum, and passes in a second finger; with these he explores the pelvis for the ovary, first on the left side; if adhesions exist, he tears them up with his fingers if possible, and brings through the wound the ovary and tube, and holds them with his thumb and fingers as you would a fold of your handkerchief. Through the broad ligament below the fingers, and of course under the tube, he passes a long handled needle with an eye near the point, armed with a strong silk ligature, its middle point resting in the needle's eye. He now drops the handle of the needle on the abdomen, and slips his right index finger in between the ligature and the shaft of the needle, and draws the double ligature farther through toward his assistant who seizes it. He then withdraws the needle. Taking hold of the loop, he carries it over the ovary and tube and places it between the free ends of the ligature, and winding them around his right hand, draws firmly upon them, and the ovary and tube are at once constricted with a double noose which can not slip. (This is known as the Staffordshire knot). The free ends of the ligature are now tied. He now seizes the pedicle with a pair or two of hemostatic forceps to prevent its escape, and a short distance above the

ligature, cuts the ovary and tube away. After carefully cleaning the peritoneal cavity of all blood, he closes it.

The operation of Mr. Tait, the removal of both ovaries and tubes, is applicable to all cases of small or medium-sized interstitial, submucous and sub-peritoneal non-pediculated tumors. When the tumor has become so large as to drag the uterus up and lengthen the cervix sufficiently to make a pedicle of it, supra-vaginal hysterectomy becomes a feasible and easy operation. The general adoption of Tait's operation will diminish the necessity for future hysterectomies.

Several methods of supra-vaginal hysterectomy are practiced:

1. The method established by Péan, Köberly, Bantock and Hegar, in which the pedicle is secured extra-peritoneally in the lower angle of the wound.

2. The methods inaugurated (and being established) by Baer, Baldy and others, in which the pedicle is secured outside of and below the peritoneum.

3. The method established by Henry Byford, of opening the anterior wall of the vagina and drawing the pedicle into the vagina, and thus securing it extra-peritoneally.

First method: This extra-peritoneal method is as follows: An incision is made in the median line as long as may be required. All vessels are carefully secured, the uterus and tumor are turned out. Large warm sponges are pushed into the abdomen in front of and behind the uterus; some are also laid over the wound, closely surrounding the neck of the uterus. A steel pin four inches long is passed through the cervix and adherent tissues at right angles. Beneath the pin a wire constrictor, or an elastic ligature, is now placed tightly around the cervix above the bladder; the ovaries and tubes are included in the constrictor. An extra sponge or two are now crowded in against the neck, and with a knife the uterus and tumor are cut away, an inch above the constrictor. Care must be taken not to wound the bladder. Re-examination of the wound for bleeding points is now made, the sponges are removed from the belly, and the peritoneum is carefully stitched around, and to the cervix below the constrictor. From the cervix to the top of the wound, the peritoneal edges are carefully united with a catgut suture. The entire wound is now closed down to within three-quarters of an inch of the cervix; the cervical canal is now touched with the Paquelin cautery, its edges are trimmed out, and the circumference of the stump is reduced by several cross sutures. Small bits of antiseptic gauze are now carefully packed in around the stump close to the ligature, and filling the portion of the wound unclosed. Over the stump a quantity of subsulphate of iron or iodo-tannin is poured and covered with more gauze. A roll of cotton and a bandage completes the dressing, which may remain undisturbed for from seven to ten days.

The results following this operation are good, and the only objection of any weight to be urged against it is, that the period of convalescence is protracted, usually from thirty-five to forty-five days. I never saw hernia follow it.

Second method: This method has been developed by Dr. Baer and Dr. Baldy. Baer describes his technique as follows: "After the required incision is made all existing adhesions of omentum, intestines, etc., are separated in the usual way, and the tumor lifted out

of the abdominal cavity. If the incision has been an unusually lengthy one, several sutures are then placed at its upper end for the better protection of the intestines. The patient may now be elevated to the Trendelenberg posture, if deemed best, and the parts thoroughly studied, so that a clear idea as to the character and location of the tumor and pedicle may be obtained before the ligation and separation are begun. The first step in the operation is the passing of a single silk ligature through the broad ligament near the cervix. This ligature is again made to transfix the broad ligament near its outer edge, to prevent slipping; it is then tied. A stout pedicle forceps is next placed under the Fallopian tube and ovary and made to grasp the broad ligament, for the purpose of preventing reflux from the uterus. The ligament is now severed just below the forceps, the incision being carried close to the tissues of the tumor.

"If deemed necessary, another ligature is now passed through the broad ligament farther down along the side of the cervix. This ligation and cutting are now repeated on the opposite side. The knife is then run lightly around the tumor an inch or two above the peritoneal reflexion of the bladder in front, probably a little lower behind, and the severed edge of the peritoneum stripped down with the handle of the scalpel for the purpose of making peritoneal flaps. The next step is a most important one; it is the ligation of the uterine arteries. This is done in the broad ligaments, outside of, but close to, the cervix. Care must be taken to avoid the ureter on the one hand and the cervical tissue on the other. The ligature may be either placed within the folds of the severed ligament or, which is preferable, made to encircle the double fold of the ligament and artery in one sweep; action here will depend upon the size of the pedicle and the consequent separation of these folds. The constant traction which is made upon the pedicle by the assistant who is holding the tumor, serves to draw out and elongate the cervix after the peritoneal covering has been incised, and thereby to permit deeper incision into the neck, which is next amputated with the knife by a sort of cupped incision. The stump is now grasped with a small volsella forceps, and further trimmed and reduced, if necessary, so that the entire supra-vaginal portion is removed before it is dropped back into the pelvis. The cervix being now released, it immediately recedes and is drawn deeply into the pelvis by the retractive and elastic properties of the vagina, where it is buried out of sight by the peritoneal flaps covering it. These flaps have been rendered so taut by the ligatures which have been placed that usually, as the cervix recedes into the pelvis, they close over it like elastic bands. The cervix is now in its natural position, and without a ligature or suture in its tissues. The operation is finished by infolding the edges of the peritoneal flaps, which may be secured by Lembert sutures if necessary. I have not found this necessary, if the ligatures which secured the uterine arteries had also grasped the severed folds of the broad ligaments, for this so tightens them that the sides are brought forcibly together when the cervix is drawn under. The bladder and surrounding tissues aid also in closing the pelvic cavity. Nothing whatever is done to the cervical canal. The portion of the broad ligament embraced in the first ligature is the same structure which forms the ordinary ovarian pedicle, minus the Fallopian tube. The other

ligatures close the opened broad ligaments, as a rule. If any other vessels are found spurting they are, of course, ligated. I have not found it necessary to employ the temporary elastic ligature." Baldy's method is very similar.

Third method: This is the method of Dr. Henry T. Byford. He first ligates and separates the broad ligaments and any existing adhesions of omentum or intestines, then separates the bladder and uterus. A temporary elastic ligature is placed around the cervix; the tumor and body of the uterus are amputated. The stump is hollowed out and so firmly stitched that hemorrhage is arrested; the elastic ligature is now removed. The other ligatures are left long. An opening is made in the anterior wall of the vagina, through which the stump is drawn by the long ligatures, which are reached by a pair of forceps passed up the vagina from below. The bladder peritoneum is now stitched with catgut to that covering the cervix. The stump now in the vagina receives appropriate treatment.

INTRA-PERITONEAL METHODS OF TREATING THE PEDICLE.

The success which has characterized ovariectomy since all operators have returned to the intra-peritoneal method of treating the pedicle, stimulated the operators on the continent of Europe to endeavor to discover a method whereby the stump of the uterus in supra-vaginal hysterectomy might be left within the peritoneal cavity.

Two points were to be attained:

1. To secure the patient against great loss of blood.
2. A method of forming a pedicle free from the danger of subsequent hemorrhage.

The method of Prof. von Billroth is to leave the stump in the cavity of the abdomen. Ligatures are placed on the blood vessels as they pass through the uterine ligaments to the uterus. When the ligaments require division, they are tied at two points and divided with Paquelin's cautery. The neck of the uterus is seized above the vaginal attachment with a pair of powerful lock-handled forceps, and literally crushed. In fact, I have seen him bite the uterus entirely off with these forceps. In the deep crushed groove thus made, a double ligature is passed through the cervix; each half is firmly tied in the groove and the ligatures are cut short. Above this ligature the uterus is amputated; the sides of the stump are securely stitched together, and the stump is dropped in. When the patient is anemic, or loss of blood is a vital point, he compresses the tumor and uterus with an elastic bandage, after the method of Dr. Leon Labbe, driving all the blood possible into the body.

Koeberle, who instituted the "serre nœud" used in the operation described, abandoned it, and leaves the stump of the uterus in the abdomen.

The method of operating by Schröder was also intra-peritoneal. He aimed to operate with as little loss of blood as possible, and to secure the pedicle against subsequent bleeding. The first point he attained by means of the elastic ligature, devised by Kleeburg, and first applied to the cervix uteri by Prof. A. Martin, placed temporarily around the supra-vaginal portion of the cervix uteri. If the tumor was a pedunculated subserous one with a reasonably-sized pedicle, he tied it in halves and cut the tumor away. If the pedicle was short and thick, he cut it off close to the uterus; if interstitial, he cut the capsule and peeled out the tumor, or cut a V-shaped

piece out of the uterus. When the cut surface on the uterus was too flat to close with sutures, he hollowed it out. The wound in the uterus was then closed with several layers of carbolyzed silk sutures. The last layer brings the peritoneum neatly over the wound. When the elastic ligature was removed no bleeding occurred. When possible, he spared the uterus and its appendages. Tumors developing downward to the cervix and pushing the appendages upward present no pedicle upon which to apply the elastic ligature. In such cases he ligated at two points, and divided between the ligatures, the opposing uterine ligaments and blood vessels. This done on both sides, the tumor or tumors were separated from the surrounding tissues, and the elastic ligature was secured around the base at, or above the junction. The uterus and tumor were now cut away above the ligature. The open uterine canal was disinfected with a strong carbolic solution, the stump was hollowed out or made V-shape, and united with several rows of silk sutures, the last uniting the peritoneum over the stump. A few deep sutures were placed at the sides, to catch if possible the points where the large vessels were divided. The elastic ligature was then removed. After a few moments' delay, if any bleeding points appeared, a few more stitches were put in to control them.

When the tumor has developed from the lower part of the uterus and extended into the cellular tissue, and risen upward, carrying the uterus with it so high that the os can not be reached per vaginam, a grave case is presented. The surrounding ligaments and vessels are first double ligatured and divided. The elastic ligature is placed around the cervix and the uterus is amputated, and the tumor is shelled out of its bed. The stump of the uterus is treated as above described. The great cavity out of which the tumor was shelled may be left open or closed, if possible, with sutures, and drained either by the abdominal wound or vagina. Schröder and Martin preferred the former route. When the bladder is adherent to the front of the tumor and carried high up, he extended the incision to a higher point, and then proceeded to enucleate the tumor from the posterior wall of the bladder. Before closing the abdominal wound the bladder and stump of the uterus were united. Martin operates by methods similar to those of Schröder.

The intra-peritoneal method of Zweifel is probably the best of its class. It is known as the continuous fractional ligature.

Says Pozzi: "Under this name, Zweifel has described a method of suturing the pedicle which certainly assures better hemostasis than Schröder's, but seems, *a priori*, inferior in technique as regards primary union of the stump and its chances of sloughing; however, the good results published by Zweifel demand attention."

In ten cases with his method there was but one death when he published his book (1888), and in February, 1889, he announced a series of twenty-two successful cases. His technique is as follows: for all his ligatures he employs sterilized silk and a needle furnished with a groove which resembles Reverdin's; the point is blunt. He first ties the broad ligaments with chain sutures. He then divides the ligaments and applies the elastic cord, the ligatures nearest the uterus being left long and the elastic cord is passed over them.

In the excision of the tumor, a small musculo-peritoneal lip is preserved both before and behind, and the cavity of the uterus and cervix are cauterized with the thermo-cautery. A sharp needle is then threaded and a series of partial ligatures passed. The peritoneum is closed by a series of superficial sutures. Drainage through the vagina by the cross-tube is necessary only when there is persistent oozing. *Ablation of the entire uterus, including the neck*, is pushing its claim for first place in the evolution of surgical treatment for fibromata. Martin of Berlin, was the first to do vaginal hysterectomy for small fibroids. This operation, for cancer, as well as for fibroids, paved the way for the entire removal of the uterus for fibroids by abdominal section. Bardenheuer and Eastman took the initiative; Krug, Polk, Hall, Mann, Sutton and others have followed it up, and complete removal of the entire organ is practiced successfully.

The methods differ but little; separation of all adhesions, the broad ligaments and bladder, proceed in order, Douglass' pouch is opened, all bleeding vessels are secured. Some operators leave the ligatures long and draw them down through the vagina. The severed ends of the broad ligaments are drawn into the vagina, which is lightly filled with iodoform gauze.

Eastman prefers to close the opening into the vagina.

Trendelenberg's posture and the staff of Eastman have made the operation much easier and safer than it formerly could have been.

It is now apparent that through laparotomy there are four ways of dealing with uterine fibroids. These are as follows:

1. Supra-vaginal hysterectomy.
2. Removal of the tumor leaving the uterus.
3. Leaving the uterus and tumor and removing the uterine appendages.
4. Total removal of uterus and tumor.

Which method shall be selected?

In fibro-cystic tumors, entire removal of the tumor is the only proper method, but such is not always the case with a solid tumor.

Every case of fibroid tumor ought to be considered on its own merits, and no rule of surgical procedure should be applied to all cases, as in ovarian cysts. It is very difficult to find general decisive principles, or hard and fast rules, regulating the indications for this operation. A woman may be bleeding to death, suffering pain from mechanical pressure, rendered an object of charity, be dying from nervous exhaustion, the result of the tumor, but the operation suitable for the case will not always be the same. In one case enucleation may be possible; in another, the removal of the ovaries and tubes may be the proper thing; in another, supra-vaginal hysterectomy; and in another myotomy or total ablation of the uterus.

The utmost care with reference to any of these operations is absolutely necessary. A clean operator and assistants, a clean patient and clean nurses, a clean room and clean tools and sponges, are of the utmost importance. The earlier, if necessary, the removal of the ovaries and tubes is accomplished the better. Once the tumor has attained considerable size the difficulty of the operation is increased. Early in the disease the incision may be very short, but later an extensive incision may be necessary. Early in the disease the ovaries and tubes are gener-

ally easily reached; later they may be under and behind the tumor. Both ovaries should be removed or neither. If the tumor is causing bleeding, or growing, or affecting the patient's health, and can not be enucleated per vaginam, the sooner the ovaries and tubes are removed the better, if the operation is suited to the case.

Tait's operation is recommended by Thomas, for large tumors. Done in such cases the result will always be uncertain, to say nothing of the difficulty of the operation. Large fibroids frequently contain cavities, which eventually become growing cysts, and have already contracted adhesions through which they are largely fed with blood.

Such, however, is the ordinary effect of the menopause on these tumors when non-cystic, that in cases of women approaching fifty years who are in fair health and doing well, it is wise to abstain from any operation; but for young women the reverse is the case. In cases requiring operation, in which it is not possible or desirable to trust to the removal of the ovaries and tubes, hysterectomy should be accomplished.

When in doubt as to the propriety of operating in many cases by hysterectomy, it is well to recall Keith's language: "Were I anxious for operations I might ere now have done two or three hundred during the last ten years; and from what I know and hear, a great number of fibroids are removed, or attempted to be removed, without the slightest necessity." He cites the following as suitable cases for operation:

1. Rapidly growing tumors in young women.
2. Fibro-cystic and suppurating tumors.
3. Soft edematous fibroid tumors.
4. Many cases of large bleeding fibroids of any age.
5. Fibroids surrounded by free fluid, the result of peritonitis, provided the fluid reaccumulates after tapping two or three times.

Dr. Mann, in a very valuable paper on "The Removal of solid Uterine and Ovarian Tumors," advocates the removal of fibro-myomata when they act as neuromata. Such cases are doubtless rare, and I can add my own testimony to his in reference to their importance, and indorse his statement: "To leave such patients to a slow, lingering, agonizing death seems to me scarcely justifiable, when so good a chance for relief and life seems to be afforded."

Pregnancy and labor are occasionally complicated by the existence of a fibro-myomata. The preservation of the life of the mother may depend upon the removal of the growth, the induction of premature labor or Cæsarean section.

Dr. James R. Chadwick published in a paper read before the Massachusetts Medical Society, at its annual meeting in June, 1885, a report and summary of ten cases of pregnancy and labor complicated by existing fibro-myomata.

Of these cases, one miscarried, two died, and seven recovered; in all of the seven cases of recovery the tumors were subperitoneal. In the remaining three cases the tumors were submucous; two of these died, and the third barely escaped death.

The question of surgical operation for the removal of these tumors during pregnancy is not a very difficult one to solve. When the tumor is subperitoneal and pediculate, pregnancy is not a barrier to its removal. Interstitial and submucous fibroids located above the internal os, can not be attacked with-

out destroying the fetus. When the tumors are developed in the cervix uteri, they should be dealt with according to preceding rules, regardless of the existing pregnancy, provided they are sufficiently large to obstruct labor.

Fibro-cystic myomata are probably more frequent than is generally supposed. Counting the abdominal sections, about 450, for all sorts of tumors, which I have witnessed, 15 were fibro-cystic myomata, and some of the women were beyond the menopause.

Péan and Urdy trace the history of gastrotomy for the removal of uterine tumors through three distinct periods.

The first, which comes down to 1843, comprises those cases in which surgeons, having opened the abdomen with a view to ovariectomy, and finding the tumors to be uterine, shrunk before the consequences of amputation of the uterus, and closed the wound.

In the second period, that of trials and groping, which comes down to 1863, during which ovariectomy made great advancement, several surgeons, Atlee, Heath, Charles Clay and Parkinson, finding uterine tumors where they had expected ovarian, did not hesitate to remove them.

In the third period, beginning with April, 1863, Koeberle, in the presence of a doubtful case, prepared for either ovariectomy or hysterectomy. Storer, Péan, and others deliberately resorted to gastrotomy for the purpose of removing the uterus affected by tumors.

Fifty years have elapsed since 1843, the end of the first period, and we are now only planted firmly on solid surgical ground with reference to these tumors, be they solid or cystic.

The credit of this great triumph in surgery belongs very largely to Kimball, Koeberle, Péan, Keith, Bantock, Schröder and Billroth, and in later years to Bardenheuer, and others, some of whom I have mentioned. The operation was of English birth. Granville did the first hysterectomy in 1837. Heath and Clay of Manchester, operated between 1843 and 1849. Burnham of Virginia, operated successfully in 1853. Since the latter date the progress has been continuous.

CRITIQUE OF MACROSCOPIC EXAMINATION OF SPECIMENS REMOVED IN THIRTY-TWO CONSECUTIVE LAPAROTOMIES.

BY F. BYRON ROBINSON, B.S., M.D.

CHICAGO, ILL.

PROFESSOR GYNECOLOGY IN CHICAGO POST-GRADUATE MEDICAL SCHOOL; GYNECOLOGIST TO WOMAN'S HOSPITAL, TO CHARITY HOSPITAL, AND TO POST-GRADUATE HOSPITAL.

The modern success in abdominal surgery excites the admiration of all. It is the outcome of systematic experiments, observation and reasoning. Its success at one time was thought to be due to antiseptics, i.e., chemic solutions which destroyed a vegetable germ. But we know to-day that simple cleanliness accomplishes all. We obtain cleanliness to-day by heat and water, two simple elements. The spray and chemic lotion have passed into oblivion with many others found not essential.

Modern research sifts matters until essentials are found and non-essentials are eliminated. The most delicate of all surgery is that of the peritoneum, which is almost as important to the human economy as the brain. The immediate and remote effects of surgery on the peritoneum should be always held in

mind. The greatest of lymph sacs brooks no insults without records. The peritoneum surrounds the visceral organs which hold body and soul together by their wonderfully balanced functions, and pathology which impairs this function should be removed. In the following cases some of the macroscopic pathology will be given to show etiology, pathologic process and final results.

Some views will be presented as to the anatomic and physiologic nature of reflexes. Some of the logical reasons for the removal of abdominal tumors will be presented.

Anesthetics.—Chloroform narcosis is such a rapid, beautiful and quiet affair that I determined to give it a good trial. It acted very nicely in England where I saw scarcely any trouble in a large series of cases. It acted nearly as well in Germany and Austria, where I witnessed a large number of patients narcotized. But I found that we could not use it with the same impunity in this country. Our chloroform does not act as safely on patients as in England and Europe. I have come to this opinion from practical experiments on dogs and careful observation on humans. In chloroform the heart fails, and quite a number of dangerous scenes for five years have made me almost abandon it in laparotomy.

Again, anesthetizers are, too frequently, untrained men who do not realize the terrible significance of keeping constantly before them the pulse, pupil and respiration.

Ether, it must be admitted may induce bronchitis and nephritis but it is the safer. We frequently employ a mixture of alcohol, chloroform and ether. It must be borne in mind that the narcosis is a very important matter in cases exhausted by the presence of tumors, suppuration or worn out by pain. Again, I have shown that many women who have tumors are afflicted with pathologic hearts, livers, kidneys and lung malnutrition.

The preparation of the patient is very important on account of the results. The urine is carefully examined for urea which is one of the standards to decide whether laparotomy should be performed. The kidneys, genitals and peritoneum are very intimately associated anatomically and physiologically, especially by nerves and blood vessels. A disturbance in one is soon followed by a disturbance in another. The kidneys and ureters both, come from the same organ, the Wolffian body. Sometimes a vaginal hysterectomy is followed in a week by death from nephritis. We examine carefully for urea for several days previous to the operation.

The urea varied from four to twelve grains to the ounce. A few days of rest soon brought about a more regular quantity of urea. I think it is not safe to do laparotomy with less than five grains of urea to the ounce. In sudden demands to operate, no time was given to find urea, but such cases were generally fairly healthy, e.g., rupture of tubal pregnancy or sudden invasion of pus. It was shown that a woman who would lie in bed for three days previous to the operation would fare better in the results, the urea would become more regular, her bowels were moved from ten to fifteen times—until the bile glistened in the stool. Her heart stood the operation better. Her abdomen was well scrubbed and a compress bound on the night before the operation. In regard to drain tubes, I used them only where pus was found or extensive adhesions were torn up. As expe-

rience increases with the years, I use less drain tubes in laparotomy. The drain tube we employ is one of my own device manufactured from aluminium, open at the bottom, perforated with round holes for one-third of the distance up and flanged at the top. The drain tube was employed from ten hours to several days. When less than a dram of fluid an hour was drawn from the tube it was removed. I believe the tube increases the danger of infection and hernia to a very considerable extent.

The patient is not allowed to get up before the twenty-first day. The amount of fluid given to the patient after the operation, I am inclined to increase. I give them an ounce of fluid an hour immediately after the operation, and soon increase it to two or three ounces an hour. Fluids flush the kidneys. The second or third day I use enema and Mg. SO₄ to secure bowel movements and intestinal contractions. Distension means intestinal paresis, and abdominal pain generally means excessive gas accumulation. The recommendation to use nux vomica to stimulate intestinal contraction was not followed. The Trendelenberg position is employed in nearly all cases. This position often embarrassed the heart by abdominal viscera pressing on the diaphragm. Four abdominal fistulæ followed which lasted many months, and two are not closed yet (six months after operation). These fistulæ arise in old cases of infected tumors.

As most of the principles employed will arise in each case, I will give an account of them in the following cases:

Case 1.—Miss H. L., age 24. She had had a laparotomy about eight months previously and the physician reported that the tubes and ovaries were removed. She became infected and lay in bed some two months with peritonitis. Dr. Franklin Martin kindly consented to assist me in the operation. On opening the abdomen the intestines were found almost a solid mass, held together by exudates. The uterus was about six inches long and proportionately enlarged. The lower portion of the uterus was so firmly attached to the left pelvic bony wall that I could move the whole woman by moving the uterus. Multiple cysts as large as a child's head existed on each side of the uterus. After careful examination and consultation with Dr. Martin it was deemed inadvisable to remove the uterus, tubes or cysts on account of the dense adhesions. The large cysts were drained with gauze and stitched to the abdominal walls.

Among hundreds of operations seldom have I witnessed such widespread and dense adhesions. A special reason for not tearing up the adhesions was that malignancy was suspected. She recovered quite well. But her subsequent history was of great interest. I kept trace of her for one year. I made the distinct observation in her case of the repeated rupture and formation of cysts without causing peritonitis. The abdomen would swell and become tense and then suddenly flatten out. As soon as the abdomen flattened out her pain disappeared. But I also noted that she had profuse diuresis for several days. This drained the cyst which ruptured into the peritoneum through the kidneys. I had made this same observation while experimenting on dogs three years previously. While operating on dog's intestines I would occasionally fill the dog's abdomen full of warm water and then close the abdominal wound. The dog would urinate profusely for two to four days. The water was absorbed by the peritoneal stomata and eliminated by the kidney. It is quite rare to observe the repeated formation and rupture of cysts in the abdominal cavity, especially when it is followed by no peritonitis. I once drew a few quarts of fluid from the cysts through the vagina but the cysts quickly refilled. At the puncture a dense adhesion formed so I concluded not to puncture any more but to wait until the filling of the cysts gave her such pain that she would seek another operation.

I wished to have another operation for two reasons: 1, it could be noted that the girl would die if not relieved; 2, also noted that the formation of the cysts had torn the uterus from its dense, firm attachment and pushed it up in-

to the abdomen, so that six months after the operation convinced me that the uterus and appendages could be removed. But I watched her every few weeks for a whole year, and her case presented a volume to any gynecologist. The cysts would fill until the abdomen stretched like a drum head. Such stretching and pushing elevated the whole uterus above the pelvic brim although its adhesions were such that they would hold 150 pounds. The pain was intense at the climax of tension. Suddenly one of the cysts would break and the abdomen would flatten. Pain would cease. Profuse diuresis would ensue. No fever arose. Slowly the cysts would refill. The greatest volume of information in this case arose from the pressure and irritation of the cysts on the viscera through reflex action. The effect of irritation and pressure on this young woman were:

1. Kidney disturbance; the irritation passed from the diseased location (pelvis) up the hypogastric plexus to the abdominal brain where it was reorganized and sent over the renal plexus to the kidney.

The kidney was forced into three troubles: it secreted *excessive urine, deficient urine* or *disproportionate* quantities of its elements. Every one of these conditions continued with this girl. She made large quantities at times, and again small quantities of urine loaded with salts and the irregular quantities. Thus the kidney was under continual irritation from the tumors. The irritation was transmitted to the kidney by reflex action by way of the hypogastric plexus, abdominal brain and renal plexus, i.e., a distinct anatomic route.

It would not take long to produce diseased kidneys if such irritation were long persistent. This effect on the kidney by reflex action from the cysts induced me to desire another operation. But I never requested her to undergo another operation. Her own condition (pain and inability to work) forced her to ask it.

2. The second effect from the cysts, I observed in this 24-year-old woman was constipation and indigestion. Her appetite was poor and capricious and at times wanting. The digestion was disturbed by the irritation passing up the hypergastric plexus, and being reorganized in the abdominal brain and sent out to the digestive tract by way of the gastric plexus (to the stomach), by way of the superior mesenteric plexus (to twenty feet of small gut) and by way of the inferior mesenteric plexus (to the large bowel). The irritation thus reflexed to the digestive tract would disturb sensation, motion and secretion of the whole canal. The result on the tract was *increased, decreased* or *disproportionate* secretions. In fact, the indigestion was so persistent that malnutrition soon appeared. Malnutrition resulted in some eight months in anemia. Curiously enough she never became neurotic. If she was allowed more time under such disturbances, neurosis would finally appear.

3. The third effect I noted this year of visceral irritation from the tumors was cardiac disturbance. The heart performed its action rapidly and irregularly. The irritation from the tumor passed up the hypogastric plexus to the abdominal brain where it was reorganized and transmitted up the great splanchnics to the three great cervical sympathetic ganglia, where the forces were reorganized and sent direct to the heart. The pneumogastric rules the steady rhythm of the heart, while the sympathetic rules the rapidity of the heart. So that disturbances of the kidney, digestive tract and heart arose from a year's irritation of the tumors. The lungs, liver and spleen so far had not manifested any disorder perceptible. She was incapacitated from labor a whole year until the next operation.

Tumors demand removal from reflex irritation through the sympathetic nerve. An abdominal tumor will cause fatty degeneration of the heart, indigestion, malnutrition, anemia, neurosis, fatty degeneration of the liver, irregular action of the lungs (asthma) and degeneration of the spleen—all through reflex action on the abdominal brain.

Case 2.—Mrs. M., age 54. She was referred to me by Dr. A. R. Martin with a diagnosis of cancer of the cervix. The hemorrhage was quite profuse and continuous with a distinct odor of decomposition. I did vaginal hysterectomy at the Woman's Hospital with the kind assistance of Dr. Franklin H. Martin. I used the ligature. The patient recovered, but I wish to note a peculiar point in regard to temperature. In twenty hours her temperature sprang up to 104; pulse was about 85. This rapid change of temperature was not due to sepsis, but to disturbance in the heat centers (reflex) from wounding and constricting the great hypogastric plexus. It was a neurotic rise of temperature. It fell suddenly in ten to fifteen hours. It may be that the injury inflicted on the hypogastric plexus by ligature is reflected to the me-

dulla or heat center and inhibits the action. At any rate the heat center lowers its tone and runs riot until it recovers from the shock of the ligature. The operation was done eighteen months ago. The cancerous mass has returned in the stump at present as large as a hazel nut, and she has begun to bleed easily again.

From the clinical and macroscopical manifestation I diagnosed cancer of the cervix, with a fibroid tumor three-quarters of an inch in diameter situated in the cervix in the site of the cancer. This specimen was warmly discussed in the Chicago Pathological Society by Drs. Van Hook, Hektoen and Angear. The opinions were divided between sarcoma or cancer. This discussion proceeded, even, with excellent specimens of the tumor under the microscope prepared by Dr. Angear. Dr. Angear has carefully worked it out, and I fully agree with him that the specimens which he so accurately prepared are cancer.

The manner of return (eighteen months and slow) show it to be cancer. If it were sarcoma it would return and grow rapidly. Recurring sarcoma grow with the rapidity of an avalanche. This shows that the microscope can not be relied upon in early diagnosis. In Vienna I have known of a dermatologist, a gynecologist and a pathologist in consultation over a disease of the labia, but utterly unable to agree as to the kind of disease they were examining. Disease is simply a change of structure, and there are early stages when clinical symptoms or the microscope will not decide its nature. Time alone will tell.

I am opposed to vaginal hysterectomy for cancer when the disease is advanced in the broad ligaments to any considerable extent. It does not elevate surgery and only shatters the renewed hopes of a despairing patient. I believe, also, that many of the reported cases of uterine cancer cured by vaginal hysterectomy were mistaken diagnoses. Cancer is a disease which will not be cured, whether in the uterus or other location. But with the incipient cancer of the uterus—in the early stage of cancer—vaginal hysterectomy is eminently proper and highly hopeful. It is the proper method of treatment.

Case 3.—Mrs. P., age 32. Two children, the youngest 6. Abortion four years previous. She had been ill since, more or less. Examination revealed the uterus fixed with a mass of exudation on its left about the size of a cocoanut. She took hot douches at home for a month. She then went to the Woman's Hospital and lay in bed some ten days. Douches and rest cleared up two-thirds of the exudate. I operated in September, 1893, removing the tubes and ovaries. She had much pain at the monthly. The tubes were very crooked and convoluted. She made a good recovery, but she was tubercular and it appeared to me that the tubercular lungs became slightly worse. However, ten months after the operation she is well in the pelvis and fairly well in the lungs.

She became very neurotic from her four years' invalidism, and would have hysterical spells. This case was a very good lesson as to what preparatory treatment will do. It made the exudate less, her recovery smoother, the operation easier and sequelæ less apt to occur. Dr. Mary Shibley and Dr. Marie White assisted me in the operation.

Case 4.—Miss A., age 22. A history of gonorrhœa was fairly evident. She was sick in bed for eleven weeks and pus had flowed from the rectum for six weeks. The case was referred to me by Dr. Chas. Simons and Dr. D. T. Nelson. I operated on her at the Charity Hospital, assisted by Dr. Franklin H. Martin and Dr. Mary Shibley. Vaginal examination revealed the whole left half of the pelvis a solid mass. On opening the abdomen, a tumor the size of a cocoanut presented, lying in a dense mass of exudates and old adhesions. By carefully separating the adhesions and enucleating the tumor, I finally brought it into the abdominal incision when its terribly foul contents burst and flowed among the intestines. Now, came a very peculiar feature in the case. The

left tube was about nine inches long and so large and dilated that it actually resembled a gut. So near did it resemble a gut that we could not decide what it was until it was traced right to the uterus. Both appendages were removed. But no hole could be found in the gut, rectum, sigmoid or small intestine, so I closed the abdomen with much misgiving for fear of leakage from the old fistula which had discharged pus for six weeks through rectum. Drainage was employed. To my surprise and delight she made a good though not rapid recovery. She walked away quite well in a month. At present writing she has a small abdominal fistula, ten months after the operation. She is in splendid health and has gained some twenty-five pounds in weight.

The specimen was from a slow progressive pathologic process. The large tumor I made out to be an ovarian abscess which had perforated into the rectum. Its contents had a fecal odor. The left tube was some nine inches long and looked like a piece of small intestine. Its peritoneum showed remnants of perisalpingitis, old adhesions, flakes of lymph and thickened from inflammatory exudates. The reason the tube was so long was because the ovary in enlarging had stretched it. The muscular wall of the tube was not very much changed except, perhaps, the longitudinal muscle layer was increased some. The muscular wall was mainly thickened by inflammatory exudates during successive inflammatory exacerbations. The essential and main changes occurred in the endosalpinx—the mucous lining of the tube. It showed all stages of inflammation. Parts were totally destroyed but most, partially. Some spots were denuded and some showed the progressive, infectious catarrhal process—gonorrhœa.

The tubal lumen was irregularly dilated. The method of closure of the fimbriated end was no doubt the chief reason of the ovarian abscess. In closing, a part of the fimbriae were left outside of the tubal lumen, while the remainder were turned in. Now those left in the abdominal cavity kept up a continual chance for renewing infection of the peritoneum. The ovary is nearly always infected by the tube, and is, therefore, a secondary disease. This ovary was cystically degenerated, i. e., the gonorrhœal process had passed from the tubal mucous membrane to the germinal epithelium of the ovary, and then passed on to the membrana granulosa which lines the graafian follicles. The gonorrhœal pathologic process had then disturbed the normal membrana granulosa, and these little cysts had abnormally dilated. The opposite tube and ovary were in an incipient stage of salpingitis and chronic ovaritis. The endosalpingitis had sufficiently started and existed long enough to have involved the ovary—it was cystically degenerated. The muscle of the tube and its perisalpinx or peritoneal covering was almost normal. I removed it because the gonorrhœal process was well rooted in both endosalpinx and ovary.

This patient had suffered so many recurrent attacks of pelvic inflammation that her peritoneum was tolerant to a severe and dangerous operation. The operation absolutely saved her life and she is made a useful citizen.

Case 5.—Operated on Feb. 28, 1893, at the Woman's Hospital. I was assisted by Dr. Mary Shibley and Dr. Marie White. She had been an invalid for six years. She was 36 years old. She aborted once, but had no children. She gave ample evidence of gonorrhœal and syphilitic infection. She had refused operation six years previous, and was now a confirmed invalid, unable to earn her own living and deserted by the man who infected her. Examination per vaginam revealed old pelvic peritonitis. The roof of the pelvis felt like thick, slowly yielding leather. The uterus was fixed and on the left was a tumor the size of a small

hen's egg. On opening the abdomen the appendages were found small and atrophied. The tumor proved to be a broad ligament fibroid of a very peculiar nature. It had around it a distinct capsule which could be peeled off. The tumor was enucleated from the broad ligament with the greatest difficulty, shocking the patient considerably. The appendages were both tied off. The abdomen irrigated and drained. She recovered well for a week, when the temperature rose to 100 and 101 for some ten days. Pulse about 100. Her abdominal wound seemed to have insufficient vitality to heal well. She finally recovered with an abdominal fistula which is still open and has a suspicious appearance of malignancy. I have had cases where a fistula developed in the wound many months after operation.

Six months after the operation she looks fairly well, but the wound is not healed. The fistula is surrounded by thickened and hardened tissues which reach down into the pelvis. It may be of a syphilitic nature. It may be observed that such old invalids, with ruined nervous system and infected venereally, do not make brilliant recoveries, but she is lately doing better.

The tumor is a typical sample of a solid hard fibroid. It had no pedicle and was surrounded by a firm capsule. It gave the woman much trouble by becoming inflamed and tender quite frequently. This inflammation and tenderness was difficult to account for, as the tumor seemed to be a broad ligament fibroid. I mistook it for the ovary on account of its tenderness. I still think the tumor did not give the tenderness, but that the tube behind it had exacerbations and made the pain appear to be in the tumor. This tumor was considered to be an ovary for six years of treatment. Both tubes and ovaries were mere relics of an inflammatory process. The perisalpinx showed signs of old inflammation. It was thick, covered with old adhesions and flakes of lymph. The muscle of the tube had almost entirely disappeared and was replaced by hard, white connective tissue.

The endosalpinx or mucous membrane was nearly all gone, except in little patches. The pathologic process indicated that the original inflammation proceeded from the endosalpinx, and it and the muscular layer were almost entirely replaced by one-fourth of an inch of solid, hard, white, glistening connective tissue. The lumen of the tube was obliterated at intervals in its course, leaving small closed cavities with endosalpinx in all stages of disintegration. The fimbriated tubal ends were closed like the fused end of a glass tube. She had not menstruated for nearly two years. The ovaries were only one-third the normal size, shrunken, covered with scars, with a few cystically degenerated follicles lying in them. One ovary had pieces of calcium salts in it the size of a pea, and smaller ones the size of wheat kernels. It was a calcified ovary, not ossified. These fragments of calcium salts were secreted by the membrana granulosa just as an egg is coated by its calcium shell as it passes through the ova duct of the hen. I have observed calcified ovaries several times. The membrana granulosa will not only secrete lime salts but will secrete a cheesy matter which I have found scores of times in the unruptured graafian follicle. In this woman, gonorrhoea had ruined her pelvic organs and syphilis was well grounded in her system. She visited my office Aug. 3, 1893, and was looking well. Her fistula had closed and about all infiltration had disappeared from the operative field. She was much more fleshy, and ruddy cheeks began to appear; pronounced herself as doing well.

Case 6.—Age 25, puberty at 13. Menstruation regular but painful, so she is always in bed for the first two days. The flow is profuse for three days. Examination revealed a

mass on each side of the uterus. She was undefinedly ill for several years; married six years. She gave me a distinct history of gonorrhoeal infection from her husband some four years previously. She was an invalid and Dr. Stillians sent her to me to operate at the Woman's Hospital, where Drs. Shibley and White assisted. She had double pyosalpinx. We irrigated and drained. She made an excellent recovery and went home in the fourth week. I saw her six months after, and instead of appearing as an invalid she is healthy, ruddy and has gained some fifteen to twenty pounds in weight. Silkworm gut was used for abdominal sutures.

The tubes and ovaries are in a solid mass. The only difference in the two specimens is the difference in the closure of the abdominal end. One of the tubes opens right into the ovary like a clay pipestem into the pipe bowl. Its fimbriated mouth never closed but simply became glued on the ovary by inflammation. That ovary was smelted with the tube into a solid mass. It presented a tubo-ovarian abscess. The ovary was infected by the gonococcus through the tube—secondarily. The ovary was cystically degenerated.

The endosalpinx was almost entirely obliterated. It was smooth as leather; all epithelia had disappeared. The muscle was so much altered that considerable was crushed out, and the endosalpinx and the muscle were replaced by connective tissue. The lumen of the tube was irregular and about the size of the little finger.

The perisalpinx was much thickened, covered with adhesions and flakes of lymph. The tube was very crooked and wound itself around the ovary. The other tube and ovary presented an entirely different spectacle due to its mode of closure. The fimbriated end had all its fimbriae nicely turned back into the tubal lumen, and they lay like the petals of a rose, neatly coiled up. This mode of closure retained the pus entirely in the tubal lumen, and the lumen would admit the thumb.

The tube—perisalpinx, *musculature* and endosalpinx—was similar in all other respects to its fellow from the gonorrhoeal process. But since the pus was retained in the closed tubal lumen, the ovary escaped the chief brunt of the infection. The ovary is only slightly infected, and now as I write, it lies before me in the water, floating almost free from adhesions. It escaped the main infection because the ostium abdominale closed before infection had passed into the ovary, before the ovary became ruined forever. This ovary has some four graafian follicles in a state of cystic degeneration, but it is otherwise a fairly normal ovary with scarcely any adhesions on it, all due to the mode of closure of the fimbriated end of the tube. The tubal wall is over one-fourth of an inch thick of solid connective tissue. The appendages show the typical progress of gonorrhoea.

Case 7.—Mrs. M., age 56. Four children. I operated on her six months previous for uterine cancer, removing the uterus and leaving the appendages and broad ligament. Drs. Shibley and White assisted me at the Woman's Hospital on Jan. 18, 1893. The lesson which I learned in this case was to remove the appendages, always if possible, in a woman over 35, along with the uterus, for Mrs. M. developed a parovarian cyst in the right broad ligament. If I had removed both appendages she would have escaped the second laparotomy. But in a woman under 35 I would generally prefer to leave the appendages in the pelvis to prevent a too sudden and precipitate menopause, i. e., a premature neurosis. The tumor as large as a child's head was easily removed and she made a good recovery. I will note here that I had used boracic acid sprinkled on the abdominal wounds on twenty cases, and four abdominal wounds suppurred and we traced it to the impure boracic acid. I

now use nothing but sterilized gauze, but I would prefer boracic acid above all other remedies as it desiccates the wound. It prevents the adhesion of the gauze to the wound stitches and dries up secretions. Boracic acid is a mere common commercial article, is put up by all classes of workmen and is apt to be impure. She was drained; pus in wound suppurated and attracted our attention, for it was a simple laparotomy. Since that time no wound has suppurred except a case of gonorrhœal pyosalpinx.

The specimen removed was a parovarian cyst containing about a pint of clear urine-colored fluid. We know it is a parovarian cyst for we can enucleate it entirely from the broad ligament on account of its position. The Fallopian tube, some six inches long, is stretched over the superior circumference of the cyst. The cyst itself is a fibrous sac; the outside is smooth and glistens. Its outer layer is composed of fine, visible fibrous strands of white tissue interlacing in all directions. Its inner layer almost exactly resembles a human bladder which had been dilated for a long period. The large fibrous strands resemble a honeycomb meshwork. It looks like the inner meshwork of muscles lining the left ventricle of the heart. The fibrous strands run in bundles in curved directions, making circular depressions surrounded by whorls of strands of coarse connective tissue. Of course these were hypertrophied by a slow process. I would account for the curved bundles and whorls of connective tissue by the stretching and displacing of the longitudinal and circular layers of tissue surrounding the tubes of the parovarian out of which the cyst arose. I could find no trace of the parovarian, except a few small blisters lying just above the Fallopian tube where it is usual to find a few, viz: close to the abdominal sphincter of the tube. The fibrous strands of the cyst wall are plain to the naked eye and very large under the lens. The cyst had a short pedicle which did not open into its cavity. The tube of Fallopius is interesting, as it is stretched about six inches long and is closed at both ends, one end from the ligature six months ago and the one fimbriated end was closed by old pathologic process.

The perisalpinx is simply thickened but notes no inflammation. The *musculature* does not show much change. But the endosalpinx or mucous membrane shows a peculiar change. There is no fluid of any kind in the tubal lumen. The tubal plicæ look much like the wrinkles in an old person's face or in the scrotum. The fine epithelium is all gone, and under the high lens the endosalpinx appears like an oiled, clean shaven hogskin with many wrinkles in it. The tubal plicæ are all in perfect parallel rows and fall to either side like the ruffles of a linen garment. In the middle of the tube there is a break in the plical rows as if they ran into a sphincteral opening, and here I find the tube has an opening only covered by peritoneum. This depression is called a tubal hernia by some, but it is simple a deficiency of the tubal wall; an attempt at the foundation of a tubal ostium. I would call attention to the idea that here is a good chance to account for some tubal pregnancies, for the ovum may drop down into this little pit, and there being deficiency of muscle it is not forced on by tubal peristaltis and so grows in the depression.

The lens shows beautifully the perfect endosalpinx subjected to senile changes. The tubal lumen is slightly wider than normal, but the stretching accounts for that. The rows of tubal plicæ have lost all villous appearances; no fringes appear; simply,

bare wrinkled folds of endosalpinx in perfect order under the lens, only now suggestive of their old wonderful function of twenty years ago. After the parovarian cyst was enucleated a splendid view of the broad ligament came to sight. It had developed in it considerable muscular tissue and connective tissue. As I previously noted, after fifteen months Mrs. M's cancer is returned in the old stump of the extirpated uterus.

Case 8.—Miss N., age 19. Puberty at 13; menstruation regular with some pain; suffers much with frontal headache. Has leucorrhœa. Has not been strong for four years. She is very tender on right side extending in pelvis and lumbar region. Bowels regular. She had been ailing for four years and at one time she was in bed for several months. She was sent to the Woman's Hospital where I repeatedly examined her for several weeks. Nothing very definite could be diagnosed, but on the right side and in the pelvis a swelling was felt. Her temperature varied and she was very tender. For two weeks I refused to operate, but afterwards several sudden rises of temperature and severe attacks of pain induced me to explore for two reasons: 1, appendicitis; 2, disease of the appendages.

It may be noted that a distinct history of gonorrhœa was told, viz: sudden acquisition of burning and scalding in making water which lasted for several months. Leucorrhœa was present. Frequent-recurrent pelvic attacks occurred. I watched her daily for some three weeks and finally concluded to operate assisted by Drs. Shibley and White. I removed both ovaries and tubes also the vermiform appendix. She did well until the fifth day when a hœmatocele appeared on the right side about the size of a large apple. The temperature sprang up to 103. I had about decided to cut a couple of stitches in the abdominal wound and introduce my finger into the swollen mass when she suddenly began to recover, i. e., the pulse and temperature went down quickly to nearly normal. It is a question in my mind whether these swellings occurring after laparotomy on one side of the pelvis are not due to infection, i. e., they are exudates and not hœmatocele. The tension of this swelling gave her much pain by pressure on nerves and that may raise temperature. I shall carefully further investigate this subject, whether it be exudate from infection or hœmatocele which so frequently follows laparotomy.

In Mr. Tait's work, I think it occurred in about 12 per cent. while I was a pupil during six months. The girl left the hospital well, some six weeks after the operation.

The specimens, viz: the tubes and ovaries and vermiform appendix, I carefully preserved in pure alcohol without allowing them to be handled. When I wish to examine them they are dropped into clear water and become soft and normal again, except in color. Both tubes are very similar. They are very short, convoluted, with sharp spirally curved angles and smaller than normal. The uterine end is very small. The peritoneum does not dip down into the angles, but stretches from one tubal convolution to another, showing that the tube is quite free in the broad ligament or mesosalpinx. It appears to me that such a contorted, spirally angled tube in a virgin is a congenital malformation. If convoluted tubes are found in the multipara it is likely a reversion to the fetal type, due to subinvolution of the longitudinal muscular fibers of the tube. These fibers are chiefly enlarged in gestation. Several years ago I discussed and presented the subject of contorted tubes to the profession, noting that it was the chief factor in virginal dysmenorrhœa. It causes tubal colic and is the phenomenon in pre-menstrual pain. This woman had quite typical, contorted twisted tubes and she suffered much pain at the menstrual period. Such tubes are difficult to drive menstrual fluid through by reason of so many bends and angles in the lumen, and thus is excited tubal

peristalsis and tubal colic. No changes can be noted in the musculature of the tubes, nor does the high lens indicate any pathology in the perisalpinx. Any pathologic changes under the eye or lens is to be found in the endosalpinx. The mucous membrane of the tube is swollen, a little edematous and is so luxuriant and abundant that it quite fills the lumen. In good sunlight under the lens it lies in folded wrinkles, not so uniform as it does in the general tube.

The tubal plicæ do not lie in distinct parallel folds, but such parallel folds are broken by whorls encircling depressions in the ampulla; such depressions lie as usual on the side of the tube not covered by the peritoneum. The depressions or pits appear to be embryologic attempts at the formation of accessory tubal ostia; for the bottom of the pit is generally only covered by peritoneum and where the tube is not covered by peritoneum the wall is made of slight muscular layers and connective tissue. These pits or whorls lying in the ampulla are in my opinion ample explanations for ectopic pregnancy.

The ovum falls in one of these depressions and there is no particular force to dislodge it as the muscular is deficient, so that peristaltis will fail to forward the ovum toward the uterus. Some of the tubal plicæ are one-quarter of an inch long. In this tube the abdominal ostium is very peculiar. The tube appeared to attempt to form a double abdominal ostium but the septum between the two abdominal ostia failed to grow or atrophied, and there is presented in this case a large irregular ostium having abnormally abundant and luxuriant folds of tubal plicæ.

The abdominal ostium is one and one-half inches across. The lens shows no break or ulceration in the endosalpinx; it is simply in the mild early stage of endosalpingitis. In this case the tubal plicæ of the endosalpinx are so luxuriant, abundant and swollen that the tubal lumen was well filled and fluids would be difficult to force through.

To force fluids through at the menstrual time would require considerable peristalsis which often amounted to tubal colic or pre-menstrual pain in her case. The ovaries were about normal, but I would call attention to the fact that there is a distinct corpus luteum in one ovary one-half inch across. But observe that she never had an abortion nor a child. The conclusions are just what I found several years ago by investigating animals, i. e., that the corpus luteum is no sign of pregnancy, and its elevation to any legal significance in courts of justice is a relic of false so-called authority.

The parovarium was normal except the dilatation of one of Kobelt's tubes to the size of a pea. Gartner's duct and the tubules were normal. The vermiform appendix was in a catarrhal condition. The mouths of its swollen glands were enlarged, red and had too much secretion. It had several ulcers on its surface which were quite plain under the lens; some of the ulcers had denuded the epithelium and some were secreting gray slimy mucus. No doubt this was an appendix which had recurrent attacks of catarrh; in fact it had an attack as often as some irritating substance entered the valve of Gerlach and irritated until it became expelled.

(To be Continued.)

ACUTE ENDOCARDITIS IN CHILDREN.

Read in the Section on Diseases of Children, at the Forty-fourth Annual Meeting of the American Medical Association.

BY GEORGE N. HIGHLEY, M.D.

CONSHOHOCKEN, PA.

ETIOLOGY.

From a practical point of view, we can not look upon acute endocarditis as an idiopathic disease; if it ever occurs as such, it has been so rarely recognized that its existence in that form seems more than doubtful. Causes like cold, etc., which seem so prolific in producing inflammation of other similar structures,—as for instance the other serous and the mucous membranes—apparently have little direct influence in setting up inflammation of the inner lining of the heart. This immunity may be due to its situation, but it is difficult to assign a cause for it. This escape from primary affection is more than counter-balanced by the frequency with which the membrane is affected through the agency of other diseases—due wholly to the pathologic condition of the blood which those diseases create.

The pathologic state which we call rheumatism is responsible for the largest number of cases of endocarditis. In the acute rheumatism of childhood it is almost always present, though frequently overlooked. This fact should be well borne in mind, and all cases of rheumatism treated with the idea that in that affection the endocardium is as prone to inflammation as are the membranes of the joints. A great many permanently damaged hearts have been found long after an attack of rheumatism, in which at the time there were no special cardiac symptoms. The principal predisposing cause of rheumatism is undoubtedly the incomplete oxidation of metabolic products—the suboxidized proteids being particularly prominent in this respect. With the blood charged with these materials, the body first over-heated and then exposed suddenly to cold (air or water), and rheumatism is the natural result. The so-called heredity of affections like this, means that habits of the body, as a whole, and of its different parts (the various organs and perhaps the individual cells) have been transmitted from parent to offspring; similar causes and conditions produce like effects.

Next in importance to rheumatism, is the consideration of the cause of endocarditis. Scarlet fever is a disease from which few children escape being attacked before they reach maturity and from which, too, hundreds and thousands annually lose their lives; many times that number suffer irreparable injury from its virulent virus. It is likely that nearly as many cases of endocarditis have originated in scarlet fever as in rheumatism.

Diphtheria, variola, pyemia, puerperal fever, and all other diseases in which the blood is contaminated with a morbid poison, may produce the disease under consideration. Alteration of the chemic or physiologic state of the blood is its chief causal factor—the pathologic condition existing in acute rheumatism being particularly active in this respect. This, however, but brings us back a step in our search for the source of the malady, and a much more difficult question then confronts us, viz.: what are the causes of the antecedent diseases? Not to enter too deeply into this broad inquiry, which would be foreign to the purpose of this paper, I will,

nevertheless, ask for a brief consideration of the cause of the two affections with which acute endocarditis is so frequently associated, viz.: rheumatism and scarlatina.

In these days, when germs and disease are so constantly associated in the minds of medical men in the relation of cause and effect, it is but natural to find a microorganism assigned as the sole cause of each and every disorder of the body. Alleged discoveries are frequently put forth in support of this claim, so that now most of the diseases have had special organisms discovered, to which it is believed they owe their existence.

Now while our bacteriologic Uhlans are welcome to this belief, if to them it is self-satisfying and sufficient, it is to be hoped that the great body of practitioners—those who meet disease at the bedside and not in the laboratory—will at least withhold their judgment until more positive evidence is adduced. For upon the opinion thus formed will depend, in a large measure, the treatment to be pursued.

In the light of present knowledge it seems most reasonable to believe that the zymotic diseases—malarial fevers, smallpox, scarlet fever, etc., have a microbic origin, but that most of the inflammatory affections,—as for instance rheumatism, pneumonia, peritonitis, etc., do not arise in that way. (I am speaking of the primary forms of these diseases.) This latter class of affections so often follows exposure to cold (a sudden chilling off,) injuries, etc., and never, so far as we know, comes by reason of exposure to polluted air or to emanations from preceding cases, that we may reasonably regard them as due to the first named class of causes and not to the last. On the other hand, no amount of exposure to cold can cause a scarlet fever, a diphtheria, or any other of the zymotic diseases, but a very slight exposure to their contagium is sometimes sufficient to infect the most vigorous child.

An attack of rheumatism is almost invariably preceded by a history of having taken cold, i. e., the warm and perhaps over-heated body has been allowed to suddenly chill off. When this occurs it is the surface which feels the change first. The action of the skin is suspended, the superficial blood vessels contract, thus forcing the blood toward the internal organs; normal metabolism is thus seriously interfered with and the metabolic products can not easily be gotten rid of by reason of the inactivity of the skin. Lactic acid and other abnormal constituents appear in the blood, inflammation of the joints, and the phenomena of rheumatism rapidly follow. Predisposition to these processes is produced by long continued over indulgence in food in excess of bodily need; or of those kinds of food which are the most readily oxidized—the carbo-hydrates and fats,—and which therefore use up the oxygen of the system at the expense of the proteids, leaving the latter in a suboxidized state.

Rheumatism and scarlet fever have a widely different origin, but their effects are to a certain extent very much the same.

SYMPTOMATOLOGY.

The signs of endocarditis are rarely very marked, and the disease may run its course without giving any evidence of its presence—a valvular lesion discovered later on being the first intimation of its

having existed. The insidious nature of the affection makes it all the more important that a thorough and frequent examination of the heart should be made in every condition in which it is likely to occur. A very rapid pulse, beyond that which the antecedent disease would naturally produce should excite suspicion. If auscultation reveals a soft murmur, a slight prolongation of systole or a tendency to reduplication of either the first or second sound, its presence may reasonably be inferred. Dr. Cheadle says: "Reduplication of the second sound, heard at the apex, and diastolic bruit, are among the most certain signs of rheumatic endocarditis." (Cyclopedia Diseases of Children, Vol. II. Keating.) Should the disease not early prove fatal, a pallid face and other evidences of anemia become marked features. This condition is due to obstruction of the pulmonary circulation. There is also much wasting of tissue, the child becomes thin and feeble. Dropsy rarely ensues, unless there be disease of kidneys coexisting. Should there be also inflammation of the heart muscle, or of the pericardium, subjective symptoms become more pronounced. The child is restless, has a distressed look, and, if old enough, complains of pain and discomfort over the region of the heart which often palpitates violently.

Sometimes embolic detachments, from the deposit of fibrin on the inflamed valves, may be carried by the blood current into the lungs, the brain, or other organs. This would give rise to a sudden elevation of temperature, increase in rapidity of pulse, together with the local symptoms caused by the affected organ or part. In addition to the special symptoms which are indicative of endocardial inflammation, there are the symptoms of the disease with which it is associated.

TREATMENT.

Perhaps the most important thing for consideration is the question of prophylaxis. Can endocarditis be prevented in those diseases in which it is so prone to occur? In many cases the answer will surely be, yes; in some, no. In all cases the severity of the attack can be greatly lessened and the amount of damage to the heart, therefore, much diminished. To achieve this end, there must be a clear conception of the pathologic condition which is the active cause of the affection. There is, in addition to the contamination of the blood with morbid materials, an elevation of temperature and an increased number of heart beats. These three elements are the important factors in the production of endocarditis. The indication is clearly then; 1, to prevent as much as possible the formation of the morbid elements in the blood; 2, to keep the temperature down; 3, and to quiet the excited action of the heart.

To achieve the first, the diet must be made to conform to the demands of nutrition, both in quality and in quantity. An excess of that requirement means, if it does not set up a salutary diarrhoea, an accumulation of sub-oxidized material within the blood. It is always a serious error to attribute the weakness of an acute illness to a lack of nourishment; whereas it is simply due to depressed innervation. It is quite different from the weakness which results from long continued illness or from continued fasting.

It is, therefore, not only useless but positively injurious to try to force food upon a patient during

the first few days of an acute affection. At this period there is usually no desire, and often a positive disgust, for any form of food except water, and that is both a remedy and a food of the greatest value. It supplies all the pabulum needed during this period, and at the same time renders active aid to the system in getting rid of the effete and poisonous materials. A bountiful supply of pure cold water is worth more to the suffering one than all else that can be done. After a few days there is need of light, easily digested, easily assimilated diet. Carbohydrates and fats should be excluded as far as possible. On account of their great affinity for oxygen they rapidly exhaust the oxygenating capacity of the systems and thus seriously interfere with the oxidation of the proteids and of the metabolic products; the result of which would be an increase of the morbid elements within the blood.

Milk has long been a standard article of diet for the sick room and it is rarely contra-indicated. In conditions such as we are dealing with, it is often best to begin by giving whey, which being of lighter nutritive value may be given more freely; it is, too, a most excellent diuretic. It should be remembered that patients may live for months on milk alone or even whey, and not be much the worse for it. Other articles,—beef essence, beef tea, egg in small quantities, properly prepared (the white of an egg beaten up with the juice of a lemon and eaten slowly with a spoon is excellent), mutton broth (free from fat) gelatin preparations and the like, are also useful to fulfill the purpose which I have stated.

2. The best means at our command for the prevention of high temperature is undoubtedly the free use of cold water, both internally and externally. External applications of cold water are well borne in the majority of cases of rheumatism, and the relief which they afford is often most marked. If the temperature persistently keeps high, ice bags should be applied about the head and over the abdomen, one or two thicknesses of a towel being first laid over the latter. Ice bags placed over the abdomen are far more efficient in lowering temperature than when applied to any other part of the body. In scarlet fever nothing acts so efficiently as pouring cold water all over the body for ten, fifteen or thirty minutes at a time; or the child should have a cold bath at short intervals. Not quite so efficient, but often of much service, is the use of the antipyretic drugs. Great care should attend their employment in treating children on account of their toxic effects upon the heart. But wisely used they often do much good.

3. To quiet the action of the heart, and thus render it less likely to become the seat of inflammation, nothing is better than rest in bed and the use of small doses of morphia. I have met with no other remedy that can serve this purpose so well. It slows the heart, relieves pain, and quiets that disturbed state of the nervous system which is particularly prominent in febrile affections of childhood. To get the best benefit from it, the dose must be nicely adjusted to suit each case—one one-hundred-and-twentieth grain for a child five or six years of age, repeated every two hours, being generally sufficient; a smaller dose will sometimes do better; a larger one is often demanded. These prophylactic measures are of the greatest importance in preventing cardiac complications, whether the case be one of

acute rheumatism, scarlet fever or any other of the various affections in which they are liable to occur. It matters not whether the antecedent disease be due to a disturbance of the metabolic functions of which the exciting cause is cold, or whether it be due to an infection of the system with microorganisms; the indication for their use remains the same.

These measures, too, for the prevention of endocarditis are precisely what are needed in the treatment of its acute stages. Special remedies for the primary disease will be given but it is not my province to consider them in detail here. The treatment of endocarditis after the acute symptoms have subsided is much the same as the treatment of the chronic form of the disease.

THE NATIONAL FORMULARY.

Read by invitation in the Section on Materia Medica and Pharmacy at the Forty-fourth Annual Meeting of the American Medical Association.

BY PROF. C. LEWIS DIEHL.

LOUISVILLE, KY.

"As the practice of pharmacy can only become uniform by an open and candid intercourse being kept up between apothecaries and druggists among themselves and each other; by the adoption of the "National Pharmacopœia" as a guide in the preparation of officinal medicines; by the discontinuance of secret formulæ and the practices arising from a quackish spirit, and by the encouragement of that esprit du corps which will prevent a resort to those disreputable practices arising out of an injurious and wicked competition; therefore, the members of this Association agree to uphold the use of the "Pharmacopœia" in their practice, to cultivate brotherly feeling among the members, and to discountenance quackery and dishonorable competition in their business."

Thus, Article I of a Code of Ethics adopted by the American Pharmaceutical Association at the meeting of its organization in 1852. Forty-one years have passed, and but very few of the members who formulated and adopted this Article are now among the living, but during all this time it has been the keynote for the conduct, not alone of the members of the American Pharmaceutical Association, but for reputable pharmacists throughout our land.

But, it may be asked, if this is true, if this Article of the Code of Ethics has been upheld by the American Pharmaceutical Association, by its members individually, and by reputable pharmacists in general, why do we find the shops of pharmacists flooded with preparations, the formulas of which are wholly or in part withheld, and which pass current and are prescribed under names not known or recognized in the text-books of the medical and pharmaceutical profession? It is a question not easily answered without stepping on some one's toes, an operation which I propose to perform with as light a step as is practicable and sufficient to the purpose.

Within so short a period as thirty years ago, the manufacturers of pharmaceutical preparations for the trade in the United States could be counted upon the human digits. Their products were confined to such as could not be profitably or conveniently made in the pharmacies, or that might be required in emergencies. With the growth and development of the country, these establishments naturally extended their trade, so that from their small beginnings they soon became a power that exerted a decided influence upon the methods of the pharmacies.

The success of these pioneers in the manufacturing

business, in its turn led to the establishment of new manufactories, and consequent competition, so that the profits of the business soon were seriously contracted. What more natural, then, than to look up new channels in which to increase the volume and profits of the business? So far the efforts of manufacturers had been confined to catering to the convenience and legitimate necessities of the pharmacists; these having been met, it became evident that a more potent factor than the good will and convenience of pharmacists had to be enlisted if reasonable success in extending their business was to be assured. And in this way it came about that the pharmacist was shelved, and the manufacturer addressed his efforts directly to the physician.

Beginning with an explanation of exceptional or improved methods for producing medicinal agents, attention was soon called to new preparations, excellent, either by reason of their potency, palatability or appearance, or these combined. From a list of perhaps half a dozen "Elixirs," so-called, the formulas for which were well understood and the common property of pharmacists, there was an annual increase amounting to dozens, the formulas for which were uniformly withheld, while their composition was, at best, only partially indicated on the label. Coated pills were introduced, with particular laudation respecting the quality and character of their coating; but soon the list of pills in common use was exhausted, and new formulas were invented or constructed in concordance with the prescriptions of popular physicians, until now there is no end to them. And so in due time came about compressed pills and tablets, tablet triturates and a host of other preparations, all of them, doubtless, useful and some of them—under the present practice—indispensable, but, in all, the result of the effort of their introducer to secure for himself the lion's share of whatever profit might be gained by their manufacture.

It is but common justice to concede to an inventor proper recompense for his time, trouble and expense, and also a reward for his invention. Our patent laws secure this to him, so far as his invention may meet with popular use and demand; but under our patent laws everything must, or should, be open and above board. A knowledge of how a patented article is made is public property, while it is the patentee's property to make, or to give the right to make it. And so A, for example, if he had succeeded in obtaining a patent for gelatin-coated pills, and declined to give consent to others, would have been the only manufacturer of gelatin-coated pills. But, insomuch as A did not secure a patent for gelatin coated pills, the process being known and easily executed by any one competent to make pills, why should the preference be given to B, when A, C and D can make and do make them just as good? The point made is simply for the sake of argument, and applies with equal force to all preparations, the formulas of which are authoritative or that are honestly offered under honest titles.

That this is the correct view is evidenced by experience and practice; for it is becoming more and more the practice of prescribers to omit the designation of the manufacturer when prescribing preparations of authoritative or well-known composition, the prescriber leaving the responsibility of quality to the dispenser. Manufacturers were not the last to

recognize this tendency; on the contrary, they found that unless resort was had to some new expedient, they would soon again be in their original position; that is to say, directly dependent upon the pharmacist for the demand for their products. And we must look for an explanation for this again to the effect of competition, for manufacturers have increased almost as fast as new preparations. Not alone that many separate manufacturing establishments have been opened; the shrinkage of profits in the wholesale drug business has prompted almost every wholesale house to open a laboratory for manufacture, in connection with their regular business. All of these, with few exceptions, have accepted and adopted the new expedient, which consists in introducing some preparation of popular drugs under a specific trade name. A palatable or presentable preparation having been secured, it suffices to give it a name, derived from its most prominent constituent, or from the specific term applicable to its medicinal use, or to prefix the manufacturer's name to a more or less abbreviated title of the preparation, and the manufacturer has a product which must be purchased from him and can not be substituted with impunity by the product of another manufacturer. To the prescriber it appears to make no difference whether the composition of the preparation is clearly indicated in the label, or not, and generally it is not; the "essential principle" of so many grains of this, that, or the other, or of a teaspoonful of codliver oil, certainly do not give us a clear conception of the preparation before us. In point of fact, many of these preparations are simply such as are commonly designated as "patent medicines," though they may by courtesy be called "pharmaceutical specialties."

I believe that I give voice to the unanimous sentiment of the reputable pharmacists of our country, when I say that it would be presumptuous for me to call attention to any single preparation, or class of preparations, that physicians do, and ought not to prescribe. It is not the concern of the pharmacist what is prescribed, so long as he is convinced that the prescriber has not made a palpable error in his prescription. But I am sure that I act within the bounds of propriety when I say that the modern tendency of prescribers to designate the product of special manufacture in their prescription, while perhaps simplifying the prescription, has complicated the business of the pharmacist to such an extent as to become a serious burden. That this burden was felt by pharmacists everywhere was shown by the adoption of formulas for various non-official preparations in common demand by a number of local pharmaceutical associations—some of which, indeed, were called into existence by this very exigency—and I could mention several localities in which the then current "pharmaceutical specialties" were knocked completely out of the field and replaced by the preparations proposed by the local associations. This success, however, was only temporary; partly because of the efforts of manufacturers to recover the ground lost, by the introduction of trade-marked preparations, and largely by the circumstance that the preparations adopted by the different local associations, though identical in name, were not identical in their formulas. And so it gradually came about that the local associations looked to the National Association to bring order out of chaos, the result

being the publication of the "National Formulary," in 1888, by the American Pharmaceutical Association. The "Formulary," in its present, unrevised condition, embodies formulas and definitions for 435 preparations, covering most of the non-official preparations in popular demand, and replacing many that are now popularly prescribed under special trade names. Among these formulas may be enumerated eighty-six for elixirs, thirty-four for syrups, ten for emulsions, thirty-nine for liquors or solutions, twenty-six for powders, including fourteen salines and effervescents, seventeen for mixtures, twelve for wines, thirty-one for tinctures and thirty-three for fluid extracts. It is within my personal knowledge that many of these formulas have stood the test of time in the localities in which they had been originally introduced, and that none of them were embodied in the work until they had been subjected to the most rigorous tests; so, that, even as the work now stands it merits the confidence of physicians, the more particularly since the formulas are explicit, and are easily followed by pharmacists even of moderate ability. With the advent of a new "Pharmacopœia," it will become necessary to eliminate some of the formulas; to keep pace with the new preparations, specialties and remedial agents, it will be necessary to add others, and the "Formulary" is therefore now in the hands of a Committee of Revision, who have made a preliminary report at the last meeting of the American Pharmaceutical Association, and will probably make a final report at an early day. The result of investigation made so far by this Committee confirms the reliability of the formulas with few exceptions, and those of no importance. I would therefore earnestly ask that physicians give these formulas their favorable consideration, and that the AMERICAN MEDICAL ASSOCIATION take such action as may be conducive to the adoption and use of the "National Formulary" by practicing physicians throughout the land.

DISCUSSION.

DR. DIEHL, in answer to question by the Chairman, said that in his opinion some of the newer drugs and preparations will be introduced in the next "United States Pharmacopœia." This will include such preparations as various elixirs, and certain drugs of recent introduction, but will not include patented medicines or trade-mark preparations. There will be no radical change, except in relation to weights and measures. The metric system will be adopted. In the formulæ for making tinctures, parts by volume will be substituted for parts by weight. The preparation of the drugs opium, cinchona and nux vomica will be provided with methods of standardization.

Speaking of the "National Formulary," DR. DIEHL said that it had proved a financial success. The first edition consisted of five or six thousand, and since that time at least five thousand more have been printed. He would like to see the book adopted as a text-book by the medical colleges.

DR. WOODBURY spoke of an instance in his own knowledge where a pharmacist was using the "Pharmacopœia" of 1870 five years after the issue of 1880 had been published. Owing to the radical changes made in the last "United States Pharmacopœia" in regard to the strength of opium preparations, etc., such neglect upon the part of pharmacists was culpable. In his opinion, the use of the "Pharmacopœia" would never become general until it was introduced into the medical and pharmaceutical colleges as a text-book.

DR. STEWART said that he was taught that pharmacy was a liberal profession, the same as medicine, and the adoption of the "National Formulary" and "United States Pharmacopœia" as text-books would favor that end.

A committee was then appointed, consisting of Prof. Good and Dr. Stewart, for the purpose of drawing up a resolution recommending the adoption of the "United States Pharmacopœia" and the "National Formulary" as text-books in medical and pharmaceutical colleges. This resolution was adopted by the Section and sent to the general session, where it was well received and adopted:

Resolved, That the AMERICAN MEDICAL ASSOCIATION recommend that the new "United States Pharmacopœia" soon to be issued, be at once practically adopted by physicians in prescribing and pharmacists in compounding. It also advises the general adoption by physicians and pharmacists of the "National Formulary," issued by the American Pharmaceutical Association, and that the leading medical and pharmaceutical colleges adopt these works as text-books.

TRAUMATIC NEUROSES IN COURT.

BY L. BREMER, M.D.

ST. LOUIS, MO.

Of all the diseases which within the last ten years have preëminently engaged the attention of the medical world, there is none that deserves more interest and is of greater practical importance, than that group of nervous disorders which have been styled the traumatic neuroses. It is especially since the meeting of the Tenth International Congress held at Berlin in 1890, that this question has occupied a prominent place in medical thought and discussion of the world over. The somewhat acrimonious debate on that occasion, not altogether free from personal antagonism, had as an immediate consequence, the effect of stimulating renewed study and producing a flood of literature on the subject.

Oppenheim's book on the traumatic neuroses had not only renewed or intensified the interest, but also excited widespread contradiction.

Oppenheim, in contra-distinction to Charcot, who classed all neuroses following accidents as hysteria, tried to demonstrate in his book that there is a type of disease quite peculiar in its manifestations particularly on the part of the nervous system, a type which is only met with after injuries, and railway injuries in particular.

The opponents of Oppenheim have contended that he described a disease which he called the traumatic neurosis, meaning thereby a well defined nervous disorder, characterized chiefly by concentric narrowing of the visual field, anesthesia or hyperesthesia, irritability of the heart and certain mental anomalies.

This disease as such, they claim does not exist. There are traumatic neuroses, however, resulting from injury coupled with shock, for instance, hysteria, neurasthenia, chorea, epilepsy, shaking palsy, etc. These neuroses constitute a family; they are more or less closely related to each other.

Most frequently among these traumatic neuroses are found hysteria and neurasthenia or a combination of the two, hystero-neurasthenia.

Whilst Oppenheim claims that predisposition and heredity are extremely rare and that the victims to his traumatic neurosis were ordinarily robust men, before the accident, Charcot and with him the French school, assert that the injury is only the provoking agent of a disease which exists in a state of latency. Without the accident the person might have con-

tinued in good health for the rest of his life; the injury and the mental shock, however, changed a dormant into an active trouble.

The French claim that Oppenheim's cases are simply hysterical-neurasthenia, i. e., graver cases of post-traumatic neuroses, and that they do not represent specimens of a clinical entity.

The drift of opinion in neurological circles is in this direction, and Oppenheim, himself, seems to have made some concessions to the French school of late.

In France, traumatic hysteria seems to be the prevailing form of the neuroses under discussion. With us, traumatic neurasthenia is certainly the predominant form, the difference being due to racial peculiarities.

The importance of these lesions, considerable though it is from a clinical point of view, has been materially increased of late years on account of the ever increasing frequency of damage suits resulting from them.

Owing to the great discrepancy still existing on the nature and import of these affections and the diametrically opposite views given by the physicians of the litigating parties, these suits generally form very knotty problems for the jury to solve.

The difficulty in the way of a righteous verdict lies in the very nature of the affections under discussion. If there is a visible injury, a fracture for instance in any part of the body, or lesion of the integuments or the deeper tissues, it is to the layman a comparatively easy matter to comprehend how such an injury may be followed by transient or lasting nervous symptoms, which may constitute, as they do in the traumatic neuroses, the chief and prominent sequelæ of the injury. This difficulty is increased by the too frequent occurrence of exaggeration or downright shamming on the part of the injured, in cases where damage suits are brought.

The trouble will, I am afraid, go on increasing owing to the spread of knowledge on the subject among the masses of the people. To this dissemination of knowledge is to be added the prevailing tendency to fleece the soulless corporations; on the other hand, the real victim to a traumatic neurosis will have a difficult task of convincing a skeptical jury, which through doctors and lawyers have been made acquainted with the great prevalence of simulation of nervous disorders.

Unfortunately the symptoms of the disease are in the vast majority of cases of a subjective nature. Hence very frequently the veracity of the claimant supported by the testimony of a physician, viz.: that such and such symptoms may result from the alleged injury, form the exclusive evidence in the case.

One of the commonest complaints of the sufferer from a traumatic neurosis is pain. How can this be demonstrated? If we possessed an instrument by which we could gauge the pain, an algometer, analogously to the æsthesiometer, matters might be considerably simplified. As it is, pain is a relative and indefinite quantity. Mucius Scaevola puts his hand into the burning coal without flinching. Charles XII smokes a pipe whilst the surgeon removes by deep incisions a bullet from his leg, but the impressionable weakling will convoke a medical faculty for an ordinary belly-ache.

Almost equally difficult of determination is the degree of anesthesia or hyperesthesia which are so

frequently complained of by such patients. It is a very easy matter to detect contradictory statements in regard to the intensity of anesthesia; and a person must not be set down as an impostor when the result of the examinations of one sitting does not tally with that of a preceding one. The degree of attention and the varying condition of the patient himself are responsible for discrepancies.

On the whole, it may be stated as a general proposition that a claimant for damages is not to be looked upon as an impostor by the examining physician, because contradiction in regard to his present condition and that of the past are discovered. For a defective memory and an instability of the perceptive faculties are among the commonest symptoms of the traumatic neuroses. Again, if the case be one of traumatic hysteria the phenomena are often almost incredible, especially to him who has no neurologic or psychiatric training. A knowledge of this latter branch of medicine is above all requisite for the correct interpretation of the symptoms and behavior of the traumatized neurotics. For it is not the peripheral nerve, nor the spinal cord which is principally affected in these neuroses, but the mind. It is a psycho-neurosis which the examining physician has to deal with. This mental anomaly, the hypochondriac-melancholic tinge which almost invariably is met with in the traumato-neurotics, has been used as an argument against the hysterical nature of the trouble, since the hysterics have generally an air of hopefulness or indifference about them and are notorious for their abrupt changes from one mood to another. But it is as strange a fact as it is incontestable, that the male hysteric is morose, despondent, embittered, quite in contrast with the female victim of the disease.

Taken for granted now, that a certain proportion of the traumato-neurotics are afflicted with hysteria or in the worst cases hysterical-neurasthenia, it becomes apparent at once why it is that the symptoms presented by such a case seem so incredible and out of keeping with what is ordinarily observed in injury and disease. Expert examinations as to eye, ear, heart, lungs, etc., and the tests usually employed to unmask imposition have, as a rule, a very bad effect on such patients and not unfrequently, what has been a simple neurosis at first, has by injudicious, overzealous activity on the part of the examining physicians, been converted into a psycho-neurosis of a grave character. It will not do to tell such a patient that he is *only* hysterical and that, being a man, he has no business to be so. Hysteria may be a grave disease, and male hysteria, especially that due to injury is apt to be particularly obstinate and intractable. The same holds true of traumatic neurasthenia which is generally less accessible to treatment than the non-traumatic variety.

In all these conditions now, there is a general tendency to exaggeration of the symptoms. It is physiological to the disease as it were, and ought not to be put down as an unfailing sign of shamming with the intent of increasing the award of damages.

We ought always to bear in mind, as stated before, that the disease is psychogenous in character and that its proper diagnosis belongs therefore to the domain of the psychiatrist and neurologist. And even he is apt to be misled in cases of this class, unless he has paid strict attention to the literature on this subject for the last four or five years, during which a

considerable stride towards better and more exact knowledge has been made.

It is not my object in this paper to describe traumatic neuroses in all their details, their fundamental and secondary symptoms. My intent and purport is, to point out the difficulties surrounding this matter, especially in cases of litigation.

The exaggeration of originally existing, and the acquisition of new symptoms, through examinations made by a number of physicians, each of them asking about, and thereby suggesting some new symptom generally or exceptionally met with in traumatic neuroses, has led to quite a new nosologic species of morbid phenomena, the litigation symptoms, so-called. To reduce them to their proper level and to eliminate them from the legitimate clinical picture, is one of the most difficult tasks of the examining physician.

As a rule, patients who have their claims in court, get worse mentally and physically. The worry and anxiety which even the healthy and vigorous individual has to undergo in a lawsuit, which is to decide on his financial future, is a particularly hard strain on the nerves of the traumato-neurotic.

The excitement incident to litigation renders his case progressively worse, and many a claimant would have fared much better in health and happiness, had he settled at a reasonable figure instead of undergoing the harassing wear and tear of a lawsuit. Not the most liberal award will repay such a man for the often deep and lasting damage his brain has sustained from prolonged litigation.

On the other hand, it is often astonishing what amount of elasticity and recuperative power is exhibited by the successful claimant. Nowhere has the gold cure celebrated greater triumphs than on the field of traumatic neuroses, if administered by a benevolent jury. There dwells a familiar figure in the memory of those who frequently have to deal with these cases, of the neurotic cripple, who has to be assisted to ascend the witness stand and gives his testimony in a feeble and broken voice, an utter, pitiable wreck, physically and mentally, who a few weeks later is capable of carrying the weight of several thousand dollars in silver, the award of damages, without any apparent difficulty.

Again cases are on record where successful litigants openly bragged after having secured their booty, how they duped the doctors, judge and jury.

Such occurrences are not frequent, but their reality is incontestable. The unjustifiable benefit which one undeserving individual derives through such practice necessarily redounds to the detriment of the deserving victim.

In order to exclude any possible errors of diagnosis, the aim of all original investigation of the subject has been to establish the objective signs of the neuroses, and, if possible, such symptoms as can not be simulated and which are characteristic enough to exclude other diseases. Unfortunately there is no objective sign which can not be successfully simulated by one who through association with real traumato-neurotics has become sufficiently familiar with the leading symptoms. The only exception seems to be the concentric narrowing of the field of vision, so much insisted upon by Oppenheim,¹ the acceleration of the pulse, especially on pressing the painful spots, as a

¹According to Charcot this is one of the most valuable, though not constant, stigmata of hysteria, whether ordinary or traumatic.

rule situated at one or more of the spinous processes, (Mannkopf's sign) and the difference of the pupil, the one on the affected side (in cases of hemianesthesia or hemiplegia e. g.) being larger than the other.

But it may be broadly stated that all these symptoms are not characteristic of the traumatic varieties of hysteria, neurasthenia, and hystero-neurasthenia, that they are as frequent in the non-traumatic forms, hereditary or acquired, and that as a matter of fact they are observed in quite a variety of other neuroses, and chronic affections in general.

It would devolve, then, on the defense to prove that the person suing for damages was neurotically tainted before the accident, which, of course, is generally a matter of difficulty and impossibility, since every claimant will insist on his previously perfect health; and there are scores of witnesses to prove it. My experience is that in quite a number of such patients a preëxisting neurasthenia could be elicited. Of course, this name does not figure in the patient's previous record; as a rule the terms, "biliousness" and "dyspepsia" are named, which generally are nothing more nor less than symptoms of genuine neurasthenia.

On the other hand, it devolves on the examining physician to establish as to their proper value, the symptoms observed in the claimant, and to find out how much of them is due to the accident and what may have existed before. A very difficult task indeed.

To illustrate the obstacles besetting the subject, especially when complicated by litigation, I shall briefly mention a few of the cases with which I have had personally to deal.

I believe that one of the most curious instances in forensic medicine, and thus far a unique one, where the problem of the causation of diseases was involved, is that of a woman who, several years ago claimed that she had been permanently injured while ascending in an elevator of one of the large drygoods houses of this city. She contended that the machinery had come to a sudden stop, throwing her forward and causing her to land on her head. Since that moment she was paralyzed in her lower extremities. The damages were laid at \$20,000. The defense, however, convinced the jury that claimant had had hysteria all her lifetime, that the alleged injury received by the sudden stoppage of the elevator, which could not be proven, was in reality one of the attacks common to hysteria, usually called hystero-epilepsy, and that a disease remained which has the uncommon and formidable name of hysterical "astasia-abasia," but which is in spite of this name a reality. The jury found against the claimant.

In another instance a railroad was sued for \$20,000 damages by a traveling salesman who had jumped from a train to avoid the effects of a collision. Since that time, or at any rate several months later (as is often the case in traumatic neuroses) he had evinced a number of neurasthenic symptoms which he claimed were caused by the accident. The train had moved at the time this occurred with a velocity of six to eight miles an hour; in jumping the plaintiff had landed on a heap of gravel and had fallen on his knees, bursting his pants at that point. There had been no injury, except an insignificant abrasion, nor had anybody else been injured, not even the engineer, who remained on the engine at the time of

the collision (the engine had been damaged only to the amount of one hundred dollars). The defense succeeded in convincing the jury that the injuries were too insignificant to be looked upon as the cause of the neurasthenia (despondency, rachialgia, inability to work, etc.), from which the plaintiff was undoubtedly suffering, there being data enough in the previous history of the patient pointing to a very strong neurasthenic diathesis.

In the third case, which may be briefly mentioned, a man, known to be an alcoholic of a pronounced type, had been struck by the beam of the barrier at a railway crossing through the negligence, it was alleged, of the watchman in attendance. The pole which, owing to the counterweight at one end did not descend with great velocity, grazed the man's head, who stumbled, but did not become unconscious. There was not the "traumatic narcosis" in the language of Bergman, so eminent an occurrence, as a rule, in accidents of this nature. The man, after the accident, if it was such, visited several bar-rooms and had later on leeches applied to the site where the beam had struck the head. Two days later a surgeon examined him, after he had returned home (the accident befell him while on a visit to this city) found nothing to indicate an injury either to the scalp or bone, not even the evidence of a contusion. The only lesion visible was the leech bites. This man soon after the injury developed symptoms of mental alienation. The symptoms were such as are generally observed in alcoholic insanity. His friends, however, thought that the disorder of his mind was referable to the injury sustained from the pole, and after he had partially recovered, he sued the company, the proprietor of the barrier where the accident had happened. It was learned that the medical experts who were to appear for plaintiff hinted at a depressed fracture as the cause of the mental trouble. The claim of damages was for \$20,000. The case never came to trial. It was compromised at \$1000. It was plainly one where the trauma did not play the least of a pathogenic rôle.

These three cases taken at random from the cases of my own experience show the importance of hysteria, neurasthenia and alcoholism in the development of traumatic neuroses and psycho-neuroses. They demonstrate the importance of the diathesis or pre-disposition and reduce to its proper value the injury, as simply the provoking agent of a dormant trouble. The task of the examining physician will be to ascertain in the first place the gravity of the existing nervous disorder, and next the probability or improbability of a connection as to cause and effect between it and an alleged accident.

If anywhere a reform is needed in the administration of justice, it is in the suits for damages. Nowhere in the whole machinery of the law are there more farcical performances found than in the courts where damage suits are tried for personal injury; and nowhere is there such an opportunity for the profession to exhibit their chronic disagreement, as on the question of traumatic neuroses. As a rule there are two opposing sets of doctors. One is trying to prove to the jury that the plaintiff is a damaged man and incapacitated for life; the other set will try to prove that there is not much the matter with him, that he is exaggerating or putting on and feigning disease which does not exist. This war of experts who as a rule are not familiar with even a rudimentary knowl-

edge of the neuroses is generally a source of great amusement to the lawyers and the jury, but does not redound to the good name of the profession; much less is it calculated to help the jury distinguish between the right and wrong. Ready wit and repartee is too often counted for knowledge and the testimony of an ill-informed tyro may outweigh that of the experienced physician. Not until trained and trustworthy experts are appointed by the state to pass on doubtful cases and instruct the jury in accordance with their finding, will there be an improvement in the defective and erroneous methods of arriving at verdicts in cases of traumatic neuroses claiming damages. Under existing conditions the true medical expert is generally hampered by counsel of the opposing party in his efforts to elucidate the case. The prevailing custom that only the experts for plaintiff are allowed to examine his person is certainly not calculated to help the jury in their effort of reaching a just verdict. The fact is that there is too much hedging and dodging done by medical experts, to help the side for which they happen to be engaged. They thus run the risk, or rather are necessarily exposed to the danger of turning advocates where they ought to be impartial witnesses.

Quite reprehensible is the practice which has been actually resorted to by some experts, of going into a lawsuit for damages on the plan of sharing in the profits resulting from the verdict. This is lowering the already low standard of our profession. What may be legitimate and proper for a lawyer to do under such conditions, is utterly unpardonable in a physician.

Some facetious observer has divided prevaricators in court into three classes; liars, blank liars and experts. Let us try to help to get the medical experts excluded from this category.

INFECTION FROM THE MOUTH.

Read in the Section on Dental and Oral Surgery, at the Forty-fourth Annual Meeting of the American Medical Association.

BY E. L. CLIFFORD, D.D.S.

CHICAGO.

Each and every day brings the thoughtful student more and more to face the fact that the scientific world is progressing; and he who has kept *au courant* with the literature of medicine must acknowledge that the results of such investigations as are now being pursued have, for a principal object, the unfolding of the prime factors in the causation of diseases, with a view to their prevention.

Recent investigators have sought to open up new fields; they have tried, and found wanting, in many instances, the beaten track, and their efforts tend to the opening of new lines and a practical departure from the pathology of the past, with an ever increasing tendency to lead us to cultivate and entertain broader, or at any rate less narrow views, as to the elements which play an important part as etiologic factors in the causation and origin of diseases.

It is not necessary, or even advisable at this time, to recapitulate the theories of the past, and our aim will have been attained if we can take a few profitable glimpses at the newer fields, allowing the lines of thought and inquiry which may suggest themselves to each to furnish a basis for intelligent discussion.

Much has certainly been accomplished in the last two decades in the field of etiologic pathology, still

much remains to be done, and upon the shoulders of some of the bright lights in our specialty, and this Section, will certainly fall a part of that task.

Investigation and experimentation in the past have been unable to specify and establish any *single* thing as a final cause of disease; and it has been said by one, eminent in our current literature, that he knew of no disease which acknowledged a *single* cause. Our work, then, if this be true, must be to search for and find out the many and ever varying factors or conditions which, as antecedents, combine to produce disease; and I am of the opinion that to the physiologic agencies within our bodies during life we will find many competent factors.

The researches and expositions of Gautier, Peter, Brown and Brunton, confirm our belief in the poisoning or intoxication of the animal economy with its own products. These eminent physiologic chemists traced and pursued their investigations from two general aspects, and Aitken in his excellent review of their work has classified them under two heads: 1, from a chemic and physiologic, or bio-chemic standpoint; and 2, from a clinical or pathologic. From the first standpoint the fact was established that in dead animal tissues, processes of putrefactive decompositions set in, by which certain alkaloids are elaborated from the proteid substances, and these alkaloids were designated by the late Selmi of Bologna, as "ptomaines." Gautier, however, further showed that in the *living* animal tissues, and that by virtue of their vitality, certain other alkaloids are elaborated, which are analogous to the ptomaines and these he has named "leucomaines." But, still further, in addition to these facts, he has demonstrated that in the living animal economy there are elaborated certain azotized uncrystallizable substances which are as yet undetermined, and which he has called "extractives" or "extractive matters," and which Aitken states are quite as unknown as the x, y, z's of an algebraic formula.

The nature of these extractives, then, remains a mystery, but this much we are told of them; that while we are assured that the ptomaines are toxic, and that the leucomaines are also toxic, these unknown extractives are more toxic or poisonous to the system than either. Different alkaloids have been obtained from different sources, both animal and vegetable, and as long ago as 1820, Kerner pointed out the resemblance between the symptoms of poisoning by the animal and vegetable alkaloids. Experimentation since has confirmed the theory. "Zuelzer and Sonnenschein obtained, both from macerated dead bodies and from putrid meat infusions, small quantities of a crystallizable substance which exhibited the reactions of an alkaloid, and had a physiologic reaction like atropin, dilating the pupil, paralyzing the muscular fibers of the intestines and increasing the rapidity of the pulse." V. Anrep obtained an alkaloid from poisonous fish, and Vaughan an alkaloid from poisonous cheese, but "Gautier, Etard, Brieger and others have given precision to the data previously acquired, and added largely to the varied and careful examinations of cadaveric tissues;" "they forced the conclusion that during putrefaction of nitrogenous animal material there are formed organic bases, fixed or volatile, presenting for their chemic and physiologic properties, the closest similitude to the vegetable alkaloids."

In fact, while it was at first supposed that these

animal alkaloids differed in their nature from the organic alkaloids formed by vegetables, and various reactions had been given to distinguish them, Brieger appears to show that the distinction can be maintained no longer; but that the animal and the vegetable alkaloids are similar in their chemic constitution; that they are both products of albuminous proteid decompositions, and that some, at least, of the so-called ptomaines are identical with vegetable alkaloids. Hence, Dr. Brunton seems justified in regarding alkaloids "as products of albuminous decomposition, whether their albuminous precursor be contained in the cells of plants and altered during the process of growth, or whether the albuminous substances undergo decomposition outside or inside the animal body, or by processes of digestion, as by organized ferments." Aitken also states that it has been shown that the alkaloidal products formed by the putrefaction of albuminous substances vary according to the stage of decay at which they are produced. At first, the poisonous action of the ptomaines may be slight; but as decomposition advances the poisons become more virulent, while after a still longer period they become more broken up and lose to a greater extent their poisonous power. (Brunton.)

"In addition to these alkaloids obtained by Brieger, a number of poisons have been got by other workers from decomposing articles of food, or from dead bodies, and even from portions of healthy animal bodies, and although these may not have been obtained in the same state of purity, not have had their chemic constituents so well defined as Brieger's, they are still as unknown extractives, x, y, z's of great interest and importance."

Experimentation has even shown that the primary products of albuminous decomposition of digestive ferments, such as peptones, are poisonous; and that pepsin will split up albuminous substances still further; and Dr. Brunton very aptly sounds the tocsin of caution against the extreme and indiscriminate use of the various digestive ferments, and of the many varied artificially digested foods which have now become common. Consequently it behooves us to study the products of albuminous decompositions as a matter of much practical importance, not only as regards pathology, but as regards therapeutics. Now it would not be possible to exclude these animal alkaloids from the general economy, for Gautier has proven that they are a necessary product of *vital physiologic processes*. His experiments show "that about four-fifths of our disassimilations are the result of transformations within the body, comparable to the oxidation of alcohol; and that the remaining one-fifth of the disassimilations are formed at the expense of the living tissues themselves, "free of all demands on foreign oxygen." In other words, "a fifth part of our tissues live after the manner of ferments, that is they are anerobious or putrefactive as to their life." "Hence the possibility of alkaloids being thus formed within the living organism, independent of bacterial fermentation is quite within our conception."

Bio-chemically, the same author states that much has been proved, and he does not doubt that poisonous alkaloids are continuously formed in healthy men and animals by the decomposition of albumen in the intestinal canal, during the process of digestion, or in the blood and tissues generally by the metabolism which occurs during the functional ac-

tivities of life. He believes that a considerable production of alkaloids takes place in the intestines, both when the digestive processes are normal, and more especially when they are disordered. Were all the alkaloids to remain within the body, poisoning would undoubtedly ensue, and Bouchard makes the statement that the alkaloids formed in the intestines of a healthy man in twenty four hours would be sufficient to kill him if they were all absorbed and secretion stopped. Another statement, made by the same author, tends to show the power of these agents as an etiologic factor, and which at this time will probably not be questioned: "That the nervous disturbance which occurs in cases of dyspepsia is due to poisoning by ptomaines;" "that they augment notably in the course of certain maladies,—in typhoid fever for instance."

Now, as to the clinical, pathological and practical aspects,—according to the different sources of poisoning, or intoxication, as it is technically called, there are correspondingly different indications, signs or symptoms which Dr. Brown classifies as follows: 1, poisoning by the extractives is attended by *hyperthermia*; 2, poisoning by "animal alkaloids" is accompanied by *hypothermia*; 3, a combination or succession of *hyperthermic* and *hypothermic* phenomena may become manifest, according to the combination or alternation of poisoning by the deleterious physiologic products, or their antagonistic action. Some contradictory evidences of the above are accounted for as follows: "Where 'extractive matters' accumulate in the blood we detect *hyperthermia*; on the other hand, if 'alkaloids' accumulate, we have *hypothermia*, while if the two factors coëxist, they may neutralize each other, or become antagonistic in their action, so that temperature may remain stationary or normal. But should one or the other predominate, immediately the scale is turned, so that some variation may be noted. In this auto-infection, this spontaneous or self-infection, of the living organism by the alkaloids and extractives of its own formation there is no question of quality, but simply one of quantity to be considered, by reason of the essential physiologic source and action of the poison. In other words, the healthy living organism may become poisoned (more or less slowly) by the accumulation within itself of deleterious substances normally elaborated, but imperfectly or defectively eliminated. Hence the slow and insidious onset of much ill-health, and from which recovery is correspondingly slow." Now, in what way does this auto-infection of the system take place? Brown tells us that it can only be understood and explained by the mode in which we regard the phenomena of life. Life is a ceaseless decay with a ceaseless repair. "Normal health is conditioned on an incessant formation, transformation and elimination of the effete or old organic materials which must give place to new. It is this effete material, which therefore, represents a series of partial deaths, and which, as the result of organic functional operations, constitutes life, during which the tissues and organs in the processes of their metabolic changes perform a constant function of disintegration, fabricating during these processes those alkaloids and extractives, those x, y, z's of pathology which must be regarded as veritable "*physiologic ashes*," (Brunton) resulting from the processes of combustion of the elements of organic tissues."

Having progressed thus far, and established the fact, we think, of the presence and power of these poisonous agents, let us for a while cast a glance at the oral cavity of man, and see if any conclusions can be drawn as to the part it plays in promoting or preventing the formation of these factors in the causation of disease.

1. We will claim that no portion of the organism is of more importance, or is more active as a veritable chemic laboratory, than the mouth. It is established, that in the processes of putrefactive decomposition, certain alkaloids are elaborated from the proteid substances. We all know that in the cleanest mouths certain portions of these proteid substances will remain, as they are ingested with the food we take, as well as the water we drink, and the air we breathe. We know also that in the cleanest and healthiest mouths, absence of bacteriologic influences is but an utter impossibility, and that these microörganic agencies, furnished as they are with the proper media or food, conjoined with a suitable temperature and abundant moisture, make the mouth one of the best incubators that can be imagined. If this be so in mouths that have been no strangers to proper hygienic influences, how much more strongly is the fact established of the influence of this territory, when carelessness and neglect have been a predominant feature? And, if we accept the theory of Aitken that these alkaloidal products vary as to their poisoning power according to the stage of decay at which they are produced, how important is it that these hygienic influences be enjoined and enforced. Then again, accepting the dictum of Gautier, that these animal alkaloids can not be excluded from the general economy, and that they are even necessary as a product of vital physiologic processes, it certainly becomes the duty of that branch of medical science to which the very entrance of the digestive tract is allotted for control and treatment, to see to it that contaminating influences are eliminated. Again, if the possibility of the formation of these animal alkaloids is acknowledged without the aid of bacteriologic fermentation, as shown by Gautier, how much more deleterious must be their effects, and how much greater must be their production when conjoined to and assisted by these physiologic agencies. If an abnormal amount of these poisonous substances are produced within the intestines when in any way disordered, how much more reasonable to conceive that the manufacturing capacity of the mouth is greatly increased, when a condition that might be termed absolute filth is no stranger to the eye of the observant dental practitioner. If the amount of these agencies formed in the intestines of a healthy man in twenty-four hours is sufficient to kill him if absorbed and secretion stopped, it will require no great stretch of your imagination to realize that enough poison could be taken from the mouth of the average dental patient to kill a small army of inoculated subjects if properly applied. Let the physician who doubts this statement recall the condition of wounds, and ponder over the difficulties of his prognosis when called to attend a traumatism caused by the human bite. The conclusions of Dr. Brunton will also go far to account for the thermal changes which take place and accompany these traumatisms, when viewed from a clinical or pathological standpoint. Miller establishes well the part played by the human mouth as a

generator of microörganic life, and his testimony is corroborated by other investigators; not only are large quantities of the animal alkaloids produced within the intestines and other portions of the alimentary tract, but large quantities are swallowed with innumerable bacteria which have already been produced in the mouth, and, as stated by Miller, they give rise to local and general disorders of the most serious nature, produced partly by the direct action of the microörganisms, and their products upon the teeth and the mucous membrane of the mouth, partly by swallowing large portions of bacteria, partly by carrying them into the lungs, particularly in cases of violent inspiration and finally by their obtaining an entrance into the blood or lymph vessels in various ways, such as by a breach in the continuity of the mucous membrane brought about by mechanical injuries (wounds, extractions, etc.) through the medium of gangrenous tooth pulps, which usually lead to abscess at the point of infection; sometimes with secondary septicemia and pyemia with fatal termination by resorption of poisonous waste products formed by bacteria; by the inspiration of particles of slime, small pieces of tartar, etc., containing bacteria, and by contact with the oral and pharyngeal cavities, whose power of resistance has been impaired by debilitating diseases, mechanical injuries, etc.

The very antechamber of man's vegetative existence, the very portal of the human body, furnishing as it does a most excellent nursery for these etiologic factors, has not received from the general profession of medicine, within the past, that attention which its importance has deserved; but, thanks to the work and investigations of some of the members of our specialty, the physician can no longer ignore these factors and feel that he has done justice to himself and the patient who has so confidently placed himself under his care. The results of the last few years have proved that if many of the diseases whose origin is enveloped in mystery could be traced to their source, they could be found to have originated within the oral cavity. And, as to the danger of such diseases as do follow from infection traced directly to the mouth, it seems there could be but one thought, when we reflect that out of a carefully prepared table of 149 cases by Miller, there resulted 50 deaths, 19 cases of syphilis, 2 cases of blindness and 2 cases of a loss of a part or the whole of one of the maxilla.

Most of the work which has been done up to this time (with the exception of that by Miller) has been with a view of attracting the attention of the dental specialist to infection which has been carried *into* the mouth from without, resulting in local manifestations which would naturally come under the supervision and treatment of the dentist. Miller has opened up, and is cultivating with skill and determination a new field of research, and it seems to be his object, as it is mine at this time, to attract the attention of the general practitioner to infections which are carried *from* the mouth and are planted in such soils as will prove favorable to their future germination and growth, hence, proving an obstacle in the path of him who would assume to treat these pathologic lesions, without due appreciation of the important part these agencies and this location play as factors in etiology. It would not be difficult to convince the observant dentist of the truths here implied; it would only be necessary, were that our object, to ask him to recall from his every-day ex-

perience ample facts to substantiate the position. He has seen many times the general health of his patients vastly improved by a proper care and attention of the mouth. He has studied, as a specialist, the chemic powers of decayed teeth, vitiated and poisoned secretions and fully appreciates their power and influence, but I am forced to the belief that the physician of the past has either wilfully or ignorantly ignored the important part this portal plays in the aggravation of diseases, or as a preventive of cure. And this thought is only enhanced and enlarged by the recent practices of the more observant and faithful, in calling to their assistance the aid of the competent orist, in assisting him to reestablish physiologic perfection.

To make the attempt to enumerate and to classify the different ailments which are either caused or aggravated by the unhealthy and unwholesome condition of the mouth, would be too great a task for one paper, if it were necessary, but it is not. Miller has done and is doing this work for us, and it is our province to assist as much as possible in bringing to the notice of the profession the excellence of his work and the importance of his conclusions. At such times as this, we can but generalize. Every physician of experience has often, no doubt, found himself in the dilemma of not being able to account for the cause of many cases in practice—and while I would not have him look to the mouth as the harbinger of all these causes, I would ask his attention to that sphere, as a possible, and I might say, a probable source in many cases.

There is no doubt that the nervous system in many instances, and by very remote manifestations, is often injured to an alarming extent by the mechanical or chemical irritation emanating from an oral organ. The alimentary tract, we know, is often deprived of the privilege of doing its proper duty by contaminations implanted into the first bolus of food, started on its course through a filthy and poisonous mouth, and added to the chemic contamination may well be mentioned the mechanical, which in cases of malocclusion, tender and sore teeth, or edentulous mouths prevent a proper mastication of food, entailing upon the stomach an office and a duty never designed by nature. This overwork of the stomach, combined as it often is with the chemic poisons of the diseased mouth, of course is sufficient to interrupt the proper function of other organs in the tract as they are reached, and consequently the whole canal becomes a source of irritation and of poison. Now, the primary source of health and growth being so far drawn from the path of rectitude laid out to furnish man with ease and not disease, it is evident that future digestion, assimilation and nutrition is only a matter of impossibility. If the ptomaines, leucomaines and extractives are found in every organism, and under all conditions, it is only rational to believe that an all-wise Providence has designed them for a specific and for a physiologic purpose. They have a function to perform, even though it were only that of scavengers for other tissues. It would certainly not be wise to place a minor importance upon the function of the kidneys, simply because their principal office seems to be that of eliminators,—on the contrary, the more reason why their integrity should be preserved and their powers not deteriorated, in order that those substances which seek this channel may be thrown

off and not left to accumulate, to contaminate and to poison what would remain healthy.

Likewise, if microorganisms are so universally present, the same facts would equally apply to them, and it is to the prevention of a growth of an abnormal quantity, and to the prevention of the introduction into the organism of specific germs, that the attention of the therapist of the future will be more particularly directed. If we could only get our medical confrères to pay more attention to the chairs of oral and dental pathology that have lately been introduced into our colleges, to the sections on these subjects that have been attached to all the congresses and national associations of late years, we believe they would more fully appreciate their importance, would more often seek the advice and assistance of the specialist, and this in turn would create a bond of union between us and them, stronger and more appreciated than any that has existed up to this time.

Aside from local inoculations and their results, which are usually classed among dental diseases, there are many forms of aberrations that the condition of the mouth may be held especially responsible for. Paralyses, pareses, anesthetics and hyperesthesias adorn the border line where it is difficult to determine whether the case is one for the specialist or the general practitioner; but these lesions having long been noticed as doubtful in their etiology, are not classed among the obscure, and are often brought to the notice of the specialist and his assistance sought. But in those more obscure cases where the cause is greatly clouded, mistakes are more liable to occur, and the physician often battles vainly in his efforts to restore a healthy status by the ever interfering and constantly infecting products of this portal to man's existence. Miller has shown that pulmonary and bronchial diseases are excited or aggravated by the inspiration of germs from the oral cavity, as evidenced in the case cited of J. Israel, where primary actino-mycotic infection followed the lodgment of a small piece of tartar within the lung. Several cases within my own practice confirmed the theory, and I have more than once seen the benefit, and been able to bring it forcibly to the notice of the attending physician, where marked improvement followed the sterilization of the mouth, when all efforts had proved fruitless prior to this step. Alimentary disorders are of such common occurrence, as a result of defective and contaminating mastication as to require no extended notice, and from this one condition all other organs are more or less affected, both nervous and vascular. Bednar, said to be the first to give clear expression to this view in 1854, states that, "indigestion may be brought about *directly*, by taking into the stomach any substance already in a state of fermentation; *indirectly*, when the food taken into the stomach undergoes subsequent fermentation on account of its disproportion of the gastric juices." Henoeh favored this conception and found in it a cause for a large number of diarrheas, while Minkowski classifies under five heads the disturbances directly caused by the fermentative processes in the stomach:

1. Substances may be formed which irritate the mucous membrane of the stomach, and bring about a state of catarrhal inflammation.

2. Considerable quantities of gas may be found heightening the mechanical insufficiency of the stomach.

3. Fermentations may lead to the production of substances having toxic properties.

4. In the fermentation of albuminous substances, alkalin products may arise which neutralize the gastric juice.

5. The gastric fermentations may exert a great influence on the functions of the intestines.

And now, what is our lesson? We would ask the general practitioner to regard the unhealthy condition of the oral cavity, with all its contents, as an important factor in the causation or aggravation of diseases having shown, as we believe, that within its boundaries lie the primary causes of many pathologic lesions; that good, healthy, clean and serviceable dental organs are absolutely essential to the enjoyment of physiologic ease, and that in many cases the dental specialist has within his power the rendering of valuable assistance in the search for this result.

DISCUSSION.

DR. J. S. MARSHALL said that the paper opened up a field of thought to all of us as dentists, and the application made to the diseases of the general system will make it valuable to the general practitioner. Almost every pathogenic microorganism has been found in the mouth by Dr. Miller, and we can not be too careful about introducing them into our own systems when operating. Upon two occasions he had pricked his finger while at work, and each time had had troublesome sores from the accidents, showing that there was more than a mere wound to deal with.

DR. TALBOT said there were, no doubt, many cases where a foul condition of the mouth was responsible for troubles in the general system, and where an improvement in health and increase in weight had followed the putting in order of the mouth. The infection from the mouth of a patient too, had often caused trouble to the dentist, such as inflammation of the eyes and perhaps sore throat, consumption, and tonsillitis.

DR. TAFT said we should promote the function of the eliminative organs; the skin should be kept clean, the liver active, the kidneys, lungs, etc., in good condition, and then there will be less likelihood of infection from these bacteria. Care should be taken to regulate the food supply as to quantity, quality, and the proper preparation; these precautions with reasonable effort towards keeping the mouth clean will be sufficient to guard against these infections. He also spoke of the habit of mouth-breathing, and said dentists should impose on all their patients the necessity of keeping the mouth closed as much as possible.

DR. CLIFFORD said that the main idea in his paper was to call attention to the effect the microorganisms of the mouth had upon the general condition. Dr. Taft spoke of keeping the eliminative organs in good condition, but this can not be done unless the mouth is kept clean, for if the mouth contains enough poison to keep the blood, liver, and skin in bad order they can not be got right until the mouth is rid of the cause of the trouble.

NECROLOGY.

Dr. DeWitt Clinton Patterson, Coroner of Washington city, died at his residence, 919 I Street, N. W., Dec. 20, 1893. He was born in Mount Washington Township, Berkshire County, Mass., August 3, 1826. His descent is from Scotch blood, but his American ancestry dates back to his great-great-grandfather, Andrew Patterson, who came to America from Leith, Scotland, and landed at Perth Amboy, N. J., September, 1686. The subject of this sketch was the son of Joseph

and Elizabeth (Kane) Patterson. Branches of the Patterson family settled in Connecticut and Massachusetts and still reside there, while others have gone the great West and founded families. The Doctor's parents removed, while the subject of this notice was yet a boy, to Loraine County in Northern Ohio, where he grew up and where he received his academic education. In selecting a vocation in life he chose the profession of medicine, and selected as a preceptor Dr. L. M. Brooks, one of the leading physicians of that day in the city of Cleveland, Ohio, in whose office he made due preparation for attending profitably instruction in a medical college. He then matriculated in the "Western Reserve College," and after attending the usual course of lectures, received the degree of M.D. from that institution in 1851, and began practice in that city. The following year he was married to Miss Amelia K. Clark.

In 1856 he removed to Winona, Minn., where he practiced until the breaking out of the war, when he returned to Cleveland and was commissioned surgeon of the Twelfth Regiment of Ohio infantry and served to the close of the war. On the restoration of peace he took up his residence in Petrolum Center, Pa.

What he had seen of Washington city during the war with the recommendation of some influential friends, induced him in 1867 to remove to the capital of the nation and there enter upon the practice of his profession. By his education and thorough medical studies he was exceptionally well equipped for the practice of medicine, while his army experience had added to his knowledge, so that by attention to business he speedily obtained an extensive and profitable patronage.

Dr. Patterson joined the Medical Society of the District of Columbia in 1867, and in 1869 he became a member of the Medical Association of the District of Columbia, and was elected to the presidency of that body in 1885. Dr. Patterson was one of the early members of the First Congregational Church, and much interested in the Centenary Church erected at the corner of Tenth and G Streets, and for many years was one of the trustees. He was also actively interested in many of the social and charitable enterprises in the city.

July 2, 1872, Dr. Patterson was appointed to the office of Coroner of the District of Columbia, a position which he filled most acceptably for a period of about twenty years, or until failing health made it impossible for him to leave his house. His last official duties were performed at the inquest over the bodies of the men killed on June 9 by the accident in the old Army Museum on Tenth Street. In this protracted and difficult investigation, although quite ill at the time, he acquitted himself with tact and ability.

Dr. Patterson was highly esteemed in this community, not only as a physician but as a citizen, and his death is severely felt by a large circle of friends and the public generally. He was eminently social in his character. His personal appearance may be described as dignified and noble; six feet in height and weighing, when in health, quite 250 pounds. He had a large, well-shaped head, regular and strongly marked features, fair complexion, bright eyes, sound teeth, light hair which had begun to whiten. He wore a full beard, clipped into manageable length. To crown all, he possessed a cheerful, sunny temperament, dignified and winning manners and a soft and agreeable voice.

In 1881 Dr. Patterson became a member of the AMERICAN MEDICAL ASSOCIATION, and has ever since been very regular in his attendance at its annual meetings. The ASSOCIATION, recognizing his business tact, elected him a member of the Board of Directors for the publication of its JOURNAL. He was also elected treasurer of the Rush Monument Fund now being collected under its auspices.

In 1890 he was Chairman of the Committee of Arrangements for its meeting in Washington in 1891. He was also a member of the Masonic Order in the District of Columbia, and a member of the Ninth International Medical Congress which met in the city of Washington Sept. 5, 1887, and served most efficiently on the local Committee of Arrangements.

Dr. Patterson leaves a widow and two children, Dr. Albert Clark and Miss Elizabeth Patterson. The former has chosen the profession of his father, and is now Third Assistant Physician at the Government Hospital for the Insane at Washington. The Medical Society of the District of Columbia held a special meeting on the announcement of Dr. Patterson's death which was largely attended, and at which appropriate resolutions expressive of the loss to the county and the Society were passed.

Funeral services were held by Rev. S. W. Newman of the Congregational Church, at his late home, in the afternoon of December 21. Dr. Patterson's remains, however, were taken to Cleveland, Ohio, for interment in Woodlawn Cemetery.

Dr. Francis Minot Weld of Jamaica Plain, Mass., died Dec. 31, 1893. He was born in Dalton, N. H., in 1840, and graduated from Harvard in 1860. He studied medicine in the Harvard Medical School from September, 1860, to May, 1862, when he received an appointment as medical cadet. He was relieved from naval duty on Jan. 11, 1864, and graduated from the Harvard Medical School. He entered the army as a Surgeon and was with Grant in the campaign from the Wilderness to Petersburg, and with the Army of the James before Richmond. He moved in 1866 to New York city, where he practiced until 1887. He was Medical Superintendent of the New York Hospital in 1876-7. He was President of the Harvard Club of New York, and one of the founders of the University Club of New York.

Dr. Jonathan P. Wood of New Lebanon, Ohio, December 30. He was born in Rhode Island in 1817, attended Brown University and Berkshire Medical College. He came to New Lebanon in 1845, where he has since resided as one of its most respected medical practitioners.

Dr. Obadiah Prentice, at Norwalk, Ohio, December 29. He was born at Lowville, N. Y. in 1821, and with his parents removed to Ohio in 1837. He was graduated at the Cincinnati Medical College in 1848.

Dr. Solon Philo Sackett of Ithaca, N. Y., died December 18, of disease of the kidneys. He was the senior physician of his section, having been graduated from the Geneva Medical College in 1843.

Dr. P. A. Clark of Lancaster, Wis., December 30. He was graduated at Yale Medical School and was 68 years of age.

Dr. L. F. Coffin of Oskaloosa, Iowa, December.

Dr. Joseph Fowler of Columbia, Tenn., January 2.

THE JOURNAL Special Commissioner's report on the great drainage canal of Chicago, will be published next week. The importance of the canal from a sanitary standpoint can not be overestimated, and with a view of ascertaining the exact status of the work, its progress, and as well the sanitary condition of the workmen, the JOURNAL sent a special representative to make a personal investigation. This report is now in hand and we are sure will be of great interest not only to the inhabitants of a single city, but to sanitarians everywhere.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, JANUARY 13, 1894.

SOME FACTS CONCERNING THE PHYSIOLOGY OF
FATIGUE.

DR. HODGE of Clark University, Worcester, Mass., began in 1887 a series of experiments to determine the nature and character of the changes due to functional activity in nerve cells. The first report of these studies, although published some months ago in the *Journal of Morphology*, is of unusual interest.

The author refers to the fact that all the energy of the body, comes directly from chemical changes and reactions in the individual cells. If we could know the processes which take place in a single nerve cell, it would be the key to all of nerve physiology, from the action of the nervous mechanism in an amœba's protoplasm through the entire animal series to the activity of the human brain. The view prevalent up to this time was, that changes could be found in gland cells because they produce a material secretion, also changes would be noted in muscle cells, because of their mechanical work, but in the nerve cells no changes would be found because their secretion was consciousness, a thing outside of physical observation. The fact was not considered that nerve cells contain masses of granular protoplasm, enclosing a nucleus, which exhibits a delicate reticulation, and contains a prominent nucleolus. Why should not the nerve cell have the same life history, of birth, maturity, and death, as other cells? Why should it not suffer from want of nourishment, fatigue, and the struggle for existence?

The study of the pathologic changes in the nerve cells was misleading, for the reason that the normal processes were unknown, and no line could be drawn between the normal and abnormal.

Hence the author sought to find what changes occurred in the cells of healthy animals from electrical stimulation. Frogs, cats and dogs were used,

and one-half of the spinal root ganglia was subjected to electrical stimulation for varying periods of time. Then sections from both ganglia were stained, mounted and examined under the microscope. Some of the animals were put under the influence of ether, and a mild current carried directly to the one side of the optic thalamus and other sections of the brain, and after a time the animal was killed and opposite sections made and examined. The results of a large number of experiments exhibited a uniform diminution and decrease of the size of nucleus of the cells, which had been subjected to the stimulation, and a change from smooth and round to jagged irregular outlines. The reticular appearance was broken up, the cell protoplasm was shrunken in size, and the nuclei was decreased in size. The sections of brain not stimulated showed no changes of this nature. Great care was taken that the electrical current should be within physiologic limits. This inquiry followed, Do similar changes occur in the normal activity of an animal from fatigue? and are they restored by rest and sleep? To answer this, numerous sparrows, pigeons and swallows were shot in the morning as they were going out, and at night when coming home after a day of activity. Sections of similar parts of the brains of the morning and evening birds were compared with each other. In all cases the brain cells of the birds at evening were greatly decreased in size, and the nucleus jagged and of irregular outline. The cell-protoplasm also shrunken, and lessened reticulated appearance. The nuclei also greatly decreased. Honey bees were caught coming out of the hive in the morning and compared with bees going in late at night. The same differences were noted in the brain cells, showing degrees of exhaustion and fatigue in one, and vigor and health in the others.

These studies conducted with great accuracy and detail for the purpose of eliminating all errors, seem to point to brain and nerve fatigue as a shrinking of the nucleus and cell protoplasm. Birds identical in appearance shot at night and in the morning brought out this fact, in the shrunken cells at night, and the full rounded cells in the morning. The conclusion is that in sleep the wasted cell recovers its functional changes from fatigue, and the failure of this restoration is the beginning of organic degenerations of all forms and degrees. The cell recovers the bundles of nerve fibers which enter into it, and are lost in the granular substance, and nucleus. Here all the impressions of the external world come in a succession of impulses, and all the outgoing commands are determined.

Something like this decrease and shrinking of cell contents and nucleus are common in old age. It would appear reasonable to suppose that failure to restore the cell contents would be ageing and practi-

cal starvation of the body. If physiologic fatigue is functional changes in nerve cells, which can be restored by rest and sleep, scientific inquiry has taken a step forward of deep significance.

Pathologic changes of cells are the constant study of many astute observers, but the changes which follow normal activities are new lands of research.

DR. HODGE has been for some time making studies of the changes which take place in nerve cells under variations of food and water supply. Also, what changes if any take place in nerve cells from birth to death from old age, from rejuvenation to senescence. These researches will be watched with much interest.

THE SMOKE NUISANCE IN NEW YORK.

The burning of bituminous coal in certain Eastern cities has been largely on the increase, of late. This has been true in so marked a degree, in reference to the down-town districts of New York city, that an investigation has been ordered by the Board of Health. The sanitary code expressly prohibits the consumption of soft coal in such a way as to become an atmospheric nuisance. The citizens most liable to this impending smoke nuisance are watching with eager interest the promised investigation, and intend to oppose the "entering wedge"—the initial soft coal burning that is "merely temporarily noticeable because imperfectly conducted." The alleged pioneer offenders claim that "mistakes on the part of the engineers and firemen, and an improper plan of 'firing' have been the sole cause of injurious results; proper firing and a little experience will remove all grounds of objection to bituminous coal." The temporary strike in the anthracite regions, and the alleged political "pull" of some of the protected industries, will probably give the citizens of New York a taste of the bituminous evil, and a chance to judge of the conspicuous advantages of a proper method of firing soft coal.

THE "DIVINE DIPLOMA."

An irregular practitioner of Garnersville, New York, named MRS. STAGG, has been the subject of a coroner's investigation. When asked by what authority she ventured to practice upon the sick, she replied that it was by "the gift given her by God." It has been her custom to go into a trance and dream out any required diagnosis or treatment. Her favorite remedies have been burdock, witch hazel, dogwood and lavender. The learned coroner came to the conclusion that no harm had been wrought by this woman, by the administration of these "simples," and she was allowed to go free with a mere caution that she had been practicing illegally. He told her that her alleged divine right to tamper with diseased persons was recognized by the laws of New York State. These practitioners, called sometimes "dream-

doctors," or "clairvoyants," get along very well until the time comes that a death-certificate becomes necessary, and even after that crisis they may have little trouble if they happen to fall into the hands of an easy-going coroner. They seldom undergo prosecution, although in many a community they are exceptionally prosperous, sufficiently so to excite the envy and antipathy of the better educated, regular type of practitioners. The latter are commonly content to ignore the pretender or to smile at his pretensions.

REMOVAL OF DEAD BODIES.

Somewhere there must be a competent authority to control the removal of dead bodies. It is necessary in order to protect the people from the spread of contagious diseases. Under a statute empowering a State Board of Health to adopt rules and by-laws to prevent outbreaks and the spread of contagious and infectious diseases, it can make a rule requiring that "Every dead body must be accompanied by a person in charge, who must be provided with a ticket, and must also present a full first-class ticket marked 'Corpse,' and a transit permit from Board of Health or proper health authority, giving permission for the removal, and showing name of deceased, age, place of death, (and if of a contagious or infectious nature) the point to which it is to be shipped, medical attendant, and name of undertaker." So holds the Appellate Court of Indiana in the case of *Lake Erie & Western Railway Company v. James*, decided Nov. 24, 1893. And it is further held in this case that, under such a rule, a railway company can not be required to carry a dead body on a permit signed by a health officer authorizing the removal, unless it shows a substantial compliance with the requirements. The name of the medical attendant, for example, must be deemed a material and essential part of this transit permit. Without giving it, the proper health officer's certificate, or otherwise regular permit, would not be sufficient.

AGREEMENTS NOT TO PRACTICE MEDICINE.

Agreements not to practice medicine come under the head of contracts in restraint of trade. Public policy forbids the making of contracts of this nature too broad in their terms. Thus, no contract could be enforced which would by its terms prevent a physician from ever again practicing medicine, or which would bar him from practicing it in an unreasonably large extent of territory. Even in cases where the law will tolerate the contracts, they will not be treated with any special indulgence. If they secure to the purchaser of a good will a guaranty against the competition of a former proprietor, or practitioner, it will not be presumed that more was intended. At the present day the occupation of a pharmacist and that of a physician are essentially

distinct. An agreement not to engage in the one does not preclude the party from engaging in the other, so long, the Court of Appeals of New York holds, in the case of *Greenfield v. Getman*, decided Nov. 28, 1893, as the one is not used as a cover for the operations of the other. Here was a contract by which a physician, in consideration of \$500 paid him, agreed that he would not practice medicine and surgery, for five years, in a certain village, or within a radius of something like five miles thereof, or, if he did, he would forfeit and pay \$1500. To practice medicine and surgery, it was further stipulated, in the agreement, should be construed to mean to prescribe for, to compound medicine for, advise or visit any person sick or disabled, or to perform any act required to be done by a person legally qualified to practice medicine and surgery. A year after making this contract, he entered into partnership with another in the business of selling drugs, books, stationery, etc., at a place two miles distant from the village referred to. Through the following four years, he once attended, as counsel, with two other physicians, upon a person *in extremis*, for which he made no charge, but was paid and accepted a small fee. On several other occasions he prescribed, as it were, for persons coming to the drug store, by furnishing them with medicines suitable for their respective ailments; but without making any charge for medical advice, and without such sales aggregating \$10. This, the court held, was not a violation of his contract. Undoubtedly, it said, the parties might have so stipulated that a single act, such as was described in the agreement, would have rendered the physician, if he had committed it, liable for the full amount of damages recoverable for breach of contract. But before such a meaning should be given to an agreement of this kind, it should appear, upon a fair and reasonable interpretation of its provisions, in the light of the circumstances under which it was made, and of the evident intent and object of its execution, that no other inference would be justly permissible. Construing this particular agreement in accordance with its obvious purpose, the definition, which should be considered as determining what was agreed upon to constitute the practice of medicine and surgery, did not enlarge the meaning of that term, but merely specified things, which, if systematically or habitually or frequently done, would be a breach of the agreement.

SELECTIONS.

Influence of Ultra-Violet Rays on Smallpox.—Lindholm of Bergen, has employed the method recommended by Finsen, of treating smallpox patients in a room from which the ultra-violet rays are shut out by red window panes, or by covering the windows with red curtains. Twenty cases, of which ten were unvaccinated children, were treated in this

manner with complete success; all recovered, although severely attacked; in one case even "black smallpox" was present. The eruption dried up shortly after its appearance, no fever of maturation took place, and the patients recovered very soon, having but few scars.—*Hospitalstidende*, 1893 p. 919.—*Universal Medical Journal*.

Cathartic Acid.—M. Gentz has obtained this acid which he calls cathartic acid from senna. It appears in the form of a brown powder, little soluble in water. This purgative may be given in the dose of five to fifteen centigrams, and its effects are manifested eight to ten hours after administration. On healthy subjects having taken the remedy solely to study its physiologic action, it causes frequent stools (about five in half a day) and mild colic. In persons affected with chronic constipation, on the contrary, colic is not observed in the generality of cases. The action of the medicine is more slow and less attended with disagreeable sensations. Thanks to this latter circumstance and taking into consideration the absence of all disagreeable taste, and the certainty and energy of its action, he was able to predict for the cathartic acid an honorable place among the purgatives.

In infants of 2 to 4 years the acid was prescribed in a dose of .05 mixed with sugar, and a dose of .15 for adults.

Dehio tried the medicine on five well persons, and five persons suffering from chronic constipation. He offers the following formula:

R Acid, cathartic05 to .15
Sacch, alb30 to .50

℞ For one powder. Of such a powder take one every hour or two.

M. Dehio has not yet had occasion to study the action of the cathartic acid for a long time, but considering the results of his ten trials, he is much inclined to hope that in these cases the remedy may render signal service.—*Journal de Medecine de Paris*, Dec. 17, 1893, from *Vratch*, No. 30, C. S., and *Nouveaux Remèdes*, 24 Novembre, 1893.

The Rhine Vintage of 1893.—The vintage on the Rhine is now in a large measure finished, and the character of the wine of 1893 can, to a certain extent, be estimated, though it can not yet be said with absolute certainty what its precise quality will be in comparison with the best vintages of preceding years.

It is admitted on all sides that the wine of the present year will undoubtedly be fine in quality, but there seems to be a disagreement of opinion as to whether it will excel the wine of all years since 1868, when a very noted vintage was obtained. Some think it will be a wine like that of 1886, or that of 1874, which were both excellent wine years, but not of a red-letter character like those of 1868 and 1865—to which the public here are constantly reverting when they speak of wine exceptionally fine—while others think that the quality of the 1868 wine will be reached by the wine of this year. Of course, it is to the interest of the wine-growers to exaggerate the probable quality of the new wine and of buyers and dealers to depreciate it.

The past summer, while very disastrous to forage plants, on account of its excessive dryness, was very favorable to fruit, and the grape did well, though a little rain now and then would have been very serviceable to it and would have still more increased the amount and raised the quality of the product. The grapes this year have all ripened, green grapes being the exception. Having ripened early, they have been untouched by frost, with, perhaps, a few exceptions, and the wine will consequently be free from the objectionable flavor often imparted by frost to wine. There were a great many overripe grapes this year, and these make the best wine.

The must weights in the better class of vineyards have been from 100° to 112° Oechsle as a common thing, while in the finest vineyards must weights up to 150° Oechsle have been noted, which is a remarkable weight. It is reported that the very best vineyards, such as the renowned Steinberg, for instance, the must weights indicate a wine unsurpassed by any of the century. The must is very sweet. In ordinary vineyards must weights have run this year from 80° to 100° Oechsle as a rule.

In the matter of quantity the vintage, on the whole, will be, so far as I can make out, what is called a full one-half crop. This is a gratifying amount, as a three-fourths vintage is a rarity and a full vintage remarkably scarce. The yields vary considerably in the different vineyards, making what the wine-growers call a *neidischer Herbst*, that is, an enviable ingathering, as some get three-fourths or more of a crop, while others have but one-third or less, which, when there is a good wine involved, makes the less lucky ones decidedly envious of their more fortunate neighbors.

The prices prevailing for the new wine are said to be rather moderate, taking into consideration the quality of the product. Buying is not as brisk as it should be. This is due to a shortness of money and to a disposition on the part of the wine trade to await the outcome of a threatened imposition of a tax on wine by the Imperial Government before making heavy purchases of new wine. But there will doubtless be a good deal of speculation in the new wine before long.

Wine, when exported, is to be exempt from taxation, it seems.—JAMES H. SMITH, Commercial Agent. In U. S. Consular reports for December, 1893.

MAYENCE, October 20, 1893.

BOOK NOTICES.

An American Text-Book of Gynecology, Medical and Surgical, for Practitioners and Students. By HENRY T. BYFORD, M.D., J. M. BALDY, M.D., E. B. CRAGIN, M.D., J. H. ETHERIDGE, M.D., WM. GODDELL, M.D., HOWARD A. KELLY, M.D., FLORIAN KRUG, M.D., E. E. MONTGOMERY, M.D., WM. R. PRYOR, M.D., GEORGE M. TUTTLE, M.D. Edited by J. M. BALDY, M.D. With 360 illustrations in text and 37 colored and half tone plates. Large 8vo, cl., pp. 713. Philadelphia: W. B. Saunders. 1894. Price \$6.00. Sold by subscription only.

Reference to our review columns will show that works on gynecology have been rather numerous in the past two or three years, the entertaining book of More-Madden and the elaborate translation of Pozzi being the latest additions to gynecologic literature. This volume is printed on good paper; the illustrations are extremely good, and its type large and clear. The subjects treated of are: the examination of the female pelvic organs; the technique of gynecologic operations; menstruation and its anomalies; sterility; anomalies of the female generative organs; genital tuberculosis; diseases of the vulva, and vagina; inflammatory diseases of the uterus; laceration of the soft parts; genital fistulæ; distortions and malpositions; malignant diseases of the female genitalia; uterine neoplasms; pelvic inflammations; ectopic gestation; diseases of the ovaries and tubes; diseases of the urethra, bladder and ureters; and after-treatment in gynecologic operations.

The scope of the work, it will be seen, is quite as extensive as could well be covered in a single volume text-book, and the treatment of the subjects mentioned is fairly representative of American gynecologic surgery. The great changes that have taken place since the pioneer work of Sims, Bozeman and Emmet, may well give rise to a just pride in the achievements of American surgeons, and the perfected practice of the day is fairly set forth in this book.

The Healing of Rodent Cancer by Electricity. By J. INGLIS PARSONS, M.D., M.R.C.S., M.R.C.P., (Lond.), cl., pp. 82. London: John Bale and Sons. 1893. Price five shillings.

In this little book the author describes his method of treatment of rodent ulcers by electricity. He uses nine needles "from two to four inches long, composed of steel

with platinum ends. The steel portion is insulated, and attached to about eighteen inches of covered wire. When they are in position the wires leading from them are connected to the battery. When the patient is fully under, the assistant at the battery is directed to use twenty cells, and then to turn the current on for one or more seconds as required. Meanwhile the other assistant holds the needles in position, while the operator keeps his finger on the pulse, notices the strength of the current as shown by the galvanometer, and observes the effect produced on the growth. After one or more seconds the current is turned off."

The number of cells is increased until the galvanometer shows a current of 300 to 400 milliampères. The duration of the operation depends upon the extent of the growth, and lasts from ten minutes upward. Where long continued use would be required, the author recommends a second sitting.

The work is interesting, and shows a thorough acquaintance with this branch of electro-therapeutics.

The Technique of Postmortem Examination. By LUDWIG HEKTOEN, M.D., Pathologist to Cook County Hospital, Chicago; Professor of Pathologic Anatomy in the College of Physicians and Surgeons of Chicago. With forty-one illustrations, pp. 172. Chicago: The W. T. Keener Company. 1894. Price \$1.75.

This is an excellent condensation of the rules for the conduct of postmortem examinations, by a very competent hand. The author well says:

"Accuracy of observation, completeness of detail and sound conclusions can be obtained only when the postmortem examination is made according to some definite and systematic plan, so that regions and organs are successively examined without disturbing the relations and appearances of structures yet to be investigated."

To promote these desirable objects, this book has been prepared.

1. **State Board of Health of New York.** Twelfth Annual Report. Albany, 1892.
2. **The Same.** Thirteenth Annual Report, with a volume of maps. Albany, 1893.

These volumes show very active work on the part of the Board, particularly in advice to towns, furnishing plans for sewerage and the like. Various general investigations, and special reports by Prof. Willis G. Tucker on food and drugs. A reprint of the monthly bulletins concludes the report.

In the thirteenth report, there is a special report on "Inspection of Cattle for Tuberculosis," and a continuation of the very interesting report on the Hudson River.

The work of the Board was augmented during 1892 by the threatened invasion of cholera. The new law providing for the inspection of cattle for tuberculosis went into effect with an insufficient appropriation, and although between six and eight thousand cattle have been examined, the work was far from complete. The Board has found ready coöperation on the part of owners.

These reports are of great value and are interesting as showing the practical details of sanitary work on a large scale.

CORRESPONDENCE.

104 E. 40TH ST., CHICAGO, Dec. 28, 1893.

To the Editor:—Allow me to call the attention of the incoming staff of the Cook County Hospital to an opportunity to encourage better medical education which its position affords. The examinations for internes will soon come off. It has been customary to examine on the eight branches of the old medical education. No examinations have been given which have afforded the student an opportunity to gain credits on laboratory work. No examinations have been given with histological or pathological material, or indeed in any way except by written questions requiring

written answers. This has resulted in disaster to those applicants who have had laboratory work as a considerable part of their course. It has resulted in a growing opposition to laboratory work in the College of Physicians and Surgeons on the part of the faculty and of the students. If the present class, which is the first to graduate on the new course of study containing laboratory work, should secure a fair representation in the coming examinations at the County Hospital, it is possible that the directors of the college will continue the laboratory work; but if the examinations are again conducted on the quiz-compend and note plan, it is almost certain to be abandoned. Few members of the County Hospital Staff are medical college men. They belong to the outsiders who are always cursing the diploma mills. Now let them offer an examination that will give a man who has worked three years, two hours a day with microtome, microscope and dissecting tools a chance to show the superiority of his education over that of the man who has listened to lectures and crammed.

It is time, too, that the applicants were considered human. It seems strange that doctors of medicine should require students to write five or six hours a day on as many different subjects. A number of strong men have left their examinations every year from exhaustion. Even a country school master would not be so inconsiderate.

Not a suggestion of a clinical or autopsical examination has ever been given. Does this encourage the teaching that makes good doctors?

My interest in this examination is a part of my interest in honest medical education. I speak freely now because though still connected with the College of Physicians and Surgeons as a teacher, I am no longer its secretary. The neglect of this and other examining bodies to introduce examinations in practical biology, histology, pathology, embryology and bacteriology has so militated against our students that my ideas could not be longer carried out by our directors without too much opposition and too much expense. Shall laboratory instruction be continued in our medical schools? What does the staff of the County Hospital say? What do the examining boards of the various States say?

I hope that this subject is of such interest that it may be discussed in the columns of the JOURNAL.

Very respectfully, BAYARD HOLMES,

Late Secretary of the College of Physicians and Surgeons of Chicago.

Should Use the M.D.

To the Editor:—Would it not be well to draw a line between an M.D. and Dr., since the higher medical education is becoming the hobby in the way of journal notoriety, much of it without practical results. The M.D. having been conferred by collegiate authority while the Dr. is the prefix of all quacks. Therefore if the M.D. is worth anything, let it be used at all times by those entitled to do so. I notice the JOURNAL you direct uses the Dr. almost exclusively.

Respectfully, etc., S. L. HENRY, M.D.

The Maltine Photographs.

The Maltine Company requests us to reprint their letter to the *New York Medical Journal*, as answer to the criticisms that appeared last week:

THE PUBLICATION OF PHYSICIANS' PORTRAITS.

NEW YORK, Dec. 26, 1893.

To the Editor of the *New York Medical Journal*:

SIR: Your reference to our calendar for 1894 demands our attention. While you did not mention us by name, the reference is so direct that the physicians who received the calendar can not but know to whom you referred.

It has been our custom for several years to send to the medical pro-

fession throughout the United States portraits of eminent physicians and surgeons, and, inasmuch as their distribution has been scrupulously confined to medical men of good repute, no objection has been offered by those gentlemen whose likenesses were reproduced. Not a copy of this calendar, nor of any of our other numerous publications, has ever been sent to the laity.

Maltine is distinctly not a "patent medicine," nor has it ever been advertised to the public, and therefore we have considered it within our province to distribute portraits just as we have promulgated testimonials from the most eminent physicians and chemists in this country and Europe.

We have statistics to prove that 90 per cent. of the physicians of the United States prescribe maltine. This fact, in addition to the fact that we reach the patient *only through the physician*, would seem to amply vindicate our use of the likeness of a physician whose pictures are on public sale and have continually appeared in the public press, and who is well known as a public man.

The portraits referred to were not used to push the sale of our preparations, as was the portrait of Dr. D. Hayes Agnew, recently published by us. It will be remembered that we printed under Dr. Agnew's portrait a facsimile of his indorsement of maltine. Our only reason for publishing the portrait of Dr. — was because we thought it would interest his medical brethren, who have shown so high an appreciation of the series of likenesses we have already published.

We should like further to say that as soon as objection was made by him we suspended the distribution of the calendars, as we would not knowingly offend even one of the honorable profession to whom we are so greatly indebted. THE MALTINE MANUFACTURING COMPANY.

SOCIETY NEWS.

Michigan State Medical Society.—Owing to change in the date of the meeting of the AMERICAN MEDICAL ASSOCIATION in San Francisco, I am requested by the President of the Michigan State Medical Society to announce that its Twenty-ninth Annual Meeting will be held in Lansing, May 3 and 4, 1894, instead of the first week in June as heretofore announced. Respectfully,

CHAS. W. HITCHCOCK, Secretary.

DETROIT, Jan. 1, 1894.

Prize of the American Neurological Association.—The American Neurological Association offers a prize of \$200 for the best essay on any subject connected with Neurological Science. This competition is open to physicians who are legal residents of States in North and South America. Essays must be sent to the Secretary of the Association on or before the first day of May, 1894. Each essay shall be accompanied by a sealed envelope containing the name and addresses of the author, and bearing on the outside a motto, which shall also be inscribed upon the essay. Essays shall be type-written, in either the English or French Languages, and with the pages securely fastened. The Council of the Association reserves the right to reject any or all essays judged unworthy of the award. Each essay must exhibit original research, and none will be accepted that has previously been published.

GREENE M. HAMMOND M.D., Secretary.

American Electro-Therapeutic Association, office of the Secretary, 68 Madison Avenue, New York. At a meeting of the Executive Council of the American Electro-Therapeutic Association, held at the office of the Secretary, March 2, 1893, the following resolution was adopted:

Resolved, That the Secretary be instructed to prepare a circular to send to Fellows of the Association, to members of the medical profession, to electrical experts, and to manufacturers of electrical appliances for medical work, containing titles of all the committees, the members serving on them with their addresses and the matter prepared for discussion and investigation by each committee.

And that manufacturers be asked to communicate with the members of the different committees, if they desire to have their instruments examined and tested, stating their claims and merits.

And that physicians, electrical experts and manufacturers be asked to cooperate in making suggestions and in relat-

ing their experience and preference for instruments, with reason and data.

And to mail this circular to all members of the Association, manufacturers, medical journals and to others who are known to use electricity extensively, asking for a speedy reply either to the Secretary or to the members of the respective committee whom it concerns.

In accordance with the above resolution the following has been prepared:

COMMITTEE ON STANDARD COILS.

Dr. W. J. Morton, 19 East 28th Street, New York; Dr. A. H. Goelet, 351 West 57th Street, New York; Dr. Wm. F. Hutchinson, Providence, R. I.; Dr. G. J. Engelman, 3003 Locust Street, St. Louis, Mo.; Mr. A. E. Kennelly, Chief Electrician, Edison Laboratory, Orange, New Jersey.

POINTS TO BE CONSIDERED.

1. Portability.
2. Practical mechanism of machines as adapted to physicians' use.
3. Range and rate of vibration.
4. Electro-motive force and its range in relation to resistances to be overcome.
5. The resistance of the coil producing these electro-motive forces.
6. The battery-power required for individual coils.
7. Shape of the generated wave of electro-motive force.

COMMITTEE ON STANDARD METERS.

Dr. Margaret A. Cleaves, 68 Madison Avenue, New York; Dr. Emil Heuel, 352 Willis Avenue, New York; Mr. W. J. Jenks, Electrical Engineer, 44 Broad Street, New York.

POINTS TO BE CONSIDERED.

1. A good meter should have a clear, legible scale, fairly uniform over the range, and not crowded at different points.
2. It should be capable of being noted or observed at a distance.
3. The resistance should be low.
4. There should be no tendency to overheat with the strongest current employed.
5. It would be advantageous to avoid a shunt, if one milliampère can be read throughout the scale.
6. The instrument should be capable of indicating in all positions.
7. Any instrument whose indications depend directly upon the local magnetic force is objectionable, for the reason that its indications are liable to be affected by iron in the vicinity.
8. The suspended system should require as little attention as possible, either for adjustment or shipment.
9. It is an advantage for the instrument to indicate with either direction of the current.
10. Portability.
11. Liability to fracture.

COMMITTEE ON STANDARD ELECTRO-STATIC OR INFLUENCE MACHINES.

Dr. W. J. Morton, 19 East 28th Street, New York; Dr. J. H. Kellogg, Battle Creek, Mich.; Dr. G. Betton Massey, 212 South 15th Street, Philadelphia; Dr. Margaret A. Cleaves, 68 Madison Avenue, New York.

POINTS TO BE CONSIDERED.

1. Electro-static machine best adapted to medical work, to be determined by its "output." Its output to be determined as follows: *a*, at, respectively, 100 and at 150 revolutions per minute; *b*, with two Leyden jars, each of whose outer metallic surfaces has the area of $4\frac{1}{4} \times 1$ 1-16 inches = 5 5-16 square inches; *c*, with discharging-rods having ball terminals one inch in diameter and arranged respectively six inches and ten inches apart; *d*, give the number of sparks per minute which will pass between the discharging-rods.
2. Give the greatest maximum length of spark with machine arranged as in Section I, except as to distance apart of the discharging-rods.
3. Give the maximum length of the brush discharge between the discharging-rods with machine arranged as in Section I, except that no Leyden jars are used.
4. Give the maximum length of spark that may be obtained by a brass-ball electrode two inches in diameter, from a person's back, seated in the usual manner upon an insulated platform—the platform connected to one prime conductor of the machine, the other being connected to the ground: *a*, with above Leyden jars; *b*, without Leyden jars.
5. Kind of electro-static machine best adapted to medical work, whether a Holtz, Wimshurst, Toepler, Voss, Carré,

Lewandowski, Toepler-Holtz, Wimshurst-Holtz or machine not here named, provided the type as constructed successfully fulfills requirements outlined in Section I.

6. Does the machine preferred easily reverse its charge? Does it maintain its charge successfully?

7. Facility and means of charging machine under all atmospheric conditions.

8. Can a good meter to measure the output of the machine be suggested?

9. Mechanical construction of machine: *a*, ease of actuating machine by motive power; *b*, durability of the mechanism causing the revolution of its plates; *c*, durability of its construction; *d*, is a glass case necessary?

10. The best means for drying the air within an enclosing glass case.

11. The best means for absorbing the ozone and nitrogen compounds formed within a glass case.

12. Is it not advisable to decide in a general way that no machine, the diameter of whose revolving-discs is less than twenty-six inches, and the number of whose discs is less than six, should be recommended by this Committee for medical work?

13. Suggestions as to a practical switch for the utilization of Morton's static induced and the transformer currents.

COMMITTEE ON CONSTANT-CURRENT GENERATORS AND CONTROLLERS.

Dr. W. J. Herdman, 48 East Huron Street, Ann Arbor, Mich., Current Controllers and Battery Tests; Dr. Robert Newman, 68 West 36th Street, New York, Primary Stationary Batteries; Dr. D. S. Campbell, Correspondence with Physicians; R. G. Brown, E. E., Brooklyn, N. Y., Secondary Batteries and Dynamos.

POINTS TO BE CONSIDERED.

1. Primary batteries.—Express what preference for a certain form of battery and give reasons therefor. Determine voltage, internal resistance current and durability. By what accessory appliances are currents from these batteries best controlled and applied?
2. Secondary batteries.—What are the defects and inconveniences? What the advantage over other forms? What the ampère hours, what the constancy, voltage and action?
3. As to dynamo currents.—What the nature of the current, what its voltages, how is it modified by the form of controller under consideration. What are its physiological effects and its therapeutical application?
4. Report new forms of batteries and improvements, with claims as to superiority over those now in use.
5. Rheostats and Controllers.—Test the various forms and devices used and recommended to modify and control currents; difference in effect produced by each, mechanically, chemically, physiologically, or therapeutically.

COMMITTEE ON STANDARD ELECTRODES.

Dr. A. Laphorn Smith, 248 Bishop Street, Montreal, Canada; Dr. Charles R. Dickson, 263 Victoria Street, Toronto, Ontario; Dr. Plym S. Hayes, 84 Washington Street, Chicago, Ill.

POINTS TO BE CONSIDERED.

1. Inactive electrodes.—*a*, what is the best material in general for the ground work of the electrode and what in special cases? *b*, how may it best be connected with its rheophore? *c*, what is the best material to cover its conducting surface? *d*, when necessary, how may it best be insulated? *e*, in what way may it be kept warm and moist when not in use, should this be necessary? *f*, what should be accepted as standard sizes and shapes, and how best designated? *g*, what other points require to be considered?
2. Active electrodes.—*a*, what is the best material in general and in special for the groundwork of the electrode? when used at the positive pole? when used at the negative pole? *b*, how may it best be connected with its rheophore? *c*, what is the best material to cover its conducting surface when necessary, in general and special. *d*, how may it be insulated when necessary? *e*, what is the best form of construction where flexibility is required for tortuous canals? *f*, what shall be considered the standard shapes and sizes; what scale shall be adhered to in considering the latter; how may their surface area be estimated when they are of irregular shape? *g*, when designated by numerals as to size and surface, how may such best be expressed when stamped or otherwise marked on them? *h*, how may simplicity of construction be best obtained and cost of manufacture reduced without impairing efficiency? *i*, how may facility of cleansing and rendering aseptic best be achieved? *j*, what other points to be considered?

3. Active and inactive electrodes.—*a*, are the terms "active" and "inactive" the best standard terms we can employ? *b*, In the case of both active and inactive electrodes, should not the threads of all screws used in construction as a means of attachment, also all plugs and sockets, etc., be of a standard gauge, that electrodes might be used with attachments of all makes, etc., and to facilitate repair.

Since this circular was issued slight changes in some instances have been made in the Points to be Considered by the various committees. A Committee on Electric Light as a Therapeutic and Diagnostic Agent, was created at the annual meeting of the Association, in Chicago, Sept. 12, 13 and 14, 1893.

COMMITTEE ON ELECTRIC LIGHT AS A THERAPEUTIC AND DIAGNOSTIC AGENT.

Dr. Plym S. Hayes, 84 Washington Street, Chicago; Dr. Margaret A. Cleaves, 68 Madison Avenue, New York; Dr. H. H. Hahn, 804 E. Federal Street, Youngstown, Ohio.

POINTS TO BE CONSIDERED.—THERAPEUTICS.

1. How can the heat of the incandescent and arc light best be utilized in the treatment of disease?

2. *a*, what form of apparatus is best adapted for the use of the electric light in the treatment of disease? *b*, is there any difference in the therapeutic effects of the incandescent and arc lights? *c*, does the coloring of the light, by causing it to pass through colored glass or similar substances, add to the efficacy of the light? *d*, is the light and heat derived from the electric light different or of greater therapeutic value than that derived from any other source? *e*, what pathogenic germs have their growth arrested, or are killed, by continuous exposure to the influence of light? *f*, can a disease produced by the above mentioned germs be modified or arrested by the continuous exposure to light?

DIAGNOSIS.

1. *a*, Illumination by means of a combination of the electric light reflectors and condensers so arranged as to furnish parallel or convergent rays of light. *b*, what form of apparatus is best adapted for general use? *d*, what for special?

2. *a*, what are the best forms of apparatus for illuminating the various cavities of the body, and at the same time enabling the physician to obtain a view of the whole or part of the cavity? *b*, is the heat evolved from the lamp employed, of sufficient intensity to require especial means for its absorption?

3. *a*, to what extent is the introduction of an electric light into the various cavities of the body, in order to determine the condition of those cavities or the translucency of the surrounding tissues, of advantage?

Your prompt and full reply is earnestly solicited to any or all of the points above suggested.

MARGARET A. CLEAVES, M.D., Secretary.

Dec. 4, 1893.

Medical Society of the State of New York.—The eighty-eighth annual meeting will be held Tuesday, Wednesday and Thursday, February 6, 7 and 8, in the City Hall, at Albany, commencing at 9:15 A.M., Tuesday, and ending at 1 P.M., on Thursday. Communications relating to the presentation and reading of papers or to any changes in the provisional program, should be addressed to the Business Committee prior to the first day of February. Dr. Henry Flood, Elmira, N. Y.; Dr. L. Bolton Bangs, 31 East 44th Street, New York City; Dr. Edward Clark, 271 Franklin Street, Buffalo, N. Y.

TUESDAY—MORNING SESSION 9:15 O'CLOCK.

President's Inaugural Address. Appointment of Committees. Executive Business. Special order at 10 A.M., to consider resolution to amend the by-laws.

Hemorrhagic Serous Effusion of the Pleura, with Report of a Unique Case; William S. Cheesman, M.D., Auburn.

Researches on the Eliminating Power of Diseases, and the Relation between Vaccinia and Enteric Fever; William Finder, M.D., Troy.

Pneumonia of the Aged; John H. Pryor, M.D., Buffalo. Diagnosis and Nomenclature of Fevers—2d Paper; Nelson G. Richmond, M.D., Fredonia.

The Therapeutics of Oxygen; Arnold W. Catlin, M.D., Brooklyn.

Simple Methods in the Diagnosis of Nervous Diseases; E. C. Spitzka, M.D., New York.

Discussion on Diphtheria; Arranged by A. Walter Sniter, M.D.

Pathology—Status Præsens; Thomas E. Satterthwaite, M.D., New York.

Observations on Diagnosis, and some Sanitary Aspects; A. Walter Sniter, M.D., Herkimer.

Croup and Diphtheria—Unity or Duality; William H. Daly, M.D., Pittsburg, Pa.

The Comparative Status of Intubation of the Larynx; Joseph O'Dwyer, M.D., New York.

Complicated Intubation of the Larynx; William Hailes, M.D., Albany.

The Local Treatment; Abraham Jacobi, M.D., New York. The General Treatment; Edward F. Brush, M.D., Mount Vernon.

The Use of Tartar Emetic in Diphtheria; H. DeV. Pratt, M.D., Elmira.

AFTERNOON SESSION, 2:15 O'CLOCK.

Treatment of Depressions in Skull of Newborn; David D. Jennings, M.D., New York.

Immediate Trachelorrhapy; Henry C. Coe, M.D., New York.

Lympho-Adenoma of the Uterus; H. J. Boldt, M.D., New York.

Senile Endometritis; A. J. C. Skene, M.D., New York. Treatment of Endometritis; Herman E. Hayd, M.D., Buffalo.

Nine Years' Experience with Alexander's Operation for Shortening the Round Ligaments of the Uterus; Paul F. Mundé, M.D., New York.

Pelvic Abscess; Walter B. Chase, M.D., Brooklyn. A case of Hysterectomy for Retention of the Menses; William Gardner, M.D., Montreal.

Discussion. Arranged by Andrew F. Currier, M.D. Topic—Menstruation and its Abnormalities.

Introduction and Normal Function; Andrew F. Currier, M.D., New York.

Dysmenorrhea—Its Causes and Its Treatment; Howard Kelly, M.D., Baltimore, Md.

Profuse Menstruation; Charles P. Noble, M.D., Philadelphia, Pa.

Scanty Menstruation; Franklin Townsend, Jr., M.D., Albany.

Irregular Menstruation; Charles A. L. Reed, M.D., Cincinnati, O.; E. W. Cushing, M.D., Boston, Mass.

Menopause—Natural and Artificial; Arthur W. Johnstone, M.D., Cincinnati, O.

EVENING SESSION, 7:15 O'CLOCK.

Urethral Caruncles; Edward M. Liell, M.D., New York. The Physical Causes of Sexual Debility in the Male, as distinguished from the Psychological Causes; F. R. Sturgis, M.D., New York.

The Surgical Treatment of the Prostate Gland; Seneca D. Powell, M.D., New York.

The Fable of the Egg; William S. Ely, M.D., Rochester. Artificial Immunity; Henry R. Hopkins, M.D., Buffalo.

Clinical Notes on Psoriasis with Especial Reference to its Prognosis and Treatment; L. Duncan Bulkley, M.D., New York.

Spinal Supports and Braces, the Indications for their Use, History and Modern Perfection. To be Illustrated with Forty Lantern Slides; A. M. Phelps, M.D., New York.

History and Pathology of the Spinal Cord. Illustrated with Lantern Slides; William C. Krauss, M.D., Buffalo.

WEDNESDAY—MORNING SESSION, 9:15 O'CLOCK.

Discussion on Abdominal Surgery; arranged by A. Vander Veer, M.D.

Disputed Points in the Treatment of Pelvic Surgery; Joseph Price, M.D., Philadelphia, Pa.

Influences Affecting the Results of Abdominal Operations; J. F. W. Ross, M.D., Toronto, Canada.

Hemorrhage after Abdominal Section. Its Place in Statistics; A. H. Buckmaster, M.D., New York.

Cysts of the Epigastrium; Dudley P. Allen, M.D., Cleveland, Ohio.

The Technique of the Abdominal Incision. Methods of its Closure and its Subsequent Management; W. W. Potter, M.D., Buffalo.

Operative Procedure for the Relief of Obstruction of the Common Duct; W. E. B. Davis, M.D., Birmingham, Ala.

Two Cholecystotomies for Gall Stones with Recovery, with Remarks on Operative Methods Based upon Five Cases; William Wotkyns Seymour, M.D., Troy.

Gall Stones, the Exciting Cause of Malignant Disease; Rufus B. Hall, M.D., Cincinnati, Ohio.

Appendicitis; Charles McBurney, M.D., New York.

An Analysis of 150 Personally Observed Cases of Appendicitis; George Ryerson Fowler, M.D., Brooklyn.

A Conservative View of the Treatment of Appendicitis; William S. Tremain, M.D., Buffalo.

Some Observations Relative to the Treatment of Suppurative Appendicitis, with Report of Cases; Willis G. Macdonald, M. D., Albany.

Palpation of the Vermiform Appendix; J. M. Edebohles, M.D., New York.

The Inch and a Half Incision, and Week and a Half Confinement in Appendicitis; Robert T. Morris, M.D., New York.

Report of a Case of Post-Peritoneal Abscess from Duodenal Ulcer, with Presentation of Specimen; L. S. Pilcher, M.D., Brooklyn.

Intestinal Perforation in Strangulated Hernia; William B. DeGarmo, M.D., New York.

Remarks on After Treatment of Abdominal Section; Carlton C. Frederick, M.D., Buffalo.

The Unexpected as Sometimes Observed in Abdominal Surgery; A. Vander Veer, M.D., Albany.

AFTERNOON SESSION, 2:15 O'CLOCK.

Recent Methods of Gastrostomy for Stricture of the Esophagus; Willy Meyer, M.D., New York.

The Influence of Physiological Rest on Prolapse of the Rectum; Joseph D. Bryant, M.D., New York.

A Contribution to the Subject of Excision of the Larynx; Charles A. Powers, M.D., New York.

Observations on 118 Cases of Cancer of the Breast, with Especial Reference to its Radical Cure by Operation; William T. Bull, M.D., New York.

The Treatment of Hernia. (Supplement to Paper read last year); Alexander Dallas, M. D., New York.

Some Cases of Brain Surgery; Herman Mynter, M.D., New York.

The Needlessness of a Mydriatic in Adjusting Glasses to the Eye; D. B. St. John Roosa, M.D., New York.

The Action of Scopolamine on the Eye; Thomas R. Pooley, M.D., New York.

The Treatment of Nasal Hemorrhage; John O. Roe, M.D., Rochester.

Report of a Case of Injury to Cauda Equina; Hermon C. Gordinier, M.D., Troy.

WEDNESDAY—EVENING.

Anniversary Address by the President, 8 o'clock, Senate Chamber. Topic—The Physician of Sacred History. Annual dinner of the Society, 9:30 o'clock, Delavan House.

THURSDAY—MORNING SESSION, 9:30 O'CLOCK.

The Treatment and Prevention of Epilepsy in the Young; Graeme M. Hammond, M.D., New York.

The Practical Workings of the Law for the Care of the Insane; Carlos F. MacDonald, M.D., New York.

Lunatics in Public Places; Wallace J. Herriman, M.D., Rochester.

The Subfrontal Gyrus (Broca's Convolution) in Man and Apes; Burt G. Wilder, M.D., Ithaca.

Acromegaly; Floyd S. Crego, M.D., Buffalo.

Report of a Case of Acromegaly, with the Exhibition of the Subject; Frederick Remington, M.D., Rochester.

Uremic Hemiplegia; Reynold W. Wilcox, M.D., New York.

Glycosuria; W. B. Vanderpoel, M.D., New York.

OFFICERS AND COMMITTEES OF THE SOCIETY.

President—Herman Bendell, Albany.

Vice-President—C. L. Stiles, Owego.

Secretary—Frederic C. Curtis, Albany.

Treasurer—Charles H. Porter, Albany.

Committee of Arrangements—Henry Hun, Albany; Seneca D. Powell, New York; W. J. Nellis, Albany.

Committee on By-Laws—H. D. Wey, Elmira; A. R. Simmons, Utica; F. C. Curtis, Albany.

Committee on Hygiene—Charles F. Bruce, New York; A. N. Bell, Brooklyn; D. S. Burr, Binghamton; H. R. Hopkins, Buffalo; Lewis Balch, Albany; E. H. Loughran, Kingston; O. W. Peck, Oneonta.

Committee on Legislation—D. B. St. John Roosa, New York; Daniel Lewis, New York; D. V. O'Leary, Albany.

Committee on Medical Ethics—John S. Warren, New York; Charles Jewett, Brooklyn; Eugene Beach, Gloversville.

Committee on Prize Essays—Franklin Townsend, Jr., Albany; A. Walter Suiter, Herkimer; Charles Stover, Amsterdam.

Committee on Publication.—F. C. Curtis, Albany; Chas. H. Porter, Albany; F. D. Bailey, Brooklyn; W. W. Potter, Buffalo.

College of Physicians of Philadelphia.

SECTION ON ORTHOPEDIC SURGERY.

At the meeting held on Dec. 15, 1893, Dr. F. X. DERGUM, Clinical Professor of Diseases of the Nervous System, Jefferson Medical College, read a paper on

SPASMODIC TORTICOLLIS AND ITS MEDICAL RELATIONS.

Before a body of learned specialists an elementary review of the subject of torticollis would obviously be out of place. Certain facts, however, owing to the paucity of our knowledge on the subject, demand repeated and careful consideration. Ordinary fixed wry neck, is of some interest to the neurologist inasmuch as most of the cases owe their origin to some primary disease of the muscles, generally the sterno-mastoid. As a result of congenital lack of development, or of trauma received during birth, the sterno-mastoid of one side is shorter than its fellow, and at the same time is rigid and sclerosed. That, however, fixed wry neck, is not always to be ascribed to this cause is shown by cases reported in which the affection was due to a tonic spasm of one sterno-mastoid, the spasm in turn being due to, or associated with, some affection of the eyes. Wadsworth in the Transactions of the American Ophthalmological Association for 1889, p. 381, reports such a case under the title of, "Spastic Torticollis Apparently Due to Faulty Position of the Eyes Cured by Tenotomy." Landolt (*Bulletin Medical*, 1890, IV, 573) records two cases, one associated with paresis of the left superior oblique and another associated with paralysis of the fourth pair of nerves. Inasmuch as both cases declined operation, the causal relation of the eye symptoms could not be determined. Of the three cases reported, two occurred in young children and one in a girl of seventeen. All had existed since early infancy. These cases are important as indicating a possible relation of cause and effect existing between torticollis and eye symptoms in children. That, however, some of these cases are due neither to eye troubles nor to trauma received in childbirth or faulty position of the head in utero, but are really due to defective development is made probable by the observation of Osler (*Archiv of Pediatrics*, 1892, p. 81) who noted the association of congenital wry neck with marked facial asymmetry.

Spasmodic Torticollis.—Spasmodic torticollis is an exceedingly interesting affection of the numerous and varied character of the problems which it presents. We know little of the physiologic action of the motor nerve cells and of muscular tissue while of the pathology of spasm we know still less. There is probably, further, some good reason why local spasms predominate in the regions of the face and neck but all we could say at present would simply be speculative.

Regarding spasmodic wry neck we must, it seems to me, admit the following propositions: 1, spasmodic wry neck is not necessarily spinal accessory spasm. While it is true that the sterno-mastoid and trapezius are decidedly involved in the majority of cases, the spasm is frequently not limited to them but involves other muscles. Further, cases are on record in which no spasm in the spinal accessory distribution was present at all and in which, notwithstanding, rotatory spasmodic movements of the head occurred. Again, muscles other than the rotators of the neck may also be involved; 2, the constantly recurring rotation of the head is at times the outcome of purely local conditions and in that sense is a local spasm; at other times, though more rarely, it is the outcome of the action of physiologically associated centers in the upper cervical cord and medulla or, more rarely still, of the morbid action of a motor center in the cortex, and in this sense resembles a volitional movement. Both of these propositions seem to me to be of great importance. Regarding the first, it is frequently possible by the careful study of the movements of the head and of the action of the muscles of the neck to determine which of the muscles are actually at fault. However, this can often be done approximately. The first point is, of course, to determine whether or not the spasm is limited to the spinal accessory supply. If not, what other muscles are involved. The importance of this study in view of operative procedures can not be over estimated and doubtless is one of the reasons why some cases of resection of the spinal accessory nerve are successful and why others fail. Having carefully studied the movements and the muscles involved, the next point that suggests itself is to determine whether the case presents physiologic associations of different and distant muscle groups. This association is seen at times in the concomitant spasm of both trapezii and of the anterior belly of the occipito-frontalis of the elevators of the upper

lip. There is present at times, also, an associated movement of the arm on the affected side. If this movement be in extension and pronation it is probably a physiologic association. Though of great importance, it is not always possible to differentiate between a purely local spasm and a movement indicative of some perversion of the normal physiologic action. If such a differentiation be possible it is of the utmost value in suggesting to us the position of the lesion if any. From what we know of facial spasm we have a right to infer that the lesion may be situated either in the cortex, the lower nerve centers, or in the nerve trunk. It is probable that the larger number of cases with which we have to deal are cases in which either the gray matter of the upper portion of the cervical cord and medulla is involved, or in which the nerve trunks of the spinal accessory, or of the cervical plexus are at fault. Certainly, if the cortex were more frequently affected we should expect, as Gowers points out, associated movements of the eyes. These are practically never observed. It is true, however, that other associated movements, especially movements of the arm and forearm are very suggestive of cortical disease. Pressure points, so frequent in facial spasm, are, as is well known, rare in torticollis, nor do we often have painful points over the spinal accessory or other nerves. Such a painful point was present in a case for a time under my observation and was situated over the spinal accessory nerve. The subsequent history of the case, however, the nerve being excised, proved that the case was not one of purely spinal accessory spasm.

Regarding the various medical measures for treating these cases it is hardly necessary that I should go into detail. All present are familiar with the utility of such drugs as gelsemium, conium and morphia, and also of their failure to cure—at least in the vast majority of cases. It is hardly necessary that I should dwell upon the various other agents at our disposal; massage, electricity, and rest in bed as they give only amelioration and fail to cure. It is to the surgeon that we turn sooner or later with the hope of securing for our patient decided, if not absolute relief. Those who follow me this evening will have a great deal to say about the various surgical procedures that have been instituted. Certain facts, however, present themselves for mutual consideration. First and foremost of these is section, or rather excision, of a portion of the spinal accessory nerve. This expedient yields in a large number of cases marked benefit, and in some instances it is followed by a complete disappearance of the spasm. In three of my own cases, however, it gave comparatively slight relief, the reason being, doubtless, that the spasm was more or less generalized, other muscles being involved. One of these cases I had the opportunity of following up and later, at my suggestion, Dr. Keen operated upon her, resecting the posterior divisions of the first three cervical nerves. The operation had originally been suggested by Dr. Wier Mitchell. This expedient was followed by a decided relief, though at last accounts the spasm had to some extent returned. We can readily understand why if the spasm be very much generalized—if a physiologic movement be represented by it—that the number of muscles involved may be very great. Thus in addition to the trapezius and sterno-mastoid, some, or all, of the following muscles may take part: the splenius, the rectus posticus major, the rectus posticus minor, the trachelo-mastoid, the complexus, the obliquus capitis superior, obliquus capitis inferior, the semispinales, the semispinales dorsi, and the multifidus spinæ. This array of muscles shows the utter hopelessness of securing absolute or permanent relief in some cases by any operation on the peripheral nerve trunks. However, such operations should always be attempted, provided the case be not clearly proven to be of cortical origin. It is both interesting and gratifying to learn in this connection that Dr. Keen's operation has been successfully repeated by Dr. C. A. Powers (New York Medical Journal, 1892, p. 253). The patient was one in whom there was very little involvement of the spinal accessory supply. Dr. Powers adopted the expedient of Dr. Keen, and the result was a complete cure. Mr. Noble Smith (spasmodic wry neck, London, 1891) has also performed the operation with a successful result. The recurrence of rotatory spasm after such extensive resection of nerve trunks as was practiced on the case adopted by Dr. Keen seems to point to the cortical origin of the disease. The propriety of a cortical operation in such a case naturally suggests itself and deserves serious consideration. The center for the rotation of the head being situated, approximately, at least, in the posterior portions of the first and second frontal convolutions just in advance of the arm

center, it would be, surgically, very accessible and could probably be electrically determined at the time of the operation. Inasmuch, however, as the center for rotation of the head and neck appears to be closely associated with that for conjugate deviation of the eyes, such an operation should only be contemplated as a dernier resort. Regarding other surgical procedures such as stretching of the spinal accessory nerve or tenotomy of the sterno-mastoid muscle, they merely deserve mention. They are little more than makeshift expedients. However, an operation devised by Collier (Lancet, 1890, I, p. 1354) deserves special mention. Collier, it will be remembered, tried the effect of a ligature upon the spinal accessory nerve. The ligature was a silver wire and was twisted with sufficient force to lightly compress the nerve fibers. Strange to say, the experiment was entirely successful, the spasm ceasing absolutely. The same expedient was, however, repeated by Drs. Mills and Deaver with failure as the result.

(To be continued.)

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 54).

DR. CHARLES R. DICKSON, of Toronto, read a paper on
FURTHER OBSERVATIONS ON THE ELECTRICAL TREATMENT OF
GOITRE.

The reception accredited a paper on the "Electrical Treatment of Cystic Goitre," which I had the honor to read at the last annual meeting of the Association, and the interesting and instructive discussion elicited has prompted me to offer some further observations along the same line, but embracing a somewhat wider scope as to varieties treated.

No statistics are presented, as I consider that to do so at present would be rather premature. For a number of years past I have been endeavoring to the best of my ability to aid in solving a question that was well and truly termed an opprobrium in medicine and surgery, by one who took part in the discussion of my former paper, and my intention is to briefly outline some conclusions at which I have arrived.

At my out-door clinic at the Toronto General Hospital, I am confronted with a large number of cases of goitre of different varieties, many of which have gone the rounds of the other departments, and finally are referred to my own, the youngest of the departments—the electrical—the result is that the greater number of the cases with which I am favored are of rather an unpromising nature. Yet for that very reason they offer the best field in which to test the value of this treatment, and though it entails a large amount of patient and careful work, still, I feel that I have been amply repaid for all the time and thought given to this most interesting subject, by the results achieved. The progress of a number of my cases has been carefully watched by many of the leading practitioners on the staff of our Hospital, and as a consequence several have intimated to me their intention to give the preference to electrical treatment in future, and already have shown in a tangible way their sincerity, by referring to me their cases in parish practice, which is the most satisfactory proof of the value of my work.

Among other points brought out in the discussion last year, one of the most valuable was by Dr. Holford Walker, as to the use of powerful currents applied by means of clay pads. I had already employed electrodes externally without puncture in some cases, but not with the powerful currents advocated by Dr. Walker, so I determined to test the utility of the suggestion, and am highly satisfied with the results; in fact, am strongly of the opinion that this should be a first step before puncture is finally resorted to—that is to say, in cases in which puncture would ordinarily be indicated—while in many cases it should constitute the sole treatment required.

The earlier a case is seen and the less previous interference, the better will be the results, and herein lies the great hope for the popularity of this treatment, for patients who dread the disfigurement, inconvenience and pain, to say nothing of the risk of surgical, and often, indeed, medical measures, and have frequently delayed consulting the practitioner till compelled by the discomfort attendant upon the increase of size, will on the first appearance of the trouble gladly avail themselves of a procedure which offers

such great inducements with so little discomfort and almost no risk.

The size of a goitre is no gauge of the attendant discomfort, and dyspnea or dysphagia may be present quite early, especially at certain times; thus when the patient is exposed to cold, or in the case of females before the establishment of menstruation, or at the menstrual period or during pregnancy and especially toward its close.

When a case presents for treatment, careful and extended inquiry should be made into the history and all points that would tend to throw light upon the subject investigated, and patients encouraged to give their own ideas on the subject, particularly as to suspected causation. Three measurements, at least, of the circumference of the neck should be taken, a fixed point, preferably the vertebra prominens, being chosen for the back, while the measure is carried above the tumor for the first, over the central portion for the second, and below the tumor for the third, and, if one of these measurements does not coincide with a circumference at the level of the Pomum Adami, that should be taken also; a vertical measurement over the median line in front is often useful. The boundaries of the tumor should then be carefully mapped out, and its probable structure determined. On the care bestowed upon your diagnosis will depend much of the success of your labors.

The cases which are probably the most favorable for treatment are those of simple vascular engorgement of the thyroid of recent origin; in these relief is experienced very early, in fact often after the first application, and reduction is usually quite rapid. For the positive electrode I use the Goelet modification of the Apostoli clay pad as in gynecologic practice, warmed and well moistened and slipped down the back between the shoulders, with a dry towel folded over it to protect the clothing and catch what little drip there may be; for the negative electrode, I use a thinner clay pad, with a single layer of gauze over its face, imbedded in it, and the edges carried over the sides of the electrode. The larger the size, the better, as it should cover all the surface of the tumor, if possible. When thoroughly moistened it is applied over the tumor and carefully adapted to all irregularities. A flexible perforated metal plate, such as tin with a spring split post to attach the rheophore, is then imbedded in the back of the clay and both held firmly in position by two or three turns of bandage drawn as tightly as the comfort of the patient will permit. The current must be very carefully turned on and shock avoided. At first the sensation is decidedly unpleasant, but the patient very soon gets accustomed to it and the strength may be gradually increased. It is always wise to proceed with caution and be content with fifteen or twenty ma., usually for ten minutes at the first application, and gradually increase the strength at future sances, which may be every second day, till the maximum the patient can stand with safety is reached. This will vary very much with different patients. I have several times gone as high as 250 ma., in one instance of a fibrous form without discomfort to the patient, but such I consider an exceptional case and 120 ma., or less is more usual. I consider a strong current for a short time preferable to a weaker one for a longer period.

I have not found it necessary to supply moisture to the positive electrode during the application as suggested by Dr. Walker—who employed a cotton covering at this pole—as it is always moist when removed, but sometimes drop from a spoon or from a pledget of absorbent cotton a solution of bicarbonate of soda on the upper edge of the negative electrode, and let it work its way down as the directive force of the current carries the moisture to the back of the negative electrode leaving the face of it dry. At the close of the sance, the electrodes should be carefully and quietly removed, and the site of the negative lightly sponged off with a cold solution of boracic acid; this is a precautionary measure as far as the skin is concerned, as well as conducive to the comfort of the patient who should also avoid unnecessary exposure during the treatment.

In later stages, even where the tumor is distinctly fibrous, it is still wise to try the clay-pad method first, as I have frequently noted it produced marked reduction; if, however, it is found that after several weeks of external treatment little is being accomplished, puncture may be resorted to, observing strict aseptic as well as antiseptic precautions. Here I employ the clay electrode positive as before, while for my negative I use either ordinary surgeon's needles or longer ones manufactured out of piano wire, insulated as required with two or three coats of collodion, each being allowed to dry thoroughly before the next is applied. If the patient is very timid, a preliminary hypodermic injection

of five to ten minims of a solution of 5 per cent. cocain and 6 per cent. antipyrin in distilled water may be made at the site of the proposed puncture, or some local anesthetic may be applied, but if possible it is better to avoid this, and if your needles are sharp and sufficient dexterity employed, there will be very little pain. I prefer to puncture through the isthmus if I can, and from as low down as possible and through the same opening each time carrying the needle to the different parts it is desired to act upon, seeing that the uninsulated portion is well within the growth and overlying tissues protected by the insulation. Direct the patient to swallow several times during the introduction and steady the growth with the unengaged hand; in this way puncture of larynx or trachea may be avoided. On the introduction of the needle great caution and the utmost care must be observed. The current must be very gradually turned on. The patient may not be able to stand more than ten ma. for ten minutes the first time, but at future sances, which may be once a week, fifty ma. may be reached; it is not often necessary to go beyond this. The current is gradually decreased and the needle withdrawn; if there is hemorrhage it may often be checked by the application of iodoform in powder or gauze, or by pressure. The puncture is then treated antiseptically. It is often an advantage to employ the clay electrodes in the interval between the punctures, the site of the puncture being protected by a small piece of gutta-percha tissue.

In the large vascular varieties, slow progress will be made with the pads; still, they will frequently effect reduction, but when they fail to do so, puncture is often indicated. Here the introduction of the needle, as well as its withdrawal, will require even more than the ordinary care, as largely dilated vessels are frequently met with, and important vessels much deflected from their usual course, and troublesome hemorrhage may ensue, but here care, pressure and iodoform should assist you.

In the cystic form, I adhere to the line of treatment presented in my paper last year. The pad treatment is of very little use in these cases, except in so far as it may reduce edema and thus afford relief from pressure. With the negative pole is connected an aspirating needle insulated to the desired extent by means of collodion, and the bare portion introduced well within the sac, being careful not to perforate the back of it also, as thin walls offer little resistance to your pressure. The contents are then aspirated and the sac filled to distension with a filtered solution of chlorid of sodium in hot, boiled water in the proportion of 5j to 5j. The positive, large dry pad having previously been placed in position as before, the current is gradually turned on to about fifty milliamperes for about twenty minutes; it is then gradually turned off; the fluid re-aspirated; the needle carefully withdrawn; the puncture at once treated antiseptically, and firm pressure made by means of a large, thick gauze pad over the dressing and retained by wide and long adhesive strips.

With the exophthalmic form, I have had less experience than with any of the others, and have nothing new to offer of any value.

As a result of a year's further experience, I still maintain that in electricity we possess one of the most valuable, if not the most valuable of agents for the treatment of the various forms of goitre mentioned. The cases which are not relieved, and relieved early, are the exception and not the rule; in many cases the first application is followed by a sense of relief from the dyspnea and dysphagia. A larger proportion of cases can be cured by this method than by any other means at present known to the profession. Many cases I have known to be cured or relieved which have resisted every other accepted form of treatment. While the injection of iodine, or even its external application, is sometimes attended with very bad results, with due precautions the electric treatment offers the safest form of procedure. Even when puncture is required the operation is safer, the pain less, and the resultant scar, if there be any, more insignificant than with any surgical measure necessary. There is no disfigurement during the time it is employed, hence patients will be more apt to resort to it early, while they are in the best condition to obtain relief. While the size of the growth is no gauge of the discomfort it is producing, neither should it influence our opinion as to the results to be expected to the extent that one would imagine, and a large, distinctly fibrous goitre the size of the two fists, has yielded more readily than a soft, flabby one the size of a walnut.

Great patience is necessary, as well as great care and considerable dexterity. The strength of current should be decreased at the close of the sance with as much caution as it is increased at its start, or great shock may ensue. A

case should not be regarded as hopeless till two or three months have been carefully spent upon it. It is well to intermit treatment occasionally for a period of several weeks, or even two or three months in the very chronic cases, and allow nature a chance to assist in the process of resolution and absorption. It may be indeed necessary to spread the treatment over a period of a couple of years in some cases. Slowness of result may be excused if cure come eventually.

The diagnosis should be very carefully made, then your battery or other source of power and all the parts of your current must be in good condition and resistance, internal and external, at a minimum, or the patient will be unable to tolerate the stronger currents.

The clay pads may be kept warm by means of Goelet's metal water bottle. Usually I keep the large one face downwards on a couple of folds of wet lintine and pour hot water over the face of it just before applying. It can readily be cleansed after using. The smaller pads I keep wrapped in a wet towel, first removing the flexible metal plate. Hot water may also be poured over these before using. All needles should be kept aseptic, while the aspirating needles and attachments will require particular care as to their aseptic condition.

DR. MASSEY said that some years ago he had absolutely cured a cystic goitre which had resisted other means, but he had found it necessary to maintain drainage also. He thought this preferable to continued puncture. He had found iodine cataphoresis produced so much irritation that it was necessary to stop the treatment. Out of six cases of exophthalmic goitre, he cured four completely, simply from external applications of currents of ten milliampères.

DR. MORROX had experimented with very strong galvanic and faradic currents combined, by the DeWatteville switch. In one case, after a month's treatment, the tumor was reduced more than two-thirds. In another instance, very powerful faradization was used transversely, and then galvanization. It was possible that there was an advantage in this combined method.

DR. WALKER referred to the case of a lady who had been formerly under the care of Dr. A. Laphorn Smith, but who now came to him as she was living in his neighborhood. She had come every year for three years, remaining each time three weeks under treatment. Relief was so marked that she could live the rest of the year comfortably. Probably three months would have given a practical cure, but she would not persist in the treatment long enough.

In answer to a question from Dr. Cleaves as to whether it was not common for the symptoms to disappear, even under the influence of mild currents, it was stated that there would be usually a decrease of one-half to three-fourths in size under each period of treatment as well.

DR. DICKSON, in closing the discussion, said he had endeavored in all cases of persistent treatment to avoid the admission of air into the aspirator, and to enforce strict antiseptis. His idea in using the fluid was to have every crevice of the sac filled with a good electrolyte. Some of his cases were relieved after the first treatment. The cases were mostly those which had received all kinds of external and internal treatment before coming to him.

In one case which was distinctly fibrous, and in which the tumor was of enormous size, there was a protrusion of the right eyeball. This diminished in proportion as the tumor was reduced, and at present it could not be appreciated by palpation. He had never tried faradization in goitre.

SECOND DAY, MORNING SESSION—SEPTEMBER 13.

The meeting was called to order at 10:15 A.M. DR. HOLFORD WALKER, Toronto, Canada, read a paper on

ASCITES TREATED BY GALVANIC CURRENT—REPORT OF CASE.

A. J. S., age 9, suffering from marked ascites, and general ill health; was brought to me by Dr. Burritt of Toronto, latter part of October, 1892. History: During the summer the little fellow seemed somewhat depressed, and sat about, an unusual circumstance for him; he was taken to a watering-place during July and August, and went into the water only up to his waist, every day, remaining in ten to fifteen minutes. At that time he was observed to become thinner generally. End of September, his abdomen was found to be very much distended. Dr. Burritt was called in, and after two weeks' treatment met Dr. Strange in consultation. They decided to tap, and endeavor to make a diagnosis of cause, the abdomen being too tense to make anything out. Three pints of fluid were removed, but without throwing further

light on the cause. Four days after tapping, the cavity was as full of fluid as ever, and patient continued to fail rapidly.

I advised exploratory incision, wash out abdomen and seek for cause. The father of the patient, however, thought otherwise, and insisted on a resort to electricity first, with the following results: Thirty-nine applications of from fifty to seventy-five milliampères were administered during the months of November, December and January, positive to abdomen and negative alternately to cervical and dorsal regions. The general health showed signs of improvement almost from the first; in three weeks it was perceptible that absorption was going on, and all fluid had quite disappeared by the end of January, together with recovery of general health. Has continued well up to date, with the exception of a mild attack of rheumatism, that occurred last month, involving the right wrist and ankle. He is now going about apparently quite well. I need hardly say that previous to electrical treatment, recourse was had to all remedial measures indicated in the case by the physician in charge.

DISCUSSION.

DR. HAYD asked the cause of the ascites.

DR. NEWMAN said he had notes at home proving the efficiency of electricity in ascites. He cited from memory the case of a man from the interior of New York who had extensive ascites and anasarca. Two physicians from Albany and five from Syracuse were called in consultation, and expressed the opinion that he could not live more than two days. He was then brought to the speaker for electricity. Inside of two days he measured three inches less, and finally he got well. The water was probably partially extracted from the body, and the secretions thereby stimulated. Without referring to his case-book he could not state what was the original diagnosis. He knew of several other cases which had been equally successful.

DR. ENGELMAN said that although it seemed hardly proper to bring up in this Association anything which would throw doubt on the electric treatment of these cases, he felt constrained to report a parallel case where two of the ablest physicians in his city were in attendance, and where he had no more doubt about the diagnosis than if he had made it himself. The patient is still living in St. Louis and has been in good health for the past eight or ten years. She was slowly sinking from renal disease, as shown by microscopic and chemic examinations of the urine, and the accumulation of ascitic fluid was enormous. His own father was the consultant, and agreed with the attending physician regarding the condition. The patient being in such a desperate condition, and the regular practitioners in attendance being unable to hold out any hope, some of the family insisted upon calling in a quack—a man who made certain "passes" about his patients. From that time on, improvement was steady, and she has since then been entirely well. The attending physician consented to be present and watched these foolish performances, and he can vouch for what was done.

DR. GEHRUNG of St. Louis, thought that most of these kidney diseases are due largely to spasmodic irritation, and that the relaxing effect of the electricity on the nervous system allowed of renewed secretory activity. He had used electricity where there was partial suppression of urine, and no symptoms of Bright's disease, and had succeeded very well in relieving the condition.

DR. GREEN asked if the reader of the paper had made a urinary analysis? About four months ago he was called to consult with Dr. Barbour in a similar case—a man 41 years of age who two years ago had an attack of septicemia. About eight months ago he began to show symptoms of asthma, and finally, microscopic and chemic analysis showed the existence of Bright's disease. His death seemed to be simply a question of a few days, as he was already semi-comatose. The attending physician suggested the use of galvanism, but the speaker did not think the suggestion of much importance. A week or ten days later, he saw the physician, and on inquiry was surprised to learn that the patient had entirely recovered. Galvanism had been used, and within four days the patient was very decidedly improved.

DR. WALKER, in closing the discussion, said that in his case a large clay abdominal electrode formed the positive pole, and because the patient was very sensitive, seventy-five milliampères was the highest strength possible. The negative pole was a large metal disc applied alternately between the shoulders and on the back. The treatment was given for fifteen minutes on alternate days. He was as much in the dark to-day as at that time regarding the diagnosis. Every

day the boy went into the water and was immersed up to his waist—whether that produced the sub-acute inflammation or whether, owing to a tubercular diathesis from the maternal side, a tubercular peritonitis had been set up, he could not say. It was with this in view that he had advised exploratory laparotomy, but the boy was in such a wretched condition that this measure seemed extremely hazardous. The kidneys were perfectly healthy. If the cure in this case were due to hypnotic suggestion, it is certainly a very tangible and practical method of calling hypnotism to our aid. Personally, he thought the cure was directly due to the continuous current.

(To be Continued.)

MISCELLANY.

Cincinnati Academy of Medicine.—The Cincinnati Academy of Medicine dedicated their rooms in the new Lincoln Club Building Monday, January 8. The rooms were ornamented with flowers, music filled the air, and there was speech-making galore.

Instance of Longevity.—John Dawson, aged 104 years and one month, and the eldest resident of the State, died at noon December 22. He had fifteen children, thirty grandchildren, sixty-four great-grandchildren and ten great-great-grandchildren. He attended the funeral of Washington, cast his first vote for Madison, and served in the war of 1812.

Deaths by Wild Animals in India in 1892.—The *British Medical Journal* states that in the year 1892, the mortality caused by snakes and other animals was 21,988 as against 23,650 in 1891. The deaths by snake-bite were returned at over 19,000, about 2,000 less than in 1891. The deaths in Bengal alone were by wild animals 1,664 and by snakes 19,025. About 85,000 snakes were destroyed, and 10,000 rupees were dispensed as rewards.

The Children's Hospital at Columbus, Ohio, was opened Dec. 30, 1893. The building is three stories, of gray pressed brick, with high tiled roof, ample windows and imposing entrance. The kitchen has been placed on the third floor, linen closets in keeping with the demands of such an institution have been put in, and many minor alterations have been made. The building is so arranged that two wards and an elevator can be added at any time in the future.

Testimony from Postmortem Examinations.—In a trial for assault with intent to commit murder, the Supreme Court of Illinois holds (case of Friederich v. People, decided Oct. 27, 1893) that it is competent for physicians to testify with regard to the appearance of a fractured skull at the time of a postmortem examination held more than a year after the assault. But such evidence can not be used to show that the person who committed the assault was responsible for the other's death.

Cook County Hospital Appointments.—The recent political change in the County Commissioners has made a corresponding change in the staff of this Hospital.

The following are the appointees, some of whom are on the present staff:

Surgeons—Drs. M. Muffat, O. J. Price, T. A. Davis, A. F. Hoadley, Francis A. Sherwood, A. J. Bouffleur, C. W. Hawley, Robert Melms, J. B. Murphy, C. W. Johnson and C. F. Greentree.

Physicians—Drs. James B. Herrick, George F. Butler, J. R. Reynolds, A. R. Edwards, George I. Sintxel, M. Meyerovitz, F. J. Mosehek, C. F. P. Korsell, W. H. Ballard, T. Turk and A. W. Baer.

St. Barnabas Hospital.—The trustees of St. Barnabas Hospital of Minneapolis, are much exercised over the prospect of losing the bequest of Mr. Martin of that city, who left a property known as the Keagan Lake property to that Hospital. It was, however, on condition that the citizens of

Minneapolis should raise \$1,000 annually for the support of the same Hospital. In case of failure to raise the amount, the property was to go to St. Luke's Hospital in New York city. As it is now said to be worth about \$200,000, and likely to grow more valuable with time, there is little disposition in Minneapolis to allow the property to pass out of their control.

Medical Legislation in Virginia.—The law regulating the Medical Examining Board of Virginia is eight years old. Much good has been accomplished for the protection of the public, but the organization of the Board is such that it has failed in some of its legal aspects. The *Maryland Medical Journal*, December 23, states that it is proposed to reduce the number of its membership to ten, taking one regular physician from each Congressional district, plus two irregulars or homeopaths, to be selected by the Governor of the State. It is also proposed to amend the laws governing the prosecution of itinerant quackery. The *Journal* instances a case wherein the present laws failed of the purpose during the past year: a notorious quack from one of the northern cities set up his stand in Richmond and successfully defied prosecution, gaining his point by pleading the unconstitutionality of the license law. Under a legal technicality, and with the aid of a shrewd lawyer, the quack continued to practice at his own option and pleasure without a license from the Board of Examiners. When a lawyer goes to work to unravel the work of another lawyer, and succeeds in his endeavor, it behooves the Board to change its legal advisers, or take lessons from the counselor who drove them out of court. Although the existing laws have been a decided benefit to the profession of Virginia, and *pari passu* have been a protection to the general public, those laws should be so strengthened that they can withstand the first serious opposition that shall be made to them. The effect, upon certain low graded medical colleges, of repeated rejections, by the Board, of their young graduates has been to raise the standard of requirements in those colleges. One member of the faculty of a distant college is reported to have said that his college had been forced to raise the tests of graduation for the reason that his faculty was tired of seeing their graduates rejected by the Virginia Board of Examiners.

CRITIQUE OF MACROSCOPIC EXAMINATION OF SPECIMENS REMOVED IN THIRTY-TWO CONSECUTIVE LAPAROTOMIES.

BY F. BYRON ROBINSON, B.S., M.D.

CHICAGO, ILL.

PROFESSOR GYNECOLOGY IN CHICAGO POST-GRADUATE MEDICAL SCHOOL;
GYNECOLOGIST TO WOMAN'S HOSPITAL, TO CHARITY HOSPITAL,
AND TO POST-GRADUATE HOSPITAL.

(Continued from page 46).

Case 9.—Age 24. Puberty at 11; menstruation regular but quite profuse, lasting about seven days. She was very pale and anemic. Menstruation was very painful for four days and compelled her to be in bed two days. Last period flowed for two weeks. Has long had leucorrhœa which has distinct odor and is yellow. She is tender on pressure in pelvis, especially on left side. She was occasionally sick in bed for two months at a time and had so much pain that much morphin was used. Two years ago she had two abortions and since that time she has been ill with pelvic trouble. I sent her to the Woman's Hospital and under rest and hot douches the exudates (size of a large apple on left side) nearly all disappeared. A renewed attack of pelvic trouble while in the Hospital induced me to operate. The recurring exudates were deposited on the left side at each attack. The diagnosis was salpingitis of gonorrhœal origin; physicians had treated her husband for several years for gonorrhœal discharge from the urethra. I operated at the Woman's Hospital Oct. 4, 1892, with the assistance of Drs. White and Shibley, removing both appendages. She made a very good recovery. Drainage for two days.

The specimens were of peculiar interest, as pus was found in the interior of one ovary on cutting it open, so that gonorrhœal virus had infected the ovaries. Both ovaries were cystically degenerated; some of the cysts were three-quarters of an inch in diameter. The tubes had carried the infection to the ovaries and infected them. The ovaries were covered with marks of old and recent inflammation. The tubes were both similar. The perisalpinx was richly covered with flakes of lymph, and organized exudates, old and recent. The peritoneum covering the tubes was slightly thickened. The *musculature* was not visibly changed. The endosalpinx showed the chief attraction. Its folds were swollen and very abundant. The lens showed no break in the mucous membrane. The swollen, edematous tubal plicæ were so large and numerous that the tubal lumen was packed quite full and she had a good deal of menstrual pain. It would be difficult to force the menstrual fluid through the tube, and the irritation would induce considerable tubal peristalsis or tubal colic. In this case the gonorrhœa had advanced through endometrium and endosalpinx where it makes a distinct home in the cylindrical epithelium of those two membranes. Now since the home of the gonococcus is in (glandular) cylindrical epithelium, it can easily affect the ovary, for the ovary is covered by germinal epithelium (glandular), and then the gonococcus advances to the membrana granulosa

which is typical glandular cylindrical epithelium. The membrana granulosa thus becomes infected by the gonococcus and soon becomes cystically degenerated. The Graafian follicle then becomes pathological. Again, to show that the infection went out at the tubal ends the parovarian in each broad ligament was distended. Kobelt's tubes were enlarged the size of peas. Five pedicled stalks existed in one parovarian.

Then, in general, ovarian and parovarian cystic degeneration is a secondary disease and derived from infection carried to them by the tubes. The pathologic condition removed from this woman has restored her to usefulness and health.

Case 10.—Mrs. S., age 40. Four children. Ill two years, since birth of last child. This woman came to the Woman's Hospital, sent by Dr. Miller. She had incontinence of urine and I treated her for two months with bladder douches and drugs. She did not improve. I dilated the urethra and explored with the finger but found nothing and it did not help her. The whole nervous system was examined but no defect discovered. The uterus was bound to the left pelvic wall and she had salpingitis. I finally concluded, after two months of treatment, that the incontinence of urine was reflex from the old pelvic disease. On Jan. 18, 1893, I removed the appendages assisted by Drs. White and Shibley. The pelvis on the left side was found full of exudate and the uterus was held down in Douglas' pouch by about twenty organized bands. The uterus was freed. No drain was employed. She recovered quite well and the bladder improved. The old organized exudates accounted for the bladder paralysis by undue pressure on the sacral nerves, especially those which supply the bladder.

The specimens show that around the abdominal tubal ostii, inflammation had spread very wide. The tubes were extraordinarily long with wide lumen. The perisalpinx had also recent adhesions on it. The *musculature* of the tube was slightly atrophied. The endosalpinx showed the chief lesion of disease. It was extremely atrophic. The lens revealed in the ampulla three large tubal plicæ which extended right to the tubal ostium abdominale. All the endosalpinx except these three plicæ was atrophied.

The folds had sunk down two-thirds of their original size. No solution of continuity could be found in the endosalpinx. This atrophy and some dilatation of the tubal lumen made the tube appear unnaturally large in caliber. No doubt the large tubal lumen enabled the infection to pass easily into the peritoneal cavity and to infect the ovaries.

This case confirms a discovery I made in investigating tubes of man and animals, which was that the lumen of the left tube is greater than the right, and that accounts for the fact that women are ill seven times out of ten on the left side. These tubes show very small abdominal ostii. The ovaries were cystically degenerated. The parovarian was normal and contained some fourteen vertical tubules. The trouble arose from septic matter passing through the tubes at the last puerperium, two years previously. It was not gonorrhœal as it had fairly recov-

ered, and only left solid adhesions which require many years to absorb.

Case 11.—Mrs. M. No children; age about 36. This woman had severe pain at menstruation and lost so much blood that she was a neurotic wreck. She had salpingitis. I operated on her May 1, 1893, at the Woman's Hospital, assisted by Dr. Stillians, whose patient she was. She made a good recovery. No drainage.

The tubes have the most typical appearance of convoluted, contorted or spiral angulation I ever saw. They are both alike and so twisted and rolled that at points they look double. The perisalpinx is considerably thickened. The peritoneum does not dip down into the depressions between the kinks of the tube. The *musculature* of the tube is slightly atrophied. The endosalpinx is considerably shrunken and atrophied. No solution of the continuity exists, and the lens in excellent light reveals no epithelial denudation. I wish here to call attention to a band running along the upper border of the perisalpinx. I never saw it described in any book, nor have I ever heard any one mention it. The only way to observe it well, is to put a typical specimen of convoluted tubes in pure alcohol, and as the alcohol shrinks the specimen, the band will show itself plainly running along the upper border of the tube in the perisalpinx. The band resembles exactly the *tænia coli*; or one of the bands which run along the colon, which give the colon its sacculated appearance. It is also shorter than the colon. The band running along to top of the tube is shorter than the tube by about the same proportion as it is on the colon. Now this band has a share in convoluting and twisting the tube; I will call it the *tænia tubæ*. Under the lens the band is composed of connective tissue.

I have observed this band (*tænia tubæ*) previously, but on searching anatomy I can not find it described. I have always found the *tænia tubæ* well made in the most typically convoluted tubes. It appears to shorten the tube in some cases one-sixth of its length and to throw the tube into convolutions. These spiral tubes are quite frequently found in women with tubal colic or pre-menstrual pain. By applying a powerful lens on the endosalpinx in bright sunlight another point is revealed, to explain pre-menstrual pain or tubal colic. For at the various angles of the bent tube the tubal plicæ lose their parallel appearance and are thrown into whorls, so that the ordinary current of fluid passing through the tube at the menstruation will be retarded and obstructed. In these whorls of tubal plicæ a secure nest may be obtained for ectopic gestation. The cilia all bend toward the uterus and the tubal peristalsis is also toward the uterus, and thus the cilia and peristalsis induce a current of fluid toward the uterus at every monthly. The fluid arises from a congested endosalpinx. The spots of denuded epithelium, the tubal hernia, the depressions in the endosalpinx and the tubal plicæ whorls all may have a share in lumen ectopic pregnancy.

So far, ectopic gestation has not been demonstrated in animals below man. The parovarian was cystic; as many as twelve cysts could be counted in one; nearly all were dilatations of Kobelt's tubes. Fifteen vertical tubes were counted. The ovaries were normal, with the exception of three to five pathologic Graafian follicles found in each ovary, filled with cheesy matter. In this woman the old gynecologic fad of "ovaritis" did not exist, in fact, but the tubes were the cause of her sickness. The diagnosis

in her case was salpingitis, pain (excessive peristalsis), hemorrhage.

Case 12.—Mrs. H., age 38. Two children; four miscarriages. Date of last pregnancy nine years ago. Menstruation regular, no pain, lasting four days. Married at 16 years. Four years ago had pain in right side, and one and one-half years ago noticed a swelling in right side. She had a myoma which had worked down between the bladder and vagina. It was the size of a hen's egg. I extirpated it per vaginam after the laparotomy, which I did at the Woman's Hospital, assisted by Drs. Shibley and White. Drain tube was used. She made a good recovery but a slow one, and left in four weeks.

The tumor found in the right side was a dermoid, size of a cocoanut. It had no pedicle, but was rotated off its axis and lodged and nourished in the lower border of the omentum. This accounts for her attack four years ago when, no doubt, the dermoid twisted off its axis which likely lay in the ovary, as nearly all dermoids arise in the ovary. When it twisted off its axis it did not become gangrenous because it was excluded from air. It nourished from surrounding organs because its twisting off created an irritation (mechanical), and that caused an exudate which re-organized and produced blood vessels, lymphatics and nerves around the circumference of the tumor. The formation of this new "nourishing pedicle" is of fine, delicate structure having a bluish tint. The dermoid contained hair, fat (sebum), and the products of the skin. In the cavity of the tumor was found one-half of the jawbone, containing one tooth of perfect form and composition as large as the adult tooth behind the canine, and another tooth of half its size, of perfect form and composition. The enamel is perfect. The jawbone is more porous than normal. Over the top of this bone lay a distinct membrane which I took to be the dura mater of the brain. These dermoids and their skeleton remains are no doubt the vain attempts of the germinal epithelium, which partially comes from the epiblast, to form complete structures. There was so much old adhesion that the right tube and ovary were not found. They may have been torn away with the dermoid and atrophied.

The left tube had salpingitis. The endosalpinx was in various stages of atrophy, as the lens would plainly reveal patches where the tubal plicæ were four times as small as normal, and other patches with abundant tubal plicæ. The tumor from the vagina proved to be a myoma about the size of an egg. It no doubt had traveled from the uterus down into the space between the bladder and vagina from the uterine rhythm during menstruation. The ovary was normal.

Case 13.—Mrs. D., age 30. One child; one miscarriage. Pain in pelvis and cystic tumor diagnosed. Laparotomy Dec. 22, 1893, at Woman's Hospital, assisted by Drs. Shibley and White. I drained one day. I removed both appendages on account of a distinct history of gonorrhœa and pelvic suffering. The tubes are normal in their perisalpinx and *musculature*. There is endosalpingitis with sero-pus floating over the mucous membrane. The endosalpinx looks unhealthy. It is edematous and friable. It is swollen in one place and atrophied in another. One tube is stretched over the parovarian cyst until it is seven inches long. The ovaries are normal. The cyst proved to be parovarian. It is five by four inches in diameter. Four gynecologists, including myself, diagnosed it a tubal cyst. It can be stripped entirely out of the broad ligament. The other parovarian is normal, containing twelve vertical tubules. The hydatid of Morgagni is as large as a hazel nut, with a pedicle one inch long.

Several small cysts in the region of Kobelt's tubes are as large as a pea, and as usual a little cyst nearly always exists on the upper border of the perisalpinx just over the abdominal sphincter of the tube, vestigial remains of the Wolffian body.

Case 14.—Mrs. H., age 22; one child, age 3 years. Puberty at 13; menstruation regular, lasts three days and stops a day and then reappears. She has painful menstruation, at the same time headache and backache. The pain is located in the pelvis, but radiates into limbs and body.

She has a yellow, bloody leucorrhœa with considerable odor. She has considerable pain, indigestion and water-brash. Bowels regular.

The diagnosis was a tumor in the pelvis, and we knew she had gonorrhœa contracted two years previously from her husband. I operated on her at the Woman's Hospital, Jan. 31, 1892, assisted by Drs. Shibley and White. Two ovarian tumors were removed about the size of a turkey egg. Drainage and irrigation, and the abdomen closed by silkworm gut.

In this operation, large numbers of organized bands existed in the pelvis, reaching far up among the intestines. Some of the bands were a foot long. Loops of the intestines passed between the bands as loops of rope would pass between the fingers of the hand. The bands held the uterus, appendages and intestines in a solid mass. The wonder was that none of the intestinal loops were obstructed or strangulated. I generally break up all such adhesions, and scarcely ever ligate any, as hemorrhage soon ceases in a band, especially if it be broken in its middle where the circulation is quite feeble.

The specimen showed double pyosalpinx. The left had nearly lost all its pus by absorption, while the right contained a dram. The endosalpinx was in various stages of disease from catarrh to destruction.

The *musculature* of the tube showed only the alteration produced by thinning of its wall. However, the tubal wall was thick, but that was due to inflammatory exudates. The perisalpinx was thickened from ancient and recent peritonitis. Bands and exudates of various ages lay on and around the appendages. Both ovaries had become thoroughly infected by two years of gonorrhœa, and cystic degeneration of the Graafian follicle had proceeded until the ovaries were the size of turkey eggs; some of the degenerated cysts contained pus. The gonorrhœa had passed from the cylindrical epithelium of the tubes to the germinal epithelium of the ovary (glandular epithelium) to the cylindrical and glandular epithelium of the Graafian follicle. The reason of the disastrous infection of both ovaries was due to the method of the closure of the abdominal end of the Fallopian tube, i.e., some of the fimbriæ were left in the peritoneal cavity after the peritoneum around the mouth of the tube had contracted. These few fimbriæ had instigated a continual recurrence at menstrual and other times, when the mucous membrane on the fimbriæ was congested, and started anew the old (gonorrhœal) infection. Ovarian infection is seen to perfection in this case.

The tubes carried the infection to the ovaries, and this gives more evidence that ovarian disease is nearly always secondary to tubal disease and caused by infection. This patient left the Hospital seven weeks after the operation. She was then well. She had a small fistula which frequently occurs after gonorrhœal pyosalpinx, as one can not remove all the diseased tissue and the ligature became infected. Six months following the operation she had the fistula. No fecal matter ever came through it. Eight weeks after the operation, about the time the patient removed home, she began to vomit and vomited steadily for three weeks, and she has vomited about once weekly the following four months.

Aug. 1, 1893, she returned from her home in Indiana for treatment at the Woman's Hospital. I found a tender spot in the region of the gall bladder and pylorus. She has lost over thirty pounds, and is of a pale saffron color. She has periods of terrible pain

and sometimes vomits. Her appetite when not in pain is good. The trouble seems to have no connection with the laparotomy. The diagnosis by Dr. Franklin H. Martin and myself is thought to be a gall stone or malignant disease of the pylorus. We are now waiting developments for a coming operation.

Stools move about every two days and are fairly natural. It appears to me that her second trouble has nothing to do with the laparotomy. (Seven weeks later this lady has gained about fifteen pounds and is looking well.)

Case 15.—Man, age 24. Ill for several weeks. Temperature varied up to 102. Pain and swelling on right side from iliac region toward lower rib. A distinct boggy tumor could be felt. It had an elongated form and distinct crepitation could be perceived by manipulating it.

The diagnosis was appendicitis. Operation evacuated several drachms of pus. The appendix was not searched for, but a drain tube and gauze were inserted. The tube was shortly after withdrawn. He made a good, easy recovery.

Case 16.—Ectopic pregnancy. Mrs. B., age 22, was married in July, 1892. In December, 1892, a practitioner produced an abortion on her of probably a three months pregnancy. From December until the last week in February, 1893, she was very ill in bed with much fever. In the last week in February Drs. Simon and Abel were called to attend her. At this time she had a severe chill and her temperature rose to 104. On February 26, I was called in consultation to see her, and I found the pelvis absolutely full of a hard, boggy mass, which extended out of the pelvis into the right side of the abdomen, in the iliac region. Aspiration per vaginam was suggested, but I did not think it best, and urged that the woman be sent immediately to the Woman's Hospital. She was in the Hospital one day and a night when I noticed the temperature was rising up to 103. On February 28 I diagnosed rupture of the pelvic cyst and infectious invasion. One hour after my leaving the hospital she had a severe chill, and the temperature rose rapidly to 106.2. Immediate preparations for an operation were made. Assisted by Drs. Shibley and White, I operated in the presence of Drs. Simons, Lucy Waite and Millman. On opening the abdomen the pelvis was found full of a hard mass, which was closely covered over by adherent omentum. Fortunately, the omentum could be stripped off the mass. The mass proved to be the fimbriated end of the tube, containing about a pint of stinking pus. The whole mass had to be literally torn out of the pelvis. After removing both appendages, the abdomen was irrigated with some eight quarts of hot boiled water and closed with silkworm gut sutures. Drainage was employed. The tube on the right side proved to have the large abscess in the fimbriated end, while in the isthmus of the tube was found the placental remains of a fetus.

The placenta was about one and one-half inches long and one inch thick. No fetus could be found.

The history of this case may be interpreted as follows: the woman first became pregnant in the tube where the fetus died. She then shortly afterward became pregnant in the uterus. Three months after, she was criminally aborted, and this abortion distributed infection anew along the right tube, which induced the tubal abscess.

The tubal disturbance at the time of death of the fetus would, no doubt, have subsided but for its exacerbation at the time of the criminal abortion and, as the os is never prepared for an abortionist, soon closed and retained the infected material, which overflowed in the direction of least resistance along the Fallopian tube. The opposite tube was healthy as far as the eye could detect.

This is a typical case to show that prompt surgical interference may save the dying. We are well aware that surgical operations on the dying are very unsatisfactory. Very often the subsequent wish arises that no operation had been done on a patient who expired almost with the completion of the operation. But this woman, who was only 22 years old, though

dying, showed a hopeful vigor that we thought might rally.

She did rally and the next day the temperature had fallen 5 degrees, and the pulse from 130 and 140 had fallen to 110. I have never known a patient to get well after a temperature of 106.2 with abdominal section.

Dr. Byford who had noted the height of temperature, said he had not known one to recover after operation with such a temperature. At the operation we took the liberty of removing the apparently normal appendage, for it may be noted that when a woman has pyosalpinx on one side that, sooner or later, the tube on the other side becomes involved. It is a very notable feature in these old cases of pelvic inflammations how the peritoneum of such women becomes tolerant to manipulation, and it also resists the invasion of infection to a powerful degree. We will note a feature in diagnosis of some troubles in the peritoneum. It may be observed that so long as the inflammatory masses remain in the pelvis, or closely connected with structures mainly supplied by the sympathetic nerve, the pain is dull and not of a cutting or short character. But as soon as the inflammation encroaches on the abdominal wall where the peripheral ends of the spinal nerves are in close proximity, then pain is much more manifest, and one can diagnose with fair certainty a localized peritonitis of the abdominal parietes. The diagnosis of this case could not be made as to whether it was ectopic or not, for we did not know that she had had an abortion produced until after the operation, as it was naturally kept a secret. This is a typical case to show that one of the great landmarks in gynecologic practice is abortion. In teaching students and practitioners, we have frequently called attention to the idea that in gynecology there are six great landmarks worth knowing, viz.:

1. Anatomy.
2. Menstruation.
3. Labor.
4. Abortion.
5. Gonorrhoea.
6. Tumors.

Each one of these landmarks presents centers around which the diagnosis will turn. Around these landmarks, as principals, must cluster the details of diagnostic conclusions.

In this case the prompt application of modern surgery saved the woman from certain and speedy death, and restored her to her family as a useful member. Time and experience strikingly confirm exploratory and confirmatory sections in cases of doubtful diagnosis—and many are doubtful. This patient came to my office seven months after the operation and she reports herself as perfectly well. She has gained some twenty-five pounds in flesh and is as robust as woman could appear.

Case 17.—Age 30. One child 11 years old. One miscarriage. Puberty at 13. Menstruation painful and irregular. Married eleven years. She has backache and headache. Leucorrhoea yellow, green or bad odor. Has been ill eight years. Has had temperature varying up to 104 for many months.

Some six gynecologists examined this patient, but none could give sufficient reasons for any diagnosis. Finally, in consultation with Drs. Byford and Martin, it was decided to operate. On Feb. 28, 1893, assisted by Drs. Shibley and White, I operated at the Woman's Hospital.

The tumor filled the pelvis and abdomen up to the navel, and lying in front of the tumor to the left was the uterus with highly diseased appendages. The tumor proved to be

a large infected dermoid universally adherent. It developed in the broad ligament and raised it up to a level with the umbilicus. It proved to be the most difficult of operations and lasted an hour and a half. She collapsed at the last, and her pulse was not perceptible in the wrist for many hours. She was bathed in cold perspiration. The foot of the bed was elevated. Hot salt enema were given per rectum. Considerable whisky was given by mouth, hypodermically and by rectum. For three days her pulse was over 140. I could frequently count it up to 180. But her temperature for those three days was about 100 and 101 per rectum. The pulse slowly went down for ten days when it was 110 and temperature 98. During all the time the drain tube did good work. The recovery of this woman is one of the most miraculous I ever witnessed and much of it is due to trained nursing.

She came to my office six months after the operation, a large, robust, healthy looking woman. She still had a small abdominal fistula which secreted a few drops daily.

The specimen is remarkable as showing pathologic progress for some ten years. The Fallopian tube has a wall of solid connective tissue half an inch thick. The mesosalpinx and perisalpinx present the thickened and roughened appearance of repeated inflammations. Bands, adhesions, exudates and flocculent deposits tell the story. The *musculature* is fully one-half an inch thick but nearly all of this is hard white connective tissue, and muscle in it is very scarce. The endosalpinx shows only fragments of its original. It is disorganized in places and atrophied in other places. A few widely separated tubal plicæ present themselves under the lens as fairly normal but nearly all atrophied. The dermoid appears to be developed out of the ovary. It has on its surface quite a number of small cysts similar to the Graafian follicles, and its wall for a large part seems to be ovarian tissue with some very small ovarian follicles growing in it. Inside the dermoid cyst a thick membrane can be peeled out which I take to be the old original *membrana granulosa*. Parts of this membrane are one-quarter of an inch thick and its line of demarkation from the ovarian tissue is complete. This dermoid has a history like almost all dermoids and that is that they grow out of the ovary; they are ovarian dermoids. The broad ligament over the dermoid was enormously hypertrophied. The dermoid was filled with sebum—a kind of oily substance of a white color and of the consistency of lard. It contained hairs and many other skin products. A dermoid is a tumor containing skin and some of its appendages as hair, teeth, nails—in fact almost any portion of the body may be found in it, that is in the region of the epiblast. I have found the skull and the cranial nerves.

Case 18.—Mrs. H. Sent to me by Dr. J. F. Percy of Galesburg, Ill. She was 48; puberty at 17. Menstruation regular and painless, lasting two days. Has had ten children, ages 27 to 12. It is eleven years since last child. She has backache and slight leucorrhoea. She has been compelled to be quiet for the last few years from simply pressure of the tumor. The abdominal swelling has increased for two years and rapidly for ten months. She was treated but not tapped. In examination a little fluctuation was detected but nothing definite could be elicited, and it was impossible to tell what kind of a tumor was before us. I could not map out the uterus. So with careful examination with inability to diagnose, it was decided to explore. At the Woman's Hospital Dec. 12, 1892, assisted by Drs. Shibley, White and Percy I operated. The tumor proved to be ovarian with some adhesions. But only a part of it contained fluid. The solid part was divided into many compartments with walls varying from one-half inch to three inches thick of fibrous tissue. The cavities contained semi-solid jelly which was probably mucus and other matter secreted by the *membrana granulosa*. The tumor weighed seventeen pounds. A drain tube was employed and the abdomen closed with silkworm gut.

She left the Hospital well on January 6, 1893. Right here is an example to show the effect of pressure on the abdominal brain by large tumors. I have noted that pressure of tumors disturbs rhythm of viscera. This lady had distressing attacks of a kind of asthma. The rhythm of the lungs was disturbed. She had hypertrophy of the heart, due to reflex action transmitted to it by way of the splanchnics from the abdominal brain to the cervical sympathetic ganglia, where the irritation was reorganized and sent to the heart on account of the pressure of the tumor on the abdominal brain causing the heart to move irregularly and rapidly. The result was overfeeding and consequent hypertrophy. Besides disturbance in the heart, this woman had constipation and indigestion due to pressure of the tumor on the abdominal brain. She had gas in the bowels. The reason of this was that irritation of the abdominal brain was emitted over the gastric plexus to the stomach, the superior mesenteric plexus to the small intestine and the inferior mesenteric plexus to the large bowel.

This irritation induced: 1, excessive secretion; 2, deficient secretion; 3, disproportionate secretion of digestive juices—result indigestion and constipation. She had gas in the bowels from fermentation. She had liver disease and was pigmented on the skin because the rhythm and secretion of the liver was disturbed. The hepatic plexus carried the irritation from the compressed abdominal brain to the liver and induced excessive, deficient or disproportionate secretion. The spleen also was disturbed in its rhythm and suffered from pigmentation. Thus through reflex action on the sympathetic nerve due to pressure of the abdominal brain, the patient suffered in every viscus. Since removal of the tumor, so far as I could find, all these "reflexes" have disappeared. In her requested annual letter to me she reports herself well and happy.

Case 19.—Miss H., sent to me by Drs. R. Zeit and Nyson from Medford, Wis. Age 15. Puberty had begun but was very irregular. She had a tumor in the middle line of abdomen and the cervix was elongated. Assisted by Drs. White and Shibley I operated at the Woman's Hospital. The tumor proved to be a very rare specimen of the ovary, the size of an apple holding locks of hair. It also had an ovarian follicle containing about a pint of clear fluid. Besides these, a large solid mass about the size of a child's head was found at the end of the ovary. This solid mass was considered to be sarcoma. Hence a dermoid, an ovarian cyst and a sarcoma were all found in the ovary of a girl of fifteen. The other ovary was somewhat enlarged and distinctly cystic so it was removed. She made a very easy recovery.

Case 20.—Mrs. G., age 48, sent me by Drs. Washburn and Jackson of Indiana. She was enormously distended in the abdomen. I operated with the kind assistance of Dr. Franklin H. Martin and Drs. Shibley and White. It proved to be a very severe operation. We removed a sixty pound ovarian tumor, part solid and part fluid. Drainage was employed and she did well until twenty-four hours after, when the pulse rose steadily higher with a viscous spring to it. The temperature went stealthily and steadily up. Her mind, from an active practical character, became slowly but perceptibly less alert to the world. She grew slowly more stupid and died fifty-three hours after the operation from, probably, acute sepsis. This was the only death in the series of thirty-two cases from the operation and they presented very severe pathology.

Case 21.—Age 56, single. This lady had a laparotomy performed on her about a year previous, for what I could not learn. The abdominal wound did not heal and I suspected malignant disease. She was narcotized and the wound thoroughly curetted. The wound led to the bottom of Douglas' sac. No ligation was found. The two following months clearly showed it to be a malignant growth in the abdominal wound subsequent to laparotomy. It was con-

sidered to be cancer. As the growth increased it obstructed the bowels. Dr. Joseph B. Bacon and myself performed lumbar colotomy on her from which she recovered. She died subsequently from the malignant affection. It is very rare to see malignancy spring up in an abdominal wound following laparotomy.

Case 22.—Mrs. R., age 39. Puberty at 11 years. Menstruation regular. She was never pregnant. She had myoma of the fundus of the uterus and bled profusely for some three years and has lost great quantities of blood for the past eight months. She was almost bloodless on entrance to the Woman's Hospital. Her tumor was a solid mass which entirely filled the whole pelvis up to its brim. I operated, assisted by Drs. Shibley and White. The mass was so dense and extensive that it was considered unwise to attempt to remove the uterus, but I carefully dug through the mass and put three ligatures around each tube, occluding the ovarian artery, and the ligature would render the tubes functionless. In November, 1892, this operation was performed. It was the first in which I ligated the ovarian artery and the uterine as it courses along the side of the uterus. Drainage was employed. She recovered. Ten months afterward she visited my office and the uterus had shrunk to less than one-third its original size; nearly every trace of exudate was gone. She menstruated or lost blood a few times. She calls herself well and strong.

Case 23.—Mrs. V., sent to me by Dr. Mary Jackson of Hammond, Ind. Age 33; seven children. She was taken suddenly ill six weeks before entering Hospital. She grew steadily worse. The abdomen enlarged. Drs. White and Shibley assisted me to operate. The pelvis was found filled with a tumor which was composed of concentric layers of blood. It appeared to come from the right Fallopian tube, as a distinct ragged aperture was found in the walls of that tube. The tumor and appendages were removed. Drainage was employed. She recovered and left the Hospital.

This was considered to be a case of ectopic pregnancy from a careful examination of the specimen. The gestation was in the right tube which showed the point of rupture. No fetus could be found, but the state of the tube indicated such.

Case 24.—Mrs. A., age 33, sent to me by Dr. Eilertson of Chicago. Ill two years; had three children, ages 13, 11 and 7 years. Has noticed enlargement for two years. One year ago the swelling suddenly subsided and then gradually increased for a year. Dr. Eilertson assisted me to operate six months ago. The tumor proved to be an ovarian cyst. The other ovary was also as large as a hen's egg. It was removed. The sudden decrease of the tumor was made plain on its removal. It had on its wall an old scar about the size of a silver dollar. This cicatrix represented the point of rupture one year before. She recovered and left the Hospital well.

Case 25.—Age 28. Ill for about one year with pelvic trouble; very ill for five months. The operation was done at Charity Hospital by Dr. Geer and myself. It proved to be a case of very severe pyosalpinx. The adhesions were extensive and dense. The enucleation demanded the tearing up of vast areas of old and recent pelvic adhesions. The bowel was wounded several times, but not sufficient to tear through the mucous membrane. Thorough irrigation and drainage were employed and the abdomen closed with silkworm gut. She did well until about the eleventh day, when the temperature began to rise and for five days it wavered; on the sixteenth day jumped up to 104. Dr. Geer and I then agreed to re-open the abdomen. She was anesthetized and the finger followed the place where the drain tube had been. As the finger entered the wound about three inches, just below the pelvic brim, some two ounces of yellow pus rolled out. The wound was irrigated, drained and the woman made an excellent recovery. She has now seven months after the operation, a small fistula in the abdominal wall, but she is ruddy and gaining flesh and is well. In this case a re-opening of the abdomen absolutely saved the patient's life.

The following seven cases of laparotomy were performed by Dr. Lucy Waite at the Charity Hospital in my service. I assisted her in each case so that a synopsis of them will be included in this series:

Case 26.—Removal of the appendages for double pyosalpinx and hematoma of left ovary resulting from gonorrhoea. Patient was 25 years of age and gave a history of gonorrhoea for three years past and a produced abortion. She was almost totally incapacitated for labor. Both tubes and

ovaries were bound down in massive exudates from which the Doctor literally dug them out. Every element in the tube and ovary was diseased; perisalpinx, musculature and endosalpinx all had widespread pathologic conditions. Considerable pus was found in the pelvis. The abdominal cavity was thoroughly irrigated and the wound closed with silkworm gut. Drainage was used. Recovery was good. Eight months after the operation she is nursing and is practically well. The reasons which justified and demanded laparotomy in this case were exactly what Dr. Waite and myself had repeatedly observed during our four months' treatment of the patient viz: periodic exacerbations of pelvic peritonitis, pain, gonorrhoea, pelvic exudates, rise of temperature, constant suffering and incapacity for labor and the downward course of the patient.

Case 27.—Removal of the tubes and ovaries for a general myoma of the uterus. The patient had had a tumor the size of a cocoon for three years with severe hemorrhage for one year. She had three children. She recovered from the operation and has had one hemorrhage since, so far as reported, in six months.

Ten months after the operation I saw her. She appears perfectly well, and says she is now healthy and hemorrhage has almost entirely stopped. Dr. Waite ligated the upper end of the uterine artery, which accounts for the almost complete arrest of bleeding.

Case 28.—Laparotomy for chronic salpingitis and ovaritis. Age 36. She was ill seven years and a neurotic wreck. The operation proved difficult, as the old organized exudates were very dense. She made a good recovery and is now very well seven months after the operation. She has improved in all nervous symptoms.

Case 29.—Removal of the appendages in a girl of 20 for hysterio-epileptic convulsions of six years duration. She recovered without an untoward event. Six months after the operation the guardian of the girl writes to Dr. Waite the following: "Your patient is doing nicely and we believe she will come out all right." It seems to me that the word, epilepsy, should be excluded from this disease, as it is a reflex menstrual disturbance and is not true epilepsy. True epilepsy does not recover from removing ovaries or testicles. It is true that this girl was a total wreck, that she could not even care for herself and that an extra attendant was required for at least a week every month to supervise her during dozens of convulsions at each period. She is recovering from a *neurosis* but not epilepsy.

Case 30.—Removal of the appendages for double pyosalpinx and abscess of uterine wall, following five weeks after delivery.

The pelvic organs were imbedded in a mass of exudates and the abscess contained about a tablespoonful of yellow pus. The peritoneum was well irrigated; the mouth of the abscess was clamped to the abdominal wound for thirty-six hours. Drainage was employed and the patient made a good recovery. Five months after the operation she is well.

Case 31.—Age 52; one child 10 years old. Ill since last child was born. Laparotomy showed the uterus and appendages consolidated into a mass. Dr. Waite separated these old dense adhesions with much difficulty. The proof of the age of the adhesions was profuse hemorrhage from newly formed blood vessels. She recovered well, and left the Hospital improved in every respect. A significant fact is that her extreme neurosis almost magically disappeared.

Case 32.—Age 22. Ill two years with pelvic trouble. She was a miserable neurotic, incapacitated for labor. She had severe attacks of pelvic peritonitis. The menstruation was becoming more and more severe with increasing pain. She reports a sudden flow of pus through the vagina besides leucorrhoea. The diagnosis was gonorrhoeal salpingitis with pyosalpinx. Dr. Waite enucleated and tied off both the appendages which were in severe pathologic conditions. Abdomen irrigated, drained and closed with silkworm gut sutures. The patient recovered well, and left the Hospital a different looking woman.

The foregoing thirty-two cases of laparotomy were performed just as they came in order. No selection was made, no picking of cases was done. The one case of death was from acute sepsis (due to what cause I know not) in a woman with a sixty pound ovarian tumor. At present (ten months after the

above operations), I know of two abdominal fistulae existing. So far as I know all other fistulae have closed. One patient died six months after the operation from acute rheumatism; one died a year after the operation from pulmonary tuberculosis.

COCILLANA—THE BARK OF AN UNDETERMINED SPECIES OF GUAREA.

NATURAL ORDER—MELIACEÆ; HABITAT, BOLIVIA.

Read in the Section on Materia Medica and Pharmacy, at the Forty-fourth Annual Meeting of the American Medical Association.

BY F. G. RYAN, M.D.

PROFESSOR OF THE PHILADELPHIA COLLEGE OF PHARMACY.

This remedy, which was first brought to the attention of the medical profession by Dr. H. H. Rusby of the New York College of Pharmacy, seems to be gaining much favor. The results of many clinical investigations indicate that this drug is destined to become one of great usefulness in the treatment of diseases of the respiratory organs.

The following botanical description is taken from the "Pharmacology of Newer Materia Medica:"

"This species was first described by Dr. N. L. Britton of Columbia College, under the name of *Sycocarpus Rusbyi*, on the supposition that it was a new genus belonging to the natural order *Anacardiaceæ*. On the subsequent acquisition of complete specimens, Dr. Britton at once recognized the true affinities of the plant as being with the genus *Guarea*, natural order *Meliaceæ*, and referred it with some doubt to the species *Guarea trichlioides*. (Linn.) While it is certainly a *Guarea*, there is much difference of opinion as to the species. Dr. Rusby is quite positive that its characters render it distinct from all known species of that genus, in which, I may remark, nearly all the species are separated by very minute differences of structure. The tree is described as reaching an extreme height of some thirty or forty feet, and a trunk diameter of nearly three feet. It is low, and broadly spreading in habit, reminding one considerably of a large apple tree. The bark is thick and ash-colored, becoming rough only with considerable age. The larger branches are horizontal, the ultimate ones somewhat erect and bearing the leaves erect, clustered at their ends. The leaves are pinnate, bearing some resemblance to those of the common sumach, but much larger, being a foot and a half or more in length by two-thirds of a foot broad, and bearing from five to ten pairs of oblong obtuse leaflets, the larger of which are six or eight inches in length. In the axils of these leaves appear the loose racemes of flowers, some eight or ten inches in length. The flowers are small, scarcely larger than the head of a small carpet tack, with the parts in fours, of a dull greenish color, very inconspicuous, and are succeeded by a somewhat woody fig-shaped fruit, as large as a walnut. It contains four cells, one or more of which are commonly obliterated as it matures, and one or two erect seeds."

Joseph Schrenk in the *Druggists' Bulletin*, August, 1888, gave the following description of the appearance and structure of the bark:

"The samples of this bark which I had occasion to examine, were evidently taken from an old tree. They were curved pieces, about fifteen mm. thick; large white patches, caused by the growth of a fungus, are seen on the tawny-yellow outer surface, which is very rough and uneven, with deep longitudinal furrows and crevices, and occasional horizontal fissures. The inner surface is grayish yellow, coarsely striate, and often roughly fibrous, with numerous detached broad bands of bast-bundles.

"The fracture, which is coarsely granular in the outer and splintered in the inner bark, shows that the 'cork' is very strongly developed, for in many places the periderm occupies about two-thirds of the entire thickness of the bark; it is of a light reddish-brown color, with numerous yellowish-white, scattered dots plainly visible to the naked eye. The inner portion of the bark is of a firmer texture and tangentially finely striate. The odor is slight, but peculiar, and the taste unpleasant (not bitter); slightly nauseous.

"On cross and longitudinal sections the periderm is found to consist of one or several layers of primary, and frequently even of secondary bark separated from the deeper living tissues by broad bands of cork. Large groups of sclerenchyma cells with very much thickened porous walls are seen in the periderm and the other parts; their number diminishes toward the interior, and in the inner half of the bast portion they are met with only very sparingly.

"The bast cells are arranged in strictly tangentially elongated groups (as seen on the cross section), but there are no radial rows, therefore the medullary rays are not so readily distinguished with the unaided eye as in some other barks. They invariably make considerable curves where they enter the zones of cribose and parenchyma tissue, which alternate with those of the bast-fibers; and as they contain a red colored substance they can easily be traced under a low power as undulating red lines. On tangential sections they appear very distinctly as narrow eclipses made up from one to three horizontal, and up to twenty vertical rows of cells. Where these rays pass through parenchyma tissue they are frequently bounded by vertically elongated, rather wide cells, distinguished by the fibrous thickening of their cellulose walls. They form a prosenchyma-like tissue, or in each vertical row of (from five to ten) cells the two terminal ones are pointed.

"The bast-cells are slender and straight, at an average of seventy-five hundredths mm. in length. Each fiber bundle is accompanied by rows of cells with very much thickened lignified walls, each containing a large calcium oxalate crystal (of the monoclinic system) entirely filling the interior of the cell, so that when the crystal is removed by the application of hydrochloric acid, an exact mold of it is left. So closely are these rows of 'crystal sacs' applied to the bast-fibers, that the latter can be brought to view on longitudinal sections only with difficulty. Calcium oxalate crystals of the same form are also seen in other cells, especially in the proximity of the stone cells. Small, rounded, simple starch grains are rather abundant in the parenchyma, and in the cells of the medullary rays can be noticed the red colored masses mentioned above, which are insoluble in alcohol."

Clinical examination of the therapeutic properties of cocillana has engaged the attention of a number of prominent physicians, complete reports of which will be found in various journals.¹ The latest of these by Dr. John V. Shoemaker,² speaks of his results as follows:

"In small doses, it has a good influence upon the appetite and digestion. In larger quantities, it produces an emetic and cathartic effect. The alvine discharges, under its use contain mucus and bile. It stimulates the sudoriparous glands and, when given in considerable quantities, causes copious perspiration, accompanied by prostration of muscular strength. Excessive amounts also give rise to giddiness. It is eliminated principally by the broncho-pulmonary mucous membrane, upon which it exerts a stimulant and alterative effect.

"Cocillana may be administered in the form of a tincture or fluid extract. The dose of the tincture is from 30 minims to 2 fluidrachms; that of the fluid extract from 10 to 20 minims. In my clinical experiments I have made use of the fluid extract, which resembles sherry wine in color, has an aromatic odor, and a bitter taste. It is, however, not unpalatable when mixed with syrup.

"The chief therapeutic value of cocillana is in the treatment of the diseases of the respiratory tract. In epitomizing my experience with this drug, I deem that I can not do better than to relate briefly the histories of a few cases in which it was employed with notable advantage. Bronchitis is the malady to which it is the most applicable, and it is particularly beneficial in the subacute or chronic stage. Cocillana stimulates the capillary circulation of the bronchial mucous membrane, and thus relieves inflammatory congestion. The secretions of the respiratory tract become more notable in character; thick and tenacious sputum is liquified, excessive expectoration is restrained, and cough is allayed.

"The amelioration of the cough allows the sufferer to obtain more sleep. The stomach likewise gains in tone under the use of medicinal doses of this drug. I have employed

it in the bronchitis of children as well as of adults. I have, in some cases of chronic bronchitis, found it fully as efficacious as iodid of potassium, and it is usually better borne, and can be used for a longer period continuously than the iodid. Cocillana should, therefore, be esteemed a very welcome addition to our therapeutic resources. In the doses which I have named, it is totally free from nauseating or depressing effect. In beginning my clinical experiments, I gave the drug alone. When I became acquainted with its properties, I combined it with some syrup for the purpose of increasing its palatability, assisting its action, or fulfilling other indications of the case."

THE SINGLE HYPOPHOSPHITES IN DEFECTIVE NUTRITION OF BONE AND NERVE TISSUES.

BY LEWIS G. PEDIGO, A.M., M.D.

CROCKETT SPRINGS SANITARIUM, VIRGINIA.

Of all the varied uses of the hypophosphites, none are more interesting to me than their employment to meet certain faults of nutrition in the osseous and nervous systems. I group these two departments of the human organism roughly together here, because my attention was directed to them in this connection, by certain rational considerations. In the chemic constitution, the growth and the maintenance of both, phosphorus plays a very important part. So it was inferred, that in certain pathologic conditions of either, especially when characterized by defective nutrition, the use of phosphorus in some convenient and easily assimilable form, is the primary and essential indication of treatment. The various clinical trials of this opinion in practice for several years, have amply justified and sustained the inference. My readers are probably familiar with the use of these remedies in cases of delayed teething in children. Aside from this familiar use, my cases have embraced instances of defective bone development in children, and a certain low type of sub-acute and chronic inflammation, occurring in the bony and periosteal tissues of scrofulous or badly nourished patients, as the result of a blow or injury. It must be borne in mind, in these cases, that the predisposing cause is the state of defective or perverted nutrition. The same traumatism which in such a constitution would cause a troublesome, tedious and prolonged inflammation, would produce very slight local effect in a vigorous healthy subject. The course of such a case under the usual treatment is very unsatisfactory. The periostitis shows little tendency to recover, and the bony tissues, so dependent on the healthy action of the periosteum, manifest a tendency to disintegrate. As a result we have a case of hip-joint disease, or Pott's disease, or some other orthopedic affection, with the prospect of a *long special* treatment, and an endless array of plaster jackets, splints, etc. Recognizing and appreciating all the good to humanity and to science that has been accomplished by the modern orthopedic surgeon, (and it is much), it is plainly the duty and province of the general practitioner, to arrest the progress of these cases in the earlier stage if possible. In my own experience, the hypophosphites offer the best means of relief in this incipient period and, in some cases, almost the only hope of resolution of the inflammatory process. If I might be pardoned the presumption of making a suggestion to a specialist in his own field, I would say to the orthopedic surgeon, that he could not do a better thing, even after this ugly inflammation has reached that stage in which

¹ H. H. Rusby, M.D., in the Therapeutic Gazette, August, 1888. David D. Stewart M.D., in the Medical News, of August 24, 1889. Reynold W. Wilcox, M.A., M.D., in the New York Medical Journal, Dec. 28, 1889.

² John V. Shoemaker, A.M., M.D., in the Medical Bulletin, February, 1893.

the tissues break down and deformity results, than put his patient on hypophosphite of lime, as adjunct to his special surgical measures. Judging by its effects in other fields, and in the first stages of the class of cases under consideration, it would impart more vitality to a failing system, furnish some much needed elements to the organism, and promote healthier action and a *tendency to repair* in the affected tissues. For obvious reasons, the hypophosphite of lime is the particular salt to be used in all injuries and inflammations of bone and periosteum. With no intention of entering into elaborate review, I recall one case sufficiently typical to exemplify my meaning. A girl 13 years of age was thrown from a horse, falling on the side, so that the left thigh struck the apex of an angular rock. Some lameness resulted—obviously associated with an injury to the femur, near the great trochanter. A slight depression in the bone could be felt at this point. Inflammation, swelling, redness followed, with considerable deep-seated tenderness and pain on walking. This condition was temporarily improved by counter-irritation—use of iodids, and various other measures. But there was a constant tendency to relapse, especially in damp depressing weather, with east winds.

The case was becoming chronic, the general health failing, the affected parts threatening a chronic abscess, with more or less disastrous effects upon the integrity of the bone and the future usefulness of the limb. The parents were justly and reasonably alarmed, because one bad case of hip-joint disease had occurred in the family as a result of a similar injury. A scrofulous taint was suspected.

The patient was directed to take a teaspoonful of Gardner's syrup of hypophosphite of lime, three times a day, with no other treatment except rest, suitable diet and hygienic precautions. Improvement began with surprising promptness, considering the peculiar nature of the tissues affected and the usually slow processes which characterize them. The most striking feature was the *control of the pain* which the remedy seemed to exercise. Of course this was not a *direct* anodyne influence, but was effected through a modification of the inflammatory processes. The case went on pretty steadily to a good recovery. It is significant that the patient observed the pronounced change in the case as coincident with the change of treatment, and expressed herself as feeling safe so long as she was taking this remedy.

As to the other class of cases alluded to above, I shall present the essential history of only one, which is sufficiently typical of a large number, to answer the purpose of illustration:

A child, male, age 6 months, was suffering with diarrhea and indigestion, associated with difficult and delayed dentition. The gums were red and swollen; teeth were developing slowly which should have appeared about the seventh month. The anterior fontanelle was very large, relatively larger even than it should have been at birth, showing retarded and defective development of the parietal and frontal bones, and indicating a general faulty nutrition, especially of osseous tissue, both in fetal and infantile periods of life. The general appearance of the child was extremely bad. It was ill-nourished, emaciated, pale, feeble and irritable, with loose, easily wrinkled skin, and a bad complexion. A treatment was adopted for the temporary relief of the dental irritation and diarrhea, and a prolonged course of syrup of hypophosphite of lime was directed, with no other medicinal treatment. I did not see the patient again for six months; (the family lived some distance away). At the end of that time, the mother brought the child to me, not for any professional service (which was obviously not needed) but for *exhibition*. The improvement was

beyond all anticipation. The fontanelle was almost entirely closed; the teething process had gone on without irritation of any consequence and had progressed much more rapidly, and the general condition was so much better, that no one could have identified the child. It was plump, well nourished, of good, clear, rosy complexion, and evidently felt comfortable and in a good humor with the world—a symptom of great significance in these cases.

I have spoken of this case as a *typical* one—meaning that it represents a *class* of cases which in my experience have been conspicuously benefited by the use of the hypophosphite of lime. I must say, however, that the *brilliant results* of treatment in this instance, must not be expected in every case. It is *somewhat* above the average in this respect, and therefore not strictly typical in this sense. But its history exemplifies and illustrates principles of treatment that will hold good in all of the class of cases to which it belongs.

Under the second division of my subject, viz: the use of the hypophosphites as nerve nutrients, it is my purpose to confine myself to one case, a specific gummatous tumor of the brain:

The patient a bright mulatto, age 26, stout and generally healthy in appearance, gave a distinct history of syphilis. At the time he came under my observation he was troubled with aphasia, with partial paralysis on the right side, walked imperfectly, scraping the floor lightly with the sole of the right shoe. He could be sent to take a note (not a verbal message), could go to any portion of the town, and find his way without difficulty, but could not remember the names of the streets. He was sent after the cows on the commons, and would get the right ones, but could not tell their names, and if he attempted to throw a stone at one of them, it dropped within two or three paces of his feet. The left hand and arm were much stronger than the right; he was obstinately constipated.

The case was vigorously treated with large doses of iodid of potassium, and small doses of mercury biniodid, with some attention to the digestion and state of the bowels. The iodid was given in increasing quantities until a dose of 60 grains three times a day was reached. This was continued for periods of about a week or ten days, alternating with short periods of suspension of the remedy. The effect was good and improvement began and continued for months. The paresis was better, the mind was clearer and more vigorous, the strength and power of endurance increased and the aphasic symptoms yielded perceptibly. After some months of this treatment, the case seemed to come to a standstill; the improvement reached a limit. Now it was considered safe to begin a *restorative* treatment—on the theory that the iodid had done its work of liquefaction and absorption of the tumor faithfully and well. The patient was placed on a small dose of tincture of nux vomica, (10 drops) thrice daily before meals and the effect carefully watched. It produced some irritation of the brain—cerebral hyperemia and evident aggravation of all the symptoms. It was withdrawn promptly and the former treatment resumed for another month, with a few doses of bromid of sodium at first, to control the untoward effect of the nux vomica. After a month the nux vomica was again cautiously tried, and this time with good effect. The symptoms—mental and physical—all improved somewhat, and no irritation supervened. After a few days another measure was added to the treatment, viz: the use of a teaspoonful of syrup of hypophosphite of lime, thrice daily, *after* eating. The effect of this step was perceptible in the decided improvement of all the symptoms. I continued the use of the hypophosphites in this case for several months, watched the effects carefully and with intense interest. I had dispensed from my office only two ounces of the syrup of the lime salt in the first place, so it was soon exhausted. When the patient returned I found I had no more of that preparation, but had a remnant of syrup of hypophosphite of manganese. I substituted this and found, to my surprise, that it seemed to act much more favorably than even the hypophosphite of lime. When this remnant was exhausted, I returned to the use of the lime, however, and the patient *noticed the difference* in his condition. He insisted that I give him the "same medicine he got the other time," which I did, and with the same result. His neighbors and friends remarked upon the mental improvement. The family reported that he could begin

to work better, remember messages more accurately, and the patient said he could "learn and recite his Sunday-school lesson better." I had ample opportunity to watch this case closely, and to differentiate the effects of the various remedies used at different times, and my conclusion is that the single hypophosphites were decidedly efficacious in the latter stages of this case.

The theory which led me to their use may be stated as follows:

In cases of gummata of long standing, the contiguous parts of the brain are subjected to constant pressure, interfering seriously, not only with their functional activity, but with the nutrition of the cells and fibers which enter into their structure. After the gummata have been partially or fully absorbed under the influence of the heroic doses of iodid of potassium—so that the brain tissue has the opportunity to expand again to something like its normal size and shape—these compressed, starved and dwarfed fibers and cells need some restorative remedy, some special nerve *nutrient*, to assist in this development. Nothing so naturally suggests itself to the medical mind for this purpose, as phosphorus in some available form.

As the single hypophosphites are my favorite preparation of phosphorus for almost all its uses, I prescribed them in this case, with the results recorded above. I have reason to believe the effects can be duplicated in other similar cases. In an old case, as this was, even when it first came to me, the physician must not expect too much of any remedy. Parts of the brain structure have been absorbed under the long-continued pressure. Other parts, even though remaining, have been so damaged, that their integrity can not, probably, be fully restored, or their functions rendered strictly normal.

In conclusion, let me warn my reader who feels sufficient interest to test the matter, not to begin the restorative treatment too early in the development of the case.

THE PHYSICIAN AND THE PHARMACIST.

A Volunteer Paper read in the Section on Materia Medica and Pharmacy at the Forty-fourth Annual Meeting of the American Medical Association.

BY L. CH. BOISLINIERE, M.D.
ST. LOUIS, MO.

A few words of protest and advice are herein offered from an old practitioner. I believe in the profession of pharmacy and I highly respect the pharmacists. They are the hand-maids of the physicians and our best friends, often our useful advisers. The two professions should work in harmony, one not encroaching upon the specialty of the other. Therefore the pharmacist should not tolerate any counter-prescribing, and the physician should not dispense his own medicines. I therefore most strongly protest against the custom, lately too frequently resorted to by physicians, of distributing among their patients any of the potent tritirates, or dosimetric granules, so elegantly put upon the market by otherwise reliable wholesale dealers. This practice is enticing, but it is often dangerous.

This protest applies chiefly to the city physicians; an exception should be made in favor of the country practitioners. For them it may be sometimes absolutely necessary and is often very convenient; they are so placed that they can not do otherwise; but it is a practice fraught with danger.

This practice, in cities especially, may be followed by suits for malpractice in case of any accident. The prescriptions on file with the pharmacist are a strong protection to the physician, as they can be referred to, and, if necessary, brought into court in case of a suit for damages. While serving as Coroner of St. Louis County, several cases of this kind came under my official notice for investigation. One was the case of a woman, for whom a most reputable physician had prescribed a mild cough mixture. The husband, at the inquest, stated that his wife walked in the garden, after taking a teaspoonful of the medicine, and dropped dead, as if shot. Happily, the bottle of medicine was in the house, properly numbered, and came from a very good pharmacist. The prescription from the file was brought to the house of the deceased and shown to the jury to be a harmless mixture. This, however, did not entirely satisfy the husband. In order to convince him, I opened the deceased's chest and showed him the heart; the pericardium was enormously distended; puncturing it, I received in a cup nearly a pint of serum. The woman had died of acute pericarditis. This amount of serum, pressing on the heart, had caused its sudden stoppage and the patient's death. The husband was satisfied and the physician discharged.

Upon another occasion, an old man had had a weak solution of morphia prescribed for nervousness. The next day I called at the house and found the front parlor full of people and crape at the door. On my inquiring about the patient his sister rushed in, in a fury, and exclaimed to me: "You dare inquire about my brother! You killed him! He walked to the mantelpiece, took a teaspoonful of your infernal mixture and dropped dead!" He died of paralysis of the heart, as was afterwards ascertained. The pharmacist, an excellent one, was requested to come immediately with the prescription, which he had on file, and which called for one grain of sulphate of morphia, of which the patient had taken one teaspoonful, equivalent to one-eighth of a grain, which certainly is not a poisonous dose. The family was finally satisfied that the fatal result was not connected with the medicine.

From these cases is seen the great advantage of filing, dating and numbering prescriptions.

In another instance, there was prescribed for a young woman a one-eighth grain dose of morphia; but, through the accidental misplacement of the bottles, she took one teaspoonful of strong sulphuric acid, and would have died had it not been for copious draughts of water, mixed with plaster scraped from the walls of the room. For several months, she could swallow nothing but milk, as she had an extensive inflammatory stricture of the esophagus.

Here the pharmacist was called in to show that the prescribed mixture was a weak solution of morphia and not sulphuric acid, which it was subsequently learned had been left carelessly in the room to acidulate a battery. I could relate more cases, but these are sufficient to illustrate my position, that often the pharmacist is the best protector of the physician.

Another point to be considered is this: Quite a reprehensible custom is that of pharmacists, on demand of patients or their friends, repeating prescriptions without the order of the physician. This is done generally because it would be impolite to refuse; moreover, they have nothing to gain by it. This indefinite refilling of prescriptions should not be

done, because it makes the patient his own prescriber, often to his own detriment, as no two patients or diseases are alike. It is a dangerous practice, and should be abolished by a mutual agreement with the pharmacists. This practice is often resorted to by designing persons for mercenary purposes. I will briefly recite a case to illustrate:

I once prescribed a mild but efficient cough mixture. What was my amazement when I ascertained that the formula had been printed and sold to many acquaintances for twenty-five cents a copy. Let, then, physicians and pharmacists live in perfect harmony, following their useful and noble professions, each respecting and protecting the other.

RETRO-PHARYNGEAL ABSCESS—WITH REPORT OF CASE.

BY REVERE H. HERROLD, M.D.

CHICAGO, ILL.

Miss T; age, 22; native of Sweden; occupation, clerk; left the land of her nativity in August, 1893, in good health as far as can be discovered. August 29 I saw her for the first time, and received a history of previous good health, except that a week before, she was seized with choking and pharyngeal spasms. These symptoms passed away and none appeared again until the day of my visit, when I found the spasms and choking present, with cyanosis, greatly increased during the pharyngeal spasms. Examination of the throat with the finger revealed no pathologic condition, leaving thus a doubt as to what caused the spasms and choking. Anti-spasmodics were administered, which only partially relieved. The patient having stated that no passage from the bowels had occurred for several days, a cathartic was prescribed and the patient left for a time. In less than an hour I was again called, and found that the cathartic, which was a powder, was being expelled from the mouth by what at first appeared to be mucus but later was found to be pus. The attempt to swallow the powder caused the rupture of abscess, which was located very low. The patient became unconscious and remained so to the time of her death. Continuous symptoms were manifest here for about thirty-five hours. The symptoms a week previous were of such short duration that no physician was called.

There is a feature of this case which deserves mentioning. The deceased left her native land to meet and marry her lover. Having no means of her own, the lover paid for her physician and saw that she received a respectable burying.

In making a brief review of this subject it may be said that a retro-pharyngeal abscess is the result of a suppurating cellulitis in the areolar tissue between the pharynx and the vertebræ, and frequently not in the median line. It is primary or secondary according to its previous pathologic state. The cause, if primary, is atmospheric or due to some irritating substance lodged in the pharynx. The secondary form may occur after measles and scarlet fever. The inflammation of the pharynx common in those diseases extends to the subjacent connective tissue and becomes suppurative. Caries of the cervical vertebræ is, however, the most frequent cause of the secondary form. When it originates in this manner it is similar to a lumbar abscess except that its proximity to the air passages renders the symptoms more urgent and dangerous. Erysipelas, syphilis, inflammation of the inferior maxilla, cerebritis and scrofula have been followed by a retro-pharyngeal abscess. Small lymphatic glands which lie in the connective tissue external to the pharynx, are undoubtedly the original seat of suppuration in a majority of cases. Often the abscess may be seen or fluctuation felt by

the finger, but when, as in the case reported, the abscess is low, it can not be positively diagnosed. It may be said, however, that when it is due to caries it is preceded by deep-seated pain, greatly increased by movements of the head. The symptoms usually described are those of restlessness, mouth dry and hot, deglutition more or less difficult, the tongue furred. After suppuration there may be alternations of rigors and fever. The tissues chiefly involved are the submucous, and the degree of redness of the mucous surface is less than where the mucous membrane is chiefly involved. Chilliness and convulsions occasionally occur, but embarrassment of respiration is the chief cause of danger, frequently beginning early, and becoming more and more prominent as the abscess increases. Dysphagia is present, and is sometimes so great that solid foods are refused, and drinks taken with difficulty.

The disease may be mistaken for protracted laryngitis owing to the resemblance in the respiratory symptoms; the voice is feeble or indistinct from the pressure of the tumor, and the respiration sometimes whistling and impeded. Dyspnea increases as the abscess enlarges, and imperfect oxygenation of the blood follows unless the abscess is opened or it ruptures spontaneously. Paroxysms of dyspnea may occur so as to threaten suffocation. The pulse is frequent and rapid, the head is thrown back, the tongue protruded, and the patient is forced to remain in a semi-erect posture. The limbs become cool, livid. Finally death results from dyspnea. Even if the abscess rupture, life may not be saved in all cases, as the case herewith submitted illustrates. If the trachea and bronchial tubes are deluged by the purulent discharge, suffocation follows. Another example of this is found in the records of the Bellevue Hospital. In May, 1871, a boy, age two and a half years, having symptoms of an abscess for three months, was brought before the Hospital class. The patient's head was carried sidewise, and rotation of the head caused pain. A laryngeal râle accompanied respiration. In this case the upper part of the tumor could be detected by the finger, but its location was so low that it could not be opened with a bistoury. Dyspnea came on and death being imminent, the class physician, Dr. Swezey, broke the abscess with his finger and pus was ejected, but death occurred almost immediately. Most of the cases reported are of infants and children. The case submitted by me occurred in a lady 22 years old. It can not be precisely ascertained when an abscess begins to form, nor can its duration be foretold. The duration will depend upon the rapidity of growth, and the direction in which it points; a lateral or downward extension not being so immediately dangerous to life as an anterior.

We should not lose sight of the fact that the thickness and the density of the wall of the abscess varies greatly. Thus Dr. W. C. Worthington reported a case in 1842 in the *Provincial Medical and Surgical Journal*, in which the case occurred from exposure to cold. The patient was a child and was treated for croup. It died from suffocation. In this case the anterior wall of the abscess was very thin. On the other hand, Dr. E. O. Hocken relates a case in the same journal and the same year, where the abscess seems to have been present from birth, the infant dying at the age of 9 weeks. It had always thrown back its head as if suffocating when taking the breast

The walls of the abscess were thick, firm, almost cartilaginous.

The treatment of retro-pharyngeal abscess needs no comment. It must be opened early. Where it has ruptured spontaneously speedy recovery has followed by the use of codliver oil and the syrup of the iodid of iron. Spontaneous ruptures, however, do not always mean a speedy recovery.

253 E. Ohio Street.

OBLITERATION OF CONGENITAL PIGMENTATIONS.

Read in the Section on Dermatology and Syphilography at the Forty-fourth Annual Meeting of the American Medical Association.

BY B. MERRILL RICKETTS, PH.D., M.D.
CINCINNATI, OHIO.

Abnormal pigmentations of the human skin have always existed and are always more or less objectionable, especially where they occur upon the exposed parts of the body. I say always objectionable, meaning the congenital ones, and I might say the artificial ones sooner or later are objectionable.

In order that we may be able to more thoroughly understand the character of the various pigmentations, I have made the following classification, which I have found to be very convenient, and which I believe answers ordinary purposes. It is as follows:

1. Elevated pigmented surfaces.
2. Non-elevated pigmented surfaces.
3. Red, elevated or non-elevated, pigmented surfaces.
4. Brown, elevated or non-elevated, pigmented surfaces.

In the elevated pigmentations, I have found obliteration much easier than in any of the other three I have mentioned. Those that are non-elevated and have a brown color, are the hardest to obliterate, and require a greater length of time for treatment, and the results are not so good.

On the other hand, the red ones, elevated or non-elevated, are removed with greater ease, especially if elevated. I believe that this classification answers every purpose in the treatment of congenital pigmentations. As to the acquired ones, I do not care at present to have anything to say. When we consider how little progress has been made in the successful treatment of these lesions, and the great number of persons possessing them together with the demands which association brings, we can not help but look with regret upon the present status of treatment. It is with horror that I look upon these deformities, and with great chagrin that we stand handicapped in giving relief to those who so often approach us with so many regrets. I believe it is the duty of every person to rid himself, so far as possible, of every characteristic that may be objectionable to his associates—warts, moles, cicatrices, tumors of various kinds, superfluous hairs, deformed nails, fingers, ears, lips, eye-lids and nose, are all of equal importance. The dentist prides himself in giving to his patient a set of teeth that is not only useful, but possessed of great beauty; the barber becomes noted in applying his artistic skill to the hair of both the head and face. With all these standing out in bold relief, we must admit our shortcomings. Possibly the remedy lies in the extirpation of these pigmentations, followed by skin-graft-

ing, as suggested by Thiersch. It may be that it is something less severe, but who is to present it? I firmly believe that where the pigmentations are large and can not be excised, and the edges brought together without deformity, that the Thiersch method offers the best results. Surely the grafts, together with the attending cicatrices, would be less objectionable than the discolored or elevated surfaces, and I am thoroughly convinced that I, myself, would resort to them, taking my chances, in preference to carrying one of these birth-marks.

If the lesion is supplied with a great amount of blood, there is but little difficulty in destroying the vessels with electrolysis. This is the treatment which I offer as the best means, so far discovered, in destroying the elevated or non-elevated red pigmentations, also where the elevations are brown, unless it be by the Thiersch method. But, where the surface is brown, so far I have been unable to lessen the deformity to any great degree by electrolysis. Thinking, perhaps, that I might be able to obliterate this discoloration, I selected a few upon myself and various patients for experiment. I decided to use finely powdered feldspar and flint. These are ground for fifty hours and used extensively in the manufacture of fine pottery. I selected needles as fine as could be had, and with great care tattooed several lesions as carefully as I could, some with flint and some with feldspar. The result was an inflammatory process, which destroyed not only the color, but also the epithelium and part of the papillary layers. In each case there was a fine white cicatrix remaining, which was smooth and a little lighter than the surrounding skin. I am not sure that either the feldspar or flint was the least beneficial. I make the statement to show what *could not* be done with them. Where the lesions are small I have had better results with electrolysis and excision than by any other procedure. If excision is to be resorted to, it should be with the greatest care, the sharpest knife, and aseptically. I have not found it necessary to use but the lightest sutures, silk-worm gut being the best; often these are not used unless there is great tension to be overcome, usually having found rubber adhesive straps sufficient to keep the walls of the wound together until primary union could take place.

I have tattooed with all remedies so far suggested, and I am free to confess that not one of them is satisfactory in my hands. Possibly the fault lies within myself, more perhaps in the application than in the prolonged treatment, for I have been faithful in their application.

There is one procedure that I value above all others in cases where any congenital pigmentation, whether elevated or non-elevated, red or brown, involves any great amount of surface. It is in the use of Thiersch's skin grafts. The great trouble is in overcoming the fear of both the operator and the patient that the grafts are not always certain. This is a very great desideratum, but one which must not be overlooked. If the operator is fearless, clean and skilful, there is no reasonable doubt but that the skin will become adherent and that the surface will become smooth and lose the objectionable deformity. Even though the grafts should not become adherent, the resulting cicatrix is far less objectionable than the condition for which the operation was made. My own experience has taught me that these lesions

when found upon the face or hands, can be removed and without any risk, unless it is in taking the anesthetic, especially where chloroform or ether is used. I do not believe that grafting is so successful when done upon surfaces which have been anesthetized by subcutaneous injections of cocain. It seems to me that the capillary supply upon which we must necessarily depend for nourishment to the graft is greatly lessened by the influence of cocain. It lessens the congestions of mucous surfaces, and why not the normal capillary blood supply to the papillæ? I would not, therefore, hesitate to use either chloroform or ether where the lesion is extensive, in preference to the subcutaneous injection of cocain. Then, too, the amount of cocain requisite to produce local anesthesia, would in all probability cause constitutional disturbance of an unpleasant character. I have now used cocain subcutaneously almost one thousand times, and with but two or three exceptions have never had any unpleasant results from it. So that, so far as the use of this remedy is concerned, I, myself, would not hesitate to use it even in the larger lesions. Then, so far as the administration of chloroform and ether are concerned, fortunately it is not necessary to prolong their administration, as the operation requires but a very short time if detail is looked after in the beginning. In removing the objectionable tissue, hemorrhage is sometimes to be encountered, especially in the red ones where there is a great amount of blood supply. This, however, can be overcome with the application of hot water containing chlorid of sodium in the proportion of one-half of 1 per cent. If this should not control the hemorrhage, and if found impossible to apply the grafts with certainty, the surface may be allowed to granulate and grafted upon later on.

The knife to be used should be the sharpest, and the tissue removed with one bold stroke. The skin to be substituted should be from the thigh or arm, which has previously been cleansed and made ready for the operation. The shavings should be as thin as it is possible to make them, there being but little capillary hemorrhage. If the surface is two, three or four inches square, the grafts should be as few in number as it is possible to cut them. If three or more inches square is required, it is best to remove the cuticle from the abdomen where the surface is flat, and the knife allowed to make one broad cut. If it is found necessary to wait several days before applying the graft, the granulated surface may be mowed down with a curette, the hemorrhage checked and the grafts then applied; however, I have made it a rule to apply my grafts at the time of the primary operation, thus giving me two opportunities to secure their growth. Any surface upon which grafts should fail to become attached at the primary operation, can be covered at the second sitting.

So far as the dressings are concerned, they should be simple but firm. I have found nothing better than as fine quality of cheese or tobacco cloth as I could procure, which enables the secretion to become absorbed, leaving the grafts as free as possible from other influences.

So far as the use of these grafts goes, I have nothing in the way of improvement to offer on the Thiersch method. He has described in detail the conditions, operations and care of them, so I feel that it would be useless to speak further upon this, the most ingenious and useful plan of skin grafting.

In conclusion, I will say that I believe this is the only available means we have of obliterating these birth-marks, unless it be electrolysis, on which I do not place so much value.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

SECTION ON ORTHOPEDIC SURGERY.

(Continued from page 67).

DR. WHARTON SINKLER read a paper entitled

THE TREATMENT OF SPASMODIC TORTICOLLIS BY CONIUM.

The treatment of spasmodic torticollis is most unsatisfactory. The pathology of the affection is so obscure, that rational treatment is all the more difficult of application. Dana, speaking of wry neck says: "In rare cases is it cured, in many others it can be ameliorated, but it generally reaches a certain stage, and then remains chronic." Drugs of all kinds have been recommended in the treatment of this affection, and splints and mechanical appliances are of no benefit, but usually aggravate the affection. From the fact that frequently the muscles principally involved are the sterno-mastoid and the trapezius, the affection has been supposed to be due to disease of the spinal accessory nerve, and treatment has been directed to this nerve.

Counter irritation, galvanism and actual cautery, applied as near as possible to the origin of the nerve have been used, but with far from satisfactory results. Surgical measures, such as stretching this nerve, and the excision of a large portion of it have been resorted to but in only a small proportion of cases has relief followed the operation. It is, therefore, evident that the disease, except in rare cases, involves the deeper muscles of the neck, as well as the sterno-mastoid and trapezius.

LEZYNSKI recommends the use of belladonna, given in increasing doses almost to the point of toxic influence, and keeps this up for four or five weeks. He has had marked success from this method, and Grey says that since he has followed Lezynski's plan, he has cured eight cases of spasmodic torticollis by the use of belladonna. I have used this remedy myself, but without success. The best results which I have seen from drugs in this disease, have been from the use of conium. This drug was recommended by Harley many years ago in the treatment of spasmodic affections, but it never has been used extensively. G. M. Hammond reports the successful treatment of a case of painless facial spasm by the use of this drug, and Rockwell of New York, recommended it in the treatment of chorea. The text-books, however, do not speak of it favorably. Hare, in his work on "Therapeutics," remarks: "That conium holds an unimportant place in the drug list of to-day." I have found in my own experience, however, that it is decidedly useful in many forms of muscular spasm, when not due to central causes.

From experiment, it has been found that conium causes paralysis of the motor nerves when given in physiologic doses. There are drooping of the eyelids, staggering and inability to walk, showing its influence upon the muscular system. It is, therefore, reasonable to expect that in the treatment of muscular spasms, when peripheral in origin, that the remedy would prove useful.

HARLEY recommended the juice of fresh leaves, but this is difficult to obtain, and the fluid extract is a reliable preparation. The dose in which it is recommended in the text-books is entirely too small to be efficacious. I usually begin with 15 or 20 drops, three times a day, and frequently increase the dose to 60 drops. There are two fluid extracts in

the market: one of the leaves, and the other of the seeds. I usually give the latter. I have seen several cases of spasmodic torticollis which were relieved by this remedy; and two or three cases of painless facial spasm which were distinctly benefited by its use, in one of which the spasm entirely ceased. I will relate two cases to illustrate the successful employment of conium in spasmodic wry neck:

Case 1.—Mary C., age 26, a shirt maker by occupation. Her general health has always been good, and there is no history of special interest in connection with her present trouble.

She applied for treatment at the Infirmary for Nervous Diseases, Dec. 12, 1887. She stated that two weeks previously there began a sense of trembling in the neck, and a heavy feeling in her head. At the same time the head began turning continually to the left side. On examination the head is found to be rotated strongly to the left shoulder. It can be turned to the front but can be held there but a few moments, when it is again rotated to the left. If the head be held by force in a straight position there are felt strong spasmodic contractions of the sterno-mastoid and trapezius muscles. She can not turn her head as far to the right as to the left. There is no pain or tenderness over the vertebrae, soreness in the sterno-mastoid muscle or sensitiveness over the point of emergence of the spinal accessory nerve.

A blister was applied over the point of origin of the spinal accessory nerve, and galvanism was used quite faithfully for four months; codliver oil was administered, and the patient was advised rest. But little change took place during this time, except that there were two brief periods of improvement, once after the treatment had been changed to the iodid of potassium. At this time the sterno-mastoid and trapezius had become more rigid, and the head after being voluntarily rotated to the front would be drawn to the left within a few seconds, by the spasm of the muscles.

The patient was now ordered the fluid extract of conium in ascending doses, beginning with 5 drops, three times a day; and the maximum dose was 20 drops three times a day. This treatment was pursued for twenty days, when the improvement was so great that the head could be held straight for several minutes. The conium was continued until the patient was well, and when seen a few months later, the patient said she was entirely relieved of her trouble. A year later there was a slight return of the spasm for a few days, but this again yielded, in a short time, to conium.

Case 2.—Miss G. M., age 44 years, was admitted to the Infirmary for Nervous Diseases August 28, 1893. Family history unimportant. She has always been well until four years ago. In November, 1888, while at work she became dizzy and fell, remaining unconscious for a few moments. It was found afterwards that her shoulder had been dislocated by the fall. The dislocation was reduced by a physician within a short time, but there was partial loss of sensation in the arm, and this has continued ever since. The head was turned towards the left, immediately after the fall. The left ear almost touched the shoulder, and the head was so much rotated that the chin reached the point of the shoulder. The head remained in this position for two or three days, when it gradually came back to the normal condition. After the first fall she had dizzy attacks every two or three weeks. She did not become unconscious, but for a few moments she could not see and would then fall. The head would assume the position above described after each attack, and would remain turned to the left for a few days, and would then regain the proper position. While the head was drawn to the left shoulder, she could place it in other positions with her hands, but it would immediately return to position of rotation to the left from the spasm of the muscles. After a time the attacks of vertigo became as frequent as two in a week.

In February 1893, she had a severe attack, in which she did not fall, but saved herself by sitting down in a chair. She was not unconscious, and could talk, but became rigid for half an hour. The head was drawn down until it reached the left shoulder. After this attack she was in bed for six weeks, and during this time she states that the whole left side was somewhat contracted. She had had no falling attack since February, 1893. On admission the patient was found to be a well nourished muscular woman; digestion normal; heart and lungs healthy; and the urine free from disease. There is no paralysis of motion, and sensation is normal, except in the right arm and shoulder, where it is delayed and diminished to tactile and thermal sense. The

knee jerks are normal on both sides. The elbow jerk is exaggerated on the right side, but normal on the left. When sitting up the head is drawn to the left and rotated so that the chin is turned towards the shoulder. All the muscles which turn the head towards the left seem to be involved, but especially the right sterno-mastoid and left trapezius. She can turn her head to a normal position, but can not hold it there for more than a few seconds, when it is again rotated violently to the left. When she is lying down, the head becomes almost straight, and the spasm of the muscles does not occur. There has been, at times, a sharp pain in the left side of the neck in the trapezius muscle, but it is now a dull and dragging sensation. The facial muscles have never been affected. If the patient places her right hand on the side of her head, so as to rest the head upon it, the head will turn to an erect position. The patient was ordered rest in bed, with general massage, faradism to the neck muscles, and the fluid extract of conium, 20 drops, three times a day to be increased. On September 7, that is nine days after the patient had begun, she was taking 30 drops of the fluid extract of conium, three times a day and it was noted that the head was decidedly better, that she could hold it straighter, and that when sitting up it did not so frequently rotate to the left. On September 14, the patient was still improving. She could hold her head perfectly straight, without support, for a few minutes. She has less of the dull feeling and dragging sensation in the left side of the neck. The improvement continued, and on October 5 the patient was able to hold her head absolutely straight, without any pain whatever. She was discharged from the Hospital, October 16, entirely relieved of the spasm of the neck muscles, and seemed to be in perfect health otherwise.

Some of the attacks from which this patient suffered were undoubtedly hysterical, and it is probable that the spasm of the neck muscles was also of hysterical origin. The trouble had lasted for over four years, and was not relieved until she was placed under treatment by the use of conium.

Dr. H. Augustus Wilson exhibited a patient, age 5 years. Two years and four months ago, patient is said to have had quinsy. Mother says the child suffered continuously for four months, which appears to cast a doubt upon the correctness of the above diagnosis.

The following history was obtained from the mother: At the very beginning of her complaining of sore throat, her neck was stiff so that she could not move it in any direction. There was decided pain throughout the chest and arms. Her sleep was disturbed. Upon rising in the morning it was necessary for the patient to support both sides of head with her hands on account of severe pain. This condition lasted for four months. Four months after she first noticed the crooked head the patient came under observation at the Jefferson Hospital.

The diagnosis of caries of upper cervical vertebrae was arrived at four months after the first appearance of wry neck, by the pressure of most marked muscular rigidity around the neck. The muscles in the upright position were tense, and yielded only upon the patient being placed in a recumbent position or when the head was well supported by the surgeon. The sterno-cleido muscles were in a state of relaxation when the patient was recumbent.

A brace was applied which not only supported the head, but maintained immobility and afforded protection, which she wore continuously until one month ago, when it was removed. During the last two months of the use of the brace, it was modified so as to permit beginning motion of the head, but restrained the tendency of the head to turn to right side.

At this time the following observations were made: Head turned to right side one and one-half inches from symphysis of lower jaw to line of mid-sternum. Flexion and extension now easily performed, rotation of head easily to the right side, but motion to left impaired by right sterno-cleido-mastoid. When the head was so turned without effort on the patient's part, there was but slight over-action of right sterno-cleido-mastoid. When the head is thrown backward both sterno-cleido-mastoids appear alike, and the same obtains when the head is bent forward on to chest. Left shoulder carried a little higher than right. There is a slight lateral curvature, principally noticeable in dorsal region.

No movements are apparent in second, third, fourth and fifth cervical vertebrae, which are less prominent than normal, while the sixth, seventh, and dorsal vertebrae move freely. The brace was adjusted towards the last so as to allow a little freedom of movement before it was taken off—about three months' time was permitted from the time it was rigid to its removal.

Since the discontinuance of the brace, light gymnastic movements have been permitted in order to develop the muscles that had become atrophied from disuse while the brace was rigidly applied. Since the head apparatus was made movable, the patient has noticed a crepitus which was only of periodical occurrence and is now very much less marked than formerly, and appeared to be of the nature of fibrous adhesions.

DISCUSSION.

DR. J. K. MITCHELL—I have very little to say this evening, but should like to report two cases of spasmodic torticollis which present features somewhat different in character from the condition as it usually appears in children, although they were both in young people. My experience has been that this condition is more common in adults, and in them it is exceedingly obstinate to treatment. In children the fixed form is more common, and either form is much more amenable to all remedies. Operation is more likely to be effectual in children than in grown persons, and this is true likewise as to treatment by mechanical measures. Apparatus alone will sometimes effect a cure, as is well illustrated by the interesting case just shown by Dr. Wilson.

My two cases were both in young people; one a man, about 20, whom I saw in St. Mary's Hospital. He had refused operation and come into the medical ward for treatment. He had been handled in all sorts of ways, with drugs and various mechanical measures, without much benefit; nor at first, can I say that he improved at all, notwithstanding everything that we could do for him, until finally I gave very large doses of gelsemium, with decided improvement—which, however, was not permanent until ice was applied. I did not try conium, which Dr. Sinkler found so effectual in some of these cases; but an ice-bag was kept upon the neck day and night, extending from the anterior border of the sterno-cleido-mastoid muscle back to the cervical spine, as low down as the origin of the nerve supplying the affected muscles. This was constantly worn, as I say, and by it the man was much relieved, the pain and spasm both diminishing very much.

The second case was in a young girl and was undoubtedly of an hysterical character, a number of symptoms pointing, as you will presently see, in that direction. She came of a nervous family, and had persistently overstudied at school, which she was obliged to leave on account of the occurrence of a violent headache and a general run-down condition, with the exhibition of uncontrollable fits of temper. Her first complaint was of pain on the right side of the nose, which extended into the eye, and for some time at first was limited to this area. It came on in paroxysms, with some twitching of the muscles of the face and, after it had lasted a few weeks, extended through the side of the face and neck as far back as the spine. It presently began to be accompanied by spasmodic movements of the sterno-cleido-mastoid and trapezius muscles, with great pain in both face and neck. These spasms occurred ten or twelve times a day, and every treatment entirely failed to relieve her. Massage, electricity, drugs—nothing had any effect. I put her to bed, and on a milk diet, and for the first two or three weeks she grew better. Then the spasmodic movements began again, and during the succeeding months increased in their extent so that she had many times a day general convulsions, usually opisthotonic. During the attacks, and sometimes between them, she had double strabismus, complete amblyopia, and pupils rigidly fixed in dilatation. At one time in an access of despair I bled her, having seen on one or two occasions bleeding do good in hysterical convulsions. We drew some eighteen or twenty ounces, and for a week she was much better. Then she relapsed again, and finally, when her family was worn out, and two or three nurses had been used up in the service, I took her to the Infirmary for Nervous Diseases, left her there with a strange nurse and under the most rigid rules of isolation, and from that day she had no attack of convulsions, the pain rapidly diminished, and she is now perfectly well.

The case, as I have said, was of course of an hysterical nature, but at least one distinguished physician, who saw it in consultation with me, was of opinion that she had meningitis at the base of the brain and would certainly die.

DR. J. K. YOUNG—The subject of torticollis has been so thoroughly discussed this evening that there remains but the mechanical treatment to be considered. A great many mechanical appliances have been proposed, but most of them are unsatisfactory when applied.

Torticollis is divided into two classes—congenital and acquired. Congenital cases are those which depend upon deficiency of the cervical vertebræ, malformation, uterine pressure, and adhesion between the amnion and the skin of

the face, as suggested by Peterson. The acquired cases may be traumatic, tetanoid, paralytic, compensatory, cicatricial or idiopathic. It is obvious that in paralytic and tetanoid cases no operation is of service. The simplest form of apparatus is that used by Dr. Ashhurst, and as originally suggested by Little. It consists of a piece of adhesive plaster about the head, another one about the upper part of the thorax, and a firm muslin roller bandage from the chest region on the side opposite the chest and front. After the operation the head may be placed in the corrected position by means of plaster-of-paris bandage. The bandage which I prefer in all operations upon the head and neck is the starch bandage which may be strengthened by strips of a wood bandage and strips of aluminium.

Another form of apparatus is the Minerva collar pattern, which may be made of felt, leather, or other material. The apparatus of Barwell, referred to under the title of "a cheap and simple apparatus for the treatment of torticollis and cervical caries," is the butterfly pattern. It may be made of felt, cut in shape and adapted to the head and neck.

Of the more elaborate forms are those on the principle of Jörg. Of this pattern there are several; the best one is that used by Dr. Schaffer of New York. It consists of an apparatus applied to the back from which is erected a head piece, a chin rest, and which is attached by a universal joint which admits of its being placed in position. Sayres' apparatus is made upon the same principle.

Dr. Davis' appliance consists of a broad piece of stiff material fitted to the back, with a peculiar shaped head piece which is attached by means of a screw. Other good examples of this appliance are found in St. Germaine's work, page 239, under the title, *Minerv De Bouvier* and Ernst of London.

Extension of the head is now used both abroad and in this country in the mechanical treatment of this condition. For this purpose, Hilliard's appliance is more elegant than the ordinary extension head piece. The one I exhibit is the apparatus used by Dr. Willard in the treatment of cervical caries. When used for torticollis it must be longer upon one side so as to make more pull upon the affected muscles.

To render the subject more complete, I should perhaps refer to the method of DeLore of the forcible correction of posterior wry neck. The patient is placed under ether on the edge of a bed, and forcible correction of the deformity is then made. In cases where this operation is employed it is necessary to positively exclude cervical caries. I had related to me by a country practitioner a case in which fatal results occurred in attempting to perform this operation.

I have seen many cases of torticollis follow cold, and in such, medical treatment has been effective in a few days. After tenotomy I strongly urge the use of massage and gymnastic exercises.

Finally, I wish to refer to a number of cases of torticollis ocularis, which I have seen in the past two years. These are due to some loss of equilibrium of the ocular muscles, and they are usually corrected by the application of the proper prisms, the superior or inferior rectus being the muscle usually affected.

When torticollis is due to cervical caries, as it sometimes is, manipulation may produce serious results.

I think I can reply to the question of Dr. Wharton in regard to the occurrence of mastoid tumor. There are two varieties of cases; in one there is simple hematoma, in the other, rupture of the fibers of the muscle. In the latter variety of cases torticollis occurs. Previous to Whitman's paper, all statements upon this subject were without foundation, in fact, and were simply the quotations from the writings of Dieffenbach.

DR. H. R. WHARTON—I agree with Dr. Willard in believing that good results follow operation in cases of fixed wry neck. I have had some experience in the treatment of wry neck both in children and in adults, and I have seen marked benefit result from simple division of the sterno-cleido-mastoid muscles. Dr. Dercum mentions asymmetry of the face in connection with this disorder. I saw this well illustrated in a boy recently under my care at the Children's Hospital, in whom there was marked asymmetry of the face and skull. I think the want of success in a good many operations is due to the fact that many of them are left without after treatment by apparatus, gymnastics, muscle stretching, etc. If this is not done a relapse is sure to follow; in my opinion it is as important as the operation itself. I should like to ask whether any of the gentlemen present have ever had any experience

with wry neck following congenital mastoid tumor. These tumors are often due to the rupture of some of the fibers of the mastoid in labor, and we might, therefore, look for wry neck in connection with the accident. A few of the cases I have seen of such tumors have not been followed by the development of wry neck.

DR. BENJ. LEE—I came here this evening expecting to be simply a hearer and to be instructed, and I need hardly say in reference to the latter expectation, I have not been disappointed. Both the papers and the discussions have been of deep interest.

The only point which occurs to me to refer to is Dr. Wilson's case, concerning which I think we may say that we accept his diagnosis without hesitation. It recalls to me a case which I saw early in my practice, some twenty-five years ago. It was a very marked case of wry neck in a child about 4 years of age. On my first examination I pronounced it to depend upon cervical caries. I employed suspension by means of a ratchet apparatus attached to the child's high chair and in a few days marked improvement resulted. Suspension was kept up constantly during the day; she was never allowed to sit up except when the head was supported. In the course of a few weeks I applied a brace with a head support. The wry neck entirely disappeared and the case eventually recovered.

This leads me to say that I believe that in every case of wry neck in a child we should examine carefully to see whether there is not caries present. I believe the former is frequently an early symptom, and that long before any deformity of the bones can be detected, we may find wry neck, resulting from pressure on the nerves at the point of emergence, or from inflammatory irritation of the cord.

The attempt to overcome the muscular contraction in either spasmodic or spastic torticollis by the sheer force of mechanical appliances, I believe to be very rarely successful.

In this connection I would say, however, that in many cases I have had good results from suspension, carried on systematically and persistently, and have attributed the improvement to diminished irritation of the nerve trunks. Contracted muscles, I think, almost invariably depend upon a central irritation existing at least as far back as the point of emergence of the same from the vertebral column. Dr. Mitchell's case is very instructive and, to me, interesting. I have been accustomed in all such cases to look for irritation in the pelvic region reflected to the upper portion of the cord. A rectal or vaginal examination will often reveal a source of irritation of some form, either rectal, uterine or ovarian in the pelvis. If this is relieved we shall occasionally find to our great surprise and delight a diminution of the central irritation with complete relief of the reflex affection.

DR. F. X. DERGUM—I do not deprecate tenotomy in *fixed wry neck*; in clonic torticollis, however, it is certainly little more than a makeshift expedient. In regard to the tumor noted in the sterno-mastoid muscle in infants, at birth, it is sometimes due to hematoma, sometimes to tear and inflammation of the muscle. When tears occur, fixed wry neck is very apt to ensue. I think that we ought to be more careful in speaking of our results; in cases of spasmodic torticollis, cases are often reported as cured when they are only relieved. Very often indeed we find a case reported as cured and find that the account ends by stating: "In six months a slight return of the spasm occurred," or "a slight movement of the head only could be observed," and other expressions of like purport. Certainly, while drugs such as gelsemium, conium, and various surgical measures give marked relief, they generally fail to cure absolutely.

DR. J. HENDRIE LLOYD—In discussing the pathology of wry neck it seems to me that it might be wise to pay more attention to the condition of the muscles; I know that it is not the fashion to look for the possibility of this disease in the muscles, either in the fiber or in the sheath. I have no scientific data upon which to found a statement that wry neck is a myopathy, but it seems to me reasonable, from the fact that this disease is not associated with any particular nerve trunk, but is distributed through irregular muscle groups. It is popular to attribute all muscular involvement to central disease, which necessarily eliminates myopathia. I do not myself believe that we are on sufficiently firm ground to positively assert that all these troubles are located in some form of meningitis, or irritation of the nerve centers. In recent years it has been found necessary to remove several diseases from the groups of central diseases and to place them among the myopathics. This may yet have to be done with wry neck.

I was much interested in Dr. Mitchell's case because it ex-

hibits a not unusual form of hysteria. Hysterical torticollis has been described by French authors. It is simply one of the varieties of hysterical contracture. In his case the convulsive phenomena, the contracture, the fact the patient was cured by isolation, are all very characteristic of hysteria.

DR. DEFOREST WILLARD—Dr. Dercum has spoken of the unsatisfactory results of myotomy of the sterno-cleido-mastoid muscle. While I grant that in a considerable number of cases myotomy does fail, yet in many instances it gives permanent relief. I have seen cases in which there has been no return of spasm for fifteen or twenty years, and this may be called permanent cure. There are a certain number of spastic cases which can not be relieved by this operation, but in inflammatory troubles excellent results can be obtained from myotomy. I advise first medical treatment; if that fails, then mechanical measures and myotomy; then neurectomy.

In regard to the question of subcutaneous or open section; at the present time we are much more inclined to the open method since there is less fear of sepsis than formerly. In a female, however, a large scar is annoying and in girls I perform subcutaneous tenotomy when it can be done with absolute safety. I make the puncture with a small oculist's knife so as to avoid the entrance of the air even, should a vein be wounded.

In many cases if the sterno-cleido-mastoid is firmly stretched, and if a very blunt tenotome is carried along the posterior face of the muscle, there will be no injury to the vein and the muscle can be entirely severed without danger to the other structures. If such division is not sufficient, the mastoid insertion is also divided and abundant correction is secured. Gymnastics and muscle stretching should be practiced for a long period. I recently saw a patient, a young girl upon whom I operated three years ago; her neck was in absolutely straight position, and it was very difficult to decide on which side the operation had been performed. She had had continued gymnastics.

I have never seen the pleura injured except in one case. It was in a case of Dr. Agnew's, and the patient died from septic pleurisy. I believe this is the only case in this city where death has occurred from such cause.

I think we ought to insist upon gymnastics being carried on after myotomy. Without it there little use of tenotomy or of nerve stretching. When medicines, hypodermics, electricity, myotomy fail, I think it far better to excise a considerable piece of the nerve. It is better to attack the spinal accessory nerve high up, before it reaches the sterno-mastoid, as then there is no reunion. Dr. Rhein recently collected for me forty cases of neurectomy and nerve stretching on record, and his figures give 80 per cent. of cases which have remained cured. There was but one death, and that from erysipelas. Thorough excision is an operation abundantly justifiable in these cases of spasmodic contraction.

In rotary cases, division of the spinal nerves is the only operation which promises much hope. Simple division of the spinal accessory would not be of much service, but I do not think excision of all the nerves should be attempted when all other means have been exhausted.

If we are positive that spinal caries exists, forcible reduction should be excluded.

THE DRAINAGE CANAL OF CHICAGO.

ONE OF THE GREAT SANITARY WORKS OF THE AGE.

As Chicago is just tasting the first fruits of the work being projected by the sanitary district, the time is propitious for a review of the work on the drainage canal to date, with some account of the relation of the canal to the city's drainage problem. The purpose of the work under way is the construction of a main channel adequate to the disposal of the sewage in the Chicago Valley. The undertaking was immense in its conception and involved the construction of a navigable channel from Chicago to the Desplaines River at Joliet, with a carrying capacity of 600,000 cubic feet of water per minute, and fed from Lake Michigan. It meant the re-linking of two great water systems by a commercial waterway and the solution of a sanitary problem the most intricate of the century. In the course of its prosecution it was necessary to divert the tortuous bed of the Desplaines

River in a straight stretch seventeen miles long, through a channel capable of caring for the flood water from 633 square miles of territory which aggregates at times a volume of nearly one million cubic feet a minute. It is the latter part of the work which is now complete, and it is estimated relieves Chicago of 75 per cent. of the trouble formerly experienced from pollution of drinking water due to backing of sewage in the river.

For the purpose of an intelligent understanding of the drainage problem, as presented by Chicago, and the eventual attempt at solution by means of a drainage canal capable of receiving the total waste, and connecting with the Mississippi system, it is necessary to know something of the topography of the country affected and the peculiar relations of the Desplaines and Chicago Valleys.

The site of the city is the interior of the low loam and sand ridge which surrounds the southwestern bend of Lake Michigan. This rim or ridge is the lowest point of the great continental water shed which separates the St. Lawrence and Mississippi regions. It trends southward opposite the lake shore about four miles inland at the Wisconsin State line, and gradually diverges until at a point on a line with the mouth of the Chicago River it is ten miles distant. On the east side of this ridge, and between it and the lake, lies the basin containing Chicago, through which run the north and south branches of the river, meeting, and forming a short, common outlet to the lake. On the west side of the ridge and running almost directly south to a point opposite the origin of the south branch of the Chicago River, then trending to the southwest just above the town site of Summit, lies the bed of the Desplaines, an elementary branch of the Illinois River. The watershed of the Desplaines includes a territory of 633 square miles, the north boundary of the oblong tract drained extending into Wisconsin about fourteen miles. The ridge is lowest at the point opposite the Bend in the Desplaines, it here rising but twelve feet above Chicago datum, or the surface of Lake Michigan. Sloping away to the east is a low, marshy tract through which runs what is known as the Ogden Ditch, a drainage trench constructed in the early days of the city and affording an outlet to a swamp region known as Mud Lake. The ditch discharges into the south branch of the Chicago River. South of it is the old Illinois and Michigan Canal connecting the Chicago with the Illinois River at Peru. This canal cuts the watershed above described and follows a course parallel to the Desplaines.

As the city developed in extent and population it was found that the sluggish Chicago River, into which most of the sewage was thrown, had become an almost stagnant cess pool inimical to the civic health not only from the

putrescent gases exhaled, but also from its pollution of the lake and consequently the drinking water supply. Heavy rains but aggravated the condition, as the sewage was flushed into the contiguous portion of the lake where for lack of a dispersing current the mass of waste lay slowly throwing off its putrid vapors to be carried by the winds through the city.

In 1879 much the same condition of offensive stagnation prevailed in the Illinois and Michigan Canal. At that time this narrow channel had a flow of but 9,000 cubic feet per minute. It held sewage in the proportion of about one to four, and thirty miles below Chicago, where the water fell over a dam, the odor thrown off, it is said, was comparable to that from an emptying privy vault. This nuisance proved so absolutely intolerable to the residents of the interior that Chicago was compelled to erect pumping works at Bridgeport with the object of increasing the velocity and volume of the stream with a view to dilution and more rapid oxygenation. The station was established six miles from the mouth of the Chicago River on the south branch and when completely equipped was capable of throwing a stream equal to 40,000 cubic feet a minute, and the maintenance of a six-foot head. This resulted in an amelioration in the condition of the canal contents, though the nuisance was by no means entirely abated. Its effect at Chicago was to set a current from the lake through the six-mile strip to the south branch, to the pumping works sufficient to effect a complete change in the water once in forty-six hours. This short strip was practically all that was affected. The Stock Yards section with its two and one-half miles of putrescent filth was unprovided for, and the north branch, with the drainage of 172 square miles of urban and tributary territory, lagged with barely current enough to force its slimy length lakeward. Added was the constant menace of sewers belching directly into the lake north and south of the river mouth. Around each exit hung a heavy bank of filth that with every wind off shore was driven to the water-works crib. Thus the city was continually confronted with the manifold dangers incident to drinking its own waste, with the dangers to public health increasing in regular ratio with the progressive growth of the city.

Floods invariably had their issue in great exacerbations of the evil. All the accumulated surface filth was washed onward and, joining with the sluggish sewer way which was the result of the river's evolution, sent a torrent of thick, murky fluid through the channels, stirring up the putrid sediment, and finally casting a disease bearing pall over the Michigan reservoir for miles.

The treacherous Desplaines was a potent factor at times in aiding this distribution. Whenever its volume increased to 50,000 cubic feet a minute the river surged out of its bed and over the Chicago divide, then through Mud lake and along the line of Ogden's ditch to the south branch. Here the sewage current would be turned and the foul mass seek the vicinity of the city water intakes. If the volume of the inundation equalled the amount being worked off by the Bridgeport pumps, the latter were forced to close down,

when the old Illinois and Michigan canal would resume its slow descent as would be evidenced by the complaint wail sent up along its route. These manifold causes of annoyance and uneasiness were evidences of the urgent necessity for a radical change in the city's drainage.

Many schemes of sewage disposal were suggested and considered. That of land disposal was impracticable from its great cost and from its being inapplicable to the stagnant Chicago River. No means of lake disposal could be suggested that secured immunity of the water supply. Chemical precipitation was expensive and did not meet the requirements of the case.

The plan of sanitary dilution was finally settled on as meeting the logic of the situation. The peculiarly advantageous location of the city almost astride the continental water shed with the practically inexhaustible waters of Lake Michigan on one side and the feasibility of a discharge by way of the Illinois and Mississippi Valleys on the other were suggested by the freak of construction left by nature's own hand. At a time not remote geologically the great lakes had found a partial outlet across the Chicago divide. It was purposed to re-establish this connection between the two great water ways. The economical and commercial possibilities of the scheme were almost unlimited as the drainage channel could be constructed of such depth and breadth as to provide transportation for craft of any size, in conjunction with necessary improvements in the channels below. To Chicago however, the great incentive was the desire to work a permanent adjustment of her drainage difficulty. In the projection of the scheme to a successful conclusion the city had to guarantee immunity from pollution to the towns on the route below. The channel was to be of sufficient capacity to afford the dilution necessary and also care for any possible volume of flood water to prevent backing sewage to the lakes. The disposal of the sewage was to be complete and rapid and in as fresh a state as possible; and dilution at the point of discharge of such quantity and character as to procure rapid oxygenation, and immunity to aquatic life.

To meet the requirements the channel had to be of a capacity of 300,000 cubic feet of water per minute for immediate needs, and so arranged that its capacity with a current velocity of $1\frac{1}{2}$ miles an hour could be increased to 600,000 cubic feet a minute. The latter volume would, it was estimated produce sanitary dilution in the sewage from a population of 3,000,000 and was anticipatory of the city's development. Such a channel flushed with the well aerated and oxygen loaded water of Lake Michigan, in conjunction with auxiliary works to meet the peculiar local conditions, gave the city the promise of efficient drainage for all time. It is thought that by the institution of special devices for the destruction of the solid organic waste, the city will be able to send from its doors a sewage stream that will stand a comparative analysis with any natural stream in the State. This last statement refers to pollution only as concerns what a chemical examination will reveal. Biological analyses under these circumstances are as yet so meager in results

that the possibility of pollution with pathogenic germs, is still a matter largely problematic in its relation to residents some distance from the source of infection.

For the purpose of prosecuting this drainage scheme the Sanitary District of Chicago was organized, Jan. 18, 1890, under a special act of the Illinois Legislature which gave the district power to raise the necessary funds, condemn a right of way, etc. Ground was broken Sept. 3, 1892, not far from the town of Lemont. Since then the work has been progressing satisfactorily and the district is fully expecting to see the completion of the main channel by the expiration of the time set—April 30, 1896.

The main channel is thirty-three miles long and extends from Bridgeport south-west parallel to and north of the old Illinois and Michigan canal. Its objective point is the Desplaines river at Joliet. About ten miles of the route is through clay, ten miles in glacial drift, and the rest in solid rock with only a slight covering of earth. In rock the channel will be cut 160 feet wide at the bottom with almost vertical sides. It will give a current depth of 22 feet. In the dirt cutting the channel at bottom will be 202 feet wide sloping to 290 feet at the top. The first work here will give a water depth of but four feet which, it is estimated, will give a flow of 300,000 cubic feet a minute, a volume sufficient to meet the immediate drainage need. As the population-increase demands it, the dirt-work may be dredged to the rock work level and eventually provide for the full flow of 600,000 cubic feet a minute.

As the line of the main channel was laid out without any reference to the bed of the Desplaines the latter intersected the route at many points. Taking advantage of the necessity for diverting the river from its course a straight and deeper channel was given it which did away with the obstructing tortuosities of the old bed and increased the capacity to a point sufficient to care for the total flood water from its water shed. For the purpose of more effectively providing against an overflow into the main drainage channel the high water line is raised by a protecting levee throughout the seventeen miles of low marshy country from Summit to Romeo the latter point within eight miles of Joliet. This bank of earth begins nearly two miles north of Summit on the crest of the water shed. At Summit it trends to the south-west closely hugging the left bank of the diversion to the terminus.

The drainage board thought it inadvisable to turn the total flood water into the diversion for fear of damage at points below. To meet this contingency, and also protect Chicago a spillway was constructed at the ridge portion over which the flood habitually flowed. The spillway is a fine piece of masonry 400 feet long and rising 16.25 feet above Chicago datum. It intercepts any flood to a volume of 250,000 feet, five times the amount formerly held back by the water shed. This will protect Chicago from any but the most extraordinary caprices of the Desplaines. The spillway will be brought up to the general height of the levee when the proposed improvements have been completed in the Desplaines bed at and below Joliet.

It is the practical utility of this spillway that Chicago now realizes and its work is the first material evidence of what the Sanitary District is doing for Chicago's relief. Before the completion of the river diversion the Desplaines periodically overflowed its water shed, forced its flood through the Chicago, compelled the stoppage of the Bridgeport plant and in the usual course led to the pollution of the drinking water. That dire consequences were the resultant may be demonstrated by a reference to the heavy mortality in typhoids following the floods of 1892. During this year heavy rainfalls occurred in the early part of May followed by an overflow from the Desplaines lasting twelve days. The flood swept through the Chicago river driving the sewage to the crib. In the latter part of the month the water subsided but June 1 it rose again and until July 6, with the exception of four days in the middle of June, the Bridgeport works were compelled to shut down. When the flood was at its height the volume of overflow was 600,000 cubic feet a minute and the intake at the water works crib was drawing in sewage almost pure and undiluted. In the district supplied by this intake typhoid fever soon became epidemic. The health department's records show that during July, 211, August, 179, and September 138 fatalities resulted from this disease, as against an average of sixty-six deaths in preceding months. In the district directly supplied the number of typhoid cases increased almost five-fold.

During this flood period the Bridgeport pumps were useless forty-three days. Had the spillway been in operation that year the pumps would have been overcome but seven days altogether. The flood scale at Riverside shows that even this would have been distributed at intervals of two or three days each and could not have led to a widespread pollution. The volume was not more than sufficient to neutralize the induced current in the Chicago river, not enough at least to back the sewage to the crib.

Relieved from the evil ensuing from deluges of flood water from the Desplaines valley Chicago has to contend with no flood water but that from its own valley. This comprises the scourings from a shed 272 square miles in extent. The completion of the main drainage channel will, *per se*, care for this.

While this drainage channel is competent to do the work claimed for it, it is really but the lever which those conversant with all the facts in the case expect to use in securing coöperation in solving the rest of the problem. In itself the channel is not practically available until after a vast amount of auxiliary work has been prosecuted. The present work, it is estimated, will cost between \$25,000,000 and \$30,000,000. As much more will have to be expended before Chicago obtains her ideal of drainage. The general expectation has been that the water supply from Lake Michigan is to be fed through the Chicago River and its south branch. In its present state the river channel is so narrow as to render it physically impossible for the south branch unaided to feed the amount of water required in the canal. The expense in condemnation proceedings incident to sufficient enlargement of the river bed is practically prohibitive, as row after row of valuable manufacturing and other plants would have to be sacrificed. Even were the improvements carried through regardless of the expense to be incurred, it is freely acknowledged by competent engineers that the physical features are such that perfect drainage could not then be secured without a further immense outlay in lateral branches and pumping works. These adjuncts to the main channel are required to overcome the difficulties presented by, 1, the Stock Yards district; 2, the large territory whose sewers discharge directly into the lake; and 3, the thickly populated district through which the north branch descends.

The proposed canal inlet from the Chicago River strikes the west fork of the south branch almost directly from the southwest. The east fork of this branch strikes the main body at an acute angle coming from the south. This latter fork is two and one-half miles long, including the Stock Yards slip, and is what is called a "dead end." There never has been a sufficient circulation through it, and as it receives the heavy Stock Yards sewage, beside several square miles of urban drains, it lays the year round a stagnant mass of foul, stench exhaling, disease germinating filth, reaching its mephitic influence over the densely populated district adjacent. Its constant power for evil is indicated by reference to the disease statistics of this section, showing a remarkable prevalence of diarrheal and miasmatic diseases, with a mortality rate for these troubles the highest in the city. In no other portion of the city does the principle of survival of the fittest work its ends more demonstrably. Only the most strongly constituted babies survive their babyhood in

this neighborhood. The infantile mortality rate excels that of any other portion of the city, which may be minus its cesspool, though as densely populated. The Stock Yards cesspool will have to be drained. The drainage channel as now contemplated will not give the circulation needed. Two suggestions for auxiliary works have been made. One is to run a lateral channel from the main canal through the district to the lake. This channel would drain directly and beside help to feed the diluent wanted for the central drainage system. The other scheme contemplates a large feeder to the lake from a point further down the river. Then the Stock Yards sewers would be centered at a point from which their contents could be pumped into the canal. In this instance the "dead end" would be filled in.

The sewers now discharging directly to the lake would be headed toward the canal, an artificial circulation to be established where necessary.

For the solution of the North Side problem the concensus of opinion seems to favor the extension of the north branch, by a navigable channel, to the north and possibly around the suburb of Evanston to the lake. This would secure a continuous natural flow without the necessity of pumping works.

One other phase of the drainage question may be noticed in passing. South Chicago is a rapidly developing, thickly populated section on the lake shore at the mouth of the Calumet River. The latter stream empties its drainage contents about twelve miles from the mouth of the Chicago River. It may some day complicate Chicago's drainage scheme by pollution of the lake. In anticipation of this it is thought possible that an additional channel may be constructed which will drain the Calumet region into the main canal.

In connection with the inquiry into the status of the drainage canal work the JOURNAL representative spent three days among the workmen's camps with a view of learning the sanitary and hygienic condition prevailing. In many instances the state of affairs is deplorable. Health regulations are disregarded entirely and the housing of the men more like that of neglected swine than of human beings. This seems due entirely to the culpable indifference of the contractors. The latter are bound by clauses in their agreement with the Sanitary District to observe the sanitary regulations. The latter are issued by the drainage board and if lived up to would secure everything healthful and disease preventive. With the lax methods in vogue no arrangements are made for disposal of sewage, shacks and shanties are located on the surface of soggy and marshy pieces of ground, insufficient privy accommodations are provided and only the scantiest provision made for conveniences of personal cleanliness.

As consequences of this rough go-as-you-please, slops and kitchen refuse are thrown on the ground from the kitchen doors, through gaping cracks in poorly laid floors arise the noxious gases of decomposition from the sewage impregnated soil, and surrounding the houses are circles of human excreta.

On comment being made the answer is that regulations are impossible of enforcement among the class of men employed on the work as it is impossible to compel them to use privies and dispose of the slops at a distance from their shanties. The excuse carries as far as concerns the personal habits of the men as most of them are the scum of immigration. It makes no defense however against the lack of drainage facilities and the failure to elevate the shanties to admit free circulation underneath them. In the neighborhood of Romeo where the laxity is most noticeable there is an abundance of stone which might be used for foundation purposes. It could be used at little extra expense.

Coming east from Romeo there is a much better condition. In the camps at the Chicago end of the route the contractors heartily coöperate with the health authorities. Ditches for drainage are put in, the men are comfortably housed, slops are collected in barrels and hauled to points remote from dwellings, and privies are so constructed that they may be flushed occasionally.

Dr. William Martin, the health inspector for the Sanitary District, with the aid of the sanitary police does all that is possible for the relief of the men. The great difficulty encountered is the impossibility of enforcing the health laws of Illinois. They entail no penalty in their breach and observance can not be compelled. Under the circumstances the most that can be done is to secure pure water by driven wells with impervious casings, keep close watch of the food and condemn bad meats and secure by diplomacy as much else as the greed of the contractors will admit.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, JANUARY 20, 1894.

THE ANNUAL HOSPITAL ACCOUNTING.

"I'll jest a twelve month in a hospital."—*Love's Labor's Lost*.

The annual crop of hospital reports is now ripe; as the news columns of the JOURNAL this week bear ample testimony. The reports, many of which are filled with details which only interest their respective localities, are yet unfailing indexes of the great charitable impulses of our country. They show in general that the hospitals are growing more and more useful to the communities in which they are placed, and that the equipments are vastly superior to those of even a decade ago. Nor is it uninteresting to the metropolitan physician to learn that the miners of Cripple Creek are to build a cottage hospital fitted with modern appliances and constructed in accordance with the latest principles of hospital construction. The great school of experiment and clinical observation from the earliest times to the present, with exception hereinafter noted, has been held in the hospital amphitheater and at the bedside. There were Asclepiades before there was a Hippocratic era, and the "handwriting on the wall" in the days of Hippocrates was the clinical notes thereon recorded of the patients treated therein.

It is thus apparent that the science of medicine was redeemed from mysticism through hospital observations. Wise, in his interesting history of medicine among the Asiatics, says that in the time of the great ASOKA, B.C. 220, "the Buddhist priests formed themselves into companies, to make pilgrimages from town to town, and from temple to temple, with the object of conversion and for the propagation of their benevolent schemes, among which was assistance to the sick.

"To South Behar, people repaired from all the provinces where the delegates remained in towns, and each establishment had a *medicine house* of happiness and virtue; more particularly in the west of India

where the Banians and Jains were numerous. The poor and the orphan, the lame and the sick of all the provinces repaired to these houses where they had all that was necessary for their wants. Physicians instructed in the ancient Hindoo medical sciences, examined and treated their complaints, and they were provided with food and drink according to their experience of what was right, and proper medicines were administered to them. Nothing was omitted that could contribute to soothe and gratify them, and to cure their diseases. At the same time the utmost liberty was given them, so that they could leave the hospital whenever they desired."

The exceptional humanity of the Buddhists induced them as well to build hospitals for animals, and at Surat there still remains an animal hospital which is now nearly two thousand years old.

"This curious institution," says WISE, "is supported by one anna per cent. on the rupee of the merchant's clear gain, to which is added the fines for certain venial offences, under the supervision of the chief Banians. In 1770, when trade had decayed, the revenue was upward of £600 a year, and so careful were they of animals, that bread and milk were provided for two which could not crop grass. The hospital consisted of twenty-five acres, surrounded by a high wall, divided into courts, and defended by sheds and wards for the accommodation of the animals." "If proper inquiry were directed to this building," writes PRINSEP, "I dare say it would be discovered to be a living example (the only one that has braved twenty centuries) of the humane acts of ASOKA, recorded at no great distance, on a rock in Guzerat."

In the days of Roman ascendancy the hospitals were regarded as an asylum offered by charity to the sick poor, and no longer as in the Hippocratic period, schools for young physicians. The oldest hospital of our era was the hospital founded by Saint Simon, in Constantinople between the churches of Saint Irene and Saint Sophia. In the time of Justinian the hospital was embellished and rebuilt.¹

Much could be written on the history of hospitals, as recorded by historians, but to us we think that very much of the knowledge of the day, and that which has placed our time in possession of so many scientific facts of use to human kind, has come from hospital observations. Some of the humblest of them may furnish material wisdom of the highest character.

THE WHOLESOMENESS OF SUBSOIL WATERS.

PROFESSOR ROBERT KOCH, in his paper on "Water Filtration and Cholera," a translation of which has been published in some of our journals, attributes the preservation of Altona from cholera at the time when Hamburg was so severely affected to the use of properly filtered water. These two cities (and a third, Wandsbeck, which like Altona owed its preservation from the epidemic to the purity of its water) are contiguous, forming a single community, yet hav-

¹ Sprengel.

ing separate systems of water supply. That of Hamburg is taken unfiltered from the Elbe above the city; that of Altona from the Elbe below the inflow of the sewers of Hamburg. Cholera restricted its ravages to the districts of the Hamburg water supply. In one street which for a long way forms the boundary between the two cities, cholera prevailed on the Hamburg side but did not cross to the side supplied by the Altona water works. The filtration at these works removed the germs poured into the river with the Hamburg sewage. The conditions of an efficient filtration such as that at Altona are stated to be a layer of sand at least thirty centimeters thick, the restriction of the filtration to a rate of 100 millimeters per hour, and the freedom of the filtered water from germs in excess of 100 per cubic centimeter. The slime deposited from the water is the true filtering medium, the sand layer constituting merely the basis on which it is formed. The value of artificial filtration having been thus premised, PROFESSOR KOCH points out the vast stores of naturally filtered water that are to be found in the subsoil, even in a soil which has been much and for a long time contaminated, as in that of the city of Berlin. "All liquids," he argues, "even those most strongly contaminated, must, before reaching the depth from which the water is raised, pass through thick and efficient filtering layers by which they are rendered absolutely free from infectious matters. Especially is this the case if the boring goes through an upper impermeable layer into deeper sand or gravel layers containing the waters."

In the last sentence he recognizes the distinction which in this country we make between shallow wells and deep wells. Our sanitarians do not question the purity of water brought from beneath an impermeable stratum, but they have no faith in the wholesomeness of the water derived from shallow wells. PROFESSOR KOCH attributes all epidemics from wells to contamination from unfiltered inflow from the surface by cracks and fissures, and proposes to remedy this by inserting an iron pump into the well and filling up around the pump with gravel and sand so as to ensure the filtration of all inflow to the lower end of the pump. Many of our municipal health officers have during the past fifteen or twenty years closed up all shallow wells within their jurisdiction, and it is doubtful if even on the dictum of the distinguished bacteriologist they would authorize their reopening. The filtration of subsoil water into shallow wells may be efficient against cholera in view of the experience at Altona; but it was the danger of the propagation of typhoid fever which led to the closure of our shallow wells in thickly settled localities. This action was suggested by the occurrence of many instances of the propagation of typhoid by subsoil water, and the subsequent lowering of the typhoid rate proved the wisdom of the measure. The life history of the bacillus of typhoid has not yet been

written in full, nor has the efficiency of the natural filtration through the upper layers of the soil been demonstrated satisfactorily as regards this bacillus. We confess, therefore, to the same fear of its presence in the water of shallow wells, that led our health officers to prohibit the use of such local supplies.

YELLOW FEVER.

The raising of the quarantine at Brunswick on November 30 was truly a day of Thanksgiving for that stricken community. For more than three months the inhabitants were practically isolated from the rest of the world, with the means of livelihood cut off, and the impending danger of contracting the disease before the anxiously looked for frost should make its appearance.

The probabilities are that if an efficient State health organization had existed in Georgia, the splendid record made by the State Boards of Gulf and South Atlantic States, and the Marine Hospital Service, in the prevention of the introduction and spread of yellow fever for a number of years past, would not have been broken.

Under the stimulus of the AMERICAN MEDICAL ASSOCIATION, Georgia was one of the first States to pass an act creating a State Board of Health, but unfortunately no money was appropriated to give effect to the law.

The suffering and loss caused by the Brunswick visitation can not be estimated in dollars and cents. Georgia is one of the few States in the Union that has not made provision to protect the lives of its citizens from pestilence. Will the Empire State of the South longer remain under this stigma? There is a movement now being made to secure the necessary legislation, but it meets with opposition. Some of the opponents seem to think that quarantine alone is necessary, and that that can be better performed, and with no expense to the State, by the National Government. This is true to a certain extent, but quarantine is only one of the sanitary agencies necessary to protect the public health of a State. Under our form of government, to provide proper sanitary protection, the municipality has a duty to perform, and if, as frequently occurs, the jurisdiction of the municipality is too limited, then the duty of the State comes in, and in like manner that of the National Government, when the State system is inadequate.

It is very important, in the interest of epidemiology, that the true history of the introduction of yellow fever at Brunswick, and its subsequent breaking out after it was thought to be stamped out and so declared officially, should be known to the public. The disadvantages under which the Marine Hospital Service labored were many, and taking everything into consideration, the officers of that Service deserve credit for limiting its spread.

CONTRIBUTORY NEGLIGENCE OF PATIENT AS DEFENSE TO CHARGE OF MALPRACTICE.

One of the most interesting decisions rendered for some time in a malpractice case, is that of the Appellate Court of Indiana in *YOUNG v. MASON* (decided Nov. 22, 1893, and just reported, 35 *Northeastern Reporter* 521). In this case the jury returned a general verdict for \$1,000 in favor of the party claiming injury, and also returned answers to forty interrogatories submitted on behalf of the physician sued. Now answers to interrogatories override a general verdict when both can not stand together, but not where they can be reconciled.

It was clearly shown by the answers in this case that the physician possessed fair and ordinary knowledge and skill, also that the manner in which he dressed and treated the injuries of this patient was, with one exception, such as is approved and followed by the most skilful surgeons in that vicinity, and which is approved by the standard authors and text-writers upon the subject of surgery. The exception was that the answers did not conclusively show that he exercised due skill and care in reducing a fracture near the wrist joint. This act, with other acts of alleged negligence, it was charged, caused a certain stiffness of joints and the loss of the use of the arm, for which damages were sought. But the answers also showed that the patient took her injured arm out of the sling, contrary to directions, and placed it on her lap, window sill, and table, and that she also refused to allow the physician to use passive motion at the times, and to the proper extent.

Indulging every reasonable presumption and intendment in favor of the general verdict, and granting that the party who brought the action established to the satisfaction of the jury every fact put in issue, except when the answers to the interrogatories affirmatively and conclusively showed to the contrary, and giving a fair and reasonable construction to the facts, which were clearly, specifically, and without conflict or contradiction found in the answers, the court concludes that the negligence of the physician in failing to reduce the fracture near the wrist, and the refusal of his patient to allow him to subject the injured joints, at the proper times, to passive motion, concurred in producing the injuries for which recovery was sought.

The authority of other courts is quoted to the effect that, "the law has no scales to determine in such cases whose wrong doing weighed most in the compound that occasioned the mischief." "It is the duty of the patient to submit to the treatment prescribed, and to follow the directions given, provided they be such as a physician of ordinary skill would adopt or sanction A person can not recover from another for consequences attributable in part to his own wrong."

In consequence of the answers to the interrogatories

showing, as stated, that the injuries complained of were certainly aggravated by the misconduct of the patient, the trial court, upon motion made in behalf of the physician, set aside the general verdict of the jury against him, and rendered judgment in his favor. This the Appellate Court affirms.

The law on this very important subject is further illustrated and summed up, by the Appellate Court, as follows: Suppose a man fractures the bones in his leg below the knee, and calls a surgeon to treat the injuries, and the surgeon negligently fails to properly reduce one of the fractures, but in all other respects gives proper treatment, and the patient, in disobedience of the directions of the surgeon, negligently removes the bandages used as a part of the proper treatment by the surgeon, or is otherwise guilty of contributory negligence, and such combined negligence of the surgeon and patient unite in producing a shortness and stiffness of the leg, for which injuries an action is brought against the surgeon, can the patient recover? The patient is certainly not responsible in such case for the original negligence of the surgeon in failing to properly reduce the fracture, but this negligence of the surgeon unites with the subsequent contributory negligence of the patient in causing the shortness and stiffness of the leg. Now it seems clear, under such circumstances, and the authorities cited, that the patient can not recover for the consequent shortness and stiffness of the leg.

Where both the surgeon and patient are free from negligence, or where the surgeon and patient are both guilty of negligence, or where the surgeon is free from fault and the patient is guilty of negligence, no recovery can be had against the surgeon in any case. It is only where the surgeon is guilty of negligence and the patient is without negligence on his part contributing in any degree to such injuries that the patient can recover damages of the surgeon.

SOCIETY NEWS.

The Minnesota Academy of Medicine met January 3 at the Ryan Hotel, St. Paul. The program submitted was: "Neurological and Psychological Freaks," a paper by Dr. W. A. Jones and a discussion led by Dr. R. O. Beard; paper, "Brain Lesions—The Result of Injury Without Apparent Fracture," Dr. C. H. Mayo, and a discussion led by Dr. W. A. Jones; "A Consideration of the Subject of Ovariectomy," with report of thirty-three cases, by Dr. A. McLaren.

Proposed Medical Society Building.—The Hartford Medical Society held its annual meeting at the residence of Dr. Gurdon W. Russell January 1. By the terms of the will of Mrs Mary C. Hunt the Society will receive \$20,000 for a new building, providing a lot is secured within two years. A subscription for a lot was started, Dr. G. W. Russell heading it with \$1,000, and Dr. G. P. Davis following with \$500. A canvass will be made and it is expected that the balance will be easily raised. After the meeting refreshments were served. These officers were elected for the ensuing year: President

H. P. Stearns; Vice-President, A. W. Barrows; Secretary, Gideon C. Segur; Treasurer, C. D. Alton; Librarian, E. K. Root; Censors, S. B. St. John, G. R. Shepherd, W. M. Hudson; Trustees, G. W. Russell, M. Storrs, A. W. Barrows; Executive Committee, Gideon C. Segur, C. D. Alton, E. K. Root; Building Committee, G. W. Russell, M. Storrs, G. R. Shepherd.

Baltimore Medical Association.—The annual election of officers of the Baltimore Medical Association was held Jan. 8 at the rooms of the Medical and Chirurgical Faculty, and resulted as follows: President, Dr. David Street; First Vice-President, Dr. H. H. Bredler; Second Vice-President, Dr. E. D. Ellis; Recording and Reporting Secretary, Dr. Eugene L. Crutchfield; Corresponding Secretary, Dr. J. D. Farrar; Treasurer, Dr. J. Ingle; Executive Committee, Dr. John I. Pennington, Dr. Steven Crowe, Dr. J. Edwin Michael; Committee of Honor, Dr. George J. Preston, Dr. Chas. H. Jones, Dr. John W. Chambers. After the meeting the physicians adjourned to Tierney's where supper was served.

New Haven Medical Society.—The 91st annual meeting of the New Haven Medical Society was held at the residence of Dr. S. Hartwell Chapman, on Church Street, January 3. There were thirty members present. Reports of Secretary and Treasurer were read and officers were elected as follows: President, Dr. Henry L. Swain; First Vice-President, Dr. J. W. Seaver; Second Vice-President, Dr. T. M. Cahill; Secretary, Dr. J. H. Townsend; Credential Committee, Drs. Francis Bacon, T. E. Beckwith; Finance Committee, Drs. H. Fleischner, C. A. Lindsley.

Dr. Gustavus Eliot, the retiring president, then read a paper on "Reciprocal Duties of the Senior and Junior Members of the Medical Profession."

Kansas Medical Societies.—The joint sessions of the Eastern Kansas and Golden Belt Medical Societies were inaugurated at Topeka January 4, and concluded in the evening. Fifty members attended. Among others: Dr. W. S. Pickard, Burlingame; Dr. J. Reynolds, Horton; Dr. L. H. Murphy, Minneapolis; Dr. A. B. McCandless, Horton; Dr. Wm. B. Dewees, Salina; Dr. H. H. Sutherland, Herington, Kan.; Dr. J. N. Ketchersid, Hope; Dr. J. H. Wetherbee, Hutchinson, Kan.; Dr. B. E. Fryer, Kansas City, Mo.; Dr. J. F. Binney, Kansas City, Mo.; Dr. Jas. Haight, Wetmore, Kan.; Dr. T. M. Zane, Osage City; Dr. A. H. Cordier, Kansas City, Mo.; Dr. Geo. Halley, Kansas City, Mo.; Dr. J. W. Felty, Abilene, Kan.; Dr. J. Block, Kansas City, Mo.; Dr. O. C. McNary (Surgeon Soldiers' Home), Leavenworth; Dr. W. S. Bunn, Lawrence, Kan.

Dr. Jas. Haight of Wetmore, Kan., advocated the electrical method of curing consumption, using the galvanic current. On the electrodes which he uses he places iodine; this is "driven" into the lung tissue, and by this means a cure is effected. He cited a number of cases in which he had brought about remarkable cures.

Dr. W. B. Dewees of Salina, in his paper on "Proper Diagnosis," said that the best position to make an examination is in the erect posture and not the recumbent posture.

Dr. J. Block of Kansas City, Mo., presented a paper on "Some Practical Observations on Strictures of the Urethra."

Dr. J. L. Gilbert of the Kansas Medical College, read a paper on the subject of cancer, in which he advocated the theory that its growth and development is due to a germ.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 70).

On motion of Dr. Hayd, seconded by Dr. Newman, the papers of those not present were ordered to be read by title.

A paper by DR. DANIEL B. D. BEAVER, of Reading, Pa., was then read by title, entitled

NOTES UPON SOME USES OF GALVANISM IN SURGERY.

A respectably large experience with electricity, covering a period of thirteen years in public and private practice, in

the treatment of nearly all the diseases to which this remedy has been commonly applied, would suggest comparison of methods and results, but as there is an abundance of material for discussion at this meeting it seems more desirable to present, as my triennial contribution to the transactions, a brief summary of observations which are comparatively new.

These notes, then, will invite your attention to the use of galvanism in a few surgical affections only, in which it has heretofore not been used, or of which so few cases have been reported that the value of its application has not yet been determined; and they are: goitre, coccidinia and ulcers.

In the treatment of goitre, my experience with electricity is limited to two cases, but as I did not employ it until after iodine and iodoform internally, and compound solution of iodine and carbolic acid injected into the enlarged gland had failed, these are exceptional ones and therefore of themselves worthy of record.

Case 1—was in the person of a man, aged 73, a frescoer by trade, whom I was called to see December, 1891, and of whose case I have these notes:

He noticed the presence of a small tumor on the right side of the neck nine years ago, which had attained the size of a walnut a year ago. From that time it grew rapidly, so that it is now the size of a large fist. It occupies the right anterior third part of circumference of the neck, extending from the sternum and clavicle to the lower maxillary bone. Below, it covers the sternum and inner half of the clavicle, and above dips behind the ramus of the jaw. Laterally it displaces the common carotid artery backward and outward, so that it can be seen beating in a line dropped from the prominence of the mastoid bone. This vessel is considerably larger than the corresponding one on the left side, and sends a large branch from its middle third to the growth. The superficial veins over the tumor are dilated. The tumor is hard, slightly elastic, and smooth on the surface. It has displaced the trachea and larynx toward the left so that the prominence of the thyroid cartilage is directly under the left angle of the lower jaw, and the trachea can be felt distinctly for an inch below the larynx in this abnormal position. The left lobe of the gland is about the size of a hen's egg, but lacks the hardness of the other.

He seeks relief because for the last month he has been taken twice or thrice a week with what he calls choking spells, every one of which he and his wife feared would be fatal. The description they give of these spells indicates them to be due to spasm of the vocal bands. His voice is variable and uncertain at all times. Occasionally it is full and sonorous, but generally of a loud whisper. He is barely able to swallow solid food, and must take liquids very carefully to prevent them entering the larynx. He has lost flesh and strength.

The indications for treatment in this case were very distinct. It was very evident that nothing but removal of part or all of the growth would give relief. Extirpation with the knife in a person of his age and condition was out of the question. My previous success with preparations of iodine, in the treatment of goitre, led me to try iodoform in 3 grain doses, thrice daily, although I believed the hypertrophy to be of the fibroid variety. This was continued a month with apparent benefit, and during this time three injections of a 7 per cent. solution of carbolic acid into the growth were made. Then the patient was taken with the gripe, and was very sick for two weeks. This left him with intense neuralgic pains in the right face, neck and shoulder. The tumor, which had become smaller under the effect of the injections and iodoform, now increased in size and became painful, and tender to pressure on the anterior surface. A week later a fine aspirating needle was driven into the tender area and a drachm of blood and pus withdrawn from a depth of one inch. The patient's dread of operations of any sort would not permit me to lay open the suppurating cavity, but the relief which galvanism gave to his painful face, neck and shoulder induced him to accept my proposition to apply electricity to it through a small opening. So then I punctured the overlying tissues with a bistoury and introduced an insulated steel needle attached to the negative pole of a 50-cell Barrett dry battery.

From this on, to February 1, electrolysis was performed once a week, for ten minutes, with the anode on the neck behind the tumor and the cathode in it. During the seance the needle was pushed into and withdrawn from three places and the current interrupted with each withdrawal and gradually increased to the full strength of the battery with each puncture.

The disintegration of the growth was so rapid that in four

weeks it lost one-half in size. By this time the patient was able to take all kinds of food and gained much in strength and appearance.

On April 21 my notes say: Electrolysis has been performed once a week since the last note, with the needle inserted to a depth of one to two inches in different directions from the initial opening. During the last three weeks it has been apparent that a large portion of the tumor has been dissolved and has left in its place a cavity, for a probe can be pushed in to a depth of three inches and the point moved quite freely in all directions without obstruction. There has been a constant oozing of purulent fluid from the opening through which the needle is introduced. Although a number of large arteries are seen coursing over the surface of the tumor, indicating a free supply of blood, the electrolysis has never been followed by hemorrhage. The patient has taken no medicine except elixir of iron, strychnia and quinin.

June 12. Electricity was applied last on May 12, since which time he has passed through an attack of inflammatory rheumatism affecting the right wrist and shoulder.

August 8. The tumor is now the size of a hen's egg. The enlargement of the left lobe has disappeared entirely, and the trachea and larynx have returned to their normal positions. The voice and deglutition have become normal. The distended right carotid artery, which had been displaced backward and outward by the growth, has receded entirely out of sight. The circumference of his neck has been reduced from eighteen and one-half to fourteen and three-quarter inches, and he says it is about its natural size. His appetite is good, his strength and appearance improved, and he says he is in better health now than he has been for many years.

I saw him last on April 13, 1893, when he told me that he was enjoying good health and had resumed his work during the winter. There was then still a small opening over the remains of the tumor, from which a little blood-stained fluid oozed occasionally. He has since then died of what was reported as an affection of the heart.

The diagnosis of fibroid disease in the right lobe is confirmed by the rapid disintegration of the growth. The disappearance of the hypertrophy of the left lobe under the influence of local treatment of the other side would indicate that it was of a different character. It is not probable that it would have thus vanished if had it been of cystic or fibroid character. It was vascular or parenchymatous, or both. That these two types are often mixed, or at least indistinguishable is quite probable. The purely vascular can be differentiated from the other forms by its greater compressibility, and by its sudden decrease in size upon puncture with a needle. The latter feature was very marked in two cases in young women, which I treated with injections of carbolic acid.

In this case the choice of treatment lay between injection, the use of a seton and the method pursued, which was a combination of injection and electrolysis.

Electricity with antiseptic precautions, with a view of absorption of the morbid tissue would have been too slow. The necessity for rapid removal and relief, and the patient's objection to anything with the appearance of a surgical operation, decided against the seton on the one hand and antiseptic electrolysis on the other. Electricity was selected for its direct resolvent and destructive action on the tissues. It may be said that the suppurative process, which was undoubtedly started by one of the injections of carbolic acid, would have continued without the aid of galvanism, but my observation of that process under other conditions convinces me that it would not have been as speedy nor as safe. There would probably have been openings in several directions, with burrowing between the overlying structures. This would have increased the danger of septic infection and constitutional irritation. With the use of the needle, one passage through the superficial tissues was kept patulous, and the destructive punctures made within the tumor all radiated from that passage, thus securing drainage in that direction, and in the greatest possible degree preventing it in other directions.

The same objections can be fairly urged against the seton, especially in the case of so large a growth. Two openings would have been necessary from the beginning; they could not have been kept as free from obstruction because of the presence of the seton itself; the destructive action could not have been directed at will to any particular part of the interior, and the wound could not have been kept so clean as was done with the use of the needle.

Aside from the time when the patient suffered with the

grippe, and later with rheumatism, there was practically no constitutional irritation present.

The result was very satisfactory, and in my judgment was due to the use of galvanism.

Case 2—of goitre occurred in a woman aged 50; had been of slow growth, and affected the right lobe of the gland. The tumor was the size of a pullet's egg, with smooth surface, and so elastic that this feature, in connection with the fact that she had taken iodine for two months without benefit, led me to regard it as one of the cystic variety. Accordingly a medium-sized aspirator needle was plunged into it and the barrel of the syringe exhausted while the needle was slowly withdrawn. The result was the extraction of about two drachms of blood. The tumor was not compressible like the vascular growth, nor did the presence of the needle contract it momentarily. It must have been of a parenchymatous or mixed character.

One week later, and once a week thereafter for two months, galvano-puncture was applied, with a steel needle for the negative electrode, and from fifteen to twenty-five milliamperes for five minutes, with antiseptic precautions. The siccations were not followed by any unpleasant reaction. At the end of the two months the tumor was reduced fully one-third in size, and harder to the touch. She was then advised to discontinue treatment, with the prospect of seeing further decrease in size.

Of coccydynia I have only two cases to report, not because I have not seen more, but because they are the only ones in which other and more convenient remedies failed. In my experience this disease has never appeared in the male, and in women could only be traced to rheumatism, lithiasis, uterine disease or derangement of the nervous system, and remedies suitable to these disorders were always tried before electricity, because the latter requires much more time on the part of both patient and physician, and consequently is more expensive and objectionable to both.

Case 1—presented itself in a lady of 20 years, who had been ill upward of a year with "pain in the lower end of the spine and soreness in the mouth of the womb," as she termed it. One attendant had given her Mitchell's rest treatment three months without benefit, and his successor had her wear a Sayre's plaster jacket eight months with equally poor effect. There was tenderness over the lower dorsal region of the spine, with the symptoms of spinal irritation, slight tenderness of the ovaries, excessive tenderness of the coccyx, and a peculiar and rare condition of the mucous membrane at the os vaginae, which I had met only twice before, and have not yet seen described in print. The papillae on the inner surface of the nymphæ were hypertrophied into the form of villi, so long that they could have been cut with scissors, and so excruciatingly sensitive that the least touch made her writhe with pain. Previous experience induced me to sear the whole affected area with a red-hot electric cautery knife. This remedy brought prompt and complete relief. Attention was next directed to the ovaries, to which galvanism, positive pole in the hands or on the nape and negative in vagina, was applied once a week, in association with bromid of potassium, arsenic, phosphorus and strychnia in succession. After six months' treatment her condition had improved very much. All the aches except that at the end of the spine had disappeared—the coccyx was still tender.

The galvanic treatment was now confined to the spine with the anode to nape and kathode over the coccyx, and applied by an assistant for two months without any apparent benefit. Then the most tender spot on the coccyx was sought and found and a steel needle attached to the kathode driven into it, and as strong a current as she could bear turned on for five minutes. At intervals of a week, two more punctures were made, and at her next visit for the fourth she reported herself well, and said the needle had cured her. Two years have elapsed since and she is still in good health.

The other case is of recent occurrence and is just about getting well after one month's galvanism with cotton-covered kathode over the coccyx and anode on the nape, which was preceded by two months' medication by her family physician. As the improvement is too recent to permit a positive opinion as to its permanence, only the progress of the cure thus far can be reported.

In the treatment of ulcers, I have used galvanism, as in goitre and coccydynia, only after other and less laborious methods had failed, and hence my experience embraces only a small number of cases, too few indeed to serve as a basis for generalization. Two of the cases, however, were so unique in character, and were so remarkably influenced

by galvanism that it seems desirable to report them:

Case 1—occurred in a young man who in June, 1892, in falling off a horse, dislocated the right hip. The injury was followed by paralysis of the muscles of the leg, and sensation in the foot and lower third of the leg. In the early part of last January he frosted this foot, and the frost bite led to ulceration of the heel, and several small areas on the sole. On the 8th of April he called on me for relief from the "weakness of the leg." There was then complete paralysis of the extensors of the foot and toes; while the muscles of the calf of the leg could be contracted just enough to produce visible motion of the foot. All the muscles were atrophied. Sensation was impaired over the foot and anterior surface of the leg. All the muscles of the leg presented the reaction of degeneration. On the sole near the heel there was an indolent ulcer the size of a dime, with overhanging edges. The capillary vessels in the skin of the outer aspect of the foot were dilated, giving the part a livid appearance from the heel to the small toe.

Galvanism was applied to the foot and leg, and the muscles gradually improved in response to the interruptions of the current. But the first marked improvement occurred in the chilblain on the outer surface of the foot. In the course of six weeks the dilatation of the capillaries disappeared, leaving the skin normal in color. During these weeks and for a month longer, various stimulating powders, salves and caustics were applied to the ulcer, and the edges pared several times, without salutary effect. Then galvanism, ten to fifteen milliamperes, with the kathode on the sore, was applied twice a week for three minutes and all medication stopped. The third application brought very distinct improvement, and a month later the ulcer was closed. The muscles did not show a corresponding gain during this time, so then the healing of the sore can not be attributed to general improvement in the nutrition of the leg.

Case 2—was presented in an iron worker, a strong, healthy man, in St. Joseph's Hospital. He had been admitted with a burn of the second degree, covering the sacrum, buttocks and back of the thighs down to the knees, the result of a fall upon hot cinders. Two months and a half after admission he came under my observation, with a granulating surface seven and one-half by ten and one-half inches on each thigh. The ulcers had been dressed with petrolatum. The surfaces were elevated, the granulations exuberant, not abnormally sensitive to pressure, and the edges were indurated. Oxid of zinc ointment was applied to both ulcers for a week. Then a dozen small skin grafts were placed upon the left, and to the right galvanism was applied daily for a week and then on alternate days. The ulcer was covered with a piece of wet muslin and the ordinary sponge electrode pressed gently upon it, at first over the edges, and after they manifested improvement, over the whole surface. The strength of current was regulated by the patient's sensations, the desire being to avoid pain, and was continued ten minutes. After four applications the granulations along the edges were visibly reduced, and the bluish-gray line between them and the cicatricial tissue around them was widened. Two weeks later the ulcer was reduced to five and one-half by eight and one-half inches in size, while that of the other leg had made no notable progress, although the edges had been touched several times with lunar caustic. During these two weeks both sores were dressed with oxid of zinc ointment, and in every respect kept as nearly as possible under the same conditions.

The next week brought decided changes. The grafts on the left leg were then growing in every direction, so that the granulating surface was divided into strips and small patches between them, and markedly diminished in area, while in the other the healing process seemed to have been arrested. The surface of this ulcer became deeper red in color, sank to the level of the surrounding parts, was uneven and granular, abnormally dry, extremely sensitive to touch, and painful. It was then an irritable ulcer, and had been made so by over-stimulation with electricity. A week before these changes were noted, the patient stated that the resident physician was applying the electricity stronger than formerly, or at least it was more painful—so much so, indeed, that he could hardly bear it; and during this week he objected to its use each time. It was now ordered to be discontinued until after the subsidence of the irritation, but a few days thereafter his wife persuaded him to leave the Hospital, and so ended our observations.

In their etiologic relations the ulcers in these two cases represent two extremes; the one having been caused by excessive cold and the other by heat—two extremes which meet, and in the human body produce like pathologic con-

ditions. Both were indolent, exhibiting deficient vitality and the proverbial intractability to treatment. One became irritable under a weak galvanic current from three to six acid, zinc carbon cells, while the other healed promptly under a current of fifteen to twenty-five ma. Such differences seem to indicate that the dose of electricity, as of drugs, can not be measured by any stiff rule or precise instrument, when given as a stimulant or sedative, but should be regulated by the patient's sensations.

This is confirmed by a limited number of observations of the effects of galvanism in chronic ulcers of the leg, so common in advanced life, which will be reported later. The best results were obtained when the current strength was kept just short of giving pain.

It may be said that the case of frost bite bore a stronger current without pain and irritation, because sensation in the foot was impaired, but such criticism would be incorrect, for sensation had improved by the time galvanism was applied to the ulcer, so that in other parts of the foot and leg the same current became painful after the electrodes were stationary for a few minutes. Then the impairment of susceptibility to the current was confined to the area of the ulcer, as indolence and irritation are in others which are uncomplicated by more central disturbance of the functions of implicated nerves, and consequently was a feature of its own character.

The favorable effect of galvanism in several cases of chronic eczematous ulcer of the skin seems to point to a large field of usefulness for this remedy in localized chronic eczema, especially in cases with infiltration and hardness of the tissues, for which Hebra's soap is now considered one of our best therapeutic agents.

DR. MARGARET A. CLEAVES of New York City, Instructor in Electro-Therapeutics, New York Post-Graduate Medical School and Hospital, read a paper on

METALLIC ELECTROLYSIS.

M. le Docteur Gautier, a distinguished French physician, and one of the Honorary Fellows of this Association, during the first three years has called attention by his published experiments and clinical observations to the decomposition, at the positive pole, of medicated solutions in contact with diseased tissues, whereby there was obtained the local action of the drug thus newly born. To this method, Gautier has given the name of interstitial electrolysis or medicamentary electrolysis. Under the same nomenclature he now includes the use of soluble metallic electrodes. As interstitial or medicamentary electrolysis deals with the use of binary compounds, such as iodid potassium, as well as soluble metallic electrodes, and as in this paper I shall only deal with the latter, I have preferred to use the term, "Metallic Electrolysis," a term for the invention of which I am indebted to Dr. W. J. Morton of New York.

By metallic electrolysis is meant a method which makes use of the chemic action of the positive pole both upon foreign substances—that is metals, such as copper, zinc and iron—and the tissues at the same time.

Prior to the observations of Gautier, M. Onimus¹ of Paris, and M. Prochovnick of Hamburg, among others worked with soluble metallic electrodes.² Prochovnick² is recorded as having used 80 to 100 ma. with a copper sound, positive, in blennorrhagia of the uterine cervix. Three to six sittings were given. The gonococci disappeared, and the purulent discharge became serous.

Steavenson³ very closely outlines the use of zinc in the conjoint work of Steavenson and Jones on "Medical Electricity," with the following paragraph: "If the electrode is made of zinc, chlorid of zinc is formed, which exerts its own specific action on the tissues, in addition to the oxidizing effect of the liberated oxygen."

But it is to Gautier we are indebted for systematizing this method into a scientific therapeutic measure. This he has done by a series of laboratory experiments and clinical observations, which have appeared from time to time in the *Revue Internationale D' Electrotherapie* during the past year, and which have also been embodied in his "Technique D' Electrotherapie." With two years' experience in the use of soluble metallic electrodes, Gautier⁴ believes that the results will justify the confidence which he has in this form of electro-therapy.

A personal experience, extending over a period of twenty months, has demonstrated that in metallic electrolysis we

¹ *Revue Internationale D' Electrotherapie*, July, 1893.

³ Steavenson and Jones, *Medical Electricity*, page 367, Chapter XV.

⁴ *Revue*, July, 1893.

possess a therapeutic measure of great activity, but I feel that we have only just begun to appreciate its value.

Ordinarily, in galvano-caustics, chemicals are manufactured by electrolysis out of the tissues themselves—at the positive pole, acids; at the negative, alkalies—which are in turn directed against diseased states. In metallic electrolysis, however, there are formed certain new salts which are utilized in the treatment of disease.

The following laboratory experiments of Gautier⁵ form the basis for this method of treatment.

In making a study of the electrolytic reactions effected by contact of the positive pole with a pure stick of red copper, the subject was considered from two points of view: one was as to the production of a copper salt, and its nature; the other, its action on the living tissues.

To establish the one and elucidate the other, the following experiments were made in connection with M. Favier, a distinguished chemist attached to L' Ecole Polytechnique de Paris:

First, experiments were made to show that there was an actual decrease in weight of the copper electrodes. Two copper needles, "A" and "B," were carefully weighed by means of the most delicate optical balances. A weighed 0 gr. 34912; B weighed 0 gr. 34645. The needles were then thrust into the muscles of a rabbit's leg, attached to the positive pole of the battery, and a current of 5 ma. passed for ten minutes. They were then withdrawn, carefully wiped with filter paper, and weighed again. The first, "A," was found to weigh 0 gr. 34900; the second, "B," was found to weigh 0 gr. 34625, showing a loss for "A" of 0 gr. 00012, and for "B" of 0 gr. 00020. This loss represented the exact amount of copper deposited in the muscles of the rabbit.

Experiments were next made to prove whether the salts thus deposited were toxic. As the serous fluids are composed half of chlorids of sodium and potassium, a 1 to 2 per cent. solution of artificial chlorid of sodium was made, and subjected to electrolysis, using copper as the positive electrode.

There was obtained as a result, an oxychlorid of copper, insoluble in water. This in turn, was placed in suspension in water, in the proportion of 1 to 2 per cent. and these latter solutions were used for intra-muscular injections in three rabbits.

In the first experiment, one cubic centimeter with 1 per cent. of the oxychlorid of copper was injected. No symptoms of intoxication were noticed in the three animals, and three days later, ten cubic centimeters of the same solution were injected. The animals remained normal. Subsequently, a third experiment was made with three cubic centimeters of the solution. Two months later there was no change whatever in the animals.

Next, in order to find out the nature of the copper salt produced in contact with the tissues, a current of 10 ma. was passed into a solution of sodium chlorid with copper for the anode. The copper used was from galvanic deposits, and its purity assured. After the circuit was closed, a green deposit was seen forming around the positive pole. This precipitate, washed and dried, became black at 110 degrees C., and analysis showed that it corresponded to the formula, $Cu Cl 2Cu O$. This was the same salt formed when muscular tissues or mucous membrane were submitted to the action of a copper anode.

Next, experiments were made to show the action of this copper salt upon the uterus of a rabbit. The experiments were made upon a rabbit six days after delivery.

Forty intra-uterine applications were made. The sittings were at intervals of three days, and were ten minutes in length, with five minutes for reversal of the poles. The current strength was 20 ma.

After the forty applications, the uterus and ovaries were removed without killing the animal. No lesion whatever was discovered. There was no congestion; the mucous membrane lining the cavity was soft and white, and the orifices normally dilated. After making these microscopic observations, a similar application to the preceding, was made upon the removed uterus, and after half an hour's interval it was demonstrated that there was, 1, an appreciable deposit of copper salt on the entire surface of the mucous membrane; 2, complete penetration of these salts into the tissues, the green color being apparent both internally and externally; 3, there was found one salt, oxychlorid of copper, which was insoluble, and another, an organo-metallic salt which was soluble.

Experiments were then made to establish the comparative microbicidal action of the oxychlorid of copper and

the positive pole of the constant current with an unoxidizable electrode.

The bacillus *pyogenes* was subjected to the action of the positive pole. It was found that while a C.S. of from 130 to 180 ma. was sufficient to attenuate after forty-eight hours the bacillus of anthrax, a current of 200 ma. applied for five minutes gave no appreciable results with the pus bacillus. On the other hand, the oxychlorid of copper at the positive pole influenced strongly after seven minutes the pus bacillus in its pigment-secreting function, and feebly in its multiplication. After a quarter of an hour with 40 ma. the function was totally suppressed, and life was almost extinct.

These experiments show conclusively that the copper salt is much more effective in its action upon the bacilli than the galvano-caustic method.

Additional observations were made to show the difference upon the uterine mucous membrane of the action of the positive pole with a platinum electrode and with one of copper.

In the first instance, with the platinum electrode, and a C.S. of 50 ma. it was found that in the uterus of a rabbit, the mucous membrane became congested, and that the positive pole was surrounded by dilated vessels, which failed to contribute to the work of reparation, and gave place to a retractile cicatrix. This polar property of the current is associated with a contemporaneous intra-polar action, concurring secondarily to the same end. The atresia to which the tissues are subjected by the chemic action serves to arrest the hemorrhage. On repeating the same experiment, however, with a copper electrode, and the same current strength, and duration of application, there could be found on a level with the soluble copper electrode no traces of destruction, or of inflammation in the vicinity. The mucous membrane was soft, infiltrated in its entire surface and profound depths with this new apple-green colored salt, the oxychlorid of copper.

In metallic electrolysis, the properties of the current which are constantly active are the electrolytic and the cataphoric.

So far as conductivity is concerned, the human body may be regarded as a 2 per cent. solution of sodium chlorid. By electrolysis of the tissues in contact with the positive pole, there are set free oxygen, acids and chlorin. These, in turn, attack the soluble metallic electrode, whether sound or needle, and we have formed as a result, an oxychlorid of copper, zinc or iron, as the case may be.

But no less important is the cataphoric property of the current, which after the formation of the salt electrolytically, causes it to penetrate the tissues rapidly in a zone around the sound or needle to a greater or less extent, according to the C.S. and duration of application. This is exceedingly easy of demonstration with either a piece of meat or a hard boiled egg into whose substance a copper needle has been thrust. This needle is attached to the positive pole, while a steel or platinum needle attached to the negative pole completes the circuit. A current of 40 ma. for five minutes will cause a diffusion of the copper salt to a distance of one-third of an inch in every direction from the needle.

(To be Continued.)

CORRESPONDENCE.

As to "Nostrum" Advertisements in The Journal.¹

To the Editor:—About a month ago, I addressed you a letter replying to one of your editorial articles. As that letter has not yet been printed and as I have not heard further in reply to my query concerning it, than that search would be made, I presume it has been lost, and I therefore beg to again communicate its substance, in the hope that it will receive an early insertion, together with this preface explanatory of its apparent tardiness. I wrote at first and again write because I desire to see the JOURNAL a perfect representative of the best in American medicine.

In your editorial you animadverted on the fact that some of your Eastern cotemporaries "lectured" the JOURNAL on the sale of its advertising columns to nostrums, and you replied that, 1, there was an attempt to make a difference

⁵ Technique D' Electrotherapie, Gautier et Larat, page 169.

¹ Published by order of the Trustees.

between a "physicians' journal" and a "publishers' journal," which you thought unfair; and 2, that no one had ventured to explicitly name the objectionable advertisements.

At this lapse of time I have had to repeat your argument as above, in order to make my answer intelligible.

While I have no concern in the question between you and your cotemporaries as to which is "pot" and which "kettle," and whether or not the etiquette that should prevail among culinary utensils has been violated by cries of "Blacky" from a soot-covered vessel, I have very much concern with the main issue, and on it I beg to respectfully differ with you in both your contentions.

1. Is a "physicians' journal" bound by more stringent rules than a "publishers' journal?"

Let me answer this by an apt illustration: At the time I brought to the attention of the Philadelphia County Medical Society the question of nostrum advertising in medical journals, I had some correspondence on the subject with a friend, an honorable gentleman, a member of a well-known publishing house. His answer to my request that his house should decline nostrum advertising was about as follows: "So long as the journal of which you are part owner sets the example of receiving such advertisements, you have no grounds on which to criticise us. When THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION declines to advertise secret preparations, we will likewise take the matter into consideration."

So you see, there is a very important difference between a physicians' journal" and a "publishers' journal." I am "part owner," to quote my friend, and every other member of the AMERICAN MEDICAL ASSOCIATION is likewise "part owner" of a journal which persists in a course of conduct that we believe to be wrong and that we seek to prevent in others. Our reform must "begin at home."

But even if this argument were not so forcible, there is one that you have persistently ignored. The Code of Ethics, which is not yet repealed, and which will not, I trust, be repealed, prohibits not only the use of nostrums by physicians, but *any action that tends to increase their use*. Surely, advertising them "tends to increase their use!" Were it otherwise, the "enterprising proprietors" would not waste their money on advertisements.

Furthermore, even if you ignore this special provision of the Code, there is the resolution adopted at the instance of the Medical Society of the State of Pennsylvania at the Detroit meeting of the AMERICAN MEDICAL ASSOCIATION, which expressly forbids the Trustees of the JOURNAL from advertising secret preparations.

The ingenious evasion by which the Trustees have sought to nullify this resolution, and which they must be aware is only laughed at by intelligent men, does more credit to their acuteness than to their straightforwardness. Nor does the fact that their action was passed over in silence at the Milwaukee meeting, render it any the less blameworthy. The fact apparently is that the Trustees have deliberately decided to disobey not only the spirit but the letter of the Code and of the Detroit resolution. They do not even "keep the word of promise to the ear, to break it to the hope," but break it to ear and hope alike. On the surface, their action seems to highly deserve a vote of censure; I will be very glad to learn that there is some justification for it, not apparent. If it be said that without the money received for this prostitution the JOURNAL could not exist, it would be very difficult to answer such a plea in respectful terms. I have no doubt that you can elicit a similar plea from nearly every strumpet. We can pity the strumpet, but surely the JOURNAL does not wish to be an object of pity!

2. Has no one explicitly pointed out the objectionable advertisements?

A number of them were mentioned in my paper before the Philadelphia County Medical Society, "Shall Physicians become Sales-Agents for Patent Medicines?" which was reprinted in the JOURNAL, and editorially commented upon. The *Pittsburg Medical Review* has frequently named them. In my letter mislaid by you I ventured to give you another list. In this communication I will content myself with naming only one—the one which is very properly headed "An Affront to the Medical Profession." But you need no other rule than that of the Code—which makes *secrecy* the sign and test of a nostrum. Yours very truly,

SOLOMON SOLIS-COHEN.

The Prevention of Pauperism.

OTTAWA, OHIO, JANUARY 8, 1894.

To the Editor:—Dr. Bryant's paper is to the point and timely, but he does not prescribe the right remedy, in my opinion. And I am sorry to see so many eminent and erudite men, in the discussion of his paper, laboring under the same delusion—*educate them to labor*.

My experience and observation corroborates Dr. Lloyd. The early settlers of this country were not paupers, but the introduction of a foreign element diseased with crime, immorality, etc., has given issue to not only paupers, but criminals. The inter-marriage of criminals and paupers not only begat criminals and paupers, but it has a contagious effect upon others not strongly endowed with energy and self-protection.

Not to give a lengthy dissertation of my convictions, I would castrate every male and female who proved non-self-supporting, caused by their own vicious habits, be such a character or habit acquired or hereditary; after a final judgment rendered by an expert jury of twelve free-born American citizens. Further, I would recommend the same punishment, if it could be so classified, for crimes, as homicide and grand larceny. I am morally sure, if such were the laws, three to five generations hence, jails and penitentiaries as well as almshouses would be of the past, and remembered only as monuments of the world's ignorance in the selection of the fittest, as we now remember the Spanish Inquisition, or of the burning of witches at Salem.

C. E. BEARDSLEY, M.D.

Dr. Howle Replies to Dr. Lewis.

"How to manage criminals"—Howle. "How to encourage criminals."—Lewis.

Doctors are better judges of disease than are laymen but not necessarily better versed in criminal law. I did not "define crime" because it was unnecessary. Your definition of criminal is incorrect by having "knowingly" inserted. I had no intention to defame our law-makers. I approve of "laws made by majorities." A "riot" may result in great good but to say that a "riot is lawful" is a contradiction of terms. I do not believe that the "absence of all human laws" "would destroy all force," nor do I believe that "law causes riot and justifies stealing," but I do believe that the object of the law is to "prohibit riot and other crimes." "Being imperfect in organization and training" would not be a satisfactory excuse for crime. "Malformation of the brain" is difficult to diagnose in a strong *healthy* criminal. The "inability to adjust one's self in complete harmony with his surroundings" is a calamity that befalls most of the human race, but is not necessarily criminal. The word "fad" may not be euphonious nor a "philological" success, but it is very expressive and easily understood. "Emotional outburst of fury" is oftener met with in the criminal than in the judge.

"Judicial revenge" is another contradiction of terms. Jokes aside, Doctor, the JOURNAL is not the place to discuss politics. If you really believe that "crime is the result of disease," say so, but don't poke fun at me.

Respectfully,

W. P. HOWLE, M.D.

NECROLOGY.

- Thos. B. Wheeler, M.D.**, Chicago, January 11.
- Dr. Patton** of Silver Cliff, Col., January 2.
- W. T. Bowker, M.D.**, of Kansas City, January 9.
- Joseph Lee, M.D.**, Roseville, Ill., December 23.
- R. S. Harvey, M.D.**, Spokane Falls, Wash., January 9.
- Melville Bryant, M.D.**, of Brooklyn, N. Y., December 24.
- J. H. Blue, M.D.**, of Montgomery, Ala., January 8, in New York.
- David Wilson, M.D.**, Robinson, Ill., January 11. He was over 80 years of age and left an estate of over \$130,000.
- George Adam, M.D.**, who died at Canaan, Conn., last week, aged 81 years, was born and lived under the same roof all his life.
- Alexander Stewart, M.D.**, died at Shippensburg, Pa., December 6, from pneumonia, aged 84 years. He was for twenty-one years President of the First National Bank of that place.
- O. A. Willard, M.D.**, Lowell, Mass., January 7. He was 28 years of age and a graduate of Bellevue Hospital Medical College, N. Y. He was a member of the Middlesex Medical Society.
- C. E. Tupper, M.D.**, formerly Superintendent of the Toledo Ohio Asylum for the Insane died January 10. He was at one time director of the Dayton Insane Asylum and for many years a Pension Examiner in Putnam County.
- Lucius A. Smith, M.D.**, Brooklyn, N. Y., January 5. He was born in Connecticut, July 11, 1831. He was graduated at the Medical Department of Yale College in 1852. He was subsequently Assistant Physician at the State Asylum for the Insane at Hartford. Of late years his attention had been given to marine architecture.
- George Schloetzer, M.D.**, died on December 5, at Carlsruhe Germany. He was a graduate of the University of Bonn, and for many years a resident of Chicago. When the Eightieth Regiment of Illinois Volunteers (Col. Hecker's) was organized he was appointed Surgeon, and served in that capacity during the war. In 1870 he succeeded Dr. Wagner as a member of the Chicago Board of Health.
- Jas. R. Freeman, M.D.**, Exalted Ruler of the Minneapolis Lodge of Elks, and one of the best known and most popular residents of that city, died of pneumonia January 4. Dr. Freeman was born in Biddeford, Me., and was 38 years of age at the time of his death. He was graduated from Dartmouth College with honors, and afterwards studied medicine, removing to Minneapolis about eleven years ago, where he has since resided.
- Wm. L. Leonard, M.D.**, Winterset, Iowa, December 19. He was a graduate of Ohio Medical College, 1852, and later of Jefferson Medical College. He was Assistant Surgeon Thirty-ninth Iowa Volunteers 1862, and in 1863 Surgeon of Seventh Illinois Volunteer Infantry, and for a time served on General Dodge's staff. He was a member of the Madison County (Iowa) Medical Association and of the Iowa State Medical Society. He was an active Mason and a Presbyterian.
- Jas. F. Gayley, M.D.**, died at Philadelphia January 9, in the seventy-sixth year of his age. He graduated at the University of Pennsylvania in 1848, and continued in the practice of his profession until a short period before his death, enjoying during that time the warmest confidence of a large

clientele of families in all ranks of life. He was the author of a history of the Medical Department of the Jefferson College, and also contributed to many medical journals during his career. He was a leading member of the Presbyterian Church, a kind and sympathetic physician, and his loss will be mourned by all who knew him, not alone for his skill, but for his charity, his attention to the suffering, and his deep religious fervor,

David Raymond Fox, M.D., aged seventy-one years and two months, died at his residence at Jesuits Bend, La., Dec. 29, 1893.

Dr. Fox was born Oct. 14, 1822, at Woodville, Miss., and was the third son of the Rev. Jas. A. Fox and Sarah Otis. He received his education at home, under private tutors, and in 1842 entered the medical department of the University of Louisiana, graduating March, 1845. He at once began the practice of his profession, first locating in Warren County, Miss. During the summer of 1847, he spent several months at Dead-man's Bend, Concordia Parish, La., where he treated the cholera of that year.

The following season he was engaged as Surgeon on board the *S. S. Pacific* plying between New Orleans and Central America, where he acquired much experience in the treatment of tropical fevers. In 1852, he located in the parish of Plaquemines, La., where he has since remained.

He has always been an active member of his profession, being one of the founders of the Louisiana State Medical Society, in which he has taken an active interest, serving several times as Vice-President, and once as President in 1886, at the annual meeting held at Alexandria, La. In 1887, he served as Vice-President of the Ninth International Medical Congress held at Washington, D. C. He has always been an interested member of the AMERICAN MEDICAL ASSOCIATION, and a liberal contributor to medical literature.

A loving father, a devoted husband, a beloved and skilful physician, he leaves a bereaved family and a host of friends to mourn his loss. T. B. F., in *New Orleans Picayune*, December 30.

Charles Gilman Smith, M.D. of Chicago, died January 10. Dr. Smith was born at Exeter, N. H., Jan. 4, 1828. At 16 he passed the examination at Harvard College, and was accepted as a sophomore, graduating in 1847 in the literary department. Soon after he began the study of medicine in his native town, taking his first course of lectures at the Harvard Medical School in 1848-49. Afterwards he went to Philadelphia and continued his studies at the University of Pennsylvania, from which he graduated in 1851. He then went to Boston, where for two years he was Attending Physician at the Almshouse Hospital. In February, 1853, he came to Chicago, and began what soon developed into a highly prosperous and successful practice. During the war he was one of the six physicians placed in charge of the prisoners at Camp Douglas in this city. In 1868 Dr. Smith went abroad to study in the hospitals of France, Germany, and England. On his return he lectured in the Woman's Medical College for some time. He was next made Consulting Physician at the Women's and Children's Hospital and at the Presbyterian Hospital. He was also a Trustee for several years for the Peck Home for Incurables, in which he took an active interest. Dr. Smith, in addition to his private practice, served a number of the more important insurance companies as their examining physician, a line in which he had an extensive experience.

Dr. Smith had a wide acquaintance among men of letters and enjoyed the confidence of many noted authors, being a personal friend of Oliver Wendell Holmes. He was President of the Harvard club and of the Chicago Literary club. He was an excellent presiding officer, and one of the best toast-masters in the city. Dr. Smith was married in 1873 to Harriet G., youngest daughter of Erastus F. Gaylord of Cleveland, O., who, with a sister, Miss Elizabeth Smith of Exeter, N. H., survives him.

He was Chairman of the Committee of Arrangements for the ASSOCIATION meeting held in Chicago in 1887.

Ralph Lesslie, M.D., of Toronto, December 20, on the Island of Dominica. He was a graduate of the University of Toronto, and had a romantic history; served as Surgeon-Major with the Turkish army during the Servian war, and was present at the siege and capture of Alexinatz; accompanied the victorious army on its march from Alexinatz to the Danube across the Balkan Mountains.

During the Russo-Turkish war served with the Red-Cross ambulance attached to Dervish Pasha's army covering Batoum, where he saw some hard fighting, and with his colleague, Surgeon Hope, accompanied the attacking column on one occasion, attending the wounded under heavy rifle fire. For the services they rendered in this battle they were publicly thanked by Field Marshal Dervish Pasha and recommended for the Order of the Medjidie, which they afterward received.

After two months' services in the Georgian Mountains, and witnessing various unimportant skirmishes, Dr. Lesslie was ordered to Kars and rode from Trebizond to Erzeroum over the road by which the 10,000 Greeks retreated. At Erzeroum he received orders to return to Constantinople, whence he was again ordered to the front to join the army of the Shipka Pass, where he again saw hard fighting and rendered good service. Thence he was sent to join the army for the relief of Plevna and was present at the battles of the Kamarli Pass and Taskeshan, where Baker Pasha, with a small force, kept Gourko's army at bay until the retreat of the Turkish army was secured.

From Taskeshan he accompanied Suliman's army on its memorable retreat, in the depth of winter, across the Rhodope Balkans to the Aegean Sea, and finding the medical service of the army disorganized, attached himself to the rear guard and attended the wounded under fire during three of the actions in which the rear guard was engaged.

At the close of the war Dr. Lesslie was appointed medical officer to the Turkish Compassionate Fund (organized by the Baroness Burdett-Coutts), and for three months was in medical charge of 7,000 refugees in the mosques of St. Sophia and Sultan Achmet. He afterward served with the English army during the Zulu war, but was not present at any of the engagements. He accompanied Clarke's column on its march to Ulandi and return to the coast, and was attached to Major Martyr's party of dragoons during the first portion of their chase after Cetewayo.

For the next two years he held resident hospital appointments in London and Trinidad, and after a visit to India, China and Australia, went to the Congo with Major-Gen. Sir F. Goldschmid on a special mission for the King of the Belgians. On his return to Europe he was thanked by the King for his services and was sent out to Africa again with Sir F. de Winton as principal medical officer of the Congo Free State.

After two years' of traveling and hard work in the heart of cannibal Africa, varied by occasional fighting with hostile natives on the Upper Congo and its tributary, the Kasai, Dr. Lesslie was again thanked by the King for his services and personally decorated by His Majesty with the Order of Leopold. A year later he received the Congo Star, an order instituted by the King to reward special service in Africa.

After five months' study in Berlin, and seven months' travel in Italy and Austria in medical charge of Sir R. Burton, the great traveler and orientalist, he went for a tour around the world, visiting India, Siam, China and Japan en route. He afterward visited Chili, in South America, and made a voyage up the Amazon.

PUBLIC HEALTH.

Measles.—The epidemic of measles is prevailing in New York.

Smallpox at Reading, Pa.—It is announced that for the first time in eleven months no smallpox signs are to be seen, although there are still a few cases in the hospital.

Diphtheria.—Recently the remains of a patient that had died of diphtheria was taken into a church at Buffalo. The

undertaker opened the coffin so as to give an opportunity to see it. Since, seven have died of the disease as the result of this exposure.

International Sanitary Congress.—The President has appointed Edward O. Shakespeare of Philadelphia, Stephen Smith of New York, and Preston H. Bailhache, M. H. S., as delegates to represent the United States at the International Sanitary Congress, which meets in Paris January 24.

Department of Public Health.—The Ramsay County (St. Paul) Medical Society at their monthly meeting held January 7 recommended the establishment of a Department of Public Health. They urge the bringing of that department on a footing with other Departments, with a Secretary at its head who shall be a member of the President's Cabinet.

Lecture by Surgeon General Sternberg.—A course of lectures to be given under the auspices of the Sanitary League of Washington, D. C., was commenced January 8 by Dr. Sternberg, the Surgeon General of the Army. The subject of the discourse was disease germs, the object of the lecturer being to show to his audience how easy it is to prevent the spread of certain dangerous diseases when they fasten on a household or neighborhood. Photographs of pathogenic micrococci, bacilli and spirilli were thrown on the screen to illustrate his remarks. Moist heat in the form of steam or hot water was represented as the best germ killer or disinfectant. Boiling was a sure germicide; at 212 degrees F. all spores perish. A heat of 140 degrees F., continued for ten minutes suffices to give safety, but it is better to increase the heat and prolong its duration. Milk, water or soup that has recently been boiled is free from infection but if allowed to stand for some time in the vicinity of danger, germs may alight upon it and breed with amazing rapidity. The germs of cholera and fevers multiply wonderfully in milk and soups. Articles of food are often infected through the instrumentality of flies. These alight on contaminated surfaces and their feet become soiled with germs which are afterwards transferred to substances prepared for table use. Sunlight is deadly to germs. Those of cholera are unable to resist an exposure of three or four hours to the rays of the sun. Drying, also, is efficient against cholera; but desiccation will not destroy the germs of consumption, diphtheria or typhoid fever, which are capable of living for months in the dried state. Lime wash or common white-wash is valuable as a disinfectant. It destroys the germs in the excretions of cholera patients. A solution of carbolic acid, five parts in a hundred parts of water, is also a good disinfectant for excreta. The products of coal tar are new and valuable agents for the same purpose. Little boxes of chlorid of lime, (bleaching powder), hermetically sealed and quickly used after being opened are suitable as a disinfectant for household use. Six ounces of the powder in a gallon of water makes an excellent disinfectant solution, but it must be used shortly after it is prepared as exposure to the air destroys its efficiency. Burning is the best method of disposing of expectorated matters. The germs of cholera and typhoid fever in the excreta and of influenza, diphtheria, pneumonia and consumption in the expectorations can be destroyed easily; but as regards the eruptive fevers, the germs of which are not fully identified, the only sure method of dealing with infected matters such as soiled clothing and exfoliations from the surface of the body is to burn them.

Minnesota State Board of Health.—The new State Board of Health met at the Governor's office January 9 to organize under the new law. The members were all present, as follows: Doctors Perry H. Millard, St. Paul; Charles N. Hewitt, Red Wing; Franklin Staples, Winona; C. F. McComb,

Duluth; K. Hoegh, Minneapolis; W. J. Mayo, Rochester; W. H. Leonard, Minneapolis; Edward Boeckman, St. Paul; W. L. Beebe, St. Cloud.

The report of the Secretary, Dr. Charles N. Hewitt, as being the report of a board now passing out of existence, was made very comprehensive, and covered practically the history of the Health Service during its twenty-two years of existence. The methods of coöperation now pursued by the State and local boards of health are the result of ten years of trial of different methods and of legislation gradually adopted. In 1885 the Service was given charge of infectious diseases of domestic animals, the control of offensive trades and the oversight of water supplies. In 1887 monthly collection of statistics of births and deaths was made obligatory, and the secretary of the State Board became registrar of vital statistics. The Service consists numerically of the State Board and 1,638 local boards. The entire population of the State, except in a few sparsely settled districts, is now provided with local sanitary service. There are in the Service 232 physicians serving as health officers. In many cases chairmen or clerks of township boards represent the service, and 70 per cent. of the reports of infectious diseases come from them.

Dr. Hewitt says that the time has come for the recognition of public health as a subject of instruction in educational institutions, and that it should be provided for at the normal schools by lectures and laboratory work. Dr. Hewitt has devoted a good deal of time and study to the culture of virus for vaccination. He uses the calf lymph produced by the London Board of Health. Since he introduced it it has been used in over 7,000 cases in the State.

After the reading of Dr. Hewitt's report came the election of a president and secretary. Dr. Staples as President and Dr. Hewitt as Secretary were reëlected for the present year.

Meeting of State Board of Health, Lansing, Jan. 12, 1894.—The State Board of Health held its regular meeting at its office in the Capitol, Jan. 12, 1894. The meeting was called to order by President Frank Wells of Lansing; Dr. Gray of Pontiac, Prof. Fall of Albion and Dr. Baker were present. The regular business of auditing of bills and accounts was transacted.

Prof. Delos Fall of Albion, Committee on Water Supply and Purification of Sewage-contaminated Water, made a preliminary report. Prof. Fall has undertaken an analysis of the uncontaminated spring waters throughout Michigan in order to ascertain the normal amount of chlorin. Ten parts per million has been considered the maximum amount of chlorin which should be found in good spring water, but he thinks that the standard will have to be raised somewhat for Michigan, as most of the samples that he has examined contain over ten parts of chlorin per million of water. Prof. Fall proposes to continue this analysis of spring waters, and would be glad to get samples of such spring water as is not contaminated by leachings from barns, stables, residences, etc. He wants a half-pint of such water in a perfectly clean bottle, with a new cork, with reliable statement of source and surrounding conditions. His address is, Prof. Delos Fall, Albion, Mich. The State Board voted to aid Prof. Fall in his work, and his report will be looked for with interest, as it will supply a standard by which to judge of the extent of sewage contamination of waters hereafter examined chemically.

The Secretary presented an invitation from the leading citizens of Menominee for the State Board to hold one of its Sanitary Conventions in that city. The Board will accept the invitation, and appointed Prof. Fall a committee to make arrangements for such a convention.

The subject of the further continuance of the Michigan inspection of immigrants was discussed. Secretary Baker thought that the Michigan inspection of immigrants which has been in progress for some time has done much to prevent

the introduction and spread of dangerous communicable diseases. He also thought that the stand the Michigan State Board had taken had been the means of raising the standard of quarantine in this country, tending as it has toward the disinfection of the baggage of all immigrants coming into this country. It is not improbable that the inspection at the border has been the means of keeping Michigan free from smallpox, and it is probable that it has lessened the introduction of other diseases. The Michigan inspection rules for disinfection were carried out during the summer at Levis, near Quebec, and are now being carried out at Halifax, under the direction of Dr. Wickwire, Port Health Officer at Halifax. Smallpox is now quite prevalent in several States, but it is hoped that Michigan will not be visited by this disease. Owing to the depression in mining, lumbering and other business, immigration will probably be much lessened. The recent judicial decision was discussed, and a resolution adopted as follows:

Resolved, That in view of the adverse decision of the Hon. Joseph H. Steere of the Eleventh Judicial Circuit, declaring the penalty portion of the Michigan Quarantine Law unconstitutional, the immigrant inspection at the Michigan border is hereby suspended from and after Jan. 13, 1894."

It is understood that legal measures have been taken to obtain a decision on the subject by the Supreme Court.

The Secretary presented a letter from Supt. Clarke of the School for the Deaf, at Flint, in which Mr. Clarke requested the State Board to send an expert to aid the local physicians in stamping out the outbreak of scarlet fever in that institution. The Board voted to send an expert.

Secretary Baker had received an invitation to read a paper before the Wayne County Medical Society on the "Prevention of Pulmonary Tuberculosis or Consumption as a Disease Dangerous to the Public Health." In view of the recent action on this subject by the State Board, and the proposed coöperation of the Detroit Board of Health in the same direction, the State Board requested the Secretary to accept the invitation.

The subject of a Chair of Sanitary Science at the State Normal School, and at the State Agricultural College, was presented by Dr. Baker. He mentioned that the State Board of Agriculture had already been memorialized by the President and other members of this Board and himself, to establish a chair of hygiene; but he thought the Board as a whole should continue to exert influence. He argued that the State law compelled the common schools of Michigan to devote time to the teaching of hygiene, but that there was not much provision for the proper education of those teachers who are compelled to teach hygiene. The State Normal School is devoted to the training and education of teachers, and the State Agricultural College has its vacation in the winter in order that its students may teach, yet neither of these institutions has a Chair of Sanitary Science. The State Board of Health had already put forth its efforts for such a chair at the Michigan University, and a Laboratory of Hygiene had been established and is now doing great good. Dr. Baker thought that the youngest pupil in our schools should have an idea of how the most dangerous communicable diseases are spread, and that it would be just as practicable to teach them the restrictive measures, as it is to teach them all about the bones, muscles and nerves, as is now attempted. Each pupil should also know just what disease causes most deaths in Michigan and just how it may be prevented or avoided. But how are these pupils to be taught such subjects, when there is practically no adequate provision for the education of the teachers? Prof. Fall said he was very glad to say that Albion College was teaching sanitary science. A large class of the best students in the College have this course of training.

On motion of Prof. Fall, the Board voted that a committee of three be appointed by the President to memorialize the State Board of Education to establish a chair of sanitary science at the State Normal School. Prof. Fall of Albion, Dr. Baker and Dr. Milner of Grand Rapids were appointed to act as this committee.

On motion of Dr. Baker, it was voted that Dr. Gray of Pontiac act as chairman of a committee to memorialize the State Board of Agriculture to establish a chair of sanitary science at the State Agricultural College. It was also voted that President Wells and Prof. Vaughan of the University be the other members of this committee.

Considerable other business was transacted, and the Board adjourned at a very late hour,

MISCELLANY.

Philadelphia Notes.

An exceptionally mild winter thus far has prevailed in this section of the country, which, though doubtless a great boon to the poor, is regarded as of questionable benefit to the entire community; since the general impression is that the prevailing humidity is in some way etiologically related to the present epidemic of influenza, or epidemic catarrhal fever. A twelvemonth ago, we had the coldest January on record for over twenty years in this locality; but this year, no evidence of cold weather is yet to be seen in the streets, and fears are expressed of an ice famine next summer. The first week of the new year showed an increase in the city mortality, directly due to grip and its results. Thus, there were 63 deaths specifically charged to this disease, besides 109 of pneumonia, and 39 of heart disorders, which were also ascribed to the grip. While the total number of deaths from all causes during this week was 613, an increase of 3 since the preceding week, and of 63 as compared with the same week of last year, there was a decrease of 40 from the rate of the same week of the year 1891, when the present epidemic began. Of the total number above stated, 188 were children under five years of age. There is also a moderate increase in the mortality from diphtheria, scarlatina and typhoid fever, which, however, are not prevailing in epidemic form. There were no deaths during this period from smallpox or typhus, and no cases of these forms of zymotic disease are now believed to be present in the city. It may be of interest to note that, during the first week after the holidays, 22 persons died of old age in Philadelphia. No epidemic of senility, however, is anticipated.

Several cases of acute, confusional insanity accompanying or due to influenza have been recently reported. One case was a medical student at Jefferson College who became violently insane during an attack of influenza and had to be removed to Jefferson Hospital. Some cases have delusions with homicidal tendencies. Thus, a professor in the High School, while suffering from what was thought to be a mild attack of grip, escaped from his room at night, and climbing by means of a veranda into a neighbor's house, he there created much excitement by flourishing a big knife and threatening to kill the neighbor, who he thought had abducted his wife. He finally came into the hands of the police, who required much explanation before they would believe that no crime had been committed, and the escapade nearly cost the patient his life. In another case the result was even more tragical, but the agency of the grip in its causation is less manifest. Professor Shortlidge until recently was the Principal of a well-known academy for boys at Media, near this city. He had been depressed by financial troubles and by an attack of grip, and had recently given evidences of some mental alienation with suicidal tendency. On New Year's day, he walked out of the house and his wife (to whom he had been recently married, having been a widower for years), went after him to bring him back. Pistol shots were heard, and the first to arrive at the grove where the occurrence took place, found Mrs. Shortlidge on the ground, dying from several wounds, and her husband leaning over her with the recently discharged pistol in his hand. He was taken to the jail, constantly asking for his wife, and only occasionally realizing for a brief moment the awful nature of the deed that he had committed. A Commission in Lunacy, consisting of Drs. Chas. K. Mills and Dr. Chas. S. Trumbull, is now investigating his mental condition, but there is no one entertains a doubt as to the result of their examination. There is a question, however, as to whether this could be properly charged to the account of the grip or

not, since the patient had made a railway journey to this city a few days before, in order to purchase the pistol, which he had kept secreted until he used it with such fatal effect. This does not look like the delirium of an acute disease, but more like homicidal insanity, in producing which the depressing effects of grip may have been an incidental factor.

Last fall, a ship came to this port from India, manned entirely by Lascars, a number of whom were sick with a disease which Port Physician Brenning pronounced beri-beri. Several deaths occurred from the disease during the voyage. About a dozen of the sick were taken to the hospital and isolated and the ship quarantined. No further deaths occurred and no new cases developed. It is believed that this is the first time that this disease has been recognized in this city.

The annual meeting of the College of Physicians for the election of officers was held January 3. Dr. S. Weir Mitchell was reelected President. Dr. I. Minis Hays has resigned from the Library Committee. Dr. Frederick P. Henry is Honorary Librarian.

The County Medical Society will hold its election next week, but as there is no other nomination for President, Dr. De Forrest Willard will be unanimously reelected to this office. Dr. Willard has just finished a very valuable course of lectures on the "Mütter Foundation on the Surgical Pathology and Surgery of the Spinal Cord," at the College of Physicians.

Prof. J. M. Da Costa, who has just recovered from an attack of grip, will deliver one or two special lectures on some topic not yet definitely determined upon, before the students of the medical department of the University of Pennsylvania in response to a very flattering invitation from the Trustees and Faculty. He continues his weekly clinical lectures at the Pennsylvania Hospital on Saturdays as usual for the winter months, during his term of service as Attending Physician.

The "Standing Committee on Cholera" of the College of Physicians, sent out 800 letters to physicians in and near Philadelphia requesting their assistance in the work of sanitation of the city during last summer, and to those who consented to act with the Committee blanks were sent, for reporting of nuisances in the form of dirty houses, yards or streets, bad paving, neglect of duty by the cleaning and paving contractors and so on. During the summer about sixty complaints of the condition of various streets and houses were received, mostly as to accumulation of filth or garbage or foulness and overfilling of privy vaults. These were referred by the Committee to the Director of Public Safety and to the Board of Health for action. Some of the members of the Committee investigated for themselves besides, and without exception the complaint so examined proved to be well founded. The authorities seem to have received the complaints addressed to them in the proper spirit and to have done what was possible to remove the causes.

A large number of complaints of the manner in which streets were torn up for miles and left so torn up during many weeks were made, and much sickness of the nature of low continued fevers was attributed by the Committee's correspondents to this cause, but in spite of their efforts to get this state of things done away with, a similar condition exists even at present, and no attempt has been made by the authorities to prevent it.

Hospital Notes.

The Woman's Christian Association Hospital at Omaha, was slightly damaged by fire January 4.

The Trustees of the Santa Fe Hospital have decided to erect a building in Topeka this year, and work will be commenced in the early spring. The building and grounds will cost \$100,000, which sum is on hand.

German Hospital in Philadelphia.—This institution according to its annual report is now supplied with water from two deep wells in the hospital enclosure. 2,485 patients were admitted during the year.

The Annual Report of the State Hospital for the Insane at Warren, Pa., shows 890 patients in the institution, representing 36 counties of the State; 276 were admitted during the year, and 206 discharged; 63 were restored and 57 died. The cost of maintaining these was \$165,000.

Amphitheater Condemned.—The Building Inspector has condemned the clinical amphitheater of the City Hospital at Indianapolis. The building was constructed about thirty years ago. The same authority also discovered that the Hospital was without fire escapes, as required by law for all buildings over three stories in height.

St. Mark's Free Hospital and Dispensary of Chicago for rectal diseases. A charter has been secured for the above named institution by Dr. Joseph B. Bacon, Dr. Isabel Fish Taylor, and E. D. Stevens, and arrangements are being made to give Chicago a free hospital patterned after the well-known St. Mark's of London.

The Trenton Gazette in speaking of a new hospital to be constructed at Trenton says:

"One of the chief requisites is absolute freedom from dust, a quantity imperceptible to the human eye, entering the incision, often producing fatal results. To secure this important condition a room is being built with enameled brick, making it dust proof."

The conclusion is sound, if the premise is startling.

Hospital for Cripple Creek.—Mother Superior Baptiste of the Sisters of Mercy has purchased a large ten-room house between Third and Fourth Streets on Bennett Avenue, Cripple Creek, Colo., and is now busily engaged, with the aid of three sisters, in getting it ready for hospital use, and on Saturday next hopes to be able to receive patients. The camp is sorely in need of a place where the sick and injured can be cared for, and the miners generally consider themselves fortunate that so competent a nurse as Mother Superior Baptiste is to be at the head of the hospital.

Officers Elected.—The following officers of the West Philadelphia Hospital for Women were elected January 8: President, Dr. Anna P. Sharpless; First Vice-President, Miss F. B. Peirce; Second Vice-President, Miss Mila F. Smith; Treasurer, Miss E. Haslem; Secretary, Miss M. Sellers.

The following constitute the Board of Advisers: B. B. Comegys, J. Roberts Foulke, Thomas Scattergood and William DeCou; Solicitor, William C. Stoeber. The District Physicians are Dr. Helena Goodwin, Dr. Elizabeth W. Griscom, Dr. Adelaide W. Packham and Dr. Elizabeth A. Ryder.

Harper Hospital.—The Trustees of Harper Hospital, Detroit, held their annual meeting January 8 and the following officers were elected: President, S. M. Cutcheon; Vice-President, J. L. Hudson; Secretary, Bryant Walker; Treasurer, C. A. Black; Chief of Staff, E. L. Shurly. M. C. Strong was reappointed superintendent and Mrs. L. E. Gretter principal of the Farrand Training School. The following additions to the medical staff were made: consulting physician, Dr. Charles Douglass; attending physicians, Drs. D. S. Campbell and J. J. Mulheron; consulting oculist, Dr. L. Connor; attending oculist, Dr. G. E. Frothingham, Jr.; neurologists, Drs. C. W. Hitchcock and David Inglis; assistant laryngologist, Dr. C. D. Anderson; gynecologist, Dr. N. P. Manton, in place of Dr. Helen F. Warner.

Insane Hospital Report.—The Indiana Central Hospital for the Insane made its annual report to the Governor January 8. The estimated value of the buildings and real estate is \$1,450,000, and the appraised value of the personal property is \$202,696.59. The financial statement shows the expenditure for the year \$259,924.19, or \$75.81 less than the amount appropriated. The hospital has turned \$2,191.45 into the State treasury during the year.

The number of patients treated in the twelve months was 992 women and 912 men. Deaths to the number of 105 occurred, and 286 patients discharged. The superintendent

has made many permanent improvements, including several thousand feet of cement walks, the building of a new kitchen, the renovating of buildings, tunnels and cellars, and the sinking of three driven wells. He has made changes in all the departments, has built sewers, a new barn and torn out old buildings. He recommends that a pavilion for contagious diseases be erected, also a cold-storage room, and a furnace for destroying rubbish.

Wilkesbarre, Pa., City Hospital.—The annual election was held January 6.

Medical Staff—consulting physicians, (ex-officio directors,) Dr. I. E. Ross and J. B. Crawford; attending physicians, Dr. J. A. Murphy, Dr. G. W. Guthrie, Dr. R. Davis, Dr. O. F. Harvey, Dr. L. I. Shoemaker, Dr. A. G. Fell.

Associate Physicians—Dr. W. S. Stewart, Dr. Charles Long, Dr. J. T. Howell, Dr. Ernest Buckman, Dr. W. G. Weaver, Dr. J. T. Matlack.

Ophthalmologist, Dr. L. H. Taylor; registrar, Dr. G. Maris Gibson; resident physician, Dr. Walter C. Kyte and Dr. J. E. Robins; committee on nurses' training school, Mrs. C. M. Conyngham, G. M. Reynolds, Dr. Lewis H. Taylor, Dr. O. F. Harvey; head nurse and principal of training school, Miss C. B. Wicks; lecturers, nurses' training school, Drs. Harvey, Shoemaker, Fell, Guthrie, Taylor and Stewart.

The Building Committee reported that the new building was proceeding as fast, if not faster than the contract calls for, and unless something unseen comes, the contractor will turn over the wards to the officers a month ahead of time. There are ten pupils in the nurses' training school, and a cooking school is to be opened this month, with a skilled nurse-cook from Boston.

Dr. Rutledge of West Indianapolis, was severely injured by being thrown from his buggy January 13. He sustained a severe fracture of the knee.

The Kentucky School of Medicine began its 38th annual session January 3, with 208 matriculates. The faculty propose the erection of a hospital building 100 by 60 feet four stories in height, adjoining the College.

Are Now Weeklies.—The *Kansas Medical Journal* and the *Philadelphia Polyclinic* are now issued weekly, instead of monthly as heretofore. Their courage and enterprise should be rewarded.

The Washington State Board of Medical Examiners held the regular semi-annual meeting in Seattle on January 2, at which time twelve of the twenty-three applicants who appeared for examination were rejected. The Board has revoked the granting of temporary permits to practice until the regular dates for the examinations.

National Dispensary.—Our readers will be interested to learn that a new edition of the National Dispensary by Lea Brothers & Co., is announced. It will include all the changes made necessary by the new Pharmacopœia. Professor Charles Caspari of Baltimore, succeeds the late Professor Maisch in the section of the work heretofore prepared by that *savant*.

Smallpox Cadaver.—A smallpox cadaver was discovered in the dissecting room of the Bellevue Hospital Medical College January 9. The body proved to be that of a man who died at Blackwell's Island Charity Hospital January 2. It was carried to the Bellevue Hospital morgue instead of the contagious disease morgue and when unclaimed, was turned over to the Hospital authorities as a suitable subject for dissection.

A Four Years' Course at Jefferson Medical College.—At a meeting of the Faculty of Jefferson Medical College held on Jan. 8, 1894 it was unanimously resolved to institute a compulsory four years' course with the session of 1895-96. This step was taken in order that the large clinical service of the Jefferson College Hospital (350 cases a day) might be utilized to the fullest extent in carrying out the desire of the Faculty to provide advanced medical education of practical character.

Dr. Louis E. Atkinson of Mifflintown, Pa., for ten years a member of the House of Representatives from the Eighteenth Congressional District, will be a candidate for the nomination for Governor at the next State Republican Convention, and will shortly make a formal announcement of his candidacy. The Doctor is a cripple and walks on crutches. He was defeated for the nomination for Congress in his district two years ago by Congressman Mahon of Chambersburg, and has since been quietly at his home in Mifflintown.

Chemic Glassware.—The Board of General Appraisers at New York have decided, in the matter of the protest of Eimer and Amend, heard Oct. 25, 1893, that 1, crystallizing dishes made of thin, Bohemian glass and used for crystallizing salts, chiefly in laboratories; 2, glass beakers, or dishes with glass covers, used exclusively for growing bacilli germs therein; and 3, glass mortars and pestles, such as are chiefly used in laboratories, are commercially known as "chemical glassware," and when for use in laboratories, are dutiable at 45 per cent. ad valorem.

National Guard.—Dr. Joseph D. Bryant, Surgeon-General of the National Guard of the State of New York, has reported to National Guard Headquarters a list of the medical equipments and appliances which he recommends are needed for fully supplying the surgeons, hospital stewards and the members of the recently organized Hospital Corps with practical apparatus.

The list represents an expenditure of about \$5,000. Adjutant-General Porter states that the various instruments will be purchased as soon as possible, though there may be some delay, owing to manufacturers not keeping such a large stock on hand.

The organization of the Hospital Corps is in active progress. The Corps takes in eight men from each regiment, four men from each battalion and one man from each separate company, battery or troop.

The College of Physicians of Philadelphia, held a special meeting on the 12th inst., to consider the expediency of the compulsory reporting of phthisis pulmonalis by physicians as cases of contagious disease. The question was brought before the College at a previous meeting by Dr. Flick, who is an enthusiastic advocate of the contagiousness of tuberculosis, and who endeavored to get a resolution adopted similar to that which the County Medical Society recently passed at his instance, petitioning the City Board of Health to place pulmonary consumption upon the list of diseases, cases of which physicians must report under penalty for neglect, and also calling for a system of espionage of consumptives and the disinfection of the premises which had been occupied by fatal cases of the disease. The subject was referred to the council of the College whose report after a full discussion was adopted and the following minute made, at the special meeting: "The Council to which the resolution and the amendment, with reference to the proposed action of the Board of Health concerning tuberculosis has been referred, offers this resolution to the College:

"Resolved, That the College of Physicians believes that the attempt to register consumptives and to treat them as the subjects of contagious disease, would be imposing additional hardship to the lives of these unfortunates, stamping them as the outcasts of society.

"In view of the chronic character of the malady it could not lead to any measures of real value not otherwise attainable.

"That strict attention on the part of physicians in charge of the individual cases, insisting upon the disinfection of the sputum and of the rooms, on adequate ventilation, and on the separation of the sick from the well as far as possible, will meet the requirements of the situation so far as they practically can be met and better than any rules that, for diseases so chronic, can be carried out by a Board of Health.

"That the College of Physicians respectfully requests that no official action be taken in the matter by the Board of Health, except the insisting upon the disinfection of rooms in which consumptives have lived and died, in instances in which such procedure is not likely to have been adopted under the direction of the attending physician."

The discussion was opened by Dr. Owen J. Wistar and was

participated in by Profs. DaCosta, Osler, Wood, Tyson, Roberts, Walker, Mays, S. Solis-Cohen and others. It will appear in an early issue of the JOURNAL, through the courtesy of the Philadelphia College of Physicians.

THE PUBLIC SERVICES.

An Army Medical Board will be in session at Washington City, D. C., during April, 1894, for the examination of candidates for appointment to the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before March 15, 1894, for the necessary invitation, giving the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from which they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal acquaintance, from at least two reputable persons, as to his citizenship, character and habits. The candidate must be between 22 and 28 years of age, and a graduate from a regular medical college, as evidence of which his diploma must be submitted to the Board.

Successful candidates at the coming examination will be given a course of instruction at the next session of the Army Medical School, beginning in November, 1894.

Further information regarding the examinations may be obtained by addressing the Surgeon-General, U. S. Army, Washington, D. C.

GEO. M. STERNBERG, Surgeon-General, U. S. Army.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from January 6, 1894, to January 12, 1894.

Capt. CHARLES E. WOODRUFF, Asst. Surgeon U. S. A., extension of leave of absence granted is further extended one month and twelve days. First Lieut. CHARLES F. KIEFFER, Asst. Surgeon U. S. A., is granted leave of absence for two months, on surgeon's certificate of disability, with permission to leave the Department of Dakota.

First Lieut. EDWARD L. MUNSON, Asst. Surgeon U. S. A., is relieved from duty at Jefferson Bks., Mo., and will report in person to the commanding officer, Ft. Assiniboine, Mont., for duty at that post.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending January 6, 1894.

FRANK C. COOK, Washington, D. C., commissioned an Asst. Surgeon in the Navy, Jan. 4, 1894.

CHICAGO, JANUARY 27, 1894.

No. 4.

ORIGINAL ARTICLES.

REPORT OF A CASE OF CEREBRAL TUMOR, DIAGNOSED BY FOCAL SYMPTOMS, WITH OPERATION, SUCCESSFUL REMOVAL OF TUMOR AND EXHIBITION OF SPECIMEN.

Read before the Chicago Medical Society, Dec. 18, 1893.

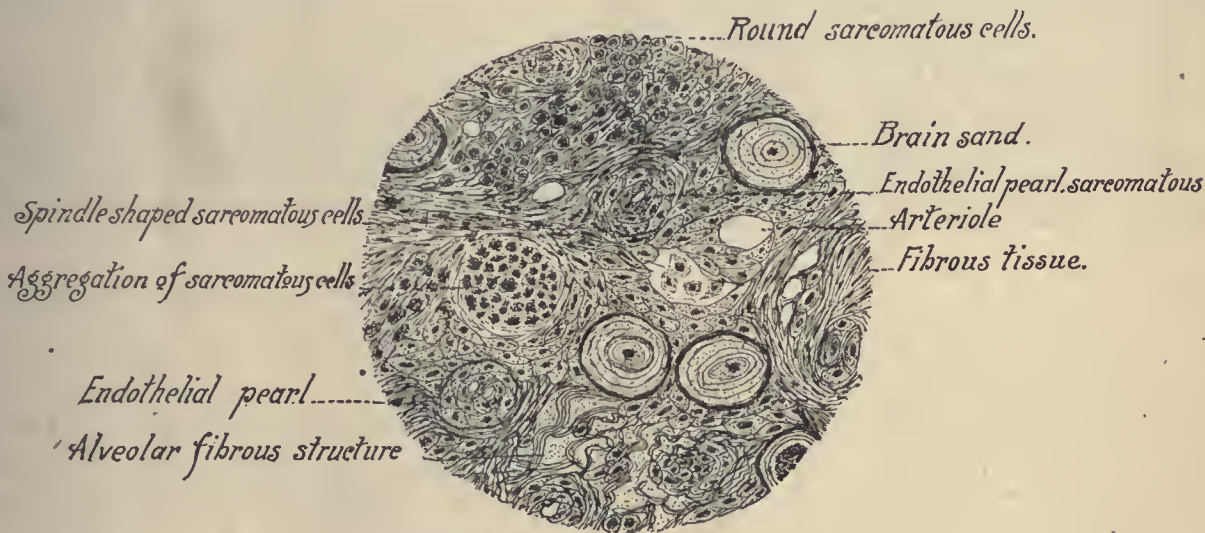

BY D. A. K. STEELE, M.D.
CHICAGO.

In reporting to you a case of cerebral tumor diagnosed by focal symptoms and successfully removed, I desire to express my obligations to Drs. R. H. Isbester, O. A. King and W. E. Quine for a careful history, thorough examination and accurate diagnosis of the case before it was referred to me for operation, and to Dr. T. A. Davis for valuable assistance during and after the operation.

a thorough examination, and placed the patient on large doses of iodid of potassium for the purpose of clearing up the question as to whether or not there might be syphilitic brain disease, although no history of any was elicited. Specific treatment produced no effect on his symptoms. November 18 the patient was operated upon. The history was as follows:

The patient, John Pierson, was born in Sweden, Jan. 18, 1852; he is 41 years old. He is the eldest of nine children, four boys and five girls. His family was always very healthy. His mother, brothers and sisters are living. His father died of old age at 77. He is a laboring man; married and has six children, four girls and two boys, all of whom are living. Upon arriving in this country, May 15, 1881, he went direct to Batavia, Ill., where he remained six years. He then went to St. Charles, Ill., and lived there until he came here for treatment.

About five years ago the patient while asleep in bed was aroused by a sharp pain of a cramping character, in the calf of the right limb, which lasted from two to five minutes. It was very severe. This pain and the following plantar contraction of the toes, constituted the first attack. About one

ENDOTHELIAL FIBRO-SARCOMA OF BRAIN.

The subject of cerebral tumors became interesting to surgeons in 1879 through the reports of cases by Macewen of Glasgow, and again especially in 1884, when Bennett and Godlee of London, arrested the attention of the surgical world by their narration of the diagnosis and removal of a subcortical tumor of the brain. Since then, many cerebral tumors have been diagnosed by focal symptoms and a few successfully removed. Horsley, Keen, Hirshfelder, Morse, Deaver, Nancrede and others have reported cases.

I desire to submit the following case as an addition to the literature of the subject:

The patient was referred from the Dispensary clinic of the College of Physicians and Surgeons to my regular Saturday clinic for operation in the early part of October. When I first saw the case I made

week later he had a second cramp, which was in severity the equal of the first. It occurred in the same region and was about the same duration. The cramps appeared at an interval of seven or ten days and were about as severe as the first. Just preceding a spasm there was a prickly, parasthetic feeling in the locality of the expected monospasm. Two things characterized these spasms: 1, that they extended up the right limb gradually until they reached the right groin; they then passed into and extended in the lower part of the trunk, when they became more painful; 2, after each spasm the limb was weaker, so that as the spasms became more frequent they caused a general weakening of the muscles and therefore lameness. The spasms continued to extend upward until the right arm and the face were affected. It took about one year for the whole right side to become affected. The spasm would always start in the same place, creep upward to the trunk, and then die away before the arm and face were affected. After the right side was affected the patient sometimes had a prickling sensation in the left leg, but at no time were there any spasms.

During the whole period of five years the patient never had an attack of unconsciousness. He often had very severe headaches, starting in the occipital region and extending to the frontal.

Examination showed motor paralysis and sensory blunting of the right leg; the right patella tendon reflex was much increased; hearing was much reduced in the right ear; there was no choke disc or optic neuritis; none of the orbital muscles were involved. Speech was slow. A diagnosis of cerebral tumor originating in the leg center of the cortical area of the left hemisphere of the brain, and extending downward and forward to the arm and face centers was made, and operation advised, after specific treatment was tried without avail.

The patient was prepared and I was ably assisted during the operation by Dr. T. A. Davis. The toilet of the operating field was thoroughly made the previous day; shaving and cleansing, and a wet 1-2000 bichlorid dressing applied to be worn until time of operation.

After the patient was thoroughly under chloroform a small solid cylindrical rubber band was passed around the head to render bloodless the field of operation in the scalp. Four stitches, as recommended by Dr. F. Shafer of this city, were introduced equidistant apart, binding the rubber constrictor to the scalp so as to prevent slipping. Owing to the extent of the symptoms, showing that the convolutions of the upper half on either side of the Rolandic fissure were involved, the nicety of delicate cerebral localization technique

Endothelial fibro-sarcoma of brain; weight 60 grams; base of tumor showing depression at point of attachment.

was dispensed with and a horse-shoe shaped flap of three inches width was turned down and fixed with one stitch to the integument beneath, to keep it out of the way of the operator. A large button of bone was then removed and the opening enlarged by the rougeur to a size corresponding to nearly that of the scalp flap, a little over three inches in diameter and heart-shaped. Palpation through the meninges showed great resistance over the region corresponding to an inch each side over the upper third of the Rolandic fissure. Below this region the resistance was normal. On opening through the meninges there was found absence of pulsation over the region corresponding to the part offering great resistance to palpation, and slight pulsation below that region.

Faradization with a double brain electrode over the dense tissue was followed by no muscular response, but at the lower margin of this tissue, and on down the Rolandic marginal convolutions there was responsive contraction of arm muscles, increasing as it distanced the dense tissue. Macroscopically the dense tissue presented a yellowish color and bulged into the wound. On digital exploration a tumor of considerable dimensions was found extending down into the brain and readily separable from it, a few slight adhesions of the tumor capsule alone offering any barrier. After outlining the free borders of the growth, a firm pedicle was found attached to the skull, or falx-cerebri at the region of the superior longitudinal sinus. The tumor was "shelled out" quite readily with the fingers leaving the firmer portion, the pedicle, which was removed with a strong curette, after cutting the skull away up to it with the rougeur forceps. A large rent in the superior longitudinal sinus was necessarily made on removing the pedicle, which necessitated firm packing with iodoform gauze of the whole intra-cranial

wound. This readily controlled the hemorrhage, which was enormous for a few seconds; but it prevented the satisfactory closure of the wound with the return of the bone chips. The regular antiseptic dressing was applied and was not disturbed for three days, when the bulk of the gauze dressing was removed, leaving only one small piece over the rent into the sinus. At the second dressing, four days later the remaining piece of gauze was removed.

Slight constitutional disturbances followed the operation; temperature 101 degrees; operation fever for thirty-six hours followed by a decline to normal on third day. There was complete motor paralysis of arm and leg for twenty-four hours following the operation, at the end of which time slight motion returned to leg, and nineteen days later some motion was observed in the arm. Slight but steady improvement has occurred since that time. Although we expected from the origin of the tumor that sensation and motion would return in the arm first, as a matter of fact they returned promptly in the leg, and later in the arm. Sensation was first felt in the shoulder muscles, the next day he could move the arm and on the third day he could draw up the forearm; and now he has good control of the whole arm except the fingers. He has no power and but little sensation in the fingers. He tells me that he is capable of exercising some muscle or making some new movement each day. The patient is now able to sit up, is permitted to walk a little and is anxious to return to his home in time for Christmas.

Endothelial fibro-sarcoma of brain, side view.

The packing prevented the accurate suturing of the scalp; there was an opening of perhaps two inches through which the ends of the strips of gauze were drawn out. At the end of a week these edges were freshened and re-sutured. Now we have a small opening of half an inch through which I keep a minute strip of gauze for capillary drainage. There is granulation tissue covering the wound, and the patient has practically recovered. One week later the wound had firmly cicatrized and the patient returned home.

In regard to the character of the tumor, the specimen was submitted to the Pathological Laboratory of the College of Physicians and Surgeons. The examination was made by S. J. Sornberger and Prof. Evans. Under microscopical examination, both of the longitudinal sinus, that is, the pedicle of the tumor, and the tumor itself, the following characteristics are presented:

1. An abundant fibrous stroma, alveolar in appearance.
2. An abundance of endothelial cells, both large and small. These cells are in places crowded together in dense concentric masses, while others are scattered profusely among the fibers of connective tissue.
3. Calcareous granules, quite abundant, distributed throughout, but rather more abundant in the small tumor from the sinus, and near its upper margin.

Diagnosis.—Endothelial fibro-sarcoma.

Remarks.—As you examine the tumor which I submit to you for inspection, you will observe that it is cone-shaped, bearing a striking resemblance to a small pine cone, although somewhat more irregular in outline. It weighs exactly two ounces. Its vertical diameter is two and a half inches and the trans-

Endothelial fibro-sarcoma of brain, convex surface.

verse diameter two inches. The base is smooth and slightly depressed in the center where it was plucked from the stem or pedicle. The surface presents a papillomatous appearance, small finger-like or tuberculous processes extending downward and outward in all directions but more marked around the apex of the tumor. If we invert it and place it in the same position it occupied in the brain, you will observe that it grows downward and forward from its point

Appearance of operation-wound at time of report.

of origin in the wall of the longitudinal sinus into the Rolandic fissure, displacing the paracentral lobules, and the surface irregularities are probably due to the varying amount of brain resistance to the outgrowth of the tumor. Some portions of it lying in

the great fissure and the smaller projections pushing between the convolutions.

The reaction under the double brain electrode may be explained in part by the atrophy of the adjacent portion of the brain, or motor cells from pressure, and in part by mechanical displacement.

We would infer that the failure to elicit reflex spasm by electric stimulation of the leg center was due to mechanical displacement of the center upward and backward by the tumor, when we find that the removal of the tumor was followed by a prompt return of sensation and motion in the leg. While the slower return of the same function in the arm speaks for pressure atrophy of the motor cells of the arm center.

240 Wabash Avenue.

THE TREATMENT OF IMMATURE CATARACT AND WHEN TO OPERATE FOR CATARACT.

Remarks made in a Conference During the Special Week on Cataract. BY GEO. E. DE SCHWEINITZ, M.D., EDWARD JACKSON, M.D., S. D. RISLEY, M.D., AND H. F. HANSELL, M.D. PROFESSORS AND ADJUNCT PROFESSORS OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC.

Dr. de Schweinitz, referring to the medicinal treatment of cataract, stated that no drugs were known which could dissipate lenticular opacities. Occasionally there was spontaneous disappearance of cataract, for example, in diabetic patients; and even, if certain reports are to be credited, for example those by Nicati, of true senile cataract; but such disappearance could not be ascribed to the influence of medicine.

In like manner, electricity, which from time to time has been recommended, is of doubtful value; in fact, there is no evidence to show that electrical currents have ever had the slightest influence in checking the growth of lenticular opacities. These statements, however, do not conflict with the propriety of treating the subjects of lenticular opacities; 1, by careful testing of the refractive error and prescribing the glass which gives the highest visual acuity; and 2, by exhibiting alteratives, particularly the iodids of soda and potash, sedatives, e. g. bromid of potash, and tonics; for example, strychnia and nux vomica. These, as has often been pointed out by Dr. Risley, diminish the congestion of the choroid coat, and while they do not check the growth of the cataract, they relieve the associated asthenopia and permit the patient reasonable use of his eyes. Moreover, as again urged by Risley, by improving the health of the ocular coats they tend to increase the chances of operative success whenever extraction becomes necessary.

Dr. de Schweinitz further discussed the advantage of the prolonged use of a mild mydriatic drug, not only for its local sedative effect but, in more advanced cases, on account of the improvement of vision through a moderately dilated pupil.

Referring to the artificial ripening of cataract, Dr. de Schweinitz, quoting White, said that these operations might be divided as follows: simple division of the anterior capsule; division combined with iridectomy, as advocated by Mooren; division and external massage (Rhomér); iridectomy and trituration of the lens through the cornea, or Förster's method and the one commonly employed: paracentesis of the cornea, and internal massage directly on the anterior capsule, particularly advocated by Bett-

man of Chicago; and finally, simple paracentesis of the cornea with external massage—a method devised by Pooley and practiced and popularized by White of Richmond. All operations were dismissed except Förster's method, internal massage directly on the anterior capsule, and White's modification of Pooley's operation.

Dr. de Schweinitz's experience was limited to Förster's method and that advocated by Bettman, with neither of which he had had unfortunate results although, following the advice of Knapp, he believed that preliminary ripening operations were generally unnecessary, and preferred the risk of extracting an unripe cataract, believing that the remnants of cortical, if confined within the capsule, produced little or no harm and could afterward be treated by a needling operation. He referred to the statement of Schweigger that the usual criteria of ripeness, namely, opacity to the periphery and the absence of the shadow of the iris by lateral illumination, are erroneous after the sixtieth year of age, when the lens may be extracted with safety, even if it is partially unclouded.

Dr. de Schweinitz expressed the opinion that it was perfectly proper to operate on monocular ripe cataract, even if the opposite eye was unaffected and had normal vision; for the reasons that if successful the appearance of the eye (these monocular cataracts usually being very white) was improved, the visual field was increased, the lens was saved from the danger of undergoing fatty degeneration, and the patient was given an eye which might be used in case harm came to the other or unaffected organ.

DR. JACKSON.—As to the age at which extraction becomes necessary for the removal of a cataract, no hard and fast line can be drawn. Two days ago, I did extraction on a young man 16 years of age and found the nucleus as large and firm as it commonly is at 40. Apparently he had a senile cataract at an unusually early age.

As to the choice between extraction and iridectomy for partial congenital cataract, it must rest mainly on the acuteness of vision that is obtained with the dilated pupil. If this be good it may be worth the while to do an iridectomy, but otherwise extraction or discission should be practiced. Theoretically by saving the crystalline lens we should in young patients save some power of accommodation. But in such cases, the power of accommodation is so slight as to be scarcely worth considering in this connection. The changes in the lens that make it partially opaque destroy almost entirely its elasticity.

For a ripening operation, the reasons that have influenced me in preferring the Pooley-White operation are, that it is done without iridectomy and that it is done without the introduction of an additional instrument into the eye. Not many years ago, it was regarded as a very important rule not to introduce any instrument into the eye if it could possibly be avoided. The operation has proved very satisfactory in my hands, where the lens had reached a certain stage of development and where there was a firm nucleus. In such cases it has always succeeded. In cases where there was no hard nucleus in young persons it has completely failed.

The length of time required for the ripening varies. I have done extraction one week after the ripening operation, but there remained some clear cortex in the posterior portion of the lens, although vision

had fallen from four-fiftieths to mere light perception. I have extracted an entirely opaque lens at the end of two weeks, but in other cases the period required for complete ripening was considerably longer. The operation is attended with very little reaction and I have never seen any iritic exudation or posterior synechia from it. Usually there is for two or three days a pericorneal zone and some little discoloration of the iris.

It may be seriously questioned whether ripening operations are necessary at all; whether it is not as well to extract the cataract still immature. With a large, hard nucleus after the age of 60 years, I would certainly do so. But where there is considerable cortical substance still clear and soft, the extraction will be easier and cleaner if some ripening operation has previously been done. I do not fear the leaving behind of some cortex so long as it is left inside the capsule, and not in the anterior chamber. I have never seen it interfere with the progress of healing, and at the worst it only renders necessary a subsequent needle operation.

As between an operation for preliminary ripening and a secondary operation after the extraction, I think the choice as to risk is small; but either of them is better than to keep a patient waiting for months or years for maturity of a cataract, after the second eye has become so far involved as to be no longer useful. Prolonged waiting in partial or complete blindness is so depressing to the patient's physical and mental health and vigor, that no gain in the ease and smoothness of the extraction can compensate for it. Marked improvement in the physical and mental condition after cataract extraction is quite frequently witnessed, and when a patient has progressed so far as to lose useful vision in the second eye, the time for a ripening operation or an immediate extraction has certainly arrived.

As to the removal of the crystalline lens for high myopia; the influence of the operation on the refraction is an additional reason for extraction, where myopia coexists with partial opacity of the lens. In myopia of very high degree, uncomplicated and with fair vision, I would not do any such operation. There is, however, one class of cases in which it seems proper to resort to it, and that is the class of high myopia confined to one eye, or of myopia very much higher in one eye than in the other. In cases of this kind the extraction of the lens from the more myopic eye will sometimes enable the patient to use the two eyes together, and thus obtain the advantages of binocular vision.

As to monocular cataract, I think that when it is mature and the patient in favorable condition, it is always proper and best to remove it and so advise. But I am always careful to explain to the patient that it will not improve his vision; (assuming that this is good in the other eye) and that it will be impossible for him to use the two eyes together; that what he will gain will be the enlargement of his field of vision; and an eye that will, by the adjustment of the proper glass, be serviceable whenever the one he now uses fails him.

DR. RISLEY.—The picture of immature cataract we are considering, I think should be studied with the pathologic background in view. In my lecture today I expressed the views which have seemed to me to be justified by my study of immature cataract, and since I have gone over this so re-

cently, and we have had such an excellent resumé of the subject by Dr. de Schweinitz, I will speak only of the management of these immature cataracts by operative interference. We should always keep the probability of their pathologic significance in mind. Having done all that is possible to restore the ocular health, then we may undertake the maturation or removal of these unripe cataracts. It seems to me we should be guided, in some measure at least, in the course to be adopted, by the condition of the urine. I must express my own conviction as in favor of the ripening operations combined with preliminary iridectomy. Since these cataracts are usually complicated, and the cortex is liable to stick to the capsule in our efforts to remove the lens, we should have as free an exit as possible, and this we secure by an iridectomy. Then, too, we should not lose sight of the therapeutic value of an iridectomy. I am sure you must have seen, again and again, tender eyes, the subject of intra-ocular inflammations; eyes which will not keep quiet long at a time, and are sure to go backward with any depreciation in the general health, grow rapidly better after iridectomy. And to my mind this is one of the signal advantages of iridectomy in this class of cases. Not only do you get the therapeutic value of the iridectomy, but it gives you an opportunity under the most favorable conditions, for adopting some method of maturation, and whether the lens is rubbed through the cornea or by direct trituration, it is more readily done and with less danger to the iris than without iridectomy.

I have again and again performed both direct trituration with a horn spatula upon the capsule of the lens, and more frequently still, have rubbed the lens through the cornea by means of the lid itself or the spatula, adopting a rotary, or up-and-down and to-and-fro movement of the spatula, being careful to lubricate the cornea with the tears, so that the epithelial layer of the cornea will not be injured. I have never seen any harm result from either of these procedures. I have occasionally failed to produce any result, but have always in such instances blamed myself for not having rubbed the lens with sufficient vigor.

It has seemed to me that the ripening of the cataract comes from breaking up the relation which exists between the capsule and the cortical layers of the lens, and that the rubbing must be done with sufficient vigor to bring about this result. Now, whether the fibers of the lens become opaque from simply bruising, as has been suggested, or whether their relation to the capsule has been disturbed and the nutritive supply cut off by this means is still an open question. To my mind the latter is the most plausible explanation of the increased opacity of the lens which results after the trituration process. You have all witnessed four cases at Wills' Hospital in which this operation had been performed. You remember the young woman who had an iridectomy performed and trituration through the cornea. In this case in two days there was a very marked increase in the opacification of the lens fibers. In the old woman whose cataract I extracted to-day, a preliminary iridectomy with trituration through the cornea, had been performed three months before, producing a marked increase in the opacification of the lens; but as you saw, in the periphery, particularly above, there was some transparent cortex; but nevertheless, the lens came out entire and left an

entirely black pupil without any cortical remains in the anterior chamber. In the old man who had the atheromatous arteries, this process had also been carried out in the same manner only three weeks before. In that case there had been in the three weeks very marked increase in the opacification of the lens. All irritation had subsided, and notwithstanding the serious pathologic condition of his eyes and his impaired health I did not hesitate at the end of three weeks to perform extraction. I think it was Dr. Jackson who has said that in his judgment the hard nucleus was one of the essential factors of success in this trituration process. Between the hard nucleus and the cornea you crush, as it were, the fibers of the cortex of the lens. I will say, therefore, again that my experience is in favor of these operations for maturation rather than for extraction without it. I prefer in most cases of immature cataract a preliminary iridectomy, since we get the early therapeutic value of an iridectomy, and also a wider exit for the lens itself, with less danger of bruising the iris. As to congenital cataract, I recall an experience I had in consultation with Dr. Norris at the University Hospital many years ago, when I had charge of the Dispensary as Chief. There was a young patient with double zonular cataract, and I called attention to it as one upon which he would possibly desire to operate. He said: "I have found in a great many cases, that these patients are markedly improved by strong glasses, and wish you would try these carefully before we do an iridectomy, or any other operation;" and to my surprise, with a plus 3 or 4 D. convex glass the vision came up from 20-200 to 20-40 or thereabouts. This is only one example of a considerable group I have seen since. In many of these cases of zonular cataract if you dilate the pupil and flood the eye with light, you will find the little elliptical zone of gray opacity, a transparent nucleus in its center and a transparent cortical on its outer side with a gray reflex showing through it, and in some cases I have been gratified, and all thought of operation dismissed from my mind by the results of careful corrections of refraction, or by the use of strong glasses which are always needful for near work, since the power of accommodation is usually *nil*. One of my procedures in these cases where the glass has been excluded is to dilate the pupil, and then, if the vision is materially improved by such dilatation, I consider the question of an iridectomy. The result, however, is often disappointing. I remember last summer having under care a young woman with zonular cataract, who was not willing to admit that we had given her any improvement by this means, and yet I could not see why. A broad iridectomy was not done; I purposely made a slit two or three millimeters wide, up and in, and it seemed to be typically placed. I could see the eyeground through it, but could not induce her to say she had been benefited in the slightest by the operation, and yet it was her only eye, the other having been lost by some accident. Regarding the question of extraction of the lens in high myopia, I recall the case of a friend with a very high degree of myopia. He is a literary man with wide reputation, his eyes having served him for an enormous amount of work. He has often sought my advice as to whether or not it would be an advantage to have the lens extracted. We have discussed it well, but have never yet been able to summon courage sufficient to

have the operation done. I think when he reaches 60 years of age, if I do also, that I should advise him to have it done, but not before.

I have changed my views regarding the propriety of operating on patients with monocular cataract. Formerly, I thought it was subjecting them to unnecessary surgical interference, since they could not in any event enjoy binocular vision. My practice has changed, however, and for the reasons already mentioned by Dr. Jackson and Dr. de Schweinitz. In the first place, it improves the appearance of the patient by removing an unsightly white pupil. But what is of more importance it renders him less liable to accident on the street by restoring his field of sight on the side of the cataract. After its removal he will be able to see approaching objects, even though the eye may not be used for reading. Then, too, if the cataract is allowed to remain too long it becomes over-ripe and the probability of a smooth extraction is much diminished. I have, therefore, of late years advised the extraction of the cataract at some opportune time, if the eye were in a moderately healthy condition, even though vision were perfect on the other side.

DR. HANSELL—In regard to monocular cataract, as a rule I do not operate upon it. While I recognize the reasons for operation that have been given, I think there are some others that are equally powerful to influence one against interference. First, nearly all cases of monocular cataract have divergence in that eye. Second, the vision obtained does not in all cases compensate the patient for the expense, the annoyance, worry and risk of the operation. Again, the defect is not particularly noticeable, indeed, the mass of the laity do not recognize a cataract. A man was lately brought into my office, blind with cataract in one eye, and the family were not aware of the nature of the trouble. But there are circumstances which would warrant an operation, and I would do it in the cases in which the patients wanted it, but I would never advise it on the ground of securing better vision. I would not allow that consideration to influence me in deciding whether to operate or not. Another point, closely allied, is when to operate when in one eye the cataract is mature and in the other incipient. Dr. Jackson has said to operate as soon as the patient is no longer able to follow ordinary occupations. I agree perfectly, only I would put it in this way—postpone operation until the patient is deprived of the vision necessary to pursue his ordinary functions. I had this rule very strongly impressed on my mind by an experience. I extracted an over-ripe cataract from the eye of a patient 60 or 70 years of age, blind in that eye for thirty years, but with vision of about 20-30 in the other eye. After operation the vision was about 20-40—a little less than vision with the good eye. I considered the operation very successful, and I congratulated myself on restoring vision to an eye so long blind. This person recommended a friend with the same trouble to another physician, saying she had expected her vision to be improved but it was not. So I would say to operate on the eye first affected when the patient was deprived of useful vision in the second eye and not before.

Replying to Dr. de Schweinitz's question: "How long I would wait if I had two unripe cataracts?" I answer, that would depend upon the age of the patient and his financial condition—by that I mean

his ability to live without the accurate use of his eyes; but I would not hesitate to extract a nuclear cataract in a patient over 60, whether or not the cortex was involved.

PHARYNGO-MYCOSIS.

BY HOMER M. THOMAS, A.M., M.D.

CHICAGO, ILL.

The term, pharyngo-mycosis, signifies a fungoid condition of the pharynx. It is a parasitic affection of the mucous membrane of the mouth, and manifests itself in white patches of varying size. These are found to contain epithelial cells and parasitic forms of a vegetable nature, the distinctive ones being called leptothrix threads. The tonsillar crypts of healthy persons are sometimes more or less plugged by these vegetable masses, but it is only when the plugs are large enough to project slightly over the surface that they come under observation. Mycosis leptothrix occurs in two forms, diffused and circumscribed. In the diffuse form the entire tongue is coated with a shiny, milkwhite mass, which is frequently of sufficient density to obscure from view the villiform papillæ. Movement of the tongue and sense of taste are not lost, and there is no interference with the general health. In the circumscribed form, white glistening points appear, resembling those seen in follicular tonsillitis, except that the mucous membrane about them preserves its normal pink hue. The tonsils, pharyngeal wall and base of the tongue are apt to be invaded. White or yellowish gray spots, usually hard, are arranged in groups or singly, and form little excrescences on the normal mucous membrane. They adhere firmly to the surrounding parts, and reappear if removed by forceps. The leptothrix buccalis is found in carious teeth and in the accumulations known as tartar; a microscopic examination of the secretions of the mouth will almost always find them. You should look for these collections in the lymphatic tissue at the base of the tongue, in the faucial tonsils and in the adenoid tissue of the vault of the pharynx.

Some of these white spots resemble a mushroom in shape, others are like pointed cones. The mass seems to be in layers, the outer one being easily smoothed off, while there is a deeper and harder substratum in the shape of little plaques. These little excrescences have their attachments on the surface and in the openings and depressions of the tonsils, or on the palatine arch, often on the posterior pharyngeal wall, the side of the pharyngeal wall being sometimes involved. When occurring on the tongue they have their attachments in the region of the large papillæ. Sometimes this mass is cheesy and easily removed; sometimes tough and stringy, running deep into the follicles, being very tenacious and difficult to remove. B. Fränkel of Berlin, first pointed out in 1873 an abundance of leptothrix threads in these products, and since then this has been noted by many observers.

However numerous these small whitish projections may be, each spot is isolated and they never form a continuous mass. After the tonsil, the glandular subtissue at the base of the tongue is most frequently affected; and the growth here may be extensive, the masses attaining the size of a pea. In some cases, mycosis involves all parts of the pharynx.

Pathology.—The gross appearance of the lesion is

that of discrete white spots, which may be connected here and there by scanty thread-like filaments. The mucous membrane covering the tonsil is the part most frequently invaded. In so-called fetid bronchitis, the leptothrix threads have been found in the tracheal mucous membrane, in the characteristic fungoid plugs; they have also been found in the sputa of pulmonary gangrene. In fourteen cases reported by Heyring, the affection was confined to the tonsils in seven; in the remainder the base of the tongue was also affected. Six were men and eight were women. The ages varied from 12 to 62, the preponderance being between 28 and 35.

The characteristic feature of the circumscribed form is, that although it quickly redevelops, often in twenty-four hours, in the same spot from which it has been removed by instrumentation, its extension to other points is comparatively slow; that is, new foci of the diseases develop sluggishly, but when once established their tenacity of life is very great and radical methods are required to destroy them.

From diphtheria this disease may be differentiated by the persistent discrete arrangement of the exudate, the general absence of surrounding inflammation, and the masses being much harder than pseudo-membrane. The tongue may also be involved, which is rarely the case in diphtheria. The absence of the Klebs-Löffler bacillus would be convincing. Mycosis of the pharynx may be confounded with cheesy masses in the crypts of the tonsil, and follicular disease of the throat, but the ease with which the cheesy masses may be expressed from the crypts of the tonsils is in striking contrast to the fixation of the mycotic masses. The constant presence of inflammation in follicular disease, and an entire absence of inflammation in mycosis, are distinctive of the two diseases. The exudation of follicular tonsillitis is a yellowish white; it frequently becomes confluent, and upon the application of the salt of iron it is readily disintegrated and may be largely removed.

Microscopic Appearance.—Microscopic examination shows a general mass of epithelial cells surrounded by an irregular collection of fungoid spores, arranged in link-like processes, their ends being rounded or club-shaped. They vary in length and some curl up at the ends into hair-like filaments; others are like rods, colorless, with sharp dark borders, the centers seeming to be full of granular matter. Besides these spores there are round or oval, highly reproductive bodies with dark borders, arranged in colonies or placed separately between the branch spores. Staining with methyl-blue brings out colored and uncolored portions on the stem spores. Jacobson succeeded in making a pure culture of these organisms. Leptothrix has the peculiarity of dissolving the chalk deposits of the salivary ducts and glands. Miller describes the microscopic appearance as a dirty yellowish deposit varying in size from the head of a pin to a pea, consisting of numerous bacterial forms and extending deep into the lacunæ of the tonsil.

Etiology.—The etiology of pharyngo-mycosis is very uncertain. Mouth breathing has been suggested as the cause. Tonsillar hypertrophy is a predisposing cause. It has been noticed as a sequel to rheumatic amygdalitis. Some observers have mentioned damp localities as favorable to the growth of this fungus. Catarrhal inflammation is a predisposing cause. It is more frequent in females than in males. Tobacco

smoking is thought by some to have a preventive action. The resemblance of the bacilli to several forms found in water, especially the water from marshes, has suggested the possibility of such a source of infection. In several instances it has been observed to follow or excite affections of the pharynx. It occurs most frequently in women and children who suffer from enlarged tonsils and are disposed to chronic pharyngitis. Some writers claim that a condition of malnutrition, with an impaired state of health, may be considered as a provoking cause; others claim a causative relation between disturbances of digestion and mycosis. W. C. Glasgow believes that some peculiar condition of the mucous membrane is a necessary factor in the development of mycosis, and that it only exists when the membrane presents a soil which favors its growth and development. The disease is not directly transmissible and is not contagious.

Symptoms.—The subjective symptoms of pharyngo-mycosis are variable; sometimes there exists a sensation of tickling and dryness in the throat, confined to the pharynx. Again, there may be a feeling as if the throat had a band drawn around it, giving rise to a slight choking or feeling of pressure; slight pain on swallowing, the feeling of the presence of a foreign body, attended with an irritation which causes a desire to clear the throat and to cough. In some cases these symptoms are greatly exaggerated, with depression, considerable fever and loss of appetite. The disease may exist without any symptoms being apparent to the patient, if not a vocalist. Mycosis in the throat of a vocalist produces great dryness and irritability of the fauces after a short vocal use of the throat. The voice is rather lowered in tone and inclined to be husky.

The objective symptoms are spots upon the pharyngeal wall, and often the circumvallate papillæ of the tongue are invaded. The color of the spots may be white, cream or yellow.

Treatment.—Dr. Kitchen has suggested hyposulphate of sodium as a means of treatment, especially if allowed to soak in well, and applied repeatedly with a swab. Peroxid of hydrogen has also been recommended. Semon claims to have cured a case with chlorate of potash gargle, and troches of tannic acid; Seiffert, with iodine and a gargle of borax, but doubt has been expressed as to the correctness of the diagnosis. Alum and sulphur have been found useless; silver nitrate resulted well in two cases that were especially tolerant to its use, but a relapse occurred later. Jacobson recommends a bichlorid gargle 1-2000. Töplitz found ferric acid useless, and others have had a similar experience with other iron salts. Carbolic acid has produced negative results. All of these agents have proved unreliable, and nearly all of them useless; fused chromic acid has given better results. At best, superficial applications like gargles can only affect the top of the growth, while its base remains firmly bedded in the tonsillar crypt, and the forcible rubbing on of solutions may abrade the epithelium and so permit the spread of the disease. Glasgow advocates the destruction of the organism with the cautery, or forcible extraction with the forceps where the growth has assumed a horny thread-like character. In some cases he advises scraping of the spots with a sharp curette and applying trichloroacetic or chromic acid freely to the surface. He has found the application of boracic acid in saturated solution of value,

in preventing the spread of the disease. The treatment is always tedious, with a tendency to return until all evidences of the disease have been eradicated. The most successful and certain treatment is the use of the thermo- or galvano-cautery. The bacillus frequently penetrates the tissues to the depth of one or two millimeters, hence the cauterization must be deep in order to destroy the germ. The bacillus thrives best in an acid medium. If the negative pole is used for cauterization, with a large positive electrode, there is a deeper action upon the tonsil and the growth is surrounded by alkalin fluids. The point of the galvano-cautery should be thrust into the root of the growth.

I am under obligations to Dr. F. D. Owsley of this city, for translations from the German, of Schech. I am also indebted to the writings of B. Fränkel, Rice, Vanderpoel, Newcomb, Hemenway, Glasgon and others.

The following case of pharyngo-mycosis was kindly referred to me by Dr. Fränkel of Berlin:

The history of the case as given by the patient, Mrs. C. B., is that during August, 1892, she suffered from a slight irritation in the pharynx. There were white spots on the tonsils, which disappeared after a few days, but returned within a couple of weeks. The physician consulted called the trouble a mushroom growth, and said it would require two or three treatments a week for some three months to effect a cure. The treatment consisted of a forcible removal of the exudate by means of forceps. This method of treatment was attended with severe pain and proved unsatisfactory. The patient becoming discouraged consulted Dr. Fränkel of the Berlin University, in November. At that time he found spots covering the tonsils and extending to the root of the tongue. His treatment consisted of swabbing the throat two or three times a week with a 5 per cent. solution of carbolic acid, and he recommended that the throat be gargled two or three times a day with pure brandy. Under this treatment the throat seemed to grow somewhat better, but still the disease was not wholly eradicated.

Having been called to this city, Mrs. B. came under my care Jan. 4, 1893, at which time the pharyngo-mycotic deposit was very extensive upon the posterior pillars of the fauces and invaded the root of the tongue, almost completely covering it, and there were extensive deposits upon the tonsillar substance.

After having confirmed the diagnosis as made by Dr. Fränkel, through microscopic examination of the deposit, I advised treatment to consist of thorough applications of the galvano-cautery. The electrode selected was one made for me in Vienna, and consisted of a very fine elongated platinum point which enabled me to introduce it directly into each one of the crypts of the tonsil affected by the disease, and also to eradicate the punctated growths at the base of the tongue. At first only three or four punctures were made at a treatment, the treatments occurring three times a week. As the patient grew more tolerant of the irritation following the use of the galvano-cautery, the number of punctures per treatment was increased, until I frequently applied the cautery to eight or ten of the mycotic masses at each treatment. The effect secured has been satisfactory to the extent that the disease has not reappeared at any of the foci cauterized.

My experience in these cases leads me to believe that the galvano-cautery treatment of pharyngo-mycosis is the nearest a specific in the management of this disease of anything we have.

Marshall Field Building, Chicago, Ill.

PATHOLOGICAL CONDITIONS FOLLOWING PIERCING OF THE LOBULES OF THE EAR.

Read in the Section on Otolaryngology, Pan-American Medical Congress,
Washington, Sept. 6, 1893.

BY MAX THORNER, A.M., M.D.

PROFESSOR OF CLINICAL LARYNGOLOGY AND OTOTOLOGY, CINCINNATI COLLEGE OF MEDICINE AND SURGERY; SECRETARY OF THE SECTION ON OTOTOLOGY, PAN-AMERICAN MEDICAL CONGRESS, ETC.
CINCINNATI, OHIO.

The custom of piercing the lobules of the ear dates from the remotest historical antiquity, being first mentioned in the Book of Genesis. It was practiced by the people of the Orient and by those of the West, and was transmitted from the races of classic antiquity, through the Middle Ages, down to our present times. Ear-rings were held among certain nations in high repute as talismans or amulets. They were, and I believe are still, superstitiously valued as remedies for eye affections. But their principal use was at all times, and certainly is now, that of ornaments, to be worn generally by women. And thus it happens that mothers, who would otherwise protect their little ones from every harm and pain, will not shrink from subjecting them to an unnecessary, inexcusable, and painful procedure, only to adorn them with the coveted jewel. This explains why such a barbaric custom as that of piercing the ears could have survived to our present times.

It is, however, barbaric, not only because of its origin, nor on account of the crude methods by which it is practiced; but more so for the reason that not rarely more or less troublesome, and even fatal consequences have been observed after this procedure. It is my pleasure to report to you to-day a number of such sequelæ of piercing the lobes, some of which seemed to me to be of more than ordinary interest, although there are scattered in literature a goodly number of interesting cases. Before reporting my own, it may be opportune to mention a few of the observations made by others.

Hufeland saw a child die of trismus following piercing of the lobule of the ear.¹ Severe inflammation of the lobe, erysipelas of the ear, large granulations around the wound, cutting of the ring through the lobule, and hypertrophic thick scars are some of the possible sequelæ mentioned by Dieffenbach.² Fibroids (keloids) have been observed by many authors and are mentioned by Knapp, Agnew, Turnbull, Finley, Bürkner, Schwartz, Politzer, Bacon and others. They occur up to the size of hen's eggs, and are said to be more common among the colored than the white race. Politzer says³ they are benign, no recurrence taking place after total extirpation. He refers, however, to the case of Agnew,⁴ in which a tumor originating in a traumatic scar returned again and again. According to some observers, recurrence of these tumors is not at all uncommon. Knapp has called special attention to the fact that they are liable to recur, and that by frequent recurrence they may become malignant.⁵ And in all cases of tumors of the auricle reported in this paper, recurrence has taken place several times. Sexton⁶

A Case of Triplets, all Males.—Mrs. Albert Stunzi, of East Eighteenth Street, New York City, became the happy mother of triplets, all boys, in the middle of December last. The mother and her sons are getting along unusually well, and the presents of cash baby clothes that showered down on the suddenly increased family were a surprise that did no harm to the prospects of any concerned. Some gifts came to hand from points as far to the westward as Omaha and Denver.

speaks of a cleft lobule from ear-rings, and saw even a portion of the lobule slough off. Kirchner⁷ says that the lobule is not infrequently the seat of an eczema, originating by preference in the pierced holes. Altschul has reported death from gangrene, following piercing of the lobes in a girl of 9 months;⁸ and erysipelas, sometimes fatal, is mentioned recently by Haug⁹ as being occasionally caused by the reprehensible practice of piercing the lobule.

It would be easy to multiply the cases, but these will be sufficient to show that there are abundant observations on record to make one reflect, why the voices of physicians, or at least of otologists, are not raised against this "truly barbarous custom," as Roosa calls it. The following cases have come under my observation:

ERYSIPELAS OF THE AURICLE AND FACE.

Case 1.—The lobule was pierced in a child 2 years old, and this was followed by a severe attack of erysipelas, involving the whole auricle, auditory canal and part of the neck.

Case 2.—A lady, 20 years of age, who had not worn ear-rings for some time was, on attempting to do so again, obliged to use some force in placing them. Pain, redness and swelling soon developed in one ear, and the erysipelatous inflammation also involved face and scalp.

Case 3.—Also in an adult, and very similar to Case 2. In this case the general symptoms were very severe, and the erysipelas, after having spread over the face and neck, invaded the pharynx. The patient recovered.

DEFORMITIES.

Two cases of cleft lobule were seen, caused by the ear-rings cutting through. In the one case, both lobules were torn. The clefts were readily repaired by the operation advocated by Knapp,¹⁰ by paring the edges and stitching the little flap left on the posterior lip over the corresponding portion of the anterior lip, thus avoiding a notch in the lobule. The result of the operation was good. The other case of cleft lobe was peculiar. It was that of a middle-aged woman, in whom the ear-ring had torn through the left lobule about ten years ago. Two years later she got tired of wearing but one ear-ring, and she had the left lobule again pierced, close to the old aperture. In the course of time this ring had also torn through, parallel to the old slit, and the woman had now a lobule consisting of three pendants. The narrow, central strip was removed, and the edges of the remaining parts united in the above described manner. The cosmetic effect was good.

One case of enlargement of the opening made for ear-rings, presented a peculiar and even ridiculous appearance. The hole on one side had gradually enlarged, from the weight of the ring, to the size of a lead pencil; and repair was desired by the patient, a young lady of 19 years, for cosmetic purposes. The edges were pared with a cataract knife, united by one suture, and healed readily. (A similar case is described by Roosa.¹¹)

ECZEMA OF THE AURICLE.

This has been observed in a number of cases to be caused by the wearing of ear-rings, especially when they had accidentally caused small tears of the cutis, and also after forcible placing of ear-rings, when the opening had been closed for some time. It was

generally the acute form which was seen, causing swelling, excoriation, formation of unsightly crusts, and bleeding often upon the slightest touch. This form is, as a rule, very painful. Removal of the cause and treatment with ointments (for instance the ung. diachylon) were sufficient to produce a speedy cure. In two cases the eczema had reached the chronic stage; in one, involving the larger part of the auricle, and more especially the furrow along the insertion of the auricle. These cases were more obstinate, but yielded also finally to treatment.

TUMORS OF THE AURICLE.

Case 1. Fibroma (Fibro-chondroma) of Auricle.—The patient, referred to me in August, 1887, by Dr. Wright, was an unmarried lady, 32 years of age; white. Had been troubled as a child with painful swellings of both lobules, which caused her to discontinue wearing ear-rings at the age of 17. At the age of 22 she noticed that the old swelling in the right lobule, which had been pierced higher than is the custom, and very close to the antitragus, began to grow, until it had reached the size of a small cherry. Two years thereafter it was removed, but showed signs of recurrence within a year. Three years ago, and five years after the first operation, it was again removed, but began soon to reappear, until it had reached the size of a small chestnut, involving the whole lobus. Removal was effected by a V-shaped excision, and the edges brought together by sutures. The tumor had not returned two years after the operation, the last time I saw the patient.

The microscope showed within a dense connective tissue formation, the structural elements of cartilage sparingly interspersed. A case of fibro-chondroma of this region has also been reported by Strawbridge.¹² The appearance of cartilage in a tumor of the lobule, finds its explanation in the fact that the lobule is not entirely free of cartilage. There is, as W. His¹³ has shown, an unciform strip of cartilage below the antitragus, called by him *lingua auriculæ*, which is the cartilaginous support of the lobule of the auricle.

FIBROMA OF THE AURICLE.

For the history of the following interesting case and the specimen I herewith present to you, I am indebted to my friend, Dr. O. Landman of Toledo, Ohio:

Case 2.—Mrs. C. E. J.; white; age 35. When 15 years old, her ear-rings were caught on a pillow, and both forcibly torn out. The wound healed, but later on a "lump began to grow" on both lobules. Two years afterwards both lobules were partially amputated. The left tumor has never returned. The tumor in the right ear returned six times, and reached an operable size about every three years. There were six operations after the first. Two years ago Dr. Landman saw the case for the first time, when the tumor had reached the size of an English walnut, involving the larger part of the auricle. He operated by amputating the entire auricle. About eight weeks ago the lady was seen again. There were at that time no signs of recurrence. The microscopic examination showed the tumor to be a characteristic fibroma, containing possibly a little more yellow elastic tissue than is usual in this kind of tumors, but which might be expected from the structures involved.

KELOID OF THE AURICLE AND FACE.

Case 3.—Miss E. P. H. of Indiana; white; 35 years old; was seen one year ago. When 18 years old a small nodule developed in the right lobule, close to the puncture. This began to grow, was painful, and was excised. Within the following seventeen years the recurrence of this tumor was the cause of untold misery for the sensitive woman. In the course of time she was operated upon six times with the knife, and caustics of every description and in untold quantities had again and again been used. Electrolysis and hypodermic medication had been tried in vain. The pain produced by these different therapeutic agencies,

especially the caustics, and the frequently unbearable pain within the growth, had undermined her health. When I saw her, a little over one year ago, there was a solid sessile tumor, the size of about a silver quarter, extending from the region below the tragus into the cheek. The lobule and lower posterior half of the auricle were gone, and from the edge of the rest of the auricle a dense and unyielding cicatricial tissue extended into the integument below and behind the ear. The tumor was flat, about one-sixteenth of an inch elevated above the surrounding skin, ordinarily pale, and not sensitive to the touch. At the time of menstruation it was usually congested, and slightly more elevated, and caused, especially at such times, but occasionally also during the intervening period, the most intense and lancinating pain.

The tumor was removed by an elliptical incision in healthy tissues, care being taken to lift it with a portion of the subcutaneous adipose tissue from its location. After severing, by deep incisions, some of the cicatricial bands behind and below the tumor, I was enabled to close the wound by sutures. Primary union. There remained a thin linear scar, the pain disappeared within a few days, and there have been no signs of recurrence as yet, one year after the operation. On former occasions the tumor showed signs of reappearance within six months.

The microscopic examination, made by Prof. Kramer of the Cincinnati College of Medicine and Surgery, showed the removed tumor to be a true keloid. The epidermis was atrophied, and hairs, hair-follicles, and glands were entirely absent. The Malpighian layer was distinctly preserved, but there were only scanty traces of papillæ. Immediately below them, and arranged in layers parallel to the surface there was a dense mass of fibrous tissue in which here and there blood vessels, some compressed, appeared. Among the bundles of fibrous tissue, occasional elastic fibers were noticed, and also, frequently, groups of spindle cells. Below this was a looser connective tissue, with many cellular elements; and a gradual merging into adipose tissue. It is too early as yet to say whether the last removal will not be followed by a recurrence.

It is true that most authors insist upon the possibility, and even probability of a return of these growths after operations. But no treatment has as yet been devised that will actually give better results; while Erichsen,¹⁴ though admitting their liability to return after excision, calls this their only treatment. And in this case, the almost intolerable sufferings of the patient, whose best years had been sacrificed in the battle with this baneful disfiguration, compelled me to do something that gave her at least a slight chance of a permanent cure.

These cases do not demonstrate anything new, but having occurred under my own observation lead me to believe that they are still more frequent than we usually think. And while in most cases no serious consequences result from the folly of piercing the ear lobes, yet there occur, from time to time, cases where a life is at stake, or where the enjoyment of life is seriously interfered with. It is time that this relic of barbarism ought to be relegated where it belongs,—to the by-gone follies of superstition and fashion. And the day is, I hope, not far distant, when it will be considered an evidence of brutality to have a tender and unprotected child subjected to such an unnecessary and mutilating procedure.

THERAPEUTIC INDICATIONS OF RHEUMATIC PATHOLOGY.

BY THOS. O. SUMMERS, M.A., M.D., F.Sc.S. LOND., D.D.S.

WAUKESHA, WIS.

Notwithstanding the fact that the literature of medicine is teeming with disquisitions and discussions upon the subject of rheumatism, there appears to be nothing within the whole range of pathologic investigation upon which the profession to-day stands so greatly at variance as upon this, perhaps the most cosmopolitan "of all the ills that flesh is heir to." Theory after theory has been propounded and exploded; remedy after remedy proposed and rejected until the whole "Pharmacopœia" has been exhausted, and the shelves of the apothecary crowded to overflowing with charlatan nostrums and proprietary preparations sufficient to float a fleet, in the apparently vain effort to find relief from this universal and intractable malady.

While, therefore, I do not propose to add anything to the fund of actual information on the pathologic principles upon which rheumatism is founded, I do propose to bring out and apply those principles in such a manner as to establish the true line of therapeutic action in its treatment.

It is very often the case that, in those diseases which are most common, the treatment is so generally ineffectual on account of the fact that our therapeutic leaders overlook the very simple pathologic principles which govern them, in their vain search for some occult factor in the problem which in reality does not exist. Most undoubtedly is this true in regard to the disease under consideration, as I hope I shall be able to demonstrate.

A great deal of the nebulosity which hangs about the subject of rheumatism arises from its peculiar relation to those specific disorders with which it has been classified by pathologists as *cousin-german*—such as syphilis, scrofula, tuberculosis *et id omne genus*—known to ultimate pathologic analysis as *leucocythemie* in origin.

I do not know that I could introduce this discussion in a more striking manner than by the relation of a little incident which occurred to me some eighteen years ago, while an associate editor of the *Nashville Journal of Medicine and Surgery*. Being the youngest of the editorial staff, the "make-up" of the *Journal* was left to my supervision. Our old foreman, "Father" Brown, as we familiarly called him, was a regular copy-fiend. He was never satisfied without a lot of extra "live matter" from which to select in "making up." One day I entered the composing room and was greeted by the old man with a regular tirade, on account of not having just the amount of matter necessary to fill out a little space, and he wanted me to prepare it at once. I snatched up some galley proof paper and began to write just what came first into my head. I had just left my microscope, upon the stage of which was resting some preparations of corpuscles from pus, from rheumatism and from normal blood which I had been comparing. So in the little "take" which I handed over to the old foreman I simply announced the conclusion at which I had arrived only a few moments before, that the cause of pain in rheumatism was undoubtedly due to the migration of the white blood corpuscle which, continuing to live out-

side the vessels, not only appropriated nutritious material to its own use at the expense of the normal tissues of the body, but became bloated with riotous living, swelled up inordinately and impinged inconveniently upon space belonging to the delicate nerve filaments distributed to contiguous structures. It was, indeed, a new conclusion to me, but I was no less surprised than pleased some time thereafter to find the little item copied by the *London Lancet* with due credit, and with a tacit, but yet apparent indorsement, and from this it went the whole rounds of the foreign and American medical press.

I may say that *I have since then found no reason to contradict or modify the conclusion then so casually and cursorily made.* On the contrary, starting with this, I carried my investigation and my reasoning farther in the same direction and was astonished to find what a wonderful field of fact was opened up before me. I saw at a glance the many and wonderful pathologic conditions capable of being brought about by this migrated corpuscle—this "*Wandering Jew*" of the organism. Protean in relation as in form, and as a vital physiologic unit capable of independent life, a most dangerous element in all pathology, involving assimilation of pabulum, and nutrition of structure.

At the risk of becoming trite in the eyes of those who are continually occupied with pathologic investigations and are familiar with pathologic technology, I shall review in a cursory manner the structural morphology and the functional relationship of this *white blood corpuscle* or *leucocyte*, from its first active appearance in the blood, directing and controlling as it were the distribution of nutrition from within the prison walls of the blood vessels, to its wanton wasail while carousing over the spoils of the organism after escape from its forced vascular confinement. In this connection it may not be uninteresting, even to the most of the JOURNAL readers accustomed to the microscopic views of the amœboid movement, to observe the relationship which exists between the corpuscle, as it floats in the plasma, and the corpuscle freed from its physiologic restraint. Unlike its red companion it has a vitality of its own and depends not for its existence upon a fixed and necessary environment. Take the red corpuscle from its home in the plasma of the blood in which it purls along content with its surroundings, and doing quietly and submissively the behest of the organism in carrying and delivering its freight of vivifying air. Not only is it content with its environment, but it can exist under no other conditions, and the moment it is removed from its normal surroundings it sinks at once into retrograde metamorphosis and final death. Not so with the white corpuscle. From the first moment of its physiologic existence it engages in an endless struggle for freedom. In its course through the organism it tries every osmotic crevice in the walls of the blood vessels, taking every shape that it may deem better adapted to its escape from prison. On its exit from the "pent-up Utica" of its tubular jail, it sets up housekeeping on its own account, and its extravascular or pathologic life is far more active than its physiologic existence, for it really seems to begin life in earnest when freed from the restraint of physiologic law. So strikingly is this manifested that pathologists have often been led to wonder why an element so necessary to physiologic integrity should show its greatest activity under pathologic conditions—a question which the limits

of this paper do not permit me to discuss in this connection.

There is, however, a point which requires our attention just here, and that is that a low nutritive condition of the blood is peculiarly favorable to the migration of the white corpuscle. Where the plasma is thick and charged with nutritive elements there is little room left in the osmotic spaces for the escape of the corpuscle, and besides it is kept in a state of constant activity in handling the nutritive freight of the organism, if we may be allowed to carry out the metaphor, to find time to look for avenues of escape, for in the physical as well as in the moral world,

"Satan finds some mischief still
For idle hands to do,"

and the greater number of pathologic conditions arise from inactivity of function, rather than from lesion of structure.

This relation of the poverty of the blood to the increased migratory tendency of the white corpuscle will suggest at once to the thinking mind the therapeutic indication in the pathologic premises. It will be clear that anything that favors osmosis, that excites absorption, thus occupying the avenues of escape with nutritive material, will not only arrest migration but prevent the preying of the corpuscles which have already escaped, upon surrounding structures. Foremost among such agents stands iodid of potassium, which seems to have a more marked effect, both in regulating the physiologic activity of the white corpuscle and in protecting the tissues from its ravages when once it has escaped and become ensconced among them. It is, then, not in the least surprising to find that in all those diseases which have been referred to as *cousin-german* to rheumatism, marked as they are by an increase of the white blood corpuscles in proportion to the red, iodid of potassium has even empirically become a standard remedy. Anything, too, which excites secretion, will also tend to check this migration and neutralize the pathologic effect of the corpuscle. And above all other therapeutic agents which have been proved effectual in this relation calomel rears its head; whatever malediction and abuse have been hurled at this grand old remedy, like Banquo's ghost, "it will not down," and a sad day it will be for medicine when, through the fashionable tendencies of the times, the profession becomes too cowardly to use a remedy that the experience of ages has tested and indorsed.

Upon the basis of what has been said, therefore, I offer my own method of treatment in rheumatism, both chronic and acute, and though the remedies may seem old fashioned, the proportion used and the manner of their combination prove their practical value and, substantiated as they are by the pathologic indications, I always administer them with confidence.

At night, before retiring, I order a hot mustard foot bath and the following prescription:

R. Pulv. Dov gr. xv.
Hyd. chlor. mit gr. x.
M. et. ft. capsul. No. ij.
S. Take both before retiring.

I always direct these capsules to be taken with a solution of bicarbonate of soda 3j, to water 3vj.

Go at once to bed and *stay* there. In the morning, if there is no action on the bowels, give a bottle of solution of citrate magnesia freshly prepared. I then order the following:

R. Potass. iodid ʒss.
 Vini colch. rad } ʒā
 Fl. ext. sarsae } ʒij.
 Tinct. cinchon. comp }

Mix.
 S. Dessertspoonful in half a glass of water one hour after each meal.

Sometimes this dose must be varied on account of idiosyncrasy—this the physician must decide in each particular case.

This treatment usually gives relief and is founded upon a true and solid pathology.

OBSTRUCTION OF THE BOWELS.

Read before the Medical and Chirurgical Faculty of Medicine at the Semi-Annual Meeting held at Annapolis, Nov. 23, 1893.

BY EDWARD ANDERSON, M.D.
 ROCKVILLE, MD.

I have had a good many cases of this trouble, as all of you who have been in practice for a number of years must have had. On being summoned to the bedside of a patient suffering from obstruction of the bowels there are three questions we should ask: What has the patient been eating? What doing? And whether he or she is of a constipated habit?

Although I have never seen complete obstruction caused by scybala, I have seen it sufficiently so to have caused death had not timely remedies been employed. I will mention a case in point later on.

I have always been able after a few hours' attendance to discriminate between those cases which required surgical interference and those which did not. If complete obstruction occurs suddenly, accompanied by pain sufficiently intense to require the administration of large doses of opium oft repeated, enemata having failed, surgical aid should at once be procured; but if the pain is not intense and we find that hard substances upon which the intestinal juices are unable to act have been swallowed, we can afford to wait, and try other means. Any smooth substance small enough to pass through the esophagus, will be sufficiently so to pass through the intestinal canal, and any number of small bodies collected together in the bowel can be dislodged without resorting to laparotomy. If we know that a large solid substance has been swallowed the best plan to pursue is to allow no purgatives to be given, and to keep the patient as much as possible on solid food until it passes. Large enemata should first be employed in every case of obstruction, particularly so when we have reason to believe that masses of small bodies cause the difficulty; and in suitable cases small doses of calomel repeated at short intervals should be used at the same time. If we can not do for our patients the very best that can be done, we ought to seek the aid of some one who can. This has always been my motto, but our best endeavors are sometimes thwarted, as the two following cases will show: on August 25, 1885, I was called to see a mulatto woman in good circumstances, about 45 years old who the messenger said was suffering from severe cramps. I found her with intense pain in the umbilical region, severe enough to require the hypodermic injection of a fourth grain of morphia every four hours. I threw a large amount of warm water into the bowel which removed some very hard fecal matter, but after that nothing could be brought away; even milk came out of the bowel as white as when thrown in. I told the family at once that an operation would be necessary; this was unwelcome

news as such news always is, especially to the ignorant, and of course the family wanted a consultation. On the second day a consultant was called in who threw out the hope that the recovery might take place without an operation; he proposed that we should give 2 grains of calomel every four hours in addition to the hypodermic of morphia and the rectal injection of milk with which I was sustaining her. Not being able to persuade the husband and children to call in a surgeon, I abandoned the case on the fourth day. I understood from those who were present that the treatment that I inaugurated was kept up until the patient's death, which occurred on the eighteenth day. Although vomiting was incessant from the beginning, it did not become stercoraceous until near the close of life. This woman's alarming symptoms came on immediately after drawing water from a well with a rope, hand over hand, without even a wheel to assist her. What condition the bowels were in I do not know, as no autopsy was held.

A little over two years ago I was called to see a negro woman about 50 years of age who was suffering from intolerable pain in the umbilical region, accompanied by incessant vomiting, which became stercoraceous on the first day. I gave her a hypodermic of one-fourth of a grain of morphia every four hours, and at the same time threw large quantities of warm water into the bowel with the effect of producing one action only, without checking the vomiting in the least. A half gallon of water that I injected was retained until the next day.

When obstruction of the bowel takes place, peristaltic action is lessened, even below the obstruction which favors rectal alimentation. I tried to procure the services of a surgeon in this case but failed to do so. On the third day I succeeded in obtaining the services of a gynecologist, but after he came I could not prevail upon him to open the abdomen, though laparotomy was of almost daily occurrence with him; I had seen him perform supra-vaginal hysterectomy for a large fibroid and do it as skilfully as any one could, yet he hesitated where the bowel was concerned, and told me to go on with my treatment until the next day, when he would come again and operate, if no change for the better had taken place. When he came again she was too weak to be operated upon, it being the fourth day of her illness, and she died at noon that day. Had I known that I could not have this woman operated upon I would have opened her abdomen myself, though I had never performed laparotomy. On opening the abdomen after death, a stone was seen just below the umbilicus, occupying the most constricted part of the ileum and almost as plainly visible through the transparent bowel as it is in my open hand. The first case of obstruction I was ever called to attend was that of a child 10 years old, the daughter of a farmer. The parents were intelligent people and had diagnosed the case properly before I arrived. They said the child had been eating cherries and they supposed had swallowed the stones, which had collected in the bowel. Three table-spoonfuls of castor oil had been given without effect. I gave a teaspoonful of paregoric to relieve the pain and used the syringe every hour during the night, with the result of bringing away a half pint of cherry stones and completely relieving the child.

An old lady, a patient whose bowels had been obstructed for a week and who could not stand the use of enemata was put upon one-sixth of a grain of calomel

every two hours for two days when the obstructing mass was removed which proved to be tomato seed. The pain she had suffered, the subsequent laxness of the bowels and a slight constitutional effect of the mercury caused her death a few days thereafter. I saw a case which was in charge of another physician, where a boy of 12 had his bowels obstructed during the Christmas holidays. In this case 2 grains of calomel were given every four hours, together with the employment of injections for three days without relieving the child, when a surgeon was called in to operate. He did not operate, however, but injected senna tea through a long tube at intervals for twelve hours when the obstruction was removed, which proved to be nuts partly masticated and held in position by the gum of raisins, of which he had also eaten freely. Had not the calomel been used in this case, I do not believe that enemas would have succeeded, for the gum from the raisins came away in flakes showing that it had formed a cast of the bowel. On August 17, 1889, I was called to see a lady of 50, on account of pain in and distension of the abdomen. I found her with a temperature of 102 degrees F., very much distended and pain sufficiently severe to require a dose of morphia. I knew she was of a constipated habit, and also that she had been living largely on constipating food, milk, and sweet potatoes; although there was slight diarrhea present I felt confident that there was almost complete obstruction from impacted fecal matter. I ordered large warm water enemas and began the use of purgatives. I gave 12 grains of blue mass at night, and a teaspoonful of Rochelle salts the next morning, and repeated the dose of salts every four hours from August 18 to September 4, with temporary relief, but on September 26 she was as bad as ever; when I commenced the same treatment again, and kept it up until October 28, with the result of bringing away a large amount of hardened matter which had probably been accumulating for years. This lady has not been sick since. We rarely meet with a case so pronounced as this, but it is wonderful how many there are which resemble it, particularly in females beyond middle life who lead sedentary lives.

The following case was the most interesting that ever came under my care: On Nov. 14, 1887, I was sent for to see a little girl on account of threatened convulsions; the child was 16 months old and belonged to a highly neurotic family. She was the most precocious child I ever saw, being able to run about the streets and speak as plainly as most children of 3 years. I found her with the left side of the face twitching violently. The mother said the child's throat was sore and she thought that she had diphtheria, but an examination revealed nothing indicating it. According to previous instructions, if a case of convulsions should occur the parents had given 5 grains of bromid of potash, which I told them to continue at intervals of four hours until I came again. I went back some hours later and learned that the child had had several general convulsions, and she showed by the way she acted that she had pain in the abdomen. I gave a full dose of calomel and left orders for the bromid to be continued as before. The calomel acted freely, and brought away a large stool, with several pieces of apple core in it, but this did not mend matters for a severe spasm came on while the bowels were moving. The bromid was kept up for four days but did not stop the con-

vulsions, four or five occurring daily. The father thought the bromid aggravated the case, as a convulsion came on after each dose, so I substituted 2 drops of tincture of belladonna, after which no more convulsions occurred, but partial paralysis of the left side was noticed, the temperature being 103 degrees F., with exhaustion sufficient to require a teaspoonful of whisky every four hours. At this stage of the case a consultant was called who had had forty years' experience in Washington, and for a great part of the time was physician to a large foundling asylum. He came on three successive days, and each time said if the child was living in the morning he would be back—showing he had no idea of its recovery. The bowels never moved except when a purgative was given. I will not weary you with the details in this case; suffice it to say that the child hovered between life and death; that it taxed my skill, and the patience of all its relatives to the utmost until the first of January, 1888, when a slight but perceptible improvement took place. On the tenth day of February of the same year it passed a china button, the largest size that is made. Although she could neither walk, talk, chew or swallow, unless liquids were poured down her throat, the child continued to improve, and at the end of nine months was able to walk—but the power of speech was never restored. Twelve months after the beginning of this trouble the mother in great glee sent me word that her child had bitten a piece out of a cake and swallowed it; improvements with many setbacks went on from Jan. 1, 1888, to Jan. 1, 1889, when a weight of thirty pounds was attained. I neglected to mention that when this patient first gained strength enough to be weighed, her weight was only twelve pounds. On February 5, she was attacked with pneumonia and died on the eleventh. Though I was in the house several times a day sometimes remaining an hour, I never heard her cough, or the slightest sound like it, the reflexes having been destroyed. There were a great many points of interest in this case: 1, the obscure nature; 2, the failure of bromid of potash to check or stop the convulsions, while at the same time protecting the brain to the extent of saving life; 3, the great length of time the obstructing body remained in the bowel; 4, the family history: The maternal great aunt became a deaf mute from a fall when 3 years old; she is now 70 and still deaf and dumb. The maternal grandmother told me seven of her near relatives had died of tetanus, some being members of her immediate family. Although we believe tetanus to be a germ disease, like all other germ diseases, it has a predilection for certain families; 5, absence of cough during pneumonia, which ended in death.

I have seen in consultation some cases of complete and some of partial obstruction caused by appendicitis, but the diagnosis was made too late to be of avail. I merely mention those cases which came under my observation, which were relieved, or ought to have been relieved.

THE HEIRS of Senator Jacob Moleschott, the famous explorer, teacher and physician, have given his valuable library, containing over 40,000 volumes of medical, philosophical and scientific works, to the Academy of Turin, where the dead man began his labors.

HYSTERECTOMY BY THE PRATT METHOD—
THE SURGICAL ASPECTS OF HYDRO-
CEPHALUS.—AN OBSCURE CASE
OF HEMATURIA.—OPERATION
FOR STRICTURE OF THE
RECTUM.¹

BY EMORY LANPHEAR, M.D., Ph.D.

PROFESSOR OF OPERATIVE SURGERY AND CLINICAL SURGERY IN THE
KANSAS CITY MEDICAL COLLEGE.

Mrs. B., a patient of Dr. R. A. Brogan, Osage Mission, Kan., who has been sent to the Hospital for operative treatment. She is 54 years of age, married at the age of 20, never pregnant, always in good health, but naturally thin. At about the age of 47 she ceased menstruating and passed through the climacteric without difficulty. Some two or three years subsequently she noticed a slight heaviness in the pelvis, and consulted her physician, who told her that she had some form of tumor growing in the womb. A little more than four years ago she began to have hemorrhages at irregular intervals. These attacks of bleeding have increased in frequency and intensity, until, as you see, she is exsanguinated and almost a skeleton. Examination of the case upon her admission to the Hospital showed that she had an intramural growth which was undergoing decomposition, and that she was suffering from septicemia induced by the absorption of the sloughing intra-uterine mass.

I made a laparotomy upon this patient with the expectation of doing one of two things: 1, removal of the uterus and tumor by suprapubic hysterectomy, if possible; and 2, if this could not be accomplished, I designed tying the ovarian arteries as a preliminary step to the operation. Upon opening the abdomen, the uterus was found so enlarged and fixed in the pelvis, that it was impossible to remove it by abdominal hysterectomy; and as the ovarian arteries did not seem to be filled with blood, I immediately closed the incision in the abdominal wall without doing anything further.

The patient now being chloroformed, I do the newest form of hysterectomy, that advised by Dr. E. H. Pratt of Chicago. In this particular case it is necessary to do two things that are not mentioned by Dr. Pratt. The first of these consists in slitting through the perineum and the perineal body so as to allow room for work, because this lady has a very close introitus, which would prohibit any manipulation within the pelvis. The next step is to temporarily tie the uterine arteries by the method which has been advocated by Dr. Franklin H. Martin of Chicago. Dr. Pratt, in his description of his method of hysterectomy, says that the preliminary tying of the uterine arteries is not necessary; but as this particular case bleeds so freely as to interfere with the operation, and at the same time jeopardizes the life of the patient, I have deemed it best to add this step to the plan advocated by Dr. Pratt. Having tied the uterine arteries, I packed the canal tightly with gauze, then cut with a knife entirely around the cervix through the mucous membrane and the submucous tissue, until I reach the free and loose connective tissue which envelops the body of the uterus. Dropping all instruments, I introduce my fingers within the slit, and rapidly tear away the uterus and its tumor from the peri-uterine structures. This is very rapidly accomplished. As I reach the vicinity of the fundus, I exercise a little more caution in the separation, lest I should penetrate the peritoneum which covers the uterus at this point. The separation is easily and rapidly accomplished, and with almost absolutely no hemorrhage. Indeed, it is surprising that there is not more loss of blood, and almost equally so is the ease and rapidity with which the enucleation was accomplished. For the removal of the uterus and the tumor, not more than ten minutes were required. The whole operation, including the sewing up of the perineum, and packing the cavity with iodoform gauze did not take us more than twenty-five minutes.

It seems to me that this operation will prove an admirable one for cases of this kind, and it is possible that it is also applicable in cases of early epithelioma of the cervix; but usually when cancer of the os has advanced far enough to be recognized by the physician there has been infiltration of the tissue above and implication of the tubes and ovaries; so

that complete hysterectomy with removal of the tubes and ovaries per vaginam (or through the abdomen) is the only treatment to be recommended.

HYDROCEPHALUS.

The second case which I present to you is a little patient who is being treated by Dr. H. E. Pearse. The child is 5 years of age, very small in development, but with an enormous head. At birth she was normal in every particular, and was as other babies are until the age of 5 or 6 months. At this time she was attacked with meningitis, or cerebrospinal meningitis; from this time on the head gradually enlarged and the child became idiotic, until to-day it presents the typical symptoms of chronic hydrocephalus—small in development, with a head which measures twenty-five and one-half inches in circumference, and eighteen inches from ear to ear, with strabismus and the idiotic countenance.

The reason this child is brought to the surgical clinic is to ascertain whether or not anything can be done for its relief by surgical measures. Dr. Pearse recognizes the fact that in a case of this kind, there is nothing but drainage of the ventricles or subdural space, which promises any hope. Results from the surgical treatment of these cases have been quite favorable, though the death rate has been much higher than in other operations upon the head; about one case in five recovers entirely; two improve and two die. The history of a successful case is usually about like that given by Illingham:

The patient, a boy of 3 years, was hydrocephalic from the age of 9 months; was unaffected as to intellect, but suffered from sleeplessness and pain; a trocar was introduced into the ventricle and a considerable quantity of clear, serous fluid allowed to escape; drainage was made with a collared cannula, but this was pushed out inside of two weeks, and an uneventful recovery resulted.

A considerable number of similar cases can be found in recent medical literature. On the other hand, an equally numerous group can be collected like the following record in my own case book:

Girl, age 4 years, hydrocephalic from the fifth month; head measuring twenty and one-half inches in circumference and fourteen inches from ear to ear; head hard; was trephined April 25, and drainage of ventricles established; temperature was never higher than 100, but from time of operation, strength (always poor) began to fail, and child died of exhaustion May 1, six days after operation.

The operation consists of removing quite an area of the skull, an inch or more by two inches, and then waiting a day or two until the brain has accustomed itself to the change in pressure; then a cannula is thrust into the ventricle (or subdural space) and fluid allowed to escape. As a result of long-continued experiment, it may be stated that the central cavities may be drained either from the anterior cornua by going through the frontal lobes, from the posterior horns through the occipital lobes, or from the body of the lateral ventricle through the parietal convolutions. The procedure for the first is to push the hollow needle horizontally inwards through the posterior extremity of the second frontal convolution; for the second, the needle must be inserted through the posterior extremity of the superior temporo-sphenoidal lobe; and for the third, the needle is thrust through the lower end of the second parietal convolution.

The quantity of fluid withdrawn must vary according to the size of the head and the effect produced. In some cases, several ounces can be allowed to escape; repeating the tapping in a few days; in others it is best to insert a strand or two of sterilized silkworm gut, and allow permanent slow drainage to proceed into the antiseptic dressings, which must be changed as soon as saturated. If too much fluid escapes,

¹ Clinical lecture delivered November 14.

convulsions will follow; this mischief may be rectified by injecting normal salt solution to the amount of an ounce or more, and temporary arrest of the drainage; or, as I prefer, iodoform emulsion may be used for injection purposes.

Sometimes traumatic hemorrhage into the ventricles is a complication. In such a case, the advice of Keen is to be followed: instant trephining and evacuation of the clots. Its early recognition, however, must be very difficult.

In this particular case, it seems to me that operation is entirely out of the question, in the physical condition of the patient, as she is suffering from a subacute bronchitis and from an edema of the glottis, from which she nearly suffocates at each paroxysm of coughing. Many of these cases die from pulmonary and laryngeal complications; and it is probable that this little patient will end its life in this way. If, however, the Doctor is successful in treating the present trouble, we can then explain the possibilities of the operation to the parents, and follow the plan which I have just described if they decide in favor of having it done.

A CASE OF HEMATURIA.

Our third patient, a gentleman age 55, has been sent by Dr. C. L. Burke of Argentine, Kan., for diagnosis. He is evidently neurotic, confesses to impotency, and complains of passing bloody urine at irregular intervals. He comes seeking relief from the latter, to which he ascribes his ill health; he is directed to this clinic for us to determine if he needs surgical treatment. The first thing to decide is whether he has hematuria or hemaglobinuria—as in each the urine may be tinged red. We may exclude hemaglobinuria by the fact that there is no cause, that is, there is no continuous use of certain drugs, like potassium chlorate, glycerin, some of the anilines, etc.; no partaking of certain edible fungi; also by the fact that this trouble has persisted for more than two years; hemaglobinuria commonly being a transient condition whereas hematuria may be long continued. But we must remember that there is a well-defined disease characterized by hemaglobinuria as its chief symptom, generally paroxysmal as in this case, and sometimes long continued; but questioning reveals the fact that the blood has appeared almost daily for months, though not always; and is not associated with exposure, a chill or violent emotion; and examination of the urine with the microscope (by Prof. Jos. Sharp) shows the presence of blood corpuscles in great abundance. So we are compelled to decide that we have hematuria and not hemaglobinuria.

Is the hematuria of urethral, vesical or renal origin? Let us see.

The endoscope reveals no pathologic condition of the urethra anteriorly and the steel sound shows nothing but a hyperesthetic deep urethra. Examination by the finger in the rectum detects an enlarged prostate; but this is usual in men of his age; and if the hematuria were dependent upon this cause it would be preceded by and associated with a marked vesical catarrh. There is no history of such a trouble and the microscope fails to show pus cells, triple phosphate and large quantities of bladder epithelium, as would be the case in vesical catarrh—so we exclude the urethra and the prostate from etiologic factors.

We now pass the hollow sound into the bladder and make careful search for calculi; none being detected the sound is made to traverse the whole area of the bladder walls, inch by inch, to discover epithelioma, papilloma or other form of tumor which might act as a cause. The sound gives no evidence of abnormality, and the patient manifests little signs of discomfort, so we would conclude that no pathologic condition exists in the bladder; but to be sure that the manipulations have caused no bleeding the blad-

der may be partially filled with warm boric solution, and this passing away uncolored confirms our opinion. There being no urethral and no vesical cause discoverable, we are forced to believe the hematuria of renal origin.

Examination, is therefore, made to determine whether or not it can be relieved by surgical treatment. Auscultation gives no evidence of cardiac lesion, percussion discloses no cirrhosis of the liver and palpation reveals no abdominal tumor—the three causes of obstruction to the return of blood from the kidneys. There is no history of colic, no pain, no tumor in the region of the kidney and no pus in the urine from suppurative pyelitis—the usual symptoms of renal calculus.

Having by exclusion, reached the conclusion that this is not a surgical case, I am compelled to send the patient to the medical clinic, as it is certain that the hematuria arises from embolism or thrombosis (the latter usually dependent upon atheroma or calcification of the vessels of the kidney), in which case the collateral hyperemia gives rise to repeated escape of blood into the tubules or into the pelvis of the kidney; or to nephritis; or to disease of the renal vessels, (aneurisms, etc.); or possibly to some depraved condition of the nervous system.

STRICTURE OF THE RECTUM.

The last patient is a colored woman of 24 years, who has a stricture of the rectum of three years' duration; it has become very close and greatly interferes with the patient's comfort and health. When she is under complete anesthesia I insert my knife through the stricture, pass it directly backward to the coccyx, and at one sweep cut through stricture, sphincter, skin and all. The inferior hemorrhoidal artery is caught and twisted, the rectum and wound thoroughly irrigated and the whole quickly packed with iodoform gauze, secured by a pad and a T bandage. The gauze may be removed at the end of forty-eight or seventy-two hours and the wound allowed to heal by granulation.

The subsequent history of a case of external proctotomy, as this operation is called, is usually quite satisfactory; far more so than in internal proctotomy (division of the stricture without cutting the sphincter or the anus) which has often been followed by pelvic inflammations, septicemia and even death. In some cases no attention is needed after the removal of the gauze, but in others it is necessary to pass a large rectal bougie from time to time to prevent too marked contraction of the cicatrix. Restoration of the function of the sphincter occurs in from a fortnight to two or three months.

PERITONITIS AND POST-OPERATIVE SEPSIS.

BY A. H. CORDIER, M.D.

LECTURER ON CLINICAL GYNECOLOGY IN KANSAS CITY MEDICAL COLLEGE;
CORRESPONDING MEMBER OF OBSTETRICAL SOCIETY, PHILADELPHIA;
MEMBER AMERICAN, MISSOURI AND KANSAS MEDICAL SOCIETIES, ETC.
KANSAS CITY, MO.

The peritoneum is a "sacred sac," and he who permits the surgeon to enter therein with unclean hands and dirty instruments will suffer (not from his own iniquities), but from the septic agents introduced into the peritoneal cavity. Cleanliness is next to godliness in intra-peritoneal surgery.

Peritonitis is a disease of the gravest character, presenting many varied types and symptoms. One case dying with a diffused septic peritonitis with a sub-normal temperature and a pulse of 55; another seemingly with the same local pathologic process

present, will have a temperature reaching a dangerous hyperpyrexia, with a pulse of 180. In one case you will find a distended abdomen, filled with parietic bowel and rigid abdominal muscles, and writhing from the pain. Again you will find a case with a like origin, with a flattened abdomen, free from pain and tenderness, and at the *postmortem* find very little evidence of so grave and rapidly fatal malady. It is from this obscurity or irregular run of the disease (peritonitis) that I have added to this discussion post-operative sepsis—a condition often mistaken for and treated as peritonitis. It is generally admitted that, with the exception of the tubercular peritonitis, this disease is always of a traumatic origin. That there exists an immunity, more or less, to septic invasion in the peritoneum, no one will doubt. This serous membrane with its endothelial covering has the power of digesting large blood clots and gelatinous extra-uterine babies, if these foreign bodies are of an aseptic character. I have seen the victim of a ruptured tubal pregnancy of tenth week recover without any operative procedure, the extravasated or free blood in the peritoneum being absorbed within a few weeks. Unfortunately this is not the usual history of these cases when not relieved by a surgical procedure.

A form of peritonitis often met with by the abdominal surgeon is one due to a ruptured ovarian blood cyst, abscess or pyosalpinx. A case known to have a collection of pus in the pelvis, should with no exception, be operated upon at once. It is true in many cases a little leakage may take place from a Fallopian tube filled with pus, and the woman escape with only a slight localized pelvic peritonitis, followed by the invariable intestinal and omental adhesions endangering her life from a strictured gut, dilated ureter and surgical kidneys, ruptured gut or bladder. The next attack may prove fatal by the local process becoming a diffused one.

There seems to be a peculiar immunity established by a slow vaccination or inoculation process, in many of these old pus cases.

I have repeatedly in "hulling out" old ovarian abscesses had a pint or more of pus escape into the pelvic cavity, and with irrigation and a drainage tube, these cases do well. If in this same case you place your patient in Trendelenburg's position and the pus is permitted to flow toward the diaphragm or in that portion of the cavity not protected by the local inoculation, as is the pelvic peritoneum, the patient will surely have greater dangers to encounter and many will die from a peritonitis regardless of the prophylactic irrigation and drainage.

The abdominal peritoneum is much more susceptible to septic invasion than the pelvic under all circumstances. You see this in comparing the recoveries in two cases where the uterus has been removed, one by vaginal, the other through an abdominal incision. In one case the operation is performed through a septic cavity, and yet the cases have a convalescence compared by one author to an "ideal puerperal getting-up." It matters not how much irrigating fluid is used, where an abscess has ruptured into the peritoneum, all the septic matter can not be removed; even though a microscope be brought to the surgeon's assistance, he could not remove it all. A few drops only of the last irrigating fluid or the fluid from the drainage tube, introduced into a clean, healthy peritoneum may induce a rapidly fatal septic peritonitis.

In appendicitis you have an acute process in the "upper peritoneum," the pus being of a most virulent character, a small quantity of which is sufficient, if turned loose into the general cavity, to produce a rapid and fatal peritonitis. Hence the practice, in operating for a "walled off" appendicitis, of never attempting to break up adhesions for fear of entering the general cavity, an accident or procedure sure to lead to the development of a dangerous or fatal peritonitis. In ovarian abscesses or *intra-pelvic* inflammatory processes, the wise procedure is to break up all adhesions, remove diseased structures and liberate healthy organs.

In gunshot, stabbed and other wounds involving the hollow viscera of the abdomen, a fatal termination is always expected (rare exceptions), from a peritonitis induced either by the weapon, missile or the escape of visceral contents teeming with pathogenic bacteria. In such cases the surgery must be *early and thorough*.

A large abdominal incision increases the dangers from septic invasion, and at the same time exposes the intestines to more handling and consequent injury. A bowel that has been exposed for a time of long duration to the atmosphere, and has been permitted to become dry and blanched, has sustained sufficient injury to materially injure its functional powers, and any agent, be it what it may, in abdominal operations that interferes with the function of this canal endangers the life and safety of the patient from the dangers attending a peritonitis. The intestines are one of nature's sewers (drainage tubes), the function of which is to absorb through the peritoneum, fluids in the abdomen, and to eliminate the same. *In a parietic bowel this function is reversed.* The peristaltic action is retarded or lost, the absorptive and digestive functions suspended, and the eliminative action absent, the contents of the paralyzed gut, already teeming with pathogenic bacteria, act as an inoculated culture tube with its two ends sealed; gases soon form in large quantities, the muscular and serous coats are dilated and thinned until the microorganisms find easy avenues of escape from the intestines into the peritoneal cavity, the function of which, as a protecting agent, is soon lost, and its great cavity converted into a vast bacterial hotbed, and the patient's whole economy saturated (from this source) with these poisonous germs and their ptomaines. Such is the progress of invasion where there have been no germs introduced into the peritoneum from without, but where the operation has been a prolonged one, with the consequent handling of the intestines and resulting injury to the great sympathetic system as a result of the prolonged exposure and traumatism.

I have seen a case go on the table with an intestinal canal empty and as flat as a tape line, and within two hours after operation find it enormously distended as a sequelæ of prolonged and unavoidable handling. All operations within the abdomen should be quickly performed by skilled and clean hands. It has occurred to me, as a good and safe procedure, where the bowel is so enormously distended and refusing to expel its contents of liquid and gases, to perform, under cocain anesthesia, a right inguinal enterostomy, wash out the intestines with an antiseptic solution, as boric glycerid, salicylic acid or boric acid, this to be repeated as often as necessary. Other drainage should be carried out. This

opening in the bowel would permit the gas to escape unobstructed by a sphincter and would give an outward drainage; it would reverse the poisonous endosmosis, and it would give the peritic gut the best chances to regain peristaltic function and tonicity. This procedure would relieve the vomiting which is one of nature's efforts to rid the canal of its offending contents. The stomach is the last of the alimentary organs to lose its contractile powers. A paralyzed peritonitic bowel will not empty itself through a hypodermic needle, but with an opening such as I have advocated, the gut will collapse and the patient will quickly feel greatly relieved from the oppressed breathing, irregular heart action and the pain from the distension. If the patient recovers, the opening can be safely closed at any time. This procedure, I think, should be resorted to early in the most desperate cases where experience has taught that all similar cases have died without it. This procedure, when salines fail, offers the best chances for the relief of the "trinity—peritonitis, tympanitis and vomiting, the furies of abdominal surgery." (Greig Smith.)

Before resorting to this procedure, salines and injections should be given a fair trial.

The usual operation for peritonitis is the procedure for the removal of the exciting cause, as appendicitis, suppurating dermoids, postpartum poisoning, etc.

The consideration of the fever following labor is one at this time receiving much attention, and is now, as it was by Dr. Holmes, fifty years ago, recognized as being of septic origin, the poison being often carried or introduced into the genital canal by the physician. An exception to this being the auto-genetic type—where the woman at time of delivery has a real pathologic process which sustains an injury during parturition and leads to the development of a peritonitis—as an abscess in an ovary or a pyosalpinx. The treatment here is the same as for other forms of peritonitis. Remove the source of infection. Unfortunately all treatment of diffused septic peritonitis has proved futile. *Only early or abortive surgery* will check the rapid and dangerous invasion of this disease. All abdominal operations should be performed under absolute aseptic precautions. The smallest incision compatible with the work to be done; the shortest period of anesthesia and the most rapid operative work leaves the patient in a condition the better able to withstand or combat any tendency to destructive invasions. Irrigation with hot sterilized water, followed by intelligent use of drainage tube, should be practiced in all cases where there exists a suspicion that the case is a septic one. These agents are used here as prophylactics. The intestinal canal may be "toned up" by giving 20 drop doses of tincture of nux vomica three times a day for a few days before the time set for the operation, and continued in form of strychnia hypodermically for days afterward. An empty stomach and intestinal canal will cause these organs to be handled and exposed less during the operation, and will conduce to the safety and comfort of the patient from vomiting and gaseous distension. If the intestines are empty the peritoneum will absorb and digest much better the fluids in its cavity. Withhold fluids for several hours after the operation. If excessive thirst exists give an enema of six ounces of peptonized milk. Avoid sweet milk and eggs by the stomach, as these articles of diet are gas forming

agents. Avoid all preparations of opium. If it becomes necessary to give any form of this drug give codeia. If drainage is being used, see that the tube is kept dry by frequent aspirations. If any symptoms arise pointing to the development of a peritonitis, such as persistent vomiting, inactivity of the bowels, distended abdomen, elevation of temperature, and quickened heart beats, give the salines (sulph. magnesia is the best) in good size doses (one to two ounces) each two or four hours until bowels act, or gas passes in abundance. To this course may be added turpentine enema (3ii to pint water) to which two ounces of salts are added. If this course succeeds, in many of the cases improvement will be noticed at once. The bowels must be kept acting each day. If patient can not retain the salts, give one-tenth grain of calomel each hour until bowels move or vomiting ceases. Many cases will be relieved of the vomiting where no peritonitis exists by giving nutrient enemata each three or four hours. Many post-operative cases die from systemic infection before the disease has had time to become general. In these cases the development may be initiated immediately after the operation, and with symptoms resembling those of shock, the patient dying within twenty-four or forty-eight hours. Here large quantities of strychnia, digitalin and whisky must be given.

The subject of peritonitis can not be discussed without considering the *trio*: 1, fermentation fever (Bergman); 2, septic intoxication (sapremia), and 3, septic infection or true septicemia. I know of no better way to make these classifications understood than by reporting illustrative cases occurring in my practice:

Case 1.—Fermentation fever, following a salpingo-oophorectomy. Six hours after the removal of sound uterine appendages for relief of the symptoms due to the presence of a uterine fibroid, my patient's temperature began to go up, reaching 104 degrees F. within twenty-four hours; was not preceded by chill; pulse increased correspondingly. The case presented no other alarming general symptoms; said she felt very well. Fearing I had the beginning of a dangerous sequela to combat, I removed my dressings and found a large indurated(?) spot to one side of my incision, in the abdominal parietes. I cut a couple of stitches and thus liberated a large collection of imprisoned blood that was forcing the fibrin ferment into the blood. My patient's temperature and pulse within a few hours returned to normal.

Some authorities doubt the existence of an aseptic fever. If there is such a condition as fermentation fever, this case belongs to that classification:

Case 2.—Sapremia (absorption of product of putrefaction) following a criminal abortion, retained placenta. After repeated endeavors with some blunt instrument, this young lady succeeded in producing an abortion. The fetus and part of the membranes and placenta were expelled. She was four months pregnant. Three days later a physician was called and found her with a temperature of 103 degrees F., having had a chill a few hours before. Pulse of the character described as indicating the absorption of the preformed ptomaines of putrefactive bacteria; a soft, compressible, quick pulse, indicating enfeebled heart's force. Vomiting, anorexia, tongue furred and dry, clammy perspiration, fetid discharge from vagina, tympanitic abdomen. I saw the case a few hours before death, at which time her temperature was 105 degrees F., pulse imperceptible, delirious, restless, clammy perspiration, dilated pupils, cyanotic, all pointing to an early dissolution. At the *postmortem* I found a large, soft uterus, with half of a rotten, stinking afterbirth in its cavity. This case could have been saved by a timely surgical procedure. Curetting, irrigation, iodoform gauze and drainage.

In this case there was some tenderness over the abdomen. The early removal of the cause will cure

the majority of these cases, unless a mixed infection far advanced exist at the time:

Case 3.—Septicemia, septic absorption, progressive sepsis. Presented the initial history of Case 2, and started as a true sapremia (absorption of the products of putrefaction) but on the third day a dirty or unsurgical curetting was done, which added a secondary (pyogenic) infection; the absorption of the products and the rapid increase of the same in the blood made the case a desperate one from this time. At the *postmortem* the peritoneum was found to contain much muddy fluid, with evidences of a general peritonitis; the local process had not progressed to that extent to account for the death, hence the certificate was signed, septicemia. An early hysterectomy with the removal of the appendages which were diseased, may have saved the patient by cutting off the supply of septic material entering the blood. The accompanying peritonitis was induced by an invasion of the germs through the Fallopian tubes.

I have reported these cases to illustrate what an easy matter it would have been to have diagnosed them as peritonitis, had they all been postoperative laparotomy cases.

In a peritonitis with well-marked constitutional septic manifestations, to resort to prophylactic or abortive measures should be early and thorough. After a laparotomy, if this condition is developing, the stitches at the lower angle of the incision should be cut, and the pelvic and lower abdominal cavity irrigated with gallons of hot salicylated or borated (boric acid) solution, and a drainage tube introduced. This washing of the peritoneum should be repeated two or three times during the twenty-four hours. It can be done without an anesthetic in the majority of cases.

SOME THINGS THAT SHOULD NOT BE FORGOTTEN BY THE GENERAL PRACTITIONER.

—BY B. C. KEISTER, M.D.
SOUTH BOSTON, VA.

First, he should recognize his duty to himself, and second, his relation to other physicians. I believe it was the late Dr. Flint who made the remark that "every physician who is true to himself should be a thorough gentleman, a thorough business man and a thorough physician."

First of all, he should be in sympathy with the Christian religion; even if he is not a member of any special branch of the orthodox church, he should certainly not be a skeptic or an infidel. It would be exceedingly difficult for a skeptical physician to hold the confidence of one of his church-going patients through any serious illness, to say nothing of the many other disadvantages, under which he would have to labor. I may be pardoned for saying that we have in our ranks, men who are not only skeptical on religion but *peculiarly so* on the science of medicine. They delight to speak disparagingly of the science and are fain to show an air of ostentation that well characterizes the peacock or the *non compos mentis*. This latter class of physicians, to say the least, are unworthy of the title they bear; for to them is due the skepticism that exists among the laity on the science of medicine, and thus a great barrier is formed between physician and patient, to say nothing of the harm done to the credit of the profession. It is true, there are wonderful changes constantly being made in the art of medicine, but generally speaking, these changes are only steps toward a better and more perfect practice of the

science. As man's constitution changes so must our practice change, in order to adapt its merits to man's necessities. Medicine is a progressive science. The advance that has been made in the past ten years in the science of medicine and surgery far surpasses that of all other branches of knowledge. Dr. Nicholas Senn, who is one of the progressive surgeons of the world, remarked to a large body of physicians a few months ago, that there had been more genuine progress made in the science of surgery within the past ten years than had been made during the previous one hundred years. Thus we see how grandly our great science is keeping abreast with all others, and I may add, since antiseptic surgery and electricity have come to our aid, we are fast outstripping all other professions on the broad road of progress.

All honor to such men as Koch, Pasteur and Sternberg who have accomplished wonderful results in their researches with the microscope, in ascertaining the cause of disease. All honor to such men as Senn and Gerster, Loomis and Osler for putting into practice the teachings of the former, and thus bringing about a grand revolution in the practice of medicine. It is the duty of every true physician to hold up the standard of his profession. And to do this successfully, he should be both a thorough gentleman and a thorough physician. He should keep abreast of the times, by spending at least three months out of every three years at the medical centers, where hospital advantages are offered to the general practitioner as well as to the specialist. This is a duty that every true physician owes to himself. If every general practitioner would do this, he would be better prepared to do his work, instead of allowing his patients to go to the city specialists to be treated for the very disease that he could have treated equally as well at home. It is passing strange that there are so many general practitioners, who from mere want of confidence in their own abilities, will send their patients to the cities to be treated by men who have had less experience and fewer collegiate advantages than they have had. I am acquainted with a physician who sends at least one-third of his cases to the city to be treated; these doubtless could be treated at home just as well. I claim that there is but one advantage the prominent city physician has over the town or country physician, namely, the hospital advantages, where good and skilful nursing is required after capital surgical operations. We need a few more McDowell's and Sims in the country villages to encourage us to compete with the city surgeons and city specialists.

I long to see the day when every village and country doctor will be as handsomely equipped in office facilities, etc., as any city specialist, and thus be prepared to treat his cases at home, instead of sending them with their pocket-books full of money to the city specialist. I am proud of the fact, that out of a yearly three thousand dollar office practice, I have thus far been able to treat my cases at home, and I mean to continue to do so as long as I remain in the practice of medicine. There is no just reason why every physician should not keep abreast of the times as above indicated, and be equipped with a full supply of the necessary surgical instruments, galvanic, faradic and cautery batteries, etc. There are many lives sacrificed, wholly on account of the attending physician not having proper surgical instruments to relieve the patient. To cite an instance of this kind: About four weeks ago I was summoned fifteen

miles in the country to relieve a man who was suffering from suppression of the urine, due to organic stricture of the urethra. The attending physician, who is a very clever man and a good doctor, did not have a urethrotome or any suitable bougies by which to relieve the patient of his intense suffering, and he had not passed scarcely any urine for the previous thirty-six hours; doubtless he would have died very soon from rupture of the bladder or uremic poisoning had he not been relieved. The pay received in this one case would have been sufficient to purchase two or three urethrotomes and a sufficient number of filiform bougies to last five years.

I claim that in nine cases out of ten it is *sheer stinginess* on the part of the physician, that he is not properly equipped with suitable instruments. Every physician should have in his office one good twenty-four cell galvanic battery, two good faradic batteries and one good galvano-cautery battery, (I like McIntosh's batteries better than any other make). If he has studied electro-therapeutics and can master it well, he will find it a wonderful help to him in the treatment of diseases peculiar to women.

I am very much inclined to believe, that in the course of time electricity will take the place of the surgeon's knife in gynecology. I can testify to its proficiency in the treatment of fibroid tumors of the uterus, subinvolution and many other diseases of this class. Conservative surgery is yielding better results every day, and I believe the time is not far distant when women's ovaries will be let as severely alone by the abdominal surgeon as the Holy Bible. Away with the idea of a physician's reputation being gauged or made by the number of laparotomies he performs or the number of women he unsexes. It was my privilege a few months ago to be an eye witness to some ten or twelve laparotomies, and I must say, with all due deference to the skilled operators, that in my humble judgment, at least two-thirds of those poor women would have been far better off without the operation. I may cite one case in particular, that had been diagnosed cystic disease of both ovaries, but on opening the abdomen and close examination the cystic disease failed to show up. The operator, however, thought it best to remove the ovaries lest the disease should show up later on. Now, this simply shows how a thing may be run into the ground by the sheer craze for reputation. There were some fifteen or more other general practitioners who witnessed this operation with me, and it was interesting to see the exchange of frowns from one to the other during the latter part of the operation. The skilled professor tried very hard to justify his theory for castrating this poor woman, but it failed to have the desired effect upon those who were present. The main symptom complained of by this woman was pain in the region of both ovaries at each menstrual period, with some irregularity of her menses. I claim that such cases can be relieved, if not cured, by medicines and electricity. Dysmenorrhea with narrowing of the internal os of the uterus can be successfully treated by three applications of Goodell's uterine dilator, followed each time with six minutes intra-uterine electricity by the faradic battery. I have never failed to cure a single case where this treatment was adopted.

I was very favorably impressed with the remark made by Prof. Bangs of the Chicago Polyclinic, in one of his lectures on gynecology, when he said,

"that after some fifteen years of active practice in his *special* branch, he had come to the conclusion that three-fourths of the diseases that women suffer from were due to constipation of the bowels." He also remarked in one of his lectures on cervical lacerations, "that three-fourths of these lacerations were almost harmless, and hence did not require operative procedures and that conservative treatment yielded far better results in such cases."

Thus we see, there is much for the general practitioner to consider before allowing his female patients to go off to be treated by the city specialist. There is no plausible reason why the general practitioner should not do as good work and get as good results in the majority of such cases, provided he has as well equipped an office as the city surgeon or specialist. In doing this he not only saves his reputation from being at the disposal of the criticising city specialist, but of equal import he saves hundreds of dollars that would otherwise leave his own needy pockets for those of the specialist. There is no reason why the general practitioner should not operate for cataract, or perform iridectomy, or remove a nasal polypus, or do any other work that he is called upon to do in the science of surgery and medicine, provided he keeps abreast of the times and is properly equipped for his work. He should consider that the city specialist's opportunities for acquiring knowledge are just the same as those of the general practitioner, for both sit side by side in the lecture hall, and hear the same lectures and witness the same operations in the same amphitheaters. It is no less the privilege of the general practitioner to take special courses at the post-graduate schools at the great medical centers, than it is the privilege of the specialists. And just here let me add, there are many who call themselves "specialists" who have taken up their *specialty* without taking a regular course in the science of medicine, thus leaving out the real ground-work of their specialty. Such men should not bear the title of doctor. They are not prepared to do their work near as well as the general practitioner. Some of your readers may infer from what I have written that I mean to cry down the specialists. I simply desire to elevate the general practitioner and place him just where he rightly belongs, regardless of the claims of the specialist. It is true, we have some very worthy and distinguished specialists, and far be it from me to detract one iota from their escutcheons. All honor and praise to such men as Chisolm, Mundé and McGuire, all of whom were once general practitioners, and well grounded in the science of medicine before they became specialists. We need more such such liberal minded men in our profession to absorb the many mushroom specialists who are constantly springing up over the country.

HYSTERICAL LOCKJAW.

BY GEORGE J. PRESTON M.D.

PROFESSOR OF NERVOUS DISEASES, COLLEGE OF PHYSICIANS AND SURGEONS,
BALTIMORE.

It is always interesting to observe the manifestations of hysteria in limited and definite areas, because if ever anything like a distinct pathologic lesion is discovered it will be in such cases. Conditions causing widespread hysteria with multiform symptoms are, like widespread lesions in the brain, too complex

for purposes of minute investigation or exact localization. It is to the limited lesions that we must look for a starting point, lesions occupying areas sufficiently circumscribed to permit of thorough examination and careful comparison with corresponding normal regions. Such conditions for example as contracture of a single limb, or a single group of muscles, monoplegia, blephorospasm and the like. These minor symptoms of hysteria do not attract the same attention as the more marked and extensive manifestations of the disease, and are perhaps often overlooked by the general practitioner or at least disregarded. For the reason given above, however, it is very necessary that these isolated symptoms should receive careful attention, and the clinical picture of the most frequent of them carefully drawn, for at rare intervals opportunities will occur to investigate the region of the brain to which such symptoms can be referred. The following cases illustrate a form of hysterical contracture, which although it was recognized many years ago is not often described:

Case 1.—Negress, age 19. Showed convulsions, ovarian tenderness, headache, and other classic symptoms. After every convulsive seizure she had rigid contraction of the temporal and masseter muscles preventing the opening of the mouth. The lockjaw continued for some hours or longer after the convulsions, and did not reappear until the next convulsive seizure. There was no record of any rigidity of the muscles of the neck, or other parts of the body.

Case 2.—Negress, age 20. Gave a history of having cut her finger three days previous to the onset of the lockjaw. As long as she was undisturbed and quiet there was no contracture, but upon the least excitement the jaws became so tightly closed that it was impossible to open them without using more force than was considered safe. There was also spasmodic contracture of the muscles of the neck and shoulders. Patient was cured by two or three applications of the faradic current aided by suggestion. She was kept under observation for some days before any suggestive treatment was instituted, and treated with antispasmodics with no benefit.

Case 3.—A young woman of about 20 years was brought to me with the history of having been unable to open her mouth for more than a week. The attack had come on suddenly, and as far as could be learned there was no emotional shock preceding it. She was of a rather hysterical temperament, but there were no permanent stigmata except the contracture of the jaw muscles. There was little or no stiffness of the neck; the teeth were tightly clenched and the greatest force that was considered safe could not overcome the contraction. Her teeth were blackened by the food and medicine that had been poured into her mouth. As the patient was rather apprehensive of hypnotism, the non-hypnotic suggestion was employed. She was carefully placed in front of a large battery, and a mild galvanic current passed through the face, the electrodes being placed one on each side of the jaw. This current was alternated with a faradic current, repeated suggestions being made that in a certain time by the watch she would be cured. In a few minutes the contracture disappeared.

In Case 2 there was the suggestion of lockjaw from the cut finger, but in the other cases there seemed to be nothing to suggest it, nor did the patients allude to their affection as lockjaw.

Incidentally the last two cases illustrate the value of non-hypnotic suggestion. The most important and useful lesson we have learned from the study of hypnotism, which has been carried on with such ardor by the French school during the past half dozen years, is that non-hypnotic suggestion is far more generally applicable, in many cases is as potent as the hypnotic suggestion, and the impression made is more enduring.

NECROLOGY.

J. M. Gatewood, M.D. of Keith, Ohio, January 19.

J. A. Hammond, M.D. of Minda, N. Y., January 7.

Hampton E. Hill, M.D. of Saco, Maine, January 9. He was 44 years of age.

R. Murphy, M.D., a member of the Wayne County Medical Society, the Michigan Surgical and Pathological Society, and for twenty years a practitioner of medicine in the State of Michigan, died in Detroit on the morning of January 20.

Thomas A. Dunkle, M.D. died at Reading, Pa., January 14, aged 50 years. Deceased graduated from Jefferson Medical College in 1863. During 1862 and 1863 he was an Acting Assistant Surgeon in the United States Hospital at Fourth and George Streets, Philadelphia. He practiced medicine in Reading over twenty years.

John K. Walsh, M.D. of Washington, D. C., January 15. Dr. Walsh was born in Washington, and graduated at Georgetown College in 1861. He was at once appointed Assistant Surgeon in the Navy and served with distinction throughout the war and afterward became a surgeon in the Army. After three years of service he resigned and took up private practice in this city and afterward accepted the position of Assistant Surgeon at the Leavenworth Soldiers' Home. He resigned three months ago and returned to Washington.

William L. Walters, M.D. of Richmond, Va., January 15. Dr. Walters had been in declining health for twelve months, but was confined to his bed only about two weeks. He was in his sixty-fifth year. He came to Richmond from Staunton about eighteen months ago. For thirty years he was an active practitioner in Augusta County where he had an extensive practice. His wife was a grand-daughter of the Rev. William Calhoun, formerly pastor of Hebron Church, in Augusta County, and was a great-grand-daughter of the Rev. James Waddell.

John A. Thompson, M.D., the well-known young physician and eye specialist of Wrightsville, Pa., died at his home in that place January 13, after an illness of about six weeks of consumption. The deceased was well and favorably known throughout York and Lancaster Counties, was about 35 years of age, and a son of the late Dr. J. A. Thompson, who died a few years ago. Dr. Thompson enjoyed a large practice. He was a graduate of the University of Pennsylvania after which he took a course in a European college. He located in Philadelphia where he enjoyed a lucrative practice. He was a member of the Lancaster City and County Medical Society, also of the State Medical Society and of the AMERICAN MEDICAL ASSOCIATION.

Joseph A. Pacetti, M.D. of Jacksonville, Fla., January 12. Joseph A. Pacetti was born in St. Augustine in the year 1838. He first commenced the practice of medicine at St. Augustine, where he followed his profession for several years. His next field of labor was at King's Ferry, in Nassau County. Just prior to the beginning of the war he returned to St. Augustine and opened a pharmacy, which occupation he was engaged in at the time of the State's secession. When war was declared Dr. Pacetti enlisted in the Eighth Florida Infantry, with the rank of Lieutenant. He was in Lee's army and fought in most of the great battles, during one of which he was wounded. For conspicuous bravery he was commissioned as Captain, and served in that rank until the surrender. After the close of the war Dr. Pacetti went to Cuba and engaged in the practice of his profession for several years in the interior of the Island. He was forced to return to this country by the Cuban insurrection, and came to Jacksonville in 1885, and has since been located there.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

F. J. REBMAN, LONDON AGENT, 11 Adam Street, STRAND, LONDON.

W. H. LOWDERMILK & CO., WASHINGTON, AGENTS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, JANUARY 27, 1894.

REGULATING THE PRACTICE OF MEDICINE IN
THE STATE OF KENTUCKY.

In the last six months more interest has been taken in this State in this question than in any other of the Union, owing to the taking effect and the enforcement of a new law. Kentucky was the first State in the Valley of the Mississippi and west of the Alleghánies to pass a law upon this subject. In fact, with the exception of North Carolina, it was practically the first to inaugurate such legislation in the United States. By this is meant the movement that at this time has carried with it nearly every State, and does not refer to the laws that had been enacted many years ago, and had become obsolete, by Massachusetts, New York, New Jersey, North Carolina, and one or two of the other original thirteen States. In 1859, the State Medical Society of North Carolina was incorporated, and a State Board of Medical Examiners created from the members of that Society. All engaged in the practice of medicine at the time of the passage were exempt from the requirements and penalties of the Act, the latter being very light. In 1874, a law was enacted in Kentucky providing for the appointment by the Governor of a Board of Examiners for each judicial district, and that no one should practice medicine unless they were graduates of a chartered medical school, or had a certificate of the Board of Examiners, or had practiced medicine honorably for ten years prior to 1874. The law also prescribed penalties for non-compliance, and the Board of Examiners was allowed to charge twenty dollars for a certificate, the Examiners to receive the fees as compensation for their services. Certificates could be granted for one year, but no longer than five years. Much good was accomplished at first, but in a few years the law became a dead letter in nearly all the districts, and in 1888

it was amended, requiring the registration of the diploma in the office of the county clerk, also the affidavit that the party had practiced medicine in the State since 1864. The diplomas of legally chartered medical colleges by the State, or of reputable and legally chartered medical colleges of some other State or country, certified and indorsed as such by one of the colleges located in the State, or State Medical Society, were recognized. On May 29, 1890, amendments were again made to the law; the most important were that the State Board of Health should certify to the character of the diplomas of colleges of other States, and to prevent traveling empirics from practicing in the State.

The defects of existing legislation were so patent, that on April 10, 1893, the present law was approved by the Governor. The main features of this are that all practitioners, and those intending to practice, have to obtain a certificate from the State Board of Health, and register it in the office of the county clerk; also gives the State Board of Health authority to refuse and revoke certificates. Section 3 of the Act gives the qualifications necessary to obtain a certificate: "First, a diploma from a reputable college legally chartered under the laws of this State; second, a diploma from a reputable and legally chartered medical college of some other State or country, indorsed as such by the State Board of Health; third, satisfactory evidence from the person claiming the same that such person was reputably and honorably engaged in the practice of medicine in this State prior to February twenty-third, one thousand eight hundred and sixty-four." Section 4 forbids any itinerant to register or to practice in any county, and Section 5 says: "The State Board of Health may refuse to issue the certificate provided for in Section 3 to any individual guilty of grossly unprofessional conduct of a character likely to deceive or defraud the public, and it may after due notice and hearing revoke such certificate for like cause. In these cases the applicant may appeal to the Governor." The Act further gives the penalties for violation, and defines what is practicing medicine within the meaning of the law.

More changes have taken place in the legislation of this State in the law upon this subject than any other, and as many of the practitioners have been called upon to comply with these changes three times, it is not at all surprising that some of this class should feel uncomfortable. The present law is a good one, and is simply what experience has taught to be necessary in order to accomplish the end desired, and has required much effort to secure its passage. Opposition to its enforcement was to be expected, but not to the extent that has been developed. A number of reputable medical men have refused to take out certificates, and thus have encour-

aged those that the interests of the people and profession demand should be suppressed. The stand taken against the advertising frauds has arrayed some of the newspapers against the Board, but so far the Governor has sustained the action taken in all cases that have been appealed. The issues involved are not alone of a local, but national character. It is clearly the duty of all reputable practitioners to encourage and support the State Board of Health in the enforcement of the law. Kentucky was the pioneer in many respects in medical legislation. Will the State that has been honored by a McDOWELL, a DUDLEY, a YANDELL and a host of other shining lights in the profession, lag behind her sister States?

WAR WOUNDS AND THE STEEL TUBULAR BULLET.

In the Report of the Surgeon General of the Army, recently published, are given the particulars of a series of experiments conducted at Frankford Arsenal, Pennsylvania, by CAPTAIN L. A. LAGARDE of the Medical Department, U. S. A., to determine the effects on the human body of cylindro-conoidal missiles of small caliber fired at various ranges. The experimental bullet was composed of lead incased in a jacket of German silver, its diameter .30 inches, its weight 220 grains. The penetration of this bullet was found to be greater at all ranges than that of the regulation .45 caliber leaden bullet weighing 500 grains. Comminution of bones and disorganization of soft parts were caused by both bullets at short ranges; but at ranges from 350 to 1,500 yards the destructive effect of the smaller bullet became reduced to a mere penetrating wound. This lessened severity is attributed to the slight amount of deformation suffered by the jacketed bullet even after impinging on bone. At ranges beyond 1,500 yards the smaller bullet again produced shattering of bones and great laceration of the softer tissues as its lessened velocity permitted of a sideways impingement. The report is illustrated with photographs of bones perforated or comminuted according to the range of the bullets which caused these injuries, showing the deformation produced by the firing and impact, and of the relative penetration of the old and the new bullet into blocks of wood across the grain. A bullet having a hard cupro-nickeled steel jacket penetrated 19.5 inches as compared with 3.2 inches for the old bullet, and with 5.3 inches for the German silver jacketed projectile. DR. LA GARDE'S conclusions are that the small jacketed projectile will increase the number of wounded and the mortality in future wars, but that the wounds as a whole will be less severe,—more humane. His paper will be republished in the Transactions of the College of Physicians of Philadelphia, Pa.

‡ But, so rapid is the progress of invention that there is already a need for another series of experiments to

determine the probable character of the wounds hereafter to be treated by military surgeons; for PROFESSOR HEBLER of Zurich, has tunnelled the small bullet and given it an ogival form in rear, as well as in front, to lessen the resistance it will encounter from the air when fired, and to correspondingly increase its range and penetration. This, the "steel tubular bullet," is now confidently regarded as the bullet of the future. It is 30 millimeters (1.18 inches) in length and 5 millimeters (caliber .20) in diameter, while its channel, bore or lumen, is 2 millimeters in diameter, widening in a funnel shape to 3.6 millimeters in rear. The funnel end is fitted with a light base cap which drops off as soon as the bullet leaves the gun. The effective range of this missile is over 6,000 yards, at which distance it penetrates nine inches into solid wood. Its maximum range is nearly 11,000 yards; and as the elevation required in using this bullet is only one-sixth of that needful for the old .45 caliber bullet, one of the difficulties of long range shooting will be removed. The effects of this bullet of the future on the human body have not yet been determined. It is probable that it will pass through leaving a clean puncture; but as it is doubtful whether the shock of such a wound would suffice to place a man *hors de combat* the return to a bullet of a larger diameter may have to be considered. With such long range small arm missiles, military tactics as well as Hospital Corps management on the field will have to be studied anew.

CRITERIONS OF PRACTICE FOR MEDICAL SECTS.

The Supreme Court of Errors of Connecticut rendered a very interesting and important decision on May 22, 1893, in the case of Force v. Gregory, which has not yet been officially reported, and which has only just appeared in the advance sheets of the *Atlantic Reporter* (No. 17 of Jan. 10, 1894; Vol. 26, p. 1116). This was an action brought by a minor child, to recover damages from a homeopathic physician, for alleged malpractice in treating her for ophthalmia.

The fact that the action was brought by an infant of tender years, incapable of contracting, and that the physician was called by her father, it was not contended in any way extended or altered the implied contract and duty of the physician. Nor does the court think that, if such a claim had been made, it would have been valid. It further appeared that this physician had, at least to some extent, been the family physician and had previously, as such, prescribed for the child; but to this circumstance, also, there was no importance attached.

Following in the line of many precedents, the court lays down the doctrine that, in the absence of special contract, physicians and surgeons, by holding themselves out to the world as such, impliedly contract that they possess the reasonable and ordinary

qualifications of their profession, and are under a duty to exercise reasonable and ordinary care, skill and diligence. In determining what constitutes reasonable and ordinary care, skill and diligence, the test is that which physicians and surgeons in the same general neighborhood and in the same general line of practice ordinarily have and exercise in like cases. In addition to this, however, regard must be had to the advanced state of the profession at the time of the treatment.

Evidence was offered, on the one side, to show that the treatment and remedies prescribed by homeopathic practitioners were adopted. On the other side, an attempt was made to prove that the regular school of medicine would treat such a case differently, and that the latter treatment ought to have been used. It was also asked that the jury be charged, "that treatment by a physician of one particular school is to be tested by the general doctrines of his school, and not by those of other schools." This instruction was refused, it being charged, instead, that if the treatment laid down by one particular school of medicine was adopted, and the medical testimony offered to prove malpractice related to the treatment prescribed by a different school, it should be considered with regard to any bias or prejudice that might influence those offering it. Doubtless, the court says, this is correct, so far as it goes. The testimony should be so weighed. But if the physician adopted the treatment, not of one particular school in the abstract, but of his own particular school, which he publicly professed and practiced, and the medical testimony offered by the other side related to treatment prescribed by a different school, such testimony should be weighed, not alone with regard to bias or prejudice influencing the testimony of witnesses, but with regard to bias or prejudice which might influence or incline the jury in favor of one school rather than the other.

Not only did not the evidence in this case stop with the statement of how, in the view of the witnesses, such a case ought to be treated, but went further, and stated how "the 'allopathic' school of medicine would treat it." Indeed, it was argued that the respective merits of the "schools" of medical practice were—and, of right ought to have been—on trial before the jury. Such right, however, the court does not concede, holding that the jury should have been told that the relative merits of the two "schools" were in no sense before them for their consideration; that, so far as the physician charged with malpractice was to be judged by either, it was by the tenets, rules, principles and practices of his own school, not by those of another; and that, if he adopted the treatment laid down by his own "school," the fact that another "school" prescribed another treatment tended in no wise to show that he was chargeable

with a lack of skill or negligence. Because of these errors, a judgment rendered against the physician was set aside, and a new trial granted.

It would also seem, from what the court said, that if it could be held negligent or unskilful in a given case, to use the treatment prescribed by the school to which the practitioner belonged, such negligence or want of skill must consist either in the mode of use, the application of such remedies under improper circumstances, or because they were intrinsically wrong, inappropriate or inadequate.

OBSERVATIONS REGARDING THE UNEDUCATED RETINA.

DR. FREDERICK A. COOK, who was ethnologist to the PEARY expedition to North Greenland, is the author of a series of papers on the peculiar facts observed by him in the far North. The following paragraph relates to the physiology of the eye, and covers a point which, so far as his and our reading goes, has not been traversed before by any explorer of uncivilized lands:

"The most remarkable peculiarity that I discovered was suggested by an accident. I had given one of the natives a lithograph of an actress. He took it to his house and fastened it to the oily walls upside down. When I saw it I changed it, but on entering the house a few days later it was again reversed.

"This aroused my curiosity, and I tried the same experiment on other newcomers, and found to my surprise that they all did the same. Without exception, every individual who was handed a picture book would invert it, and then in awe and amazement carefully examine the pictures. The individuals upon whom I noticed this strange peculiarity had never seen a book, picture, printed or written paper before.

"I asked them to draw for me a polar bear. To this they rapidly responded, but drew the image inverted. Other images and pictures were drawn with the same result.

"After thinking the matter over and more closely examining their eyes an explanation readily presented itself. It is a well-known fact among ophthalmologists that things which we see are transmitted to the retina inverted by a process or a physical law similar to that which inverts a picture in a camera. Thus far, the physiologic phenomena is the same in all men and animals. But in the next stage, where the image or its interpretation is transmitted from the retina to the brain, is where the important difference lies. These natives in their infancy of civilization have not been educated, as we have, by a long series of training and probably heredity, to read pictures as they would natural objects, but instead they hold the picture upside down, so that the image will be transmitted to their retinas in a reverse position, and hence the impression is transmitted to the brain in the most natural way."

On his return from North Greenland, DR. COOK visited Labrador, and while there observed the same characteristic of vision, to a less extent, among the mountaineer Indians; and later still he has seen a number of young persons in civilized countries, who have not yet been taught the art of picture reading, who have a manifest tendency to hold their pictures upside down.

MEDICAL AID TO LABRADOR.

Both the English and Newfoundland men have joined to sustain an itinerant medical service for the help of the deep sea fishers and the temporary

dwellers along the coast of Labrador. The English sent the ship *Albert*, with a surgeon who visited in her and from her deck thirty-five harbors, and who treated at least a thousand patients. The settlers are largely of English extraction or birth. They were found to be in destitute condition and were greatly benefited by the presents of clothing taken out by the *Albert*. It is estimated that over thirty thousand fishermen and their families reside, for three to four months, in the natural harbors and islands along the Labrador coast; and during this time the only medical attention available for them is such as is sent out by the mission hospital societies. Two hospital stations have been originated in harbors at which the fishermen are apt to call on their passage up and down the coast.

VACANCIES IN THE ARMY MEDICAL CORPS.

SURGEÓN GENERAL STERNBERG has issued a notice which we printed in the JOURNAL of last week, that a Board will be convened in Washington, D. C., in April next for the examination of candidates for the Medical Corps. There are six vacancies to be filled. The circular of the Surgeon General gives full information for those desiring to compete, as to the mode of application, the conditions and requirements, the scope of the examination, etc., and as to the advantages accruing to the successful candidates. There are no more desirable positions open to young graduates than those in the Medical Corps of the Army. Among the inducements to enter the military service are a special education at the Army Medical School qualifying the individual as a sanitary officer, a permanent position with fixed duties and responsibilities, rank, pay and emoluments increasing with length of service and provision for disability from accident, sickness and old age. A set of the examination papers used by the board in session in Washington, D. C., in October last, was published in the JOURNAL of Oct. 28, 1893.

CHOLERA IN BELGIUM.

Ten days ago it was announced that a prominent officer of Brussels had died from cholera. This meant that there were other cases there, but nothing was said about them. The disease is now reported as having appeared at Anvelais near Charlevoi, and that on January 16 twelve deaths occurred, and that many of the inhabitants have been attacked. It is safe to assume that many more cases occur and in different localities than are reported by the authorities, and the history of the past warrants the assumption that a recrudescence of the disease in many localities will take place as the temperature rises.

The very latest "remedy" for the morphin habit is potassium permanganate.

ASSOCIATION NEWS.

We desire again to call attention to the official notice of the change in the date of the next meeting, to be held in San Francisco. At whatever cost of time and money, we are confident that those who make the trip, will feel themselves most amply repaid. Doubtless the best of railroad facilities will be at command and hardly a more favorable date for the meeting could be named. A very large representation from east of the Rocky Mountains should be in attendance, and to those who know the physicians of the Pacific Coast no assurance need be given of the royal hospitality with which their guests will be entertained.—*North American Practitioner*, January, 1894.

Application Blanks for Membership.—On advertising page v we print a convenient form of application blank that is being circulated by the ASSOCIATION JOURNAL. Any physician desirous of joining the ASSOCIATION can cut out this blank, and, having properly filled it, can mail same with his subscription to the Treasurer. As many physicians seem to be waiting for these blanks before joining the ASSOCIATION, it is pertinent to remark that the blank is not a necessity but merely a convenience. The essential is a certificate signed by the President and Secretary of a [regular] State or local Medical Society, and this, accompanied by \$5, will be duly honored by the Treasurer. Dr. Kerr, the Secretary of the Medical Society of the State of California, has announced that the circulars of his Committee of Arrangements will on this occasion be mailed to every physician in the State, and will be accompanied by blank applications for membership in the ASSOCIATION. Meanwhile our readers will find each month the regular application form in our advertising columns, and we shall be at all times ready to afford any information in these matters.—*Occidental Medical Times* January, 1894.

To the Medical Press of the United States.

The undersigned, appointed at three successive meetings of the AMERICAN MEDICAL ASSOCIATION as Chairman of a Special Committee to appeal to Congress to establish a Department and a Secretary of Public Health, begs to say, that though a formal petition to the fifty-second Congress was made to grant our prayer, yet on account of the newness of the proposition and various other adverse circumstances which were duly set forth in my report of progress to the ASSOCIATION in Milwaukee, the Congress adjourned without granting our request.

It had not been expected that such an advance movement for the promotion of the medical profession to its true rank and dignity in the State, however beneficial it would be to the public welfare, could be granted without a complete organization of the profession throughout the Nation, and an invincible purpose to sustain its claim to be represented in the Presidential Cabinet on a parity with the Departments of Finance, of War, of Justice, Agriculture and the other Departments, and I request the publication of my letter to Senator Harris of Tennessee, which will explain the attitude of the medical profession on the subject. The committee is now engaged in the preparation of the bill to be introduced into the present Congress. We are seeking to bring about a great organized movement and hope to arouse the activity of our vast profession to secure its passage. It certainly can be accomplished. We entreat the aid of the medical press to give publicity to all our publications and to sustain our cause.

Very respectfully,

C. G. COMEGYS, Chairman.

Cincinnati, Ohio, Jan. 18, 1894.

CINCINNATI, OHIO, Feb. 1, 1893.

To the Honorable the Senator Isham G. Harris, Chairman of the Senate Committee on Infectious Diseases.

Dear Sir:—I venture upon your courtesy for further con-

sideration of the petition and bill in your hands for the establishment of a Department of Public Health and a Secretary of Public Health. I earnestly request your patience to read my remarks.

I was not aware until I returned to Cincinnati that you had introduced a bill in regard to public health and that it was referred to your committee. On looking over it, I find that it is an admirable measure to secure a more thorough quarantine service; but it does not consider as extensively as the AMERICAN MEDICAL ASSOCIATION bill, other relations of the medical profession to the social conditions of the people for the prevention of sickness, growing out of their mode of living and the nature and exactions of their employments.

Prof. Dickenson of London, said in a public address fifteen years ago, that more people had been destroyed in Great Britain in one year by diseases that might have been prevented (diseases not imported) than were destroyed in France during the Reign of Terror; or during the recent Franco-German war; yet this great destruction of life by disease had created no public excitement. Nevertheless, his remarks, reinforced by a multitude of other medical writers, brought about parliamentary action that has effected, through improved sanitary measures, a great saving of life and relief of public distress. I beg to say further in regard to your bill for the establishment of a National Board of Health that there is no provision for the collection of vital statistics—marriages, births and deaths—and the relation which these events bear to conditions of prosperity or adversity of the people at large. Again, there is no provision in your bill to determine by collective investigation the primary and secondary causes and the results of medical treatment of inflammatory and fever diseases that exist in the various regions of our country. To collect this information it seems to me, is a positive duty of the general Government and which could be accomplished by a Health Department being brought into correspondence with State Boards of Health. In Great Britain such disclosures have been of great value.

In your bill no reference is made to the importance of higher medical education. There are over one hundred medical schools—of all systems—in the Union; and it may appear to you that nothing further is required; but these schools are not equally possessed of means or local opportunity to teach on the highest plane of advanced science. It is only recently that a somewhat general agreement has been reached which demands an examination for matriculation; and that the course of study in college should be lengthened to three full years. All experienced practitioners know that besides a good preliminary entrance examination, four full years are required to train a student thoroughly in general and special departments of practical medicine, in order to render him trustworthy as a practitioner. It is the desire of the medical profession that a course of instruction shall become available that will constitute physicians, everywhere, a body of learned practitioners commanding the respect and confidence of the people. It is plain that such professional qualities are of the utmost importance to the people. The influence of the Department of Public Health would greatly promote the elevation of practical instruction and bring about concord and increased efforts in all schools to accomplish the best kind of work.

I further beg your attention to the constitution of your National Board of Health, in regard to the employment of three scientific men at a salary of \$5,000 each, to carry on sanitary investigations. The Government is already possessed of laboratories and men of science connected with the Military, Naval and Marine Hospitals, in the Geodetic Department of the Coast Survey and in the Department of Agriculture, sufficient to accomplish every investigation in sanitary and biological science. Moreover, in all the universities and general hospitals throughout the land, biologic and bacteriologic research is in continuous operation; and the same may be said in regard to investigations of food, water, and everything belonging to domestic economy and a healthy mode of living. If any unusual researches should be required, it would be much less expensive to employ some of these establishments to do the work, than to build new laboratories at Washington.

It is with the utmost respect for your eminent character and experience as the head of the Senate Committee on Contagious and Infectious Diseases, that I venture to ask you to so modify your bill that instead of creating a National Board of Health you make it conform to the proposition of the AMERICAN MEDICAL ASSOCIATION bill as introduced by the Hon. John Sherman. This can be done by combining

all you say in your bill, in regard to the more thorough treatment of the quarantine question, with the plan of a Medical Department of Public Health and a Secretary of Public Health, and it will cost less than the one you propose. I am not certain as to the salary of a Cabinet Secretary, but it would certainly be less than that of three scientists at \$5,000 a year each. The same retinue of clerks, would, I suppose, be required for either case. The Army Library and Museum Building could furnish quarters for the Health Department.

Let me ask your patience for a further consideration of the medical office in the body politic. Some are startled at the idea of a physician being made a minister of the State. Why should there be a Secretary of the Navy, of Finance, or Agriculture, etc., any more than one of Public Health? Can not any one of these Departments be as well conducted by a board of specialists as a Department of Public Health? The objectors to a Medical Secretary in the State, limit too much the functions of such an officer. He could collect all the facts connected with his profession from all the regions of this immense nation and by an interchange of ideas derive from them the most valuable suggestions on the well-being of the people. There are no citizens so closely in touch with individuals and families as the doctors; and there has descended to us through all the ages the maxim that the health of the people is a supreme law. For the medical profession to be able to exert all its benign influence on society, it must have the rank and dignity attached to it by the general Government that is so readily accorded to other Departments. It is worthy of such distinction because it is one of the most learned professions. Its methods of practical research are the same as those employed by lawyers, engineers, machinists, and in the whole range of the natural and physical sciences. It is a science of observation; while it has not the quantitative precision of mathematics, it has the qualitative that attaches to all the sciences of observation. The methods of the calculus employed in the study of the perturbations of celestial bodies are the same as those employed in the problems of pathology. In short, the clinician proceeds in his investigations regulated by the canons of logic. Hence it is that the opinions of well-trained and experienced physicians are on as high a plane of certainty as those of lawyers, judges, statesmen, engineers, architects, divines, bankers and merchants. Medicine has never been cultivated in the highest degree in nations where it has had imperfect recognition as an element in the State. In the British Empire it has always been under the watchful care of State authorities; at this time its eminent practitioners are frequently receiving the honor of knighthood; and, as evidence of its higher public importance, there is an increasing contingent of physicians in the House of Commons. The Senates of France, Italy and Germany contain some very eminent physicians; a physician is a Cabinet Minister in Italy.

Physicians like Mungo Park and David Livingstone have been explorers and pioneers of civilization. The progress of Christian missions is successful because of the physicians, women as well as men, who go with them; without their great success in curing the ailments of the uncivilized, the missions would become failures. China, Corea, India and Africa are accessible through the influence of physicians.

The progress of medicine in saving life in times of great distress is shown in the practice of midwifery. A maternity hospital of Philadelphia reports a thousand successive cases without a single death. The Paris Maternity Hospital reports two thousand successive cases and not a death. The discovery of antiseptic and aseptic management has accomplished this wonderful success. The deaths in surgical treatment have been very greatly reduced by the same methods; the deaths in surgical practice in hospitals for 1891 were but 3½ per cent. In the surgical diseases of women the rate is still less. Thus you can appreciate how enormously the volume of human grief, agony and bereavement has been assuaged. This has all been accomplished within twenty years. Pasteur of France, and Lister of England, are the two famous men who have led the van in these triumphs. One-half the children under five years of age in American cities die; it is a disgrace to our civilization. This fearful mortality can be reduced under the agency of State preventive medicine.

Let me speak briefly on the increased light which human physiology and pathology have shed on the relations of the brain and the mind. For a long time the brain has been known as the centers of sensation and motion; but only within a few years have they been located in the great mass of nervous matter,—the brain and the specialization of ter-

ritory in relation to these functions is now so defined that we know the very seat, not only of mere faculties of sensation and motion and their coördination for the execution of instinctive and purposive movements; but we can put our fingers on the exact region where exists our capacity to think—the area where sensations are shaped into concepts—where ideas are symbolized in language,—where memory holds its seat and the imagination displays its marvelous powers. All the apparatus of our animal life, the organs of respiration, digestion, circulation, excretion, the great neuro-muscular systems, is merely to sustain and develop a definite area of the periphery of the brain, which you may cover with your two hands; it is the realm of consciousness,—the plane where matter and spirit greet each other,—and the healthy life which enables a man to say: I know, that I know; I feel, that I feel; I think, that I think; it is where the consciousness of man counterpoises the immensity of the universe. Gravitation is instantaneous in its action; consciousness just as rapidly reaches from the center to the circumference of the cosmos. Who has the right to supervise this dread region but the physician? Closer than the minister of religion, or the ties of blood, he stands as the guardian of its illimitable faculties. Through medical physiologic research, psychology has been lifted above the subtle reasoning of the schoolmen into the light of a new day and is now comprehended as never before. Metaphysics is no longer a jugglery with words and phrases, but is a function of consciousness only existing in healthy brains; it is the purest and highest expression of reason and a free will and can not be displayed but by the healthy brain; it is a psychologic systemization of terms under the regulative faculty—the will,—whereby the intuitional phenomena of thought and the phenomena derived through the senses from external objects,—the ideal and the real,—the subject and the object, are brought into accord and the consciousness is freed from baleful illusions, hallucinations and delusions. The imperfect state of consciousness in unsound sleep wherein ideas flow, regulated only by their automatic association, represents an abeyance of the metaphysical function. We are led everywhere by the most grotesque, absurd and often fearful ideation, without any self-control, until further aroused, to break the spell. There is no metaphysics, or free will in dreams. The above argument, I hope you will believe, is legitimate in considering the relation to all the affairs of the social and political state founded upon the dogma that the healthy brain is necessary to free will. All abuses of appetite in eating and drinking, all violence to the brain by over-work, over-strain in excitement of any kind, deteriorates at length the health of the brain, and impairs the mind for reasonable thought and action. The business world, owing to hazardous trading or gambling, continually presents a spectacle of disaster, caused by the wear and tear in winning and losing. The questions of automatic and reasonable actions are embraced in the discussions which constitute so much perplexity in medical jurisprudence. The race of cranks that infest society are unfortunates who are deficient in brain health and are in so many ways irresponsible. They are victims of ideas which make them often dangerous to society.

I will not weary you further; but merely state that it is not for their personal aggrandizement the medical profession makes this appeal to Congress, but only for the benefit of the people. My whole purpose, however, is to show that physicians are of absolute necessity to civilization and the progress of society in all its phases; and, on account of their intimate relation to the people, should be placed in the best attitude by the State for the promotion of the health and happiness of all.

I have the honor to be your obedient servant,

C. G. COMEYS,

Chairman of the Special Committee of the AMERICAN MEDICAL ASSOCIATION.

SOCIETY NEWS.

Eleventh International Medical Congress.

To the Editor:—I sincerely hope you will, in behalf of those medical men who intend to visit the Eleventh International Congress (Rome, March 29), publish the accompanying circular, probably the last I shall be called upon to distribute, or as much of it as you deem proper. It contains all the

particulars, which may still be of service, and in regard to which I am constantly receiving personal inquiries.

Very sincerely yours, A. JACOBI,
Chairman American Nat. Committee.

110 W. Thirty-Fourth Street, New York.

Jan. 10th, 1894.

A letter directed to the undersigned by the Secretary General of the Eleventh International Medical Congress and dated Dec. 19, 1893, contains the following communications:

"American members will pay on the English, French and Italian railways single fares for double journeys, and will obtain a reduction of 20 per cent. on fares for Italian round-trip tickets.

"The documents required for their identification will be sent to you in January, and Americans intending to visit the Congress will have to apply to you for them.

"Full particulars concerning the journeys will accompany the documents.

"Messrs. Thos. Cook & Son, London, Paris, Rome and Naples, should be applied to for accommodation and for tickets for the excursions at Rome, Naples, and to Sicily. Such excursions will be arranged at Rome under the guidance of Mr. Forbes, member of several scientific societies and correspondent of the *Times*—for Naples, three days, including Vesuvius, Pompey, Capri, Sorrento, Castellamare, Bajae, etc.—for Sicily, ten days from Naples, including Messina, Taormina, Catania, Girgenti, Siracusa, Palermo, and return to Naples.

"The fares for members of the Congress will be considerably reduced and comprise hotel accommodations, carriages, guides, boats, etc.—about 70 francs each for the three days, and 285 francs for the ten days.

"Full particulars concerning these excursions will be contained in a leaflet to be added to the instructions and documents for the journey."

From former communications the following are herewith quoted: The members' fee is \$5, that of their wives or adult relations \$2 each. Checks or money orders may be sent to Prof. L. Pagliani, Rome, Italy. Credentials have been promised in the near future. When they arrive (none were received last year), they may be too late for many who have started or are about to start. The undersigned, who is not informed of the cause of delay, proposes to supply in as official a form as he thinks he is justified in doing, credentials which are expected to be of some practical value. The North German Lloyd has promised to recognize them. It is suggested, besides, that a passport may increase the traveler's facilities.

Only the North German Lloyd (22 Bowling Green) and the Compagnie Générale Transatlantique (3 Bowling Green) have thought fit to grant any reduction to Congressists.

The reductions on Italian railways are available from March 1 to April 30.

A. JACOBI, M.D.

110 W. Thirty-Fourth Street, New York.

Jan. 11, 1894.

The New Jersey State Board of Medical Examiners met at Trenton, and were engaged in examining applicants for license on January 9 and 10. Seventeen candidates were present.

The Schenectady County Medical Society met January 9 for election of officers. The following were elected: President, Dr. John A. Heatly; Vice-President, Dr. D. L. Kathan; Secretary, Dr. F. V. Brownell; Treasurer, Dr. H. C. Van Zandt. Dr. W. T. Clute was elected a delegate to the annual meeting of the State Medical Association to be held in the city of Albany in February next.

A New Neurological Society.—The Baltimore neurologists have united in the formation of a society having social aims and the discussion of the problems of psycho-pathology and neurology. The next meeting will be held on the second

Wednesday in February, Dr. Henry M. Hurd in the chair. The place of meeting will be the Johns Hopkins Hospital. Among the charter members are Drs. G. J. Preston, H. J. Berkeley, G. H. Rohé, S. J. Fort, William Lee, E. N. Brush, H. M. Thomas and C. G. Hill.

There is a project on foot in Detroit to unite the different medical societies of that city in one organization. Committees from the various societies have been appointed and are now discussing the matter. It is hoped that the profession may have a building of its own.

New York State Medical Association.—The Tenth Annual Meeting of the Fifth District Branch of the New York State Medical Association will be held in Brooklyn on Tuesday, May 22, 1894. All Fellows desiring to read papers will please notify the Secretary,
E. H. SQUIBB, M.D.
P. O. Box 760, Brooklyn.

The New York County Medical Association met January 15 and elected the following officers: President, Dr. S. B. Wylie McLeod, who has served three terms; Dr. Augustus D. Ruggles, Vice-President; Dr. P. Brynberg Porter, Recording Secretary; Dr. William W. Van Arsdale, Corresponding Secretary; Dr. John S. Hinton, Treasurer, and Dr. John Blake White, member of the Executive Committee for four years.

The Regular Meeting of the Tioga County Medical Society, N. Y., was held January 9. A large number of physicians were present, as the regular business was the election of officers for the coming year. The following officers were chosen: President, Dr. George M. Cady, Nichols; Vice-President, Dr. A. J. Harris, Candor; Secretary, Dr. I. Vreeland, Waverly; Delegate to State Society, Dr. D. S. Anderson, Owego.

Philadelphia County Medical Society.—The Philadelphia County Medical Society is without a second vice-president. The Society met on the night of January 17, to elect its officers for the year, and the only nominee for the second vice-presidency was Dr. Clara Marshall, Dean of the Women's Medical College. This was regarded by some of the members as an innovation as, so far, no women have been elected officers of the Society. Dr. George de Schweinitz was named against Dr. Marshall at the last moment and the vote resulted in a tie. At the next meeting, which will be held in February, the question will be finally settled.

At the Annual Meeting of the Camden, N. J., Medical Society January 10, the following officers were elected: President, Dr. Joseph H. Wills; Vice-President, Dr. O. W. Braymer; Secretary, Dr. Sophia Priestly; Treasurer, Dr. A. H. Lippincott; Reporter, Dr. Daniel Strock; Librarian, Dr. Joseph L. Nicholson; Standing Committee, Drs. J. M. Ridge, G. E. Kirk, W. S. Bray; Legislative Committee, Drs. George W. Henry, D. W. Benjamin, J. M. Ridge. Managers for the Camden City Dispensary Association were also elected as follows: Drs. O. B. Gross, H. Genet Taylor, A. M. Mecray, J. S. Baer, E. L. B. Godfrey, George T. Robinson, W. A. Davis and J. F. Stock.

Wayne County (Michigan) Medical Society. (Detroit) Wednesday evening, the 17th inst., about two hundred physicians, members and friends of the Wayne County Medical Society, listened to a paper on "Peritonitis and Appendicitis," by Dr. Roswell Park, Professor of Surgery at the University of Buffalo, which the Doctor had been invited to read before the Society. The paper dealt principally with the bacteriology and pathology of peritonitis and appendicitis and was largely the product of original researches. It was discussed by Drs. Donald McLean, E. W. Jenks, E. L. Shurley, G. H. Carstens and A. N. Collins of Detroit. The whole subject

of peritonitis and appendicitis, etiology, pathology and treatment, was thoroughly canvassed. At the conclusion of the discussion, a collation was served and all members and friends of the Society were given an opportunity to meet the essayist.

Dauphin County Medical Society.—The following officers were elected January 16, at a meeting of the Dauphin County Medical Society of Pennsylvania: President, Dr. F. W. Coover; First Vice-President, Dr. W. J. Middleton; Second Vice-President, Dr. E. H. James; Secretary, Dr. Paul Hartman; Treasurer, Dr. E. H. Coover; Board of Censors, Dr. H. McGowan, Dr. Orth, Dr. Gorgas; Board of Examiners, Dr. Hamilton, Dr. C. A. Rahter, Dr. F. W. Coover; Delegates to AMERICAN MEDICAL ASSOCIATION, Dr. W. T. Bishop, Dr. W. H. Seibert, Dr. E. H. Coover, Dr. H. McGowan, Dr. J. F. Culp; Delegates to State Medical Society, Dr. Gerhardt, Dr. W. E. Ellenberger, Dr. J. W. Roof, Dr. E. H. James, Dr. D. S. Funk, Dr. J. B. McAllister, Dr. J. F. Culp, Dr. A. T. Bishop, Dr. W. H. Jones; Trustees, Dr. H. McGowan, Dr. S. R. Gorgas, Dr. E. H. Coover; Sanitary Committee, Messrs. Hartman, McGowan, Gerhardt, F. W. Coover, Middleton, Hamilton, Ruhl, of Middleton.

The Erie County Medical Society held its annual meeting, January 9, when the election of officers for the current year was held, and the Society completed the revision of the by-laws, upon which it has been engaged for some time. The election of officers resulted as follows:

President—Dr. William H. Gail of East Aurora.
Vice-President—Dr. F. W. Bartlett.
Secretary—Dr. Franklin C. Gram.
Assistant Secretary—Dr. George F. Cott.
Treasurer—Dr. Edward Clark.
Assistant Treasurer—Dr. Eugene A. Smith.
Librarian—Dr. William C. Callanan.
Membership Committee—Drs. John A. Pettit, J. W. Putnam, and G. W. McPherson of Lancaster.
Censors—Drs. J. Krug, J. S. Porter, J. H. Potter, A. L. Benedict, and Henry Lapp of Clarence.

Delegate to State Medical Society—Dr. J. H. Pryor.
The revision of the by-laws was necessary because some of the sections had become obsolete through the action of the Legislature during the last ten or fifteen years, and other conditions had arisen in the same manner which were totally unprovided for.

One addition to the by-laws was the adoption of an article for a Committee on Hygiene, which is intended to act in the direction of public health, and to cooperate with the Board of Health when necessary. The following were appointed: Drs. H. R. Hopkins, Edward Clark, W. W. Potter and E. C. W. O'Brien.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOLETT, M.D., President.

(Continued from page 95).

METALLIC ELECTROLYSIS.

I have often succeeded in plating the needle with metallic copper in the following manner:

After obtaining the oxychlorid of copper as just described, a perfectly clean steel needle is attached to the negative pole, and a platinum needle to the positive pole. The steel needle is then placed within the zone where the oxychlorid of copper was deposited, and the other needle inserted in another portion of the meat; it is found on removing the needle after five minutes, that it has become coated with what appears to be oxid of copper. To prove this, it is only necessary to substitute this needle for the ordinary negative element of an Edison-Lalande battery, and wait for a few minutes, when the needle will be found to be coated with metallic copper. This method is not a caustic one, as in ordinary galvano-caustic applications, simply because the organic acid set free attacks the oxidizable electrode instead of the tissues.

The synthesis of this electrolytic action, Gautier sums up in a series of physico-chemic phenomena, as follows: 1, voltaic decompositions; 2, secondary chemic actions; 3, endothelial diffusions.

The first action of the treatment, on the uterus for in-

stance, is to saturate all the uterine cavity with the newly born salt, whether of zinc, copper or iron. This is diffused into the mucous membrane, the glands, the blood vessels, and the muscular tissue of the uterine body successively. This impregnation is much more considerable, according as the current which favors the cathodic action is high and long continued.

In living tissues, I have seen the dissemination of the copper salt very marked in the treatment of cystic degeneration of the cervix uteri by means of cupric puncture, and about the meatus urinarius in the treatment of the female urethra.

This interstitial saturation, of whose microbicidal effect there is no doubt, causes a transient congestion of the uterus. The glands become congested and empty their contents; the mucous membrane is detached in shreds, or as a whole; there is in a word, a work of elimination and repair which takes place in the neighboring tissues without pain and without inflammatory reaction. This process extends over a period of eight days.

On the one hand, the Apostoli or galvano-caustic method, is characterized by unoxidizable electrodes, high intensities, and short sittings; while on the other, the Gautier method or metallic electrolysis, is characterized by the use of oxidizable electrodes, low intensities and long sittings.

In favor of the low intensities and long sittings, Gautier⁶ refers to observations made by Heidenham, concerning the actions of prolonged applications of currents on fatigued muscles, and upon vaso-motor nerves. Heidenham has shown that to restore a fatigued muscle to its primitive vigor, prolonged applications of the continued current are necessary, and that to act upon vaso-motor nerves, treatments of long duration are necessary; and Cyon has found the same. As an argument for the use of weaker currents, he quotes the observations of the Weber brothers.⁷ When they stimulated the vagus by strong currents they stopped the heart in diastole, while Pflüger and Van Bezold proved afterwards that with feeble currents to the same nerve, the heart was slowed only. The Weber brothers, instead of stimulating the nerve, exhausted and paralyzed its excitomotor action. Admitting, then, that electricity, acting on the uterus excites the terminal filaments of the sympathetic nerves which end in that organ, and that the result is stimulation of vaso-dilators or vaso-constrictors, then strong excitation ought to produce a *vaso-dilatation* of the large arterial region of the abdomen, while feeble and prolonged excitation would produce the opposite effect.

In gynecologic work, Gautier claims for this method, as opposed to that of Apostoli, less pain, and an abridgment of the time of treatment, with better and more lasting results.

The advantages of the method over the topical application of sulphate of copper in stick or in solution, of zinc in paste or solution, or of iron in solution are as follows:

In the first place, ability to localize the medicinal action of the metallic salt used directly upon the diseased surface. For instance, in the treatment of a deep sinus, a copper probe may be carried to the bottom and the copper salts manufactured there where most needed; 2, drugs introduced into the system in a nascent state are much more active than in chemic combination; 3, by cataphoresis the salts thus formed are driven into the tissues, rather than laid upon the surface of a mucous membrane, as in ordinary topical applications; 4, there is obtained at the same time the beneficial action of the physiologic properties of the current.

The technique of the treatment is that of any galvano-caustic application, save that necessarily the positive pole is always the active one, and for the usual electrodes there are substituted sounds and needles of copper, zinc and iron. These are the metals which seem to have the widest range of usefulness as therapeutic agents.

So far as the published reports indicate, Gautier's observations have been made with pure red copper only, but he invariably refers to the use of soluble metallic electrodes in which category may be placed iron and zinc. The latter, as well as the copper, have been used by Dr. W. J. Morton and myself in the Electro-Therapeutic Clinic of the Post-Graduate Medical School, as well as in private practice.

After each application the electrodes should be carefully rubbed with emery paper, in order to secure an unoxidized surface for the next application.

In gynecologic work, a C. S. of from twenty-five to forty

or fifty milliampères should be used. This maximum intensity should not be exceeded. The first sitting should be of fifteen minutes' duration, with—according to Gautier—from six to eight minutes for reversal of the poles, using a current of five to ten milliampères in order to loosen the electrode which has become adherent to the tissues. A constant and gentle manipulation of the electrode may be safely kept up in suitable localities during the treatment, thereby preventing any adhesions, and the necessity of polar reversal.

The length of the sittings should be progressively increased up to thirty minutes or more, according to the indications, and the tolerance of the patient. Both Gautier⁸ and Delineau⁹ find that prolonged sittings of metallic electrolysis, twenty to thirty minutes, are much more successful in combating hemorrhage than strong currents of short duration. The latter reports that he finds the hemorrhage is usually stopped after the first sitting. Gautier also finds rapid cures from metallic electrolysis in disease of the endometrium, even in cases where gonococci have been demonstrated.

In uterine hyperplasia, in pelvic exudates, and in certain inflammations of the tubes he has also found it very effective and harmless, relieving and curing the patients. His published reports, as well as those of Delineau include uterine fibroids as well as the conditions above enumerated.

These applications should only be made three or four times a month in intra-uterine treatment. In this, as in the galvano-caustic method, results are compromised and retarded by too frequent applications. The work done as the result of this intra-uterine electrolysis with an electrode of copper is, as has been pointed out, one of congestion, elimination and repair, and as we have stated, is completed in eight days.

"The elimination of pathologic tissues being imperfect, the mucous membrane would still be adherent in some points, and would adhere to the electrode, rupturing some blood vessels, and causing a slight hemorrhage."¹⁰

In my own experience, I know that I have in several instances retarded my results by too frequent applications. In a case of granular degeneration of the cervix, four applications of zinc electrolysis were made, the first, second and third times at intervals of two days. A current strength of ten milliampères was used. Four days after the third application, the cervix was most deeply congested, of an intensely red color, and completely devoid of epithelium. A fourth application was made with a current strength of ten milliampères for two or three minutes. Nothing further was done in the way of local treatment until one week later. At that time I made a speculum examination, and found the cervical congestion markedly diminished, the color normal save one tiny point of redness, the secretion profuse but normal in character, and the eroded surface almost entirely covered with delicate newly-formed epithelium.

From the history obtained when the case first came under observation, as well as from the condition presented, the trouble was evidently of long standing, and it had defied all the classical measurers, as well as cupric electrolysis. In the light of my subsequent experience, I am satisfied that the second and third treatments were distinctly harmful, and that the first and fourth would have accomplished the desired result.

Dr. A. H. Goelet, President of the American Electro-Therapeutic Association, has used zinc electrolysis somewhat extensively in chronic inflammatory conditions of the uterine mucous membrane accompanied by induration and sclerosis; also in fibroid and keloid growths. He has not used it as it was used by Gröh many years ago, viz.: to destroy degenerated tissue like cancerous growths, but to obtain the characteristic action of zinc chloride upon morbid tissue. At the June meeting of the New York Electro-Therapeutic Society, Dr. Goelet called the attention of the members to his work with zinc electrolysis, as above outlined, and reported a case of extensive keloid under observation that had markedly improved under zinc puncture.

At the same meeting, Dr. W. J. Morton referred to the action of the zinc element in body batteries upon the skin, and reported a case of keloid where this action had been utilized with a considerable degree of success, and he had previously used zinc needles.

It is not only in gynecology that metallic electrolysis is of avail, although Gautier has established it as a precise and scientific therapeutic measure more thoroughly in gynecology than in other conditions. It has also been used

¹⁰ Techniqne d Electrotherapie Gautier et Larat, p. 222.

by him, as well as by others, in hypertrophic rhinitis, ozena, chronic coryza, nasal polypi, sebaceous cysts, chronic urethritis, hemorrhoids, anal fissure, epithelioma, canceroid and chronic conjunctivitis.

In the July number of the *Revue Internationale D'Electrotherapie*, M. M. R. Verhoogen of Brussels, reports a case of aneurism—described as an enormous vascular tumor—subjected to the action of a copper electrode. At the time of his making the report, no result had been noted.

Twenty months ago, Dr. W. J. Morton, Professor of Electro-Therapeutics at the Post-Graduate Medical School and Hospital of New York City, began the use of metallic electrolysis in his clinic. At that time a typical case of trachoma, affecting both eyes, and of many years' duration, was treated by means of cupric electrolysis. About the same time the same method was used in ozena, as well as in many other cases.

A little later, a vascular tumor at the angle of the mouth received two applications of metallic electrolysis. A steel needle was thrust into the tumor, and there was secured the styptic action of the oxychlorid of iron upon the blood circulating therein. At the first sitting, a current of fifteen milliampères was passed for ten minutes, and at the second, twenty-five milliampères for ten minutes. The tumor, which before treatment had a diameter at the base of three-quarters of an inch, was reduced to one-third its former size. Almost complete destruction of the part of the needle buried in the tumor ensued. With the greater C. S., reversal of the poles was necessary to loosen the needle, and prevent tearing of the tissues.

The entire system of metallic electrolysis with all the soluble metals, and even with plated metals, has been systematically and continuously taught to the Post-Graduates, since its first announcement in this country, now some two years ago. Personally, I have used it in hypertrophic rhinitis, trachoma, urethritis, endometritis, uterine, fibroids, granular degeneration of the cervix uteri and cystic degeneration, with gratifying success.

I append a few cases taken from my case-book, and from that of the Electro-Therapeutic Clinic of the Post-Graduate Medical School and Hospital of New York City.

Case 1.—Miss O. D. presented herself for the treatment of a hypertrophic condition of the nose and throat which had existed for three years. Her voice was thick, and she complained of an irritative cough, and a disposition to swallow almost constantly. Six applications of cupric electrolysis with a current of ten milliampères were made, and on June 9 it was noted that all her symptoms had disappeared. She has remained well ever since.

Case 2.—A. R., 9 years of age, came under observation Oct. 21, 1892, because of a profuse muco-purulent discharge from the nose, and the usual symptoms attendant upon nasal and pharyngeal obstruction. The trouble had lasted one year. Fourteen intra-nasal applications of cupric electrolysis were made, their duration being five minutes, and the current strength five to ten milliampères. After the second application, he slept all night without snoring, and there was a steady and gratifying improvement, both in his local and general condition.

Case 3.—Miss G. A., 26 years of age; had had for several years a nasal stenosis on the right side, and inflamed and hypertrophied tonsils. Fifteen applications of cupric electrolysis were made to the nasal passages between April 25 and June 30, 1893, a current of ten or fifteen milliampères being used for five to ten minutes at a time. After the fifth sitting her voice became so much clearer that she was able to sing again. Negative galvanism, five milliampères was then successfully employed to overcome the nasal stenosis. By July 18, her voice had become strong and clear, and the other symptoms proportionately improved. In this case, as in the foregoing, attention was paid to the general nutrition.

Case 4.—M. J. C., was treated by the same method for the relief of symptoms due to marked nasal stenosis, arising from a double deviation from the septum. With a current of ten to fifteen milliampères, applications were made to the anterior and posterior nasal passages, and after two sittings there was complete relief from the post-nasal dropping and cessation of the muco-purulent discharge.

Case 5.—N. R., 11 years of age; for two days before coming under observation had a purulent conjunctivitis. Examination showed trachoma of the upper and lower lids of both eyes. Six applications of cupric electrolysis with a current of two milliampères were made for one minute to each lid. After the first treatment, there was less photophobia, and the granular points were decidedly smaller. The patient completely recovered and there has been no relapse.

Case 6.—F. D., age 8; with double trachoma, was brought from an institution where there were twenty-four boys, "all with sore eyes." He had purulent conjunctivitis with congestion and edema of the surrounding tissues, and the lower lids were covered with enlarged conjunctival papillæ, the upper showing the frog-spawn granulations very markedly. Treatment was begun July 21, 1893. Five applications of cupric electrolysis were made in this case by means of an oval copper electrode, which I show here, insulated on one face to prevent its coming in contact with the edge of the lid, as there is danger of this when the pain becomes severe, and the lids gradually contract and retract. A C. S. of from three to seven milliampères was used from three to five minutes. A solution of cocain was dropped in the eye prior to the application. The treatments were given at intervals of three, twelve, eleven and nine days. After the first treatment, less soreness, lacrymation and photophobia were present, and the trachomatous bodies were much softer. Recovered.

Case 7.—E. G., 21 years of age; right trachoma. This case and the preceding one were referred to the Electro-Therapeutic Clinic of the Post-Graduate Medical School by Dr. Francis Valk, Department of Ophthalmology in the same school. Photophobia and lacrymation were excessive, and the history dated back a year, during all of which time there had been lacrymation and pain. There was marked ptosis of the right upper lid from the congestion and swelling, and the "sago-grains" were abundant on the lids. There was also extensive inflammation of the cornea.

On July 21, 1893, cupric electrolysis was used to the upper and lower lids of the right eye with a current of three milliampères for five minutes.

July 24. The patient says he is better; no pain, swelling of lid and ptosis much diminished. Less photophobia, soreness and lacrymation. Trachomatous bodies very much softer; not so much like grit under electrode. Cupric electrolysis, ten milliampères from two to three minutes.

July 26. Edema of lids has entirely disappeared; slight ptosis only; no lacrymation; trachomatous bodies no longer isolated; cornea almost entirely clear; not using atropin any more.

Application repeated as on the 24th and again on the 28th.

July 31. After the fourth treatment, the trachomatous bodies were found to have melted away into the conjunctival membrane, and the other symptoms were still further diminished. He was seen by Dr. Valk, who stated that the result was 50 per cent. better than he could have secured with the classical methods of treatment. Cornea perfectly clear. Six other applications were made in the same way. The patient was not seen for nearly four weeks, and was then entirely free from symptoms, except some conjunctival redness and slight sensitiveness to bright sunlight.

(To be Continued.)

CORRESPONDENCE.

Medico-Chirurgical College of Philadelphia.

PHILADELPHIA, PA., Jan. 17, 1894.

To the Editor:—Please insert the following in the news column of your JOURNAL: The Faculty of the Medico-Chirurgical College of Philadelphia, has created three new clinical chairs, viz.: genito-urinary surgery, orthopedic surgery and otology. These together with the vacancy in the chair of clinical medicine will be filled permanently at the end of the present session.

Thanking you in advance, I am,

Very truly yours,

ERNEST LAPLACE, Dean.

Squelching a Quack.

JERSEYVILLE, ILL., Jan. 20, 1894.

To the Editor:—The State Board of Health, through Judge O. B. Hamilton, brought suit in this city against one "Dr." Fred Blankner who was traveling through this region advertising himself and wife as the "champion tooth pullers of the world," by flaming posters and advertisements in the local papers. This interesting couple also sold electric belts and "yaw soap" which last was recommended as an unfailing cure for sundry and divers diseases. A judgment was recovered

against the defendant for \$100 and costs, with an order that he stand committed in custody until fine and costs were paid. The wily faker took the train for St. Louis before the jury returned their verdict, and so he is still at large.

The technical charge against him was that of violation of Section 11 of the Medical Practice Act, Chap. 91 R. S. of Illinois, as an itinerant vendor of drugs, without license from the State Board of Health.

The squelching of this quack will doubtless prove beneficial. Yours truly, MEDICUS.

MISCELLANY.

Circumcision.—A bill has been introduced into the Ohio Legislature forbidding circumcision.

Dr. Enoch V. Stoddard was nominated January 11 by Gov. Flower to succeed the late Oscar Craig as a member of the State Board of Charities of New York.

A Centenarian who Smoked.—Miss Hulda Arnold died at Milford, Mass., last week, at the reputed age of over 104 years. At the age of 14 she began smoking to relieve the asthma, and thereafter was an inveterate smoker.

Mathews' Medical Quarterly.—We have received the first number of this interesting publication, which is "a Journal devoted to Diseases of the Rectum, Gastro-Intestinal Disease, and Rectal and Gastro-Intestinal Surgery." Joseph M. Mathews, M.D., of Louisville, is editor and proprietor, and Henry E. Tuley, M.D., is his associate. The Quarterly is in every way excellent.

Physician to the Preston Retreat.—Dr. Richard C. Norris was elected physician in charge of the Preston Retreat, Philadelphia, to succeed Dr. Joseph Price on January 16. Among the candidates for the place was Dr. Anna Fullerton of the Woman's Medical College. There were several members of the Board of Managers whose wives were very ardent in their support of Dr. Fullerton, and as the result of their efforts she received five votes. Dr. Norris is a graduate of the University of Pennsylvania and since 1889 occupied the position of Demonstrator of Obstetrics in that institution.

A New Way to Execute Criminals.—A bill has been introduced in the Legislature of Ohio opposing hanging and providing that all murderers sentenced to death shall be put out of the way by means of anesthetics which are to be administered under the supervision of a board of physicians and scientists. The condemned man having been placed in a painless sleep, the scientists are to be permitted to take the top of his skull off and watch the actions of the brain and lay bare his heart and other organs and study life there.

The author of the bill is a physician and argues that its passage would give scientists an opportunity to study the currents of life as they have never been studied before, and would undoubtedly result in the most wonderful discoveries to the benefit of humanity.

"The Sulphate of Electricity."—The so-called "science column" of one of our daily papers is responsible for a statement that a spring, and its effluent water, may be charged with electricity. The item reads as follows:

"During the prevalence of a thunder storm in the neighborhood of Seis, in the Tyrol, the lightning struck a heap of old wood which was piled on a rock, splitting the latter and setting fire to the former. When the flames had been extinguished it was noticed that a stream of water flowed from amid the rubbish. Further examination showed that the stream proceeded from the lightning-created cleft in the rock, and chemic analysis demonstrated that the water was impregnated with iron and magnetism in the form of sulphates."

Hospital Notes.

Hamot Hospital Association.—The annual meeting of the Hamot Hospital Association, (Pa.) was held January 9 for the election of officers for the ensuing year.

New Ward for the Episcopal Hospital.—The new surgical receiving ward, which is being built for the Episcopal Hospital of Philadelphia, is approaching completion. The surgeons were cramped for room before it was decided to build the present addition, which is being built in a style and of material to conform with the Hospital buildings.

German Hospital Election.—At the meeting of the Chicago German Hospital Association, January 18, the following officers were elected: President, Frank F. Henning; Vice-President, John Kolnig; Secretary, John C. Burmeister; Directors, Adolph Sturin, two years; D. Pakentrus and Henry Herman, three years.

St. Joseph's Hospital.—The annual meeting of the staff of St. Joseph's Hospital, Denver, Colo., was held January 10 in the new building. The following officers were elected: President, Dr. L. E. Lemen; Vice-President, Dr. C. B. Burns; Secretary, Dr. C. E. Walker; Executive Committee, Drs. L. E. Lemen, A. L. Lobingier, W. W. Grant and Hugo Mager.

The Virginia Hospital at Richmond, was formally opened January 11. This institution, the outgrowth of the public spirit of some of Richmond's most prominent citizens, was erected at a cost of \$18,000, and is now completely equipped. Dr. Hunter McGuire is President, Major Lewis Ginter, Vice-President, and Dr. Hugh Taylor, Secretary and Treasurer.

Presbyterian Hospital.—At the annual meeting of the corporation of the Presbyterian Hospital of Philadelphia, the following Trustees were elected to serve three years: Rev. Dr. Charles A. Dickey, Frank K. Hipple, Rev. James D. Paxton, Charles H. Mathews, Thomas B. Wanamaker, Rev. Dr. J. R. Miller, Henry N. Paul, Andrew Blair, Charles F. Hazlettine and William A. Patton. The officers elected were: President, Dr. Dickey; Treasurer, Frank K. Hipple; Secretary, John H. Converse; Solicitor, Charles H. Mathews.

Germantown Hospital.—At the twenty-fourth annual meeting of the Board of Managers and contributors to the Germantown Hospital, Pa., the following officers were elected for the ensuing year: President, William H. Haines; Secretary, Thomas B. Horner; Treasurer, Joseph M. Shoemaker; Managers, Galloway C. Morris, Jones Wister, William H. Scott, Elliston P. Morris, Owen J. Wister, M.D., William E. S. Baker, William Hacker, Frank J. Firth, Francis Stokes, Reed A. Williams, Jr., Alexander W. Wister.

The Adirondack Cottage Sanitarium.—The ninth report of this institution shows that 156 patients were under treatment for pulmonary tuberculosis during the year 1893. Of that number 68 are now under observation, 86 have been discharged and two have died at the Sanitarium. One of the latter was complicated with pneumonia. There were 27 cases treated by tuberculin or modified tuberculin with improved conditions in ten of the cases and no deaths. Seven of these cases lost weight, while six gained weight at the rate of eight pounds, average, per patient. In three cases no bacilli or no expectation were noted when the treatment was concluded. The report is written by Dr. E. L. Trudeau, President of the Board of Direction, who acknowledges his indebtedness to Dr. Irwin Hance, the present Resident Physician, in carrying out the exacting details of this plan of treatment. The results in some of the cases thus treated, in former years, are noted in the following paragraph: It is to be noted that ten of these thirteen cases belonged to the "advanced" or "far advanced" class, which are generally beyond the reach of treatment, and to many of these the tuberculin was administered at their own request as a last resort. Of the six cases treated by this method at the institution and hitherto reported as discharged cured, five, which have remained at home during periods varying from one to two years, are known up to date to have shown no signs of relapse, and the sixth can not be traced.

The Naval Hospital of New York Harbor.—The hospital at the Brooklyn Navy Yard is stated to have some objectionable, if not dangerous, features. It has been allowed to drift along like an old-fashioned sailing craft, but Rear-Admiral Gherardi proposes now, if he can get the fuel, to get up steam. A bill without which no form of animated nature can subsist now-a-days has been introduced in Congress for the modernization and extension of the old building. If this bill becomes a law the Secretary of the Navy will be empowered to put the hospital in thorough repair and to build, equip and maintain additional sick quarters of modern construction and fitted with all modern hospital appliances.

Toledo Hospital.—The Board of Trustees of the Toledo, Ohio, Hospital held a meeting January 15, and elected the following officers for the coming year: President, Mrs. S. C. Schenck; First Vice-President, Mrs. W. S. Thurston; Second Vice-President, Mrs. S. W. Nettleton; Recording Secretary, Mrs. A. E. Scott; Corresponding Secretary, Mrs. J. G. Gould; Treasurer, Mrs. H. H. Perrin. The following Advisory Staff was chosen: Messrs. Richard Waite, Chairman; S. C. Schenck, W. H. Scott, A. L. Spitzer, W. S. Thurston, F. O. Paddock, W. V. Barbour, J. H. Bronson, T. J. Brown, W. J. Walding, M. A. Scott, G. H. Ketcham, I. N. Poe, F. B. Shoemaker, C. H. Buck, James Secor, Clarence Brown, J. H. Bowman, W. E. Terhune and T. H. Walbridge.

THE PUBLIC SERVICES.

Circular of Information for Candidates Seeking Appointment in the Medical Corps of the United States Army.

The Medical Corps of the Army consists of a Surgeon-General with the rank of brigadier general, six Assistant Surgeons General with the rank of colonel, ten Deputy Surgeons General with the rank of lieutenant colonel, fifty Surgeons with the rank of major, and one hundred and twenty-five Assistant Surgeons with the rank of 1st Lieutenant, mounted, for the first five years, and the rank of captain, mounted, thereafter until promoted to major. Promotion through the intermediate grades of rank from that of captain to that of colonel is by seniority, but there is an examination for the rank of captain and another for that of major, to ascertain the fitness of the officer for promotion. Advancement to lieutenant colonel and colonel takes place without further examination. The Surgeon-General is selected by the President from among the members of the Corps. All vacancies are filled by appointment to the junior grade.

PAY AND EMOLUMENTS.—To each rank is attached a fixed annual salary, which is received in monthly payments, and this is increased by 10 per cent. for each period of five years' service until a maximum of 40 per cent. is reached. An Assistant Surgeon with the rank of 1st Lieutenant, mounted, receives \$1,600 per annum, or \$133.33 monthly. At the end of five years he is promoted to captain and receives \$2,000 a year, which, with the increase of 10 per cent. for five years' service, is \$2,200, or \$183.33 per month. After ten years' service he receives \$2,400, after fifteen years \$2,600, and if he remains a captain after twenty years, \$2,800 per year. The pay attached to the rank of major is \$2,500 a year, which, with 10 per cent. added for each five years' service, becomes \$3,250 after fifteen years and \$3,500 after twenty years. The monthly pay of lieutenant colonel, colonel, and brigadier-general is \$333.33, \$375, and \$458.34 respectively. Officers in addition to their pay proper are furnished with a liberal allowance of quarters according to rank, either in kind, or where no suitable Government building is available, by commutation. When travelling on duty an officer receives four cents per mile and reimbursement of money actually expended for railroad or other fares. On change of station he is entitled to transportation for professional books and papers and a reasonable amount of baggage at Government expense. Mounted officers, including all officers of the Medical Corps, are provided with forage, stabling, and transportation for horses owned and actually kept by them, not exceeding two for all ranks below a brigadier. Groceries and other articles may be purchased from the Commissary and fuel from the Quartermaster's Department at about wholesale cost price. Books and instruments are supplied in abundance for the use of medical officers in the performance of their duties.

ARMY MEDICAL SCHOOL.—By a recent order the Secretary of War has authorized the establishment of an Army Medical School in the city of Washington for the purpose of instructing approved candidates for admission to the Medical Corps of the Army in their duties as medical officers.

The course of instruction will be for four months, and will be given annually at the Army Medical Museum, in Washington City, commencing on the 1st day of November.

Five professors have been selected from among the senior medical officers of the Army, stationed in or near the city of Washington, and as many associate professors as may be required to give practical laboratory instruction in the methods of sanitary analyses, microscopical technique, clinical microscopy, bacteriology, urine analysis, etc.

The faculty of the Army Medical School will consist of—

1. A *President of the Faculty*, who shall be responsible for the discipline of the school, and who will deliver a course of lectures upon the duties of medical officers in war and peace (including property responsibility, examination of recruits, certificates of disability, reports, rights and privileges, customs of service, etc.).
2. A *Professor of Military Surgery* (including the care and transportation of wounded).
3. A *Professor of Military Hygiene* (including practical instruction in the examination of air, water, food, and clothing from a sanitary point of view).
4. A *Professor of Military Medicine*.
5. A *Professor of Clinical and Sanitary Microscopy* (including bacteriology and urinalogy).

DUTIES AND PRIVILEGES.—A medical officer after completing the course of instruction at the Army Medical School will be assigned for some months as junior at a large military post before he is thrown upon his own responsibility. His stations after that are likely to alternate between

the frontier and more desirable points, a tour of duty being usually four years at one place.

Leave of absence on full pay is allowed at the rate of one month per year, and this when not taken may accumulate to a maximum of four months, which at the end of four years is then available as one continuous leave. Beyond this an officer may still be absent with permission on half pay. Absence from duty on account of sickness involves no loss of pay.

Medical officers are entitled to the privilege of retirement at any time for disability incurred in the line of duty, or after forty years' service. On attaining the age of sixty-four they are placed upon the retired list by virtue of law. Retired officers receive three-fourths the amount of their pay proper at the time of retirement.

It is the intention of the Surgeon General to recommend the assignment for duty, as attending surgeons in the principal medical centers of the United States, of medical officers who have not yet passed their examinations for promotion to a majority, and, so far as may be practicable, in the order of their seniority. These details will be made for one year only, in order that as many medical officers as possible may be enabled to avail themselves of the opportunities thus offered to become familiar with the practice of the leading physicians and surgeons in this country, and of attending medical lectures, meetings of medical societies, etc. At the end of this tour of duty medical officers will be required to make a detailed report to the Surgeon General, showing how much of their time has been occupied by their official duties and to what extent they have availed themselves of the advantages offered for professional advancement.

EXAMINATION AND APPOINTMENT.—Appointments to the Medical Corps of the Army are made by the President after the applicant has passed a successful examination before the Army Medical Examining Board and has been recommended by the Surgeon-General. Due notice of the meeting of the Board is usually published in the medical journals. The date of meeting is about April and October. Permission to appear before the Board is obtained by letter to the Secretary of War, which must be in the handwriting of the applicant, giving the date and place of his birth and the place and State, of which he is a permanent resident, and inclosing certificates based on personal acquaintance from at least two reputable persons as to his citizenship, character and habits. The candidate must be a citizen of the United States, between twenty-two and twenty-eight years old, of sound health and good character, and a graduate of some regular medical college, in evidence of which his diploma will be submitted to the Board. The scope of the examination will include the morals, habits, physical and mental qualifications of the candidate, and his general aptitude for service; and the Board will report unfavorably should it have a reasonable doubt of his efficiency in any of these particulars.

The physical examination comes first in order, and must be thorough. Each candidate will in addition be required to certify "that he labors under no mental or physical infirmity or disability of any kind which can in any way interfere with the most efficient discharge of any duty which may be required." Errors of refraction, when not excessive, and not accompanied by ocular disease, and when correctible by appropriate glasses, are not causes for rejection.

The mental examinations are conducted by both written and oral questions, upon—

I. Elementary branches of common school education, including arithmetic, the history and geography of the United States, physics, and upon general literature and ancient and modern history. Candidates claiming especial knowledge of the higher mathematics, ancient or modern languages, drawing, analytical chemistry or branches of natural science, will be examined in those subjects as accomplishments and will receive due credit therefor according to their proficiency.

II. Professional branches, including anatomy, physiology, chemistry, physics, hygiene, pathology and bacteriology, therapeutics and materia medica, surgery, practice of medicine, obstetrics and the diseases of women and children.

Examinations at the bedside will also be conducted in clinical medicine and surgery, and operations and demonstrations upon the cadaver.

Hospital training and practical experience in the practice of medicine, surgery and obstetrics, are of great importance to candidates seeking admission to the Medical Corps of the Army, and they will be fully appreciated and duly credited to those who have had such advantages.

The Board has discretion to deviate from this general plan of examination in such manner as it deems best when necessary for the interests of the Service.

To save unnecessary expense to candidates, those who desire it may have a preliminary physical examination and a mental examination in the "elementary branches of a common school education," by a medical officer of the Army stationed most conveniently for this purpose, who will act under instructions from the Medical Examining Board.

The merits of the candidates in each of the several branches, and also their relative merit as evinced by the results obtained from the entire examination, will be reported by the Board, and in accordance with this report approved candidates will be appointed to existing vacancies or to such as may occur within two years thereafter. An applicant failing in one examination may be allowed a second after one year, but not a third. No concession will be made for the expenses of persons undergoing examination, but those who receive appointments will be entitled to travel allowances in obeying the first order assigning them to duty.

There will probably be six vacancies in the Corps to be filled.

To illustrate the general character of written questions submitted to candidates under examination, a few examples from the records of an Army Medical Examining Board recently convened in the city of New York are hereto appended.

Approved: DANIEL S. LAMONT, *Secretary of War*.
WAR DEPARTMENT, SURGEON-GENERAL'S OFFICE,
WASHINGTON, D. C., Jan. 2, 1894.

EXAMPLES OF WRITTEN QUESTIONS.

ARITHMETIC.

1. Find the interest on \$400.00 for 2 years, 5 months and 25 days at 8 per cent. per annum.
2. Find the depth of a reservoir 12 feet square from which 336 cubic yards of earth has been removed.
3. How many grains are there in 184 milligrams?
4. What is $\sqrt{\frac{9}{4}}$ carried to four decimal places?
5. What is $3\frac{1}{4} \times 15\frac{5}{7} + \frac{2}{3} \div \frac{2\frac{3}{4}}{3}$?
6. The shadow of a church tower extends 57 yards; what is the height of the tower when the shadow of a 2-foot rule in a vertical position extends 2 feet, 9 inches?

GEOGRAPHY.

1. Which of the United States are bounded in part by the Atlantic Ocean?

2. What are the principal mountain ranges in the western part of the United States?
3. What rivers of North America flow into the Pacific Ocean?
4. Bound the States of Michigan and New Hampshire.
5. Over what waters would a vessel pass in sailing from Washington to Sebastopol, by the shortest route?
6. When it is 12 o'clock, noon, standard time, in New York City, what is the standard time in San Francisco? Describe the system of "time belts" in the United States.

HISTORY AND LITERATURE.

1. Which were the two first permanent English colonies in North America? When, where, and by whom were they established?
2. Name the thirteen original States of the Union in the order in which they were settled.
3. What were the principal causes that led to the Revolutionary war in this country?
4. What poems have especially distinguished the following poets: Virgil, Milton, Young, Gray, James Thomson, and Goethe?
5. Under what Roman emperor was the capital of the empire removed from Rome, and what city became the new capital?
6. Name the principal battles fought in the Persian invasion of Greece by Xerxes.
7. Name the kings and queens of England embraced in the line of Tudor.

CHEMISTRY.

1. State the "law of multiple proportions." When was it discovered?
2. Give the symbols and atomic weights of the bivalent, non-metallic elements.
3. What are the physical and chemical properties of the element represented by the symbol Sb, and by what tests may it be recognized?
4. What do you understand by the following formula: $Fe_2SO_4 + 6NH_4HO = 2[(NH_4)_2SO_4 + Fe_2O_3 + 6H_2O]$?
5. What is the formula for ethyl ether, and how is it prepared?
6. What substance is represented by the formula $C_6H_{12}O_6$? Where is it found in nature, what are its physical characters, and by what chemical tests may it be recognized?

PHYSICS.

1. What is weight? Is the weight of a body constant? If not, why does it vary?
2. What is osmosis? What conditions are necessary to osmotic action? Give an illustration from the human body.
3. How is dew formed? What circumstances influence its formation? What is meant by the dew point?
4. Upon what fundamental laws of light does the action of lenses depend? Why does a convex lens magnify?
5. What is the velocity of sound? Does it vary, and how?
6. What is the relation between the dynamo and the electric motor? What is the principle of the dynamo?

ANATOMY.

1. Give the anatomy of the fourth ventricle, including the origin of nerves.
2. Give the anatomy of the coracoid process.
3. Make a diagrammatic sketch showing the relation of parts in a cross-section through the middle third of the right arm, proximal surface.
4. Describe the internal pudic artery and its relations.
5. Give a short description of the minute structural anatomy of the kidney, with or without schematic diagram.

PHYSIOLOGY.

1. Tell what you know about the cerebral localization of the functions of motion and locate some of the so-called motor areas.
2. What are the functions of the thyroid gland and the consequences of its removal?
3. What is the composition of atmospheric air and of expired air?
4. Give a list and a short description of some of the animal albuminoids.
5. What is urea? What is the normal quantity in proportion to body weight? How is it estimated?

SURGERY.

1. Give in detail the preparatory and several following steps of a so-called aseptic surgical operation.
2. What is the nature and origin of pus? What is sepsis and also anti-sepsis?
3. Describe Chopart's amputation through the foot, with diagram.
4. Give the points of diagnostic differentiation in cases of lupus ulceration, syphilitic ulceration, and epitheliomatous ulceration.
5. Describe the different methods of procedure for the reduction of luxations of the head of the femur.

HYGIENE.

1. What is the normal amount of CO_2 in the atmosphere, how much of this gas is considered admissible in inhabited apartments, and how is the amount determined?
2. What amount of cubic air space per bed would you consider a suitable allowance in a hospital ward?
3. What substances in well or river water indicate, by their presence, contamination from excreta or other organic matter of animal origin?
4. How is the hardness of water estimated and to what is it due?
5. What are the constituent alimentary substances in milk, and how does cow's milk differ from human milk?
6. What vegetable products used as food contain the largest proportion of carbo-hydrates and what the largest proportion of proteids?
7. What parasites dangerous to man may be present in the flesh of animals used as food?
8. How would you disinfect the excreta of patients sick with cholera or typhoid fever?

PATHOLOGY AND BACTERIOLOGY.

1. What are the different stages of exudative inflammation and what the products of such inflammation?
2. What are the causes of thrombosis, what the composition and varieties of thrombi, and what changes they may undergo?
3. What pathological changes are found in the spinal cord in posterior spinal sclerosis?
4. What changes occur in the liver as a result of chronic interstitial hepatitis?
5. What bacteria are commonly found attached to the diseased valves in mycotic endocarditis?
6. What are the morphological and biological characters of the bacillus of diphtheria, and what are the evidences of its etiological relation to this disease?

THERAPEUTICS, MATERIA MEDICA, AND TOXICOLOGY.

1. By what various agents may antipyresis be produced? Give an example of each class of antipyretics and state how it acts.
2. In a case of typical acute pleurisy state the indications for treatment in its several stages and how you would meet them.

3. What is salol? Give its physiological action and therapeutic uses.
4. Give the source and therapeutic uses of cocaine, the dose in each case, and its dangerous effects.

5. With what condition is poisoning from opium most likely to be confounded? How would you make a diagnosis and how treat such a case?

6. What are the poisonous effects of the lead salts? How is their presence detected? State briefly your plan of treatment.

PRACTICE OF MEDICINE.

1. Give an account of the etiology, symptoms, physical signs, and differential diagnosis of lobular pneumonia.
2. Give an account of the etiology, physical signs, and treatment of empyema.
3. Give an account of the etiology, symptoms, differential diagnosis, and treatment of dilatation of the stomach.
4. What are the causes and symptoms of intestinal obstruction and what is the treatment?
5. What are the causes and results of mitral stenosis and how would you recognize this condition?
6. Give the differential diagnosis between smallpox and measles.

OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN.

1. Describe briefly the usual mechanism of a breech presentation; what dangers are to be guarded against and what difficulties to be met?
2. Under what circumstances is premature delivery demanded and how would you perform it?
3. What symptoms would lead you to suspect the presence of a uterine fibroid? State how an exact diagnosis can be made in such cases.
4. What measures, preventive or remedial, would you use in a case of puerperal convulsions?
5. What early symptoms indicate probable onset of the chief eruptive fevers in children? In which does temperature range highest, which has the shortest period of incubation, of invasion, of eruption?

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from January 13, 1894, to January 19, 1894.

Major EDWARD B. MOSELEY, Surgeon U. S. A., is hereby granted leave of absence for one month, on surgeon's certificate of disability.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending January 20, 1894.

Surgeon CLEMENT BIDDLE, detached from duty, Marine Rendezvous, Philadelphia, Pa., and wait orders. Rendezvous closed.

P. A. Surgeon E. P. STONE, detached from Marine Rendezvous, Boston, Mass., and continue on special duty in Boston, Mass.

P. A. Surgeon T. A. BERRYHILL, authorized to take a course of instruction at the Naval Hospital, Brooklyn, N. Y.

Medical Director J. MILLS BROWNE, retired, granted two months' leave of absence, with permission to go abroad.

ORIGINAL ARTICLES.

HISTORICAL, CHEMICAL, PHYSIOLOGICAL AND THERAPEUTIC NOTES ON THE MED- ICINAL PROPERTIES AND VALUE OF THE SULPHITES AND HYPO- SULPHITES.

BY JOSEPH JONES, M.D., LL.D.

PROFESSOR OF CHEMISTRY, TOXICOLOGY AND MEDICAL JURISPRUDENCE
IN MEDICAL DEPARTMENT, TULANE UNIVERSITY OF LOUISIANA.

A—HISTORICAL.

Notwithstanding the use of sulphur in former days and of hyposulphites as anti-fermentive or anti-zymotic in the dissecting room, in certain cases and occasionally in medical practice, no great attention was paid to this valuable class of remedies, until Burgreave (de Gaud) employed the sulphite of soda, in 1862, in solution as a lotion for healing different kinds of wounds. The advantages of this method may be summed up as follows: 1, anesthesia of the wound; 2, prevention of nervous accidents; 3, excitation of granulation and acceleration of cicatrization; 4, diminution of the quantity of pus, which it renders viscid, sweet, inodorous and neutral.

The value of the sulphites was fully confirmed by Constantin Paul, Farrini, Tagiuri, Gritti, Vignole, Galligo, Questa, Sagrini and Polli. Paul published his excellent article in *Le Bulletin Therapeutique* of 1865, Nov. 4, 5, 6, etc.

One of the first, if not positively the first medicinal application of the sulphites, was to the treatment of the sarcina ventriculi, a curious microscopic fungus, which was discovered in the stomach in certain cases of yeasty vomiting. This use of the remedy, was, I believe, made at the suggestion of Prof. Graham, and was founded on the fact familiar to him, that sulphurous acid is peculiarly hostile to the lower forms of vegetable life. The medicine was found effectual in the destruction of the sarcinae, but had little effect in relieving the disease, of which the fungus was merely an attendant, and not a cause. Afterwards one of the sulphites was employed, upon the same principle, by Dr. Jenner of London, and others, with satisfactory results, in the treatment of cutaneous diseases known to be connected with or dependent on microscopic fungi in the skin. It was but a single step in advance to apply the remedy to the destruction of morbid fermentative processes believed to depend upon the action of the minute organisms always found associated with them. The idea of the use of this remedy seems to have first occurred to Dr. C. Polli of Milan, whose numerous experiments have gone far to prove the reality of such a power in the sulphites and their consequent applicability to the treatment of a large circle of diseases.

In April, 1866, Dr. Thaddeus L. Leavit of Germantown, Pa., published in the *American Journal of Medical Sciences*, pp. 388, 389, an interesting article entitled, "On the Use of the Hyposulphite of Soda in Intermittent Fever," from which we extract the following, as illustrating the theory upon which the sulphites and hyposulphites have been employed in Europe and America:

"Intermittent fever and its analogous affections result, as is generally believed, from a contamination of the blood caused by the introduction into it of organic poisons, generated by heat, and the decomposition of vegetable matter constituting the marsh miasma of writers. These vegetable germs or sporules floating in the atmosphere of malarial regions, each one in itself a living organic power, on entering the circulation act as a ferment, and the oft recorded results follow—the disturbance of the nerve centers, the blood thrown upon the internal organs, the chill, the reaction, Nature's mighty effort to establish an equilibrium in which she overshoots the mark and fever follows. Then the pouring out of the watery constituents of the blood in the sweat, the debility, etc."

This theory of the fermentation of the blood, though not by any means a new idea, is not universally believed, though indirectly proved by the success of the remedies exhibited. Dr. Samuel Jackson of this city, taught this doctrine in his late lectures at the University of Pennsylvania, and enthusiastically believed in the correctness of the theory of this ferment existing, as the *materies morbi* in the blood of the intermittent fever patient, and that any remedy that arrested and neutralized this action wrought a cure, hence the efficiency of cinchona and its preparations.

The powerful property of the sulphite of soda as an anti-ferment is a domestic fact well known to the farmer who, by its addition preserves his cider sweet for months. Acting upon these principles, this new remedy was administered with the following results:

Miss W., age 19, who resides in a malarious district was attacked with remittent fever, and continued for a few days without any medical advice, feeling miserable and unfitted for any duty. Finally the chill set in fairly, morning, noon, and night, with scarcely a cessation of a few minutes between the stages. Sulphate of quinia was administered immediately in varying doses and its constant use continued until at the end of four weeks the stomach became intolerant and not the slightest influence on the regular routine of chill, fever and sweat was perceptible; the patient also suffered from excessive nervousness, which somewhat complicated her case. Quinia was again, after two days' suspension, renewed, but with no remediable effect.

October 12. This afternoon I began with 15 grain doses every three hours, of the hyposulphite of soda in solution with a little orange flower water, which formed quite a pleasant preparation, to be continued through the night. At my visit the next morning at eleven o'clock, the pulse was eighty-four beats in a minute, and no chill had been felt, the first omission in the exacerbation for over four weeks.

The sulphite was continued for three days, and then at longer intervals and effected a perfect cure.

In those cases which resist the beneficial influences of quinia, the hyposulphite will prove of great value, while its rapid absorption and speedy action render it in congestive and malignant types, where

relief must be furnished immediately, a prompt and efficient remedy. The principle of its action holds good in all diseases of blood poisoning and of zymotic origin, hence the success of Polli of Milan, Cummins of Cork, and others. Dr. Leavit in 1866, speaks of the decay of the cinchona tree and warns us to seek in time a substitute for this most valuable drug, which he firmly believes is to be found in the hyposulphites.

In October, 1866, Dr. W. H. Baxter of Moscow, Iowa, writes to Prof. N. S. Davis that he was induced by Dr. Leavit's statement in the *American Journal of Medical Sciences* for April, as to the efficacy of the hyposulphite of soda in malarial fever, to employ that article. In the last month Dr. Baxter says he has treated over one hundred cases of simple intermittent and remittent fever with this remedy alone, and in no case has there been an exacerbation after taking the remedy a reasonable length of time. He gave it in 15 grain doses in solution in water. He has not trusted to this remedy alone in pernicious or malignant types.

Dr. Wood devotes considerable space in his "Therapeutics and Pharmacology," to the sulphites. The late Dr. Charles Turpin, a distinguished and accomplished physician of New Orleans, published a valuable article on "Sulphites and Hyposulphites" in the *New Orleans Medical and Surgical Journal*, for July, 1866.

B—CHEMICAL AND PHYSICAL CHARACTER OF THE SULPHITES AND HYPOSULPHITES.

The sulphites are compounds of sulphurous acid and salifiable bases, and are employed, almost to the exclusion of sulphur itself and sulphurous acid, as internal remedies or prophylactics, in diseases supposed to have a zymotic origin. The special salts employed are the sulphites of soda, potassa, ammonia, magnesia, and lime. These salts are prepared by passing sulphurous acid through a solution of the alkalis or their carbonates. Such, at least, is the case with the sulphites of soda, potassa, and ammonia; but the less soluble of these salts, as the sulphites of magnesia and lime are more conveniently prepared in the way of double decomposition. If one of the soluble sulphites, but especially sulphite of soda or ammonia, be added to a soluble salt of the base, the sulphite of which it is designed to prepare, as the chlorid of magnesium or calcium, in solution, the sulphite of the base employed, as of magnesia, or of lime, will be precipitated. The sulphite of lime, however, may be procured, like the alkaline sulphites, by passing the acid gas through lime suspended in water (Thénard). In all instances, the evaporation should be carefully conducted so as not to drive off the acid, and with as little exposure to the air as possible; as the sulphites in solution are strongly disposed to absorb oxygen from the air, and thus pass into the state of sulphates. Even in the solid condition, they slowly undergo the same change; and they should, therefore, when prepared, be kept, so far as can be conveniently done, from contact with the atmosphere.

These salts have in general a sulphurous taste, and, on exposure to heat, or by the addition of an acid, emit the characteristic odor of sulphurous acid, familiar to every one as that arising from a burning sulphur match. As before stated, they are disposed to absorb oxygen from the air, and are finally con-

verted into sulphates. They are distinguishable from the hyposulphites, which, though occasionally used, are thought to be less efficient, by depositing no sulphur when their solution is treated with diluted sulphuric acid. In both kinds, sulphurous acid escapes, known by its peculiar odor; but with the hyposulphites a deposit of sulphur takes place, which the hyposulphurous acid gives up, when converted into the sulphurous. As the sulphites all operate through the qualities of their acid, they may be used indiscriminately in relation to their efficiency, though some of them are preferred for peculiar qualities, regarding convenience and administration. The bisulphites are sometimes used indiscriminately with the sulphites, and it may not always be very easy to distinguish them. The bisulphites, however, are neutral to test-paper, while the proper sulphites have a slight alkaline reaction. They are prepared by passing sulphurous acid gas *in excess* though the alkaline solution (Thénard). They are probably quite as efficient as the sulphites, and perhaps more so in consequence of their larger proportion of acid.

The hyposulphites consist of salifiable bases, combined in equivalent proportions with hyposulphurous acid, which as now generally viewed is composed of two equivalents of sulphur and two of oxygen (S_2O_2). This acid, however, exists only in composition; being decomposed into sulphurous acid (SO_2) and sulphur when separated from its salts. The hyposulphites may be prepared by boiling a sulphite or bisulphite for some time with sulphur; in the former case, the sulphurous acid taking up an additional equivalent of sulphur; in the latter, one equivalent of the acid escaping, while its place is supplied with an equivalent of sulphur. The hyposulphites are more stable than the sulphites, passing with greater difficulty into the state of sulphites by contact with the air. The alkaline hyposulphites, as well as those of lime and magnesia, are very soluble in water. They are known by the precipitation of sulphur when decomposed by an acid (Thénard, 6e éd. iii. 280), 460), sulphite of soda. According to Berzelius (iii. the salts formed by passing sulphurous acid through a solution of carbonate of soda, until the liquid shall sensibly redden litmus paper, is the bisulphite of soda. If to this be added a quantity of soda equal to that already contained in it, the neutral sulphite results. This salt crystallizes in prisms, which have a feeble alkaline reaction, and a taste like that of sulphurous acid; are soluble in four times their weight of cold, and in somewhat less than their weight of boiling water, and on exposure to the air are converted into sulphate of soda; while the former salt or bisulphite is neutral to test-paper, and by exposure becomes the bisulphate. Sulphite of soda is among the sulphites most used, and is especially preferred for external application. Sulphite of potassa is obtained in the same manner as the preceding salt. It crystallizes in plates or needles, decrepitates when heated, and effervesces in the air, at the same time absorbing oxygen. Berzelius states that there is also a bisulphite which crystallizes more readily than the sulphite, but is usually confounded with it by authors. (iii. 389).

Sulphite of ammonia is formed when the two gases are brought into contact; but may, no doubt, be prepared like the others by passing sulphurous acid gas through a solution of carbonate of ammonia. It has an acrid sulphurous taste, becomes moist in the

air, and afterwards dries, having been converted into the sulphate. It is dissolved in its weight of cold, and in less than its weight of boiling water. When heated, it decrepitates, loses a part of its ammonia and water and then sublimes as supersulphite of ammonia.

Sulphite of magnesia may be prepared by double decomposition between any two soluble salts, the one of sulphurous acid, the other of magnesia; sulphite of magnesia being thrown down, when the two salts are mixed in solution. It is, as thus prepared, a white powder, but slightly soluble, of a pale, earthy taste, with a sulphurous after-taste, but less disagreeable than that of the more soluble salts. It is soluble in a solution of sulphurous acid which on evaporation yields transparent crystals. These dissolve in twenty parts of cold water, and effervesce upon the surface on exposure to the air. If the salt is exposed to a great heat in close vessels, the acid is driven off, and pure magnesia remains. It is preferred by some for internal use to all the other salts.

Sulphite of lime is also prepared most conveniently by double decomposition. It is a white powder requiring 800 parts of water for complete solution. By an excess of acid it is rendered more soluble, and from a hot saturated solution is deposited, on the cooling of the liquid, in long six-sided needles.

C.—PHYSIOLOGIC ACTION OF THE SULPHITES AND HYPOSULPHITES.

In accordance with the experiments of Polli, upon animals, neither vomiting, or diarrhea, or any general disturbance is observed as affecting dogs which have taken half an ounce (15 grammes) of the sulphite of soda or of magnesia. These experiments demonstrate that these salts, in doses of 2, 3 or 4 drachms daily, continued during ten to fifteen days, produce no inconvenience; and that, of all these preparations, the sulphite of lime appears to be the one best tolerated; and further, that autopsies made at several different periods of the treatment have always shown the intestinal mucous membrane in normal condition.

Experiments on man, similar to the above, have afforded like results. During the entire continuance of the treatment, the patients have presented only negative evidence of the action of these remedies, and especially have never voided sulphurous gas by any outlet. The urine remains clear, and free from ammoniacal odor, though long exposed to the air. A remarkable phenomenon, occurring in man, as in animals remains to be noticed, namely, that dead bodies and their fluids resist putrefaction when they have been impregnated with the sulphites. (Polli).

The sulphites remain in the body in the condition of sulphites, and are eliminated in the urine, where they are found undecomposed several hours after their injection, and they are not transformed into sulphates before the expiration of twenty-four hours. The reverse occurs with the hyposulphites, which preserve their characteristics intact though eliminated in the same manner. To test their presence, it is necessary to introduce a paper, rendered blue by the liquid of iodid of starch, into the mouth of a tube containing the urine previously acidulated with sulphuric acid. The paper loses its color if a hyposulphite is present.

Giving credit to the conscientious experiments of Polli and of Burgreave upon animals, it becomes

difficult to refuse to admit: 1, that these salts exercise upon the economy a very marked action, an action almost specific in certain cases; 2, that their administration is able not only to retard death, but also to alleviate the symptoms of purulent infection, produced by the introduction into the circulatory system, in large doses of pus, or of blood rendered putrid by divers poisons, and to effect a cure in a marked number of such cases. Purulent infection, purulent diathesis and metastasis, phlebitis, pyemia, putrid infection, puerperal fever, form a group of septic diseases presenting a special character of putridity and a mixed alteration of liquids and solids. It is well known how grave the prognosis is in all these affections, and how powerless and uncertain are all therapeutic means. The indications can be much better met, and success becomes much more certain with the sulphites.

D.—THERAPEUTIC ACTION OF THE SULPHITES AND HYPOSULPHITES.

Illustrating the idea of Jobert and Robin in regard to the analogy between ferments and the toxic agent which appears to play the principal part in purulent infection, Dr. Polli, by his theory and experiments, induced a large number of confrères to use the sulphites, who, by their labors (Tagiuri, Capparelli, de Ricci, Mirone, Rodolfo Rodolfi, Spencer Wells), have greatly contributed to generalize their employment, and to demonstrate the real services which they are capable of rendering. To prove this, it is only necessary to quote the words of Semmola, clinical professor at Naples, whose testimony is all the more weighty, since he does not partake of the enthusiasm of his confrères, and has endeavored to specify, as far as possible, the cases in which the uses of the sulphites may be advantageous: "The diseases against which the action of the sulphites is incontestably remarkable, are putrid infections, not resulting from a specific cause. Thus, pus in putrefaction, depraved intestinal chylification, abnormal urine, produce intoxications, against which the sulphites are almost specific. They paralyze the action of the absorbed putrid substances, completely suppressing the putrid local emanations, provided that the topical applications of these remedies be added to their internal administration." In all the observations made, the dose of the sulphites has always been enormous (10, 15, 20 scruples in twenty-four hours), and their use long continued. Is this mode of employment a necessary condition for success?

The sulphites were indicated, in advance, in paludal intoxications, and the following table, prepared by Constantin Paul, illustrates the results obtained. It must not be forgotten that they are only substitutes for the sulphate of quinia, and that their action is much slower.

Fevers treated with the sulphites:

	CASES.	SUCCESSFUL.	UNSUCCESSFUL.
Mazzolini	403	336	36
Capparelli	1	1	0
Poma	15	7	8
Lattini	11	11	0
Maraglio	2	0	2
Ferrini	3	1	2
Tagiuri	2	0	2
Total	437	356	50

Ratio: cured, 81.46 in 100; unsuccessful, 11.44 in 100.
 Fevers treated with quinin: Mazzolini, 184 cases; 102

cured; 82 relapses. Ratio: cured, 55.42 in 100; relapses, 44.56 in 100.

TYPHOID FEVER.

Before accepting the opinion of Dr. Polli in regard to the zymotic nature of typhoid fever, in which he admits the existence of a morbid and specific ferment susceptible of being neutralized by the sulphites, it is better to agree upon the signification of typhoid fever. This is difficult to accomplish, because of the difference of opinion as to the nature of typhus and typhoid fevers entertained by the various authorities, physicians of the French and English schools. Thus, by the French school, it is characterized by a lesion of inflammatory nature, seated in the glands of the Peyer and mesenteric ganglia, while the physicians of London, Edinburgh, and of Dublin, attach less importance to these lesions, because they have less occasion to observe them. This difference would probably continue to exist if the labors of Shattuck of Boston, of Gerhard and Penock of Philadelphia, had not proved that there exists in the United States and England two diseases formerly confounded under the name of typhus fever, but really distinct and resembling each other only in some of the general phenomena. One, affecting young subjects, is the typhoid fever of the French school, while the other, common to all ages, is a distinct disease from the former, which bears the name of typhus fever.

As typhoid fever is less common in Italy than anywhere else, and as there is some doubt as to the nature of the typhoid fever treated by Terri, Parrigini, Finamore, Calapreta, Capparelli, Farrini, Tagiuri and Caverci, it is best to abstain from forming any conclusions in regard to the results furnished by the sulphites in this disease.

A similar reserve will be maintained in regard to rubeola, scarlatina, variola, aartre, scorbutus, muguet, etc. In purulent catarrhs of the bladder and in cancers of the womb at a certain stage, injections of the sulphites are very active, either as disinfectants or as preventives or curatives of the nervous intoxication due to putrid fermentation (Semmola, Rodolfi, Capparelli).

I have thus endeavored to call the attention of the American medical profession to the well-known facts illustrating the chemic composition, the physiologic action and therapeutic value of the sulphites and hyposulphites. I would most respectfully urge upon the attention of the medical societies scattered over this great republic, the following subjects for careful examination and record:

1. Diphtheria, its systematic treatment with the sulphite of sodium, internally and also externally. It has been said by some that if the sulphite of sodium, in a recent case of diphtheria, be given in doses of 20 grains dissolved in a wineglass of water, every two hours, for a period covering several days, the disease will be arrested. Let the truth or falsity of this statement be determined by actual experiment. Let, then, the sulphite of sodium be systematically used, both locally and generally, in the treatment of diphtheria.

2. It has been affirmed that the hyposulphite of sodium given internally in regular doses, even in the presence of the poison in a yellow fever epidemic, will completely ward off this disease. I have no facts with which to prove this statement, but would advise that it be put to the test, as might easily have

been done, as I suggested, in the recent epidemic at Brunswick, Ga.

3. Similar assertions as to the prophylactic powers of sulphite of sodium have been made in regard to scarlet fever, measles and typhoid fever. With reference to all these bold and highly important assertions, we have not a single recorded or well authenticated observation, and hence I would urge upon the American medical profession the importance of investigation.

156 Washington Ave., New Orleans, La.

A CASE OF REMOVAL OF UTERINE MYOFIBROMA BY ENUCLEATION AND DRAINAGE THROUGH THE CAVUM UTERI.

BY J. H. ETHERIDGE, A.M., M.D.

CHICAGO.

The following report of a case of utero-myomectomy illustrates a means of avoiding the sacrifice of the Fallopian tubes, ovaries and uterus. The usual operations for removing uterine fibroids by hysterectomy or by tying off the broad ligaments are only too often necessary. Where these growths can be safely removed without sacrificing the organs that give to women her sex characteristics, no arguments can obtain to the contrary. The dangers from enucleation arise from imperfect drainage. The large cavity left in the uterine wall after turning out a myofibroma becomes a source of septic peritoneal infection unless the freest drainage be effected.

In performing a laparo-hysterotomy for fibroids, only selected cases can be taken. The steps of this operation consist of enucleation of the growth and securing drainage down through the uterus and vagina. The operation is wholly extra-peritoneal, the incision through the capsule being permanently closed. The two essentials to success are free drainage and complete hemostasis. In rare cases the sac can be sewed to the abdominal incision and drainage in this manner secured through packing it with iodoform gauze firmly enough to stop hemorrhage. By thus effectually closing off the peritoneum all danger of infecting this organ is averted.

To the distinguished surgeon, Dr. Senn, is due the credit of first describing the operation of laparo-hysterotomy with drainage through the uterine cavity for selected cases of uterine myofibroma. This procedure should hereafter be known as "Senn's operation."

The patient, age 47 years, had ceased menstruating two years previously. She had borne four children, the youngest of whom was 12 years old. Two years before the last confinement she began to have post pubic pains with much vesical irritability. These symptoms she continued to have till her operation. Between her third and fourth confinement she had had two miscarriages with great loss of blood, doubtless due to the beginning growth of her uterine tumor. After her last confinement she also experienced an enormous uterine hemorrhage. Ten years later—two years before her operation—she passed through the menopause somewhat abruptly. A year later there began a series of hemorrhages that eventually brought her to the Presbyterian Hospital in Chicago, in an anemic condition that threatened to extinguish her life.

Examination revealed a large myofibroma, freely movable, extending to the umbilicus. It was smoothly rounded and as uniform as a pregnant uterus in its contour. The cervix uteri was crowded firmly against the symphysis pubis, and the uterine cavity was four inches deep, the sound passing up directly behind the bladder. The tumor had developed wholly in the posterior wall. The usual preparations were made for an abdominal hysterectomy.

On May 25, 1892, the operation was performed. The usual median line incision was made. As soon as the nature of the tumor was determined the incision was lengthened to seven inches, the mass, free from adhesions, was everted, and the intestines were held back by a broad gauze compress. The fact that the mass sprang from the posterior wall of the uterus at once became evident. The entire uterus was outlined on the anterior surface of the mass with singular and striking clearness. After the elastic ligature was securely tied about the lower part of the growth an incision in the median line, five inches long, was made from before backwards across the top of the capsule. The entire growth was enucleated with astonishing ease without opening the *cavum uteri*. The cavity extended down to the Douglas cul-de-sac, and about six inches below the lower angle of the incision. Hemorrhage was entirely absent, apart from the escape of the residual blood of the capsule and the uterus. The lower two-thirds of the collapsed capsule was brought into strong coaptation with large catgut. An incision was then made into the uterine cavity with a scalpel, from just above the internal os to the fundus uteri, in the median line of the posterior wall. One end of a long piece of iodoform gauze four inches wide was then carried down into the vagina with a dressing forceps, and the remainder of it was crowded into the collapsed capsule. It was placed like the pleats of an accordion in order that its removal could be accomplished without unnecessary disturbance.

Afterward the incision in the capsule was closed over the packing as tightly as large catgut could draw it. The edges of the incision which were half an inch thick were closed with three rows of sutures, the inner one, heavy catgut, the second of the smaller catgut, and the third of silk. The greatest care was exercised in placing the second row of stitches, the object being to bring in contact a layer of the peritoneal surfaces about one-third of an inch wide on either side of the wound. For this purpose a cutting needle was avoided. An ordinary sewing needle was used. Seven interrupted stitches were placed, two to the inch, the incision having contracted about an inch and a half. The needle was inserted nearly half an inch from the edge of the wound and emerged a line or two from the free border. It was made to include the peritoneum and considerable of the substance of the capsule tissue to prevent tearing out. Upon the opposite side of the wound a similar method of introducing the suture was used. After this second row of closing sutures was tied, a third row of intermediate sutures of fine silk, cut short, was introduced. Thus was effectually secured a coaptation of the serous surfaces over the incision in the capsule, and the entire cavity of the peritoneum was shut off.

The time had now arrived for testing the efficacy of the hemostasis. The elastic ligature was removed, and at once arterial blood oozed freely from between the stitches. Recognizing the fact that the blood supply must come from below, three heavy, double, saddler's stitches of large catgut were introduced through the capsule from side to side, extending from before backwards. The first was placed well into the substance of the cervix, the second one-half an inch posterior to that, and the third still farther posterior to the second. They were tied as tightly as they could be drawn. Afterward, no further hemorrhage appearing, the abdominal incision was closed with interrupted silk sutures, and the patient was put to bed in good condition. The amount of hemorrhage could not have exceeded three ounces. Time of the operation, thirty-five minutes.

For two days afterward there was free drainage of blood and serum. The first night the patient slept two hours soundly. On the fifth day the gauze was easily removed. From that time the progress of the patient was entirely satisfactory, and she left the Hospital on the thirty-fifth day, and has remained well ever since.

The condition of a patient, before the menopause, undergoing this operation of laparo-hysterotomy—or Senn's operation—compared with what it would be after an abdominal hysterectomy, with its abruptly induced menopause and nerve storms, so graphically described by Professor Goodell in a recent lecture, can but be impressed upon the mind of the gynecologist.

BRIGHT'S DISEASE.

Read before the Pennsylvania State Medical Society, 1893.

BY JOHN M. BATTEN, M.D.

PITTSBURG, PA.

J. McK., age 40, a molder, while putting up an iron fence, Nov. 16, 1885, sat on the cold damp ground; the following evening was taken with chills, fever and backache. In a few days afterward I was called in and found him with general anasarca and urine almost suppressed. Upon examination of the urine I found it highly albuminous and his bowels constipated. I ordered him to take a very hot bath, wet cups to back and compound jalap powder in 30 grain doses, three times a day. With this treatment, continued to suit the varied conditions of the case, the patient recovered in about two weeks.

F. S., age 6, a male. In June 1886, suffered with an intractable albuminuria and hematuria, following a mild attack of scarlet fever which came near ending my little patient's life. The anasarca had extended all over the body, so that he looked more like an alabaster statue than a human being. This condition had developed, notwithstanding I had almost exhausted all remedies, internal and external, within my therapeutic knowledge till I had about lost all hope of my little patient's recovery. In this dilemma I put him on small doses of muriate of pilocarpine gr. 1-12, three times a day, when the anasarca and hematuria soon began rapidly to subside and he recovered.

R. S. E., a painter, a male, age 21, came into my office on Sunday, Jan. 10, 1891, complaining of dizziness and imperfection in vision, accompanied with great pain in the back, loss of appetite and bowels constipated. He stated that he had been at an oculist's in the month of May last, and the oculist had ordered him to wear glasses. On this examination I could not make a satisfactory diagnosis. I ordered him home and to bed and to take a dose of compound jalap powder. On the following day I examined his urine which revealed albumen in it. I prescribed iodid of potash, a number of wet cups to back, and milk diet. On Jan. 19, 1891, the highly albuminous urine became very bloody with great pain in region of right kidney. So great was the pain that I suspected calculus in this kidney. I ordered wet cups applied over loins and ergot combined with the iodid of potash. On Feb. 7, 1892, the blood and albumen in the urine disappeared, sight became normal and patient recovered.

This patient no doubt had had albuminuria since May when he was fitted for glasses. He gave no cause other than his business for his sickness.

In albuminuria with anasarca following scarlet fever, I have found the following medication successful in many cases:

- R Submuriatic hydrargyri gr. iv.
- Pulv. jalapæ gr. vi.
- Antimonii et potassii tartras gr. ¼.

M. ft. pulv. in chart. dividendi T (1) Sig. To be given to a child 5 years old. After the bowels have been moved freely put the patient on

- R Potassii nitrates ʒi.
- Tinc. digitalis ʒij.
- Aquæ ʒvi.

M. Sig. A tablespoonful carefully given every six hours.

The frequency and size of the dose may vary according to age and condition of the patient. A hot bath may be given daily to encourage diaphoresis. The patient should be kept in bed.

M. B., a boy 5 years old; anasarca, convulsions and albuminuria following scarlet fever. Patient very sick. I followed the above line of medication and he recovered.

I have found that the tincture of the chlorid of iron given in suitable doses, together with fresh sweet cider *ad libitum* in the convalescence of scarlet fever to be very useful remedies in preventing albuminuria. Patients should not leave the bed too soon after an attack of scarlet fever.

On Friday, Oct. 24, 1890, R. S., age 11 years, female, came into my office with the assistance of her mother after having convalesced from a severe attack of typhoid fever. Her gait was shuffling with right shoulder depressed; she complained of backache, colicky pains in bowels, loss of appetite and inability to walk erect. I ordered her home to bed.

dry cups to back, and hot poultices to bowels. The following day I found albumen in her urine. I ordered her nitro-glycerin internally, milk diet, dry cups repeated to the back and hot poultices continued to the bowels. Under this treatment she did not improve. Nov. 1, 1890, I substituted iodid of potash in 5 grain doses for the nitro-glycerin, and Nov. 21, 1890, the urine became normal, the shoulder resumed its wonted position, the shuffling and uncertain gait disappeared, the appetite improved and patient recovered.

The cause of this girl's sickness was obscure because of the difficulty of determining as to whether the disease of the kidneys might not have been secondary to a disease of the spine, which I at first suspected. I finally concluded and correctly, too, that the drooping right shoulder and shuffling gait was secondary to the disease of the kidneys.

In 1872, I examined and prescribed for a case of chronic albuminuria and anasarca in a man, age 50 years; addicted to alcoholism. I remember that my prognosis of the case at first was not very encouraging, but to my utter surprise and entire satisfaction the patient recovered. My treatment at first was compound jalap powder in suitable doses two or three times a day, till the anasarca was relieved, when I put him on 10 grains of iodid of potash three times a day till he recovered. The rapidity with which he recovered under a specific treatment would point to a syphilitic taint which I have no doubt he had.

On Friday, March 24, 1893, I was called to see P. D., age 37, a saloonkeeper; intemperate; occasionally got intoxicated and would remain so for a week; high liver. When I saw him he had been sick for about a month under the care of a doctor, but continued to get worse till the urine was almost suppressed and highly albuminous, and there were anemia, ascites, general anasarca of the body, constipation, orthopnea, great tension of heart's action, and cough. I ordered patient to take a hot bath, go to bed and then commence to take 3 grains of compound jalap powder every eight hours. I continued the hot baths once every day and compound jalap powder as directed for about a week, till ascites and anasarca disappeared. Then I put him on a tablespoonful of Basham's mixture of iron with 5 drops of tinc. digitalis every eight hours, 1 drop of nitro-glycerin in 9 drops of absolute rectified spirits of wine every eight hours alternating with the Basham's mixture, and dry cups to back three times a week; the bowels to be kept open once or twice a day with the compound jalap powder, and the patient to be kept on milk diet. The albumen did not diminish in his urine as rapidly as I had hoped it would do, and I suspected my patient might have had syphilis, although he positively denied ever having had that disease. However, on April 17, in addition to the other treatment, I put him on 10 grains of iodid of potash every eight hours which iodinated him. After he had suffered with intense headache, swollen face and eyelids, scanty urine and hoarseness for three days, and after he had taken a drachm and a half of iodid of potash, I suspended all medication for twenty-four hours and wet cupped my patient over the loins. At the end of this period I resumed the Basham's mixture, tinc. digitalis and nitro-glycerin. The urine commenced to flow and my patient became more comfortable. Sunday, April 23, the urine, for the first time since I saw patient, is free of albumen and he passes about three pints of that fluid daily; his appetite is good, tongue clean, and says he feels well. The specific gravity of the urine is 1000. The bowels move once or twice a day by taking a wine-glassful of Vichy water three times a day.

The following day the patient was up and about his room and passed three pints of urine with 10 per cent. of albumen in it. He continued to be up and about his room and to pass the same amount of urine daily but the albumen in it ranged at different times from 10 to 20 per cent. till May 12, 1893, when it became clear, straw-colored, and free of albumen. Specific gravity, 1010. The same treatment has been continued. I think now my patient has fully recovered, and he will be allowed to go out during favorable weather. The same diet will be continued for some time.

I wish to emphasize what appears to me to be a fact, that is, that there are certain pathologic conditions in chronic albuminuria which should not be overlooked in making a prognosis of the case. It is a well-known fact that a part of one kidney or a

part of both kidneys may be diseased, while the healthy parts of one or both kidneys may perform the necessary functions of those organs. Again, only one kidney may be affected, while the healthy kidney will perform the function necessary for both. In the examination of the urine of such cases, albumen and casts may be presented and the physician learning these facts by testing the urine will be apt to give an unfavorable prognosis. In the case where only a part of one kidney or a part of both kidneys are diseased, the prognosis would be favorable, according to the extent of the kidney or kidneys involved.

We should carefully inform ourselves as to what may have been the cause of the kidney disease; whether acquired or hereditary? If acquired, the causes of the disease should be searched after and if possible eliminated. If he has been a gormand his diet should be prescribed. If sedentary in his habits he should take more exercise. If intemperate in alcoholic beverages he should abstain from drinking them. If he is syphilitic, specific treatment should be inaugurated. When the cause is hereditary there are many irregularities in the constitution that are worthy of study and thought, and there are many conditions arising in the course of the disease that may be ameliorated by hygiene, diet, climate and drugs.

Nitrite of amyl and nitro-glycerin relax and dilate the whole arterial and capillary system. Iodid of potash makes the heart's action more regular. Digitalis increases the force of the heart's action, but at the same time contracts the arterioles. Aconite and veratrum viride make the heart's action slower and more feeble. Convallaria makes the heart's action slower and stronger. Hydrate of chloral dilates the arterioles. The volume of blood can be diminished by blood letting and by eliminating the plasma of the blood indirectly by sweating, purging and diuresis. Now, no doubt we can give relief to a patient suffering with Bright's disease by judiciously prescribing the above remedies, suitable to the varied conditions which may arise in the course of the disease.

If, upon examination of the urine, we find albumen, we may give nitro-glycerin. If there has been a previous history of syphilis, iodid of potash should be prescribed in large doses three times a day well diluted in water, or mercury may be given in small and repeated doses, or the iodid of potash and mercury may be given combined. If the bowels are constipated, we may give the compound jalap powder in suitable doses to keep them sufficiently open and soluble to accomplish what may be indicated in the case. If dropsy and anasarca have made their appearance accompanied with pain in the back, we should put our patient to bed, apply wet cups to back, order a hot bath taken every day by the patient and give nitro-glycerin, iodid of potash, or compound jalap powder as may be indicated by the condition of patient. If there are indigestion and nausea of the stomach we should direct our remedies to that organ by giving vegetable bitters, diluted muriatic acid, diluted sulphuric acid or alkalis.

If there is irregularity in the heart's action, we should direct our remedies to that organ; if irregular, iodid of potash with small doses of opium. If the heart's action is increased and strong, aconite or veratrum viride may be given. If weak, digitalis. If the volume of the blood is too great, we should

give cathartics, diuretics and diaphoretics. In the earlier stages of dyspnea, iodid of potash in 5 grain doses, combined with small doses of opium may effect a relief. In severe attacks of dyspnea, dry cups to the chest and the inhalation of oxygen may be beneficial. In the worst cases of dyspnea it may be justifiable to keep the patient under the influence of an anesthetic. If there are convulsions, opium may be resorted to. The old doctrine that opium is a very dangerous remedy in Bright's disease of the kidneys is true, yet it is equally true that it is a very useful remedy. If the patient is anemic we should give large doses of tincture of the chlorid of iron and oxygen. In certain conditions sometimes one of the natural mineral waters, such as Carlsbad water, may be given.

In the later development of the disease we have restlessness, sleeplessness, headache, twitching of the muscles of the face, nausea, vomiting, delirium, convulsions and coma. To relieve these varied conditions we may resort to opium, hydrate of chloral, nitrite of amyl, convallaria, digitalis, caffein, blood letting, sweating and cathartics.

The diet in the management of a case of Bright's disease of the kidneys is a very important feature. It would seem, as nitrogenous ingesta in great part undergo metamorphoses and yield their nitrogen to be carried off in combination with a portion of other elements under the form of urinary products, that a non-nitrogenous diet or one approximating it, is the proper food in this disease, notwithstanding, Dr. Ephraim Cutter asserts that he has seen a full-fledged case of Bright's disease of the kidneys restored to health by absolute beef diet in six or more months.

THE WATERS OF THE GLEN SPRINGS, WATKINS GLEN, NEW YORK.

WITH COMPARATIVE TABLE BY J. K. KING, M.D.

Read in the Section on Materia Medica and Pharmacy, at the forty-fourth Annual Meeting of the American Medical Association.

BY F. E. STEWART, M.D., PH.G.

WATKINS, N. Y.

It has long been our habit as physicians to send our patients to the healing waters of Europe for health and recreation. When it is considered that there are nearly a thousand mineral springs in the United States of America, many of them fully equal to any that may be found abroad, this fact seems anomalous. One feels like saying with Naaman, the Syrian, "Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel? May I not wash in them and be clean?" While it is true that the Spas of Europe, being older, are, as a rule, better equipped with establishments where the waters may be used under the direction of physicians specially trained in their administration, there are similar places in the United States, and I believe in developing the resources of our own country. Advantages may be given to our patients in America similar to those found in Europe at a figure within the means of the ordinary American citizen. But we must study the subjects of balneology, climatology, hydrotherapy, etc., that we may send our patients to American Spas where the correct principles of treatment are carefully carried out.

Dr. Titus Munson Coan of New York city, who has made the subject of the mineral springs of the United

States a special study, says in his paper on "American Mineral Waters with some remarks on American Climates," read before the Ninth International Medical Congress: "There are about six hundred mineral springs in the United States now utilized as places of resort. At few of these, indeed, are there fine hotels; at fewer still are there regular establishments. But the constant process of natural selection, swifter among us than elsewhere, will cause rapid progress in all that relates to balneology among us. Of all the communities of the world, that of the United States is the one for which the restful influences of spring treatment are indicated."

And how are we to realize this development of American Mineral Spas, except through the efforts of the medical profession? Institutions should be established at the mineral springs in convenient parts of the country from Maine to Florida, and from the Atlantic to the Pacific. Such establishments should be put in charge of competent physicians for their development. But they can never reach the high standing desirable until the medical profession, as a whole, educates itself to know and demand the higher class of facilities.

Quoting again from Dr. Coan's paper: "And what data have we for the survey of this vast territory from the balneographic point of view? We have the various surveys, whether made by States or by the general Government. A considerable number of monographs by different geologists and physicians and medical societies, notably the AMERICAN MEDICAL ASSOCIATION, and a lesser number of general treatises. We have, as yet, little to show that will compare with the learned works of Trouseau, Durard-Fardel, Braun, Hellft-Thilenius, Rotureau and Leitchenstein. Dr. Walton has produced an excellent manual, one that may be called a pioneer work in this direction, though it is necessarily incomplete from the lack of sufficient data. These, however, are now being developed on every hand, and particularly by the United States Geological Survey, to whose publications the student of American mineral waters is under great obligations, and especially to Dr. Albert C. Peale's recent monograph, 'Lists and Analyses of the Mineral Springs of the United States,' published as Bulletin 32 of the Geological Survey, a work which must be consulted for the fullest data yet available in the matter of analyses, of which 859 are given."

In the light of such facts as these, no apology is necessary for bringing to your notice the waters of several mineral springs in central New York, near Watkins Glen, which hitherto have not been mentioned in literature.

The existence of a mineral spring on the hillside near Watkins Glen, New York, has long been known to the residents of the town, who have for many years ascribed to it marvelous healing powers. The spring is on the site of an ancient "deer lick," and was known to the Seneca Indians, who had erected a log curbing around it, the remains of which were found during subsequent excavations. The waters closely resemble those of the European Spas, Kreugnach, Hall, Duerkheim and Krankenheit. Professor Chandler's analysis of this spring shows it to contain chlorid of sodium and of potassium, the bromid and iodid of sodium, the bicarbonates of ammonium, iron, calcium and magnesium, with traces of other mineral salts, among them bicarbonate of lithium.

Specific Gravity								

For a statement of the percentage composition, see the comparative table kindly furnished by my friend, Dr. J. K. King, appended to this paper. The waters of the Deer-lick Spring are clear and limpid, without odor, and with a slightly astringent, mildly saline taste.

Several years ago certain parties were boring in the hillside not far from the Deer-lick Spring, and hoping to discover natural gas. Seventeen hundred feet below the surface the tool struck a layer of strong brine. This brine was found to contain upon analysis a large proportion of calcium chlorid, thus unfitting it for the manufacture of salt for commercial purposes, and the well yielding neither gas nor brine fit for manufacturing purposes, was abandoned. The waters, however, resemble the celebrated brines of Kreugnach, Rheims and Nauheim, and are now being used for medical purposes.

According to Professor S. A. Lattimore of the University of Rochester, this brine, which has a specific gravity of 1.133, each gallon yielding 1.62 pounds of salt, contains per gallon 3,499.08 grains of calcium chlorid, 6,368.33 grains of sodium chlorid, and 635.67 grains of magnesium chlorid, with traces of the iodid and bromid of sodium, iron and alumina. He says it differs from all brines that he has hitherto analyzed, and from nearly all those whose composition has been reported, on account of the total absence of calcium sulphite (gypsum) which is almost invariably present in brine everywhere. No other sulphates are present in this brine, and he says: "The very large percentage of lime (calcium) in the form of chlorid is equally exceptional in my experience." The name, Neptune, has been given to this spring.

Two other mineral waters were struck by the drill in the same locality last summer. One of them is a delightful table water, and has been named Salubria, to perpetuate the ancient name of Watkins, which it bore before Dr. Watkins purchased the real estate in the neighborhood and gave the town its present name. The other spring contains iron, and has received the name, Vulcan.

Salubria water contains in each sixteen fluid ounces

196.28 grains sodium chlorid, 19.68 grains calcium carbonate, .05 grains magnesium carbonate. It is therefore a saline calcic water. In composition it resembles in some respects the waters of Vichy, Tachingen and Bilin, but is more closely related to the waters of Kissingen, Homburg, Wies-Baden, Baden-Baden, Mondorf, Constatt and Sodan. It also resembles the waters of Saratoga. The taste of the water is quite similar to Kissingen. When artificially charged and bottled in the same manner as similar waters elsewhere, it compares favorably with those now on the market.

Professor Lattimore's analysis shows the Vulcan Spring to contain in each sixteen fluid ounces calcium carbonate 29.80, magnesium carbonate 11.37, iron carbonate 1.87, sodium chlorid 149.05. The water also contains much carbonic acid gas. By consulting the comparative table it will be observed that this water stands midway between the Pandur and Maxbrunner waters of Kissingen in regard to the amount of chlorid of calcium present; that in regard to the amount of iron the Kissingen, Racogzi, contains in each sixteen fluid ounces, 1.92 grains; the Pandur 1.62, while the Maxbrunner contains no iron at all. It is evident, therefore, that the Vulcan water possesses the great advantage of being more mildly saline than either of the waters of Kissingen containing iron.

The site of these springs is a beautiful spot on the shores of Seneca Lake, west of the village of Watkins, and about ten minutes walk from the famous Watkins Glen. The altitude of the spot is about three hundred feet above the surface of the lake, and seven hundred and thirty feet above sea level. The hotels in the village are good, and well patronized in the summer time. The Sanitarium situated near the springs was established by representative physicians from similar institutions at Clifton Springs and Dansville, and is an assured success as a sanitarium doing scientific work, and an attractive summer resting place, with bathing facilities, massage, electric treatments, etc.

Therapy.—The medicinal value of these waters is the same as that of similar waters in other parts of the world. The water of the Deer-lick Spring, therefore, is tonic and alterative, diuretic and mildly aperient. The use of waters of this class results in an improvement of the appetite and digestive processes. Tissue metabolism is promoted, and the red globules of the blood increased. This being the physiologic effect of their administration they are recommended by all authorities in the treatment of anemia, chlorosis, hysteria, neurasthenia, chronic diseases of the kidneys, glycosuria and diabetes, and in various diseases peculiar to women, such as chronic endometritis, dysmenorrhea, amenorrhea, etc.

Like the waters of the celebrated Spas of Kissingen, Homburg, Wies-Baden, etc., which it resembles in many respects, the water of the Salubria Spring is a stimulant to the mucous surfaces generally, especially to that of the stomach and bowels. This class of waters, according to the leading authorities, when taken into the stomach dissolves the mucus, and by increasing the secretion of gastric juice and bile, promote the absorption of food. This effect is probably enhanced by the well-known property of sodium chlorid upon osmosis. In large doses these waters are purgative. They aid tissue building by increasing both constructive and destructive metamorphosis. They are used extensively in Europe in the treatment of catarrhal processes, especially of the stomach and bowels, also in chronic inflammation of the pharynx, stomach, duodenum and bile ducts, in constipation, in congestive affections of the abdominal and pelvic organs, chronic endometritis, hepatic and splenic congestion, chronic inflammatory diseases of the respiratory tract, obesity, scrofula, gout, rheumatism and neuralgia. Salubria is eminently a table water, and when put up in bottles, it rivals Apollinaris.

The Vulcan water of the Glen Springs, as already pointed out, belongs to the same class of mineral waters as those of the Kissingen Spa. Like the

Kissingen, it is somewhat alterative, diuretic, tonic, and mildly aperient. In gout this class of waters prove useful by exciting the secretion of the intestines, kidneys and the skin thereby reducing the habitual plethora, eliminating the gouty poison, and promoting a healthy tissue metabolism. They have been highly recommended in scrofula (though the ioda-bromated waters such as the Deer-lick are preferable), in chronic catarrh of the stomach, abuse of alcoholic stimulants, deficient secretion of gastric juice, congested liver from sedentary habits, calculus and catarrh of the bladder, and externally in various swellings of the glandular organs.

For external use, however, the Neptune brine is preferable. Like the chlorid of calcium brine of Kreugnach, so celebrated for its healing virtues, this water has a place in the treatment of a certain class of diseases. The baths given at the European Spas of Kreugnach, Rheims and Nauheim are of various kinds, and known respectively as ordinary baths, wave baths, froth baths, graduated brine baths, and baths with the addition of mother lye. The latter has great popularity. By comparing the analysis of the Neptune water with that of the graduated brines of the European Spas, it will be found that the American water does not require concentration to make it fully equal to the best of them.

Brines are graduated at the European Spas by letting the water run down great scaffoldings of thorns whereby it is concentrated by evaporating from the extensive surfaces thus exposed to the air. When the evaporation has been repeated several times, and the brines are concentrated to such a degree that they contain from 140 to 180 grains of salines to the pint, they are in many places boiled, in order that those salines which are not easily soluble, such as chlorid of calcium, silica, carbonate of lime, carbonate of magnesia, alumina, iron and manganese may be precipitated, and removed from the liquid. That which remains after several weeks boiling is called "Mother Lye." This is half salt and half water, containing from 2,000 to 4,000 grains of salines to

the pint. Its chief solid constituents are chlorid of calcium, magnesium and potassium, and bromid and iodid of sodium and magnesium. The water of the Dead Sea will serve as an illustration of Mother Lye. There is no visible outlet to the great basin of saline water, and the waters, concentrated by evaporation in the sun, precipitate the more insoluble salines, and hold those which are more soluble in solution. The most celebrated mother lyes in Europe are those prepared at Kreugnach, Halle, Volterra and Durchein. The quantity generally added to baths varies from two to thirty quarts. By a fourth concentration, crystallization ensues, and the hard substance finally remaining is known as "Mother Lye Salt." This contains a certain proportion of water, and is very hygroscopic, so that when exposed to the air, it soon becomes liquid again.

Arrangements have been made at Watkins for evaporating the Neptune brine for the purpose of preparing salt for giving what are known as salt-rubs. As will be seen, however, the water does not require concentration, but dilution, for use in bathing. Indeed, for some purposes, especially in treating uterine troubles by irrigation, great dilution is required at first, to be gradually employed in stronger solution if required.

TREATMENT OF PIGMENTATIONS OF THE SKIN.

Read by title in the Section on Dermatology and Syphilography at the Forty-fourth Annual Meeting of the American Medical Association.

BY JOHN V. SHOEMAKER, A.M., M.D.
PHILADELPHIA, PA.

Every blemish upon the skin is the source of anxiety and mortification to its possessor. In addition to those lesions produced by inflammatory, hypertrophic and neoplastic processes, we meet with a number of affections in which the normal pigmentation is decidedly altered. A generalized or local discoloration is produced by various causes, some of which are constitutional while others are local in their action. In some cases we are able to improve the quality of the blood or remove the exciting cause and in this manner to restore the normal hue. In others the discoloration of the skin is one of the least important manifestations of the disease and depends upon conditions which are beyond the reach of remedial agents. We are constantly consulted by patients whose chief trouble would seem to be abnormality of pigmentation. It is necessary in each case to ascertain the origin of the difficulty before we can adopt a rational therapeutics or form a sagacious prognosis. The constitutional maladies attended by discoloration of the skin belong to the domain of general medicine and surgery. Even those, however, which we classify among diseases of the skin frequently depend upon the operation of some systemic cause. The integument is a faithful index of the healthy action of the organs and tissues of the body. In constitutional maladies the skin is blanched, discolored or subject to inflammatory processes.

Chlorosis.—This affection is characterized by a peculiar greenish or greenish-yellow tinge, indicative of the loss of hemoglobin. The number of red cells is not greatly diminished but the quantity of hemoglobin is disproportionately diminished. When viewed under the microscope the red cells are per-

ceptibly paler than under normal conditions. The impoverishment of the circulating fluid, associated with imperfect ovarian function, accounts for the symptoms of the disease. The limits of space forbid any present discussion of its symptomatology and etiology.

The first indication of treatment is, therefore, to restore the wasted hemoglobin. This object is, in brief, accomplished by the administration of iron, with which arsenic may often be advantageously combined. As, however, chlorotics have weak stomachs, we are compelled to feel our way very cautiously in regard to medication. We should lay great stress upon the requirements of hygiene. The patients need fresh air, sunlight, gentle exercise, a nutritious but digestible diet and cheerful, or even gay surroundings. Their apartments should be well ventilated, windows should be kept open when weather and season permit; they should take short walks every day or carriage rides wherever practicable. Among the poor, in summer time, the open street cars furnish an inexpensive mode of procuring fresh air. Sunlight is of decided value in these cases, stimulating, as it does, both digestion and absorption. Sanguification proceeds favorably under the influence of light while its absence favors or perpetuates the loss of hemoglobin. The living rooms should, consequently, be sunny as well as airy. A change of climate is frequently the best initiative in the treatment of chlorosis. The mere change of surroundings, by rousing the attention and interesting the mind, is of decided assistance, for both the production and cure of chlorosis are decidedly influenced by mental conditions. In general terms, the best climate for chlorotics is one which allows the patient to spend the day in the open air, swinging in a hammock, taking a short walk or a ride—horseback or bicycle exercise if the strength is sufficient. According to the season of the year, we may select the seaside, the mountains, Florida or Southern California. Increased oxygenation is an important factor in the cure of chlorosis. Ventilation, exercise and a suitable climate promote oxygenation and thus aid in the generation of hemoglobin. One of the most valuable therapeutic measures is a sea voyage. Salt air provokes an appetite, improves digestion, stimulates the activity of the glandular follicles and viscera of the alimentary system, strengthens muscular tissue, invigorates the heart, improves circulation and respiration, communicates oxygen to the blood and promotes sanguification. The uncertain, fastidious and perverted appetite becomes normal, the discoloration gradually disappears, the lips and mucous membrane acquire a rosy hue, the skin becomes soft and acquires a healthy color, and by the time the voyage is ended the patient is restored to health or on the high road to sure and speedy recovery.

The direct inhalation of oxygen gas is beneficial in chlorosis. The use of ozonized water is another efficient method of introducing oxygen into the system. The practice of massage is likewise followed by improvement. This procedure operates favorably in several ways. It induces an increased absorption of oxygen, invigorates the general muscular system and the action of the heart, stimulates the circulation, strengthens the nervous system, excites secretion of the digestive fluids and, consequently, improves the appetite and digestion. Massage is likewise of value by exciting peristalsis and relieving the constipation

which generally attends chlorosis. Moreover, it exerts a favorable influence upon the womb and ovaries, and thereby regulates the menstrual function, which is so notably deteriorated in this disease. Music, by its effect upon the nervous system and circulation is also capable of doing good in chlorosis, and for this reason concerts or operas generally assist in improving the condition of the patient.

I have casually alluded to diet and have mentioned several important methods by which appetite and digestion are strengthened. As regards the nature of the food, it should contain as large a proportion of albuminous material as can be appropriated. It is necessary to be very circumspect in beginning the treatment. Oysters, plainly cooked, sweetbread, underdone beef with bread, with potatoes well boiled, mashed and covered with meat gravy, together with a little wine or ale, are generally tolerated. In extreme cases it is advisable to commence with the administration of prepared or predigested food. Kumyss is an excellent preparation in these cases. At once nutrient and stimulant it fulfills all the indications of a food. It is almost invariably well borne and, in fact, is usually effective in relieving gastric irritability. It stimulates the appetite and the action of the heart, deepens the respiratory movements, increases the proportion of hemoglobin in the blood. Kumyss now can be readily made from the kumyssgen powder. Another form of fermented milk which answers the same purpose is known as kefir. This preparation has a pleasant, acidulous taste, is acceptable to the stomach and has been used with advantage. It possesses less alcoholic strength than kumyss. Kefir, however, is less easily procured in this country.

In the medicinal treatment of chlorosis it is essential that the bowels should, from the beginning, be kept open, relieving the system of waste products which otherwise are re-absorbed and assist in the destruction of hemoglobin, perpetuating the morbid condition. Aloes or aloin, given in pill, combined with iron and with the addition, perhaps, of belladonna, strychnin, ipecacuanha and myrrh, as prescribed by Sir Andrew Clark, answers a good purpose. Instead of aloes, Hugh Woods makes use of the double sulphate of iron and magnesium in the dose of 10 grains three times a day. The old-fashioned ferro-saline mixture, consisting of sulphate of magnesia, cream of tartar and dried sulphate of iron, dissolved in water will efficiently fulfill the same indications, provided its styptic taste does not prove a bar to its use. Colocynth, also, in conjunction with iron, has been employed with advantage. *Collinsonia canadensis*, by improving appetite, digestion and elimination, is serviceable in chlorosis. Dr. Alexander claims to have secured improvement by the hypodermic injection of camphorated oil in the dose of 15 minims. Iron is the remedy *par excellence*. The form of its administration depends principally upon the tolerance of the stomach. Bland's pill is an excellent preparation and is generally well borne. When there is excessive gastric irritability we may make use of some of the more recently introduced preparations, such as the albuminate, solution of the malate or lævulose of iron. Again, chalybeate spring water may beneficially enter into the treatment. Another excellent method consists in the direct administration of hemoglobin. This substance, it has been shown, is well borne by

irritable stomachs, does not excite dyspeptic symptoms and is rapidly absorbed. It increases the number of red corpuscles and restores their normal composition. Hemoglobin improves the appetite, promotes menstruation, increases body-weight and strength and favors the excretion of urea. Modified forms of hemoglobin have recently been produced by Prof. Kobert, and have been presented to us under the names of hemol and hemogallol. The hypodermic injection of salts of iron is also advocated as of especial value in severe cases. Given in this manner it is rapidly absorbed and rapidly efficient. It acts directly upon the entire blood-forming apparatus. A combination of arsenic will often enhance the efficacy of iron in the treatment of chlorosis.

Local therapy is of but little value in chlorosis. All that is necessary is scrupulous attention to the hygiene of the skin by means of warm baths.

Chloasma.—As chloasma usually appears upon the face of women its successful treatment is a matter of much interest. The patches exhibit great variety, both as regards size and color. The hue may be yellowish, yellowish-brown, dark brown or even black. Chloasma may depend upon local causes, such as scratching, pressure or friction, or it may be produced by systemic affections, as tuberculosis, cancer, malaria, uterine and ovarian affections. It may also develop in the course of scleroderma, morphea, etc. Chloasma uterinum may be due to pregnancy or to disturbances of the menstrual function. Chloasma may also be associated with grave anemia.

The treatment of chloasma embraces both constitutional and local measures. Internal medication must, of course, be dependent upon the cause of the affection. If the pigmentation is merely symptomatic of a wasting affection we are not justified in expecting a favorable result from our efforts. Our attention must be directed to maintaining the general condition and checking or retarding the progress of the constitutional malady. When the discoloration has been induced by uterine or ovarian disease, we must aim to correct the disorder upon which it depends. Chloasma as the result of pregnancy usually but not invariably disappears after delivery.

Local therapy should be governed by two principles. As the pigment is deposited in the rete mucosum the removal of the epiderm will be attended by the removal of the pigmented spots. At the same time, active irritants must be avoided, as their application favors pigmentation and whatever improvement they may effect by the destruction of the affected cuticle will be but temporary. I would for this reason discountenance the use of mustard, cantharides, mineral acids and croton oil. The cautious employment of strong acetic or carbolic acid may, however, be attended by success, each spot being touched by a pledget of cotton dipped in the agent chosen. Merck's concentrated lactic acid, diluted with three times its bulk of water, applied upon a glass rod, is recommended by some writers. An ointment or plaster containing 5 per cent. of salicylic acid has also been employed. Alkalies, in the form of soap, especially the green soap, may be effectual. A solution of borax in the tincture of green soap is a good remedy. Another method consists in painting the patches with tincture of iodine. The tincture of benzoin may be used with success. The veratrine ointment of the "Pharmacopœia" spread upon the patches, will sometimes cause disappear-

ance of the pigmentation. A method of treatment much in vogue is that by some form of mercurial, corrosive sublimate; white precipitate, nitrate of mercury and mercurial plaster are the preparations most frequently employed. Hebra was accustomed to dissolve 5 grains of corrosive sublimate in an ounce of distilled water, alcohol or collodion, apply it upon a compress for four hours, prick the resulting blister and dress the surface with powdered starch. Unna, after washing the surface with alcohol, recommends the application over night of a plaster containing ammoniated mercury, which is removed in the morning and succeeded by an ointment of which the subnitrate of bismuth is a principal ingredient. In every case, when too much irritation is produced by the agent used, an emollient application should be placed upon the surface. The ointment of nitrate of mercury, either of official strength or weakened, may be preferred. The sulphocarbonate of zinc, in the strength of about a drachm to a pint of water, glycerin and alcohol, has been advised. Some practitioners rely upon plasters containing sulphur, and the late Professor Hardy mentions with approval the use of sulphurous mineral waters in the form of douches. Dr. G. H. Fox gives a formula for 4 per cent. carbonate of potassium and 2 per cent. of chlorid of sodium dissolved in orange flower water. Dr. White recommends a 1 per cent. solution of chlorid of ammonium with 15 per cent. of cologne water. Some authors advise the use of oil of cade. Professor Leloir, after cleansing the surface with soft soap or alcohol, applies several layers of a 15 per cent. solution of chrysarobin in chloroform. After the liquid has dried he covers it with a coating of the solution of gutta percha.

My own preference is for remedies which, if more slow in action, are productive of less cutaneous irritation, an effect which, as I have already stated, it is desirable to avoid. The preparations upon which I generally rely are the ointments of mercuric or mercurous oleate or an ointment containing from 30 to 60 grains of copper oleate to the ounce of excipient. A good procedure, also, is to cover the pigmented patch with the solution of hydrogen peroxid, applied by means of a camel's hair brush. Finally, I can recommend the frequent application of the galvanic current as one of the most efficient and reliable agencies at our command.

Jaundice.—A sallow complexion is the result of functional activity of the liver. The digestive disturbances and the cutaneous discoloration are best relieved by an appropriate regulation of the diet, by active exercise and by occasional employment, when an emergency arises, of a purgative dose of calomel, or by the use of such remedies as nitro-muriatic acid, or ipecacuanha. When the bile is produced in sufficient abundance but its passage into the intestine is prevented, the fluid is reabsorbed and occasions the yellow discoloration with which we are all familiar. Under these circumstances our principal aim must be the removal of the obstruction. In many, perhaps in most cases, the occlusion is due to swelling of the mucous membrane or impediment by a plug of mucus or a gall-stone. In other instances the common duct is compressed by a tumor and the outflow of bile is thus arrested. As long as the tumor is present, the jaundice will endure. Many of these new growths are of malignant character and, therefore, our efforts are necessarily devoted

to relieving, as far as possible, the symptoms to which they give rise. Hydatid tumors are amenable to operative interference and with the absence of pressure the jaundice will gradually vanish. Occasionally a colon enormously distended with impacted feces presses upon the common duct and causes jaundice. Here our indication is to unload the colon. If obstruction be due to the presence of a calculus in the ductus choledochus we must administer a purgative, such as resin of podophyllin or calomel in small and repeated doses and relieve the pain by hypodermic injection of morphin and atropin and the administration of ether and chloroform. The phosphate of sodium is of value when the concretion occupies the gall-bladder as it softens and breaks up the mass. Patients who exhibit a tendency to the formation of biliary calculi should be careful as regards diet, should consume alkaline mineral waters and take an abundance of exercise. In catarrhal jaundice if, as is frequently the case, the tongue is heavily coated, it is serviceable to begin the treatment with an emetic dose of ipecacuanha. If there is decided irritability of the stomach, broken doses of calomel are efficient. This procedure allays nausea and loosens the bowels but requires to be watched closely as it is liable to excite salivation. If constipation is present a full dose of calomel, alone or combined with sodium bicarbonate, a purgative dose of rhubarb, aloes or colocynth should be administered and repeated if required. Instead of these drugs, a saline mineral water may be ordered. In chronic cases sulphurous waters are beneficial. It is of importance to regulate the diet. The food should be simple and of easy digestion. Fat should be avoided and starches are not generally well borne. Skimmed milk, oysters raw or stewed, mutton or chicken broth, sweetbread and baked potatoes are sufficiently nutritious and will not strain the digestive organs. Undigested food within the alimentary tract aggravates the duodenal catarrh and prolongs the jaundice. The activity of the kidneys should be maintained. This can be accomplished by the use of the vegetable diuretics, the acetate or bitartrate of potassium, sweet spirits of niter, etc. Frerichs was fond of giving from 1½ to 3 ounces of lemon juice in the course of the day, finding it well borne and an efficient diuretic. The skin, also, must be kept active by means of baths. The vapor, the Turkish or Russian bath may be used with benefit. This practice alleviates the itching and diminishes the pigmentation. Water impregnated with soda accomplishes the same purpose. In some cases sulphur baths are preferable. Nitro-muriatic acid added to the bath has likewise been used with advantage. A Dover's powder at bedtime is serviceable on account of its action upon the skin. Pilocarpin, however, is much more efficient. Warm baths and diaphoretics favor elimination of toxic products. Massage, likewise, is of service in reducing the discoloration and allaying pruritus. Enteroclysis has proved a valuable device in the treatment of both catarrhal jaundice and that due to the obstruction of gall-stones. Enteroclysis is a method of introducing, by means of the fountain syringe, large quantities of water into the bowel, the fluid being carried, by an antiperistaltic motion, through the ileo-cecal valve into the small intestine. A simpler method of injection has been practiced by Krull, from two to four pints of water at the temperature of 60 degrees F., being thrown into the rectum and retained as long as pos-

sible. The procedure is repeated two or three times a day and is reported to be very efficient.

Certain drugs are of decided service in catarrhal jaundice by relieving inflammation of the mucous membrane, softening mucus plugs and permitting the free escape of bile. One of the best of these is the phosphate of sodium, which may be administered alone or in combination with the arseniate of sodium. The phosphate of calcium can also be recommended. The chlorid of ammonium yields good results. Small and repeated doses of the iodid of ammonium can be given with benefit. Nitro-muriatic acid is a good remedy in obstinate cases. It has a good influence upon the gastro-duodenal mucous membrane and facilitates the passage of bile. Chelidonium, taraxacum, tritium repens and carduus benedictus are of assistance in the treatment of jaundice. The oxid of manganese has been given with success in catarrhal or malarial jaundice. The bicarbonate of sodium, conjoined with rhubarb, is serviceable in the catarrhal form. The oxid or the nitrate of silver are recommended in the same condition. Oxgall is of utility. It may be administered alone or associated with the chlorid of ammonium. Narcotic remedies, such as morphin, belladonna, hyoscyamus or conium, are sometimes of service. If obstruction is due to a stone they relax spasmodic contraction of the duct and quell pain. They also probably aid in allaying inflammation of the mucous membrane. The passage of a calculus is facilitated by the use of massage and electricity.

Malaria.—The yellowish pallor observed in chronic malaria, or malarial cachexia, represents a waste of red blood cells and hemoglobin. Not infrequently, an actual jaundice occurs, from the presence of gastro-duodenal catarrh and the deleterious influence which miasm has exerted upon the liver. Local measures, further than the frequent use of warm baths, are of but little avail in this condition. The first step toward recovery should be, wherever practicable, removal to a country in which malaria is not prevalent. A sea-voyage is one of the most valuable means of restitution to health. The toxic impress will, however, often linger long after departure from the region which gave it birth. We must aim, therefore, to regenerate the normal constitution of the blood. Quinin is, in such cases, of comparatively little efficacy. It is of value only as a general nerve tonic, given in moderate doses and associated with iron and arsenic. Iron is the remedy upon which we must chiefly rely. Irritability of the stomach may, for a time, interfere with its administration. In that case it is best to begin with some of the more elegant ferruginous preparations alluded to when discussing the treatment of chlorosis, or the ammonio-citrate of iron may be subcutaneously injected. An excellent plan is to begin the treatment by the use of kumyss. Small doses of Fowler's or Pearson's solution of arsenic assist the action of iron. Black pepper will also aid the action of the remedies mentioned. Podophyllin or podophyllotoxin is of service when there is decided hepatic involvement. The functions of the liver may likewise be promoted by the administration of euonymus or iris. Eucalyptus is a good remedy in chronic malaria. Dioscorea villosa, or wild yam, is of undoubted service and may be advantageously used in conjunction with iron, quinin and arsenic. I esteem the chlorate of potassium as of value in this condition by virtue of its favorable influence upon the composition of the blood.

Amyloid Degeneration.—Amyloid disease occasions a peculiar waxy pallor of the skin. Inasmuch as this degeneration is secondary to chronic suppuration, especially of bones, its therapy must be regarded as rather prophylactic than remedial. After deposits have taken place in the liver, spleen or kidneys, the case is not far removed from a fatal issue. The chief causes of the infiltration are scrofulosis, tuberculosis and syphilis. It is essential, therefore, that a correct and early diagnosis be made and every possible measure be taken to prevent or avert the course of chronic suppuration. Antiseptic methods and improved surgical technique have abbreviated the course of many chronic suppurative processes, and we may infer that amyloid degeneration is not now as common as it was a quarter of a century ago. Surgical intervention, together with the use of iodoform, aristol, euophen, alumnol or other disinfectants operate upon the original cause. The constitution needs support by the use of codliver oil, phosphorus, iron, strychnin, hoang-nan, kumyss, alcoholic beverages, etc. If syphilis underlie the degeneration it claims its own appropriate treatment.

Graves' Disease.—The normal pigmentation of the skin is sometimes disturbed in exophthalmic goitre. Most commonly it is accompanied by discolored patches, resembling chloasma. In other instances the opposite condition obtains, and spots devoid of pigment, similar to those of vitiligo, are seen. These patches may receive the local treatment adapted to an abnormal increase or decrease of pigmentation. In treating the constitutional cause we endeavor to moderate the excessive action of the heart and derangement of the nervous system and to improve the quality of the blood. The best means at our command for fulfilling the last requisite are travel, change of scene and climate, cheerful company, a nutritious diet, an out-door life, and the administration of iron and arsenic. In order to strengthen the nervous system and allay cardiac excitability we must rely upon belladonna, digitalis, aconite, strophanthus, veratrum viride, spartein, sulphate, opium, cannabis indica, the bromids and hydrocyanic acid. Galvanism is also of service.

Addison's Disease.—The bronzing of skin and mucous membranes which usually occurs in this affection is generally associated with degenerative changes in the supra-renal capsules. Caseous, cretaceous, fatty, tubercular and cancerous lesions have been found in different cases. Exceptions exist to the general statement, however, for on the one hand, pigmentation may occur without disease of the capsules, and on the other, structural alterations of the adrenals may be unaccompanied by pigmentation of the skin. In some instances of pigmentation the capsules are unaffected but lesions are found in the solar plexus, cœliac plexus or semilunar ganglion.

These facts of pathology leave little room for hope of improvement. The malady steadily progresses to a fatal termination, and therapeutic efforts seldom exert any influence upon its course. It is proper to administer reconstructive medicine together with a nutritious diet. The late Professor Flint mentions a case in which decided improvement, both as regards general symptoms and the bronzing, took place in consequence of general faradization and galvanization of the sympathetic. The amendment continued for two years, when a rapid decline was followed by death within a few weeks.

Leprosy.—Leprous macules vary in color from pale red to dark brown. Exceptionally they are white and shining. The nodules or tubercles are of a deep red or brown tint. In those rare instances when tubercles are absorbed, an atrophied and pigmented spot indicates their former situation. A white or pigmented cicatrix is also left after rupture of the bullæ which precede an outbreak of anesthetic lepra. Patches of discoloration and other anomalies of pigmentation are observed in this disease. Unfortunately, our ability to ameliorate leprosy bears no correspondence to our knowledge of its etiology, pathology and symptomatology. Improvement is sometimes observed from the persistent use of chaulmoogra oil, gynecocardic acid, ichthyol, and the external use of gurgun oil or cashew-nut oil, etc.

Syphilis.—Spots resembling chloasma sometimes occur during the first year of syphilitic infection. They are more common in women than in men, appear most frequently upon the face and neck, are smooth to the touch, vary in size and shape, and range in color from dark gray to yellowish brown. Sometimes spots occur having a blanched surface surrounded by a darkened periphery. The so-called "pigmentary syphilide" is not a direct manifestation of syphilis, but is rather the result of the toxic influence of that disease upon the terminal filaments of the cutaneous nerves. The discolored spots are uninfluenced by anti-syphilitic treatment. The deposit is situated principally in the deep strata of the epiderm, though the superficial layer of the derma is, to a less degree, infiltrated.

These pigmentations may be treated in the same manner as chloasma dependent upon other causes.

Heart Disease.—A pallor is the result of the anemia which develops in the course of chronic heart disease, especially fatty heart and stenosis of the mitral or aortic valves. Our efforts in these cases must be directed to keeping up the nutrition of the cardiac muscle by means of iron, strychnin, kola nut, potassium chlorate, etc., together with fresh air and nutritious diet. The habits must be regulated and the action of the heart influenced, according to the circumstances of the case, by digitalis, caffeine, strophanthus, etc.

Morbus Cæruleus.—Cyanosis depends upon malformation of the heart, great vessels or lungs. The color varies from a duskiness to purple or almost black. It is not always the same, but is deepened by physical exercise and mental excitement. The blood is deficient in oxygen and contains an excess of carbonic acid. All that can be done in the way of treatment is to maintain bodily heat by warm clothing and warm rooms, to avoid excitement, to restrict the diet to easily digested food and to administer digitalis with the aim of strengthening the heart.

Carcinoma.—The alteration in the composition of the blood induced by cancer is evidenced by the cancerous cachexia, a peculiar icterode and earthy hue of the skin. Of the treatment of cancer I need say no more than that I attribute some importance to the exclusion of meat from the diet for periods of months at a time. No drug has any certain action upon the progress of the disease. Early excision, especially if the growth be superficial, may be followed by complete recovery. A continuous use of corrosive sublimate in alternation with arsenic may retard the course. In tumors unamenable to operation I should be disposed to try the effect of injec-

tions of pyoktanin, as practiced by Professor Moorhof. The published results are, indeed, conflicting, but good seems to have been accomplished in some cases.

Melanosis.—Excessive pigmentation occurs in certain cases of both sarcoma and carcinoma. These varieties are always rapidly destructive, and little good can be effected by any mode of treatment.

Argyria.—This dull bluish-gray discoloration is comparatively infrequent at the present day, since we no longer rely upon silver in the treatment of epilepsy and have learned to use it cautiously in locomotor ataxia. It has been sought to remove the color by the use of iodid of potassium but the results have been very unsatisfactory. Alkaline lotions have also entirely failed. Silver is valuable in the management of many chronic nervous maladies, but should never be uninterruptedly administered for a longer period than a month or six weeks. The advent of argyria is indicated by the appearance of a bluish line upon the gums, similar to that produced by lead.

Arsenicism.—The prolonged use of arsenic sometimes gives rise to a yellowish or brownish-yellow discoloration of the skin. The pigmentation may be diffuse or localized to regions already the seat of some cutaneous malady. This discoloration gradually disappears after suspension of the remedy.

Freckles.—In this common lesion the pigmentation is removed by the same local measures which have already been described as efficacious in chloasma. Among the most reliable agents to employ are copper oleate, corrosive sublimate, and salicylic acid.

Striæ atrophicæ.—Atrophic lines and spots, of a glistening, bluish-white color, due to partial or complete rupture of the superficial bundles of connective tissue by extreme distension, the common causes of the stretching of the integument during pregnancy, dropsy and obesity. They may also be produced by flatulence and the presence of abdominal tumors. These lesions are permanent.

Vitiligo.—I have seen no result from any form of internal treatment. The most success attends the effort to remove the darkened margins which surround the white patches. This object may be accomplished by means of galvanism, mercurials, tincture of iodine, soft soap, acetic acid or carbolic acid. It has been attempted to excite pigmentation in the patches by the use of sinapisms, cantharides, capsicum, croton oil, turpentine, ammonia and other irritant substances.

Morphœa.—This disease requires constitutional treatment. The most effective remedies are codliver oil, phosphorus, iron, quinine, arsenic and the chlorid of gold and sodium. The most promising local measures are massage, galvanism, mercurial potash soaps and mercurial lotions. These applications may be used singly or in combination.

Scleroderma.—Hygiene, nutritious food, change of climate, and tonic medicines, such as iron, quinine, strychnin, arsenic and codliver oil are required in this affection. Locally, massage, electricity, warm baths, and stimulating ointment are the most efficient means at our command. The ointment of copper oleate, half a drachm to the ounce of lard, or a mixture of half an ounce of green soap and an ounce of mercurial ointment are the most satisfactory unguents. Electrolysis, in the hands of Brocq, produced decided improvement. As a rule, treatment is but of little avail in scleroderma.

Tinea versicolor.—The yellowish or brownish discoloration of this affection can be removed by the use of a parasiticide of which I give the preference to the oleate of copper, which can either be diluted with oleic acid or made into a 10 or 20 per cent. ointment. This remedy not only destroys the parasite upon the surface but penetrates the interstices of the cells. It is of importance, also, that the surface should be cleansed by means of medicated lotions of borax and thymol, for example, instead of plain water. I am satisfied that the use of water facilitates the development of the fungi. Other agents which may be used are alcohol, naphthol, resorcin, carbolic acid, creolin, and an ointment containing chrysarobin and a 1 per cent. of picrotoxin.

Nævus pigmentosus.—The best treatment for this lesion is excision. The ethylate of sodium, galvanocautery, the actual cautery or the ligature may also be successfully employed.

Xanthoma.—These yellowish patches or tubercles can be removed by excision, cauterization, the application of a 10 per cent. solution of corrosive sublimate in collodion and by electrolysis. As the cause is unknown we have no rational constitutional treatment and can only use systemic remedies in response to the general condition of the health. A course of nitro-muriatic acid, with an occasional blue pill, and followed, after a time, by the administration of arsenic was suggested by Erasmus Wilson. Besnier advises the administration first of phosphorus and subsequently of turpentine.

Xeroderma pigmentosum.—This rare affection begins at an early age. The lesions generally appear upon the face and under the eyes. At first they resemble freckles but, at a later stage dilated capillaries can be discerned upon or between the lesions. Finally the affected spots become more or less atrophied. It is apt to be followed by new formations which, in most instances, are of malignant character. It is advisable to remove the tumors at an early date. No treatment seems to have any influence upon the disease.

A CASE OF AMŒBIC DYSENTERY.

BY FRANKLIN E. MURPHY, M.D.

KANSAS CITY, MO.

Cases of amœbic dysentery, which have been reported in recent years, are of especial interest as evidence is afforded which shows that not only may the so-called tropical dysentery exist at a distance from the tropics, but also that the disease may originate in localities very much farther north than has heretofore been supposed.

The case reported and described by Osler in 1890 called attention to its occurrence in the United States. The report of this case, the first reported in North America, prompted a special study of chronic dysenteries and since that time other cases have been reported.

At the Johns Hopkins Hospital, the most extended study of amœbic dysentery has been made.

Councilman and Lafleur (*Johns Hopkins Hospital Bulletin*, Vol. II, 1891) review the literature of this disease, and analyze a number of cases occurring in Osler's wards, together with a few other cases; in all fifteen.

A case has been demonstrated by Musser in Philadelphia. Stengel, in Philadelphia, has also demon-

strated the disease. Other cases I have seen reported, have been by West of Galveston and Harris of Atlanta. Hektoen of Chicago, reports the case of a man who contracted the disease in Texas.

The history of the following case is given as determining the existence of the disease in this part of the country, and as a case having its origin here:

R. H., age 30; tailor, native of Russia, has been in the United States ten years. Six years in New York; four years in Kansas City. Family history excellent; has never at any time in his remembrance been sick in bed. In this four years residence in Kansas City, he has never been away from the city. Patient first seen Oct. 11, 1893.

About June 1, 1893, patient was attacked with diarrhœa which he attributed to indigestible food taken. This continued for some days when he noticed the stools were blood tinged. He was treated by a physician and improved. Relapse after relapse occurred, each relapse greater in severity than the preceding. At one time the number of stools passed in the twenty-four hours was fifteen to twenty.

He went to a hospital and under treatment became much better. When he left the hospital he was having about three semi-solid passages in the twenty-four hours. Since that time he has been growing steadily worse until at the present time and for the past week has been having thirty to forty stools in the twenty-four hours. The stools are very offensive and he suffers more at night.

The shop at which he works is supplied with water from a shallow well. At his home, city water is used.

Patient is greatly emaciated and anemic; skin of a sallow earthy color, dry and harsh; tongue flabby and slightly coated. Temperature 99½, pulse 90, respiration 22. Examination of chest negative; no enlargement of the liver could be made out. Abdomen soft and very tender to pressure in epigastrium, and in the area corresponding to the splenic flexure of the colon. The stools were watery, brownish in color, contained much mucus and were alkaline in reaction. At times they contained blood-tinged gelatinous masses.

On microscopic examination were found blood corpuscles, pus cells, epithelium, crystals of triple phosphate and amœbæ in active motion.

The amœbæ correspond to descriptions given. They were five to eight times the diameter of a red corpuscle and in the active amœba a division into ectosarc and endosarc could be clearly made out. The granular interior contained microorganisms and some contained red corpuscles. In one very active amœba five red corpuscles were counted. Larger or smaller vacuoles were present in the body of the amœbæ and a change in size of larger vacuoles was detected. The movements were of progression and thrusting out of blunt pseudopodia. In the gelatinous masses found in the stools were at times present, shreds of a material lighter in color, in which the greater number of the organisms were found. In feces brought a distance of several squares, through the cold, no movement in the amœbæ could be detected. On slightly warming the slide the movements were induced. I had several opportunities of examining the feces immediately after being passed. In these were found the most actively moving amœbæ. Slowly moving amœbæ would be stimulated to more active motion on gently warming the slide.

Among the amœbæ in motion were found bodies a little larger than white corpuscles. They were motionless, granular, contained a nucleus and were highly refractive. These bodies, I think, correspond to those described by Losch and thought by him to be spores.

In the treatment of this case, rest was enjoined and the usual dietetic treatment instituted. High, rectal injections of dilute solutions of quinin limited the number of stools and the amœbæ were decreased in number. The best results were obtained from large enemata of water acidulated with nitric acid, the internal use of salol and Dover's powder and tonic doses of quinin.

A sufficient length of time not having elapsed, I am not justified in pronouncing a cure in this case. The general condition of the man is good. He is gaining flesh, and is at work. From this, I am encouraged to think there will be no return of the symptoms.

WHAT THE GENERAL PRACTITIONER
SHOULD KNOW ABOUT DISEASES
OF THE EYE.

BY W. A. FISHER, M.D.
CHICAGO.

Yesterday I noticed an article in the *American Practitioner and News* with the above title, written by a professor of diseases of the eye in a medical school, and read before a State medical society. His ideas were so foreign to mine and so different from most of the teachings of the present day, that I am prompted to write this article.

It is conceded by most of the teachers of medicine to-day that the recent graduate should know more of diseases of the eye than most physicians now practicing their professions as regular practitioners. It is injurious to the doctor, the specialist and the patient that he does not know more. The patient often suffers by not being referred to the specialist in time, simply because the doctor does not make a diagnosis and patients are often sent to the specialist, or drift into his hands when it is too late for any one to be of service to them. As a rule the student has no examination on the eye, or so little that he gives it little or no attention. If he was compelled to know some things that would be of practical benefit to him he would learn these the same as he does other things that are required. The student is supposed to know how to use the microscope to a limited extent and it is highly proper that he should. He puts in a good many hours on work that is not as useful to him in many ways as the use of the ophthalmoscope, when one-half that time spent in use of this valuable instrument in a practical way would be of much more importance to him in his every-day work.

The article that inspired this one, cautions the doctor against glaucoma, advises its early diagnosis and prays him to send it to the specialist. This is good advice, and I think all will agree with him. But the same article advises the doctor not to attempt the use of the ophthalmoscope for several reasons; among them, it will not pay, the instrument costs too much, the time for learning the use of it will be too long and he can not keep in practice. He is also advised not to fit glasses. In answer to the first one, we might ask what will pay better? The cost of the instrument is trivial; the best, or one of the best ophthalmoscopes on the market, the one I and many others use, costs \$10. The time necessary for learning is comparatively short, and if he once learns how can he forget it? The writer of the article alluded to also says the doctor should not attempt to fit glasses. He surely does not advise the doctor to refrain from fitting glasses because it will not pay. If it were not for the specialist's refractive work his income would be seriously contracted. It is a matter of very great importance to diagnose glaucoma early, but if he is barred from the use of the ophthalmoscope, how can we expect him to make an early diagnosis? The doctor does not want to send a case to the specialist for operation, and have him returned with a pair of glasses and a complete cure. Then how can we expect him to refer his cases of glaucoma until he knows he has glaucoma; and barring the ophthalmoscope he would be seriously handicapped in an early diagnosis. Any doctor with ordinary intelligence should be able to diagnose glaucoma, with the aid of the ophthalmoscope, in less than a dozen hours in a

practical way, and if he can do that in such short time with the instrument costing \$10, I consider his time well spent; and when he can do that much, he can do more. Unless he can use the ophthalmoscope he will be at a loss to tell much, if anything, about diseases of the eye. If he can diagnose glaucoma with the aid of the ophthalmoscope, he can diagnose atrophy of the optic nerve, and how valuable it will be to the physician to be able to diagnose glaucoma and optic atrophy in the early stages. It will certainly be a great help to his patients who chance to have these dreaded diseases. It is not much to the doctor's credit to diagnose glaucoma and optic atrophy when the patient is blind, only to recommend him to some asylum for the blind. The time to make a diagnosis of either of these diseases, to be of service to the patient, is in the early stages; to demonstrate this, I will mention a case sent to me for consultation by a former student, Dr. Shinn, of Chenoa, Ill:

Mr. B.—, age 58, retired farmer, consulted Dr. S.— about October 1, 1892. Diagnosis, beginning optic atrophy of both eyes. Mr. B. has been an excessive drinker and smoker; advised to stop both; he partially quit. Dr. S.— referred him to me Oct. 10, 1892, as he thought with another opinion he might have better control over his patient. R. E. V. = 20-40; L. E. V. = 20-60 +. Diagnosis, optic atrophy. Not only advised total abstinence, but told him if he did not abstain he would certainly be blind. This he seemed to appreciate. Dr. S. put him on strychnia hypodermics. A letter from Dr. S. Jan. 1, 1893, says: "Patient is a total abstainer." He is not able to give exact results as Mr. B. is away for a short time, but he is no worse.

Dr. Shinn made the diagnosis and realized the importance of early abstinence from alcohol and tobacco, and sent him to me to have the diagnosis confirmed and the patient impressed with the importance of early treatment. This patient has had the benefit of the profession, for his diagnosis was made when he complained to his family physician. Dr. S. recognized the worth of the microscope and ophthalmoscope; came here last summer and learned to use them. He has certainly made it pay if he never gets another chance, and whatever benefit the patient may receive he will owe to Dr. S. How much credit should he receive if he had made the diagnosis when his patient was blind?

(Dr. S. has received \$25 for his trouble in this case and says he has had more than that much satisfaction; and while he don't consider himself an expert with the ophthalmoscope, he could not get along without it in a general practice.)

The doctor ought to know enough about the microscope to diagnose troubles he might find by examining urinary deposits, etc., at least; he can learn the use of the ophthalmoscope just as easy and in as short a time. The doctor should know how to use the ophthalmoscope to aid him in spinal affections, particularly tabes dorsalis, locomotor ataxia. Last week a doctor was referred to me by an optician to fit his wife with a pair of glasses, he failing to get any improvement in her vision. I found she had atrophy of both optic nerves. Upon further examination found she had tabes dorsalis. We often find atrophy when the ataxic symptoms are slight or absent. Albuminuric retinitis often gives us such a distinct picture that from it, alone, a diagnosis is often made.

I will not attempt to say what eyes the doctor should treat; it depends upon his diagnostic ability, and if he can not use the ophthalmoscope he will not make many early diagnoses of diseases of the fundus, and if he does not have the diagnosis, treatment is out of the question. I would not advise a

physician to use a drug in a single case in which he has not made a satisfactory diagnosis; but if he can make a diagnosis and has some good text-book on ophthalmology, he can often find good treatment for his patient. Diagnosis first always, then treatment. I will report a case of glaucoma where the ophthalmoscope was not used:

Mr. K., age 64; first taken with severe pain in eyes and loss of vision four months ago. The doctor ordered hot applications; the attack passed off in a few days; returned with severe pain one week later—same treatment. This treatment was kept up with medicine internally until I saw him about four months after first attack, when I told him there was nothing to do for him, that promised anything, but an operation, and that did not promise much. He was astonished, for he had never had an intimation of an operation. He consented to the operation, which was done next morning; was relieved from pain, but no improvement in vision.

I do not say all cases of glaucoma would have useful vision with an early operation, nor do I say this one would, but early diagnosis in glaucoma and optic atrophy is the only chance the patient has, and for such cases, if for no other reason, why should the doctor ignore or be barred from using the ophthalmoscope?

Primary glaucoma is a common disease, constituting about 1 per cent. of all cases of eye disease, and the general practitioner sees many of the cases early. Many cases are unfortunately sent to the ophthalmologist too late for any benefit because of an improper diagnosis in the beginning. Inflammatory glaucoma is often confounded with iritis and irido-cyclitis, and treated with atropin, which is contraindicated in glaucoma. Cases of glaucoma simplex which present no external symptoms are often mistaken for beginning cataract, and put off to get ripe until iridectomy is too late.

I saw a patient in the hospital to-day, with senile cataract of both eyes, who spent one year in a poor-house and was sent to the blind asylum, where he remained four months. He was resigned to his fate, learning to make brooms as other blind people do, when he was found by an oculist and sent to the hospital for an operation. He has good perception and good projection, and I have every reason to believe he will be reading a newspaper by the time this is in print. Then why should the doctor ignore the ophthalmoscope?

Now for the fitting of glasses. From a specialist's standpoint, the doctor might be barred from fitting glasses, and I believe with the surgeon that cases of laparotomy should be done by the surgeon; but there are some cases of laparotomy that must be done by the doctor or not done at all, "and the doctor must do something." Some patients must have glasses prescribed by the doctor or not prescribed at all, and if he is looking for the financial gain, to say nothing about the good he does his patient, he will find it quite successful work. If he makes a mistake and gives the wrong glasses he has not done an irreparable damage, but can make another effort and change the glasses, and if he finds he can do no good he will have done no harm. I will report my first dozen cases I fitted with glasses when I was practicing general medicine:

Case 1.—Annie R., age 16; symptoms, headache and blurred vision; could not read or sew but a few minutes when everything would blur and run together; if she persisted she would have severe headache.

L. E. V. = 20-20; R. E. V. = 20-20; no improvement with glasses ordered.

R. Atropin sulph gr. iv.
Aq. dist ʒi.

M. Sig. Gtts. ii in each eye four times a day for three days. L. E. V. = 20-80, with + 0.25 C, with + 1.25c 180 = 20-20. R. E. V. = 20-20.

Ordered above for continuous work; result, complete relief from all headache; can read and sew as long as she wants to; no blurred vision.

Case 2.—Ethel McK., age 17; nearly constant headache; had to go to bed two or three times a week with sick headache. R. E. V. = 20-20, with + 0.50 = 20-20; L. E. V. = 20-20, with + 0.50 = 20-20.

Ordered atropin as in Case 1. R. E. V. = 20-120, with + 1.50 = 20-20; L. E. V. = 20-120, with + 1.50 = 20-20.

Ordered above for continuous wear; result, relief from all headache. She did not think the glasses helped her looks and left them off one night to go to a spelling match. Sick headache returned; she tried it several times with the same result and found she could not get along without them.

Case 3.—J. N. K., age 39; sick headache so often and had tried so many things he thought it was natural, and would take a dose of morphia and sleep it off. R. E. V. = 20-20, accepts no glass; L. E. V. = 20-20, accepts no glass.

Ordered atropin as above. R. E. V. = 20-40, with + 1. = 20-20; L. E. V. = 20-40, with + 1. = 20-20.

Ordered above for continuous work; they seemed to help him for awhile, but soon laid them aside.

Case 4.—Mrs. H. M. E., age 27; watering and burning sensation in eyes. R. E. V. = 20-20, accepts no glass; L. E. V. = 20-20, accepts no glass.

Ordered atropin as above. R. E. V. = 20-80, with + 1.50 = 20-20; L. E. V. = 20-80, with + 1.50 = 20-20.

Ordered above for constant use; could not wear them; changed to +1. each; no benefit.

Case 5.—Eliza C., age 17; constant headache. Others, as well as myself, had treated her at different times with temporary benefit.

R. E. V. = 20-20, with + 0.25 = 20-20; L. E. V. = 20-20, with + 0.25 = 20-20.

Ordered atropin as above. R. E. V. = 20-60, with + 1.25 = 20-20; L. E. V. = 20-60, with + 1.25 = 20-20.

Ordered above for constant use; headache all disappeared.

Case 6.—Hattie H., age 10. Chorea for several years; others, as well as myself, having treated her with varying success.

R. E. V. = 20-20, accepts no glass; L. E. V. = 20-20, accepts no glass.

Ordered atropin as above for one week.

R. E. V. = 20-60, with + 1.25 = 20-20; L. E. V. = 20-80, with + 1.25 C with + 0.25 c 65 = 20-20.

Ordered above for continuous wear. Medicine stopped to see what glasses would do; result better than when taking medicine; so much improved the parents thought she needed no more medicine. Two years later all nervous symptoms had disappeared and she is well.

Case 7.—Mrs. J. R., age 30. Eyes have been failing for the past year; can not see to do close work; headache when attempting to do such work.

R. E. V. = 20-20, accepts no glass; L. E. V. = 20-20, accepts no glass.

Ordered atropin as above for three days.

R. E. V. = 20-80, with + 1.50 = 20-20; L. E. V. = 20-60, with + 1. = 20-20.

Ordered above for constant use; result perfect; says she could not do without them.

Case 8.—Mrs. J. D. C., age 26; headache and blurred vision. R. E. V. = 20-20, accepts no glass; L. E. V. = 20-20; accepts no glass. Ordered atropin as above for three days.

R. E. V. = 20-50, with + 1. = 20-20; L. E. V. = 20-50, with + 1. = 20-20.

Ordered above for constant use; result perfect; could not get along without them. Ordered a duplicate, so would not be without glasses if they should break.

Case 9.—Thos. F., age 19. Medical student. While taking his first course of lectures he was troubled with headaches; about Christmas they were so severe he consulted one of the professors, and he advised him to go home, fearing typhoid fever. After being home for a few days his headaches disappeared and he felt all right. As I was beginning to be an eye specialist, I attributed his trouble to his eyes.

R. E. V. = 20-20, with + 0.50 = 20-20; L. E. V. = 20-20, with + 0.50 = 20-20.

Ordered atropin as above for three days.

R. E. V. = 20-120, with + 1.75 C with + 0.50 c 100 = 20-20; L. E. V. = 20-120, with + 1.75 C with + 0.25 c 90 = 20-20.

Ordered above for constant wear. He returned to school and has had no more trouble; has graduated and is now wearing same glasses; could not get along without them.

Case 10.—Mr. G. F. F. age 25. Farmer. Eyes water and burn when reading in the evening.

R. E. V. = 20-20; accepts no glass; L. E. V. = 20-20 accepts no glass.

Ordered atropin as above for three days. R. E. V. = 20-40, with + 0.50 = 20-20; L. E. V. = 20-40, with + 0.50 = 20-20.

Ordered above for constant use and to my surprise they gave perfect satisfaction; he also had duplicate made after he had broken them so he would always have a pair.

Case 11.—Maud G., age 18; blepharitis marginalis both eyes. R. E. V. = 20-20, accepts no glass; L. E. V. = 20-20, accepts no glass.

Ordered atropin as above for three days.

R. E. V. = 20-60, with + 1. = 20-20; L. E. V. = 20-80, with + 1. C with + 0.50 c 90 = 20-20.

Ordered above for constant wear; result, complete recovery. I had treated her many times with temporary benefit with yellow oxid of mercury ointment.

Case 12.—Annie S., age 3 years. Converging squint alternating for one year. Ordered atropin same strength as above three times a day for one week; fitted her by retinoscopy; examined in four weeks; result, perfect when glasses are on; converging when glasses are off.

Case 3.—Was a case of muscular asthenopia and he might have been relieved had he been in more competent hands, but while I did him no good, I did him no harm.

Case 4.—Received no benefit. I do not think I could benefit her any now if I were to try again. She did not like the looks of the glasses and that may have had something to do with the result; at least, I did not benefit her any.

I had a patient in my clinic, Illinois Charity Eye and Ear Infirmary, not long since, suffering from headaches. She was relieved by glasses, but she had a divergence. She was operated upon for convergence by a surgeon not long since. Had she been fitted with glasses in first place she might have saved herself two operations, the one the surgeon did and the advancement to correct it.

Operations for squint should not be attempted by the doctor unless he can correct errors of refraction.

WAS IT SYPHILIS?

BY S. F. ROGERS, M.D.
TROY, NEW YORK.

This question could in all fairness be asked, after a careful analysis of the subject, particularly the evidence presented, in the very able paper, read last June before the Section on Surgery and Anatomy at the forty-fourth annual meeting of the AMERICAN MEDICAL ASSOCIATION, bearing the title, "The Antiquity of Syphilis, and Moses as a Health Officer," by Dr. J. T. Jelks of Hot Springs, Ark. In this paper the Doctor has evidently touched the keynote of discussion; and without doubt, has been the means of turning many thinking men in a direction hitherto not sought, for clinical evidence in the diagnosis of disease. I think it quite worthy the profession to turn aside for a moment from our text-books, and consider some of the leading points in the arguments presented by Dr. Jelks, from a Scriptural standpoint. However, it will be our aim (as the reader will observe), in the treatment of the subject, to have it suggestive, rather than exhaustive; to render full justice to every argument and quotation presented by Dr. Jelks, would swell this paper to a volume of no small dimension.

The reader will observe the necessity of first carefully perusing Dr. Jelks' paper, and then, with the open Bible, study with us the evidence presented; not forgetting the fact, however, that—for a purpose—the Doctor has quoted from the writings of Dr. Buret, who carefully gathered all his *Scriptural* evidence from the Latin version of the Hebrew text (edition of 1715, found in the National Library at Paris).

Let me state for the benefit of the reader, this Latin version is an obscure volume—the very location teaches that—an edition known to a few; used by Dr. Buret, however, to prove his arguments. His purpose, as you will very readily see, could not be met, had our more modern or common versions been consulted. The great difference will be plainly seen, by comparison of the quotations, which will account for the remark by Dr. Buret: "We show our preference for the Latin version." (1715). (Why?) It will be unnecessary to remark, that, granting the preference to either the Latin or the more common versions, the evidence is very hypothetical in the former, and much more so in the latter. With our knowledge of Hebrew history, it would not be arrogance to suppose that syphilis did prevail to some extent, and was a disease then as now, much to be dreaded.

We are not, however, justified in asserting that syphilis was prevalent among the prominent Bible characters. A great deal of question hovers over such terms as plague, pestilence, etc., words used in the Scripture many times, without any definite meaning, i. e., specific name; thus we are not at fault if we do not know just what the plague was. The declaration shows a visitation on the people, of divine judgments. However, there are many instances given (I think about one-half), where the nature of the plague and pestilence are fully defined. The ten plagues which visited Egypt during the captivity; as also the leprosy. This latter is amply elucidated in Leviticus, thirteenth chapter. I would ask the reader to carefully peruse this chapter throughout, and see if he does not see in it more of the laws and tokens given to enable the priests to correctly establish the differential diagnosis between leprosy and a prevailing, yet harmless skin disease, than he does of any symptom accompanying syphilis.

It will be well to remember also, that this chapter is referred to by Dr. Buret in his endeavor to prove secondary and tertiary syphilis. As before remarked, Scriptural writers have in many instances given us but a vague idea of what many plagues were. See in this connection Num. 16: 46. Here a plague is spoken of as begun, also the same chapter (fiftieth verse), the same plague was stayed. Num. 11: 33 records a like instance. Not to over-tax our readers farther, we will close this line of thought with this fact; that plagues were administered in various ways, not necessarily in the form of sickness or bodily infirmity. (See plagues of Egypt also, Deut. 28: 59, 60, 61.) These verses in Deuteronomy might be accepted as the key to the term, plague, by enabling us to assimilate our minds to the circumstances and conditions of the people living at that age, and upon whom the plagues rested.

Let us bear in mind the fact, that medical men are not *entirely* exempt from all weaknesses of the flesh; one of which is a great tendency on the part of human discoverers to plainly see what they are seeking for; particularly a "diagnosis." It has been said the "seekers after a miracle will accept anything rather than be disappointed." It is not ours to say such is the case with either Dr. Jelks or Buret whom the former quotes. We observe, however, objects can be presented to the vision in varied hues, according to the color of the light cast upon them; rendering many times the true pigment quite obscure.

In the case before us, Dr. Jelks accepts the diag-

nosis of syphilis among the Hebrews, made by Dr. Buret, who "shows a preference," for the obscure Scriptural light before alluded to. We are free to confess, the Doctor's object *could* be gained by the aid of such a light reflected upon the science of etiology—with less strain upon the imagination than any other. When Scripture is called upon to prove, not only the antiquity of syphilis, but any other reasonable doctrine, men are quite apt to grasp at the old and sacrilegious adage with a great deal of vehemence. True, there are some rather strong passages quoted to prove such doctrines.

We recognize in the subject before us, a possibility of producing some which could be used as a fulcrum, upon which to place the strong lever of scientific research, viz.: the twenty-fifth chapter of Numbers. In this, if there be any, is the strong hold of the syphilitic argument, and yet the writer would feel safe in saying there is not a physician at the present day who would dare to diagnose so grave a disease as the one in question with so little clinical evidence.

The plague here spoken of *might* have been syphilis. Evidence is lacking to warrant a too decisive opinion in either direction. However, we do claim the evidence is greatly wanting to prove this disease, in the persons presented by Dr. Buret, and from whom Dr. Jelks quotes. Space in this JOURNAL will not permit a too lengthy discussion of every detail; therefore we will cast some glances at Scripture along the narratives in which Sarai, the wife of Abram, and David the king of Israel occupy a prominent position. Sarai is mentioned by Dr. Buret as being the infective agent in the household of Pharaoh. (See narrative in Gen. chapter xii to end.) We here see that Sarai's beauty was the passport of admission. At the same time we must not lose sight of the existing custom among Egyptian rulers: Gen. 12: 15. This action of Abram was the result of his best judgment, founded on a knowledge of this custom; and to save his life these methods were resorted to. Abram explains his situation and feelings in a similar peril. (Gen. 20: 11.) "I said, surely the fear of God is not in this place, and they will slay me for my wife's sake." This also applies to their condition while with Pharaoh, vividly marking the character of that ruler, whose unbridled lust would not stop at murder to gratify its passions.

When the offended Deity troubles Pharaoh for his sin, he lays the blame to Abram for leading him astray by this device. Right at this point the question presents; could Sarai be afflicted with syphilis, and Abram have no knowledge of the same? Again, if such was her condition, would not Abram have presented the fact to Pharaoh, as the strongest possible argument against prevailing custom or passions? Would a syphilitic subject be so extremely comely as to attract the attention of the king? Have we any just reason to presume, that both Abram and Sarai were ignorant of the fearful consequences accompanying syphilis? Not in the least. This could not possibly have been the true situation.

Note also the time of their marriage relations. Sarai's barrenness, yet in possession of great beauty; so many years a syphilitic subject, in a land where therapeutic measures were simply rudimentary, if known at all. Again, please consider the intervening time between the admission of Sarai into Pharaoh's household, and the visitation of the plague mentioned. Was it sufficient for the true nature of

syphilitic poison to manifest itself among so many? correctly considering the stages of incubation, primary lesion, etc.! We have reason to suppose—if this were the case—the word, wife, would have been supplemented by the word, syphilis, or its equivalent Hebrew term, to finish the interrogation of Pharaoh to Abram, when Sarai was returned to him: "Why didst thou not tell me that she was" (syphilitic)?

Can we presume for a moment this disease was not known among so licentious a people as the Egyptians? Let me ask you to turn to Gen. 17: 1 to 6. Here we find Abram, at ninety-nine years, covenanting with the Almighty (verse 4); here we notice a change in name occurs (verse 5); also a change in name for Sarai (verse 15); the promise continues, viz.: "She shall become a mother of nations." This occurs prior to the sojourn at Gerar; also (to continue the narrative) we see Sarah, "old and well stricken in years, and it ceased to be with Sarah after the manner of women." (Gen. 18: 11). At this time we recognize Sarah as having passed the menopause, and to this the passage refers; and to this Sarah herself refers, when she laughed at the announcement. In this condition she is found by Abimelech the king, as before alluded to. (See Gen. 20: 2.)

Now it would be quite reasonable to ask Dr. Harmonic of Paris—to whom Dr. Jelks refers—what causes the barrenness in Sarah at this time, syphilis or menopause? Our modern Scripture (Gen. 18: 11) says, "and it ceased to be with Sarah after the manner of women." In this statement we recognize the menopause, at which time, (according to the quotation by Dr. Jelks from Dr. Harmonic's "Monograph on Venereal Diseases among the Hebrews," the Doctor in alluding to Sarah says: "It is not irrational to suppose that syphilis was concerned in this sterility. It disappeared with age in Sarah, who became pregnant late; which is good proof that her sterility was not due to organic causes; and, outside of syphilis, we can not see any other disease of genital origin, which would correspond with the foregoing facts.") We see by this quotation that the disease "disappeared." Granting the Doctor's statement correct, we would ask how Sarah could convey the disease to Abimelech, after all the foregoing changes mentioned had taken place? All of which did occur, prior to her sojourn at Gerar. And yet, notwithstanding all this, the Doctor charges Sarah with the crime of imparting syphilis to a man whom the Scriptures declare she had no connection with, nor ever saw, prior to the period of menopause; at which time, according to the Doctor's own statement, the disease (if she ever had it) had disappeared. It will be well to state, before leaving this part of our subject, the penalty in the case of Abimelech is more definite than in the similar incident with Pharaoh, the term, plague, being used without a specific definition; while in this latter case the plague is well defined (see Gen. 20: 18): "For the Lord had fast closed up all the wombs of the house of Abimelech, because of Sarah, Abraham's wife."

The writer already feels like asking forgiveness for so much time and space already taken, and will briefly consider the part taken in this by Israel's king. That David was a great sinner, as also a great repenter can not be denied. Yet according to our common versions of Scripture we fail to find evidence that he was a syphilitic subject. Dr. Jelks quotes Dr. Buret in his paper as authority that he was. To

prove the argument, the Latin version (1715) is again "proffered." The statement is advanced that David contracted syphilis from Uriah's wife, (see narrative chap. xii. Kings). The reader will remember that this Latin version does not give the same division of its contents into books and chapters, as our common version, which we prefer; and we ask your attention to II. Samuel, chap. xii. In this we recognize the blackest chapter in the life of David. Much more space is given in the Bible to this one crime than to many of his virtuous achievements. The object in this will be seen by the Bible scholar as obvious; a line of thought which, were we to follow would lead us farther from the subject now in hand; and we will but glance at it from this direction, viz.: the simple fact that this was a great sin against God and Uriah, does not establish the fact that Bathsheba had syphilis. Again, the child dying does not prove the same. While the twenty-fourth verse, tells us that, "David comforted her and went in unto her, and she bare a son, and called his name Solomon, and the Lord loved him."

The reader will very readily see the time here mentioned is remarkably short for Bathsheba and David—both pronounced syphilitics—to recover sufficiently to bring forth so healthy an offspring as Solomon. If the first was a case of congenital syphilis, what can we look for in the second? Our best judgments in this case would hesitate before pronouncing either of them syphilitic. Stopping just to glance at the lamentations referred to by the Doctor, we would ask the reader to consider the following, (these are all the quotations contained in the Scriptures, wherein the word, bones, is mentioned) and see if there are any syphilitic bones to be discovered among them: Ps. 6: 2; 22: 14; 31: 10; 32: 3; 35: 10; 38: 3; 42: 10; 102; 3: 5. Particular attention is asked to the prophetic psalms, the twenty-second having been quoted by the Doctor, which is conceded by our most biased Bible scholars to contain no allusion whatsoever to David, but is a grand prophetic description of the sufferings of Christ, whom none would declare to be syphilitic.

The reader will see many words occurring in the Latin (1715) so preferred by the Doctor, that do not occur in any place in our common versions. For instance, the words, cure and mocked, do not appear in the Psalms. As for the words, opprobrium, healthy, ulcer, or ulcers, they are not in the Bible, i.e., our common version. The careful student, looking more for Scriptural facts than a diagnosis of syphilis, will plainly see the Psalms, especially the prophetic, are speaking so beautifully and often in poetic metaphor of the coming Christ, and not the syphilitic symptoms of which David the king, is supposed to be the direct sufferer. Proof of this will call our attention to the thirty-eighth Psalm as a sample of what they contain, regarding the punishments by disease inflicted upon David, as mentioned by Dr. Buret. I would ask the reader to consider, with this Psalm, in order to better define our argument, what the punishment was: See Ps. 6: 1; Deut. 32: 23; II. Sam. 16: 12; Ps. 31: 10; 40: 12). By this, we are more enlightened regarding the use of such terms as arrows, bones, loins, etc. The word, loins, being considered by all Bible scholars as being the seat of strength; a weakened or exhausted condition therefore calls forth groans, etc. (See Rom. 8: 26).

The reader of Dr. Jelks' paper will notice great em-

phasis is laid on such symptoms as are recorded in the seventh verse of the thirty-eighth Psalm. This is one of the very strongest arguments that David was syphilitic: "For my loins are filled with a loathsome disease: and there is no soundness in my flesh." See also, second verse of same Psalm: "For thine arrows stick fast in me, and thy hand presseth me sore." These have been previously alluded to and commented on. The word, tongue, is found only in the following Psalms: (Ps. 22: 15; 35: 28; 39: 1, 3; 45: 1; 51: 14; 66: 17; 119; 172; 137: 6; 139: 2). The reader of these will see at a glance there is no reference whatsoever to a disease of any kind. The worship of Baal-peor, as quoted by the Doctor will, I think, receive the indorsement of all Bible students, as the narrative seems clearly to show that this form (and they were many) of Baal worship was connected with licentious rites. The bloody health officer, Moses, however, did not slay (kill by the steel) twenty-four thousand. Here another great difference may be seen between the two versions: Verse nine of this twenty-fifth chapter of Numbers reads: "Those that died in the plague (what plague, syphilis or?) were twenty and four thousand." However, you will see in I. Cor. 10: 8, only twenty-three thousand perished from pestilence. By this, we must remember Moses includes the thousand *only* who died by the execution of the judges. In other words, Moses only caused to be killed, one thousand.

Dr. Buret's Chinese history will permit of no question by the writer—neither the historic skulls and tibiae excavated from the caves and dolmens of France, the tombs of the Incas, or mounds of the United States; in these every physician will agree, having any knowledge whatever of syphilis and its lasting results.

To the medical profession, the writer would say: This has been written in reply to those arguments presented by the Doctor, regarding the persons mentioned; not defending the great wrongs, which were many (especially David's), but as the old saying reads: "Give the Devil his due." After a careful study of the subject the writer does not dispute the existence of syphilis among the Hebrews, and every other people that ever existed, since the foundation of the earth. But we think our common versions *will not bear us out*, in pronouncing the disease upon either of the prominent Bible characters mentioned by Drs. Jelks or Buret. A glance at Bible history will convince the reader, why these Latin versions (and they are many) are not pronounced to-day as correct versions, particularly the version of 1715.

MIGRATION OF SYPHILIS FROM EAST ASIA INTO AMERICA BY WAY OF THE BEHRING SEA.

BY ALBERT S. ASHMEAD, M.D.

NEW YORK.

LATE FOREIGN MEDICAL DIRECTOR TOKIO HOSPITAL, TOKIO, JAPAN.

In the October issue of the *Sei-I-Kwai Medical Journal* re-appear two articles of mine, both on pre-Columbian syphilis, in which I endeavor to show a possible relation between East Asia and pre-Columbian America.

The antiquity of syphilis in Japan and China is admitted by all Japanese students. Waké and Tamba, who both belong as far back as the seventh

century, mention this disease. The authors of the *Dai-do-rui-shiu-ho*¹ refer to a medicine used against it by Sukunahiko, the Esculapius of Japan, who lived in the time of Jimmu Tennō (660 B. C.) In China, syphilis was certainly known in the Chu dynasty 1122 B. C. to 314 B. C. From China the disease is supposed to have come to Japan, in the migratory way, landing first at some harbor in the Hijen district, it may have been Nagasaki. Hence, the newcomer spread in all directions over Japan.

China itself seems to have imported syphilis from the south, as it has received smallpox from the north. Both these facts are affirmed by very hoary authorities; they call syphilis the demon of the south, and smallpox the demon of the north. They have no doubt but that the first of these monsters originated in heat and moisture, the southern elements, and that the other was born from cold and frost, the elements of the north.

If I observe here that smallpox penetrated first into northern Japan, being introduced from Tartary, the reader, remembering what I said before, that syphilis first settled in Hijen, will be struck by the fact that the same thing happened here as in China: syphilis from the south, smallpox from the north. We may presume, therefore, that there was some reason for the belief of these ancient writers, that syphilis arose in heat and moisture, and smallpox in cold and frost; besides, it is but fair to consider that these writers were 3,000 years nearer to the origin of both plagues than we are.

Let us see whether the same manner of introduction which we have found in China and Japan, is also that of American syphilis.

Syphilis is admitted by Prof. Brinton to have existed in America when Columbus landed. Yet this author will not see any connection between ancient Americans and East Asiatics; in fact, he denies it positively. He is inclined to think that the disease existed independently in America and in Europe, and that Columbus, therefore, could not have introduced it from Europe to America. Now, if syphilis existed in America, that is the now Spanish America, before the arrival of Columbus, it either originated in the south, in moisture and heat, to speak with the Chinese, for nowhere but in the south have we any evidence of its presence, or it was brought over, say from China or Japan. This happened, if at all, by way of migration, for commerce there was none. We hear, indeed, of a drifting of Chinese junks to ancient Peru and Ecuador; of course, this may be only a myth. But the fact that the Aztecs of Mexico, and the Incas of Peru, the most ancient American races, came from the north, is not mythical. If they came from the north, say from the Behring Sea, it is reasonable to believe that they crossed from the nearest point of Eastern Asia.

Mr. Farnsworth, recently, in *Science*, speaks of the carvings and designs of the Alaskans and Vancouver Indians as being Japanese in appearance. He also believes that at some remote period, some people from Japan had drifted into these regions, and left there traces of the arts of the mother country. It seemed to him that some Indian traditions clearly point that way. "In looking over the collections in the Exposition at Chicago," says Mr. Farnsworth, "it occurred to me to verify these facts. In the Anthro-

pological Building was a large collection of 'totem poles,' carved implements, and drawn figures from Alaska, also from California, Mexico, Central America and Peru, as well as from other parts of the Americas. In many places Japan was largely represented.

"There is a most striking difference between the arts of the Western coast and the interior of America. They have something of the grotesqueness of Japan, but not much other likeness. They are akin to those of ancient Mexico, and would indicate that the arts and the people of the Western coast were of like origin; that the 'totems' and other figures of Alaska and Vancouver are survivals of the arts of Central America and ancient Mexico."

Now, if a Japanese settlement was formed in Alaska, syphilis must have existed in it, and if the Alaskans and Vancouver Indians were directly connected with Central America and Mexico, the syphilis of these two countries from which we derive our first knowledge of American syphilis, had a northern origin.

Judge Wickersham of Tacoma, Washington, thus speaks in *Science*, Dec. 8, 1893, under the title, "Pottery on Puget Sound." "That the reader may not be misled by the above headline, I hasten to say that there never was any aboriginal pottery made either on the Columbia River, Puget Sound or in the regions northward to Alaska. Baskets of such strength, firmness and texture were made, however, that the absence of pottery was not a hardship upon the Indians, for they carried water in baskets, and even boiled food in them by the use of hot rocks constantly dropped in the water. But what lesson, if any, can the ethnologist learn from the absence of pottery on this Northwest coast?"

"Let us first look at the character of the civilization existing here prior to the advent of the white man, and compare it with that of other localities—say San Francisco Bay, but a few hundred miles farther south on the same shore. The Indians of Oregon, Washington, British Columbia and Alaska made and constantly used the finest canoes in the world, capable of holding fifty or sixty men. They fearlessly pursued the whale on the Pacific Ocean far out of sight of land; and fastening their harpoons to the monster, by the use of inflated bladders they caused him to float, and after his death he was towed by a line of great canoes to the shore, where, landing the huge carcass, his captors feasted in truly Indian style. But a few hundred miles away the Indians of San Francisco Bay rode on a raft or bundle of reeds! The conclusion follows irresistibly that a different aboriginal civilization existed from the Columbia River northward to Alaska than that on San Francisco Bay. From a careful examination of the archaeological remains it seems quite certain that the lines connecting the middle type of civilization of the Puget Sound region with other American civilizations lay—one up the Columbia and across to the Ohio region, and the other by way of the Snake River, Great Salt Lake and the Pueblo region, and connecting with the Mexican country. But in each of these regions—in Ohio and Mexico—we find pottery in abundance, but none in the Puget Sound basin. This can not be on account of lack of material, for the finest potter's clay exists in great beds throughout this region on the surface, and many potteries now work it. What is the conclusion,

¹ A work composed 806-809 A. D.

then? It is that the high civilization of the Northwest coast did not come either from the East or South!

"This middle type of civilization on Puget Sound made splendidly carved war canoes; the finest basket work in America; featherwork like the Aztecs; metates like those of Moqui; woven blankets equal to the Navajo; worshiped the sun like the Mexican, and made stone gods equal in carving to those of Central America; as carvers of wood they have no equals in America; they were artisans skilled in carving, weaving and painting; they built permanent homes of great posts and cedar boards, exactly like the Mongolian tribes of Asia—exactly like the Japanese; their beds were arranged on each side of the house on platforms in the true Mongolian style; their language yet preserves the identical tongue spoken by the Apache and other southern Athapascans; many pure Aztec words linger north of Puget Sound—and yet they made no pottery!

"No nation ever lost the art of pottery-making. The art never was known to the people of this north-west country; though they are cousins to the Algonquins and Aztecs, and brothers to the Apaches, yet they had not the art possessed by these people of making vessels from clay. Not a trace of the potter's work can be found in the Columbia River or Puget Sound regions. Although these people are of kin, yet in this particular they are as distant as the poles. It follows that the Athapascans of Mexico learned the potter's trade after they left the early home of their kinsmen on Puget Sound; it also follows that the Apache and kindred tribes were migrants from the North, and it is true that the Algonquin was not a potter until after he reached the Mississippi Valley.

"It seems to me that one certain result follows from the known facts, viz.: That the Athapaskan tribes of Mexico, and possibly the Aztecs, migrated to Mexico from the Puget Sound region—for if our Athapascans came to the North from Mexico and settled in the Puget Sound basin, why did they not bring that most characteristic manufacture, pottery, with them? I take it that the conclusion must be conceded that the migration was southward, and not by San Francisco Bay, either, but via Great Salt Lake to Mexico.

"Humboldt, Prescott and other eminent authorities place Aztlan, the ancient Aztec hiving place, in the Puget Sound region, and certainly the absence of pottery here is a strong additional fact in support of their statements. If, now, it be conceded that the hiving place of the Aztecs, Apaches and other southern Athapascans was on Puget Sound, may it not also be granted that this is some further proof of the Asiatic origin of the same tribes?"

If the conclusions of Judge Wickersham are true, they directly connect the Ohio mound-builders and the Aztecs with the northwestern settlement I have referred to above, and therefore the earliest traces of syphilis in America, which we find in the bones of Ohio and Tennessee mound-builders and of ancient Mexicans, have also an East Asiatic origin.

This becomes still more probable, if we consider the extreme of antiquity of syphilis in Eastern Asia. An autochthonous syphilis in America, which we should have to admit, if we accept Dr. Brinton's assertion that there is no connection between East Asiatics and Americans, commends itself to us as

little as the autochthonous syphilis and smallpox of the Chinese.

The route from Behring Sea seems to me the only satisfactory solution.

SELECTIONS.

Experiments with Intra-Venous Injections of Solutions of Sodium Chlorid in Cholera Asiatica.—In a paper read before the Dorpat Medical Society, Dr. Karl Dehio gives the results of numerous experiments pursued by himself and his colleague, Dr. Graubner, in the treatment of Asiatic cholera. These experiments consisted in the intra-venous injection of warm salt solutions in the later stages of cholera. Dr. Dehio considers the hypodermic method of injecting, as recommended by Samuel and Cantani twenty years ago, of no value whatever, as it is not only painful to the patient, but the solution is not as quickly absorbed as the serious condition of the case would necessitate. Dr. Dehio states that he uses a process similar to that employed by Ziemssen in his well-known operation of blood transfusion. A sharp, hollow needle about three times the size of an ordinary hypodermic needle is introduced through the skin into a large subcutaneous vein, to which is connected the rubber tube of an Esmarch irrigator, which has previously been filled with a warm, sterilized salt solution. A vein is selected in the forearm near the elbow-joint or on the posterior aspect of the leg. The introduction of the needle is usually difficult, owing to the very slight distension of the vein, but this was overcome by compressing it over the seat of the intended puncture, and by a stroking motion of the hand from below, the vein becomes more prominent. By preventing the overlying skin slipping, the vein could be easily pierced. Between the needle and rubber tubing is fastened a glass connection or tube of about 5 cm. in length by which, besides furnishing a convenient handle, the presence of air in the tube could be at once detected, and prevented from entering the needle. The temperature of the injected fluid was kept at from 37 to 39 degrees C., and was easily controlled by a thermometer introduced into the receptacle. As it was necessary to prevent cooling during its passage through the tubing, the fluid in the reservoir was kept some degrees above body temperature. A height of from two to four feet furnished sufficient pressure for the fluid to flow steadily into the vein, and within a half hour as much as one to two liters was introduced.

Antisepsis was thorough, and the needle, apparatus and field of operation were all sterilized before proceeding with the operation. If the needle could not be as quickly introduced as was necessary, a small incision was made in the vein, and after the operation closed with cotton and colloid dressings.

In this manner, Dr. Dehio, in connection with Dr. Graubner, chief physician of the Dorpat Cholera Hospital, performed thirty intra-venous injections in eighteen cholera cases. These experiments were all made on patients in whom there was pronounced collapse and an almost imperceptible radial pulse. All were deeply cyanotic and ice-cold. As much as 2 liters of the saline fluid was injected at one time, but usually 1½ liters was found to be sufficient. The operation was discontinued as soon as the radial pulse could be distinctly felt and counted, and was repeated whenever the cyanosis and pulse indicated approaching collapse.

In nearly all instances the patient seemed to revive somewhat, the pulse became stronger and the heart sounds clearer, and the patient again complained of the muscular cramps from which he had ceased to react. The effect, how-

ever, was only temporary, lasting from three to six hours, the case again relapsing into its former condition.

Dr. Dehio details a number of cases and the different effects of the intra-venous injections, the effect of which were all marked. The pulse became stronger, the eyes which before were deep sunken and glassy, brightened, the patient became conscious of his surroundings and able to answer questions put to him. Of the eighteen cases detailed, only three were saved. In five of these, however, the stage of asphyxia was safely overcome and the direct cause of a change for the better was clearly due to the injections, but death was caused by the sequela.

In conclusion Dr. Dehio says: "One thing is certain, that the injections are infallible to enliven the heart's action and circulation, and as it can not be assumed that these injections of salt solutions had any chemic or therapeutic action on the heart, the actual strengthening of the heart-beat can only be explained by the fact that the injection increases the volume of blood in the vascular system. The blood pressure is increased, and as we know, every elevation of blood pressure necessitates a stronger heart contraction. In so far as the weakness of the circulation in cholera depends on the thickening of the blood, from loss of its serum, we certainly have it in our power to prevent this. Although, notwithstanding the fact that we have succeeded, in only a few cases, in keeping up the heart's action it is proof that the fatal cardiac failure does not alone depend on the diminished volume of blood, but must have other causes. These causes I consider the poisoning of the system by the absorption of the toxin in the bowels. It is this which injures the heart's automatic action and above all, acts directly on the heart muscle causing the weakness of the circulation.

"In all of the postmortem examinations made there was invariably found a high grade of parenchymatous changes in the heart.

"It is clear that the thinning and increasing of the blood through the saline injections is in itself unable to eliminate the poison; if it were, recovery would be certain. It is not to be expected that these injections contain specific anti-toxic action; in order to eliminate the poison we must depend on the action of the kidneys. Our experience has shown that the injections have no effect on the kidneys; the anuria is not relieved by increasing the blood-circulation, a fact which proves that in the kidneys of cholera patients we have not to deal simply with an ischemia, but parenchymatous changes, which like those in the heart muscle, is due to the toxic poisoning.

"Although we have in these intra-venous injections efficient means to overcome the cardiac weakness, the main point is not reached any nearer than in the old hypodermic method.

"Where the poisoning of the system is not severe enough to destroy life in itself, and where heart failure has not become irreparable, then the injections are able to save life. In the majority of cases, however, the conditions are not so favorable. We have noticed in *postmortems*, that the universal dryness throughout the body, (as in the serous and mucous membranes, et cetera) is not found where these injections have been used. The fact that the injections are less effective when undertaken later in the disease, is due to the higher degree of poisoning present at that time.

"I quite agree with the views and experiences of Rumpf in the recent Hamburg epidemic, with the intra-venous injections. That these saline injections are, with rigid antiseptis entirely safe. Fränkel has already shown. The edema of the lungs was not found more frequently than in the other cholera dead who were not injected.

"Better results might be expected if these intra-venous injections could be combined with diaphoresis. The favorable effects of hot baths in the algid stages of cholera, as well as the great praise given to hydrotherapy might be a point in its favor. It is possible that the peripheral circulation could be improved and more fluid absorbed if the patient could be brought into a free perspiration. Then possibly the increased activity of the skin would replace the function of the kidneys and eliminate the toxic products."—DR. KARL DEHIO in the *St. Petersburg Medicinische Wochenschrift*, December, 1893. [Abstracted for the JOURNAL.]

BOOK NOTICES.

Hernia: Its Palliative and Radical Treatment in Adults, Children and Infants. By THOS. H. MANLEY, A.M., M.D., Visiting Surgeon to Harlem Hospital, etc. 8 vo. cl. pp. 231. Philadelphia: Medical Press Co. 1893.

The scope of this work is sufficiently indicated by its title. Its author is a well-known member of the AMERICAN MEDICAL ASSOCIATION, and an experienced general surgeon.

The author while pessimistic as to the advantages of the operation for the radical cure of hernia, nevertheless gives a resumé of the different operations in vogue, and furnishes a table giving the results of his own operations.

The author's conservatism is shown in the following from page 227, where referring to his own operations:

"At the present time, my purpose, when I herniotomize, is not so much to secure a radical cure as to place the hernia in such a position that it will give no inconvenience, and may be safely controlled by a truss support."

The book is marred by many typographical errors, but notwithstanding is a valuable addition to the literature of the subject.

A Practical Treatise on Nervous Exhaustion. (Neurasthenia); Its Symptoms, Nature, Sequences, Treatment. By GEO. M. BEARD, A.M., M.D. Edited with notes and additions by A. D. ROCKWELL, A.M., M.D. Third edition (enlarged) 8 vo. cl. pp. 262. New York: E. B. Treat. 1894. Price, \$2.75.

In this edition of this excellent monograph, Dr. Rockwell has added a short chapter, recapitulating some points in the etiology and pathology of neurasthenia as developed by recent investigation.

The book which everywhere preaches the gospel of temperance, and advocates rest as the panacea, concludes the volume with a quotation from Benedict: "If the Americans would learn from the Germans how to amuse themselves, instead of yawning on holidays, the danger of neurasthenia would be diminished. Whoever has not learned how to play and jest, easily succumbs to mental work."

How to Use the Forceps, with an introductory account of the female pelvis and of the mechanism of delivery. By HENRY G. LANDIS, A.M., M.D. Revised and enlarged by CHARLES H. BUSHONG, M.D., Asst. Gynecologist and Pathologist to Demilt Dispensary. Illustrated. New York: E. B. Treat. 1894. Price, \$1.75.

The views of the late Prof. Landis upon this important topic were published first in 1876, and in book form in 1880. Dr. Bushong, thinking the monograph contained too much of value to let it be lost to the science of midwifery, has revised the present edition. The book like all Gaul, is divided into three parts. The first is devoted to the mechanism of labor; the second to the forceps, and the third to the application and the recital of typical cases. The book is thorough, well written and trustworthy.

A Clinical Text-book of Medical Diagnosis for Physicians and Students. Based on the most recent methods of examination. By OSWALD VIERORDT, M.D., Professor of Medicine at the University of Heidelberg, etc. Authorized translation, with additions by FRANCIS H. STUART, A.M., M.D. Third revised edition, with 178 illustrations, many of which are in colors. Pp. 700. Philadelphia: W. B. Saunders. 1894.

The success of Vierordt's diagnosis has been very great, for we now have a third edition in a very short space of time. The notice of the first translation was published in this JOURNAL, Vol. XVII, 1891, p. 275. It was then greeted as a welcome arrival, and fully described. In this system of diagnosis, normal anatomy and physiology are the lamps by which the pathologic processes are illuminated. Anatomy is ever kept in the foreground, and its necessary features are frequently brought forward. No scholar can examine

the work without pleasure, and no student can study it without profit. The favorable opinion expressed in respect of the first translation, can be repeated now with the accumulated interest the lapse of time causes us to greet the reappearance of an old favorite.

Transactions of the American Association of Obstetricians and Gynecologists. Vol. VI. Philadelphia: Wm. J. Dornan. 1894.

This volume contains the proceedings and the papers read at the annual meeting of the Society for the year 1893.

These papers have for the most part been published as a part of the current medical literature of the year.

The book is beautifully printed and handsomely illustrated, and like every other work performed by the accomplished Secretary, Dr. Wm. Warren Potter of Buffalo, is well done.

Braithwaite's Retrospect of Medicine. Vol. CVIII, July to December, 1893. Issued January, 1894. Pp. 412. London: Simpkin, Marshall, Hamilton, Kent & Co.

This well-known periodical, established more than half a century ago, lies on our table and contains the usual condensation of the original articles that have appeared during the preceding six months, in the coterie of excellent journals from which the *Retrospect* quotes, and considering the limited sources of its supply, it has really done a great deal toward establishing the truth of its assertion that it contains a "retrospective view of every discovery and practical improvement in the medical sciences." This rather broad statement would seem to require that the sources of supply be somewhat enlarged. Continental journals are only quoted at second-hand, and only six journals in America published on the eastern fringe of the continent are quoted—those on the fimbriated extremity, so to speak.

The Diseases of Personality. By TH. RIBOT, Professor of Comparative and Experimental Psychology in the College de France. Authorized translation. Paper. Pp. 157. Chicago: The Open Court Publishing Co. 1894. Price 25 cents.

The book treats of organic and emotional disorders; disorders of the intellect and dissolution of personality. The author seeks to prove that "the organism and the brain as its highest representation, constitute the real personality, containing in itself all that we have been, and the possibilities of all that we shall be.

"The complete individual character is inscribed there with all its active and passive aptitudes, sympathies and antipathies; its genius, talents, or stupidity; its virtues, vices, torpor or activity. Of all these, what emerges and actually reaches consciousness is only a small item compared with what remains buried below albeit still active. Conscious personality is always but a feeble portion of physical personality."

NECROLOGY.

W. W. Waugh, M.D. of Faribault, Minn., January 8, aged 47.

William Clark Collins, M.D., a veteran of the war with a brilliant record died at Bucksport, Me.

Samuel W. Duff, M.D., at Salem, Ind., January 13, age 53, of apoplexy. He was graduated at Miami Medical College, in 1878.

Engene Tisler, M.D. died recently at Falkenstein, Germany. He was Director-at-large in the Board of Freeholders, served in the Franco-German war, and was 44 years old. For several years he resided at Baltimore, from whence he went to Newark, N. J., where he had much influence among his countrymen. He went abroad for the benefit of his health.

Joseph Hobbins, M.D., died at his home in Madison, Wis., January 24. He was a member of the Royal College of Sur-

geons, London; Fellow of the Geological Society of England, and Corresponding Member of the Royal Horticultural Society of England. He was born Dec. 28, 1816, in Wednesburg, Staffordshire, England, and was educated in his native country. In 1854 he settled in Madison, where he has lived ever since. He organized the medical department of the State University, and was elected a Professor in 1856. He was a member of Madison's first City Council. He was President of the State Horticultural Society for five years, and by his untiring efforts gained the title of "Father of Horticulture in the Northwest." He was surgeon-in-charge at Camp Randall during the war. His first wife died in 1870, and in 1872 he was married in Baltimore to the youngest daughter of the late Louis McLane of Delaware. The wife and four children survive. A daughter is the wife of Robert P. Porter, Chief of the Census Bureau.

Herbert Judd, M.D., died at Galesburg, Ill., Jan. 10, 1894, of apoplexy, aged 50 years. He was born in Franklin, N. Y., when after a common school course, he went through all the grades at the Franklin and Delaware Literary Institute. He then began the study of medicine with Dr. Albert E. Sullard, remaining with him for two years; then he went to Albany, N. Y., and studied two years with Drs. Freeman and Craig, during which period he attended the Albany Medical College, from which he graduated in 1867. In the spring of 1868 he began the practice of medicine at Galesburg, and in May, 1872, was married to Mary S. Slater, whose death in November, 1892, was a severe blow to him. For many years he occupied a prominent position in the profession, and took a great interest in the medical organizations with which he was connected. He was, for several years Secretary of the Military Tract Medical Association; a member of the Illinois State Medical Society, and also of the AMERICAN MEDICAL ASSOCIATION, to all of which he contributed papers of value mainly upon matters pertaining to railroad surgery. He was for several years Surgeon of the C. B. & Q. Railroad Company, but at the time of his death was Surgeon of the A. T. & S. F. Railroad Company.

Professionally he was strong, and took great delight in exposing fraud. In this, however, he was not always politic and as a result became involved in unnecessary litigation. With all his idiosyncrasies his impulses were right and kind. The writer last saw him in June, 1893, and then noted that he was both physically and mentally breaking. He leaves three sons and many friends to mourn his death.

Hon. James Cecil Phillippo, M.D., L.R.C.S., Edin., of Kingston Jamaica, died recently in his sixty-third year. He was the son of the Rev. James Mursell Phillippo, who, in 1825, at the age of 25, was appointed by the Baptist Missionary Society for service in Spanish Town. He was a graduate of the University of Edinburgh. On returning to Jamaica he began to practice, and in 1856 was appointed Physician to the Middlesex City Gaol. He rapidly made his way in his profession, and was very popular, from the urbanity of his manners not less than from his care and patience as a medical attendant.

In 1860 he was made a Justice of the Peace for the parish of St. Catherine, and in 1863 became a member of the Board of Visitors to the Public Hospital, Kingston, and of the Central Board of Health in 1873. He was President of the Medical Council in Jamaica, and was the first President of the Jamaica Branch of the British Medical Association, and to him, in conjunction with Mr. Gayleard, is due the formation of this, the first Colonial branch of the Association. He was re-elected President in 1885, which office he held until December, 1888. There are now fifty-six members of the Jamaica branch, and it meets regularly for the discussion of scientific and other questions.

Dr. Phillippo was appointed a member of the Commission to inquire into the condition of the juvenile population in 1876, and in 1889 he became a member of the Privy Council of Jamaica. He took a leading part as delegate from the British Colonies at the recent Pan-American Medical Congress.—*British Medical Journal*.

The announcement of his death will be received with sincere regret by the many friends he made during his recent visit to this country, and especially those who came in contact with him during the Congress. He was a good speaker, with a hearty, pleasing manner, and of commanding presence.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, FEBRUARY 3, 1894.

SUPERFLUOUS SPECTACLES.

A recent discussion in the New York Academy of Medicine gave evidence of a healthy reaction against the one-sidedness which has of late years been noticeable in American ophthalmological literature on the subject of asthenopic complaints. DR. TH. R. POOLEY related his experience with asthenopia not dependent upon errors of refraction and insufficiencies of the ocular muscles, and his views seemed to receive general indorsement.

Germany has not inaptly been called the land of spectacles. But the reason which has led to their extensive employment in that country, viz.: the great frequency of myopia, fortunately does not apply with us to the same extent. Yet it has become the practice of many of our oculists to advise glasses for weak eyes at a rate which would soon lead to their use on nearly as large a scale as in German cities. Is this sound practice?

Of all facts in medicine none are better founded than the knowledge that even moderate degrees of far-sightedness or astigmatism lead in many persons to discomfort in the use of the eyes and often to headaches and other nervous disturbances. The basis for the rational prescription of convex glasses and cylinders is hence as positive as the results are gratifying.

But does every optic defect need correction and is every case of painful vision curable by glasses?

No ophthalmologist can overlook the fact that many persons can tolerate moderate optic defects and some even high degrees of ametropia without ever suffering therefrom. This fact has been well brought out by a statistic published over a year ago by DR. ROOSA. Among 100 persons with normal eyesight and *who had never suffered from asthenopia*, he found only 9 emmetropic. Forty-five persons had

hypermetropia of about one dioptry, thirty-nine of about two dioptries and seven over two dioptries. Of the total number only twenty-five had no astigmatism measurable with the ophthalmometer, seven had astigmatism of 0.25 to 1 D in one eye only, thirteen had 0.25, twenty-three had 0.5, two had 0.75, twenty-five had 1 D and four had more than one dioptry of astigmatism in both eyes.

On inquiring into the general health of patients complaining of eye-strain and its consequences it becomes apparent that the amount of optic imperfection which can be tolerated without distressing sensations depends on the vigor of the system at large and especially the condition of the nervous system. It is not rare that patients call for correction of moderate far-sightedness or astigmatism, accept the glasses with satisfaction for the time, but lay them aside as unnecessary after some improvement of their general condition.

Since errors of refraction are stationary conditions, (except progressive myopia which is foreign to this topic) there is hence no object in correcting them, unless they cause some annoyance, be it by poor sight or in the form of discomfort or headache or distress of any kind. If, however, any discomfort referable to the eyes is present, what is the lowest amount of ametropia which can be considered as the cause of the eye-strain?

It is the general experience that a hypermetropia of 0.75 D or any degree of hypermetropia uncorrected to the extent of 0.75 D can cause distress in many persons. But that a hypermetropic eye can appreciate a correction of half a dioptry or less will not be admitted by most observers. There is more diversity of opinion as to the amount of astigmatism which may require correction. While again 0.75 D represents the lowest cylindrical lens which is ordinarily of benefit, cases do occur beyond doubt in which half a dioptry of astigmatism leads to discomfort or headaches.

Such cases, however, are exceptional and occur as a rule only when the general health is below par. It is true that a cylinder of 0.25 D is not only employed but even highly recommended by a few prominent oculists, but they have as yet furnished no proof that such lenses benefit their patients. The majority of oculists have learned from their own experience, as well as from the failures of the champions of the 0.25 D cylinder, that such weak glasses are merely of mythical value.

The history of therapeutics furnishes so many instances of remedial measures highly praised by their originators, endorsed for a short time by their followers, but soon discarded as useless, that we may well decline to believe in the efficacy of 0.25 D. cylinders until convincing proofs are furnished. It must not be forgotten that the accuracy in measuring refraction

has its limits. Whenever the patient's vision is not markedly improved by correction, two equally competent observers can easily disagree up to $\frac{1}{4}$ or even $\frac{1}{2}$ D. of the astigmatism present.

From the short report of DR. POOLEY'S paper and its discussion it does not appear whether the fact was brought out that asthenopia may be of ocular origin independent of the refraction. There are cases of slight blepharitis and mild chronic conjunctivitis often associated with lachrymal obstruction, in which the asthenopic complaints do not depend on ametropia, even if a low degree of it be present, while the patients can be cured by proper attention to the lids or lachrymal ducts. In another small per cent. of patients with asthenopia not curable by glasses, the cause can be found in some intra-nasal lesion and the discomfort removed by appropriate nasal treatment. It is not to the credit of the profession if such patients are ordered to wear useless and often expensive glasses.

DR. POOLEY further emphasized that discomfort in the use of the eyes may be due to a general neurasthenic condition and to derangements in distant organs, the teeth, kidneys and uterus. More stress might have been laid on the relation of digestive disturbances to asthenopia, as observations in practice frequently show not merely a coincidence of the two, but also decided improvement in the eyes when the stomach and bowels receive due care. It is a matter of doubt whether asthenopic complaints can logically be considered as reflex disturbances due to gastric or uterine derangements, or whether they should not more properly be viewed as a part of the neurasthenic condition to which chronic disease of the viscera can lead.

At any rate, the discussion in the New York Academy will be productive of good if it teaches oculists that the eye is one of the organs of the general system, and that in all of those cases where asthenopia is not clearly the result of a demonstrable optic imperfection, its cause must be sought by an inquiry into the patient's habits and general health.

SMALLPOX.

Outbreaks of smallpox were reported during the past week at a number of places in the country. Chicago and New York seem to be the main points of infection. The former city has almost daily for the last two weeks had its smallpox sensation, in patients riding in street cars and entering crowded public buildings, and finding an infected nest in the Ironside lodging building, where there are now quarantined about one hundred inmates, but nothing like the outbreak that has occurred in the Charity Hospital, Blackwell's Island, New York. The Warden and ten patients suffering from the disease were removed to North Brother Island, and on January 18 the Hos-

pital was placed under rigid quarantine, and the inmates, about one thousand in number, vaccinated. A woman having smallpox was removed from the Florence Mission. The inmates of the Mission are also under quarantine and have been vaccinated.

All these cases came from a single case in which the nature of the disease was not recognized until after death. The patient was taken from a lodging house to Gouverneur Hospital, where the case was diagnosed as a malignant blood disease. On December 26 he was taken to Bellevue Hospital, and the next day was transferred to the Charity Hospital, and placed in the ward where skin diseases are treated, and on January 2 died. His body was removed to the morgue, where it was kept nearly a week to give friends an opportunity to claim it. Then it was taken to the Bellevue Medical College for dissection. So obscure was the disease that it was only here that suspicion was excited with regard to its true nature, and the Chief Inspector of the Bureau of Contagious Diseases was notified, and upon investigation pronounced it smallpox. It is asserted that the man had two diseases which seemed to run together. The woman taken from the Florence Mission had been employed to keep the ward clean in which the patient was lying.

CHOLERA.

Cholera still prevails at St. Petersburg, and cases also occur in Belgium. A commission was appointed to investigate the cause of the recrudescence of cholera in St. Petersburg. The commission reports that the fresh outbreak of the disease is not an exceptional occurrence, as exactly similar outbreaks were observed in many parts of Russia toward the end of the epidemic in 1892; that no one particular circumstance or condition can be pointed to as the cause of the recrudescence; and that it can not be ascribed to the increased consumption of dried or salted fish. As the revival of the epidemic followed not long after the commencement of the pre-Christmas fast, when salted fish form the principal article of diet among the orthodox, it was thought that some form of poison had developed in the fish, and that the cases that were set down as choleraic were in reality due to some irritant poison. The commission, however, declares that though many samples of fish have been examined, in none has any poison been found. Many of the cases first thought to be due to irritant poisoning have since been proved to be choleraic by bacteriologic examination of the dejecta. This occurred in a number of cases among the attendants of two orphan institutions in the city. Between December 16 and 20, fifty of the attendants in these institutions were attacked with diarrhea and vomiting, the illness following the consumption by the attendants of salted fish and unboiled water. It was

only after the patients had been removed to the Marie Hospital that the symptoms were found to be due to cholera and not to poisoning as at first supposed.

The disease, however, seems to have altogether disappeared in Germany. There were only six cases of a mild type reported in the German Empire between December 6 and 22, and since the latter date none at all. The *Times*' (London) Berlin correspondent reports that in 1892 there were 19,719 cases of Asiatic cholera in Germany, of which 8,590 died. Between January 1 and March 4, 1893 there were 213 cases and 89 deaths registered, and during the summer there were 569 cases and 288 deaths. In addition to these, there were 92 cases, in which cholera bacilli were discovered in healthy persons who had been infected by intercourse with cholera patients, without, however, suffering any great inconvenience.

THE JOURNAL.

In our issue of January 6 we printed the following table:

July 1, to December 30, 1893.	Journal Am. Medical Asso- ciation.	N. Y. Medical Record.	N. Y. Medical Journal.	Boston Medi- cal Journal.	Philadelphia Medical News.
Number of Original Articles . .	240	176	158	182	175
Number pages Original Articles	665	334	380	300	397
Total unumber pages	1,024	860	816	660	756

The *New York Medical Record* of January 20, asserts that we gave a wrong impression of the relative size of this JOURNAL; "as there are nearly a hundred and fifty more words to a page on the *Medical Record* this is not a fair presentation of the matter."

We were aware that the *Record* page is a little longer than that of the JOURNAL, but the type differs. Thus: in the issue of the *Record* for January 20, there are 32 pages, and an average of 1,400 words to the page; this gives for that number, a total of 44,800 words of long primer type.

The JOURNAL of the same date had 16 pages of long primer with an average of 1,250 words to the page, making 20,000 words of long primer. There were 16 pages of brevier type (counting the nonpareil as brevier) with 1,720 words to the page, making 27,520 words of brevier, and a total for that issue of 47,520 words or 2,720 words in excess of the number printed in the *Record*.

This is really an under statement, for the JOURNAL usually has from one to two columns of nonpareil type, one-fourth smaller than brevier, which would give a still greater number of words.

If we multiply the number of words in that issue by 26, the number of issues in a volume, it will be seen that on an equal number of pages, the JOURNAL

led in amount of matter by 83,720 words, and then if we add one-half the number of pages in excess of those of the *Record* it will be seen that the JOURNAL led for the volume by the enormous number of 329,060 words!

We had no intention of emphasizing the fact that the AMERICAN MEDICAL ASSOCIATION, now publishes the largest weekly medical journal in America, beyond letting the friends of the JOURNAL know that they were doing well, but as the *Record* challenged the statement, we were forced to complete it. The table, therefore, as will now be seen was rather an under than an over statement.

We have great and enduring respect for the old publishing house that furnishes the medical profession with so excellent a journal as the *Record*, but the AMERICAN MEDICAL ASSOCIATION is greater than any single firm; the JOURNAL is its property, and it has only fairly started. Just wait!

DENTISTS ARE NOT PRACTITIONERS OF MEDICINE IN MISSOURI.

Dentists are not "practitioners of medicine." So the Supreme Court of Missouri holds, in the case of *State v. Fisher*, decided Dec. 5, 1893. A statute of that State provides that no person exercising the function of "practitioner of medicine" shall be compelled to serve on any jury. A dentist possessing a diploma, granted him by a reputable dental college, and a city register's certificate, showing the filing of that diploma and the enrollment of his name on the "roll of dental surgeons," steps in, and claims the exemption. But it is denied him.

After an exhaustive consideration of the statutes, to see if they can be given a broader construction, the court becomes somewhat humorous. It says the dentist "evidently feels unsteady on his logical legs," if a sole reliance is to be on the statutory exemptions noted, and so he resorts to the lexicographers, and quotes the definition of "dentist" from the *Century Dictionary*. If he "had delved more deeply into the science of definitions, and had turned another page of the same work, he would have found: 'Chiropodist. One who treats diseases or malformations of the hands or feet; especially a surgeon for the feet, hands and nails; a cutter or extractor of corns and callosities; a corn doctor.' So that if he is exempt from jury duty because, as he says, he 'treats, professionally, diseases of the oral cavity,' so also is his less pretentious professional brother, who with equal scientific skill treats diseases or malformations of the hands or feet, and who is content to be dubbed 'corn doctor.' Certainly, the argument and definition which would support the exemption of the dentist as a 'practitioner of medicine and surgery' would also equally support that of his cognate scientist, albeit of humbler pro-

fessional pretensions. The disposition of persons to magnify and exalt their callings or occupations has become wonderfully prevalent in these latter days."

It is perhaps only fair, after quoting so much of the court's opinion with regard to the dentist—who is also here, by implication, classed with the mechanic who is no longer called a "carpenter," but an "architect and builder;" the solicitor of orders from our retail merchants, who is no longer a "drummer," but a "commercial traveler;" and the loquacious individual who is no longer a "barber," but a "tonsorial artist"—to state that JUSTICE BRACE dissents. He says, among other good things, that while dentistry may have had a humble and comparatively recent origin, it has now become a very important branch of medical science, quoting as his authority, "Address N. S. DAVIS, M.D., to the AMERICAN MEDICAL ASSOCIATION."

SECRECY IMPOSED UPON CONSULTING PHYSICIANS.

The same rule which governs a regular attending physician in any case, with regard to the communication of what he learns in that capacity affecting his patient, applies as well to a consulting physician. Thus, in the case of *Morris v. N. Y., O. & W. Ry. Co.*, decided Dec. 1, 1893, the Supreme Court of New York, general term, holds that what either a regular attending physician or another called in professionally, as consulting physician, says in consultation in the presence of their patient is inadmissible in evidence. Nor will the fact that they do not agree upon the disease, permit the confidential relation between physician and patient to be rendered nugatory. Here the court cites and follows the decision of the New York Court of Appeals, rendered in the case of *Renihan v. Dennin*, decided some years ago. In that case it was further held to be of no moment that the patient did not himself call or procure the consulting physician's attendance. He was called by the attending physician. To bring him within the regular rule, it was considered sufficient that he attended as a physician upon the patient and thereby obtained his information.

WITHIN THE SCOPE OF A PHYSICIAN'S AUTHORITY.

When it comes time for settlement, the question of whether all the services rendered were within the scope of a physician's authority may be an important one. Thus, in the case of the *Succession of Short*, decided by the Supreme Court of Louisiana, Dec. 18, 1893, some of the legatees contended that the physician's bill was excessive. Among other things the doctor at different times remained a number of extra hours beyond his professional visits, in order to administer medicine and nourishment to his patient, an old gentleman and a personal friend, who refused to receive them from any other hands than those of

his physician. Now, where the patient, being feeble, and in a nervous and delirious state, requires attention entirely unusual, and the services are skilfully and faithfully rendered; where surgical operations are performed, and extra time is devoted by the physician in endeavoring to relieve the patient from his sufferings, which are intense, the court holds that the performance of the operations, and the time, in addition to the regular visits, taken in attending the patient, are within the scope of the physician's authority, if, in his judgment, it is necessary.

A MEDICAL STATESMAN.

DR. GUIDO BACELLI, the Professor of Medicine in the Policlinico of Rome, is sometimes styled "the Virchow of Italy." He has recently been appointed Minister of Public Instruction. He had formerly held the same portfolio from 1881 to 1884. He was late President of the Board of Health for the Kingdom of Italy. He is an eloquent orator, and has been chosen to preside over the International Congress, to be held in Rome, next Easter.

PROFESSOR BACELLI will be remembered as having made the eloquent response, in Latin, to the address of welcome, at the Tenth International Medical Congress. To those who never before heard the Latin language spoken by an Italian, its effect was thrilling beyond expression.

CORRESPONDENCE.

Proposed Revision of the Constitution and By-laws of the American Medical Association.

To the Editor:—As the report of the Committee, in the form of a *revised Constitution and By-laws* for the AMERICAN MEDICAL ASSOCIATION, made at the last annual meeting, is to come before the next annual meeting to be held in San Francisco, June next for final action, it is desirable that its provisions should be considered with candor and thoroughness. In carefully comparing the revised document as presented by the Committee, with the Constitution and By-laws as they now exist, I find but four proposed alterations of sufficient importance to require notice. These four are: 1, the very faulty, ambiguous, and even contradictory style in which the revised instrument is written; 2, the omission of all provision for general addresses except the one from the President; 3, the abolition of the Nominating Committee and the giving of the nomination of general officers and the recommendation of the time and place of the annual meeting to the General Business Committee; and 4, the total abolition of the representative character of the ASSOCIATION; the abolition of all permanent memberships and the limiting of the annual membership solely to the membership of the several State and Territorial medical societies.

In regard to the first of the foregoing specifications it is no exaggeration to say, that every paragraph of the present Constitution is expressed in language so plain, direct and explicit as to be easily understood, and to admit of no ambiguous or doubtful meaning. Let every reader take up a copy of the Constitution as it is, and compare the clear cut and expressive language in which the origin and objects

of the ASSOCIATION are expressed in the introductory preamble and resolution, with the introductory paragraph called "history," proposed by the Committee on Revision as a substitute. The first says the ASSOCIATION is organized "for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor, and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those who are engaged in it." The proposed substitute says it is "formulated for the purpose of promoting the *best activity* of a general medical organization of the profession in North America." What a contrast! What kind of *activity* is the "best activity?" And what is meant by "a general medical organization of the profession?" Is it intended for a general organization of the medical profession or the general organization of some profession on a medical basis in accordance with physiologic and pathologic laws? And again, by what process can we extend such an organization from the Rio Grand south to the Isthmus and from the Great Lakes to the North Pole? Leaving the initial paragraph, let us briefly as possible compare the language of the present Constitution with that of the proposed substitute in relation to *membership*. The first says: "The members of this institution shall collectively represent and have cognizance of the common interests of the medical profession in every part of the United States; and shall hold their appointment to membership either as delegates from State and local institutions, as members by invitation, as permanent members, or as members by application." The proposed substitute says: "Membership shall be limited to members of the several affiliated State medical societies recognized thereby or represented therein. As membership in these societies is open to all reputable practitioners in each State, the membership in the AMERICAN MEDICAL ASSOCIATION is open to all reputable physicians in North America." Now, which are "the several affiliated State Medical Societies" mentioned in the first sentence, and how are they *affiliated*; and what is meant by the "recognized thereby or represented therein?" Do the "thereby" and "therein," refer to recognition by the affiliated State societies or by the AMERICAN MEDICAL ASSOCIATION?

After long study, I had arrived near to the conclusion that the Revising Committee intended to declare that, "Membership shall be limited to members of such State medical societies as have been heretofore recognized by or represented in the AMERICAN MEDICAL ASSOCIATION." Such a conclusion, however, only involved me in greater difficulty when I encountered the logic of the next sentence which is in true syllogistic form as follows: "As membership in these societies (meaning of course the affiliated State societies) is open to all reputable practitioners in *each State*," therefore, "the membership in the AMERICAN MEDICAL ASSOCIATION is open to all reputable physicians in *North America*." Or, if we put the several parts of the syllogism in more direct connection they would read thus:

1. "Membership (of the ASSOCIATION) shall be limited to members of the several affiliated State medical societies recognized thereby or represented therein."

2. "As membership in *these societies* is open to all reputable practitioners in *each State*," therefore

3. "The membership in the AMERICAN MEDICAL ASSOCIATION is open to all reputable physicians in North America." But why stop at North America? Are there any more "affiliated State medical societies in British America, Mexico, Central America and the West Indies, than there are in South America or in the several States of Germany? Are there any

petitions on file from the physicians in all the inhabited parts of North America asking for *annexation* to the affiliated State medical societies" of the United States? Or does the Committee on Constitutional Revision intend to take them in *vi et armis*?

While, as has been shown, the first sentence of the section relating to membership positively declares that membership in the ASSOCIATION "shall be limited to members of the several affiliated State medical societies," yet before we get half way through that section we read: "Any member of a recognized State or local medical society may become a member of the ASSOCIATION by presenting," etc.; and a few lines further, we read: "All members of the recognized State or local medical societies who are unable to attend the annual meeting may become members of the ASSOCIATION," etc. It is quite as difficult to understand how the membership of an association can be limited to members of State societies, and at the same time receive members from various local societies, as it is to see why the eligibility of reputable physicians to membership in the several State societies of the United States and through them to membership in the AMERICAN MEDICAL ASSOCIATION, should make all the reputable physicians in North America eligible to membership in the same ASSOCIATION. Still further on in the same section we find the expression: "All State medical societies with their constituent local societies," without anything to indicate what is meant by a "constituent local society." It is well known that there is no uniformity in the organization of State and local medical societies throughout the United States. And consequently there is no recognized standard by which to decide what constitutes a recognized or "constituent" local medical society, except as given in the present Constitution, namely, "such county and district medical societies as are recognized by representation in their respective State societies." But this definition is rendered inapplicable by the fact that the Committee on Revision throughout the section on membership takes no recognition of *representation* by delegates or otherwise, but directly abolishes all representation by delegates so far as relates to the AMERICAN MEDICAL ASSOCIATION. The introductory paragraph called "history," and the section on "membership" from which we have been quoting, constitute nearly all the original work of the Committee on Revision, the rest of the revised instrument being nearly all copied from the present Constitution and By-laws. And the ambiguous, indefinite and inconsistent if not positively contradictory language in which they are expressed, should cause their prompt rejection by the ASSOCIATION, if there were no other objections to the work of the Committee.

The second important change in the Constitution and By-laws proposed by the Revising Committee, is the omission of the provision for three general addresses at each annual meeting. Section XIV of the present By-laws reads as follows: "The ASSOCIATION shall annually elect on the nomination of the Nominating Committee, three members of the profession, eminent in some of its departments, to deliver addresses in the general session of the next ensuing annual meeting—one on some topic or topics relating to general medicine, another relating to general surgery, and the third relating to public medicine, including under that head hygiene, sanitation, prophylaxis, education and medical legislation, each of such addresses not to exceed one hour in its delivery." Under the operation of this rule, each annual meeting has been provided with one important, carefully prepared address for each general session, by including the address of the President on the first day; and in no other part of any general session is the audience so large or so attentive as during the hours assigned for the delivery of these addresses. They are the most efficient items on

the program of each general session to enlist the attention of the many general practitioners and hold them in attendance from day to day. These addresses are, with very few exceptions, among the most important papers that fill the Transactions of the ASSOCIATION. Similar general addresses have constituted, certainly, one of the most attractive features of the annual meetings of the British Medical Association throughout its whole history. And the AMERICAN MEDICAL ASSOCIATION, instead of omitting them altogether, as is done in the revised By-laws of the Committee, should only exercise greater care in obeying the letter of the existing By-laws by electing *only* members of the profession actually "eminent in some of its departments."

The *third* important change proposed by the Revising Committee is the abolition of the Nominating Committee and the requiring of all nominations of officers and the recommendation of the times and places of the annual meetings to be made by the General Business Committee, which is to consist exclusively of *ex-chairmen* of the several Sections. This identical change was proposed when the amendment of the Constitution creating the General Business Committee was adopted at the meeting in Detroit in 1892, but was stricken out by a decisive vote. It was claimed with much emphasis that the general officers and place of annual meeting for a truly National organization, like the AMERICAN MEDICAL ASSOCIATION, should be nominated by a committee composed of, at least, one member from each State and Territory having members present. On the other hand, the General Business Committee is, or will be hereafter, composed exclusively of *ex-chairmen* of the Sections, and therefore almost certainly concentrated in a few large cities, instead of representative of the profession of the whole country. This is well illustrated by the fact that of the thirty-six members constituting the General Business Committee at the present time, eight are residents of Philadelphia, five of Chicago, four of Cincinnati, and two of Detroit. And of the twelve present chairmen of Sections, who will become members of the Business Committee at the close of the next annual meeting, one-half are from two cities, namely, three of Philadelphia and three of Chicago. A committee thus constituted may prove practically efficient for the better regulation of the work of the various Sections, and may constitute a convenient and safe body to consider and report upon such questions and topics as may be referred to it by the ASSOCIATION, but it certainly can not be regarded as a direct representative of the profession in all parts of the country. Consequently, if the nomination of the general officers of the ASSOCIATION should be confided to it, as is proposed by the Committee on Revision, it would constitute a long step in the direction of lessening the interest of the great body of general practitioners in the ASSOCIATION and of concentrating all control in the hands of the specialists. Objectionable, however, as are the three foregoing proposed changes in the Constitution and By-laws, they are far less important than the fourth, which is embraced in the section relating to membership. For, whatever may be the faults and inconsistencies of language used in its construction, as I have already pointed out, there is no difficulty in seeing clearly that its adoption would at once destroy the representative character of the ASSOCIATION, and rapidly reduce its National character by placing the control of each annual meeting directly in the hands of the profession of the State in which the meeting is held. It makes no provision for delegates representing State, county or district medical societies, and no conditions for permanent membership. A very careful study of the whole section will show that four conditions are made essential for the acquisition of membership in the ASSOCIATION: 1, the applicant must be a member of some one of the "several affiliated State medical socie-

ties recognized thereby or represented therein;" 2, the State society, to be recognized, must have accepted the Code of Ethics of the ASSOCIATION; 3, the applicant must present to the Treasurer of the ASSOCIATION a certificate that he is a member of a recognized State society, in good standing, accompanied by five dollars as the annual membership fee; 4, if he desires to attend or participate in the work of any meeting of the ASSOCIATION, he must present to the Committee of Arrangements, both a certificate of his good standing in his recognized State society and his receipt from the Treasurer of the ASSOCIATION that his dues for the year are paid. And if he fails to comply with the foregoing conditions for one year his name must be stricken from the roll of members. The section also declares that, "no person shall be permitted to take part in any annual meeting until he or she has completed the conditions of membership at that meeting and can exhibit a certificate to this effect from the Committee of Arrangements."

The whole section would have been much more explicit and easily understood if it had simply declared, that the members of all State and Territorial medical societies adopting and upholding the Code of Medical Ethics of the AMERICAN MEDICAL ASSOCIATION shall be eligible to membership in the last named organization; and that any member of such State or Territorial medical societies may at any time become a member of the National organization by sending to the Treasurer a certificate showing that he is a member of his State society in good standing, accompanied by the annual subscription price of the JOURNAL OF THE ASSOCIATION, five dollars, and therefor shall receive the JOURNAL one year; and during the same year may attend and participate in an annual meeting, by presenting his receipt from the Treasurer and an additional certificate of his good standing in his State society to the Committee of Arrangements. If he fails to renew his subscription to the JOURNAL for one year his name must be stricken from the roll of members. No thoughtful reader can fail to see that the adoption of the section under consideration, as proposed by the Committee on Revision, would utterly destroy the general representative character of the ASSOCIATION and rapidly reduce the permanency of its membership. The several State and local medical societies no longer appointing delegates with any special or important functions, the attendance from parts more distant from the place of meeting would be less; the interest of the State and local societies in the ASSOCIATION would grow less from year to year, and each annual meeting would be completely under the control of the members living within one hundred miles of the place of meeting, one-half of whom would allow their membership to expire the very next year for non-payment of dues. By thus abolishing the representative character and permanency of membership on the one hand, and the placing of all nominations and business questions in the hands a Business Committee composed exclusively of *ex-chairmen* of the several sections it would not take five years to convert the AMERICAN MEDICAL ASSOCIATION into as perfect an aggregation of specialists and with as limited a basis of membership as is the so-called Congress of American Physicians and Surgeons. While the Committee on Revision make considerable pretension of placing the ASSOCIATION more "in touch" with other medical organizations, and of even taking in "all of North America," every important change they propose would actually produce directly the opposite effect as I have shown.

On the other hand, our present Constitution by its liberal provision for *delegates* from State and local medical societies, most effectually encourages the formation and support of such societies in every part of our country; and by limiting the privilege of voting to such *delegates*, it equally estab-

lishes and maintains its own true National representative character, and guards against centralization and local or sectional dominance. By awarding to such delegates the privilege of remaining permanent members and participating in all the doings of the ASSOCIATION except voting, by continuing to pay the annual dues; and by the section on admission of permanent members by *application* without the expense of attending an annual meeting, the door is kept wide open for every member in good standing in the recognized State and local medical societies to make himself or herself a member of the NATIONAL ASSOCIATION whenever he chooses to do so.

Consequently, the present Constitution and By-laws are more liberal and more in harmony with every legitimate interest of the medical profession in the United States and their representative or delegate feature is far more in accord with the modes of thought and action of all English-speaking people, than is the substitute proposed by the Committee on Revision. Then why not stop wasting valuable time every year in tinkering constitutions and by-laws? Neither the legitimate interests of the ASSOCIATION nor the value of its JOURNAL will ever be advanced by mere constitutional or by-law changes. They can be advanced only by such earnest, thoughtful, persistent work as will bring to every general meeting better addresses; to every Section more original papers and more thorough discussions; and to the JOURNAL more and better material for its pages. More patient scientific research, more complete aggregation of facts and close deductive reasoning, and more care in the preparation of papers, with less desultory talk or office hunting, should be the motto of every friend of the AMERICAN MEDICAL ASSOCIATION, not only at the coming meeting in San Francisco, but at all the meetings of the future. At least, such are the deliberate sentiments of one who has studied the practical working of medical organizations, and all other interests of the medical profession for nearly sixty years.

Chicago, Jan. 23, 1894.

Yours truly,

N. S. DAVIS.

The Income Tax.

To the Editor:—The determination of Congress to adopt the income tax as a source of revenue, calls for some remarks on its application to practitioners of medicine. It is to be noted that there are no exemptions in the bill in favor of certain methods of earning a living, but that all incomes, no matter how created, are lumped together. Justice would seem to require a distinction to be made between certain and permanent incomes and those which are precarious. Some incomes result from investments and require no expenditure of work or money to earn them, on the part of those by whom they are enjoyed. Others are derived through personal services rendered to employers or the public, and perhaps inadequately paid for. Some incomes are not diminished by the temporary illness or absence from duty of their earners, while others are immediately arrested when they are even for an hour off duty. The President may go fishing for a week, and his *per diem* is paid as punctually as if he were at work in his office. But a medical man takes a holiday or occupies a sick bed only by paying a penal fine for the privilege. Nevertheless, the bill treats both incomes alike. The exemption of small incomes from the tax is not unjust, inasmuch as a minimum living income should be exempted, and also because small incomes are generally precarious and earned by personal services. But a medical man's personal service is even more disadvantageous than that of a mechanic working for wages in a factory. The latter is sure of pay for every hour he works; the doctor has all the risk of collecting his dues. Again, if the me-

chanic falls ill, his wages stop; but, on recovery, he resumes his income as before his illness. The medical man falling ill loses his income during his incapacity, and further loses many patients, who used to treat with him regularly, to some other doctors. He not only suffers loss of a portion of his income for the work that he was unable to do, but breaks up his business to a certain extent also. Hence, the physician is in a worse plight as a payer of income tax than even a mechanic.

The bill, to be just, should make a distinction between precarious and permanent incomes; and a special exemption should be granted medical practitioners on account of the risks that their earnings are subject to, beyond those of any other members of the community. Certainly, in returning an estimate of income a physician should be entitled to deduct so many days for necessary recuperation and illness; he should make another deduction for the difficulty of collecting his fees; which all State laws seem to increase; and he should make a further deduction for the extra cost over lawyers, ministers, office holders, clerks and mechanics which he has to incur in carrying on his business. It is a well-known fact that doctors who seem very prosperous have to expend almost up to the margin of their earnings to keep up their business. This is a subject for the county societies to discuss and, if possible, take action upon.

W. P. WHERY, M.D.

Fort Wayne, Ind.

From Dr. Lewis.

CHICAGO, Jan. 22, 1894.

To the Editor:—Until you published Dr. Howle's answer—which is proper—to my communication on "Crime and Criminals," I hesitated to ask an explanation for the "heading" to my correspondence.

So, now, please state in the next number, that the "heading" to my correspondence was put to it in the JOURNAL office—not by me.

My objection to the JOURNAL heading is, that it is short three words; with these, it would read: "How to Encourage Criminals to Eschew Crime."

As to the answer, I beg leave to ask Dr. Howle to re-read my correspondence, for I am inclined to the opinion that he will find sufficient ground therein to justify his making a new version. This, however, I will leave to him and other readers of your most excellent JOURNAL to determine.

Respectfully, CHARLES J. LEWIS, M.D.

ASSOCIATION NEWS.

OMAHA, Jan. 28, 1894.

To the Editor:—Proposed Amendment to Art. II, Sec. 2, Constitution of the Nebraska State Medical Society:

"That any legally qualified practitioner shall be eligible for membership in this Society, whatsoever his source of education, provided that he or she proclaims in writing adherence to no particular dogma or line of practice other than rational medicine."

Will some one kindly answer the following: Is there any reason in Code or Constitution of AMERICAN MEDICAL ASSOCIATION why the above amendment should not be adopted by the Nebraska State Medical Society? If such is adopted does the Nebraska State Medical Society lose its affiliation with the AMERICAN MEDICAL ASSOCIATION? This amendment is to be voted on this year.

Respectfully, GEORGE WILKINSON,
Sec'y Nebraska State Medical Society.

American Medical Association.—Don't forget about that \$5 to be sent to Dr. J. B. Eagleson with your application for

membership in the AMERICAN MEDICAL ASSOCIATION. This is the opportunity of a lifetime for Pacific coast doctors and they must not forget it. To live in this region and not go to San Francisco this year, when you can take in the Midwinter Fair and the AMERICAN MEDICAL ASSOCIATION all at once and with fare the cheapest on record, would not only be a shame, but almost inexcusable. Pay that \$5 now. Eagleson, you know, lives in Seattle.—*Medical Sentinel*, Portland, Oregon, January, 1894.

SOCIETY NEWS.

The Queen's County, N. Y., Medical Society met January 30. Papers were read upon "Milk," "Appendicitis," "Infant Feeding," and "Long Island Water Supply."

North Central Illinois Medical Association.—Dr. J. C. Corbus of Mendota, was recently elected President of the North Central Illinois Medical Association, at the session held in Princeton.

The King County (Wash.) Medical Society at its regular annual meeting held at Seattle, Wash., January 22, elected the following officers for the coming year, viz.: President, Dr. W. A. Shannon; Vice-President, Dr. F. S. Palmer; Secretary, Dr. P. W. Willis; Treasurer, Dr. D. A. Mitchell.

Gloucester County, Penn., Medical Society held its annual meeting at Woodbury January 25. The following officers were elected: President, Dr. H. A. Stout of Wenonah; Vice-President, Dr. E. T. Oliphant of Bridgeport; Secretary and Treasurer, Dr. George E. Reading of Woodbury. Drs. S. F. Flick, M. Price and J. N. Rhoades of Philadelphia, were the guests of the Society.

The Annual Meeting of the Fulton County Medical Society, N. Y., was held at Gloversville January 11.

The following officers were elected: President, H. C. Finch; Vice-President, L. J. Dailey; Secretary, A. L. Johnson; Treasurer, J. K. Thorn; Board of Censors, W. C. Wood, J. E. Burdick, Eugene Beach. The afternoon session was devoted to the reading of papers and discussions on interesting topics. The following papers were read: "A Protest against the Excessive Use of Coal Tar Products," by Dr. Wood; "Food," by Dr. M. Helen Cullings. President C. M. Lefler gave an address on "Some Thoughts of a Physician on Modern Surgery." Those present at the meeting were: A. L. Johnson, L. J. Dailey, P. R. Furbeck, Wm. C. Wood, Eugene Beach, C. M. Lefler, I. DeZouche, J. K. Thorn, F. W. Shaffer, F. A. Mead, M. Helen Cullings, of Gloversville; D. S. Orton, Fish House, M. Francis Drury, H. C. Finch, Broadalbin; F. Beebe, John E. Burdick, J. W. Joslin, J. K. Young, of Johnstown.

Capital District Medical Society.—About thirty physicians from the central portion of the State attended the annual meeting of the Capital District Medical Society held at Springfield, Ill., January 18. The following officers were elected for the ensuing year: President, George N. Kreider, Springfield; Vice-Presidents, E. P. Bartlett, Springfield; W. M. Catto, Decatur; and J. W. Hairgrove, Jacksonville; Secretary, B. B. Griffith; Treasurer, E. J. Brown, Decatur; Judicial Council, C. E. Black, G. F. Stericker, L. J. Harvey, W. B. Hostetler and J. Townsend. The remainder of the session was devoted to the program as follows: "Rectal Surgery," J. W. Hairgrove; "Management of Natural Labor," L. A. Malone, discussion led by B. B. Griffith; "Disease of the Bladder and Kidneys," W. K. McLaughlin, discussion led by W. M. Catto; "Prophylaxis of Typhoid Fever," E. P. Bartlett, discussion led by L. J. Harvey; "Report of Three Cases of Graves' Disease," E. J. Brown; "Psychical Influence in the Treatment of Disease," J. S. King. At noon the Society adjourned and partook of a toothsome spread.

Medical Society of the District of Columbia.—Program of the literary exercises of the celebration of the seventy-fifth

anniversary of the Medical Society of the District of Columbia, to be held at the National Rifles' Armory Hall, G. Street, between 9th and 10th Streets, N. W., Washington, D. C., Friday, February 16, 1894, beginning at 7:45 o'clock P. M.

Overture. Invocation, Rev. Wm. A. Bartlett, D.D. Address by the President, Samuel C. Busey, M.D., LL.D. Music. Address of Congratulation, Theophilus Parvin, M.D., LL.D., Representative of the College of Physicians of Philadelphia. Music. Address—"History of the Medical Society of the District of Columbia," Wm. W. Johnston, A.M., M.D. Music. Address—"History of the Hospitals of the District of Columbia," J. Ford Thompson, M.D. Music. Address—"History of the Medical Colleges of the District of Columbia," Thomas C. Smith, M.D. Music.

Music by the U. S. Marine Band. Committee of Arrangements.—Samuel C. Busey, M.D., Chairman; C. H. Stowell, M.D.; H. H. Barker, M.D., Treasurer; S. S. Adams, M.D.; T. E. McArdle, M.D.; G. B. Harrison M.D.; and Geo. C. Ober, M.D., Secretary.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 151).

METALLIC ELECTROLYSIS.

Case 8.—L. S., 22 years of age; single. Prolapsed and anteverted uterus with subacute metritis; endometritis; endocervicitis; erosion and cystic degeneration. Uterus extremely painful on pressure; canal normal in depth; patulous; profuse muco-purulent discharge. Menstrual habit free, regular, but premature; recurring every three weeks. Duration 5 days. Dysmenorrhea spasmodic, beginning three days before the establishment of the menstrual function. Backache; constant frontal and vertical headache; capricious appetite; neurasthenic symptoms; urethritis; painful micturition.

March 22, 1893. Intra-uterine, fundal and cervical, cupric electrolysis, 6 milliampères, for ten minutes; reversal to loosen the electrode. Application followed by slight colicky pains which lasted for twenty-four hours.

March 24. Reported herself better. Two more applications were made as above on the 24th and 27th. Less pain during and following the applications.

August 16. Patient reported that she had been very well ever since—now nearly five months ago. Dragging pain and backache entirely disappeared; leucorrhœal discharge, slight, mucoid, and only once in two weeks. She eats and sleeps well; nutrition better, and she is less depressed. Urethritis entirely cured.

Case 9.—A. B., married; 34 years of age. June 14, 1893. Condition almost identical with that of the preceding patient, save that the uterus was retroverted, and the urethritis was severe. Two intra-uterine applications, fundal and cervical, of cupric electrolysis at intervals of seven days, ten to fifteen milliampères; also applications to the interior of the urethra and to the eroded cervix were made. These were followed by marked improvement in all the symptoms. In this case, as in the other, treatment was followed by slight colicky pains, lasting to a greater or less extent during the subsequent twenty-four hours, and accompanied with abdominal soreness. Ultimate condition not recorded, because she did not return to the clinic after July 28, when she reported herself much better.

Gautier does not refer to the uterine colic which is liable to occur in intra-uterine cupric electrolysis. The following case illustrates very clearly that this condition may follow on such treatment:

Case 10.—A. M., married. Dec. 20, 1893. Intra-mural fibroid; uterine measurement three and one-half inches; developed anteriorly and to the right; endometritis; severe dysmenorrhea. The usual pressure symptoms were present, and were first noticed in 1886. Patient had been treated with intra-uterine negative galvano-chemic cautery at intervals for a year or more. On Dec. 20, 1892, intra-uterine cupric electrolysis, electrode within the cavity of the body, thirty milliampères for eight minutes; reversal, fifteen milliampères for five minutes. This was followed by the most intense uterine colic I have ever seen. It was an hour or more before she could leave the office for her home. For three days, there was increased discomfort, but since then, the patient's health has been very much better than for nearly six years.

July 11, 1893. Menstruation accompanied with very little pain; able to attend to all her duties (the active ones of a business woman) with only a little rest on the second day. Before treatment she was obliged to go to bed during the time. She dates her improvement from the cupric treatment.

Case 11.—Mrs. P., 36 years of age; married. External and internal hemorrhoids. There was an immense cluster of external hemorrhoids, the largest being the size of a pigeon's egg. A number of smaller ones formed a ring around the anus. The internal ones frequently became strangulated, giving rise to intense pain.

Feb. 25 and 27, 1893. Two mild applications of cupric electrolysis C. S. five milliampères for three minutes were made to the external tumors. March 1. After applying cocaine, an application of twenty-five milliampères was made to the internal tumors, and this treatment was repeated on March 3 and April 25. On May 9, she had a perfectly-natural movement of the bowels, without pain, the first in years. She continued to improve up to June 6, when she passed from observation.

On September 6 I heard from this patient and she continued perfectly well. There has been no trouble whatever from the hemorrhoids since the last treatment.

DISCUSSION.

DR. MORTON said that the entire subject had been most admirably outlined in the paper. It was seldom that he rose to discuss a subject which he felt more important than this, for, instead of speculating on the action of the current, we could obtain the salts of the metals used in our soluble electrodes. Not only have we got a definite medicine which we can place at the point desired, but we can by means of the cathodic action of the current drive this medicine deeply into the tissues. It is greatly to the credit of Gautier that he has gathered together the facts scattered through literature, and has built up the system which he calls "interstitial electrolysis." In the speaker's opinion it is better to call this treatment, "metallic electrolysis," for interstitial electrolysis may take place anywhere where there is a continuous current, regardless of whether or not the electrode is metallic. This idea that metals can be dissolved at the positive pole is by no means new. He had found in Butler's book, published in 1887 by the homeopathic firm of Boericke & Tafel, New York, a similar method of treatment. This author goes thoroughly into the subject of zinc electrolysis, and describes distinctly how the needle is changed into chlorid of zinc, and how one obtains the two actions—that of the current, and that of the zinc chlorid formed from the metallic electrode. He makes no reference, however, to gynecologic work. Gautier deserves the credit for developing this department, as well as the entire subject.

DR. MORTON then presented a number of instruments which had been devised and brought into use during the two years in which he had studied this subject.

The first instrument was a piece of flexible copper wire tipped at the end, and having a sliding insulation. It was used for treating the nasal cavity. A current of five to twenty-five milliampères was used, and the oxychlorid of copper thus deposited in the deepest recesses of these passages. A set of copper electrodes were also exhibited, which were devised originally by Dr. Goelet for intra-uterine treatment. The copper uterine sound first employed by Dr. Cleaves was also shown, as was also the "protected electrode," designed for use in a case of ulceration of the rectum. Dr. Morton said that the adhesion of the electrode was probably due to the formation of a soluble albuminate of copper—the soluble salt found, and alluded to in the paper. This adherence of the electrode is particularly marked in urethritis. When he first began to use cupric electrolysis, a patient who claimed to have had gonorrhea for three months presented himself. A current of two to three milliampères was used at first, but on increasing it to five milliampères the instrument was found to be adherent. About four or five minutes were occupied in the gradual withdrawal of the instrument. One year later the patient returned with a fresh attack. He stated that the discharge had entirely disappeared within two or three days after the first application. This second attack was treated in the same way and with the same good result. He had employed cupric electrolysis in a dermoid cyst on the side of the neck, measuring over one inch in diameter. The parts were made numb by electro-cathaphoresis and cupric electrolysis performed for about ten minutes with twenty to thirty milliampères. On a previous occasion the cyst had been punctured, the fluid withdrawn, and an attempt made to secure decomposition of a solution of iodid of potassium injected into it, but this

was a failure. The result of the second application was that the cyst gradually disappeared, leaving no trace except a tiny needle mark. The patient was unwilling to be cut, and was afraid to take ether.

When a copper bulb is placed against a hemorrhoid, the tumor can be seen to shrink under the electrolytic action.

There is probably no more common slight ailment than hypertrophic or atrophic rhinitis, and the gratifying results obtained from cupric electrolysis seem on this account specially interesting. Usually in three to five weeks, and after six or seven applications, they feel "cured." He was unable to say yet how long this relief would continue. In atrophic rhinitis, the effect of the treatment is: 1, a gradual increase of secretion; 2, disappearance of the scabs; and 3, a greater feeling of comfort in the nose. From a theoretical standpoint it would seem probable that the activity of a number of the glands not yet destroyed is restored by the treatment.

Foul sinuses may be very conveniently treated, as the antiseptic is manufactured as one proceeds.

DR. HAYD said he had had no practical experience with the subject, but he thought there were certain objections. Just as soon as one magnifies the importance of local applications, one increases the dangers of intra-uterine medication. He had been led to believe that the effects of electricity were due, not so much to the local action of the current, as to the influence on the nerves and lymphatics supplying the part; for, if there were only a local effect, how could we explain the cure of certain conditions by electrolysis, when they had resisted curetting and the application of chlorid of zinc or nitric acid? In the second place, just as soon as the séance is prolonged, in intra-uterine applications particularly, the dangers of the treatment are increased. The mere fact that it is admitted that the electrode adheres to the tissues is in itself a very serious objection, for this adhesion will result in a trauma which will sooner or later prove disastrous. He thought there was a dangerous tendency in the Association to be unduly enthusiastic in the use of local applications, and until he had been assured that these recorded successes had been treated unsuccessfully by the ordinary electric treatment, he could not be convinced of the superiority of metallic electrolysis. The mere fact that a piece of meat may be stained by the copper or zinc did not prove to him that it is because of this deposit the results are obtained.

DR. MASSEY said the objection raised by the last speaker regarding the dangers of intra-uterine applications did not apply to the *expert* use of such treatment where it seems to be imperative. He had employed such treatment for months at a time without mischief following.

He had been struck with the fact that in recent literature there had been a sudden reversion in favor of a more general use of the positive pole in electric applications. While our efforts are being directed to the action of the base metals with reference to the active pole, we forget that we have metallic electrolysis every time we use a galvanic current, unless the patient be protected by a very large pad. The clay is probably particularly useful, in that it catches the particles of copper or other metal derived from the plate used with the clay electrode as a conductor. A few years ago he employed iron wire in this connection, thinking that the introduction of the iron into the body would not be harmful; he found the iron disappeared so rapidly that it was impracticable to employ this metal at all.

In a case of prolapsed and ulcerated rectum he found that a current of forty to fifty ma., caused the reduction of the rectum when a carbon positive electrode was used, showing that it was the action of this pole and not of metallic electrolysis.

He had had some experience in atrophic rhinitis. In one case where he used what was supposed to be a 14 karat gold electrode, it was quickly tarnished by a current of six to seven ma. The effects of treatment were, however, very much disguised by the simultaneous application of cocaine; this renders the treatment agreeable and probably more efficacious. One such treatment often relieves the sensation of obstruction for many days, and a treatment for six months will destroy the tendency of a patient to constantly "catch cold."

DR. GREEN said that this valuable paper contained suggestions of uncertainty. He could not feel that this indiscriminate probing of the uterus is safe. Intra-uterine medication should be guardedly used. Again, while one can regulate the dose of electricity by the meter, he saw no way of regulating the dose of the metallic salt deposited by electrolysis.

He had treated one case of hydrocele occurring in a

gentleman who would not submit to the more usual methods. A zinc needle was passed into the sac without withdrawing the fluid, and a current of seven ma. used for about fifteen minutes. On the withdrawal of the needle he was astonished at the large quantity of zinc which had been removed from the needle. The case was, however, promptly cured, and there had been no relapse.

DR. HAYES said that while there is much danger from intra-uterine treatment when employed indiscriminately, in properly selected cases and in the hands of experts it is not as dangerous as the introduction of medicine in any other way. By electrolysis more of the metal is introduced, and so gradually as not to excite the uterine colic ordinarily following other methods of this kind. The dosage is more accurate in fact than the administration of substances by the mouth, for a certain strength of current causes the deposition in the tissues of a certain amount of metal.

The adhesion of the positive pole to the tissues is to a certain extent a trauma, but it is very easy to limit this to the most superficial tissues; indeed the author had explained how the electrode could be liberated without causing injury to the tissues.

The paper also emphasized the activity of substances when in the nascent state. For example, a piece of beef stearin after being in the laboratory for several months has a much higher melting point than a piece freshly manufactured; in other words, the rigidity which it eventually assumes is such that it requires more heat to pull it apart than at first. This illustrates what is meant by the greater activity of substances when in the nascent state; hence it is obvious that this method of treatment has a power peculiar to itself. It also should not be forgotten that by cataphoresis the salt is deposited deeply in the tissues, and hence its vast superiority over such caustics as nitrate of silver. Those who have made a study of gonorrhoea know that the reason it is not quickly cured by the usual injections is because the gonococcus penetrates deeply and lives in the submucous tissue. It would seem therefore that in metallic electrolysis we have a very superior method of treating this obstinate disease.

DR. GERNUNG said that not only is the nascent condition important, but the medicine is carried in so gradually that one portion is swept along by cataphoresis before another particle is presented to the tissues, and so the spaces of the latter are not clogged up by the medicament.

THE PRESIDENT said he had at first called attention to the fact that although Gautier claimed that with cupric electrolysis there was relief from pain, it frequently excited intense uterine colic. For this reason he had looked upon it as dangerous. No harm followed in his cases, however, but the colic prejudiced the patient against the treatment. Further observation convinced him that the colic was due to insufficient drainage, the result of the astringent set free in a narrow cervical canal. He had subsequently made applications to some of these same patients where the uterine colic had been excited, and by previously dilating and keeping the cervical canal patulous, had been able to avoid colic.

He did not use the copper applications so much in endometritis as he had done formerly, as he considered zinc superior. He knew of nothing equal to cupric electrolysis for the control of uterine hemorrhage at the time of the application. Its action is immediate; at most there is not more than a slight dribbling for a few hours after the application. It is by no means necessary to use the excessive current strengths recommended by Gautier; he usually employed twenty to thirty ma. for ten or fifteen minutes, and kept the electrode still, as he found that after turning off the current, if the instrument be carefully revolved on its axis it can be removed without doing violence to the tissues. He knew of nothing which would cure granular degeneration of the cervix so promptly and satisfactorily as zinc electrolysis. In one case after six applications of only ten ma. a very bad granular cervicitis was completely cured. He brushes the electrode over different parts of the surface, not to prevent its sticking, however, as this is not nearly so noticeable with zinc as with copper. He had not employed the iron electrodes referred to by Dr. Massey in cases of uterine hemorrhage.

Another useful application of cupric electrolysis is in fissure of the anus. With a current of five to ten ma. applied with a bare copper electrode for two or three minutes the cure has been prompt and satisfactory. Zinc electrolysis is also useful in promoting healing of the sac left after incision and evacuation of suppurating vulvo-vaginal glands.

Intra-uterine applications are perfectly safe in the hands of the expert gynecologist if perfect cleanliness and free drainage are secured.

He had treated a large keloid on the anterior surface of the thigh by punctures with zinc needles around the margin. Two prominent surgeons had refused to operate. The applications were made once or twice a week, and extended over a period of two months. After two months cessation of treatment there was absolutely no occasion for further treatment and the case was considered cured. It was found that there was less destruction of tissue and the result was better if only five ma. per needle were used, instead of ten, as employed at the beginning.

In one case three punctures with zinc electrodes and a current of ten to twenty ma. caused diminution of a hard uterine fibroid to one-third its former size. Some time before this one puncture had been made with a platinum needle and a current of fifty m. a., but without any result.

DR. CLEAVES, in closing the discussion, said she was very much averse to a great deal of the intra-uterine treatment advocated, as much of it is unnecessary; but in a certain class of cases she was satisfied quicker and more lasting results could be obtained. Nor could metallic electrolysis be objected to on this ground, as the applications were made only once in eight days, and not more than three in a month, while the entire course of treatment was markedly lessened. In cases of persistent cervical degeneration she had had exceptionally good results from zinc electrolysis. In one of the cases reported all the usual measures had proved ineffectual, and yet within a week after the zinc electrolysis there was a perfectly normal condition of the uterine cervix and the patient went on to complete recovery. She doubted very much if it were wise to move the electrode in the uterine cavity. The medicine certainly penetrates deeply. The dosage is more accurate than when administered by mouth, and infinitely more so than when applied by solution or stick, as then most of the application fails to reach the desired point. Gautier's experiments go to prove that no toxic effects are produced by this treatment. She believed there was no need of exceeding thirty ma., and in the case of severe uterine colic reported this was the strength used, and the application was made entirely within the body of the uterus.

She doubted if cocaine had anything to do with the relief of the sensation of obstruction in the nose, for this follows very rapidly on cupric electrolysis.

The needles which she presented were the same as used by Gautier, while the electrodes she devised for the treatment of trachoma and granular conjunctivitis.

PUBLIC HEALTH.

A Bill to Establish a Department of Public Health.

The following is the Public Health bill recommended by the Committee of the AMERICAN MEDICAL ASSOCIATION, C. G. Comegys, M.D., Chairman:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled,

SECTION 1.—That there shall be established a Department of Public Health. There shall be appointed by the President from the medical profession, by, and with the advice and consent of the Senate, a Secretary of Public Health who shall be intrusted with the management of the Department herein established. He shall be paid an annual salary of \$8,000.

There shall be appointed by the President, with the approval of the Senate, an Assistant Secretary of Public Health, at an annual salary of \$5,000.

The Secretary of Public Health shall, with the approval of the President, provide suitable offices for the Department, and shall employ such assistants and clerks as may be necessary.

SEC. 2.—It shall be the duty of the Secretary of Public Health to obtain through all accessible sources, including State Boards of Health, municipal authorities, and the Surgeon Generals of the Army, Navy and Marine Hospital Service of the United States, weekly reports of the sanitary condition of all ports and places within their territories and departments, and he shall publish weekly abstracts of the information thus obtained and other pertinent matters received by this Department. The said Department also shall, as far as possible, by means of the voluntary coöpe-

ration of State and municipal authorities, of various general and special hospitals, sanitariums, public associations and private persons procure and tabulate statistics of marriage, births (noting those that are illegitimate, and deaths from epidemic, endemic and all other diseases, specifying those of a degenerative character, such as malignant growths, and affections of the nervous, circulatory, respiratory, secretory, digestive and reproductive organs, and from violence, accidents, suicide, murder and data concerning the fruit of consanguineous marriages and the transmissibility of insane, alcoholic, syphilitic, nervous and malignant types of constitution to offspring and to evils of race miscegenation. He shall also procure information relating to climatic and other conditions beneficial to health and especially in reference to the most favorable regions in the United States for the cure or relief of chronic diseases, particularly tubercular consumption. He shall also procure information as to the prevalence and ruinous effects upon the body and mind by intemperance and prostitution. He shall endeavor to ascertain the extent, the origin and classification of insanity in the several States and territories of the country. He shall investigate the state of comfort of the laboring classes in respect to their lodgment, their trades, occupations, the healthfulness of their workshops and the contents of the atmosphere they habitually breathe, and the prevalence of premature degeneration of the nervous and muscular systems by the exactions of piece-work employment.

He shall obtain information as to the soundness of their food and purity of water supply. He shall ascertain the ages at which the children of the poor are put to work and its hindrance to their physical development, and their lack of common school education. He shall seek through the State Boards of Health information of the hygienic state of public school buildings respecting their illumination, ventilation and the presence of noxious elements in the circumambient air. He shall seek information in regard to the pollution of streams and navigable waters and public and private wells. He shall attempt, through the cooperation of the authorized medical schools in all the States, to promote the most extended and thorough training of students in order to fit them for the responsible duties that devolve upon practitioners of medicine.

Besides the reports of the state of the public health which he shall make from time to time, the Secretary shall make an annual Report to Congress, with such recommendations as he may deem important to the public welfare, and the Report, if ordered printed by Congress, shall be done under the direction of the Department. The necessary printing of the Department shall be done at the Government printing office upon the requisition of the Secretary, in the same manner and subject to the same provisions as that of other printing for the several Departments of the Government.

SEC. 3.—The President is authorized, when requested by the Secretary of Public Health, and when the same can be done without prejudice to the public service, to detail officers from the several departments of the Government for temporary duty, to act under the Department of Public Health to carry out the provisions of this Act, and such officers shall receive no additional compensation except for actual and necessary expenses incurred in the performance of such duties. When a detail of such officers can not be made the Secretary, approved by the President, may employ such experts, and for such time and in such manner as the funds at the disposal of the Department may warrant.

SEC. 4.—That to defray the expenses in carrying out the provisions of this Act, the sum of fifty thousand dollars, or as much thereof as may be necessary, is hereby appropriated to be disbursed with the approval of the President, under the Secretary of said Department.

This Act shall take effect sixty days after its passage, within which time the Secretary and Assistant Secretary may be appointed.

He shall, whenever any epidemic disease is spreading abroad, or in any country which by commercial or other relations may endanger the health of the inhabitants of the United States, have power to call a conference of the Surgeon Generals of the Army, Navy and Marine Hospital Service and the executive officer or officers of the various State boards of health throughout the country, to consider and advise with him in regard to the best methods to be pursued to protect the country against the invasion of any such epidemic disease, and the results of such conference shall be, by the Secretary of Public Health, communicated to the President for such action as may be deemed wise and expedient.

SEC. — Repealing clause.

Pennsylvania Sanitary Convention.

HARRISBURG, PA., Jan. 27, 1894.

The *Public Ledger* of Philadelphia, a sheet known all over the country for its conservatism and moderation says in its Harrisburg letter of yesterday: "Harrisburg is a city of conventions; but a more interesting assemblage than that which Governor Pattison called to order in the Supreme Court room this morning never met here. The Sanitary Convention under the auspices of the State Board of Health promises to be fruitful in results far-reaching and important." While the first of these two assertions may possibly be a little extravagant, the second is amply justified. This convention was in point of fact a conference between the State Board of Health and the local boards, the great majority of the latter having but recently come into existence, under the Act of 1893, "to enable boroughs to establish Boards of Health." It is safe to say that it marked a new era in health administration in this conservative old State. The two hundred delegates, representing more than one hundred boards, were there with one common purpose; that of acquainting themselves with the most efficient methods of discharging the important and responsible duties assigned to them by their respective municipalities. From the moment that the venerable Bishop McGovern concluded his opening prayer, until the announcement of adjournment by the Governor, attention never flagged for one moment. In the past, Pennsylvania has unquestionably been a laggard in the great march of sanitary reform. It needed ten years of earnest effort to obtain the establishment of a State Board of Health, and it has taken nearly the same period for that Board, seconded by the efforts of all the sanitarians of the State to procure the passage of a law to enable towns other than large cities, to provide themselves with this essential department of municipal government.

No one who looked into the eager faces of the intelligent, dignified, and for the most part cultured men who crowded the Supreme Court chamber to overflowing, and who reflected that they represented every section of the Commonwealth from the Delaware to the Ohio, and from Maryland to the Great Lakes, and who listened to the able and exceedingly instructive papers which were read, and the pertinent discussions and acute interrogatories which followed them, could doubt for a moment that "the former things had passed away," and that Pennsylvania was rapidly forging forward to a foremost place among those States which intelligently appreciate the necessity for official sanitary supervision.

The following is the program of the meeting. The practical character of the subjects can not fail to arrest attention. The opening address by His Excellency, the Governor, showed his entire sympathy with the movement, and his intelligent appreciation of the requirements for the protection of the public health:

FRIDAY, JANUARY 26, 1894.

1. Prayer, by the Right Rev. Thomas McGovern, D.D., Bishop of Harrisburg.
2. Opening Address, by His Excellency, Governor Pattison.
3. "The Authority and Mission of the Local Board of Health," by M. G. Lippert, Vice-President of the Board of Health of Phoenixville. Discussion (limited to five minutes for each participant).
4. "The Duties of Local Boards of Health in the Management of Contagious and Infectious Diseases," by Wm. H. Ford, M.D., President of the Board of Health of Philadelphia. Discussion.
5. "Sanitary Engineering, or, the Prevention of Preventable Diseases," by Howard Murphy, C.E., Engineer Member of the State Board of Health of Pennsylvania. Discussion.
6. "Sanitary Sins of Omission and Commission in our Common Schools," by S. T. Davis, M.D., President of the State Board of Health of Pennsylvania. Discussion.
7. "Powers and Possibilities of Local Boards," by Major M. Veale, Health Officer of Philadelphia. Discussion.
8. "How the State Board and Local Boards of Health may be Mutually Helpful," by Benjamin Lee, A.M., M.D., Secretary of the State Board of Health of Pennsylvania. Discussion.
9. "To what Extent should Compensation be made for Losses Sustained to Protect Communities in Cases of Contagious Diseases," by J. H. McClelland, M.D., Ex President of the State Board of Health of Pennsylvania. Discussion.
10. "The Local Board as a Sanitary Instructor," (illustrated by the stereopticon), by Joseph F. Edwards, A.M., M.D., Member of the State Board of Health of Pennsylvania.

Reception by His Excellency, Governor Pattison, at the Executive Mansion, to the visiting delegates, from 9 to 10 P.M.

SATURDAY, JANUARY 27, 1894.

11. Prayer, by the Rev. Dr. Dimmick, Pastor of Grace Church, Harrisburg.
12. "A Few Needed Reforms in the Health Service," by Crosby Gray, Esq., Department of Public Safety, Pittsburg. Discussion.
13. "A Paper," by Pemberton Dudley, M.D., Member of the State Board of Health of Pennsylvania. Discussion.
14. "The Ounce of Prevention," by Abraham M. Beitler, Director of the Department of Public Safety of Philadelphia. Discussion.

While all the essays were full of careful thought and useful suggestions, that of Major Moses Veale, the efficient Health Officer of Philadelphia and President of the State Quarantine Board, was so admirable a statement of the powers of boards of health, and of the manner in which those powers may be exercised to the best advantage, that the State Board of Health was requested by vote of the Convention to have it printed and distributed to all local boards as a circular of information.

So deep was the interest felt by the delegates, that the proposal to form a permanent association was received with enthusiasm. By-laws were adopted, making provision for an annual meeting, the publication of a volume of proceedings and the issuing of occasional addresses to the public. The Governor of the State was made President *ex officio*.

Dr. John H. Rauch, late Secretary of the State Board of Health of Illinois, who was in Harrisburg during the session of the conference, was invited to a seat upon the platform, and, by a rising vote, elected the first honorary member of the "State Associated Health Authorities of Pennsylvania." Dr. Rauch, in briefly acknowledging the honor conferred, took occasion to contrast the lavish expenditures made by the Legislature of Pennsylvania, his native State, for the cure of disease in appropriations to hospitals, amounting to about half a million dollars at each session, with the niggardly provision of \$6,000 annually to its State Board of Health for the prevention of disease. He also complimented the State Board of Health on the results which it had accomplished with the very limited means at its disposal.

The officers elected were: Major Moses Veale, Health Officer of Philadelphia, First Vice-President; Hon. Thomas P. Merritt, ex-Mayor and member Board of Health of Reading, Second Vice-President; Dr. James H. McClelland of Pittsburg, former President of State Board of Health, Third Vice-President; William B. Atkinson, M.D. of Philadelphia, Medical Inspector to the State Board of Health for the Delaware District, Secretary; Jesse C. Green, M.D., member of the Board of Health of West Chester, Treasurer.

MISCELLANY.

Dr. J. L. Forwood of Chester, Pa., was a delegate to the National Board of Trade which was in session in Washington last week.

Dr. Acuff of Franklin Junction, Va., was recently shot by an unknown assassin. The bullet was extracted and the Doctor is recovering.

Nutmeg Quacks to Go.—It is stated that hereafter the Connecticut State Board of Health will vigorously prosecute irregular medical practitioners, and if possible drive them out of the State.

Millions for the Sick and Afflicted of London.—It is estimated that not less than \$27,000,000 will, in 1894, pass into the coffers of the various charitable institutions having their headquarters in London. Howe's *Directory of Metropolitan Charities* for the present year gives the above estimate.

International Medical Magazine.—The copyright and subscription list of this magazine has been sold by the J. B. Lippincott Company to the International Medical Magazine Company. Prof. John Ashurst of Philadelphia, Prof. Jas. T. Whittaker of Cincinnati, and Prof. Henry W. Cattell, will supervise its publication.

No Good for Advertising.—First Quack—Here is a letter it would not do for us to publish. A man writes: "I have just taken my first bottle of your medicine and I—"

Second Quack—Well?

First Quack—There it breaks off short and is signed in another handwriting, "See executor."—*Medical Sentinel, from Philadelphia Item.*

Pennsylvania State Medical Examiners.—On January 17, Governor Pattison of Pennsylvania, appointed the following State Medical Examiners under the act of May 18, 1893: H. G. McCormick, M.D., Williamsport, three years; Henry Beates, Jr., M.D., Philadelphia, three years; W. J. R. Kline,

M.D., Greensburg; A. H. Hulshizer, M.D., Philadelphia, two years; N. S. Foster, M.D., Pittsburg, two years; J. E. Stillman, M.D., Erie, one year; Samuel W. Latta, M.D., Philadelphia, one year; seven Homeopaths, and seven Eclectics.

Indianapolis Plans for a Pest House.—President Hays of the Indianapolis Board of Public Health, presented the plans and specifications for a pest hospital to the Board of County Commissioners January 23. The estimated cost of the structure is between \$5,000 and \$6,000. The Commissioners took the matter under advisement.

The New Mannlicher Missile.—The London letter of the *New York Sun* contains the following paragraph regarding the new weapon of European armies, that is said to carry two miles and a half:

"The chief surgeon of the Roumanian army has been making grewsome experiments with the new Mannlicher rifle, with which the forces are being equipped. He placed a number of human bodies in rows, like soldiers on the field of battle. At 600 meters five bodies were placed a half yard behind each other. A single bullet went through three bodies in succession. Upon the soft parts of the bodies the wounds were perhaps less serious than those inflicted by the old-fashioned rifles, the hole made by the bullet being smaller and more even; but on the whole the injuries are far more terrible. The range of the new rifles is about two and a half miles."

The Commissioner of Education.—Upon the recommendation of the Secretary of the Interior the President has determined to continue Dr. William T. Harris as Commissioner of Education. Dr. Harris owes his retention to the facts that he is not in any sense a partisan and that he has made an excellent officer. He was appointed in 1889 by General Noble because of the great reputation made by him as Superintendent of the city schools in St. Louis. In 1888 he had voted for Mr. Cleveland for President. The office is not political and Dr. Harris has been so signally successful that eminent teachers in all parts of the country have united in requesting his retention.—*Washington Post.*

In Quarantine at Vera Cruz.—Prominent Americans detained with twenty-two smallpox patients on board the *Seguranca*. The Ward line steamship, *Seguranca*, from New York was quarantined off the port of Vera Cruz with twenty-two cases of smallpox on board January 18. Among those on board were James E. Ward and Joseph O. Ward of the Ward Steamship Company; Aaron Vanderbilt, the millionaire; several leading Catholic clergymen of the United States; Bishop Fitzgerald of New York; Rev. J. Thompson, the Methodist missionary in South America; Rev. S. P. Carver and wife, and Dr. O. E. McDonald, all of whom were on the way to the General Mexican Methodist Conference which opened at Orizaba. The ship was held by the authorities until full precautionary measures were taken. It is thought the pest was taken on board by a number of steerage passengers who embarked at Havana.

The Missouri Medical College is about to erect a capacious new building, on the completion of which it will vacate its old quarters on Twenty-second Street and Lucas Avenue. About three years ago the College absorbed the St. Louis Post-Graduate Hospital and Polyclinic Free Dispensary at the corner of Jefferson and Lucas Avenues. The new structure will be erected on the vacant lot adjoining the latter, which is now known as section 2 of the Missouri College. The lot fronts 60 feet on Jefferson Avenue and runs back about 150 feet. Thus, taken in conjunction with the Post-Graduate Building, which will be remodeled to harmonize with the new part, the Missouri Medical College of the near future will occupy a space of about 120 feet by 150 feet. A premium of \$500 for the best plan is now being competed for by four selected architects. Plans and specifications are to be submitted early in February, and as soon as the award is made the work will be begun. The College as recon-

LECTURE.

REMARKS ON CLINICAL CASES.¹

1. POISONING BY ELDER, OR ALDER (?)—2. DOUBLE PHLEGMASIA, OR MILK LEG, AS A SEQUEL OF CATARRHAL PNEUMONIA.

From a Clinical Lecture delivered at the Pennsylvania Hospital,
Jan. 20, 1894.

BY J. M. DACOSTA, M.D., LL.D.
PHILADELPHIA.

The patient, now wearing a mask on his face and with hands and forearms bandaged, was admitted into the Hospital Jan. 15. He is a locomotive fireman, and usually enjoys good health and, in truth, was well when this inflammation and eruption upon his face and hands appeared. He gives the following account of himself: When on a visit to the country two weeks ago, he took a walk and was poisoned by a plant by which he has been poisoned once before. He cut a switch from a bush of red elder (not the edible variety), and incidentally applied his hands to his face and also to his genitals, while wet with the juices of the plant. This occurred January 7, and in a few hours was followed by an acute inflammation of the skin of the parts exposed. When he was admitted a week later, upon the reddened surface were seen many scattered papules and a few vesicles. This was associated with marked itching and burning, but not much secretion. The parts affected were the face, both forearms and hands and the genital organs.

It appears at first glance as if the patient were suffering from an acute eczema, but he says that he has previously been poisoned by the same plant, with which he is quite familiar, and that he is sure that in his walk he touched nothing else; and is quite certain that he did not come in contact with rhus, or poison ivy, on that day. With this eruption, there have been very few constitutional symptoms. He had no elevation of temperature and no other evidence of fever. The urine presented nothing abnormal. Burning and itching were the local symptoms of which he most complained.

This poisoning seems to us a very strange thing from either the elder or the black alder, both of which are used medicinally, and the leaves used as local applications, or infusions of the twigs, employed in the treatment of various forms of skin disease. It has been suggested that he might, in spite of his denial, have unconsciously come in contact with rhus, which we know to be poisonous, had he not asserted that it is the second time that he has been poisoned by the same plant, which he knows by the name of the black elder—which he tells us is not the edible variety, but the one that bears a cluster of red berries; it is probably the *prinos verticillatus* or black alder. We might still have believed that he might be mistaken, were it not for the fact that a distinguished physician of this city remarked to me that he himself had been poisoned in the same way several times, when a boy, by the elder plant.

As regards treatment, on account of the similarity

of this inflammation to erysipelas, he was given, by the mouth, tincture of chlorid of iron 20 drops every four hours at first, and subsequently four times daily. As the skin was hot and, for the most part, dry, he was allowed one-sixth of a grain of pilocarpin, hypodermically, and this was repeated three times a day until sweating was produced, which gave him considerable relief. We observed also, following this, an eruption of vesicles upon his face. The pilocarpin was evidently of great service. Local treatment was also used which afforded marked relief. The fluid extract of witch-hazel diluted (1:4) was applied to one arm, bicarbonate of soda solution to the other, while ichthyol ointment containing soda, glycerin and water was used for the face. In this way, we instituted a comparison of different remedies ordinarily used for this purpose. The effect of each was observed. The soda gave temporary relief, and so did the witch-hazel, but the best result was obtained from the ichthyol, which was a great success. It not only gave such prompt relief as to attract the patient's notice, but the inflammation of the skin subsided more rapidly when it was applied. It was a 10 per cent. ointment of ichthyol in lanolin that was employed in this case.

In the treatment of this patient, two things were of marked benefit, the pilocarpin given hypodermically and the ichthyol locally. As he is rapidly improving, we will continue the ichthyol ointment as a local treatment and reduce the iron to 10 drops three times a day. The pilocarpin is no longer necessary and will not be continued.

[The patient was again presented before the class, a week later. His face was clear except two small furuncular spots on the forehead. The hands and forearms were free from inflammation and the skin was desquamating. The patient expressed himself as feeling well enough to return to his work and was discharged a few days later. It was noted during the healing process that the intense itching was promptly relieved by applications of alcohol diluted with water.—REP.]

I will now present you a case of quite another character:

Thomas McC., born in Ireland, a rigger by occupation, 34 years of age, was admitted Dec. 26, 1893. Occasionally uses alcohol, and constantly uses tobacco. He had a severe attack of grippe six years ago, and a second attack two years ago. Last November he was treated in the Newark Hospital for pleurisy, and was discharged about the first of last month after four weeks' treatment. He was then well and returned to work, in which he was much exposed to the weather. One week before admission here he had severe pain in his right side, with cough, slight expectoration, short breath; no headache or pains in limbs. On admission he had dullness on percussion at left base in axillary line, with diminished vesicular sounds and distant bronchial breathing; a few mucus râles. Urine contained neither albumen nor sugar. Heart examination was negative.

From the notes which you have heard read, you would say that this was a case of very marked

¹ Reported for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

catarrhal pneumonia. The distinctness of physical signs, the flushing of the face and short breathing, even in the absence of other symptoms, led us to recognize the nature of the case and treat him accordingly. But it is not on this account that I bring this patient before you; but he speaks of a most extraordinary sequel in this case. Ten days after admission, he was nearly well, the shortness of breathing was relieved, the physical signs in the lung were gradually passing away and he was convalescing comfortably when he called our attention to a pain which he had in his right leg. We found tenderness upon pressure, especially below the saphenous opening and following the course of the vein. Presently, or rather the following day, there was enormous swelling of the whole limb; it was not quite twice the size (girth) of the left leg. With it there existed the following signs: The leg was cold, the veins were much distended, so that the whole appearance of the parts from the thigh downward, was that of a dark blue surface. The femoral vein was evidently occluded, and it was extremely hard and tender to the touch. The condition of the limb referred to extended upward into the lumbar region. The pain from the swollen limb was so severe that for four days the man could not get any rest, and only slept when he was given opiates.

Now, the condition of things was finally and very favorably modified by elevation of the leg and hot moist applications. At first, poultices were used but were soon succeeded by warm fluid extract of hamamelis. Under the treatment the pain has disappeared, and the leg, though still somewhat swollen, has resumed a more natural appearance. All this time, strange to say, his temperature showed no elevation; the slight elevation, indeed, which previously existed passed away. Lately, indeed, during the last four or five days the temperatures in the morning and evening are somewhat abnormal.

The urine examinations which were made carefully and repeatedly showed nothing wrong in the kidneys; 1018 is the record of specific gravity; no albumen, no sugar. There were no marked digestive symptoms. Early in the case, when he first came here, there was some nausea and vomiting, but nothing of the kind has occurred since he complained of the pain in his leg.

You would naturally suppose that on seeing a case of this character, we at once asked questions as to the abdominal circulation; whether or not pressure upon venous trunks existed to explain this phenomenon. This we did, but could find nothing of the kind. Also, in following out this line of thought, we examined for enlarged prostate gland through the rectum. This also proved unavailing. In other words, we could find no explanation in the abdomen for this condition. His tongue is slightly coated; appetite fair; no vomiting; bowels regular, though we have had to aid in this matter because he has shown a tendency to constipation throughout the disease, even since admission.

I will now proceed to examine his heart: The first sound is feeble, as it has been throughout; the second sound is distinct. There is no increase in size of the heart; simply a feeble action, just as is sometimes met with in rather low fevers, especially in typhoid fever. That was a feature from the very beginning of the case. In the lungs, he has no longer any dullness anteriorly. I will not examine

him posteriorly as I do not wish to disturb him, but from my last examination I can say that the lung symptoms have passed away; nothing was found in the posterior portion of the lungs when he was last examined in the wards.

On coming to the abdomen, you will see that he has a poultice now on his abdomen. This was applied because he complained of pain in the region this morning. There is some distension of the abdominal veins, especially now on the left side. There is no tenderness, no eruption, and I will further add that we have examined him for typhoid fever by applying Ehrlich's test to the urine, but with negative result.

I shall show you that this man has not only swelling of the right leg, but you will also see this morning a curious state of things. The left limb now is swollen until it is larger than the right. This swelling of the left leg is of recent development; it only began day before yesterday. But seeing him this morning, you will hardly believe my previous statement as to the relative size of the legs. The right is still somewhat swollen, although much reduced, but the left is now the larger limb. In other words, this man has double phlebitis; on the right side subsiding, on the left only recently begun.

Let us study the case a little more closely. He has now no pain in the right leg. The cordy condition of the veins has passed away. He has still numbness in the right foot. The thigh still looks somewhat blue. With the exception of the numbness and the color, there is nothing especially abnormal now in the right leg. But look at the left! The thigh is subject to pain and tenderness on pressure; there is marked sensitiveness in the calf; there is considerable soreness in Scarpa's triangle, and the veins are distended in the upper part of the thigh to as intense a degree as on the right side when it was at its worse. There is manifest swelling with pitting upon pressure with the finger. The veins on the surface around the saphenous opening are distended, and there is slight tenderness over the left femoral vein. The limb is large and discolored in the same manner as the right one was.

The diagnosis is clear enough. The case is one of double phlebitis of the lower limbs, coming on first in the right leg and then in the left. I may add that the same treatment is pursued with the left leg as with the right one. The limb is elevated and kept bathed with hot hamamelis solution. He is taking 12 grains of quinin a day and has been taking as a cardiac stimulant carbonate of ammonia, 5 grains, every four hours, which I will now stop and order in its place the tincture of digitalis, 10 drops, four times a day. At the same time, we will see that the kidneys continue to act well and if the digitalis prove not sufficient as a diuretic, let him in addition take 2 drachms of acetate of ammonium, in solution, daily. This can be aided by occasional saline laxatives. I have now stated the treatment and will briefly consider the pathology of the case.

You will naturally ask what is the cause of all this? I have already told you that this is an extremely rare case. Double phlebitis of the legs following catarrhal pneumonia is so far from being common, that this is the first case of the kind I have seen. I have seen one or two case of phlebitis after pleurisy. In truth, an instance came to my notice of phlebitis in pleurisy proving fatal by the throm-

bus being detached from the vein and finding its way to the heart, as the autopsy proved. As you noticed in the history of this case, this man also had pleurisy and you might say that this was the cause of it all. And I should also think so, were it not for the fact that, on admission, all signs of pleurisy had passed away, and we only accepted the history of pleurisy because of the statement of the patient that he had been treated for pleurisy at a hospital, where we know that the physicians were fully competent to make the diagnosis, and we, therefore, are willing to take this as part of the clinical history of the case. We know that he did have catarrhal pneumonia, which must have appeared after the pleurisy had gone. He stated that he had been well after the attack of pleurisy and was again at his work. There is in the case a possibility that this thrombosis may be due to pleurisy because the man actually had pleurisy; but I can not accept this theory of the case for the reasons stated. The phlebitis came on during convalescence from pneumonia and, as I have said, it is the first case of the kind I have seen. Phlebitis, however, is not uncommon. I have seen it in many cases; dozens of times in acute fevers, such as typhus and typhoid. In cases of fever where the circulation becomes feeble, there is this tendency to coagulation of blood in the veins. It is most common as a sequel to parturition, and may be an expression of blood poisoning such as occurs in pyemia. I have never previously seen it in an acute inflammation of any viscus, and have searched medical literature without success for a similar case to the one now presented. You might say that it is a coincidence, and that the pneumonia and the phlebitis have nothing to do with each other, were it not that the phlebitis has appeared also in the left leg, which shows something in the man, or something peculiar to his condition which makes it possible for the phlebitis to occur.

Now, is it possible that this catarrhal inflammation of the lung was in reality only a part of an attack of influenza? It would be much easier to explain the occurrence of this complication if the patient were suffering from a general disease than if he had simply an acute attack of pneumonia. The patient states that he had two attacks of influenza before this illness. I can not, however, entirely accept this view of the case because when the man was admitted he had no pains in the bones or muscles; he had no headache, in short, none of the ordinary signs of influenza.

Whether it be due to catarrhal pneumonia or to influenza; how can we explain this phlebitis, this coagulation of the blood in the veins? It can only be through the circulation. All through the case feebleness of the heart's action has been observed. Notwithstanding the iron, notwithstanding the carbonate of ammonia, his condition has been throughout, as it is now—"feeble first sound, feeble pulse." It is possible that with this feeble circulation a certain condition of the blood was present which favored the formation of a clot, and that the phlebitis occurred in consequence of the plugging of the vein with a thrombus. Indeed, here I can find no other explanation. It has been said that the lowered state of the circulation in typhoid fever is due to a poison circulating in the blood, and possibly this may be derived from the ulcerations in the intestines, or in other words there

is set up a condition of septicemia. No such explanation can be offered here; we can invoke nothing but a poor condition of the blood and general feebleness of the circulation as the cause of the thrombosis. What is the prognosis in this case? The man will get well. The right leg has almost recovered, and the left is improving under the elevation of the limb, upon which I lay great stress, and the warm fomentations. His recovery is undoubted, but after he goes about there may be some stiffness, swelling or tenderness along the veins for a time, interfering with active exercise, so that convalescence may be slow; very much like what takes place after typhoid fever.

A PLEA FOR ASEPTIC VACCINE VIRUS AND ASEPTIC VACCINATION, WITH A CASE IN POINT.

BY ROSA ENGELMANN, A.B., M.D.

CHICAGO.

PROFESSOR OF THE DISEASES OF CHILDREN IN THE POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; ATTENDING PHYSICIAN TO THE UNITED HEBREW CHARITIES DISPENSARY OF CHICAGO.

On the continent every effort is made to secure aseptic lymph. Its asepticity can not be otherwise than probable, until the specific germ or tox-albumen of cowpox shall be isolated, and a laboratory product placed upon the market. However, it is not unreasonable to now require that a vaccination abrasion be treated as is any other abraded surface, viz: aseptically. Since the vitiation of bovine virus by twenty or more demonstrable germs can not as yet be excluded, added infection from skin and air can, at least, be prevented by the antiseptic preparation, operation and dressing of the arm.

Should an ulcer, erysipelas, lymphangitis or phlegmon appear, treat each as you would surgical complications elsewhere. Granting them to be infectious, it follows that their invasion and effects must be minimized.

In the proceedings of the Pediatric Section of the New York Academy of Medicine, reported in the January, 1894, number of the *Archives of Pediatrics*, Dr. J. Lewis Smith describes a case of fatal sepsis and death following vaccination. Dr. J. H. Fruit-night mentions a case of tetanus in this relation. Home and foreign literature contributes its quota of cases. The editorials in an early summer number of the *British Medical Journal* entitled, "Militant Antivaccinators" and "The Vaccination Craze," unintentionally reveal the same unfortunate state of affairs. Consequently, the relevancy and justice of this opposition can not be overlooked.

Dr. J. Lewis Smith's case is commented upon as follows: "Inasmuch as the symptoms of sepsis had not developed for a week or more, the inference was that the wound became infected subsequent to vaccination. The case taught the lesson that greater care should be taken to protect the vaccination wound against infection."

Doubtless great and general carelessness prevails in this respect, but the criticism is not far-reaching enough, in that it fails to touch the root of the evil, the contamination of the virus itself. Reference has been already made to the unavoidable microbic pollution of the lymph. A little study, or better still,

a visit to a vaccine station, will convince one that there are other and many extrinsic sources of defilement. Here, in America, there is no certainty that the cow is prepared or the virus secured in accordance with the dictum of surgical bacteriology. The vaccine stables are private commercial institutions subject to, absolutely, no federal, State or municipal regulation. It is not sufficient that the stock be select and healthy, and the stables hygienic; the most rigid adherence to antiseptic principles in the bovine inoculation, subsequent dressing, and securement and preservation of the lymph, should be demanded as well.

An epidemic, if not pan-endemic, of sore arms imperatively calls for organized effort on the part of the profession, in order to effect improvement in the present vaccine supply. Proper investigation, organization and legislation with reference to this, so important a subject necessitates time, while its exigency requires immediate attention. The emergency might be dealt with through the agency of accredited representatives of the local medical societies. These agents might instruct owners and managers of vaccine stations as to the requirements of the profession; the refusal or acceptance of these requisites to be met on the one hand by a boycott, and on the other hand by the offer of a premium for purer virus. My earnest consideration of this subject was stimulated by a case of thrombo-phlebitis, pyemia and death that occurred in my practice two years ago.¹

A nursling, although marasmic and feeble from prolonged confinement to a ward that had been quarantined for an outbreak of measles, was vaccinated because of a smallpox endemic in the institution. The operation was antiseptically done but, to my astonishment, almost every member of the large ward developed some vaccinal complication.

A recent visit to the stable from whence the virus was then obtained explains these manifestations.

The arm of this child, however, presented nothing abnormal and the wound over the left deltoid was about healed, when the nurse called my attention to an abscess on the superior antero-internal aspect of the left arm. Other abscesses rapidly and successively appeared in the left axillary, infra-scapular and pectoral regions, and finally another was found over the lower part of the internal saphenous vein. Nodulation and ecchymosis, involving the affected vein and contiguous tissue, occurred in each instance. Nasal and aural hemorrhages and the rapidly progressive prostration simply confirmed the original diagnosis.

At the autopsy, I found a thrombus in the cephalic vein but a short distance from the normally foveolated scar. The relations of the cephalic to the basilic, subscapular, thoracic and axillary veins demonstrates the infection, atrium and course. Its transmission through the heart and lungs into the general circulation needs no further explanation. Though not creditable, the case has taught me many lessons, and I trust will rouse the profession to a realization of the septic condition of the vaccine virus in general use.

3444 Indiana Avenue.

¹ Reported with other cases in my article, "A Contribution to the Study of the Accidents of Vaccination," in the June number of the North American Practitioner.

THE TREATMENT OF ULCERS OF THE LEG.

Read in the Section on Dermatology and Syphilography at the Forty-fourth Annual Meeting of the American Medical Association.

BY LOUIS FRANK, M.D.

MILWAUKEE, WIS.

The treatment of ulcers of the leg has at all times been the *crux medicorum* and has heretofore, as a rule, been assigned to the field of the surgeon, although in most cases a true affection of the skin. The vast number of remedies advocated for the relief of this pathologic condition only speak for the difficulties offered in its treatment. The entire old arsenal and an array of new remedies, as iodoform, salol, dermatol, euophen, aristol, ichthyol, etc., have been successively brought forth as remedies, par excellence, in the therapeutics of ulcers of the leg. The cause of the failure in the accomplishment of the required result lies not so much in the non-efficaciousness of the above named drugs as in the faulty adaptation to the pathologic condition of the parts. A close study of the relations and the etiologic condition ought to convince us that a particular drug is incapable of meeting all the requirements, which the treatment of the chronic ulcer of the leg demands. Even a simple ulcer on any part of the body, caused by a local lesion, requires, according to its indications, a treatment which can not be followed out by one particular remedy; how much more a chronic ulcer of the leg, which usually presents such a varified appearance of pathologic complications.

We can easily understand why one particular remedy is incapable of fulfilling all indications in relation to the cure of an ulcer, and why it is absolutely necessary to study the pathologic appearances which an ulcer at the time presents, to apply the proper measures. At one moment we will find the ulcer shallow with a necrotic base; at another time its surface covered with exuberant fungous granulations, and our treatment must be directed accordingly.

The causes which lead to the formation of ulcers of the leg are principally the unfavorable anatomic relations of the parts. In the first place its arterial circulation is diminished on account of its greater distance from the heart; second, the centripetal circulation of the venous system is impeded by the pressure of the venous vessels during walking or standing. Under the influence of this stasis and the peculiar tension of the skin on the anterior border of the tibia, a very trifling lesion, as the bursting of an eczematous vesicle, the opening of a furuncle or any mechanical insult will result in the formation of an ulcer.

The manner in which an ulcer begins, varies according to its origin on the surface or in the depth of the skin. If it develops on an inflamed portion of the skin, a condition of stasis being present, an infiltration of wandering cells takes place in the superficial layers of the cutis, the papillæ are enlarged and the connective tissue of the papillary layer is softened and macerated. The epithelial layer of the superficial stratum fails to regenerate itself, the cellular layer of the rete Malpighii is exposed and a suppurating surface, whose upper layer consists of wandering cells and the lower of the enlarged papillæ, appears. Beneath this layer of necrotic or pus infiltrated tissue the base of the ulcer is always hyperemic. If the ulcer takes a favorable

course, the hyperemic surface will, after the necrotic tissue is thrown off, develop into granulations which consists of new loops of vessels covered with young granulation cells. The process of healing going on, the granulations arrive at the level of the borders of the ulcer. Then there becomes visible at its edge and at times on the summit of some of the granulations, a soft epithelial covering which grows denser as it grows toward the center of the ulcer. The granulatory tissue shrinks to a mass of firm elastic tissue and cicatrization takes place.

After these preliminary remarks, in which I have attempted to describe the etiology and formation of an ulcer, the pathologic processes during its development, and consequent cicatrization, and before passing to the treatment (proper) of ulcers of the leg, I deem it advisable to refer to a classification of ulcers which would aid in the correct diagnosis and treatment of the same.

Among the older authors, Bell has first divided ulcers into local and symptomatic ulcers, or those dependent on the consequence of a general systemic disturbance. Langenbeck has made a similar nomenclature, dividing ulcers into two great groups; primary and secondary ulcers, and Billroth likewise mentions two classes of ulcers: 1, the local idiopathic ulcers, including the erythritic, fungous, callous, etc.; and 2, the symptomatic ulcer including the scrofulous, syphilitic and so on. On the basis of this last classification I have attempted to classify the ulcers, which are apt to affect the leg, as seen by this chart:

Idlo- pathic or Local.	1. Simple	<ul style="list-style-type: none"> Faulty vitality . . . Faulty secretion . . . Faulty floor of ulcer Faulty granulation Faulty border . . . 	<ul style="list-style-type: none"> Hyperesthetic Asthenic . . . Erythritic Torpid Putrid Gangrenous Edematous Hemorrhagic Fungous Hypertrophic Callous

SIMPLE ULCER.

The simple ulcer usually occurs in persons, in whom there is no constitutional defect connected with nutrition, circulation or innervation, and is usually the result of mechanical injury. The surface of such an ulcer is depressed, red, and presents irregular projections of granulating tissue all over; the margins consist of healthy skin of more than the usual vascularity, the borders appear white with an inner line of a pinkish hue, which shades off into the bright red of the granulation.

The treatment of simple ulcers requires nothing but cleanliness and protection for their cure.

Among the ulcers complicated with a faulty vitality must be distinguished the hyperesthetic and the asthenic ulcer. The former, also called the inflammatory ulcer, is characterized by a very red ulcerating surface, slightly swollen and bleeding readily. Its treatment consists of soothing applications, and I have been in the habit of prescribing a lotion recommended by Crocker:

- R. Pulv. calaminæ prep ℥ij.
- Zinci oxidi ʒiiss.
- Ol
- Aq. calcis rû ʒj.

M.

The asthenic ulcer may be erythritic; that is, abnormally hyperesthetic with little tendency to heal, and the torpid ulcer characterized by a very diminished sensibility. The former is best treated by nitrate of silver or the actual cautery in order to convert it into a simple healing ulcer.

The treatment of the torpid ulcer will be considered with the treatment of the callous ulcer, which it resembles in many particulars.

Among the ulcers complicated with faulty secretion, we include the putrid ulcer, which on progressing causes a breaking down of the surrounding tissues and is changed to a phagadenic or gangrenous ulcer. The secretions are putrid and of a greenish-gray appearance. The treatment of this form of ulcer consists in the application of strong antiseptics, particularly carbolic acid, chlorid of zinc, sublimate, especially iodoform, which quickly destroys the smell. If the putrid ulcer has already become gangrenous, the destruction of the gangrenous parts, including some of the apparently healthy tissues, by the thermo-cautery is indicated. Thiersch has advised to make hypodermic injections of nitrate of silver 1:1500 into the cuticle at the distance of one centimeter from the margin, one centimeter apart, until the whole border of the ulcer is swelled.

Among the ulcers complicated with faulty granulation may be mentioned the fungous and hypertrophic ulcer. This form of ulcer is characterized by prolific exuberance of spongy granulations (wild flesh), extending far over the under surface of the ulcer. In mild cases it suffices to apply the stick of nitrate of silver to the granulations. If, however, the granulations have a tendency to grow and extend, it is advisable to remove the same with the scissors or the Volkmann spoon, under antiseptic precautions.

I will now confine myself to the discussion of the chronic ulcer of the leg, the callous ulcus cruris.

CALLOUS ULCER.

which is the typical ulcer of the leg, the old sore shin of the laboring classes, and the one which should chiefly engage our attention. It exists frequently without constitutional complications, in robust, healthy persons past the middle period of life. At first a simple sore, it suffers from neglect, the clothing irritates it and secretions are allowed to collect on and about it. In the beginning it tends to heal like any healthy ulcer, but it is injured again and again until each successive appearance increases its indolent and callous character. The surface is depressed and presents a yellowish-gray appearance, with perhaps here and there a red or pink granulation peeping through, the edges are elevated and abrupt, covered with a thick, scaly epithelium, the surrounding parts are hard, callous and infiltrated. The circulation is feeble and insufficient and showing no inclination to bleed.

The general practitioner, even the surgeon, does not take a correct view of the treatment of this chronic ulcer of the leg; the true nature of the disease is imperfectly understood, because the knowledge of its pathology is not properly comprehended; and it is not an uncommon thing to meet with

patients who have been afflicted with a sore leg for ten and twenty years or more. This is particularly true of the poorer hardworking classes, especially of women who have borne many children. Heretofore the treatment of this class of patients has devolved on the surgeon, and I believe only during the past years the dermatologists have taken a livelier interest in the therapeutics of the *ulcus cruris*. I am of the opinion that the treatment of this complaint belongs to the field of dermatology, as the *ulcus cruris* proper is virtually only a skin lesion, although many times associated with disturbances of remoter organs and irregularities of circulation.

The two main principles that govern the treatment of the chronic ulcer of the leg are rest and cleanliness, including protection. Unluckily, however, these two indications can not always be strictly carried out as in a hospital; the patient is unwilling to be confined to his bed for a trouble which does not concern his general health and welfare. Especially if we consider that it is usually the hardworking class which is so affected. Means must be devised to treat the patient ambulatory and this can be quite satisfactorily accomplished by the following methods of treatment. The one is according to the principles laid down by Dr. Unna of Hamburg, consisting of a zinc-gelatin dressing, which I am in the habit of applying in the following manner: after the ulcer itself has received proper attention by means of antiseptic washes and according to indications, make applications of nitrate of silver if there should be hypertrophic granulation, or iodoform if the surface is putrid, torpid and lacking granulations. The leg is washed and shaved and a moderately thick layer of warm zinc gelatin prepared according to following formula:

Zinci oxidi	30.0
Gelatin alb	40.0
Glycerin	50.0
Water	90.0

M.

Applied by means of an ordinary brush up to the limits of the ulcer. A small pad of medicated cotton or gauze is added as a covering to the sore, a gauze roller beginning at the toes, wound firmly around the limb. When a firmer dressing is required, for instance, if it is intended to remain for a longer length of time, I cover the above layer of gauze with another layer of gelatin and continue the bandage over the same from above downward. It is then allowed to cool off and become dry, whereupon the patient can be dismissed without further precautions. If the discharge is very profuse I repeat the identical dressing after about three days, until the discharge becomes less profuse, when I allow it to remain eight days and longer. The chief advantage of the dressing is: 1, the perfect protection it offers to the diseased parts; 2, the gentle but even compressor which is exerted on the leg by elasticity of the gelatin, for which reason it is especially well adapted for similar lesions in connection with varicose veins. Furthermore, the discharge is effectually prevented from coming into contact with the healthy skin. The simplicity and cheapness of this dressing are likewise greatly in its favor. Not only the ulcer, itself, is greatly improved by this method of treatment, but also such complications as are dependent on the ulceration, as edematous infiltration, chronic squamous eczemas and varicose conditions are permanently relieved by it.

Following is a report of the German Hospital, Dalston, of the treatment of *ulcus cruris* by Dr. Unna's method. It comprises sixty cases of the various forms of ulcers, viz:

Ulcer.	Healed.	Discontinue attending.	Unsuccessful.	Total.
Callous	14	6	2	22
Varicose	7	—	—	7
Healthy	7	—	1	8
Sloughing	2	—	1	3
Indolent	1	—	—	1
Syphilitic	—	—	2	2
Diabetic	1	—	—	1
Inflammatory	4	1	—	5
Eczematous	4	1	—	5
Eczema cruris	5	—	1	6

In connection with the above treatment I can not speak too highly of the great value of resorcin, in producing new epithelial formation, only second in value to actual transplantation of skin in the healing of ulcers. I usually apply it as soon as healthy granulations begin to make their appearance. It is most conveniently applied in a 10 per cent. plaster made by Beiersdorf in Hamburg.

Notwithstanding the remarkable and gratifying results obtained by above method with the zinc gelatin dressing, it is ineffectual where a callous, dense, infiltrated condition predominates and we must have recourse to other treatment, especially if the treatment is to be ambulatory. To accomplish this object, it has been customary for many years to apply a dressing first described and introduced by Boynton, which consisted of the application of strips of adhesive plaster, of the width of two fingers beginning below the ulcer and encircling the whole affected part of the limb tile-like, and finally wrapping up the leg in a flannel bandage. By this process the borders of the ulcer are drawn towards each other, the circulation improved and granulation encouraged. I have found much occasion to apply this mode of treatment with very good results. However, I have noticed that the plaster, unless it was a very good one, incited an inflammatory condition of the healthy surrounding skin and the discharge escaped from the ulcer and communicated with the adjacent normal parts. I, therefore, substituted for the ordinary adhesive plaster, the diachylon plaster or ointment of Hebra, which exerts a beneficial action on the condition of infiltration, at the same time compressing the limb. In order to lessen the callous condition and hasten the absorption of the infiltrated tissues, I make use of a preparation of tar, preferably the *oleum fagi*, with which I paint the thickened surroundings of the ulcer.

The method I usually employ for callous ulcers is as follows: After thoroughly cleansing the ulcer and the leg with a corrosive sublimate solution 1:1000, I apply the *ol. fagi* to the infiltrated tissues surrounding the ulcer. I then take strips of diachylon plaster about two inches wide and one-third longer than the circumference of the leg or similar strips of linen covered with the fresh diachylon ointment, and beginning at the foot, encircle the leg in a manner so that one strip slightly overlaps the other up to the distance of the knee-joint. I find it a rule that the pain of the ulcer ceases after the first application, and within a week's time the sluggish, torpid and undermined appearance of the ulcer is changed to that of a simple, healthy granulating one. At the beginning of the treatment, I change the dressing daily, until the discharge becomes less profuse, when

a period of four or five days may elapse before a new dressing is needed. I find it necessary to treat the ulcer locally at each change of the dressing, according to indications, washing it with antiseptic solutions, applying iodoform when the granulations are sluggish, and nitrate of silver or the ferrum candens where the granulations threaten to become hypertrophic. I believe that this treatment conscientiously carried out will in the great majority of cases, prove successful.

FIBROID TUMORS OF THE UTERUS.

TREATED BY DR. FRANKLIN H. MARTIN'S OPERATION OF LIGATING THE BROAD LIGAMENTS—TWO CASES.

BY J. B. GREENE, M.D.

MISHAWAKA, IND.

Mrs. P. of Grand Rapids, Mich., had for several years been a subject of frequent and profuse uterine hemorrhage; during the years of 1892 and 1893 she suffered greatly with pelvic pain, and constipation. In November, 1893, I was sent for to perform hysterectomy, the physician in charge having diagnosed the case as one of uterine fibroid. Upon examination I found a fibroid almost completely filling the pelvic basin, and so adherent that it was entirely immovable. I should judge that the tumor would weigh ten pounds at least. I did not look upon hysterectomy in that case as promising much more than a coffin, and as I had but a short time before had a talk with Prof. F. H. Martin of Chicago, on his recent experiment in the ligation of the uterine arteries, (this conversation was before Prof. Martin had reported his experiment) I determined to adopt that method, adding thereto the ligation of the ovarian arteries, or one of them. Accordingly I made the ligation of the uterine arteries and a part of the broad ligament after the method described by Martin, but found it impossible to reach the ovarian artery per vaginam. I then cut through the abdomen, and with considerable difficulty was enabled to pass a ligature around both ovarian arteries, passing my needle under the Fallopian tubes, and then back and around the vessel, tying close to the uterus; the uterus showed such a great engorgement of blood that I felt certain there would be no danger of gangrene of the uterus, as there was sufficient collateral circulation from branches of the ovarian artery to maintain life in the organ. After the operation I left the patient in the care of her physician, hearing from her several times during the first two weeks, each report being favorable; after that I heard nothing. Jan. 9, 1894, I was in Grand Rapids, and called upon her. I was indeed surprised to see the great change that one year had made. She was the picture of health, and she informed me that she had never been better. She granted me the privilege of an examination. I thought that I could discover some enlargement of the uterus still remaining, but, if so, it was so slight that it was not worth considering, in the light of the great decrease in the size of the growth. She menstruates regularly and apparently normally, excepting that she has a slight pain during the first day, not often of sufficient severity to cause her to take her bed.

In August, 1893, I was called to see Mrs. H., Mishawaka, Ind., age 31 years. She had for two years been suffering with repeated floodings, not profuse, but frequent. Examination revealed a subserous fibroid in the posterior uterine wall, about as large as an unhulled walnut. She was anxious for relief, but objected to hysterectomy until everything else had been tried. I, therefore, decided to ligate the uterine arteries. She suffered no pain, and I was unwilling to ligate nerve fiber if I could avoid it, accordingly I passed a "guy" through the cervix and close to the os made an incision, entirely encircling the cervix, down to the cellular tissue; then with a "spud" or dry dissector I peeled the tissues back almost to the peritoneum. The uterine arteries were thus brought plainly into view, and with no trouble I passed my ligatures around them, tied and cut them short; then drew down the external uterine coat and with a continuous catgut suture I stitched it in natural place. I had no trouble with the case after; she never had a fraction of a degree of fever, suffered no pain, and in two weeks was out of the house; has menstruated regularly ever since, and has had no floodings. I have not examined her since, so can not say as to the condition of the tumor.

TECHNIQUE IN TÆNIA TREATMENT—REPORT OF A REMARKABLE CASE.

BY C. M. FENN, M.D.

SAN DIEGO, CAL.

In the absence hitherto of any unfailing tænicides or specifics, it may be profitable to inquire if there are any other methods available for the safe and certain expulsion of the various cestodes. Personally, having abandoned the search for such a remedy, for the reason that it might imperil the well-being of host as well as guest, I find that some of the standard tæniacides, if employed in adequate doses and supplemented by attention to certain details, to be noted farther on, may be made to accomplish all that we desire. For example, during the local prevalence of tape-worms which followed the importation of a measly herd from Mexico, some years ago, I came to use kameela in doses of 8 to 12 grains (3ii-3iii), and ethereal extract of male-fern to the extent of 4 to 10 grams 3i-3iiss). These apparently large doses, exceeding those recommended by the authorities of that period, were successfully administered and upon the hypothesis that a parasite which merely imbibes its sustenance, having neither mouth or intestine, and suckers for prehension only, must require quantity as well as quality. In the matter of details referred to, jalap was selected for the before and after cathartic, in preference to several others commonly used. For instance, castor oil, so widely commended in such cases, was believed to be deficient as a peristaltic persuader and practically inert in the presence of mucus. Senna is equally insufficient in its action and aloes correspondingly tardy, expending its force on the lower bowel. Jalap, on the contrary, besides having somewhat of an anthelmintic reputation is safe and admirably adapted for children, to whom it may be given clandestinely in gingerbread or cookies. Following the last dose of the purgative it is advisable to employ frequent enemata of cold water, with or without salt or soap. These appear not only to chill the worm but to measurably increase peristalsis.

Of the three species of tæniæ which mature in the human intestine, tænia saginata, tænia solium and *bothrioccephalus latus*, the first is of more frequent occurrence in tropical latitudes like this owing, doubtless, to the greater consumption of beef in comparison with other meats.

That tænia solium (pork-worm), however, is not unknown here may be inferred from the following case which may also be considered a fitting résumé of the foregoing remarks:

A little boy, on his first legs, injured a toe, to which his mother applied a bit of fresh pork. A second application, soon required, was about to disappear as mysteriously as the first when he was detected in the act of eating it. Three or four months later during a convulsive seizure several segments of a tænia solium were expelled. Believing it to be an instance of *post hoc propter hoc*, active measures were then taken to relieve the child of his unwelcome guest, and before reaching his third year he passed through ten severe ordeals, expelling in the aggregate 110 feet¹ of tape worm! The first three doses, by homeopathic direction, the parents believe were kouso or kameela in combination with some other drug. At all events, after each attempt the child was "sleepy, feverish and a source of great solicitude for twenty-four hours." A fourth dose by another attendant was known to consist of 15 drops of chloroform and one drop of croton oil! This was followed a few weeks subsequently by an emulsion of creasote. Still later, at the suggestion of

¹ Measurements reported by parents.

friends, two attempts were made with emulsions of pumpkin seeds. In justice to all parties, it is proper to state that in every instance starvation and purgation with castor oil, castoria, etc., were rigidly enforced. This is confirmed by an incident in the history, when the little patient led his only sympathetic relative to the cupboard and with tears running down his cheeks exclaimed: "Grandpa, I'se so f'ungry! I'se so hungry!" Meanwhile, reports of the case had reached relatives in the East, who immediately sent out a quantity of pelletierine tannate, with assurances of success. Two trials of this specific (?) quickly followed bringing away a few feet of the worm as other remedies had done. A small dose of the pomegranate alkaloid remained, but in view of previous failures it had almost been decided to await the natural demise, or suicide (?) of the parasite at the end of four or five years.

The tenth and successful assault was reluctantly undertaken by the writer. Though I should have preferred kouso or koussin for a child, the remainder of the pelletierine was given.

Without special restrictions as to diet a full dose of jalap preceded the taniafuge about twelve hours, and was repeated next day an hour or two after the exhibition of the anthelmintic. After thoroughly scotching the parasite, indicated by the appearance of large segments in the dejections, frequent enemata of plain and salt water were employed. Traction upon the worm was interdicted, but rather it was advised to strap the protruding extremity to the nates and continue injections. At a later hour the head intact and erect with fifteen feet of the tænia gave assurance of its unconditional surrender after a siege of nearly twelve months.

CONJUGATE DEVIATION OF THE EYES WITH MIDDLE EAR SUPPURATION.

Read before the Chicago Medical Society, Jan. 8, 1894.

BY OSCAR DODD, M.D.

ASSISTANT SURGEON ILLINOIS CHARITABLE EYE AND EAR INFIRMARY;
CLINICAL INSTRUCTOR OF EYE AND EAR COLLEGE PHYSICIANS
AND SURGEONS, CHICAGO.

Upon June 13 last, I was called in consultation to see the following case, on account of the serious symptoms which had supervened three days before. The history of the case was given as follows:

John W., aged 18, had a discharge from his left ear during childhood. This had ceased and remained well until the present attack. After having influenza seven weeks ago, a severe otitis media on the left side with profuse discharge followed. Under treatment he was progressing favorably until three days ago when he had chills, severe pain in left side of head, dizziness and vomiting, since which time his temperature has ranged from one-half to three-quarters of a degree above normal, but has not exceeded that at any time. It was also noticed that the discharge was less profuse.

Condition Present.—Patient very weak, perspiring freely. Temperature 99 degrees. Pulse 120. Dizziness so bad he could not stand or walk alone, having a tendency to fall to left side, and the dizziness did not entirely disappear upon lying down. Moving or rising from the bed was always followed by a spell of vomiting. Pain over left side of head. Mastoid process normal in appearance and only tender upon pressure at one point behind meatus, corresponding to the antrum. Meatus filled with thick creamy pus tinged with blood. After removing this, a polypus about the size of a pea was seen projecting through a perforation in the upper part of the membrana tympani and covering a small perforation in the lower part. After removing the polypus with a snare the openings seemed large enough to allow a free exit for the pus. Upon examining the eyes I found that the movement of both to the right was defective but could be overcome by an effort.

June 14. The patient felt somewhat better, pain in left side of head had disappeared and the dizziness and vomiting were less severe. Temperature normal. Pulse slower. The eye symptoms were more marked, as they were unsteady when looking directly in front and could only be moved to right of median line with difficulty. No diplopia. Slight paresis of left facial nerve, more marked at lower part of face.

June 15. Patient improving but still very weak and dizzy upon moving. Both eyes were strongly deviated to

the left side and could not be turned to right of median line. The impairment in movement was about equal in each eye when tested separately. There was no diplopia and none could be elicited by careful testing. Convergence seemed to be retained for objects when held to left side. Pupils normal in size and reaction. Vision was not perceptibly impaired. Field of vision normal. The paresis of left facial nerve had disappeared.

June 16. The condition of the eyes was the same as on previous day. Dizziness still continued but patient could walk without assistance. As the perforations did not allow a free flow of pus I enlarged the lower one by a horizontal incision.

The improvement continued and the dizziness and ocular symptoms gradually disappeared within a few days, so that when he called at my office, two weeks later, no trace of any ocular trouble could be seen. Vision was normal and movement of the eyes perfect. The discharge from the ear was less profuse.

The suppuration ceased about a month later, and nothing now remains of the ear trouble but a slight amount of deafness with tinnitus, the perforations having cicatrized.

The important question in the treatment of this case was the cause of the ocular symptoms. Were they due to an affection of the brain or the meninges, and if so, what was its nature; or were they only a reflex symptom from irritation of the auditory nerve? In favor of the former view were the severe general symptoms as the chills, fever, dizziness and vomiting; but considering the speedy termination of the symptoms after the local treatment and the peculiar muscular symptoms, I am of the opinion it was the latter.

In support of this view is the intimate connection of the auditory nerve with the nerves governing the movements of the eye, especially those of conjugate lateral movement. Associated lateral movement of the eyes is under the control of a single nucleus, that of the abducens or sixth nerve. This nucleus, besides supplying the external rectus of the same side, also sends fibers which, according to most authorities (Fuchs,¹ Morris²), join the third nerve of the opposite side and go directly to supply the external rectus or, as Gowers³ believes, go to the nucleus of that portion of the third nerve supplying the internal rectus. This innervation is separate from that governing convergence, which is supplied by the nucleus of the third nerve.

A connection of the auditory nerve and the nucleus of the abducens has been demonstrated anatomically. S. Freud⁴ describes a connection of the vestibular portion of the auditory nerve by curved fibers going directly to the nucleus of the abducens of the same side. Other authorities, as Politzer⁵ and Gowers, consider the superior olivary body as the center for reflex movements of the eye, as it receives fibers from the auditory nerve and is directly connected with the abducens nucleus.

To show the direct connection of the movements of the eyes with aural vertigo, a number of physiologic experiments have been performed. Cyon⁶ found that operation upon the semicircular canals of different animals gave different results. In rabbits they were manifested principally by movements of the eyes. He also found that they were not compensatory, but came directly from irritation of the nerve. Irritation or section of one auditory nerve would produce a strong deviation of the eyes to the same side. Upon section of the other nerve the deviation would cease.

Lucæ⁷ experimented upon some of his patients by increasing the pressure in the tympanic cavity. He found that by increasing the pressure, lateral nystagmus was produced, and when still further increased

to 0.4 atmospheric pressure, the eyes were deviated to the same side.

Högyes⁸ showed by a number of experiments upon animals that associated movements of the eyes and dizziness are produced by irritation of the endings of the auditory nerves. He considers that he has demonstrated a reflex cycle, consisting of the muscles of the eyes and the ampullary nerves, by which a reflex stimulation is transmitted from the labyrinth to certain ocular muscles. He found that movements were different according to the portion of the labyrinth affected, e. g., by irritating the horizontal semi-circular canals or ampullæ, there was oscillation or deviation of the eyes in a lateral direction toward the irritated side.

Baginsky⁹ also produced nystagmus and, when the pressure was increased, conjugate deviation of the eyes to the same side, by the injection of fluids into the tympanic cavities of young dogs. He believed that the symptoms were due to the increase of the cranial pressure, as the fenestræ were always ruptured by the force employed.

Besides these physiologic experiments, clinical observation has shown that pressure in the tympanic cavity and irritation of the auditory nerve will produce ocular movements. Kipp¹⁰ saw nystagmus in three cases of middle ear suppuration. It could be produced at will by syringing the ear or touching the tympanic wall with a probe. Pflüger¹¹ saw a woman, age 65, with otorrhea accompanied by dizziness. There was a polypus in the posterior superior part of the meatus, partly attached to the wall of the tympanic cavity. Lateral oscillating movements of the eyes were always produced whenever this was touched with a probe or an attempt made to remove it. Cohn¹² reports four cases of nystagmus with middle ear suppuration. The eye movements could be easily produced by syringing or irritating with a probe. He considers the movements due to a reflex from irritation of the auditory nerve, the inflammation having rendered the endings of the nerve in such a condition as to make this possible.

C. R. Holmes¹³ of Cincinnati, reports a case where conjugate deviation of the eyes to the left side, with severe dizziness and vomiting, lasted about two hours after an operation on the mastoid. The attic and antrum had been opened and the stapes mobilized with a probe. The eyes could be moved past the middle line by a severe effort, but would return at once to the extreme position toward the left.

Dr. Spear¹⁴ of Boston, with the assistance of Dr. Chandler, acting upon the statements of Högyes that the semi-circular canals and the vestibular portion of the auditory nerve were a peculiar end-apparatus regulating the movements of the eyes, examined a number of ear cases with dizziness and unsteadiness of gait as to their ocular symptoms. The results of their investigations showed an intimate connection between the sixth nerve and the vestibular portion of the auditory nerve. All patients with dizziness had exophoria of varying degrees dependent upon the intensity of peripheral irritation.

One case, a strong, able-bodied man, had a post-nasal hypertrophy of the right inferior turbinated occluding the Eustachian tube, severe otitis media with a small perforation of the membrane, the exudate causing pressure on the fenestræ, unsteady gait, staggering forwards and to the right. He appeared to have complete paralysis of the internal rectus of

the right eye with diplopia, as it was strongly deviated outwards and could not be brought to the median line. After applying cocain to the hypertrophy, in about ten minutes the patient could converge and walk naturally, and the pain in the ear and side of the head ceased. Another case with swelling of the turbinated and closure of the Eustachian tube had a divergence for which prisms had been given. Upon removing the obstruction to the Eustachian tube the movements of the eyes became normal. These cases were undoubtedly due to a spasm of the external rectus muscle from reflex irritation through the auditory nerve as Dr. Spear considered them. Why there was not deviation of both eyes instead of one is hard to explain, unless, as Gowers³ states, there is a center regulating the conjugate movements of the eyes aside from the abducens nucleus, probably the superior olivary body, slight irritation of which only affects the external rectus, but when the irritation is increased the internal rectus of the opposite side and ultimately the head is deviated.

I have not taken into account here the large number of cases with conjugate deviation due to lesions of the brain, either in the cortex, corona radiata or nuclei. Knies¹⁵ states that conjugate deviation to the opposite side may be produced by irritation of almost any portion of the cortex, but especially the cuneus or occipital lobe, the cortical center for vision, but if the lesion is sufficient to produce paralysis, the eyes will be deviated toward the affected side. But a cortical lesion in this case sufficient to produce a deviation toward the affected side would have been accompanied by some other symptom of paresis or paralysis or have affected vision to an appreciable extent. Of the large number of cases reported with conjugate deviation due to a cortical lesion they were all accompanied by some other symptoms such as deviation of the head, hemiopia or some affection of vision, and paralysis or paresis of the muscles of the opposite side of the body.

A lesion involving the pons or nucleus of the sixth nerve on the same side, could produce these symptoms alone, provided it was slight enough to only produce an irritation, but nuclear lesions are rarely so limited as that. It is not probable that a nuclear lesion could have been present in this case, considering the rapid termination and absence of later trouble.

A basilar meningitis would have affected the nerves during their course and the manifestation would have been that of a peripheral lesion. The sixth nerve would have been affected without the implication of conjugate movement, which is distinctly a cortical or nuclear manifestation.

The occurrence of the facial paralysis is of no special importance, as it occurs very frequently with middle ear suppuration from the extension of the inflammation to the Fallopian canal.

In reporting this case, I do it hoping that while it is unique (as I was unable to find a parallel case in the literature) it may be of service in calling attention to the fact that reflex movements of the eyes simulating paralysis or paresis, may be due to local affections of the ear. While the cases cited here only touch upon certain points, I think they are of service in justifying my diagnosis of a reflex spasm of the ocular muscles due to irritation of the auditory nerve.

CAN TYPHOID FEVER BE ABORTED?

Read before the Mississippi Valley Medical Association, October, 1893

BY J. E. WOODBRIDGE, M.D.
YOUNGSTOWN, OHIO.

The answer echoed and reëchoed from the great thinkers of the profession we all love and practice, from all over the civilized world, is one prolonged and emphatic negative, nowhere more emphatically spoken than in the great representative body of American physicians—the AMERICAN MEDICAL ASSOCIATION. At its last meeting in the city of Milwaukee the original papers, the discussions on them, and the editorial comments in the Society's JOURNAL clearly indicate this, and that the medical profession is not at all agreed on its treatment. The most divergent methods were advised; some condemned what others strongly advocated, these again advising different methods, only to be condemned again, and all were finally disposed of by the editor of the ASSOCIATION JOURNAL, who under the caption, "The Treatment of Typhoid Fever," says: "In the topic which heads this editorial the medical profession is certainly as much interested as it is in the treatment of pulmonary phthisis. The able papers and discussions which we have presented to our readers in the columns of this JOURNAL, during the past few weeks, have been of great value as reflecting the opinions of active practitioners whose practical experience is of inestimable service to less favored colleagues, yet the fundamental rules governing the management of enteric fever are not modified by these expressions of opinions. Differences in belief may exist, as to whether intestinal antiseptics is desirable or obtainable in typhoid fever, and whether this temperature or that, is to be treated as a dangerous symptom; but the important fact, that enteric fever is a disease in which good nursing and watching are the real factors productive in bringing about recovery, is universally recognized. In typhoid fever, above all other diseases, the physician must recognize that a cure is impossible, that he can guide the patient through the storm, but not stop the storm, that the only object he may expect to accomplish is the control of symptoms which directly or indirectly affect the patient unfavorably.

"While he may not be able to remove the cause of the symptoms, the very relief may be advantageous; then a delirium indicative of great physical or mental distress, or the presence of some complication inducing pain, may so exhaust the patient's vitality as to seriously impair his chances of recovery, and measures directed to the relief of these symptoms may save the particles of strength needed to carry the case over some crisis in his attack. There is, therefore, no specific or routine treatment by internal methods which should be resorted to when the diag-

nosis of typhoid fever is established, but there are two external methods aside from feeding which may be applied to so nearly every case as to be called routine, namely: absolute rest in bed, flat on the back, and the use of the bath in a more or less modified form; a simple mixture designed to maintain free action of the kidneys or stomach may be advised in each case, chiefly to comfort the patient and his friends, but beyond this nothing is to be used without a distinct indication by some prominent symptom. The necessity of absolute rest in early stages of enteric fever is known to every one, yet it often requires the most strenuous efforts on the part of the physician, particularly if he is not aided by a trained nurse, to maintain the degree of rest necessary. If there is one factor potent in rendering a prognosis unfavorable in enteric fever, it is the neglect of this precaution in the smallest detail, and every rising to stool may be regarded as a most unfortunate cause of future trouble and danger. The use of the bath, or more correctly water in any form during typhoid fever stands next in importance and next in its approach to routine.

"It is a mistaken idea with many physicians that the water treatment of typhoid fever is solely indicated by high fever; nothing can be more erroneous. While high temperature is without doubt a most important indication for the bath treatment, extreme restlessness is also a positive reason for its employment.

"Farther than this, there can be no doubt that the use of water not only lowers extreme temperature, but prevents its rapid return, and in some way advantageously modifies nutritional changes.

"Restlessness and insomnia accompanying fever too slight to require the full bath, are often entirely relieved by a tepid sponging, which soothes the irritated skin, and equalizes the circulation, refreshing and invigorating the patient.

"Each part sponged should be immediately rubbed dry, so that the patient may not be relaxed by soaking. We presume this does not apply to the cases of high fever, in which friction with the hand must be used to bring the blood to the surface where it may be cooled. We have not tried to indicate in this article the medicinal treatment required by various complications, as space forbids, but we are sure that if these views are followed, complications will be less frequent and a firm basis maintained for rational measures sometimes necessary for the relief of accidents."

These are the expressions of the matured thoughts of the members and of the editor of the JOURNAL of that ASSOCIATION, of which one of the leading medical periodicals of Great Britain, a not too partial critic, said nearly a quarter of a century ago: "That it is probably the most learned medical body in the world." I do not believe the great AMERICAN MEDICAL ASSOCIATION has taken any retrograde steps, and I do believe that we may accept these opinions, emanating from its members and from the trusted editor of its JOURNAL as coming, not only from the most learned medical body, but as the expression of the most advanced opinions of the highest medical authority in the world. And yet these are not extreme views. Everywhere you turn in medical literature, you see the same dark and gloomy picture of typhoid fever.

Now and then a new remedy is proposed, or some

one advances slightly more hopeful views, but he and his futile hopes are soon buried in oblivion, and his hapless patient in the ground, and no one dares to say that the physician ought to or can, cure the disease.

I fully realize the responsibility he assumes who would undertake to criticise adversely the teachings of a hundred generations of thinkers. It is said that "old beliefs die hard," and the one I propose to endeavor to destroy has all the charm of extreme antiquity. Long before typhoid fever was isolated from typhus it was taught, as the great teachers now teach, that it could not be cured, but must run its course. Then a new era dawned—typhoid fever was recognized as a distinct disease, and yet the same theory was promulgated, and in almost the same language, used in the teachings of 1893. Time passed; the profession made most wonderful strides in the pursuit of knowledge. It was learned that many diseases, and among them typhoid fever, were due to, or at least accompanied, by a germ in some sense peculiar to themselves, and yet the same teachings were again handed down. Let us take them up with iconoclastic hands, and see if the pitiful story that typhoid fever can not be cured, may not be retold in a more cheerful vein.

On the seventeenth of July, last, I read a paper in my local society in which I said: "Those of you who were present at the meeting of this Society, held in my office twelve or fifteen years since, when this disease was under discussion, will remember that in criticising a paper on typhoid fever I said, that while the paper was in strict accordance with the teachings of the best authorities on the subject, that I thought it was so radically wrong that if you would leave undone everything the author said to do, and do everything he said not to do, you would be nearer my idea of the correct treatment of the disease; which I proceeded to give in detail. It was not, however, well received. The author of the paper condemned it most severely, but afterwards said in the Society that, although he had condemned the treatment in the very strongest language at his command, that I had set him to thinking, and he had searched his library for my authority without finding any; that there was nothing in the books bearing on my theory, but nevertheless I was right, and he would not now dare to treat a case of typhoid fever in any other way. I wish now to call your attention to a few cases, illustrating the most marked results of my work during the intervening years, selecting only such cases as were diagnosed by able physicians; bore such well-marked symptoms characteristic of, or were surrounded by such circumstances, as would indicate beyond the possibility of a doubt, that they were true typhoid fever.

At this point I wish to express my regret that of my earlier cases no bedside charts were kept. No idea had entered my mind of inflicting my theories upon an already over-worked profession.

The bedside charts of the later cases are in my possession and open to the inspection of any member. The limits of this paper will, however, only admit of the presentation of the most salient features of those cases which best illustrate a point. And in estimating the value of the cases, you will please bear in mind that none of the teachings of the editorial were followed in my practice. Patients were allowed to get up, or move about, or go out of doors at pleasure.

Nurses, trained or untrained, were allowed to sponge them or not sponge them. No other baths were given, except to meet the ordinary demands of cleanliness.

Very little effort was made to "control symptoms." No "simple mixtures designed to maintain free action of the kidneys or stomach chiefly to comfort the patient and his friends" were ordered. No medicine was ever exhibited for the purpose of directly reducing temperature, and while the patient and his attendants were generally cautioned against the danger, real or supposed, of eating solid food, the warning was not always heeded, some eating on the seventh to twelfth day; others all of the time.

On July 17, 1882, I was called to see Dr. Ferran's son after the attending physician had made a diagnosis of typhoid fever. He made a complete recovery in twenty days. His temperature having been nearly normal for several preceding days.

A young gentleman died of typhoid fever on Rayen Avenue. Clara Potts lived in the same house and assisted in taking care of him. Three or four days later I was called and made a diagnosis of typhoid fever, and answering direct questions, I said she would probably be well in ten or twelve days. Later I was told that another physician had made a previous statement, that the girl had typhoid fever and would be ill four or five weeks at the least. Her temperature went up to 104 $\frac{1}{2}$. Tympanitis and rose-spots were well marked. She made a good recovery and drove out on the twelfth day.

The wife of one of our leading druggists, W. W. McKeown, had typhoid fever. She made a good though not very rapid recovery. Mrs. Johnson Wick and her son both had typhoid fever; recovery in eleven and fifteen days respectively.

Last winter when typhoid fever was so fatal at Beaver Falls, Mr. Louer, Jr., was brought home with the disease from which he recovered in twelve days.

Ulysses Speer was brought home from a boarding house in Wampum, where at least one death had resulted from typhoid fever. Dr. Wickham made a diagnosis of the disease and treated him three days, when I was called. I found a well-marked and typical case of typhoid fever with a history of ten days' sickness. Temperature 105 4-5; pulse 124; bowels very tympanitic, petechia abundant, tongue brown, hard and dry, stupor so profound that he could with difficulty be sufficiently aroused to show it. My first visit was made on October 25. The last on November 3, when he was sitting up. On November 10 he called at my office and settled with me.

When typhoid was so prevalent and fatal near the corner of Bryson and Spring Streets, I was called to see the two daughters of Jos. Dore, diagnosed as typhoid fever by a nurse of long experience in the disease; found both cases well marked. Both recovered in less than ten days. John H. Walker, who lived in the same locality made a good recovery in ten days. His symptoms were well marked.

Thomas Evans of Girard, came to my office. After examining him two or three times I told him he had typhoid fever. When he told me that his wife was very sick, I gave him medicine for her and himself and told him to send her to me as soon as possible. The next day I found her lying on the sofa in my office, having come by train five miles. Her temperature was 104 $\frac{1}{2}$; bowels very tympanitic and tender, and all symptoms pointed to a very severe attack of typhoid fever. She was told to come each alter-

nate day to my office, as was also her husband. The latter was permitted to work at his usual occupation, that of a stationary engineer, throughout his illness. After a few days, Mr. Evans told me that the doctors in Girard were laughing at him for going away from home to a — fool of a doctor who would tell him that he had typhoid fever and could work. I asked him if they doubted his ability to work. He said: "No, they know I can work; they say I have not had typhoid fever." I told him that if that were true, when he and his wife recovered, that would be the end, while if they had typhoid fever there would be more cases around them. Within a few weeks thereafter, I was called in consultation to nine or ten well-marked cases along the Little Valley in which they lived, and all within a stone's throw of their home. After several had had hemorrhage of the bowels, and four or five had died, there was no further question as to the character of the disease.

The President of this Society can tell whether some of these cases were typhoid fever or not. So, also, can the distinguished ex-President of the Ohio State Medical Society now present. Mrs. Evans was not able to come regularly, but had occasionally to miss two days at a time. She was refused passage by one of the railroad companies, and had to travel by the less convenient route.

On May 8, 1893, I was called to see G. W. Powers near North Jackson (whose son had just died of typhoid fever after repeated hemorrhages of the bowels) and found that Mr. Powers (who had nursed his son thirty-five days) had himself been ill with typhoid fever seven days. I assured him that he was in no danger of dying and that he would probably be well in ten or twelve days. He had a normal temperature on the tenth day.

On May 27, I was called again to North Jackson to see Wallace Eckenrode (the son-in-law of the last case) who I believed had typhoid fever, a belief which was not shared by his family physician who promised if I would leave the case in his hands, to telephone me within two days. I heard nothing more of him until I saw the notice of his death, from typhoid fever, in the local paper.

Prior to the date at which this series of observations begins, I had had large experience in the treatment of typhoid fever with unsatisfactory results, and when I listened to the papers read in the Section of Practical Medicine, at the AMERICAN MEDICAL ASSOCIATION in Washington, I was reminded most forcibly of these earlier experiences, and my imagination pictured them in sharp contrast with the happier results of later years; and wishing that others might share with me the pleasure of curing so dread a disease, and that humanity might benefit by any knowledge I might possess, I told the Chairman of the Section, Dr. Victor C. Vaughan, that if possible I would prepare a paper and read it in the Section before adjournment, advising a more hopeful method of treatment. My work on the committee for reorganization of the Section, however, took so much time that the preparation of a paper was an impossibility. On the last day of the meeting Dr. Vaughan reminded the Section of my unfulfilled promise. I then said I hoped to be able to present the paper on the treatment of typhoid fever at the next meeting. Anxious to present a good array of aborted cases with their treatment, I availed myself of the opportunity of criticizing a paper on the treatment of typhoid fever, read in my local Society,

and, after condemning some of the remedies advised as worse than useless, since they tended to aid the disease to destroy the patient, (a criticism justly applicable to many of the methods of treatment advised by some very learned professors) said, that having long believed the disease to be due to a germ whose earliest habitat in man was the alimentary canal, that the logical conclusion was that gastro-intestinal asepsis should be the prime object of treatment, and when it could be obtained the problem of the abortive treatment of typhoid fever would be solved; that I believed I had already attained it, and that if any member of the Mahoning County Medical Society would aid me in making a demonstration, I would not only provide medicine and treatment free of charge, allowing all fees to go to the said members, *but that I would pay him a dollar and a half for each day of treatment after the tenth.* I then consulted the President of the Ohio State Medical Society, as to the advisability of publishing a paper on the treatment of the disease, and was advised not to do so until I had demonstrated to the profession that the methods in vogue could be improved upon.

On receipt of a letter from the Mayor of the City of New York, I went there and spent a week seeking an opportunity to demonstrate the curability of typhoid fever, under the observation of some of the learned professors of the metropolis. Failing, I returned home discouraged. I tried Philadelphia next, and for ten days devoted myself to a fruitless effort to have some one give my method a trial without publishing a treatment that might prove valueless or misleading. Again I returned to my home, this time most heartily discouraged. Believing myself to be able to cure the most fatal disease of the Mississippi Valley, I did not dare to give to the world a treatment that on more thorough trial might prove to be a failure in the hands of more able but less enthusiastic practitioners, and the action of which I could not then and can not now explain. After this I corresponded with the health departments of all the principal cities in the United States and Canada, and to the honor of these gentlemen be it said, not one failed to give me all the information in their power; often at an outlay of great labor and no doubt considerable expense. I give them, one and all, most hearty thanks. During the intervening years, I visited the most important cities from Potomac to the Pacific coast. In Pittsburg, in St. Louis, in Washington, I gave the principals of the largest hospitals, where typhoid fever was treated, the best knowledge I possessed at the time. They politely promised to try it and probably forgot all I had said before dinner. In Chicago, I succeeded in interesting the Commissioner of Health, Dr. John D. Ware, who asked me to give him a letter that he could show to the superintendents of the hospitals, and as this letter and the answer may become, in the future, interesting reading I present them here:

YOUNGSTOWN, OHIO, May 5, 1892.

JOHN D. WARE, M.D., Commissioner of Health, City of Chicago.

My Dear Doctor:—You are well aware that in writing in fulfillment of my promise to you, and giving expression to my peculiar views of typhoid fever, I am winning for myself the uncoveted cognomen of "crank."

You will remember I told you that I believed the life of every uncomplicated case of this dread disease could be saved; that I believed the disease could be aborted, and that I believed the excreta from properly treated cases of typhoid fever would prove to be innocuous. Long before I

even hoped for such results I believed that the disease was due to a germ; that the germ was, in the earlier stages of the disease, confined to the alimentary tract; and that if the entire tract could be saturated with a germicide at once fatal to the germ, and harmless, or better still, beneficial to the patient, the happiest results would follow.

That I have for fifteen years been doing all this without having published a word about it, should not be a discredit to me since it has taken years of testing to satisfy even myself, and no one likes to have to eat his own words, especially after they have gone into cold type.

Now, Doctor, if you can, as soon as possible, secure a ward for male and one for female patients, with a day and night nurse for each ward, and give me as many cases as possible, none of which have had the disease more than eight days, I will go to Chicago and appear before a committee of your selection, consisting, of course, of members of the regular profession upon whose judgment and integrity you could rely; explain to them fully my plan of treatment, and if they find any medicine that I wish to administer is in the proper dose dangerous, they shall refuse permission to make the test, but for no other reason; you to invite any members of the regular profession, as many as you wish, to watch the patients from day to day, and if my test is entirely satisfactory I am to have the privilege of giving the treatment and the results of the test to the profession through the AMERICAN MEDICAL ASSOCIATION.

Very respectfully, JOHN E. WOODBRIDGE.

CHICAGO, May 27, 1892.

JOHN E. WOODBRIDGE, Esq., 29 W. Federal St., Youngstown, Ohio.

My Dear Doctor:—Your letter of May 5 arrived while I was away from the Department sick. I did not return until the 20th, and have endeavored from that day to this to interview the physicians at different hospitals relative to the subject matter of your letter.

Replying I will say, I have visited the superintendents with whom I thought possibly I might prevail upon to coincide with our views relative to treatment of typhoid fever. I have also talked with some of the prominent men in the profession, and I believe without a single exception each and every one of them have said this: "Why does not Dr. Woodbridge read his paper before the NATIONAL ASSOCIATION next June?"

I have said all that I could say relative to the subject, which is one that I have become deeply interested in, but being only one man it has been impossible apparently to make any impression upon the members of the profession.

By reading between the lines you will probably understand more than is written. I do sincerely hope that you will read this paper before the NATIONAL ASSOCIATION as I believe that it would result in a revolution in the treatment of this disease. No one would dare question your paper so far as your results in the past have been concerned, no matter how skeptical they might be in some other matters.

Trusting that you will pardon the delay in replying, I am, sincerely yours,

JOHN D. WARE,

Commissioner of Health.

Finally, after having spent years of valuable time, much money, and traveled many thousands of miles, I heard of the epidemic of typhoid fever at Ironwood, Mich., and although I had been too busy to go to the Milwaukee meeting of the AMERICAN MEDICAL ASSOCIATION a few days before, I again sacrificed both time and money, and in a day was on my way to the scene of the worst epidemic of which I have any knowledge. It presented largely the characteristics and symptoms so common in our sporadic cases. In some cases, however, the poison seemed to be so virulent as to lead one to despair almost from the very outset. A good representative of this class was Miss T. S., No. 22, whose bedside chart I hand you.

When seen on June 25, 1893, her pulse, as you will see, was 120; her temperature 105; her bowels were intensely tympanitic, marked dullness over the spleen, tongue dry, hard and brown, slight wandering delirium, which soon became so profound that we were unable to take her temperature under the tongue again for several days. Altogether her con-

Case No. 22, Case 23. ———. Diagnosis, typhoid fever. Names T.S. and P. S.

Case No. 25, No. 27. No. 28. ———. Diagnosis, typhoid fever. Names, Mrs. S., Mr. S., Miss S.

Case No. 29, No. 30. ———. Diagnosis, typhoid fever. Names, J. A. and C. E., Cured in thirteen days.

dition was so bad that her attending physician, Dr. McLeod, a physician of marked ability, after the examination was completed turned to me and said: "You don't want that girl; she will die." I answered: "Not if I treat her." After our second or third visit, Dr. McLeod said, as we went away: "If you can cure that girl you are a dandy." Her temperature touched normal on the tenth day, but before she began to improve on the night of the third day, Dr. McLeod came to my hotel to tell me that she was exceedingly delirious, pulse 140, temperature, as well as could be taken in the axilla in her extremely restless condition, was $104\frac{3}{4}$, that her bowels were exceedingly tympanitic, and she was bleeding so profusely that he had to plug both posterior and anterior nares.

In the same room with T. S., No. 22, lay her sister, P. S., No. 23, taken sick at the same time; an equally typical though milder case; her temperature, as you see, was never high and was lower than normal on July 4, the ninth day of treatment.

The chart of Mr. F. S., No. 24, is very interesting as showing the result of treatment against continual reinfection. The case bade fair to be a very severe one, but the temperature of $103\frac{1}{2}$ of June 26, dropped to $99\frac{3}{4}$ on the 30th, and again rose on discontinuing treatment to $104\frac{3}{4}$ on July 2, when investigation showed that he was drinking water from a well from which a dozen very severe cases had originated.

Mrs. M. T., No. 25, temperature in the afternoon of June 25 was 103; the morning of June 26 was $103\frac{1}{2}$; was normal on July 9.

C. O., No. 26, on June 26, temperature 101; July 4, $98\frac{1}{2}$.

M. T., No. 27, on June 25, had a pulse of 120, temperature 103; on July 5 had a pulse of 84 and temperature $98\frac{1}{2}$.

Mrs. T., No. 28, on June 25 had a temperature of $101\frac{5}{10}$ which was reduced on July 4 to 98.

C. E., No. 29, on June 30 at 10:30 in the morning had a temperature of $100\frac{3}{4}$; in the evening the temperature was $102\frac{5}{10}$, and again at 8:15, $103\frac{5}{10}$, and on July 8 was reduced to $98\frac{3}{4}$.

J. A., No. 30, on June 26 at 7:30 P. M., temperature 103; on July 8 at 10 A. M., had a temperature of $98\frac{1}{2}$.

Mrs. L., No. 31, June 25, pulse 96, temperature 102; on July 5, pulse 72, temperature $98\frac{3}{4}$.

E. T., No. 32, June 25, temp. $101\frac{1}{2}$; on July 8, $98\frac{1}{2}$.

Mr. M., No. 33, June 25, in the morning temperature 102 and July 9, $98\frac{1}{2}$.

A. O., No. 34, June 28, pulse 120, temperature $103\frac{1}{2}$; July 8, pulse 72, temperature $98\frac{3}{4}$.

E. O., No. 35, June 23, temperature $103\frac{8}{10}$; July 9, $98\frac{8}{10}$.

G. T. G., No. 36, admitted June 26, highest temperature 104; July 9, temperature 97, pulse 76.

John A., No. 37, chart says that he had been sick three days when admitted on June 24. His treatment may be regarded as a failure. His temperature was $100\frac{6}{10}$ when last seen on July 9. He had probably been ill longer than we had supposed.

We made two or three such mistakes. One of the cases selected on the supposition that he had been ill less than eight days, was found to be dying of perforation of the bowels when we went to him to administer the first dose of medicine. Another case, after having been put under the treatment, showed conclusive evidence of having been well along toward perforation; died a few days later.

These records were kept by the physicians attending the patients, and by the trained nurses in the Typhoid Fever Hospital. The physicians were all gentlemen of unusual ability, and of very large

Case No. 41, ———. Diagnosis, typhoid fever. Name, J. H. Diet: Ate beefsteak on the seventh and eighth days of treatment, milk diet on the ninth, and solid food thereafter.

experience in the diagnosis and treatment of typhoid fever. Dr. McLeod, the able Superintendent of the Union Hospital, is a gentleman who would be an

ornament to the profession of the world's most enlightened capitals. Dr. Niven, the Health Officer of the city, is a gentleman whose skill and ability were factors of prime importance in fighting this fearful epidemic. Under his magic touch, the conception of to-day became the finished work of tomorrow; and the Armory, resounding to-day to officers' commands, became a hospital for typhoid fever, perfectly equipped under his able superintendence, and instead of echoing to the soldier's martial tread, the soft foot-falls of a corps of trained nurses scarcely broke the silence. It is enough to say of the nurses that they were trained in the city of Chicago, and it was the freely expressed opinion of both physicians and nurses that they had never seen typhoid fever patients do so well or feel so well. I present here a letter voluntarily handed me by Dr. Niven:

IRONWOOD, MICH., July 9, 1893.

This is to certify that all the patients whose bedside histories are in the hands of Dr. Woodbridge, were diagnosed as typhoid fever by Drs. McLeod, Niven, Holmes and Woodbridge, in the city of Ironwood, State of Michigan, and that they were all under Dr. Woodbridge's special treatment, no other medicine being exhibited during their sickness.

I also can state that in no case did any serious condition arise, as did in other cases treated side by side by the same physicians with the older, most approved methods of modern treatment.

J. K. NIVEN, M.D.,
Health Officer of the City.

Physician-in-Charge of Typhoid Fever Hospital.

On the day my paper was read in my local society, I was called to see Ed. M., No. 38, whose chart is offered. I found him with a temperature of 104½. The next day it was 104 2-5, and the day following, 104 4-5, from which time it gradually declined to normal the morning of the eighth day, although he had a slight rise of temperature for several days thereafter; he walked out on the eighth day; ate a slice of bread on the tenth day for supper. For breakfast on the eleventh day ate two slices of bread, two eggs and two cakes, and continued eating heartily from that time.

On July 24, his little son was taken sick and on examination gave the following register: temperature 104 which rose to 105, pulse 112 which was at one time 160, his bowels became intensely tympanitic, petechia appeared in profusion, and all symptoms pointed to an exceedingly severe attack of typhoid fever. Turning to Mr. Madden, with the thermometer in my hand indicating a temperature of 105, I said: "Fifteen years ago, had you been lying there with typhoid fever, your wife showing well-marked symptoms of the disease, and these symptoms present in this boy, I should have said sadly: 'he is very ill with typhoid fever; he will probably be sick four or five weeks or longer;' and if asked for a prognosis would have said: 'he is in great danger;' now I cheerfully say: 'He has typhoid fever; will probably be sick ten days or two weeks and may be mildly sick somewhat longer. There is no danger.'"

These cases were examined at various times by Dr. H. H. Hahn, Dr. Thomas, and Dr. Gibson, President of the Mahoning County Medical Society, and positively diagnosed as typhoid fever. You will find their statements on the charts.

On Aug. 11, 1893, I was called to see Lizzie, No. 39, who had been sick a few days prior to August 1 when she first consulted a physician, who reported a tem-

perature of 103 on that day, and treated her four or five days, when another physician was called who had not fully made up his mind whether she had typhoid fever or not. When I was called I found a temperature of 104½; I hesitated whether to attempt antiseptic treatment at so late a day; for six days the afternoon temperatures were 104½, 103½, 103½, 102 3-5, 101½, 101 1-5, when the evening temperature was 100 1-5. The improvement in the patient's general condition, however, was greater than the fall in temperature would indicate. She became cheerful, complained of hunger, and wanted to get up; the bowels which were tender and very tympanitic lost for a time all tenderness and tympanitis. Both, however, returned in a slight degree after a few days, and the temperature remained above normal for two or three weeks, all antiseptic treatment being abandoned after the twelfth day. This case is interesting as showing the effect of what I believe to be germicide treatment, even when too late to abort the disease. While visiting this patient I was called next door to see the daughter of ex-Marshal Crowley, symptoms of typhoid fever well marked, temperature 103, pulse 112. She recovered in less than a week.

On Sept. 17, 1893, I was called to see J. H., No. 41, positively diagnosed as typhoid fever by three or four physicians. His symptoms were well marked, and petechia very abundant. His pulse and temperature ran a very common course; I give them daily under the dates: September 17, temperature 103 3-5, pulse 92; September 18, temperature 104 3-5, pulse 92; September 19, temperature 104 4-5, pulse 98; September 20, temperature 103, pulse 80; September 21, temperature 102½, pulse 84; September 22, temperature 102 1-5, pulse 78; September 23, temperature 101½, pulse 76; September 24, 100 3-5, pulse 72; September 25, temperature 100 3-5, pulse 70; September 26, temperature 97 3-5, pulse 64; September 27, temperature 98½, pulse 68; September 28, temperature 98 1-5, pulse 64. On September 29, this patient's brother living in the same house was taken ill and is now lying sick with typhoid fever. I will give his chart in a future paper, as also six or eight other cases now under treatment.

On Sept. 23, 1893, I was called to Washingtonville, to see William Walters, sick with typhoid fever, diagnosed by his attending physician, Dr. Powers, confirmed by Dr. Bertelott in consultation. His temperature was normal on the twenty-ninth, and so continued to the last.

These cases comprise all of the worst cases and worst results I have had in my private practice for more than twelve years, during which time I have had no death from typhoid fever, and I have had a large number of cases recover in from three to twelve days without showing pathognomonic symptoms of the disease. I therefore believe thoroughly in asepticizing the alimentary canal at the earliest possible moment in all suspicious cases.

Keenly alive to the ignominy and disgrace that await me, should future observations contradict the results and conclusions of the past; aware too of the danger of the too implicit reliance on a limited number of observations, and with all due respect for the teachings of the great thinkers of the profession, whose wisdom has with strange unanimity taught the contrary, I yet wish to answer my question: "Can typhoid fever be aborted?" in the affirmative.

ACUTE INTESTINAL OBSTRUCTION—ANASTOMOSIS WITH MURPHY'S BUTTON—RECOVERY.

BY A. H. CORDIER, M.D.

CLINICAL LECTURER ON GYNECOLOGY KANSAS CITY MEDICAL COLLEGE;
MEMBER AMERICAN ASSOCIATION OF OBSTETRICIANS AND
GYNECOLOGISTS, ETC.
KANSAS CITY, MO.

Henry Binford, Nashville, Tenn., age 22. Some two years ago this young man had an attack of peritonitis, the origin of which, from his vague history, I am unable to obtain. Since that time he has had to be very careful with his diet, lest he bring on an attack of "colic." He has a slight "pulmonary trouble," leading to a suspicion of a tubercular peritonitis origin. On November 5, 1893, while on the street, he was taken with a severe pain in the region of the umbilicus, the intensity of which caused him to consult Dr. Chas. Lester of this city, who prescribed the usual antispasmodics and anodynes to relieve an intestinal colic, due to indigestion, and directed him to go to bed. The pain continued with unabated severity, and the doctor was called to see him, and prescribed salines to rid the bowel of the offending agent causing the suffering. His previous attacks had been of a similar character, indicating that there existed, and had for at least two years, a partial intestinal obstruction. (About 68 per cent. of the complete cases show previous manifestations of the existence of an incomplete constriction, and 32 per cent., previous history of peritonitis).

The Epsom salts brought no results and the pain continued with increased severity, accompanied by marked prostration, a tympanic abdomen, etc., evidences of injury to the abdominal sympathetic system, and paretic or obstructed bowels. The bowels refusing to act, large enemas were given with the result only of emptying the colon of gas and some fecal matter. He remained in this condition, continually growing weaker, up to the time I was called by Dr. Lester to see him. I found him with the peculiar pinched-looking countenance so often seen in intra-peritoneal injuries or acute inflammatory conditions. His temperature was 97; pulse 120, when I first saw him. This was November 15. Had been vomiting fecal matter frequently. An operation for the relief of the obstruction was advised at once, but valuable time was wasted in telegraphing his relatives in Nashville, Tenn., for advice as to whether the operation should be performed at once or delayed until their arrival.

I saw the case again the next day, and we decided that if anything was to be done it must be done at once or not at all, regardless of the absence of his relatives. At this time, November 16, he had well-marked evidences of intestinal perforation, as the liver dullness was absent, and his condition was that of shock. Temperature, 96.5 F.; pulse 140; delirious. I operated as soon as he could be removed to the hospital, Drs. Griffith and Lanphear assisting. Dr. Lester administered the anesthetic, ether, one-tenth grain nitrate strychn. was given hypodermically, before beginning the ether. Every preparation was completed before administering the ether, that the anesthesia might be short, as these cases bear "chronic surgery" and prolonged anesthesia badly.

A median incision was made. On opening the peritoneum, intestinal gases with some fecal matter escaped through the incision. The bowels had perforated some time before, as evinced by absence of liver dullness and symptoms of profound shock, before the operation. The bowel above the stricture had partially emptied itself into the peritoneal cavity. A paretic intestine does not contract rapidly when opened, and in these cases there is always partial paralysis of the bowel above the constriction. Some little difficulty was experienced in keeping the bowel from rolling out through the incision.

Many recent adhesions were found in the pelvis and right inguinal region. I found a very hard vascular band running from near the right internal inguinal opening, attached to the abdominal parietes, running upward and inward toward the umbilicus, crossing a coil of the ileum and attaching itself to a coil of the small bowel higher up. It was at this point that the perforation was found—due to the taut state of the band. The band being anchored at one extremity and pulled on by the enormously distended bowel to which it was attached, and across which it pursued its course, caused the walls of the gut to give way at its intestinal attachment.

My diagnosis had been strangulation by a band of a coil of the ileum. Coils of the ileum, from their location in the pelvis and proximity to the appendix, are more likely to be

strangulated by bands than other parts of the intestinal tract. This is easily understood in the present pathologic knowledge of pelvic peritonitis and inflammatory diseases in the region of the vermiform appendix.

It was at the point where the band crossed the ileum that the stricture was found. The constriction was circular and complete and of long duration, the complete occlusion being of late origin. In these old partial strictures from a band or other cause, if for any reason there be a rapid and large increase of the gases in the gut the pressure thus produced on the blood vessels may convert the case into an acute and complete obstruction.

After closing the perforation with silk I ligated the band in two places, and divided it between the ligatures, thus liberating the adherent and strictured gut, so that it could be brought up into the incision. I quickly decided to do an anastomosis (lateral) using the Murphy button. The strictured part of the gut being of a non-malignant character, it was left undisturbed.

The intestine was emptied by "milking" away from the stricture, and the Murphy clamps applied to the convex borders or surfaces of the bowel, above and below (three inches). Having introduced the "puckering" sutures the stricture was incised, button halves introduced, ligatures tied about the stems and the halves clasped together. "I pressed the Murphy button, and left it to do the rest." (See cut).

The peritoneum was thoroughly irrigated with gallons of hot sterilized water, and a drainage tube introduced to the bottom of the pelvis. The patient was put into a warm bed and the nurses instructed to empty the tube each half hour.

No morphin. During the thirty minutes occupied in doing the operation he took very little ether. At no time following the large dose of strychnia (one-tenth grain) was there any muscular twitching.

1.—Site of intestinal rupture. 2.—Location of stricture.
3.—Band taking its origin at internal inguinal ring.
4.—Location of lateral anastomosis.

It was noticed during the operation and after clasping the button, that the larger gas-filled gut above the stricture contracted enough to empty itself, (in part), through the stem of the button, into the bowel, below the stricture. The glass drainage tube continued to do its work, by removing the septic material as fast as it gravitated to the bottom of the pelvis.

Up to the morning of the 18th, when at two o'clock, during the absence of the nurse he pulled the tube out, his temperature was normal. Within six hours from that time it rose to 103 F., and his pulse increased from 84 to 120, showing that the drainage tube does drain, and that patients may suffer much risk when the indications for its use are present and are not heeded.

I cut the sutures in lower angle of the wound (abdominal) and with a tissue forceps introduced into abdomen through the tube opening, dilated the incision and irrigated the lower peritoneal cavity with hot boracic acid solution, and finished with pure peroxid of hydrogen, introduced strips of iodoform gauze as far as possible, to act as a capillary drainage—a poor substitute for the glass drain. The tube could not again be introduced without guiding it to the bottom of the pelvis with the fingers. This would have necessitated the administration of an anesthetic.

After the washing his temperature fell to 99.5 F., and pulse to 96, but his bowels were distended with gas and caused him much pain. This was relieved by a large warm water enema to which was added two or three drams of turpentine, and an ounce of glycerin. This enema brought large quantities of gas and copious liquid stools. The first movement of the bowels took place three hours after the operation. He was from the day of the operation ordered nutrient enemata each four hours. Liquid diet.

Following the removal of the tube he became quite delirious, and remained so for two days. The protracted vomiting, so prominent at the beginning of his illness, ceased from the day of the operation.

There are several features in this case deserving special notice, as to the etiology, history, pathology, treatment and sequelæ. As a causative factor of the original attacks of peritonitis, appendicitis may have been its source, but I am inclined to doubt this as a cause, as his history does not warrant such a conclusion. The appendix was perfectly free and sound. He had an attack of typhoid some years ago that may have given rise to a perforation at a Peyer's patch and led to a protective localized peritonitis, (adhesions) but recognizing the fact that a typhoid perforation usually takes place at a late stage of the disease, when the patient is in a poor physical state to resist such an accident, and that typhoid perforations are almost invariably fatal, I believe that this disease may also be justly eliminated in the consideration of the causes. I could obtain no history of any injury, such as a kick, fall or blow.

Since early childhood he has had the habit of biting his nails and swallowing the little sharp pieces, and to this dangerous practice of taking into the stomach these sharp and indigestible foreign bodies, I am inclined to attribute his former attacks of localized peritonitis, and the invariable after and dangerous adhesions.

His history of recurring attacks of colic, and other symptoms of a partial intestinal occlusion, may be easily understood when one is acquainted with the symptoms of a partial occlusion from a band or stricture. Any undigested substance of a solid character may produce by its presence at the site of a partial occlusion, a complete obstruction, or by its presence act as an irritant, thus producing an inflammatory edema, or obstruction to the return flow of blood, and convert an incomplete into a complete occlusion. An intestine distended with gas in a case like this, may, where the band is anchored, by pulling on the band, produce a complete strangulation or occlusion of the intestinal canal.

It is worthy of note that the adhesion had produced a rupture at its intestinal attachment, and that fecal matter and intestinal gases were set free in the peritoneal cavity. It is rare for the peritoneum to tolerate the presence of this form of septic material, for as many hours as elapsed in this case from the beginning of the attack to the period of the operation. It is remarkable that the contractile powers of the semi-paretic gut were regained so soon after the operation. The post-operative history of the case illustrated that the nausea and vomiting in strangulation of the intestines is due as much to the non-elimination of septic material in the bowel, and to the great distension of the intestines, as to the injury sustained by the sympathetic system at the point of constriction, as is claimed by some authors. The results of the treatment in the case, lend encouragement to operate on all cases of a like character, regardless of the seemingly unfavorable, and almost

hopeless general condition of the patient. The utility of drainage was demonstrated by the bad symptoms (temp. 103 F.) following the removal of the tube by the patient, and the good results that may be obtained by early flushing, in a threatened septic invasion of the peritoneum.

The Murphy button undoubtedly was the best device to use in this case, as the time occupied in doing the operation was of vital import to the patient, in his desperate state.

The stricture, being non-malignant, was left. That portion of the bowel between the location of the button and the stricture will soon atrophy, and by its presence cause no harm. The button, up to the fourth week, has not passed. Its non-soluble character is, in my mind, quite a serious objection to its use. Should the button at any time give rise to alarming symptoms by its detention in the bowel, its removal by another operation will come up for consideration. It could be done by dividing the gut near the location of the button, and removing it through the slit, and closing the opening with a few Lembert sutures.

The diagnosis of intestinal obstruction by a band was made by Dr. Lester before I saw the case, and an operation urged by him early in the attack.

GASTROSTOMY BY WITZEL'S METHOD FOR PRIMARY CANCER OF THE ESOPHAGUS.

Read in Philadelphia Academy of Surgery.

BY WILLIAM W. KEEN, M.D.

PHILADELPHIA.

PROFESSOR OF THE PRINCIPLES OF SURGERY AND OF CLINICAL SURGERY,
JEFFERSON MEDICAL COLLEGE.

The patient, S. S. aged 48, occupation puddler in rolling mills, was admitted to the Jefferson Hospital July 31, 1893, at the request of Dr. A. G. Miner of Niles, Ohio. His father died of asthma, his mother of cancer of the breast. He has always had good health with the exception of an occasional brief attack of rheumatism. For the past thirteen months he has experienced trouble in swallowing; seven months ago he could swallow solid food without much discomfort, but now can swallow nothing but liquids. He states that the constriction came on gradually and that he noticed from time to time the lessening of the caliber of his esophagus. When he takes nourishment he feels first an impediment to the passage at a point corresponding to the sterno-clavicular articulation; then the food passes with comparative ease until it reaches a point which corresponds to half an inch above the lower end of the ensiform appendix. Here he says he can feel a distinct obstruction, and while the food is passing this point he experiences pain in the median line posteriorly, under the inferior angles of both scapulæ (more severe under the left), in the epigastric region, though slight, and in the precordial region. The pain is darting in character.

During the past four months he has had slight attacks of hæmatemesis. On July 27, 1893, he lost considerable blood, enough to make him faint, but he attributes this to the introduction of an esophageal bougie. He has had gradually increasing emaciation, and has lost forty-nine pounds in the last thirteen months, his weight in June, 1892, being 168 pounds, and in July, 1893, 119 pounds. During the last ten weeks he has had œsophageal bougies passed

twice a week. On July 31 I passed a No. 3 rectal bougie through the stricture.

He has never swallowed any corrosive fluids, and has had no traumatism. He does not indulge in alcoholic stimulants stronger than beer, and limits this to two or three glasses a day. He denies all history of syphilis. His appetite is impaired, tongue coated and bowels constipated. The urine is negative.

There was a resistance in passing the esophageal bougie (circumference 4.2 centimeters) at ten and a half inches from the teeth, and at twelve inches the bougie would not pass.

Operation, Aug. 2, 1893. An incision four inches long was made, beginning at the middle line and running to the left, a finger's breadth below the border of the ribs. The muscular fibers of the rectus were separated by the fingers and not divided. The liver was seen as soon as the peritoneal cavity was opened. Two fingers thrust in, however, very readily seized the stomach. This was brought forward and outside the wound, the margins being packed with gauze. A rubber tube, five inches in length (Size 25, Fr. catheter scale), was introduced into the stomach and infolded by two rows of Lembert sutures, after Witzel's method. The opening in the stomach was made toward the cardiac extremity and the tube lay parallel to the external wound, its external end emerging near the median line. Three stitches were now inserted into the walls of the stomach but not tied before it was returned to the abdomen, their needles being left threaded. As soon as the stomach was returned these needles were thrust through the abdominal wall and the stomach brought up to the margin of the opening. The tube was retained in place by a catgut stitch passed through the wall of the stomach and through a part of the wall of the tube so as not to open its caliber. About one inch of the tube was thrust into the stomach. The edges of the abdominal opening were now sutured by silk-worm gut and the ordinary dressing applied. A clip was placed on the tube to prevent the escape of the contents of the stomach.

Sept. 28, 1893. The patient made an excellent recovery, without incident, excepting in one respect. On the second day after the operation the dressing became twisted in his movements in bed, and the tube was pulled out of the stomach. In order to replace it I was obliged to cut three stitches in the external wound. When the tube had been replaced these stitches were re-inserted. Apparently, however, such adhesion had formed that no harm was done by this accident excepting to delay the closure of the wound.

By the middle of September he began to expectorate some bloody mucus, presumably coming from the ulceration of the carcinoma in the esophagus. He has gained about four pounds in weight, however, since the operation. For some weeks he has been unable to swallow even a mouthful of water. What nutritive gain there is from feeding, I presume has been almost counteracted by the progress of the disease. Immediately after the operation he was fed for two days by rectal enemata. Then I began with small amounts of milk, poured into the stomach through the tube. This feeding has been gradually increased, until at the present time his daily food may be summarized about as follows: Milk, two quarts; beef, mutton and chicken broth, each about

twenty ounces; and a dozen eggs. This is varied by substituting gruel, thin custard and other similar food. He is walking about with much comfort. The tube is held in place by a gauze dressing, which in turn is retained by rubber adhesive plaster on each side. This is laced through eyelet holes. No escape of the gastric contents has taken place alongside of the tube.

Nov. 1, 1893. The patient is still doing well three months after the operation. There is absolutely no leakage whatever.

Greig Smith states that the operation of gastrostomy was first proposed by Egebert, a Norwegian surgeon, in 1837, received its name from Sedillot, in 1846, but had a very unsatisfactory history and development until the time of Sidney Jones of St. Thomas' Hospital, London, in 1874. Since then it has made rapid progress in favor in the profession, and a variety of different methods of its performance have been devised, until now its technique is presumably so satisfactory that but little improvement can be made upon it. The conditions which demand the operation are, of course, any cause which prevents the introduction of aliment into the stomach by the mouth, for instance, stricture of the esophagus from any reason, whether by cancer, cicatricial constrictions from caustics, etc., occasionally from the pressure of extra-esophageal growths, from malignant disease in the mouth or pharynx. Whitehead¹ has reported a case in which gastrostomy was done on account of obstruction due to a diverticulum.

There are practically five methods by which gastrostomy is done.

1. The method originally proposed by Egebert, and modified in its details by Fenger and Howse.² In this an abdominal incision is made parallel with the border of the ribs, and the stomach is attached by sutures to the abdominal wall. Two sutures are placed in the wall of the stomach in order later to identify the exact position for puncture (Bryant), and the stomach is not opened until the third or fourth day. This method has given rise to so much trouble, however, especially from leakage, that various devices have been employed for the purpose of preventing this annoyance, which, in consequence of the irritation from the escaping gastric juice, caused widespread eczema or even ulceration. Handford³ notices, for instance, "a hernia-like protrusion of the mucous membrane of the stomach from the fistulous opening, forming a red, mushroom-shaped, insensitive mass, nearly two inches in diameter. This was easily replaced, but led to constant leakage of the stomach contents." Moreover, it is very important to observe that in Whitehead's case, above alluded to, the postmortem showed that the adhesions of the stomach to the abdominal wall had so loosened by traction that they were very slight indeed when the patient died, six months and a half after the operation. Hence, the importance of secure suturing of the stomach to the abdominal wall, as I believe I have obtained in my own case by suturing the stomach to the abdominal wall.

2. The method of Von Hacker.⁴ This operator proposed to use the belly of the rectus muscle as a sphincter. In the first method of operating, fibers of

¹ Lancet, 1891, 1, p. 11.

² Heath's Dist. of Surg., p. 590.

³ Lancet, 1891, 11, p. 988.

⁴ Weln. Med. Woch., 1886, Vol. xxxvi, 1073-1110, and Wien. klin. Woch., 1890, p. 693.

this muscle are divided by a transverse incision. Von Hacker proposed to make a vertical incision and a blunt dissection of the belly of the muscle, hoping that the rectus fibers would thus act as a sphincter. Girard⁵ modified this by crossing the fibers of the muscle so as to form a more efficient sphincter. Von Hacker himself has been obliged to use the Scheimpflug canula in order to prevent leakage.

3. The method of Hahn.⁶ In this a return is made to the original transverse incision, but a second incision is made in the eighth intercostal space. The stomach is drawn through this space, and fastened there between the cartilages. In addition to the danger of possibly opening the chest, necrosis of the cartilages has taken place, although Hahn affirms that there is no danger either to the diaphragm or the pleura. He believed that the cartilages of the ribs acted like a sphincter or stopcock.

4. The method of Witzel.⁷ In this method the abdominal cavity is opened, the stomach drawn out, and a moderate-sized rubber tube is inserted into the stomach toward the cardiac extremity, through as small an opening as will admit it. The gastric end is then buried for about two inches by two rows of ordinary Lembert, or Cushing right-angled sutures. The free end of the tube is then brought out through the abdominal wound, and is either fastened there, or possibly after a time may be removed and inserted as needed.⁸ The great advantage of this operation is the ureter-like, oblique entrance of the tube into the stomach; and as is shown by the postmortem examination in one of Meyer's cases,⁹ the result is a nipple-like protuberance into the caliber of the stomach, which will prevent effectually the escape of any fluids.

This seems to me to be by far the best method yet devised, as it is simple, moderately rapid, and, above all, as in the present case as well as a few others in which the operation has been done, it is effectual in preventing any leakage.

I did not immediately begin feeding the patient through the tube, as I deemed it safer, the patient being in very fair physical condition, to nourish him for a couple of days by rectal enemata. I did, however, introduce an ounce of milk into the stomach the moment the tube was inserted, in order to make sure that perforation of the mucous membrane, as well as the muscular wall, had been effected. I think it likely that in another case, with the courage born of experience, I should be disposed to nourish the patient by small amounts through the tube immediately after the operation. I wished to try with this patient a method which has been used by others, the effect of his chewing meat which had been previously finely hashed, and then washing it into the stomach through the funnel. This gives the patient the satisfaction of mastication and of taste, and at the same time mixes the saliva with the food before its introduction into the stomach. Although not a man of especially sensitive nature, the idea of doing this seemed to disgust the patient so much that he was not willing to attempt it. The result, however, shows that he has received sufficient nourishment to gain somewhat in weight. Whether his constant hunger,

in spite of the nourishment taken, is due to the want of satisfaction of his sense of taste, I do not know.

(5) Frank¹⁰ has reported still another method practiced in the clinic of Albert, in Vienna. After making the abdominal incision parallel with the costal cartilages, a narrow fold of the anterior wall of the stomach is drawn out of this wound. A second incision is next made through the skin, half an inch above the first and over the costal cartilages. After separating the skin from the underlying parts, the fold of the stomach wall is drawn out, first through the abdominal wound, then under the skin, and, finally, through the second opening, and is fixed there, the mucous membrane being stitched to the skin. Whether experience will show this to be more valuable and more easily done than the method of Witzel can not yet be determined. It is said that no leakage occurs. Of course, as pointed out by the author, it would not be advisable in cicatricial stricture of the esophagus, because the fistula could not easily be closed, should it be desired to do this at any time.

It is interesting to note that Zweifel¹¹ of Leipzig, has used the same process as Witzel in making an artificial urethra. This idea was suggested by Witzel in his paper. In a case of carcinoma of the urethra in a woman, Zweifel extirpated the entire urethra and part of the bladder, closed the latter viscus, and then by a supra-pubic cystotomy made an artificial urethra after Witzel's method.

The mortality of the operation was last collectively investigated by the late Samuel W. Gross.¹² At that time Gross collected 207 gastrostomies, with 61 deaths, a mortality of 29.47 per cent., with a prolongation of life, on an average, at the date of the last reports, of 83 days.

Comparing gastrostomy with other procedures, there were thirty-two cases of esophagostomy, with nineteen deaths; a mortality of 59.37, and a mean duration of life of fifty-two days. Nineteen internal esophagotomies, with 6 deaths, or a mortality of 31.57, and an average prolongation of life of 256 days. Five combined esophagotomies have resulted in 2 deaths, a mortality of 40 per cent., and a mean duration of life of 168 days. Five esophagectomies gave 3 deaths, a mortality of 60 per cent., and a mean duration of life of fifty days. Three retrograde divulsions all resulted in recovery, with a mean duration of life of twenty-two days.

In the case of Handford, already alluded to, some very interesting physiologic experiments were made. He introduced a small rubber tube attached to a female catheter into the stomach, and connecting it with a Marcy's registering tambour and clockwork revolving drum, he found the respiratory and cardiac curves well marked, but absolute absence of any peristalsis. This he accounted for by the adhesion of the stomach to the abdominal wall. Yet digestion was efficiently performed, probably due to the replacement of this motion by the movement produced by the heart and diaphragm. He observes also that "the rapid introduction of large quantities of food into the stomach, the absence of pleasure in eating and the normal perception of flavors are not incompatible with very perfect digestion and active nutrition." Fine division of the food determined its

rapid and easy digestion. Lactic acid was found as early as half an hour after eating. Hydrochloric acid was absent until as late as two hours after the meal.

A PROPHYLACTIC MEASURE AGAINST ONE OF THE POSSIBLE CAUSES OF CANCER OF THE TONGUE.

BY JOHN W. O'NEILL, M.D.

HOUSE PHYSICIAN ST. JOSEPH'S HOSPITAL, CHICAGO.

On the subject of cancer of the tongue many writers affirm that one of the predisposing causes is traumatism. This being true, the biting of the tongue during an epileptic fit, eclampsia, etc., or in making forcible traction on the tongue, is not without danger; a danger none the less terrible, even though the consequence lies in the future. Much of this injury, that can readily be avoided, occurs during the administration of an anesthetic when it becomes necessary, as is often the case, to pull the tongue forward. The customary practice being to seize that organ with a tongue or artery forceps, locking the handles to prevent slipping, but subjecting the portion of the tongue between the jaws of the forceps to injurious pressure. This, aside from the question of cancer, may be considered as being somewhat barbarous.

To overcome these objections, especially in patients during the administration of anesthetics, the writer devised a mouth gag and a method of holding the tongue with dry gauze. Both have been in use in St. Joseph's Hospital for some months, demonstrating that traction can be made on the tongue for an hour without injuring that organ in the least.

The mouth gag (Fig. 1) consists of a soft rubber wedge (or a metal wedge, covered each time it is used with a narrow ring cut from the end of a rubber tube). The wedge is thirty millimeters high, fifteen wide and twenty thick, measuring from bottom of grooves. The ridges along sides are three millimeters in height; they prevent lateral slipping. The wedge is riveted to a metal handle ten centimeters long, shaped like one blade of the O'Dwyer mouth gag, excepting that the lower part of handle is hooked to fit the side of the anesthetizer's hand. It is used as follows: When the patient is partially under the influence of the anesthetic place the gag in position, wedge between the jaws; the soft rubber preventing injury to teeth, gums or metal work as gold crowns, etc. The handle hangs perpendicularly at side of cheek, its weight holding it in position. But should patient struggle, or it is desirable to still further open his jaws, the anesthetizer presses downward with the side of his hand which rests in curve at lower end of handle.

Two things have now been accomplished. First—the teeth being held apart the jaws can not be locked, and the position of the tongue can at any time be examined or grasped and drawn forward. If mucus collects in mouth it can be removed without delay. Second—a clear air way is assured, an advantage in case the natural air passage is not free, as in catarrhal conditions. Again, the air passing through the open mouth dries the tongue and cheeks, somewhat, and the secretions which are so disagreeable, especially when ether is employed.

Method of using gauze to hold the tongue: The

anesthetizer should never be without an artery forceps fastened to his gown, preferably one with jaws four millimeters long, slightly curved, with teeth ground dull. Pèan's curved jaw artery forceps are good, but a pair with jaws opening parallel are best of all, the curve being a help when mopping mucus from throat. Should it become necessary to draw the tongue forward, remove mask, taking forceps in right hand, pass it into the mouth, curve downward, grasp the tongue gently and without injury, at least one-half inch from the point, and lift it up. When the tip protrudes between the teeth, grasp it with a piece of dry gauze held in the left hand. The forceps are then removed.

Figure 1.

If traction is to be maintained for a short time only, it can be done with the fingers; if for many minutes or for an hour or more, a piece of dry gauze, fifteen centimeters square, is folded from side to side until it is two centimeters wide. This is passed around the tongue with the right hand, pressing it down as far from the top as possible. Then twist the ends together until the tongue is firmly grasped in the loop of gauze. Remove left hand and snap the forceps on the strip around tongue to prevent it untwisting. (See Fig. 2.)

Figure 2.

One word of caution: If patient wishes to swallow or threatens to vomit, the tongue must be allowed to fall back.

For patients with puerperal convulsions a double mouth gag is made, by fastening a small rubber wedge on each end of a semicircular steel spring, the length of which can be regulated. The spring passes back of head, fitting the neck snugly and holding a wedge in each angle of the jaw.

W. H. LOWDERMILK & CO., WASHINGTON, AGENTS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, FEBRUARY 10, 1894.

ANTISEPSIS IN OBSTETRICS.

"For all women in the perils of childbirth." . . .
"We beseech Thee to hear us, Good Lord." So runs the liturgy of the Church of England and the Episcopal Church of North America, copied from that of the mother church of Rome; an echo from the Dark Ages, when the midwife was the only one who ministered to the wants of the suffering parturient, long before the practice of obstetrics became a science, and when the patient, if she survived the actual labor, had to face the risks of puerperal fever literally brought to her by the hands of those who meant to help her.

It will long be the boast of the nineteenth century that antiseptic methods in surgery and obstetrics first became settled truths in medical practice. Yet, in an editorial which appears in the *Charlotte Medical Journal* for January, 1894, we note the following passage: "It has appeared to me, when reading the various contributions of those who write so learnedly on the necessity of extreme antiseptic measures in parturition that they should ask themselves the important questions, Is the mortality of lying-in women any less by such means? Or is the death rate any less now than it was fifty years ago? If they do ask themselves these questions, they assuredly can not reply in the affirmative."

If the learned editor means by "extreme antiseptic measures" the antepartum and postpartum douching of the patient with an antiseptic solution, and the washing of the accoucher's hands in a similar solution previous to touching the patient, those obstetricians who advocate and practice the methods condemned most assuredly do answer the question in the affirmative and point to the convincing fact that, by the use of these methods, puerperal fever is far less common than in the days when DR. OLIVER

WENDELL HOLMES wrote his immortal essay, showing so plainly the contagious character of the disease and the awful responsibility that rests on the physician.

A certain mortality there will always be from childbirth, but it should be due solely to the complications and should in no way be chargeable to dirt or neglect of cleanliness on the part of the attendant. One does not hear now-a-days of a lying-in hospital being closed on account of an outbreak of puerperal fever; even the old milk fever is banished from the lying-in chamber and the puerperium should be afebrile. The Preston Retreat, in Philadelphia, shows a record of over a thousand deliveries without a death, and antepartum and postpartum douching of patients with full antiseptics on the part of doctor and nurse is practiced there. Philadelphia has reason to feel proud of this institution's statistics, which lead the world, yet other maternity hospitals can show an almost equally good result. These are institutions built for this sole purpose and fitted up with the latest devices in the way of sanitary plumbing, etc., for the guarding from harm of those who are compelled in time of need to take refuge within their walls. If antiseptics is needed in such places, how much more is it needed in the homes of the rich where it is so usual to find a water closet immediately adjoining the bed chamber, or a wash basin connected with the sewer, in the room. The poor, while they may not possess these questionable luxuries of the rich, yet are equally exposed; how often is a bucket filled with filth found standing just outside the door of the room?

The puerperal woman is in one sense a surgical case. The vagina is full of minute abrasions, if not ruptured, in places, and the opportunities for the entrance of septic material from without are numerous. The surgeon does not think his duty rightly performed if he leaves any avenue by which infection may reach his patient; why should the obstetrician? We have in the puerperal vagina a bruised surface, to a certain extent,—a wound—and it should be treated as such.

That the author of the editorial in question does not mean to entirely decry antiseptics is evident from another passage, where he refers to five hundred cases attended by him in which cleanliness proved sufficient. Yet, he admits one death from puerperal fever among the number. Cleanliness may be all that is necessary in the remote country districts, where the patient has pure air and plenty of it; where she is removed from the boasted civilization of the city, that carries with it venereal diseases and a possible infection from gonorrhoea contracted by the husband in the days when he sowed his wild oats. An antiseptic douche in those cases where there is reason to suspect such infection certainly

lessens the risk and does no harm to the patient.

There is one other point—the baby's eyes. Contact with a purulent discharge may cost the sight of those eyes. An antiseptic douche during the early stages of labor lessens the danger. Take the statistics of our blind asylums and see the numbers of inmates whose blindness is due to ophthalmia contracted at birth. Take the statistics of fifteen or twenty years ago and compare them with those of to-day. There are fewer cases. Why? Partly because more physicians have recognized the importance of the antepartum douche. Is it right that by any omission on the doctor's part the child should be deprived of the light of God's sun and (in the case of the poor), made a charge upon the State for support through life? The antepartum douche is not troublesome and does not in reality lessen the vaginal secretions, to any appreciable extent, and so interfere with the progress of labor, as has been charged against it.

As an opposite to all this, is the extreme to which antiseptic midwifery has been carried in certain quarters. This it is which the editorial mentioned apparently means to warn against. The scrubbing of the vagina with antiseptics, accompanied as it must be with an amount of friction which abrades the delicate mucous membrane, does interfere with the natural secretions of the part and adds to the dangers to be averted. This is meddling and bad, but the simple ante- and post-partum douche can do no harm, when properly given, and may save the life of the mother and preserve the brightness of her baby's eyes, instead of sending it through a darkened life a living evidence of some one's negligence.

RECENT APPLICATIONS OF GUAIACOL.

Some recent clinical applications of guaiacol invite a consideration of its chemie and therapeutic relations. "Guaiacol is a substance that occurs in wood-tar, and is also produced by heating pyrocatechin and potassium methyl-sulphate to 180 degrees, C. It is a colorless liquid that boils at 200 degrees, C., and has a specific gravity of 1.117. It is readily soluble in alcohol, ether, and acetic acid, and is recommended instead of creasote in pulmonary tuberculosis."¹ This substance is a prominent constituent of the best creasote, into which it enters to the extent of about 60 per cent., although in the cheaper kinds it may be much less than this. Along with the guaiacol, are associated a number of more or less objectionable substances. Among these, according to ALLEN, are phenol, paracresol, cresol, kyleneol, creasol, homocreasol, cœrneignol, and four methylic ethers of trihydric phenols. Many of the foregoing are distinctly toxic, but pure creasote, HUSEMAN declares to be non-poisonous. Those who

are in a position to know about it, however, state positively that there is much poisonous creasote in the market.² The "United States Dispensatory" states that: "Commercial creasote almost always contains carbolic and cresylic acids from coal tar; and indeed much of what is sold for creasote is nothing more than impure carbolic acid." This is not written in order to discredit the use of pure beechwood creasote in medicine, as originally suggested by SOMMERBRODT; but, to explain why chemists and clinicians have diligently sought for a similar preparation possessing equally beneficial effects, but having definite and uniform composition. Thus creasotal, or creasote carbonate was brought out by DR. CHAUMIER in a paper read before the Academy of Medicine of Paris.³ DR. F. WALZER reported favorably upon benzosol, (a compound of benzoic acid with pure guaiacol, forming benzoylorrhoxyanisol) which has the advantage over the preceding in the fact that it is a solid, being a colorless crystalline powder almost free from smell and taste. In the digestive tract it splits up again into its constituents, guaiacol and benzoic acid.

It might also be of interest to note that recently Drs. A. GILBERT and L. MAURAT have reported favorably upon the effects of a chemically pure form of guaiacol, which is made artificially, (synthetic guaiacol). This substance appears in the form of white, rhombohedral crystals, fusing at 28.5 degrees, C., and boiling at 20.5 degrees, C., with a specific gravity of 1.143. It is practically insoluble in water, but is soluble in alcohol, oils, and anhydrous glycerin. It possesses a sweet taste at first, which soon changes to a pricking and burning sensation.⁴ It melts into a sticky paste at the temperature of the surface of the body. This has been used, combined with oil, in capsules, for internal administration in phthisis principally.

Drs. WEIL and DIAMANTBERGER, since 1889 have administered pure guaiacol in sweet almond oil (equal parts of each) by subcutaneous injection, in all the forms of pulmonary tuberculosis, and claim to have had very good results.⁵ Of eighty-two patients, sixty-two were improved, two remained stationary, and eighteen became worse while under this treatment. Of the sixty-two cases, twenty-seven were considered cured. In the majority of cases the unfavorable symptoms of the disease were strikingly modified after a relatively short time.

About a year ago, DR. SCIOLLA⁶ made the remarkable observation that external applications of guaiacol to a small area of the general surface, were promptly and uniformly followed by a reduction of the bodily temperature. This was soon corroborated

¹ Definition from advance sheets of Gould's "New Medical Dictionary."

by the results obtained in tuberculous cases by BARD and also by LANNOIS. Subsequently ROBILLARD of Lille⁷ also repeated these observations upon guaiacol and confirmed SCIOLLA's statements concerning its powerful antipyretic effect. Drs. CASSOVICE and SIGALEA modified SCIOLLA's method by not applying the remedy in a pure state, but in combination with the tincture of iodine (one part guaiacol to five parts of iodine). Of this, about 2 drachms are used for a single painting, applied on the affected side all along the posterior part of the throat, every evening. These paintings are said to give rise to a considerable fall in temperature, abundant perspiration, and increased diuresis. In a severe case of left pleuritic effusion, in which puncture did not bring about any improvement, the fever disappeared and after a few applications, the extravasation was promptly absorbed.⁸

Quite recently, DA COSTA⁹ gives his experience in the external use of guaiacol in reducing high temperatures in typhoid fever and other febrile diseases. He communicates the clinical notes of several hospital cases, with very striking temperature charts, showing conclusively the heat-reducing action of guaiacol when simply painted upon the skin, with or without friction. He found that the action was gradual and rather slow, not reaching its maximum effect until about three hours after the application. The place he usually selected was the abdomen, in the iliac region of right side, and the quantity usually employed was 30 drops. Larger doses were found to bring the temperature down below normal, and the patient was depressed and chilly, but the dose of 30 drops was well borne even by the typhoid cases. It produced no evident depressing effects upon the circulation or the respiration, but was likely to cause moderate perspiration. No obvious effects upon the urine, no albuminuria or other sign of kidney irritation were detected. This distinguished authority on clinical medicine pronounces it a valuable adjunct to the treatment of typhoid fever, or other diseases attended by high temperature, especially where the attendant circumstances would not permit the use of the cold bath. Where there is a tendency to intestinal hemorrhage, he advised abstention from resorting to the cold bath treatment, and declared that it is in these cases that guaiacol will be found of special advantage used in the manner mentioned.

It must be conceded, in the face of so much concurrent testimony concerning the action of guaiacol upon bodily heat, that we have come into possession of a remarkable agent for the treatment of high temperature, when this symptom calls for special therapeutic management. It is to be hoped that all who may subsequently experiment with guaiacol may observe the caution given by DA COSTA, of not using

an unnecessarily large dose; for although not considered a toxic agent, it can not be expected that a remedy capable of such potent action may be administered recklessly, or in doses unsuited to the physical development and condition, as well as the age of the patient. The suggestion to watch the kidneys it is also well to keep in mind, for it may be found that, just as with other drugs, there may be cases of idiosyncrasy, in which guaiacol might cause such distress or depression as would threaten the patient's life.

There are many surprises among the untoward effects of drugs, and what these may be in the case of guaiacol remains to be seen. In the meantime, however, therapeutics has been enriched by a potent and (as the rule at least), non-poisonous antipyretic possessing decided advantages over similar substances obtained from among the aromatic series of coal-tar products.

SMALLPOX.

There is not much change in the smallpox situation. In Pennsylvania there are nine points where the disease exists, five of them in Berks County, and at nearly all of them under complete control. The case found at Williamsport on January 26 is the first new infected locality reported in three weeks. Philadelphia has, so far, escaped and the outlook in the State is hopeful. New cases are daily found at Chicago and New York, and the disease is slowly increasing in both cities. A case was reported at St. Louis, and one at Cotton Hill, Ill., the origin of both being traced to Chicago. On January 22 two cases were removed from the old Homeopathic Hospital on Ward's Island, and three days later one was taken from the Insane Asylum on Ward's Island. A short time ago there was a case found in one of the public schools of Boston, and on January 27 three cases were discovered in the Cook County Hospital, Chicago. The existence of the disease has also been reported at several places in Virginia near the Tennessee line.

Chicago in 1893 had 130 cases of smallpox with only 19 deaths. Without exception, all who died had not been vaccinated.

The smallpox hospital of Birmingham, England, had over two hundred patients at the end of 1893.

DISCRIMINATION BETWEEN EFFECTS OF DISEASE AND INJURY.

Members of the medical profession are likely, as personal injury litigation multiplies, to be called more frequently to discriminate, if possible, between the effects, in given cases of disease, or an unhealthy internal condition, and of external injuries. A striking precedent is furnished by the decision of the Supreme Court of Michigan rendered Jan. 9, 1894, in

⁷ Societ  de Biologie, July, 1893.

⁸ American Med. Surg. Bulletin, November, 1893; from Semaine Medicale No. 52. ⁹ Medical News, Jan. 27, 1894.

the case of *Shumway v. Walworth & Neville Manufacturing Company*. This was an action brought to recover damages for the loss of certain fingers injured in a machine. But it was contended, on the other side, that the loss of the fingers was not the result of the injury, but was the result of the man's own condition, he being unhealthy. There was evidence tending very strongly to show that he was, previous to the injury, afflicted with a scrofulous disease; and the inference, perhaps was justified that such serious consequence would not have followed from the injury, had not this been his condition. The trial court in commenting upon this testimony, instructed the jury as follows: "In consequence of there being something wrong about his own constitution, the injury was aggravated, and it amounted to about this: That the permanent injury was partially or quite the result of just that thing, rather than the result of the accident itself, in the machinery. Now, you may decide this question: How much of the injury which he has suffered is the consequence of that, rather than the consequence of the injury itself? There is no kind of question, of course, that the accident or injury there—the hurting of his hand in the machine—did cause him some injury; but whether it was all caused by it, or the greater part of it, or only a small part of it, is another question and a question which you will have to decide." In another portion of the charge he stated: "If it be true that his constitution is in such a condition that a little injury, which is liable to occur to many men at any time, will have these aggravated results, he is not a man in such a condition and situation as a man who is sound, and the diminution of his capacity to work may not be as great." These instructions, the Supreme Court holds, were sufficiently favorable to the company sued. The fact that the man was afflicted with a scrofulous difficulty, which rendered it possible, or even likely, that a slight injury would produce more serious results than if inflicted upon a perfectly healthy person, would not put him beyond the pale of the law, or prevent a recovery of such actual damages as he had sustained.

CRUDE COCAIN IS NOT A MEDICINAL PREPARATION.

Crude cocain is not a medicinal preparation. True, it is used in the manufacture of cocain wines, which are generally proprietary preparations, and of oleates, but it is not employed in filling prescriptions. Its occasional use, for the sake of economy, upon the surface of the skin for surgical purposes, or for dental purposes, does not change the case. Neither does the fact that crude cocain is extracted from the leaves of the plant coca, by the aid of diluted alcohol, according to the decision of the United States Circuit Court of Appeals, in the case of *Hirzel v. United States*, rendered Dec. 5, 1893, constitute it a medi-

cal preparation in the preparation of which alcohol is used, within the meaning of the tariff act of Oct. 1, 1890. Under that tariff it is, therefore, dutiable at 25 per cent. ad valorem, rather than at 50 cents per pound.

IN UNITED STATES COURTS.

The United States Circuit Court of Appeals holds, in the case of the *Mutual Benefit Life Insurance Company v. Robinson*, decided Nov. 13, 1893, that under the provisions of the United States statutes, and the constructions of the Supreme Court upon them, a federal court is governed by the law of the State in which it sits with reference to the admissibility of the testimony of a physician in any given case. Consequently, where a State statute makes communications to a physician, properly intrusted to him in his professional capacity confidential and privileged, a United States court held in that State must treat them in the same way.

LEGAL PRESUMPTION AS TO THE DEAF AND DUMB.

However the deaf and dumb may have been regarded in times past and in other countries, the Supreme Court of Missouri holds, in the case of *State v. Howard*, decided Nov. 21, 1893, that the presumption that a person deaf and dumb from birth should be deemed an idiot does not seem to obtain in modern practice,—at least in the United States. Such unfortunate persons may be witnesses, if able to communicate their ideas by signs, through the medium of an interpreter, or by writing, if they write and read writing.

PROOF OF ABORTION BY CIRCUMSTANTIAL EVIDENCE.

Abortion can be proved entirely by circumstantial evidence. Thus, in effect, holds the Supreme Court of New York, general term, in the case of *People v. Van Zile*, decided Dec. 1, 1893. Among the facts which it is proper to take into account in such a case is the death of the woman from miscarriage. So also may the subsequent conduct of the person charged with the crime be considered.

THE FEMALE MEMBERSHIP IN THE BRITISH MEDICAL ASSOCIATION.

The *British Medical Journal*, January 6, gives a list of the ladies who have been allowed to enter the great National Association. The list contains twenty names, headed by Mrs. GARRETT ANDERSON of London. At the annual meeting of the Association, last year, at Newcastle, the by-laws were so amended as to expunge all clauses that have hitherto rendered women ineligible for membership in the main Association and in the branches. The number of lady doctors in the United Kingdom was 135 in 1892, whereas in 1878 there were only 8.

CORRESPONDENCE.

Fluid Drinks After Laparotomy.

To the Editor:—The occasion of these remarks is the appearance of a nicely written little book on the "After-Treatment of Laparotomy" by Dr. Christopher Martin, the trusted assistant of Mr. Lawson Tait. Dr. Martin's book is just issued and as it is not published in this country, he kindly sent me one of the first numbers. In 1890, I was a pupil of Mr. Tait's for six months and at this time Dr. Martin had full charge of the after-treatment, as Mr. Tait seldom saw many of the patients after he had performed the operation. I then had ample opportunity to witness the after-treatment by *special permission* of Mr. Tait. Dr. Martin is a skillful surgeon and a keen observer of natural phenomena in the field of laparotomy. His little book is based on the after-treatment of 1,000 cases of abdominal section. He is possessed of independence sufficient to assert his own opinions whenever he may differ from Dr. Tait. It is, to me, gratifying that a man who has had ample opportunity of observing all the after-treatment of 1,000 cases in the service of any distinguished surgeon, that he will rise and assert his opinions in direct opposition to his instructor. Dr. Martin boldly writes against the *non-antiseptic practices* of Mr. Tait. This is after several years of close association with Mr. Tait and the observation of 1,000 abdominal sections of that distinguished surgeon.

I am personally acquainted with some conditions which would explain the difference of opinion, between Mr. Tait's ideas of antiseptic practice and those of Dr. Martin. But the chief object of this letter is to strongly protest against the practice of both Mr. Tait and Dr. Martin in the administration of fluids after laparotomy. Dr. Martin reflects Mr. Tait's practice and coincides with it himself when he writes: "In some mysterious way the mere opening of the peritoneal cavity—as in exploratory incision—induces a terrible thirst and this is aggravated by the *forty-eight hours' enforced abstinence from fluids.*" (Italics mine.) It is against this cruel "forty-eight hours" that I wish to protest. While I was with Mr. Tait for six months, I was awfully impressed with the intense suffering which a patient endured for the first two days with no fluid to drink, and I determined that I would try other means after laparotomy. I do not think I ever heard patients beg so pitifully as I heard Mr. Tait's beg for a little water. The desire for fluids after laparotomy becomes absolutely intense and I do not see why a laparotomy patient should long and hope and beg for a little fluid. Nature knows more than all the doctors combined. Thirst demands drink. Besides it seems to me to be therapeutic foolishness to withhold fluids from a patient whose system should be drained. To drain a marsh we establish a duct so that the whole fluid can flow out of the canal. The kidneys can best drain the system by having the material to be carried out well diluted. The waste-laden blood can be best filtered through the kidney by a full volume of blood in a dilute state. Again, the blood has been dehydrated by the active saline cathartics previous to the operation so that sound therapeutics would indicate to give fluids after abdominal section in order to reinstate a normal blood condition. Not only this, but *water is no doubt the best known diuretic.* I believe in washing out the kidney with water after laparotomy.

Since my experience with Mr. Tait, three years ago, I have been *advocating* and *practicing* the giving of drinks after every abdominal section. I give immediately after the operation an ounce of that fluid an hour if the patient desires it. In eight to twelve hours after the operation I give two fluid ounces an hour if the patient desire. Hot fluids slake the thirst better than cold fluids. I use no cold

fluids for three to four days. Under this practice of giving fluids after abdominal section, in order to show that it is practical, I can present series of recoveries equal to most statistics. For example, with ample drinks after laparotomy, we had one series of *thirty-two* consecutive cases with one death, and that death had nothing to do with drinks. These cases were not selected, but operated on just as they came in order. Dr. Martin well says: "Ice must be shunned as poison." I am fully convinced that ice is a most disastrous agent after laparotomy and should never be used. The ice entices blood to the mucous membranes which induces more and more thirst while hot fluids slake thirst most effectually. I know two well-known gynecologists—one gives hot fluids after abdominal section and scarcely ever has any kidney trouble. The other withholds fluids after the operation and I know that he reports at least *five times* as much kidney trouble as the first gynecologist.

I have long advocated and practiced giving ample hot fluid drinks after laparotomy and I think experience and sound therapeutics has proved that it is a wise and humane course. I base it on the following conclusions:

1. Thirst demands drink.
2. *Water is the best diuretic.*
3. Waste material is best removed from the blood in a dilute state.
4. By saline cathartics the blood has been dehydrated before the operation and should be diluted immediately after the operation.
5. Drinks lessens severe suffering.
6. Hot drinks stimulate the shocked system and hasten depletion.
7. Fluid drinks induce sweating and deplete the skin.
8. Drinks serve as a source of nourishment and keep up the patient's strength.
9. Experience teaches that results with drinks are equally good and I think better than without drinks.
10. Drinks lessen kidney complications following laparotomy.
11. Hot drinks check vomiting and quiet irritation.
12. Ice and cold drinks must be avoided.

Florence Nightingale astonished the doctors by giving the sick soldiers what their appetite craved. Such nursing did not kill the soldiers, though it disturbed the dignified authority of the great physicians.

A year ago Dr. Byford informed me in conversation on the subject of drinks after laparotomy that he was also giving considerable fluid, and he remarked that his patients did better than previously. I also write from another standpoint.

Some seven years ago I became infected from dressing a wound. I was in bed about six weeks with a high fever. During that time free drinks were not allowed me. I never suffered so much from thirst in my life. Such measures are not sound in physiologic principle. The distinguished surgeon, Mr. Tait, has been the very man who has taught us how to save so many laparotomy patients by *draining* the alimentary canal with salines. Why not drain by the kidney with water!!! I believe that "enforced abstinence" from fluids after laparotomy is not wise therapeutics nor sound physiologic doctrine, and I give, as a final result that systematic experience and systematic observation and reasoning prove to me, that the wisest plan is to give hot fluid drinks after (human) laparotomy.

Respectfully,

F. BYRON ROBINSON.

Chicago, January, 1894.

The New York Academy of Medicine and the Public Health Bill.

To the Editor:—The JOURNAL for Dec. 30, 1892, reported the action taken by the Chicago Medical Society regarding the request of the New York Academy of Medicine to cooperate with it in securing the enactment of a public health bill, and stated that the Society refused this cooperation because the bill did not accomplish the purposes implied by its title, and in general, "the criticisms on this bill might be almost in-

definitely extended." Yet Dr. J. H. Girdner, apparently speaking as a representative for the Academy of Medicine, appeared before the Congressional Committee who were considering the bill, and misrepresented the position of the Chicago Society by the statement that its opposition to the bill was based on the ground that the latter was not radical enough. When asked where the Marine Hospital Service was weak, and in what particulars it did not cover the work outlined in the proposed bill, this advocate replied that he was not there to make war on the Marine Hospital Service, but in the interest of good legislation.

The farcical nature of this latter statement may be appreciated when the bill is compared with the law of Feb. 15, 1893, and it may be seen that twenty-three of the twenty-eight sections of this proposed bill are sections of the former law.

Perhaps it would be well for the members of the AMERICAN MEDICAL ASSOCIATION, and of the various State and local medical societies, to be acquainted with the true inwardness of this bill. In the early months of 1893, the New York Academy of Medicine, by one of the largest votes that has ever been polled, decided by a majority of less than twelve to prepare a bill for a National quarantine. This vote was taken when the law of February 15 had just passed Congress and was awaiting the President's signature.

The President of the Academy appointed on the Committee, A. Jacobi, a consultant and general practitioner; T. M. Prudden, a pathologist; L. A. Sayre, the well-known surgeon, once Health Commissioner of New York; C. C. Lee, a gynecologist, since deceased; Laurence Johnson, a general practitioner, since deceased; A. H. Smith, a general practitioner, Daniel Lewis, a surgeon; E. Bronson, a dermatologist; C. L. Dana, a neurologist; W. T. Lusk, an obstetrician; C. C. Rice, a laryngologist; T. M. Markoe, a surgeon; Mr. Allen Starr, a neurologist; S. B. Ward; C. McBurney, a surgeon; J. D. Bryant, surgeon, once Health Commissioner of New York; R. H. Derby, an ophthalmologist; E. G. Janeway, a consultant, once Health Commissioner of New York; T. Gaillard Thomas, a gynecologist; David Webster, an ophthalmologist; Stephen Smith, a surgeon, once member of the late National Board of Health; J. H. Girdner, a general practitioner; D. B. St. John Roos, an ophthalmologist; and J. West Roosevelt, a consultant.

A sub-committee, consisting of J. D. Bryant, President, R. H. Derby, E. G. Janeway, T. Gaillard Thomas, David Webster, Stephen Smith,¹ and J. H. Girdner was intrusted with the preparation of the to-be-proposed law. The Committee was originally appointed with power to act, and the bill was formulated by the sub-committee without even referring it to the Academy for approval or amendment.

As might be imagined, a bill that was formulated by men, however experienced and eminent in their respective specialties but who were with but one or two exceptions, unknown and unknown in sanitary science, was a hodge-podge of past and present sanitary measures.

Almost every year Congress is approached by tyros in sanitation, whose knowledge of the subject whereof they would speak is in an inverse ratio to the enthusiasm and energy they display in exploiting their views, and who seem to be afflicted with a species of paranoia that takes the form of, what it is sarcasm to designate as their knowledge of the sanitary necessities of the United States. And this year we witness such a bill, advocated by a person whose name has never been heard in any sanitary society or congress in this country, and who endeavors to enhance the desirability of the adoption of his measure by casting slurs and innuendoes on the competency and qualifications of the officers of

the Marine Hospital Service. By chance, the writer happens to know of the many medical colleges in the United States that have been glad to have these alleged inexperienced men as members of their faculties, and of the many medical societies that have honored them by electing them as their presiding officers. Sanitarians know that the officers of the Public Services form the sole permanent medical corps of officers trained in sanitary methods in this country.

The intimation that has been made that the Academy of Medicine's bill should not receive the support of the regular medical societies of this country, because that body started the code fight and has since elected Homeopaths into full membership is not a valid reason for refusing to support it in work for the public or professional weal.

But when it advocates a measure in which a large minority of its fellows do not believe; when such a measure claims to establish a bureau of public health that is nothing but a bureau of seaboard and inter-state quarantine; and when that measure aims to overthrow existing and efficient institutions for the purpose of creating a board that, in the nature of existing customs will become the refuge of the political spoils-man, then it seems desirable that our societies should not only display the true inwardness of the bill, but also protest against its enactment.

There is a large and not unimportant minority in the New York Academy of Medicine who deprecate the influence of the Academy being exercised in endeavoring to secure legislation of the kind proposed, especially as there is good evidence that all the proposed bill can accomplish is being better and less clumsily accomplished under existing National health laws.

ONE OF THE MINORITY OF THE NEW YORK
ACADEMY OF MEDICINE.

No Vivisection Without Anesthesia.

CHICAGO, Jan. 29, 1894.

To the Editor:—I am glad to see (from your article of 23d ultimo) that you agree with me in the main part of my contention, viz.: That there should be no vivisection (as the word is commonly understood) without anesthesia. The leading words in my article (which you speak of but do not quote) are: "No one objects to vivisection with anesthesia." I am also glad to join you in your pride in the results of surgical researches, assisted by anesthesia. There you know vastly more than can be known to a layman. But when you say: "Under all circumstances, when mutilation and cutting is resorted to, anesthetics are used," I think you make an assertion which thousands of men know to be untrue.

Not to take up your valuable space by multiplying examples, I merely cite the following account extracted from the article by Dr. Albert Leffingwell in *Lippincott's Magazine*, August, 1884:

"There is a certain experiment, one of the most excruciating which can be performed, which consists in exposing the spinal cord of the dog for the purpose of demonstrating the function of the spinal nerves. . . . It is not the cutting operation which forms its chief peculiarity or to which special objection would be made. At present all this preliminary process is generally performed under anesthetics. It is an hour or two later, when the animal has partly recovered from the severe shock of the operation, that the wound is re-opened and the experiment begins. It was during a class demonstration of this kind by Magendie, before the introduction of ether, that the circumstance occurred which one hesitates to think possible in a person retaining a single spark of humanity or pity. 'I recall to mind,' says Dr. Latour, who was present at the time, 'a poor dog, the roots of whose vertebral nerves Magendie desired to lay bare to demonstrate Bell's theory, which he claimed as his own. The dog, mutilated and bleeding, twice escaped from under the implacable knife, and threw its front paws around Magendie's heel, licking as if to soften his murderer and

¹ Members who in the past had had Sanitary Service.

ask for pity. I confess I was unable to endure that heart-rending spectacle.' This experiment—which we are told passes even the callousness of Germany to repeat; which every leading champion of vivisection in Great Britain reprobrates for medical teaching; which some of them shrink even from seeing, themselves, from horror at the tortures necessarily inflicted; which the most ruthless among them dare not exhibit to the young men of England,—this experiment has been performed publicly again and again in American medical colleges, without exciting, so far as we know, even a whisper of protest or the faintest murmur of remonstrance! The proof is to be found in the published statements of the experimenter himself. In his "Text-book of Physiology," Professor Flint says: 'Magendie . . . showed very satisfactorily that the posterior roots (of the spinal cord) were exclusively sensory, and this fact has been confirmed by more recent observations upon the higher classes of animals. We have ourselves frequently exposed and irritated the roots of the nerves in dogs, in public demonstrations in experiments on the recurrent sensibility, . . . and in another series of observations.'

Now to bring this citation down to the present day, I beg your attention to the address of Philip G. Peabody, A.M., LL.B. of Boston, delivered in London, June 14, 1893. He says, among other things:

"In explanation of my allusion to the largeness of the number of animals vivisected, I may say that in two institutions which I have within a few days visited in Paris, in each of which I was expressly told that they keep *small* supplies for daily use only, and replenish the stock every day or two, I nevertheless saw, I should say, over a thousand animals intended for vivisection or actually undergoing it, including horses, dogs, monkeys, rabbits, chickens, ducks, pigeons, rats, mice, guinea-pigs, frogs and fish, and was told that they had cows and cats also; the small cages *alone*, in each institution, intended, remember, for one day's supply, would easily hold, I believe, five thousand animals, each the size of a medium sized dog.

"Relative to anesthetics, I will say that out of a large number of vivisections extending over several days, and including various different kinds of animals, no anesthetic or pretence of it was used in one single case. I saw no anesthetics in or about either institution, and feel sure that none is ever used, except perhaps in some unusual case. When a dog is convulsed with agony, he is readily soothed by a caress so as not to disturb his tormentor, and usually licks the hand of his torturer. Any one who will observe a vivisector at work, will see not only that, as one infamous perjurer inadvertently confessed, he is absolutely regardless of the suffering to his victim, but that it must be so. His cutting, mangling, burning, is frequently, I may say habitually, just exactly the same in the case of the living dog as in the case of the dead one.

"I have within one week seen animals operated upon on Saturday afternoon, when the vivisectors left their laboratory, left alive in the laboratory evidently, and as I was told by the operator, to remain until the morning, perhaps Monday morning, unless released sooner by an accidental death, before undergoing the conclusion or continuation of the experiment."

Supposing that you admit the validity of these reports, I think you should join me in the effort to forbid, by law, all vivisection unaccompanied by anesthesia.

JOSEPH KIRKLAND.

The Hyposulphites in Yellow Fever.

WAUKESHA, Wis., Feb. 4, 1894.

To the Editor:—In the last number of the JOURNAL, February 3, on page 138, in a paper by Dr. Joseph Jones of New Orleans on the value of the sulphites and hyposulphites I note this statement:

"2. It has been affirmed that the hyposulphite of sodium given internally in regular doses even in the presence of the poison in a yellow fever epidemic, will completely ward off this disease. *I have no facts with which to prove this statement but would advise that it be put to the test as might easily have been done as I suggested in the recent epidemic at Brunswick, Ga.*" (Italics mine.)

Now it is a little humiliating to read such a statement,

and from such a high source, when the facts are these: In the great yellow fever epidemic of 1878 which created such ravages in Memphis, Granada, Miss., and New Orleans, I not only recommended the free use of the hyposulphites, but in 492 cases then reported, I administered it freely and with most pronounced effect, both as a prophylactic and as a therapeutic measure throughout the course of the disease. After the epidemic I wrote a little book on "Yellow Fever", which was published by Messrs. Wheeler Bros., in Nashville, Tenn., where I held at that time the Chair of Anatomy in the same institution in which Dr. Jones was Professor of Physiology just previous to my entrance to the Faculty. In the spring of 1879 I presented, in person, to Dr. Jones a copy of this work, and it certainly was never read by him as the chapters on prophylaxis and treatment were full of reports anent the action of the hyposulphites as anti-zymotics. I do not write this as a self-advertisement, but I do think that after extensive reviews of my work which appeared at the time it was issued, and the indorsement which the suggestion of this treatment received by those of my colleagues then engaged with me in that awful siege, and its further successful use in the Jacksonville epidemic of 1888, reported extensively through the journals, it is somewhat remarkable that such a statement should appear at this late date, and in such a sweeping manner, especially as I had called in person on Dr. Jones and laid before him a copy of my work for his perusal. Although it is sadly true that "a prophet is not without honor save in his own country," it might perhaps be well to remember that occasionally, at least, "some good may come out of Nazareth."

T. O. SUMMEAS, M.D.

Superfluous Glasses.

IOWA CITY, Feb. 5, 1894.

To the Editor:—In the editorial on "Superfluous Glasses," in the JOURNAL of February 3, there are several points which I can heartily indorse, and some, naturally, that seem to me not well taken. I write now because I am preparing an article on asthenopia, based on records of more than a thousand cases seen in private practice, nearly all among professional people and students. The notes do not cover refractive errors alone, but constitutional conditions, general and local diseases, etc. More than six hundred had errors of refraction, and while relief of refractive error has always been to the advantage of the patient, the cure of asthenopia, in my experience, often requires more than simply making the eye the most perfect optical instrument possible, or securing the so-called equilibrium of muscular movement of both eyes. Asthenopia occurs with one eye, with emmetropia, hyperopia, myopia, all forms of astigmatism, anisometropia, with ear, nose and throat diseases, with uterine and rectal disease, with bad hygienic surroundings, etc.; and all of these conditions occur without asthenopia. Indeed, among my cases of refractive trouble, a little more than half the cases were asthenopic, in each variety. Asthenopia is more frequently found among those with very acute vision than among those with very poor.

While I very much doubt the influence of 0.25D. of hyperopia, or even astigmatism, in the production of *asthenopia*, there is no doubt but that acuteness of vision may frequently be greatly increased by even this apparently insignificant correction. The subject of asthenopia is one deserving more attention from the profession at large than it receives, for it has an important bearing upon occupation and habits through life, and plays an active part in many neurotic complications. If you desire it for the JOURNAL, I will prepare my analysis of cases, and deductions therefrom especially in reference to causation.

C. M. HOBBY, M.D.

ASSOCIATION NEWS.

Success is Assured.—It is very gratifying to be able at this very early date to assure our readers and members in the East that the AMERICAN MEDICAL ASSOCIATION meeting for 1894 promises to be a grand success. We are in receipt of enthusiastic letters from medical men in various parts of California, Oregon and Washington, informing us that they contemplate coming to San Francisco in June to attend the ASSOCIATION meeting and become members of the organization. We can assure them that everything will be in readiness on our part. The various committees are sparing no pains to provide literary feasts and social pleasures to all who may honor us with their presence. There will be grand dinners, balls, excursions on the bay and into the country, receptions, etc., etc. California has already gained laurels as hostess and we can promise that she will do justice to her friends on the occasion of June 4, 1894.—*Pacific Medical Journal*.

Join the American Medical Association.—We would urge every medical man to become a member of his county society, then join the State Society and thus become eligible to membership in the AMERICAN MEDICAL ASSOCIATION, which meets in San Francisco June 4, 1894. The ASSOCIATION should take in at least one thousand new members from this coast. The British Medical Association has a membership of over 5,000, whilst the members of the AMERICAN MEDICAL ASSOCIATION number only 2,000.—*Pacific Medical Journal*.

This is an error. The AMERICAN MEDICAL ASSOCIATION has nearly 5,000 members, while the British Medical Association has over 15,000.—*Editor. JOUR. AM. MED. ASSOCIATION.*

SOCIETY NEWS.

Medical Society of the Missouri Valley.—The spring meeting of this Society will be held in Omaha, Neb., March 15, and continue in session one day. Members contributing papers must send titles to the Secretary prior to February 20, so they can appear on printed program, mailed March 1. Applications for membership can be sent to J. F. White, M.D., Council Bluffs, Iowa, with a fee of \$2 enclosed. A full meeting is expected; a profitable session desired.

F. S. THOMAS, M.D., Sec'y.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 168).

H. E. HAYD, M.D. of Buffalo, read the following paper on
SOME OBSERVATIONS ON THE FINE WIRE COIL OR CURRENT
OF TENSION.

The fine faradic coil or coil of tension has found a recognized place in scientific medicine, and more particularly in gynecologic therapeutics, where its sedative properties are so strongly, as well as satisfactorily, demonstrated. Certain conditions are, however, necessary in order to obtain this sedative quality of the faradic secondary current. The wire must be long, and very finely attenuated, and the interrupter must be capable of very quick and smooth vibrations. The batteries ordinarily sold to the trade can not be depended upon, as the coils are too short, the wire is too thick, and the vibrations too slow. It is, perhaps, a very difficult matter to decide how fine the degree of attenuation of the wire shall be, and whether, after a certain point, the difficulties of insulation become so great as to interfere with the properties and the powers of the current generated. Yet Engleman has demonstrated that a coil can be made six thousand feet in length, and of a wire No. 36, (Brown & Sharpley scale) which is capable of producing a very steady and uniformly soothing quality of current. In my own practice, I have used a coil thirty-five hundred feet in length, No. 32, and tapped at three points, and making it possible, by reason of a convenient little switch, to use fifteen

hundred feet, or twenty-five hundred feet, or thirty-five hundred feet of wire as desired. My vibrator is capable of at least two hundred to two hundred and fifty vibrations per second. Goelet recommends a wire forty-five hundred feet in length, No. 36 in size, and a vibrator from three hundred to three hundred and fifty per second.

Various explanations are given for these great differences in the physical and physiologic properties of the current generated with these different sized coils and wires; and, at the same time, certain indications for employing slow or rapid vibrators.

We are all aware that the immediate and occult effect of the faradic current is to cause tonic contraction of muscle fiber, and if the wire be coarse, this contraction is not only most marked, but decidedly painful. Moreover, this contraction, as well as pain, is increased when a slow vibrator is employed. Consequently, if mere muscular tone and muscular exercise is the desired indication, the wire should be accordingly coarse and the vibration slow, so as to give sufficient time to enable the muscle to thoroughly contract, and then relax itself. On the other hand, if the interruptions be very rapid, the muscles are unable to respond to each vibration and are brought into a condition of constant contraction or rigidity. The sensory nerves of the part, subjected as they have been to this constant and intense stimulation, cease to be impressionable and, as a result, a temporary paralysis or anesthesia takes place, of more or less prolonged duration.

Accepting this reasonable physiologic explanation, Apostoli, Engleman, Goelet, and many others have used the fine coil, or coil of tension in acute inflammations, and have been enabled to provide this subtle but powerful opiate for the relief of the pain accompanying these conditions.

They, (Engleman and Goelet) have demonstrated, what any one of you can verify by a simple trial, that the interrupter or vibrator influences the quality of the current wonderfully. You will find that a fine, rapid vibrator, when used with a coarse short coil, softens the character of the current generated; and that a slow vibrator, when used in conjunction with a long fine coil, gives a harsh, painful and penetrating effect. Therefore, to the interrupter, as much as to the coil, must we ascribe the sedative effects of the current and in order to bring about the most sedation, in an excitable and inflamed area, a fine coil of at least thirty-five hundred to five thousand feet in length, and a vibrator capable of at least two hundred and fifty to three hundred and fifty vibrations per second is an absolute necessity.

I desire, more especially, to call your attention, however, to the application of this wonderful force in relieving and curing many conditions which heretofore have been the *bete noir* of my practice. Slight and not dangerous, but, nevertheless, most annoying symptoms; distressing to the unfortunate patient, and harassing to the medical attendant.

Those cases of neuralgic or neurotic dysmenorrhea, found in young women, associated with much pain and tenderness over the ovaries, and often excruciating pain upon pressure in the epigastrium and pit of the stomach; various reflex dyspeptic symptoms, nausea and vomiting at the menstrual epoch, and constricting pains in the throat, and globus hystericus. Upon vaginal examination there is no fixation, no shortening and distortion of the tubes, and in fact, other than perhaps vaginismus and tenderness in the vaginal vault, no gross evidences of disease whatsoever. I believe in these cases the fine coil may be considered a specific, so satisfactory and delightful have my experiences been. The painful menstrual crises have ceased; the gastric irritability, and epigastric pain and tenderness have passed away as if by magic, and the patient returns for a second treatment, cheerful; after having freely partaken of food and nourishment, which previously not only distressed her, but occasioned pain and immediate vomiting.

Various nervous manifestations due to some irritable condition of the nervous mechanism of the bowels; flatulence, roaring, and croaking noises, which so seriously disturb the comfort and happiness of so many young women. In one case, that of a young unmarried woman, in whom I had tried every medicine known to me without appreciable effect, and where the condition was so exaggerated that she was denied the pleasure of society, and was fast becoming a hopeless hypochondriac. I found the ovaries tender and sensitive to the touch; pain was elicited by pressure over the pubic and iliac regions, and there was also marked epigastric tenderness. Ten treatments in all were given, and a perfect and permanent cure was effected. This case I reported in the March, 1892, number of the *Buffalo Medical and Surgical*

Journal. This treatment has proved especially valuable in those acutely retroflexed uteri, where the body is so hypersensitive that even the slightest pressure provokes the most distressing pain. In inflamed, tender and prolapsed ovaries, the pain has often been relieved sufficiently to enable a proper fitting support or pessary to be borne with comfort and satisfaction. Moreover, it is a valuable agent to complement the treatment of painful conditions; in fact, to supplement galvanism, vaginal or intra-uterine, when indicated. I have also found it occasionally of very great service in relieving the post-operative pains of salpingotomy and in one case in particular, (that of a young widow, from whom I removed two large pus tubes and ovaries,) it was especially valuable. She returned after two months, suffering great pain in the region of the left stump. No apparent reason could be assigned, and the condition was treated empirically with the fine faradic coil. Relief was immediate and permanent after a few treatments.

I have not met such encouragement in the treatment of the pain and local tenderness of slight salpingitis; those cases where the uterus is not fixed and its movements not specially restricted, but simply pain and tenderness are complained of on elevating the organ, or moving it laterally from side to side, and especially at the cornual junction. Nor has the tenderness of endocervicitis, and endometritis and metritis yielded as kindly; making me, therefore, feel that the fine coil is more especially useful in those irritable nerve conditions or neuralgias, dependent upon some peculiar vaso-motor influence or disturbance.

But, it may be possible with a wire forty-five hundred feet in length, and a vibrator capable of at least three hundred and fifty vibrations per second, that a current of less stimulation, and of more sedative qualities would be obtained; and therefore bring about more encouraging results. Its application has the great advantage of being practically without danger, and it can be administered in the vagina by reason of a simple bi-polar vaginal electrode.

And to those of us who have studied the causal relationship between uterine disease and intra-uterine medications and applications of all kinds and sorts, this consideration offers very great consolation. The difficulties of diagnosis in rare uterine troubles are often very great, while pain, the symptom so commonly complained of, can often be relieved and without adding an element of danger, by reason of perhaps uncalled for and unnecessary intra-uterine manipulations.

Let me briefly give the histories of two interesting cases, not previously recorded, that will demonstrate in unmeasured terms my appreciation of the fine faradic coil in properly selected cases; (I must also add that these two cases are but two of a large number of similar ones):

Miss E., age 22, well nourished, healthy blonde of Irish extraction, consulted me for stomach trouble. Nausea, vomiting and inability to retain any food, not even teaspoonfuls of water; great pain in the pit of stomach, mental distress and anxious forebodings; menstrual periods were regular, but accompanied by great pain for twenty-four hours previous to their appearance. These symptoms were always associated with the menstrual molimen, and would last for some days after the flow ceased, but never in such an aggravated degree. I ordered her to swallow broken pieces of ice, and to apply mustard plasters to the pit of the stomach, and prescribed acid hydrocyan, dil. and soda bicarb. No relief was obtained, and the nausea was simply increased. Small doses of ipecac were tried, and then Gill Wylie's tablet of bismuth and oxalate of cerium. But to no avail. Finally, a hypodermic injection of morphia gr. $\frac{1}{4}$ and atropia gr. I-150, but this only gave temporary relief.

As matters were becoming alarming, a vaginal examination was made. Nothing was manifest to the eye. The hymen was intact. No preputial adhesions, and the nymphæ were not enlarged or rugose. The rectum was healthy, and free from erosions and fissures. The vaginal vault was excessively tender, and so much pain resulted from the examination that I was forced to desist. The iliac regions and the epigastric pit were especially tender upon slight palpation. The medium sized fine bi-polar vaginal electrode of Apostoli was inserted, and the current gradually increased. The sèance lasted about fifteen minutes, until all pain and tenderness had entirely disappeared. A vaginal examination was then made and other than a slight anti-flexed uterus, nothing abnormal could be made out. The stomach distress at once disappeared, light food was taken, and inside of forty-eight hours a very generous and wholesome diet indulged in. The treatments were given twice a week until the following menstruation appeared. It came regularly,

and with no pain, and no stomach distress. The cure has been permanent, and seven months have elapsed since the last treatment.

The next case I saw in consultation with Dr. Morrison: a young unmarried woman, age 26, with the following history; menstruated first at 17; much pain and frontal headache. Fairly regular, but at intervals from thirty-four to thirty-six days, and the flow would last four days. Dysmenorrhea, frontal headache, great nervous excitement, nausea, vomiting and aphonia were the usual menstrual accompaniments. I found her in bed, where she had been for six weeks. Very thin and emaciated, and suffering with a good deal of abdominal pain. She had been vomiting for some days, and could take but very little liquid nourishment, and consequently, had been fed by nutrient enemata. Valerian, assafetida injections, and the usual hysterical remedies had been faithfully tried. There was no fever present, but the aphonia existed, and the stomach distress was very great. The pain and tenderness upon pressure over the ovaries and epigastric region were marked, as well as the hyperesthesia of the vaginal vault. The fine faradic coil was advised, and the most gratifying result followed its employment. Dr. Morrison told me that the pain and tenderness immediately disappeared, and after the second treatment, the dysphonia. The treatments were continued bi-weekly for two months. The subsequent periods came without any manifest inconvenience, and the young woman is now in good and robust health.

Another case of this same class suggests to my mind the wide field of possible usefulness of the fine faradic coil:

A young girl, age 17, well nourished, and of rather large, coarse, muscular build, but quite intelligent, with the following history: menses first appeared when 13; no pain. Irregularity, intervals from two to three months. Falling fits, occurring frequently, and of late, two and three in a day; unconscious during the attacks. Sometimes froths at the mouth; occasionally pulls her hair out, and once bit herself on the arms and hands. Upon examination there was great pain and tenderness, over the ovarian and epigastric regions; and while pressure was being made over the pit of the stomach, a fit was induced. It was of the nature of hystero-epilepsy. The arms and legs were thrown into violent spasms, and the body presented a horribly distorted appearance. The lower jaw was pulled to the left side, and the eyes half open, and looking to the right with the head semiflexed on the right shoulder. Violent respiratory movements occurred; the nostrils were blown in and out, but the face was not livid, as in epileptic, or uremic convulsions. The jaw was fixed, and no frothing occurred at the mouth. The fit lasted about two minutes, and by continuing the pressure over the epigastric pit, another paroxysm occurred; and seemingly any number of paroxysms could be induced by the pressure. While unconscious, the small sized electrode was inserted into the vagina, and by pressing on it so that it pressed against the vaginal vault another paroxysm resulted. The current was turned on, and after five minutes, firm pressure could be made in the vaginal vault and over the pit of the stomach, without inducing any pain or convulsive manifestations whatsoever. She seemed to be tired and sleepy after the sèance, and therefore was placed on a lounge; where she remained in a sound sleep for an hour. She returned in three days, and upon pressure in the epigastric pit no pain or spasm could be provoked. She also said, that previous to the fit she complained of a sick funny feeling at the pit of the stomach, and probably it was from this excitable and sensitive area, that the aura proceeded. She is still under observation and so far, three weeks, has had no falling attacks.

DISCUSSION.

DR. A. LAPHORN SMITH said he could heartily corroborate everything said about the use of the fine wire. He had treated at least a half dozen cases in which laparotomy and removal of the appendages had failed to help the patient, and yet they were completely relieved of all symptoms by the fine wire current.

DR. ENGELMAN said that the paper stated that 300 or 350 interruptions per second were obtained with the author's apparatus; yet as good an interrupter as he could find, i.e., the one on the best of Gaiffe's instruments—gives only 3,000 interruptions per minute, or 50 per second. If the author had really used 350 interruptions per second, the patient would not have felt the current. To get the best results we must know the dosage and precise method of application. The average vibrator on the ordinary instrument—makes 2,000 to 2,500 interruptions per minute. This is what

is called fast vibrations. Variations in adjustment will vary this rate within moderate limits.

It is important to know the number of windings on the coil—more so even than the number of feet of wire. The windings mean lines of force, and this means voltage.

Dr. MASSEY moved that the discussion on this subject be adjourned until other papers of like import had been read. Seconded and carried.

(To be Continued.)

NECROLOGY.

Wm. B. Baker, M.D. of Bristol, Pa.

Edward S. Lawrence, M.D. of Philadelphia.

C. Refkowsky, M.D. of Chicago, January 23.

Dr. Harold Haas of Wabash, Ind., at Deland, Fla., February 4.

George W. Parvis, M.D. of Centerville, Md., died January 26, age 67 years.

Mathew T. Scott, M.D. of Lexington, Ky., died in Texas, January 26, age 38.

Erasmus M. Kent, M.D. of Bristol, Vt., January 26, age 57. He represented Bristol in the Legislature in 1890.

Willis O. Gilson, M.D., at Erie, Pa., January 25. He was graduated at the Western Reserve College, and was about 35 years of age.

Samuel Warde, D.D.S. of Cincinnati, January 24, age 71. He was an active member of the Mississippi Valley Dental Association and had received generous recognition of his skill in mechanical dentistry, by the presentation of medals from various societies and institutions.

Adolph Sauerherring, M.D. of Mayville, Wis., died January 24, at the advanced age of 73 years. He was a practicing physician for over half a century, and was buried under the auspices of the Masonic Lodge of Mayville on Friday, the 26th inst.

Benjamin S. Anderson, M.D., died near Media, Pa., suddenly, from heart disease age 71 years, January 24. He had been in Philadelphia at the meeting of a medical society the night before, and was on his way home when he became sick. He was a popular and successful practitioner.

Horatio N. Buckley, M.D. of Delhi, N. Y., January 24, age 74. He had lived at Delhi for the last fifty years. He was twice Treasurer of Delaware County, and sixteen years Postmaster, and for many years had been the President of the Trustees of the Delhi Academy.

Dr. Edward Griffin Crafts died at his home in East Maine, Otsego County, N. Y., January 26. He was born in Cherry Valley on July 4, 1821. Graduated in 1850 from Geneva Medical College, soon after was appointed by Cornelius Vanderbilt as Surgeon of the California steamship, *Northern Light*. In 1853 he was appointed Resident Surgeon and Agent for the Transit Company at Virginia Bay, Nicaragua, Isthmus of Panama. He later practiced in Binghamton and removed to East Maine in 1879.

Edmund Burke Haywood, M.D. of Raleigh, N. C. He was born in Raleigh in 1825; was graduated with the class of 1847 from the University of North Carolina, and received his medical degree from the University of Pennsylvania in 1849. He was Surgeon of the North Carolina State troops in 1861, and in 1862 appointed Surgeon in the Confederate Army, and placed in charge of the general hospitals at Raleigh. He was the founder of the Raleigh Academy of Medicine, and an ex-President of the State Medical Society. He was greatly beloved and esteemed by the community in which he lived.

Prof. August Hirsch, M.D., Privy Medical Councillor, died at Berlin on January 29. He lectured at the University on

pathology and the history of medicine, was celebrated for his researches into the geographic distribution of epidemic diseases, and was the most distinguished epidemiologist who ever lived. His chief work was published by the Sydenham Society, and the labor and care taken in its preparation was simply monumental. For forty years the writer has been familiar with the epidemics of this country, and can testify to the accuracy of the facts as stated by him in many instances. When we last saw him in Berlin he was engaged in revising his great work and bringing it up to date. Sanitary science owes him a great deal, and sanitarians will deeply regret his death.

John H. Murphy, M.D. of St. Paul, Minn., Jan. 31, of carbuncle. He was born at New Brunswick, N. J., Jan. 22, 1826. His father was an officer in the army of the United States in the war of 1812, but was by occupation a shipbuilder. He removed to Adams County, Illinois, in 1834, and established a farm near Quincy. Here young Murphy received his early education, and afterwards was a pupil of Abram Hull, M.D., of Lewiston, Ill. He was graduated at Rush Medical College with the class of 1850, and at the time of his death was President of the Alumni Association of that institution. After his graduation he practiced at St. Anthony, Minn., where he resided until 1864, when he removed to St. Paul. In 1861 he joined the volunteer service as Acting Surgeon of the First Minnesota Volunteers, and six months later was commissioned Surgeon of the Fourth Minnesota. While in the field near Vicksburg he suffered from sunstroke and returned home, but recovered and rejoined the service as surgeon of the Eighth Minnesota Infantry. At the close of the war he resumed practice in St. Paul, and for a long time was chief surgeon of the railroads passing through St. Paul. He was Surgeon General of Minnesota for twenty years, having been appointed to that office in 1874. During his long and eventful life he occupied many positions of honor in the building up of the new State, having been a member of the Legislature of 1852 and of 1855, and of the Constitutional Convention of 1857. He was a member of various Masonic bodies, and was held in high esteem by the old soldiers, no reunion being deemed quite complete without the presence of Dr. Murphy. He was married June 28, 1848, to Miss Mary A. Hoyt, and they have had seven children. He was a regular attendant at the meetings of the AMERICAN MEDICAL ASSOCIATION, where his genial presence and his sturdy common sense views on medical subjects made him a general favorite. He will be greatly missed by the older members, and as well by many who had only recently become members of our great medical organization.

Roswell G. Bogue, M.D.—The following is the report of the Committee of the Illinois Commandery of the Loyal Legion, on the death of Dr. Bogue of Chicago:

Major Roswell Griswold Bogue was born in Louisville, St. Lawrence County, New York, May 2, 1832, and died in Chicago Dec. 8, 1893. He was educated at the Castleton Academy, Vermont, and spent the earlier years of his young manhood in teaching. From the East he came to Columbus, Ohio, where he read medicine with a distinguished surgeon of that time, Dr. Norman Gay. He then attended the College of Physicians and Surgeons of New York City, from which he received his degree in the winter of 1856 and '57, and in the spring of 1857 located in Chicago and began his successful career in the practice of medicine. He found friends at the outset of his career, fitted as he was for the healing art, both by nature and education.

Upon Aug. 5, 1861, he was commissioned Major and Surgeon, and assigned to duty as Surgeon of the Nineteenth Illinois Infantry, and continued constantly in this service, until mustered out on July 9, 1864.

The Regimental Surgeon of the United States Army enters upon his duty with no expectation of increased rank or pay. He can hope for increased honors and responsibilities—and these came to Dr. Bogue. He served with his regiment through the Missouri, Kentucky, Tennessee and Alabama campaigns up to March, 1863, when he was appointed Medical Director of the second division of the Fourteenth Army Corps, commanded by General Negley. When the Army of the Cumberland was reorganized in October, 1863, Dr. Bogue was transferred to the third division of the Fourteenth Army Corps commanded by General Baird, and

again honored by the appointment as Medical Director. He was with this command in all the battles in which it participated, notably those of Chickamauga, Chattanooga, Mission Ridge, Buzzard's Roost and Resaca. In all of these posts of duty there is one continuous record of faithfulness and efficiency.

Dr. Bogue was a man of deep sympathy and he did not know what it was to spare himself when a wounded soldier was begging for help. After a battle it was no unusual experience of the faithful surgeon, to work all night, sometimes leaning over the operating table until he found it impossible to straighten himself into an erect attitude, without the aid of his assistants. It was there amid such surroundings, performing the most difficult operations of surgery by the glaring light of torches and tallow candles, with body and mind taxed to their utmost, that he doubtless laid the foundation for the disease that later on destroyed the nerves of his eyes, and then ended his life by attacking the brain.

At the close of the war, Dr Bogue returned to Chicago, and again entered upon the practice of his profession. He had a natural aptitude and love for surgery and sought as much as possible to give up his general practice, and devote himself exclusively to it. This he found it difficult to do, honored and loved as man and physician, in a multitude of homes. In addition to his skill as an operator, he was masterly in diagnosis, and his opinions were widely sought by his professional brethren.

He was one of the organizers of the Cook County Hospital, and was for thirteen years one of the Attending Surgeons. He was the first Professor of Surgery in the Woman's College, and was for many years the Attending Surgeon for the Hospital of Women and Children. He was Consulting Surgeon for both the Presbyterian and St. Joseph's Hospitals from their organizations until his death. Major Bogue joined this Commandery Dec. 5, 1883, and it is safe to say no member more keenly enjoyed its privileges. After he became entirely blind the members of the North Side made it their pleasing duty, to take turns in escorting him to the meetings, whenever the weather and his failing health permitted; and he frequently expressed his gratitude, and spoke of the meetings as the enjoyable events of the month. Blind and shut off in a large measure from later events, he loved to live over again the old army life in the papers, the old songs and the reminiscences of life in camp. Both socially and professionally the old soldier always found a sympathizing friend in Dr. Bogue, and as a citizen he was a man among men.

He was a profoundly religious man who exemplified its teachings by his every-day practical life of "doing good." Called from us before his three-score years and ten, yet his was a beautiful, well-rounded life, and one whose memory this Commandery will cherish. While we enter upon our records our high appreciation of our departed brother and express our own sorrow, we desire to tender to the loved ones in his stricken home our profound sympathy.

OLIVER W. NIXON, EVERETT B. PRESTON, ALBERT L. COE,
Committee.

BOOK NOTICES.

Addresses, Papers and Discussions in the Section of Ophthalmology at the Forty-fourth Annual Meeting of the AMERICAN MEDICAL ASSOCIATION at Milwaukee, June, 1893.

It was a happy innovation inaugurated three years ago by the Section on Ophthalmology to collect all papers read at its meetings and to republish them, after they were published in the JOURNAL OF THE ASSOCIATION, as the "Transactions of the Section."

In the present volume we miss the familiar names of some members who in the past had been among the most active workers, and who always had something interesting and instructive to present to the meetings; but on the other hand it is gratifying to note the number of new contributors; for this is a hopeful sign of the growing interest taken by the ophthalmologists all over the land in the work of the Ophthalmological Section of the ASSOCIATION.

There were thirty-three papers read in this Section at Milwaukee, and although they are not all of the highest grade of excellence, every one interested in ophthalmology will find much valuable information in this book, which he can obtain at the small expense of \$1.00 by applying at the office of this JOURNAL.

SELECTIONS.

A Case of Intussusception, Operation, Recovery.—An eleven-year-old boy was attacked suddenly with persistent vomiting and bloody stools. A sausage-shaped tumor was discovered in the left hypogastric region. The lower end of the tumor appeared to be near the ileo-cecal valve; the upper end disappeared under the circle of the lower rib. There was tenderness on pressure. Laparotomy was performed and the invagination, which consisted only of the colon, was reduced with great difficulty. A gangrenous spot was discovered, about the size of a 5 cent piece, under which a tumor the size of a hazel-nut was found. An artificial anus was made, and closed in eleven to twelve weeks. The boy made a good recovery and was discharged five weeks after operation.—G. LINDEMANN in the *Centralblatt für Chirurgie*. January, 1894. [Abstracted for the JOURNAL].

Academie de Medicine de Paris.—Session of Jan. 10, 1894, M. Proust called attention to the fact of an outbreak of malignant pustule having occurred, which was traced to an importation of Chinese goatskins.

M. A. Voisin reported a case of a female attacked with melancholic mania following a right facial neuralgia dating from 1870, which had resisted all treatment, and the woman died in his service from a uterine cancer, which was found at the necropsy. There was also compression of the frontal and parietal right ascending convolution by a sort of pool formed by the cerebro-spinal fluid. In a case of this kind, craniotomy was evidently the only efficacious treatment.

M. Galeowski read a paper showing that glaucoma is due to a lymphangitis of the eye obstructing the lymphatic channels and, notably, the canal of Schlemm. Repeated external sclerotomy is the best means of relieving the obstruction.—*Progrès Médicale*, Jan. 13, 1894. [Abstracted for the JOURNAL].

E. Bassini's New Operative Method for the Radical Cure of Femoral Hernia.—This method of operating for the radical cure of femoral hernia is designed on an anatomical basis and besides being very simple has the advantage of showing many lasting results. It is evident that it will soon become as popular as Bassini's method for the cure of inguinal hernia.

Bassini shows that the femoral canal which is a funnel-shaped or triangular opening with its apex downward, is closed normally by the cribriform fascia which is directly connected with the fascia lata, Poupart's ligament and the fascia pectinea, and that neither the falciform process or Gimbernat's ligament exist as such, but are formed by the tearing and giving way of the cribriform fascia, thus forming the rupture. This occurs at the narrowest part of the canal in the femoral or crural ring.

Bassini here illustrates from a plaster cast, made by injecting plaster-of-paris into a femoral hernia, which shows plainly the position of this ring whose lower boundary is marked by the close underlying great saphenous vein at its junction with the femoral vein.

This position, as well as the normal tension of the femoral sheath, explains the fact that in a stricture or compression of a femoral hernia these veins are not affected. Normally, the tension of Poupart's ligament with the fascia lata and the cribriform fascia form a sufficient barrier against the descent of a hernia. The relaxation of these parts, as well as the separation of the fibers of the cribriform fascia, is accountable for the formation of a femoral hernia. This is also the cause of its greater frequency in women, who besides this have a broader pelvis than a male, and in whom the abdominal walls give way more easily.

The object of the operation is to bring the prolapsed and crowded parts back to their normal position and tension.

Bassini lays bare the sac, the fascia lata and fascia pectinea

by an incision close under and parallel with Poupart's ligament. The sac is drawn well up above the crest of the pubis and an incision is made through it and the contents replaced in the abdominal cavity. The sac is then twisted on itself, pulled well forward and secured around its neck with clamps. The neck is then transfixed with several ligatures, the remaining portion cut away, and the stump replaced. This leaves the femoral ring plainly exposed and the structures forming the canal lie free. This is now closed with six or seven stitches as follows: The first stitch begins well up near the pubic spine and passes through Poupart's ligament. The next two stitches, near the femoral vein, lie parallel to the above, the fourth pierces the falciform process and the pectineal fascia, while the last stitch will be close to the point of exit of the saphenous vein. The ligatures are now tied, beginning from above, thus forming a letter, C. This is caused by the tension of the first three sutures which are depressed in the middle and lie close to the os pubis. Including the suturing, the entire operation lasts only from fifteen minutes to half an hour.

Bassini allows his patients to leave their beds in from eight to ten days, and dispenses with the use of a truss. In this manner he has operated on fifty-four hernias in fifty-one individuals (forty women and eleven men) ranging from 17 to 70 years of age. All recovered without complications. Eight left the hospital on the ninth day, twelve on the tenth day, five on the eleventh day and four on the twelfth day; the remaining twenty-one on the thirtieth day. None wore a truss and all resumed their usual occupations. Twenty-seven were kept under observation from three to nine years.

These good results speak clearly enough in favor of this operation, which for its simplicity should be recommended above all others.—ESCHER in *Centralblatt für Chirurgie*, January, 1894. [Abstracted for the JOURNAL].

MISCELLANY.

A. L. Neeley, M.D. of Leavenworth, Kan., has been appointed United States Marshal.

Back Number.—Members of the Association who do not keep a file of the JOURNAL will confer a favor by mailing to this office their copy of the issue of January 6, 1894.

Charles D. Rogers, M.D., formerly of Troy, N. Y., has been appointed Clerk of the United States District Court for the District of Alaska.

Dr. Laveran, well-known for his researches on the hemozoon of malaria, was elected to fill the vacant chair in the Therapeutical and Natural History Section of the Academy of Medicine, Paris.

Restrictions against Tuberculous Patients Not Wanted.—During the past week a committee of the College of Physicians and Surgeons called upon the Philadelphia Board of Health, and in compliance with instructions protested against placing restrictions upon the movements of tuberculous patients.

Oppose Vaccination.—The Lutheran clergy and the local Turner Societies of Milwaukee have joined the anti-vaccination league, and it is said will try in court to fight the order of the Board of Health which requires all school children to be vaccinated.

The Greek Government has appointed Dr. D. Pavlides, Consul of Greece at San Francisco. He was educated at the Greek National College at Constantinople, and in medicine at the Ecole de Medicine of Paris. He is said to speak six languages.

Two Physicians Expelled.—A recent Berlin cable says that the Society of Physicians in Leipsic have expelled two members because they belong to the local executive of the Social Democratic Party. The physicians were at first requested to resign, but they refused to do so. The meeting which resolved to expel them decided also to amend the Society's regulations so as to exclude from membership all Social Democrats. This step is justified on the ground that many

members of the Society who are army surgeons would be obliged to resign in case Social Democrats were admitted.

The Southwark Church Dispensary, Philadelphia.—The sum of \$25,000 has been devised to the above named charity, by the will of the late Capt. George W. Stever of Philadelphia. Three other institutions will receive the like sum. The Protestant Episcopal Hospital, of the same place, has a donation of \$5,000, under a bequest by John Boyer of Norristown.

Diphtheria.—Secretary Hunt of the New Jersey State Board of Health, has censured the Chesilhurst Township Committee, which is also the Township Board of Health, for dereliction of duty in the case of the two children of Michael Ball, who died recently of malignant diphtheria. The local Board of Health failed to compel the family to hold a private funeral as directed by County Physician Iszard, and a public funeral was held and many people, including nearly all the school children in the township, viewed the bodies, thus endangering their health and lives.

Infectious Diseases in France.—The French Minister of Public Instruction has issued certain regulations regarding the management of children sick with diphtheria, where those children are attending school. The period of exclusion of the sick child is placed at thirty days; successive disinfections must be practiced; no fruit may be consumed by the children during play hours. In respect to scarlet fever, the period of exclusion must be forty days, and the school is to be closed if several cases spring up within the first five days after the disease has been verified.

Another "Cancer Cure" Losing Ground.—The *Medical News* has been paying its respects to the notorious Mr. Stead—editor of the *Review of Reviews*—now in this country, for his advocacy of the nostrums of Count Mattei. Plain water was sold in London under the names of white, red and green electricity, at exorbitant prices, until an investigating committee compelled Mr. Stead to withdraw his approval from the smart scamps who had been trading on his reputation. A brave English journal, *Food and Sanitation*, states that the income of the representatives of the Count Mattei remedies was for a time at the rate of a half-million dollars a year.

Higher Requirements for Entrance to Medical Colleges.—The Illinois State Board of Health amended the schedule of requirements for admission to medical colleges by taking out of the hands of the college the examination in the elementary branches of education, and requiring either a certificate or diploma from a literary and scientific college or high school or, at least, a second-grade teacher's certificate. A curriculum of studies for schools of midwifery was also adopted. A committee was appointed to draft an outline of sanitary work throughout the State, and the Secretary was ordered to issue a "preventive disease" circular on tuberculosis.

The officers were reelected as follows: Dr. William E. Quine, Chicago, President; Dr. J. W. Scott, Springfield, Secretary; and Dr. B. M. Griffith, Springfield, Treasurer. The Governor has reappointed Dr. Julius Kohl of Belleville, a member of the Board.

Minnesota Lunacy Law Unconstitutional.—The Board of Trustees of the State Hospitals for the Insane met at St. Paul, January 30, for the purpose of considering what action, if any, can be taken to meet the circumstances arising from the recent decision of the Supreme Court declaring the insanity law of 1893 unconstitutional. The officers in charge of the various asylums and the members of the State Board find themselves in a very peculiar and delicate position, owing to the fact that there are at present some 740 insane patients in the various asylums who were committed to their custody under the unconstitutional law. It would be a calamity to release these insane patients, and there might arise some difficulty in detaining them. The meeting was called to devise some method of meeting the complication, and it was considered the wisest course to meet in executive session until a satisfactory plan is decided upon.

Those present at the meeting were President J. W. Mason,

ORIGINAL ARTICLES.

THE SCOPE OF DERMATOLOGY.

Chairman's Address read in Section of Dermatology and Syphilography,
at the Forty-fourth Annual Meeting of the American Medical
Association.

BY LOUIS A. DUHRING, M.D.

PROFESSOR OF DERMATOLOGY IN THE UNIVERSITY OF PENNSYLVANIA.
PHILADELPHIA.

On the occasion of the last annual meeting of this Section of the ASSOCIATION, the honor to preside over the deliberations of the present meeting was conferred upon me. It affords me pleasure to greet you as members of the ASSOCIATION, and especially as attendants upon the work of this Section, whose importance I believe must be more fully recognized by the profession with each succeeding year. Before taking up the original papers to be presented for reading and discussion I would ask your attention for a few moments to consider of what dermatology actually consists. The subject, I believe, will not prove uninteresting nor without profit practically. Let me propound the questions, What are so-called skin diseases, and what is their nature? Which diseases are entitled to be designated "skin diseases?" Is it possible to separate them from the many general diseases accompanied by cutaneous symptoms?

Answers to these questions may at first thought appear easy, and so they seemed to the writer many years ago, when thoroughly imbued with the spirit of local pathology, as taught by his former and respected master Hebra, it was deemed all-sufficient to study cutaneous diseases purely objectively. But the questions propounded upon investigation really became difficult problems, especially with the light that has been thrown upon dermatology by comparatively recent studies. The field, viewed in every direction, has become immensely enlarged, and the amount of work done, both clinical and pathological, has been remarkable. I believe, however, that a satisfactory solution of these problems may be found. The questions that immediately confront us are, shall the term, "skin disease," continue to be used in its ancient sense? Shall the affections of the skin be looked upon as morbid entities, as diseases whole and complete in themselves and confined to the skin? Or, taking a broader view of the subject, shall they be defined so as to include all manifestations that may occur upon the integument irrespective of the symptoms, cause or nature.

The first and restricted proposition is that according to which these diseases were studied and classified a century ago, by Plenck in Germany and by Willan in England, when the list of diseases was small and knowledge of them meager. I have no desire to belittle the work done by the fathers of dermatology. Willan, especially, was an eminent general physician as well as a distinguished dermatolo-

gist. His treatment for the commoner affections of the skin was both judicious and successful. But the important questions of etiology and pathology were then for most diseases not at all understood. Very little was known on those subjects. The origin of most disease was regarded as "obscure." The facts that a mite was the sole cause of scabies, and that ringworm was due to a fungus were still unknown, while the observation that almost all the drugs in the "Pharmacopœia" are capable of producing disorder of the skin was not even suspected. Affections of the skin were regarded mainly objectively, and were studied much as a model or a picture might be viewed. Beyond the actual expression on the integument they were not closely investigated; the causes were regarded as obscure; and this mode of studying them has held good through decades, up to almost the present date. This method is in no way to be criticized, so far as it goes, but by itself and without the assistance of general pathology, it is far too restricted to meet the requirements of existing knowledge. It fails to recognize the important fact that the integument is a part of the whole organism, and therefore is subject to the great laws of general pathology, and that diseases affecting the integument are not only to be studied as localized areas of disease, but also in their relation to the system at large.

For the majority of cases no laws can be laid down tending to separate the local from the so-called general diseases. This is particularly true of the inflammatory affections, and I believe in many cases it is wise not to press such questions too closely in our endeavor to determine these intricate problems. Local pathology, interesting and satisfactory as it is as a study, must never be permitted to outweigh the general process, to which in many instances we must look as the *fons et origo* of the disease. That some diseases are strictly local in all their aspects will be denied by no one, but it is practically often difficult to decide where to draw the line between such affections and those due to influences and causes remote from the skin, as, for example, in the case of the many and often obscure reflex affections.

On the other hand, it is not difficult with our knowledge of to-day, to give examples of some true skin diseases. Notably among these may be mentioned the local parasitic affections, the inflammations due to numerous external causes, as for example the rhus plant and certain of the hypertrophic, atrophic and neoplastic diseases, such as callositas, clavus, cornu, molluscum fibrosum and molluscum epitheliale. In these affections, and in some others that might be cited, as far as our knowledge extends, the skin is the only organ of the body invaded at any time in the course of the disease. But while this holds true for a considerable number, there are still many that are in reality widespread diseases,

the skin being only one of the organs involved by the process.

As instances of such may be cited the so-called exanthemata, as well as other eruptive fevers, the eruptions due to various poisoned states of the system, as in septicemia, glanders, leprosy and syphilis. There also exists another group of well-known cutaneous manifestations in which it is difficult to determine whether the process is really confined to the skin, and whether it does not also involve other structures of the body as, for example, the epithelium generally, as in pityriasis rubra and dermatitis exfoliativa. Another group would comprise herpes zoster, pemphigus and the like, where the nervous structures, central or peripheral, are in some way at fault.

Still another class consists of diseases which, while eminently skin diseases, are in some cases, at least, dependent upon certain peculiar states of the economy for their existence, as a type of which psoriasis may be given. As an example of the effect of the state of the system at large upon this disease, I may cite the case of an old gentleman, an experienced physician, whose chronic and inveterate psoriasis had resisted all manner of internal and local treatment, but who upon going to sea immediately experienced relief and a rapid diminution in all the symptoms, so that in less than a fortnight he had practically recovered from a disease which had for a long period proved entirely intractable to our best remedies.

Another well-defined disease attacking the skin is eczema. While this is often a local affection, it may also be started into existence and kept up by serious internal derangements of the economy. In the latter cases it must be regarded in part, at least, as a symptomatic affection, as in the case of other symptomatic disorders, as urticaria; for with improvement of the digestive and assimilative functions or nervous system the eruption improves or disappears. These observations are particularly striking in the case of infants and children.

But it is not so much my purpose to specify and to differentiate the local from the general diseases affecting the skin, as it is to direct attention to what I believe to be an important truth in medicine, namely, that many cutaneous lesions which have long been and still are regarded as local skin diseases are really cutaneous expressions of certain general pathologic processes, due to varied causes. If this proposition, which might be elaborated, be accepted as an accurate observation, it brings us to the point I am desirous of establishing, namely, that our ideas of dermatology should be greatly enlarged. I am firmly of the opinion that this branch of medicine should include all morbid manifestations that appear on the skin, whatever may be their cause, their nature and their character. Dermatology has properly to do with the integument and all that pertains to it, and moreover with all the varied causes that may disturb that organ. Thus the exanthematous and the numerous and diverse symptomatic eruptions, whether superficial or deep-seated, fugitive or persistent, are all entitled to a place in the group. One observation in support of this view is that practically it is often impossible to differentiate the several varieties of cutaneous inflammation which resemble one another, except through the causes which produce them. It is a notable fact that the same pathologic state of the skin and the same

lesions may be produced by several and even diverse causes, directly or remotely, entirely distinct from one another, as in the case of acne, acne rosacea and urticaria.

Thus we note in practice that the lines separating the so-called idiopathic from the symptomatic diseases are far from being so sharp as is generally supposed. Authors of text-books and systems of dermatology would have us believe that the various diseases may all be arranged and satisfactorily classified, and that they may in all cases be readily differentiated from one another. While this undoubtedly holds true for the majority of cases, ample allowance must be made for atypical, irregular and anomalous forms of disease, of which there occur, I am convinced, more examples than most authors are disposed to admit. Nor is sufficient latitude given in describing disease in general for complications which may occur, nor for the merging of pathologic processes into one another. On this latter point, in particular, I would lay stress, especially as expressing certain anomalous forms of diseases. Mr. Hutchinson, of London, was one of the first to direct attention to this point, of which we all I am sure have seen examples.

As our knowledge of disease grows, so does the list of diseases increase, new affections, new varieties and combinations appearing and being described. To illustrate this observation we have but to look over treatises on dermatology published twenty-five years ago and to compare them with the works of to-day. The growth in this direction has been remarkable. Not only has the list increased, but it is still growing from year to year. Observations of this kind go to show, I think, that it is only a matter of time when every lesion that may occur on the integument must be included in dermatology. There was a period, not many years ago, as most of us can remember, when erysipelas was regarded as an exanthema—an exanthematic fever, and as being therefore altogether beyond the pale of dermatology. In those days that disease, it was said, was not a skin disease but a constitutional or a general disease, and that its relation to the skin was only incidental. How fallacious was this view, how slight our knowledge about this disease then, I need not more than refer to. I believe that before long certain other diseases will be recognized as being properly entitled to a place in cutaneous medicine which now are relegated elsewhere. Such a grouping should obtain, not with the view of magnifying the subject, but that the various similar and dissimilar diseases and the expressions which they are capable of producing on the skin, may be brought together for purposes of study and comparison.

The time has arrived when we should endeavor to recognize not only the particular form of eruption, but what is more important, also, the cause which has produced it, upon which success in treatment may depend. Diseases of the skin must be studied from the standpoint of general medicine. It is not possible to comprehend the meaning of certain forms of inflammation of the skin without taking the broadest view of the subject. Thus if we are inclined to regard such diseases as dermatitis exfoliativa, pityriasis rubra, lichen ruber, dermatitis herpetiformis, and the like as mere local cutaneous inflammations we fail to understand the significance of the symptoms. Symptoms and causes must be studied together. The former are elementary, and constitute

the alphabet of dermatology, which it need not be stated must be learned. But eruptions in themselves, as mere forms of superficial inflammation, are by no means so important as the relation of the lesions to the causes. To express this idea more plainly, take the disease, eczema, as an instance. Here in some cases, as in neurotic eczemas, the discovery of the causes at work in producing the eruption is the key to the situation, without understanding which no success in the treatment will probably be obtained, and many other similar instances might be cited. Thus it happens that some diseases are practically uninfluenced by local treatment, and that not until we investigate their possible relations with the general economy do we appreciate their nature. The general practitioner, who has been trained in cutaneous diseases, has the opportunity of advancing dermatology quite as much as the specialist, and his services in aiding the good work can not be dispensed with. Some of the best work latterly has been done by men who are not only accomplished dermatologists but equally distinguished general practitioners of medicine and surgery. We owe a great deal to such writers and teachers as Jonathan Hutchinson, Paget, Stephen Mackenzie, Fagge, Pye-Smith, Robert Liveing, Duckworth and McCall Anderson.

The objective study of skin diseases is fascinating, and has without question its uses in more ways than one, but it is important that we take steps to advance beyond this elementary stage of knowledge, by attempting to recognize and understand the meaning of the local manifestation. It has been, and still is, too much the custom to study diseases of the skin in the light of pathologic pictures, to name the local manifestation and to so label it as a disease. It is much easier to give the disease a name and to label it than it is to comprehend the process at work. The former is comparatively unimportant for the patient, the latter a point upon which recovery may depend. The nature and meaning of the process in connection with the cutaneous symptoms has not received enough attention, and I believe this to be one reason why the treatment of many of these diseases in the past has been so notoriously unsatisfactory. At all events the relations of the cutaneous disturbance to other structures and to various states of the economy should be much more thoroughly investigated by dermatologists than is the present custom.

To recognize any one disease, say syphilis, in its varied manifestations on the skin, requires familiarity with all other diseases with which it is liable to be confounded. Therefore, to be an accomplished diagnostician, one must be conversant with every form of eruption to which the skin is liable, including the not rare atypical and aberrant forms. In regarding only the well-known and clearly defined obvious diseases of the skin as belonging to dermatology, this branch of medicine is not only belittled, but the true meaning of many lesions on the skin is not appreciated. I would insist, therefore, that the manifold and varied changes that take place in the skin due, as we now know, to such a multitude of diverse causes, should be viewed as phases of cutaneous medicine rather than as skin diseases. The idea of this vast array of diseases being morbid entities, for which the integument alone is accountable, must in many cases, at least, be abandoned in favor of the principles of general medicine.

Allusion has been made to the fact that the same

or similar lesions may be called forth by wholly different causes. This also is a point to which attention has not been sufficiently directed by writers. As illustrative of the observation, the similarity in the eruptions of eczema and scabies may be referred to. Here the causes at work are different but the result, as far as the skin is concerned, is much the same. On the other hand, the same cause may produce entirely different cutaneous lesions. A striking example illustrating this idea is found in dermatitis herpetiformis. Here the same cause at one period of the disease gives rise to an eruption resembling erythema multiforme, at another period to herpes, again to impetigo, and finally to pemphigus. We note thus that one process may occasion numerous distinct lesions, which individually may resemble what have been heretofore regarded as well-known distinct diseases.

If we would study dermatology with the view of learning all that it can teach us, not only of the skin but of general medicine, we must look in the majority of cases beyond the mere eruption, valuable and important as this is in all cases as a guide to the pathologic process at work. While, even in the case of local affections, it may not be necessary to look beyond the skin itself, we may nevertheless find interesting facts bearing on cause and pathology by searching within the economy. The cutaneous disturbance in many instances is distinctly indicative of some irritation or disorder in other regions, organs, structures or fluids of the body. That we are not able always to discover and to designate the causes, merely shows our ignorance. I am of the opinion that the relations of the skin to other parts and functions of the economy are at the present date only partially understood, and that there are many points which will sooner or later be elucidated which will bring cutaneous medicine still closer to general medicine. Much, however, has been accomplished in this direction during the past twenty-five years, and I am pleased to add that a fair proportion of this good work has come from the labor of our countrymen.

This brings me again to the question propounded at the beginning of these remarks, viz.: What are so-called skin diseases? The answer, I believe, has been given through the principles to which attention has been called. It is simply this, that our conception of the scope of dermatology must be so widened as to include every pathologic manifestation which occurs in the integument, irrespective of the cause or the nature, from a practical standpoint. The great value and importance of dermatology is that it should teach us to know the nature of various processes, as they affect not only the skin but the whole economy. Dermatology should be for the physician as a key with which the skin is made to reveal, in many instances at least, the nature of the process at work in the general system or in special organs, which without this aid might remain obscure. Striking examples supporting this view are noted in syphilis and in leprosy, where the cutaneous manifestations are sometimes the only indication of the presence of these diseases in the body. The recognition of the nature of the cutaneous lesions is often of the greatest value in the general diagnosis. This observation applies pointedly in the case of the erythemata and certain general infectious diseases.

While, therefore, not losing sight of the fact that

some cutaneous diseases are strictly confined to the structure involved and have no other than a local significance, there are many in which the skin lesions must be regarded as being merely one set of a series of symptoms due to some special or general cause having its seat in other structures as well as in the integument. The part that the nervous system plays in the production of varied diseases of the skin is, I am firmly convinced, immense. While its power and influence as a factor is well understood to-day, owing largely to the special writings of such observers as Eulenberg and Guttman, Bulkley, E. Long, Fox, Crocker, Schwimmer, Kopp and many others, I am of the opinion that its influence over the skin is at present far from being properly recognized. The nerves are avenues by which a multitude of diverse influences reach the skin. The future will, I feel sure, see this particular subject much more elaborated than it is to-day.

ERYTHEMA EXFOLIATIVUM RECURRENS.

Read in the Section on Dermatology and Syphilography, at the Forty-fourth Annual Meeting of the American Medical Association.

BY A. H. OHMANN-DUMESNIL, M.D.

ST. LOUIS, MO.

The erythemata have always possessed a large amount of interest for dermatologists, and the numerous apparently aberrant forms which have been observed in late years have invested the subject with an amount of importance which was not conceded to it heretofore. It is more particularly in regard to the etiology of the different forms that research has been made. In addition to this there have been presented certain forms which have excited much interest on account of their assumed rarity, but which are, possibly, not so infrequent either on account of mistakes in diagnosis, or ignorance of this pseudorarity, or an indifference to making any record. These circumstances, singly or combined, have conspired to produce an impression in many instances that a certain condition or group of symptoms was rare, when in reality it was common and had either escaped attention or failed to arouse any interest, under the mistaken idea that it was so well known as not to deserve even a passing mention. Under these circumstances, every new record helps to swell the list and without detracting from the credit of those who first noted the matter, it contributes to a vulgarization of a certain amount of knowledge which should come within the grasp of every one. It is for this reason that I wish to place upon record a condition which is an apparently unusual one, but which in my opinion is observed much more frequently than medical literature would lead us to suppose. I refer to intermittent scarlatiniform erythema or erythema exfoliativum recurrens. Medical literature, up to the present, seems to be rather meager, so far as the number of accounts of this trouble is concerned. A hasty search through current medical literature and works on dermatology has yielded but small results and larger returns will have to be left to the future.

Before entering into any farther considerations upon the subject, I will give the history of a case as furnished by Dr. Edward C. Bennett, under whose care it occurred, and to whom I am indebted, not only for the anamnesis but for the specimens which are figured, as well. I am desirous of returning my thanks to him for this, as he kindly conferred with me

regarding the case which he very justly considered an unusual one.

In order that a more complete record of the disease under consideration may be made, I will append condensed histories of other cases which have recently appeared in print, in order that a more easy reference may be made and the points of similarity, both from a clinical and etiological point of view may be made more apparent, and thus enable the reader to follow the reflections deduced, with greater facility.

The cases which I propose giving do not by any means include all those which have been reported, but they are sufficiently numerous to give a general idea of the characteristics of the disease, as well as to give a certain amount of information in regard to the clinical peculiarities of the process, and thus afford an opportunity of drawing some conclusions in regard to the etiology of the process. In addition to this, it affords us almost a certainty in deducing conclusions as to its comparative frequency. If we are to judge from the number of cases which have recently appeared in current medical literature, we would be led to the conclusion that the trouble while not frequent is far from being unique or even rare.

With these few prefatory remarks, I will proceed to give a brief résumé of a few cases which have recently been described and then make a brief analysis of them:

Case 1.—(J. Frank, M.D. and W. C. Sandford, M.D., in the *American Journal of Medical Sciences*, August, 1891.)—John H. P., miner, 34 years of age, well-built and healthy. Skin is perfectly normal. His parents are living as also maternal grandmother; is the second of a family of thirteen, all of whom are living. On July 24, following his birth (Dec. 29, 1857) he was suddenly taken ill, vomited and in a few hours the entire surface of the body was scarlet red. The symptoms subsided in a few hours, but on the fourth or fifth day following the attack the entire cuticle was cast off, and a few days later the nails of his hands and feet were also shed. This was repeated every year on the same date. The patient first remembers the shedding in 1865 and he states that these attacks occur each year on July 24, usually at 3 P.M. and never later than 9 P.M. The paroxysm begins abruptly. Patient has a feeling of lassitude and weakness of fifteen to twenty minutes duration, followed by muscular tremors, nausea and vomiting, a rapid rise of temperature, skin and mucous membrane of tongue and mouth become red and inflamed, and are hot and dry. No perspiration appears after the paroxysm begins until the cuticle is cast off. The patient has been delirious three times during these attacks, once for nine days. In his early life the cuticle began to shed on the second or third day after symptoms appeared, and was complete by the fifth day; but each succeeding year it takes a little longer, until now it is ten or twelve days before shedding is complete. The cuticle can be detached in large sheets, and from the hands and feet in the form of gloves and moccasins. The nails are loosened and crowded off in about four weeks after the acute stage.

Here follows a detailed account of the attack:

Vomiting took place, the erythema extending visibly. Pulse 68; temperature 97 degrees. The highest pulse noted and temperature observed during the attack were 92 and 103 degrees respectively. July 26, two days after the beginning of the attack, the skin appeared normal, the temperature having returned to the normal. July 27 the epithelium of tongue and mouth came away. July 28, perspiration was free on forehead and under eyes. The cuticle on chest was raised in the form of blisters by the perspiration. Desquamation then set in and continued until August 11, when the left moccasin was removed. After the removal of the cuticle the skin was very soft and delicate; and where the former was normally thick the new skin was very sensitive. August 26, the nails of the little finger and second finger of right hand were shed. September 2 those of the little finger, second and third fingers of the left hand were retracted. Both thumb nails removed September 5; and the nails from

the big toes which were the last to come off, on September 8. The other nails were cast off in pieces while patient was at work, so that the exact dates could not be noted.

The above is certainly unique in one respect—the recurrence of the trouble on exactly the same day of

desquamation which occurs, through this graphic representation, than mere words could convey. As may be seen we have presented a picture of the patient desquamating and one of the portions of exfoliated epidermis which were secured.

Fig. 1. Dr. Frank's case of erythema exfoliativum recurrens.

Fig. 2. Epidermis shed in Dr. Frank's case.

the year for so many years in succession. It is certainly deserving of more than passing attention for this reason.

Through the kind permission of Messrs. Lea Brothers & Co. of Philadelphia, I am able to present the illustrations occurring in Dr. Frank's excellent paper. A much better idea may be gained of the

Case 2.—(Henry William Blanc, B. S., M.D., *International Clinics*, October, 1891.) J. C., white, male of 23, whose occupation was cotton scoreman. Both parents living and in good health. Three brothers and two sisters living and in good health. When 10 years of age he was treated for what was called scarlet fever, which lasted several weeks, leaving him perfectly well after desquamation. The following spring all the symptoms of scarlatina reappeared. From this time until 1884 he had two attacks annually. In 1884

he had none. Latterly the attacks have been irregular, although generally appearing twice a year. The intensity of the fever and eruption has been growing milder and the desquamation more marked. On several occasions all the finger nails have fallen off.

The attack begins by a feeling of malaise followed by a fever lasting forty-eight hours. The rash appearing on the second or third day, lasts about four days. Paroxysms of itching occur during this time. The skin dries up and formation is present. An attack lasts about five weeks, although when the nails are shed it occupies one month longer.

Epidermis shed from hands and soles of Dr. Blanc's case. The only rupture of the gloves occurred when the hands were withdrawn.

Epidermic glove removed almost complete from Dr. Blanc's case of erythema exfoliativum recurrens.

Fig. 3 and Fig. 4.

In the description of an attack we do not find nausea mentioned. There existed constipation, however. The highest temperature recorded is 102 degrees; pulse 85. Patient feels nervous as eruption is spreading over body.

When the patient was peeling in large flakes, the skin was noted to be dry and in some places raised like a blister, but containing no water beneath. The new skin was very tender. Patient stated that each

time he desquamated all of his freckles passed off. The patient complained of a cold sensation and very tender surface when desquamation had set in, and he declared that when the skin first began to crack he had had a chilly feeling lasting four or five hours.

Through the courtesy of the J. B. Lippincott Co. of Philadelphia, I am enabled to present a plate illustrative of the gloves and moccasins shed by this patient. As will be seen the gloves are complete with the exception of those portions which were adherent to the nails. The soles, only, of the moccasins are presented as the sides were torn into small pieces by the shoes of the patient. He also stated that he ordinarily wore gloves during the period of desquamation of his hands.

Case 3.—(Henry William Blanc, B.S., M.D., *International Clinics*, October, 1891.) Mrs. S., aged 21 years. In 1883, when 13 years old, she had an attack of scarlatina lasting about eight weeks. She was well until 1885, when she had a second attack of scarlatina lasting about six weeks. Nothing especially noticeable was observed in the second attack, except that the desquamation was excessive. In October, 1889, a scarlet rash similar to the others appeared, unaccompanied by fever. It remained two or three days and disappeared, followed by profuse desquamation which lasted from five to eight weeks, the epidermis peeling in large flakes. During the intervals between these attacks her health was very good, menstruation being regular and painless.

In March, 1890, she was married, and during the next month another athermal rash appeared. It was not very deep except on the hands and feet. A large amount of desquamation followed. In January and February, 1891, she had the rash followed by peeling of the epidermis. She had borne a baby during the preceding month of December, and during her attacks she nursed the baby regularly without communicating the disease.

There existed hyperesthesia of the skin when seen during the desquamation of the February attack. The skin had a slightly transparent appearance suggesting anemia. On the neck, forearms and legs the skin was dry and scaly, peeling easily when rubbed. The patient stated that immediately following the rash there was diminished sensation, which became transformed to hyperesthesia when the desquamation occurred.

Five weeks after this examination the patient contracted a severe cold, and the next day had a burning sensation in the fingers, palms of the hands, toes, back, throat, tongue and eyes. These parts were fiery red. This was another attack.

No history of vomiting or nausea is given.

Case 4.—(Case of Dr. W. T. Bolton, reported by Henry William Blanc, B.S., M.D., in *Journal of Cutaneous and Genito-Urinary Diseases*, January, 1893.) Maggie P., age 20, while perspiring freely had perspiration suddenly checked, May 6, 1892. Had nausea and vomiting with pains in back and limbs. Was given a purgative. May 9 the temperature was 99.6, pulse 104, nausea and vomiting. Dizziness and pain present. Skin of face swollen. Face, neck and upper part of chest erythematous. Patient stated that she had had a similar eruption in February, 1890, and in August, 1891. May 10, 1892, the rash had extended over whole surface of body. On next day epidermis of upper eyelids beginning to desquamate. On May 12 the mucous membrane of roof of mouth exfoliated in a solid mass. On that and the two following days the epidermis of the entire body was thrown off. The epidermis of the hands and feet came off without a break. The nails were loose but did not come off.

May 31, twenty-five days after the beginning of the last attack, she was again attacked in a similar way, the symptoms being milder. June 4 the exfoliation occurred.

The nails of the fingers and toes fell off after the first attack, and also after the two previous ones.

Therapeutic interference was very little. One dose of quinin and phenacetin, two grains and a half of each, was given in the course of the disease, and several times the skin was anointed with vaselin and quinin.

None of the relatives of the patient has ever suffered from a similar condition. The first time it occurred the patient supposed that she had scarlet

fever. A fact observed was the low pulse rate and comparatively small febrile reaction.

It will be observed that in the three preceding cases, a particular note is made of the fact that the parents were healthy persons who never suffered from any similar trouble. In fact, this seems to be noted in all the cases observed.

Case 5.—(Personal. Case seen through the courtesy of Dr. Edward C. Bennett. Unpublished.) Mrs. A., a brunette of medium height and weight, 28 years of age, has always enjoyed fair health. She has one child and has had one miscarriage, since which time her menstruation has been irregular and painful. In September, 1891, she became ill, the symptoms being ushered in with nausea and vomiting, high fever and pain distributed over the entire body. On the succeeding day there appeared an eruption which extended over and involved the entire cutaneous envelope with the exception of the face and neck. The eruption was an erythema accompanied by intense itching. The third day after the skin assumed an appearance suggestive of edema, being clear and apparently puffed up. It began to crack and separate from the body, i.e., the horny layer of the epidermis began to exfoliate. The patient removed this exfoliated epithelium from her hands and feet entire, in the form of gloves and moccasins. She also removed long strips from her trunk, arms and legs. There was desquamation of every part of the body with the exception of the scalp and face, in which there was no change whatever. The nails were not shed, nor was there any falling out of the hair discoverable in any portion. When the desquamation had arrived at an end, the exposed new skin was intensely red in color and glazed-like in appearance. In addition to this there existed marked pruritus. In about one week from the onset of the attack the affected epidermis had returned to its normal state both objectively and subjectively.

In June, 1892, Mrs. A. had another attack which was in every respect an exact counterpart of the one which has just been detailed, the onset being the same, and the various periods intervening between the different conditions being of the same duration.

Dec. 15, 1892, was the date of a third similar attack, with this exception, however—the patient was suffering at the time with typhoid fever.

So far as the treatment employed is concerned, it may be well to state that it always consisted in the administration of the following, which seemed to act efficiently:

R. Quinin sulphatis gr. iij.
Pulv. capsici gr. ¼.

M. Ft. tal. dos. q. s.
Sig. One such dose every three hours.

The symptoms of the case were always strikingly malarial, and on this account the quinin was administered.

For the condition of the skin which succeeded the desquamation, the following ointment was ordered with complete success, as it proved efficient in relieving the sensitiveness of the denuded integument and caused a disappearance of the pruritus, besides acting as an efficient protective during the complete restoration to the normal of the horny layer:

R. Campho-phenique ʒj.
Albolene (solid) ʒiij.
M. Ft. ungt.

A few points which have been noted by the patient and to which she has drawn attention are the following: Each attack of desquamation comes on just one week before the menstrual flow. Her attention was called to this circumstance by the fact that it occurred each time in that manner, and it can hardly be looked upon as a coincidence. She further states that after taking an ordinary dose of quinin, she experiences a prickling, tingling pain in the skin of the thumb. On this account she is inclined to believe that the general desquamation is due to the remedy, but it is evidently a *non sequitur*.

The plate illustrates portions of the exfoliated epidermis obtained at two different periods. The upper one, which is nearly a perfect glove, was removed in June, 1892, but little care being taken. The lower figure is a representation of the epidermis of the palm which was removed in December, 1892. There was no intention of preserving this, which accounts for its rather ragged and incomplete appearance. However, the two are good examples of the manner in which the desquamation occurs—*en bloc* and distinctively separate from examples of furfuraceous or large squamous exfoliation.

The above cases are given without making any attempts to resuscitate more or less doubtful analogous cases from literature. The present ones are

Fig. 5. Epidermis shed in author's case.

distinctly marked out, and have been described without much inclination to fit them to any particular pathologic view. Besides this, they have occurred within a very few years of the present day, and under the light of a more extended knowledge of dermatology, thus avoiding their being labeled with names which are not only inappropriate but absolutely misleading. For there is no doubt, whatever, in my mind, that the various desquamative erythemas have led to a great confusion of terms; not to mention the almost impenetrable chaos which has been occasioned by the mixing up of these various affections with the dermatites having analogous characteristics and yet

wholly distinct in many respects. These distinctions are not wholly etiologic in character nor is it an absolute necessity to make anatomic-pathologic studies to establish them. Close attention to clinical details will suffice to accomplish the task, as well as to clearly distinguish from each other the various processes which are incidental to the problem. It is for this reason that I propose to discuss, primarily, whether the disease before us is a dermatitis or an erythema.

To begin with, I desire to speak of the clinical characteristics of the two processes, before examining into the pathologic anatomy of the conditions. So far as observation can teach us, an erythema is always a transitory condition, in so far as it remains in *statu quo*. Its natural termination is embodied in a retrograde metamorphosis eventually leading to the normal condition. Moreover, there is no destruction of tissue, properly speaking, but merely the loss of such epithelial formations as are superficial and which are susceptible of degeneration, without the necessity of the formation of substitutive fibrous formations, such as are ordinarily denominated under the name of cicatricial tissues. In the case of inflammation, we find that the process is entirely distinct. In the inflammatory process the changes are not limited to the superficial structures, but they encroach upon the deeper formations and, as a result, we have their involvement manifested by a perceptible thickening which is a characteristic of the change. Destruction of a more or less limited extent goes on and in the reparative stage the loss of tissue is made up by a substitutive formation which does not always share in the nature of the tissues which formerly existed.

So far as the skin is concerned, we find that erythema is characterized by an increased vascularity of the epidermis, chiefly, although the cerium may participate in the exaggerated circulation. The process is essentially an angio-neurotic one, and may manifest itself in a generalized or a circumscribed form attended or not with edema, and certain subjective sensations. The lesions, however, which are present are almost entirely included within the limits of increased vascularity, and the presence of various and varied subjective sensations. The most prominent symptoms are superficial in character as well as in their limitations, and the culmination of severe forms is manifested in desquamation which may vary in intensity from a furfuraceous type to a separation of the horny layer in large sheets. In inflammation we are confronted with an entirely different history and appearance. We find that a prominent subjective symptom is pain of a deep-seated character. There is also a susceptibility to an aggravation of the condition manifested by lesions of a more or less destructive character, suppuration being a not infrequent accompaniment and necessarily including in its development more or less destruction of tissue which is objectively manifest. It may be stated, however, that true inflammations of the skin exist wherein we do not have any clinical manifestations beyond a marked hyperemia and abundant desquamation. But it should not be forgotten that, in such cases, there is more than such a superficial survey would indicate. We have clinical evidence of the deep nature of the process shown by the thickening of the skin. Not only this, but there are general symptoms which are also indicative of

the graver character of the malady. The chronicity of the process itself is an indication pointing to its inflammatory nature and the general disturbance, so often noticeable, is of such a character as to determine the existence of more than a superficial process. It will be found in this connection that in erythemata the general symptoms are of an acute character, oftentimes quite marked, yet of a comparatively transitory nature as a whole. In inflammations, on the other hand, they are not of so acute a character, but are more lasting; and it is this very element of persistence which exercises so patent an effect in the production of inflammatory changes in the integument.

I will not weary you with the recital of examples in illustration of the few generalizations I have presented, but will enter upon a particular reference to the cases I have hastily summarized, in order to justify the opinion that they should properly be included under the erythematos diseases, in preference to the exudative or inflammatory, and that the name which has been proposed for this unusual process is one which is proper and distinctive.

We find, upon examining the records of these cases that the scarlatiniform eruption which preceded the desquamation spread with great rapidity resembling very much, in this respect, the erythematos processes occasioned by the ingestion of particular remedies in certain individuals. Another peculiarity attendant upon this generalization of the hyperemia, is the fact that it suddenly stopped short at a particular point, when the process of retrogression seemed to take place immediately. These are certainly not the usual marks of an inflammatory process, such as we ordinarily observe. For it must not be forgotten that the desquamation which is so abundant in the disturbance with which we are dealing, is rather a result of the process than a part of it. In the same manner, the exposed epidermal tissues are the objective indications of a loss of a certain portion of substance due to the sudden hyperemia causing an exfoliation of the horny layer, and thus leading to the condition observed. If we take any marked dermatitis or inflammatory condition of the skin, no doubt whatever can exist as to the complete difference existing between it and the process under consideration; and an inquiry into the pathologic anatomy of each one will completely establish the fundamental characteristics of each in such a manner as to leave no room whatever for any reasonable doubt as to the proper position to be assigned to the trouble I have described.

Dermatitis is a term which has been much abused in dermatologic nomenclature, and it has been the cause of leading many into errors which they would never have adopted had another word been used. Thus we find the generic appellation of "dermatitis medicamentosa" applied to a series of cutaneous phenomena having in common a similar causation, but frequently differing widely in the manifestations which are presented. The majority, I might say, are erythematos in nature and the homely expression of "medicinal rashes" is rather more close to the mark if not as elegant in diction. Another error which has led to a misconception of proper terms is the erroneous idea that desquamation is necessarily a result of inflammation, than which no greater mistake could be made. In the particular case in point, a further source of error would be

furnished by the observation of cases of dermatitis exfoliation or of pityriasis rubra, which to the superficial observer present many points in common with erythema exfoliativum; although an accurate observer would certainly be able to see so many distinctive characters as to almost draw the line of demarkation with sufficient sharpness to make it patent even to one not trained in the observation of diseases of the skin. I will now briefly consider the pathologic anatomy of the two conditions, as it will contribute in no small degree in throwing light upon the question before us.

The microscopic anatomy of a typical pathologic dermatitis and of an exfoliative erythema will serve better, perhaps, to explain the difference in the clinical pictures presented. I have chosen as illustrative examples two conditions which are sufficiently

In some parts of the rete mucosum the prickle cells do not appear to have gone beyond the embryonic stage (T) while we find embryonic cells about the blood vessels and scattered up to the papillæ. Even the hair follicle contains hyaline globules. Many of these apparently embryonic cells have some of the characteristics of lymph cells or wandering corpuscles, testifying to the fact that the process which has called them forth is of a character denoting its recent occurrence. Moreover, the general contour and outlines of the papillæ are preserved as well as the interpapillary prolongations of the rete. In the latter the prickle cells have preserved all of their characteristics, the cell walls and nuclei being sharply defined and only modified here and there by being apparently replaced by embryonal cells. (T.)

On the other hand, a picture of a marked inflammatory trouble is so widely different as to immediately attract attention. I have chosen for an exam-

well marked to demonstrate the points in question. In order to eliminate any possible personal equation, I have borrowed the illustrations from other authors. It will be found that the essential differences between the two are so well-marked as to leave no possibility of a doubt. Petrini presents a section of a case of relapsing desquamative scarlatiniform erythema (Comptes Rendus du Congrès Internat. de Dermat. et de Syphilig. de 1889. G. Masson, 1890, p. 44 et seq.) which for all practical purposes is a disease identical with the one under consideration. Here we note that the upper portions of the stratum corneum are distinctly exfoliating, the lowermost portion remaining adherent to the stratum mucosum. The Malpighian layer has intercellular vacuoles in it and the papillæ are covered with embryonal cells.

ple a section of impetigo herpetiformis figured by Theodore du Mesnil (Archiv. f. Dermatologie u. Syphilis, 1891, September 5) in which can be seen a well-marked round-cell infiltration. Here we note a cellular infiltration and edematous exudation of the papillæ, which are apparently prolonged by the actual lengthening of the interpapillary prolongations of the stratum mucosum. The stratum corneum is intact, not having undergone any apparent change. The stratum mucosum is filled with lymph cells throughout its extent and at the edges where contact is effected with the papillæ a limited round-cell infiltration is visible. In addition to this, the blood vessels and lymphatics are markedly dilated and surrounded by a cellular infiltration. Pigment cells are found in the papillæ, an evidence which tes-

tifies to the fact that the process has existed for some time as is also shown by the other conditions present.

The two pictures given should certainly prove sufficiently conclusive as demonstrative of the rational differences existing between an erythema and a dermatitis, and as Petrini's demonstration is that of a process so nearly analogous as to be almost identical with relapsing desquamative erythema, such as described in the cases I have mentioned, it would appear to me that a careful consideration of the various points which I have brought forward would establish the fact, beyond the shadow of a doubt, that erythema exfoliativum recurrens is an erythema in the true sense of the word and not a dermatitis; and that the term, dermatitis, which has been applied to it is not only incorrect but misleading. It should be abandoned to give place to a term which is not only pathologically exact but which clinically is more clear, and which has the further advantage of placing the disease in its proper place in dermatologic nosology.

The etiology of the disease under consideration possesses more than passing interest. From the more or less imperfect histories of the few cases which are available it is a very difficult matter, indeed, to formulate anything of a definite nature. We can find but very few characteristics that are held in common by all the cases, beyond the exfoliation. The onset in each case is different, as also the course, duration and termination of an attack. The periods between separate attacks vary, not only in different individuals, but in the same one as well, in some cases. So far as determining a common cause is concerned, it can not be done. The alleged causes given by the patients differ, and no possible reason can be given by others for the peculiar affection which manifests itself in their persons. Taken altogether, we are confronted with a problem which appears rather difficult of solution, and the best that can probably be done is to weigh the probabilities in each case and determine that which seems the most worthy of consideration. It may be remembered that in a consideration of the scarlatiniform erythema of typhoid fever (*Journal of Cutaneous and Genito-Urinary Diseases*, August, 1890) which is relapsing in character, and to which the disease under consideration bears a remarkably close resemblance, if it is not identical in character, the opinion of Besnier was advanced, that the cause in scarlatiniform erythemas is never an exclusive one (*Ann. de Dermat. et de Syphil.*, January, 1890). This author states that, in his opinion, the eruption depends more on the subject himself; that there exists a predisposition. The individual becomes more susceptible to the process and this brings about a tendency of recurrence at continually shorter intervals; a circumstance which may be noted in all the cases given above, with the possible exception of the first in which the period of recurrence remained the same. Excluding toxic, septicemic, medicamentous and such similar causes, we are finally brought face to face with one conclusion which seems inevitable—that the cause is one dependent upon the nervous system and more particularly that portion in intimate connection with the vascular system. Dr. J. W. Moore long since regarded (*Dublin Journal Medical Science*, December, 1888) the trouble as one which probably depends on a reactive inhibition of the vaso-motor system of

nerves. That this is the most probable cause is amply testified to by the opinions of those authors who have ventured to advance one. Leon Perrin regards the condition as a reflex dermatosis agreeing in this respect with Fournier, Lewin, Besnier and others. Dr. Frank, in referring to his case (Case 1) says that the fact that the recurrence of the symptoms appears on the same day, and even the same hour of each year, can be possibly accounted for by the fact that it is a disease of the nervous system, as it is analogous in its recurrences to certain types of hay-fever. To this, Dr. Blanc demurs somewhat by calling attention to the fact that there may enter a disturbing psychological element. Dr. E. L. Standlee reports a case of annual shedding of the nails (*American Medical Journal*, December, 1891) accompanied by some exfoliation, but the entire report is so incomplete as to afford no clue, beyond the fact that the first attack occurred after contracting typhoid fever, a disease which is very prone to leave its effects on the nervous system. Dr. Perret (*Lyon Médical*, 1885), has attributed the cause primarily to rheumatism acting secondarily through the nervous system, whereas M. Rossigneux (*Lyon Médical*, March 21, 1892) is inclined to regard a possible nervous cause. An ingenious theory has been advanced by Paul Blocq (*France Médicale*, Jan. 23, 1886) to account for the various periodical attacks which are observed in certain individuals. He looks upon the cause as some microorganism, which multiplies continuously, until a certain period of time has elapsed, when it seeks an exit and in this very effort to escape, the symptoms which are observed are produced. This is certainly clever, but it can not be made applicable to the disease under consideration, and could only possibly refer to infectious troubles such as relapsing erysipelas.

To my mind, relapsing desquamative erythema is, beyond all possibility of a doubt, a trouble due to disturbance of the trophic nerves. In the cases which we have detailed, as well as in the numerous instances which occur scattered throughout medical literature, we find distinct nervous symptoms mentioned. The patients suffer from headache, or itching, or localized tingling sensations, or some other purely nervous trouble. Again, we find that the thermic phenomena are either a low fever, or none, or a state of hyperpyrexia out of all proportion with the condition present. Delirium may be present (Case 1), or a state bordering almost on melancholia. So far as the influence of the trophic nerves on the circulation of the skin is concerned, there is no doubt of it at this day. The erythema pudoris or ordinary blushing may easily become transformed into a morbid condition. The blush which was at first easily elicited, later on comes on without any apparent reason, and becomes recurrent unknown to the subject. It is some functional nervous trouble, probably residing in the sympathetic ganglia, and if we but generalize the condition and make it more marked, we find it transformed into a universal erythema. Add to this the greater implication of nerve structure, and we find then a symptom showing itself which is characteristic of nervous trouble of a trophic character—exfoliation. That the disorder must reside in the trophic system is corroborated by the negative results which have attended all examinations for nerve alterations. That an angioneurosis is intimately connected with the process in the production of recurrent exfoliative

erythema is shown by the fact that slight edema accompanies the first manifestation. The skin appears more or less translucent and, in some cases, vesicles make their appearance. The appearance of these lesions, more or less grouped, constitutes another link in the chain of evidence pointing to a neuropathic origin for the trouble. Another circumstance which seems to indicate this, is the comparative shortness of duration of the acute period of the trouble. Following this, there is apparently good health, during which the exfoliation is taking place. The whole force of the attack seems to spend its fury in a few days, and the period following this is passed in getting rid of the *débris* of the nervous storm which has occurred. The exfoliation is rather slow, as the separation is but partial and must be completed by the gradual process of the relaxation and tightening of the skin. This is further evidence of the superficial nature of the pathologic process. In desquamative processes of a marked inflammatory nature, such as psoriasis, pityriasis rubra or chronic eczema, the shedding of the horny layer is continual and rapid, the regeneration not only keeping pace with but often exceeding the loss.

Before closing the consideration of the etiology of the process, one question still confronts us—and it is one which is by no means easy of solution, if there be any for it. It is the periodicity of the attacks. It is no explanation to say that it is of nervous origin, as we find it in hay fever. This is merely shifting the ground of discussion. Why should this periodicity exist? Besnier's dictum that it is a predisposition is an explanation which explains nothing. The very fact of recurrence attests to this. Why this predisposition should exist is the question which we desire to solve. We may invoke idiosyncrasy, but in no case so far recorded, with the possible exception of the toxic and medicinal erythemas, do we find mention made of any possible cause to account for the trouble and which was observed prior to each attack. Blanc has made one suggestion which might have a bearing upon this, when he speaks of the possible influence which the mind might have. We know that self-suggestion is potent in bringing about certain nerve disturbances, and in one susceptible to an erythematous reaction consequent upon trophic nerve disturbance, this might possibly be an explanation. A better one, perhaps, would be the direct influence of telluric or atmospheric causes upon the cutaneous envelope. We can easily understand how such would act upon the sympathetic nerve centers, and these in their turn bring about a reflex disturbance of the trophic nerves leading to the appearance of the erythema. And there is a history, in some cases of scarlatiniform erythema, of the attack following an exposure to a cold wind or chilling atmosphere. Moreover, herpes zoster is observed to supervene upon exposure to cold and damp surroundings, as also being caused by the purely psychical disorder of anger. I do not wish to pursue the subject at greater length, deeming what I have said sufficient not to convince, but rather to incline one to the theory of the neurotic origin of recurrent desquamative erythema.

The treatment is a very simple one, consisting merely in protecting and soothing measures. While, in many cases, symptomatic treatment has been employed, there is no evidence that it exercised any particularly beneficial action, so far as the cutaneous symptoms were concerned. The protective measures

employed have certainly had a direct effect as prophylactics in preventing a possibly graver condition which might be induced by irritation due to an extraneous source. Of course, such measures are not only proper and rational, but even imperative. To neglect their application would certainly argue not only a disregard for the patient, but also a serious disregard for the exigencies of the case in hand. In the last case detailed, the patient was always supposed to be affected with malaria when the symptoms first declared themselves, and was accordingly given quinin, to whose effects she attributed her trouble. Still, others having the same prodromic symptoms and the same subjective sensations are recorded as never having taken any medicine, so that we can not conclude that the therapeutics had any effect whatever in calling the disturbance into being.

Is erythema exfoliativum recurrens a rare disease? We are inclined to say that it is not. There seems to be quite an amount of confusion existing in regard to its nomenclature and, for this reason, it has been described under a multiplicity of names which have only led to confusion. Idiopathic scarlatiniform erythema of a recurrent type, as well as recurrent dermatitis exfoliativa are, beyond a doubt, examples of the same affection. Many isolated cases are described, under various designations, whose descriptions and clinical histories coincide with the affection I have attempted to portray. Much confusion has been added by denominating it a dermatitis, as well as by magnifying certain minor attributes which are disproportionately enlarged and dwelt upon at the cost of others apparently more trivial and perhaps more important. As this paper has already transgressed upon the limits which it should occupy, I will close, hoping that it will have awakened a certain amount of interest in that ever shifting and varied group of cutaneous affections included in the classes of the angioneuroses and erythemas.

PNEUMONIC FEVER; ITS SYMPTOMATOLOGY.

BY EDWARD F. WELLS, M.D.

CHICAGO.

NERVOUS SYSTEM.

Headache of more or less prominence is encountered in almost every case.¹ In my experience it has not seemed to differ in character from that met with in other febrile disorders. It is a symptom of the early periods of the attack, in adults usually diminishing or ceasing after a few days. In children it is often a most distressing symptom,² continuing throughout the attack and possibly overshadowing all others. Severe frontal headache is so constant and prominent in senile pneumonic fever that its occurrence in an aged person should lead to an examination of the lungs. The headache is greatly aggravated by efforts at coughing and vomiting.

Juergensen³ has met with two cases of pneumonic fever following exposure of the bared head to the hot sun, in which the seizure began with lancinating pains in the head and the symptoms of insolation.

It has been thought that headache is more constant and severe in those cases accompanied by nephritis, but I have met with nothing in my experience to confirm this view. In some cases there is an extraordinary pulsation of the temporal and retinal arteries, and in these I have thought the suffering to be more acute and severe.

Dizziness is sometimes an early symptom.⁴ Vertigo and syncope are also rare phenomena.⁵

A male, age 44, after a two weeks' spree, was attacked, Nov. 11, 1886, with a severe chill, followed by several lesser ones, cutting pains in the right side and great distress. The pulse rose to 132 and the temperature to 100.4 degrees. The respirations were jerky and 45 per minute. The skin was hot and dry and the face flushed. Over the right lung there was bronchial breathing, mucous râles, increased vocal fremitus and a full, hollow percussion note. On the fifteenth day the patient had a fainting fit, with loss of pulse, labored breathing and death. At the autopsy the right lung was found hepatized, with rib-marks, and the right side of the heart dilated.⁶

My own patient was a farmer, 65 years of age, and the subject of a long-standing bronchitis. He was taken, Dec. 19, 1885, with the ordinary symptoms of pneumonic fever, locally affecting the lower lobe of the left lung. The cough was unusually severe and spasmodic, and every effort was followed by convulsive movements of the facial muscles of the left side, the head would be drawn around toward the left, and he would then fall back upon his pillow in a faint. The convulsive movements and unconsciousness were only of momentary duration. Recovery ensued after two weeks' illness. During exacerbations of his chronic bronchitis the cough has been, before and since, at times as severe and spasmodic as during the pneumonic attack, but syncope was not a feature.

Delirium is a common symptom in pneumonic fever.⁷

It was present in 14 of Caton's⁸ 85 cases; in 29 of Chomel's⁹ 240 cases; in 14 of Hermann's¹⁰ 44 cases; in 12 of Holt's¹¹ 173 cases; in about 20 per cent. of the cases of Andral¹² and Louis¹³; in 52 of Sauter's¹⁴ 331 cases; in a very large number of Heintze's¹⁵ cases; in 26 per cent. of Satterthwaite's¹⁶ cases; in about 8 or 12 per cent. of those of Huss¹⁷ and Briquet;¹⁸ and in about 20 per cent. of my cases.¹⁹

Grisolle²⁰ and others have encountered it oftener in males than in females.²¹ This has also been my experience, but I attribute the fact to the greater consumption of alcohol by males²²—it being well known that delirium occurs vastly more frequently in the subjects of drunkenness than in those who are temperate drinkers or abstainers.²³ Excluding those who use alcohol to excess, from my list of male patients, and the proportion of delirious cases is about the same in the two sexes.

Delirium is encountered oftener in some regions than in others,²⁴ and is profoundly impressed by epidemic influences.²⁵ Individual peculiarities will also influence the development of delirium in this disease. Thus there are some persons who become delirious with the advent of the slightest provocation, while in others the inherent tendency is in an opposite direction. It is very common in infantile²⁶ and senile²⁷ cases. It is also said to be more common when the inflammation is apical,²⁸ spreading²⁹ or double, although my experience does not confirm the statement.

Delirium may come on at the onset of the attack³⁰ or, and this is more common, it may make its first appearance after the disease has³¹ reached³¹ or passed its acme. It usually makes its advent at night, is always worse at this time, and may be noticed only at this period. In the severer cases, however, it is constant. The duration varies from a temporary outbreak to several days.

The development is, in some cases, quite sudden and without warning, but usually the delirium is preceded by very significant prodromata, e.g., restlessness, sleeplessness, headache, heaviness of the head, dizziness, vertigo,³² tinnitus aurium, a peculiar change of voice, forgetfulness of pain, absence of mind, manifestations of surprise at ordinary occurrences, extraordinary acuteness of the mind and

special senses, brilliancy of the eyes, intolerance of light and noise, heat of the head, flushing of the face, increased force of the cephalic circulation and other anomalous symptoms. In those cases in which the delirium seems to be merely a sign of approaching death the countenance may be pale and collapsed, the eyes sunken, the surface cold, and other obvious evidences of an adynamic state.³³

The character of the delirium varies greatly in different cases, and at various times in the same case. It sometimes manifests itself in a simple inclination to loquacity, although the patient's conversation may be germane to the subject under consideration and quite rational. I have often met with this form and have always viewed its appearance with considerable anxiety.³⁴ In other cases the aberration of mind may be very slight—barely noticeable—and of a mild character. From these mild forms at one extreme, we may meet with every possible and imaginary gradation to the delirious tremor of the confirmed drunkard and the furious delirium of the raving maniac at the other.

In some cases the delirium may be of a low, muttering and dreamy kind, like that met with in typhoid fever. This form usually comes on late and in adynamic cases, and should be viewed as a signal of imminent danger, it being usually a fatal indication.³⁵

In the case of drunkards the delirium is apt to be of the variety known as delirium tremens.³⁶ It usually comes on early in the attack,³⁷ either suddenly or preceded by restlessness, sleeplessness, etc., and is often so prominent as to mask the pulmonary affection. The delirium is a busy one, the patient being in incessant motion and constantly jabbering away at imaginary persons and things. There is usually present one dominant and unpleasant idea, which may be either fixed or changeable. Fear is constantly before the patient, and he is forever engaged in plans and measures for defense, escape and, possibly, attack. There are delusions of sight in which he sees noxious and horrible animals, demons, etc. The delusions often point towards the pneumonic disorder; "thus the patient declares that the air is stifled, that his nose is obstructed, and that demons are sitting on his chest."³⁸ Along with the delirium there is a tremor of all the voluntary muscles of the body, especially marked in those of the tongue and extremities.³⁹

The delirium is sometimes furious, wild and even maniacal,⁴⁰ especially in the young and strong.

An intemperate man, aged 52, was seized, Jan. 14, 1884, with rigors, weariness and headache. On the second day the temperature was 102.2 degrees, and there was dyspnea, acute pain in the chest and crepitation in the right lung posteriorly. On the third day there was dullness and bronchial breathing, and the disease was well developed. The temperature ranged between 100.4 and 104.1 degrees, and fell to below normal on the sixth day. During the seventh night he was restless and somewhat delirious, although he lay quite still. On the seventh day, at 9 o'clock, he had a staring look, directed upwards, twitching of the facial muscles, dilated pupils and abolition of hearing. There was no noticeable fever and the pulmonary consolidation was undergoing resolution. In the afternoon actual frenzy developed. He would attempt to leave the bed and scale the wall. There was an incessant and rattling talk, and he would count in a gallop, in which exercise his wife must accompany him. In case she made a mistake he would stop and correct her with loud curses. He refused his medicine and imagined that his nurses were trying to poison him. He would pound upon his abdomen as upon a drum; twist the bed clothes into ropes; laugh and talk quite sen-

sibly at times, and, all at once, would spring from the bed and attempt to flee away. The various visions which passed before him were described in a loud voice. He would see a beautiful castle surrounded by lovely gardens and magnificent parks; a dangerous black man hidden behind the stove; a fire into which he is to be cast; purgatory and a clock which strikes but once a century, the finger of which approaches the striking time, which he awaits with great anxiety. This continued for three days, when he entered upon a tedious convalescence and eventually recovered.⁴¹

In rare cases the mania may take on a homicidal or suicidal form. One of my cases presented the latter feature.

A nervous gentleman, aged 67, was taken, Feb. 12, 1886, with pneumonic fever, locally affecting the base of the left lung. On the third day delirium arose and soon developed into mania. At first he was an emissary from Christ, sent to evangelize the world, and he was continually preaching to vast audiences. All who heard him ceased their occupations and followed him from place to place—in number a countless multitude. Soon he began to doubt his abilities, motives and availability, and his discourses were interspersed with wild lamentations, self-condemnation and self-chastisement. This soon gave place to a profound melancholy from which he could not be aroused, and during the continuance of which he several times attempted suicide, generally with imaginary daggers and once by precipitating himself from the bed—an imaginary precipice—to the floor. On the thirteenth day he lapsed into a drowsy state from which he emerged rational two days later. Recovery ensued after a protracted convalescence.

A soldier, aged 20 years, sickened April 27, 1879. For a week he had slight fever and complained of headache and shooting pains in various parts of the body. The fever increased, his tongue became coated and there was developed cough, pain in the region of the zyphoid process, dullness on percussion and bronchial breathing at the base of the right lung. The fever continued and maniacal symptoms were developed on the 29th inst., on which day he attempted suicide. Death occurred on the following day, the mania continuing to the last. At the autopsy the base of the right lung was found hepatized and the brain edematous.⁴²

Departure, in various directions, from these types are noticed.

A lady, 60 years of age, was taken with pneumonic fever, locally affecting the right lung. There was great dyspnea and she often said: "Kill me! I am suffocating." She finished every spoken sentence with a peculiar cry. On the tenth day she was very passionate, expressed a fear of becoming blind, had slight convulsions and was delirious at night. On the next day the right side was paralyzed, she was unconscious and passed her stools involuntarily. She remained in this state for days and died on the sixteenth day. At the autopsy two-thirds of the right lung was found in a state of gray hepatization.⁴³

A young man, aged 19 years, suffered an attack of pneumonic fever, with crisis on the seventh day. For sixty hours all went well, when, suddenly there came on extreme dyspnea, with gasping, struggling, turgid face, staring eyes and profuse perspiration. He was quieted and relieved by moral suasion. On the following morning he had a similar attack, with dysphagia, apprehensive fright and violent trembling. He was again quieted and drank a glass of milk. Recurrent attacks occurred, with dilated pupils, excessive jactitation of the whole muscular system and a rise of temperature to 106 degrees, followed by death.⁴⁴

Even in children the delirium may take the form of persistent delusions,⁴⁵ as occurred in one of my cases.⁴⁶

Insanity may follow as a sequel, as in the following case:

A farmer, aged 42, had a severe attack of pneumonic fever in March, 1889. During the attack the mind was clear but at the end of the prolonged convalescence simple melancholia, with delusions developed. He had financial delusions; thought people were plotting against him; that he had lost the respect of his friends, etc. His speech was slow and hesitating. After six months there was progressive improvement.⁴⁷

It is sometimes very difficult to draw the line of demarkation—which is at best an insensible and arbi-

trary one—between the milder forms of delirium and the operations of the rational mind. It may be said, however, that all outspoken images of the mind which are confused, unconnected and irrelevant are delirial aberrations of the intellect, and are due to an abeyance or destruction of the regulating powers of the reason. Delirium has been compared to dreaming, but it is much more profound and is due to different causes.

In pneumonic fever the delirium may depend upon an irritation of the cerebral organs from an increase or diminution of the blood supply to the parts; or it may be due to lesions of structure of these organs; or finally, it may depend upon a supply of blood to the brain lacking in proper nutritive or stimulating properties, or loaded with septic or noxious materials which preclude its nourishment or paralyze its functions. It is rare that the delirium is due to encephalic inflammation, although this was a common opinion of the older writers.⁴⁸

Money,⁴⁹ in analyzing all the cases of delirious pneumonic fever occurring in the records of University College Hospital, London, found that pyrexia had but little influence upon the production of delirium. This coincides with the observations of Heinze⁵⁰ and myself.⁵¹

The gravity of delirium has been variously estimated by different authors.

Thus Laennec⁵² did not consider even a furious delirium as denoting the presence of any great danger, although this was opposed to the views of Cullen⁵³ and the majority of observers, both before and since his time.⁵⁴ Gregory⁵⁵ was accustomed to state in his lectures that he had never known of but one pneumonic patient to recover after having had delirium, but this clearly can not apply to the experience of any other physician of much practice.⁵⁶

My own observation has led me to the conclusion that very little need be feared when the delirium comes on early, especially if the patient is robust, or is predisposed to delirium under slight febrile provocation. On the contrary, if it comes on late in the course of the attack and is persistent, or if the patient is old, or enfeebled, or is a drunkard, the symptom is of the gravest import.

In a large number of cases with delirium there is developed a soporose condition or veritable coma which adds greatly to the gravity of the case. As a fact, the majority of the cases ending fatally and which are accompanied by delirium die comatose, although in some instances the mind temporarily regains its clearness shortly before death.

In the low, typhoid, or adynamic form of the disease the patient may be almost continually in the dreamy, half-waking state known as coma-vigil, or he may lay in a more or less profound coma. Coma may also be developed in those cases in which the blood fails in being properly aerated, and is surcharged with carbonic acid and effete materials which should be eliminated through the respiratory apparatus, and other channels, now not able to properly perform their functions. If the patient is the subject of diabetes, coma may be suddenly developed.⁵⁷ It is superfluous to state that any form of coma indicates a dangerous case.

When the coma is unconnected with organic cerebral disease it is less deep than when there is a brain lesion; continues two or three days and, if the case proves successful, subsides with the decline of the fever.⁵⁸

Aside from the delirium the intellect is not so much interfered with as in most other diseases of equal gravity. Indeed, in many cases of the utmost gravity—even fatal ones—the mind is remarkably clear and penetrating, even to within a few moments of death.⁵⁹

Sturges,⁶⁰ in commenting on one of his cases, makes use

of the following language: "The best feature of his case—which was a very grave one—was his acuteness of perception and attention to his own distress." With this I can only partially agree. That a patient should be sensible of his sufferings is indeed of good augury; but acuteness of perception in general has been so often associated with a fatal termination, in my experience, that I look upon the symptom, when it occurs in connection with others of gravity, with apprehension and dread."

There is usually considerable anxiety of mind, especially early in the attack. With all the anxiety the patient generally remains contented and hopeful, although he may be greatly depressed in spirit,⁶¹ especially when under epidemic influences.⁶²

In pneumonic fever there is about the same amount of restlessness and sleeplessness as in other febrile disorders of equal gravity. The restlessness is much more marked in the early stages of the attack than at a later period. At the height of the disease the patient, even a child, is usually quiet and tractable. There is usually a regular evening exacerbation, continuing far into the night, which interferes with sleep during the hours usually devoted to this purpose, although with this obstacle more sleep is generally obtained than is ordinarily supposed.

The patient and attendants will often inform the physician that little or no sleep has been obtained when such has not been the fact. Many times have I had an accurate record kept of the hours and minutes passed in sleep, showing that the patient was obtaining much—perhaps many fold—more sleep than had been estimated. When sleep is had only in short periods and is disturbed by sighs, groans, dreams and frequent awakenings there arises an erroneous impression of sleeplessness. It is, nevertheless, true that some patients pass several days with scarcely any sleep.⁶³ On the contrary, a few sleep more than in health, the sleep being peaceful and refreshing. Quite a considerable number of such cases are to be found in my collection. I have found them, with scarcely an exception, mild and tending toward recovery, and I consider the symptom of good import.

Convalescence is often ushered in by a prolonged and very profound sleep—a critical occurrence—from which the patient awakes, feeling that he has passed the danger line.

During convalescence, in many cases, the mind remains somewhat weakened, as is evidenced by irritability and restlessness on the one hand or too much contentment or apathy on the other.⁶⁴

The increased blood pressure in the cerebral vessels in certain cases of pneumonic fever may lead to their rupture,⁶⁵ especially in the aged, followed by the ordinary symptoms of apoplexy, viz. hemiplegia,⁶⁶ aphasia and other paralyses.⁶⁷ Failure of the circulation may lead to cerebral softening⁶⁸ or abscess,⁶⁹ and these are not very rare accidents in this disease.

Inflammation of the cerebral⁷⁰ and cerebro-spinal⁷¹ membranes, with effusion of serum, lymph or pus is a comparatively frequent occurrence.

It was present in 1.2 per cent. of 1,172 cases treated at the Zürich clinic;⁷² in 12 per cent. of Kühn's cases in the Moringer epidemic;⁷³ in 16 per cent. of Louis' cases;⁷⁴ in 3.7 per cent. of Caton's eighty-five cases;⁷⁵ in 6 per cent. of the cases analyzed by Hermann;⁷⁶ and in 1 per cent. of the 8,000 Vienna cases.⁷⁷

A negro, aged 28, was admitted into the Marine Hospital, Cairo, March 17, 1886, with pneumonic fever. Meningitis developed next day, and he died March 25. At the autopsy the right lung was found in gray hepatization, except a small portion at the base. There was intense congestion of the scalp and pia mater. There were deposits of lymph in the longitudinal fissure. The cortex was flattened and the texture softened in patches. A large quantity of serum was found in the ventricles and sub-arachnoid space.⁷⁸

A widow, age 58, on the fourth day of an attack of pneumonic fever, locally affecting the upper lobes of the right lung, suddenly began breathing noisily, failed to answer

questions, but soon recovered her senses. With the occurrence of occasional delirium she died on the seventh day—after having passed her urine and feces under her. The autopsy disclosed extensive purulent meningitis.⁷⁹

In some cases the cerebral symptoms are so prominent as to mask the, perhaps equivocal and misleading, pulmonary ones. Under such circumstances care is requisite to avoid being led into diagnostic error. Thus in children, especially, there may be cervical rigidity, tenderness of the vertebræ, cephalalgia, projectile vomiting, intolerance of light and sound, etc., without the presence of meningeal inflammation.

Davis⁸⁰ has given us a vivid picture of one of a few cases witnessed by him at a time when cerebro-spinal fever was present in the same locality.

"The first symptoms were very severe pain in the head, most severe in the occipital region, with great restlessness and anxiety, hurried breathing, and only little elevation of temperature. After about twenty-four hours the pain drifted to the lower part of the chest, extremely acute, causing the respiration to be short or stifled, very frequent, and pulse sharp and quick; but the closest examination detected neither the friction of the first stage of pleurisy, nor the crepitant râle of pneumonia; nor the dullness on percussion of the second stage of either. After the pains in the side and the other symptoms mentioned, with temporary feeling of sinking had continued for nearly forty-eight hours, the pains ceased, the mind became calm, but the respiration continued short and frequent, like one weary from physical exertion, and giving exaggerated or puerile respiratory murmur, but no râles or dullness over any part of the chest, and no expectoration. During the next twenty-four hours, however, the patient became gradually more dull or drowsy, the respiration shorter, with first or crepitant râle over the right side of the chest, which gave place in less than eight hours to sub-mucous râles, some bloody expectoration, and marked dullness on percussion, with a weak and frequent pulse. In less than twenty-four hours after the first indication of pneumonic exudation, the whole of the right, and the lower part of the left, lung were completely filled with the exudative material and the patient died."⁸¹

It is a remarkable fact that in those cases in which there are cerebro-spinal symptoms, without actual inflammation, these symptoms decline with the greatest rapidity or cease abruptly with the advent of convalescence from the pneumonic inflammation.

A male child, 3½ years of age, was taken April 4, 1880, with fever, cough, thoracic pain, headache and the objective symptoms of pneumonic fever, locally affecting the bases of both lungs. There was marked spinal tenderness, retraction of the head, the characteristic cerebral cry, suffusion of the eyes, convulsions, etc. The disease pursued a severe course, and on the fourth day the temperature was 103.5 degrees, pulse 140 and respirations 40. The fever did not attain so great an elevation on the following day and deference occurred on the sixth day. The cerebro-spinal symptoms ceased abruptly and complete recovery ensued.

In children the cerebral symptoms are very often connected with dentition.⁸²

A male child, age 8 months was taken, Jan. 25, 1889, with cough, diarrhea and febrile symptoms. On examination two days later, the base of the right lung was found hepatized. The general and local symptoms quickly subsided but on February 3, coldness of the extremities and vomiting ushered in high fever and hepatization of the left lung, which began below and gradually extended upwards until the entire lung became involved. The course of the disease was very severe, but after a week resolution commenced in the upper lobe and proceeded so slowly that it was not complete for a week. Resolution did not begin in the lower lobe until the sixteenth and was never completed. Dental irritation was noticed early in the illness and the two lower lateral incisors appeared during the second week, but irritation continued from other teeth, both upper and lower, with frequent febrile exacerbations. February 17, for a short time there were spasmodic contractions of the muscles of the right side, without impairment of function upon their subsidence. On the next day convulsions confined to the

right side, with paralysis of this side occurred and continued until death on the twenty-third, after five weeks of illness.

General convulsions, especially in children⁸⁹ are met with in a certain proportion of cases. Probably this does not indicate greatly increased danger⁸³ when it occurs early in the attack, but as a late symptom or in connection with other cerebral phenomena it is usually a forerunner of death. In some cases there are local or general muscular spasms,⁸⁸ especially in the low, adynamic or comatose forms of the disease.⁸⁴ Chorea,⁸⁵ epilepsy,⁸⁶ neuralgias,⁸⁷ and other so-called functional nervous affections are occasionally associated with pneumonic fever.⁹⁰ In two of my cases, in epileptics, the fits were held in abeyance by the pneumonic fever and did not reappear until convalescence was fully established.

A slight diminution of hearing, together with tinnitus⁹¹ is sometimes present, but pronounced deafness is rare,⁹² save in connection with typhoid fever, cerebral complication, obstruction of the Eustachian tubes⁹³ or middle ear inflammation.⁹⁴

Every practitioner must have noticed with what frequency inflammation of the naso-pharyngeal mucous membrane accompanies pneumonic fever, especially in the young. The Eustachian tube, acting as a drain for fluids accumulating within the tympanic cavity and mastoid cells and as an equalizer of the atmospheric pressure within and without these cavities, affords a ready way for the extension of any inflammation affecting the naso-pharynx to the cavities at its other extremity. Otitis media is one of the most painful complications which can befall the pneumonic patient. In these cases the lateral sinuses are often involved, with a great increase in the danger.

Gull⁹⁵ has reported three cases in which this condition was present. The first was a man, age 21, who, after exposure to cold, had rigors, with pain in the right ear, extending over the side of the head and neck, and vomiting. Simultaneously there were developed the symptoms of pneumonic fever, complicated with pleurisy and pneumo-thorax. The patient died on the ninth day. The other cases were similar, with death on the twenty-first and twenty-fifth days, respectively.⁹⁶

In these cases the pneumonic symptoms are very frequently overshadowed by those of the ear and brain⁹⁷ and are easily overlooked by a careless diagnostician.

I have encountered otitis media as a complication of pneumonic fever six times. Of these there were cerebral complications and fatal terminations in two, while four recovered. One of the latter cases well illustrates the series:

A healthy young woman, age 20, complained of slight deafness and pain in the right ear for two days, when she was awakened in the middle of the night by a severe chill and agonizing pain in the ear, which was greatly aggravated by a short, dry cough. High fever, alternating with rigors followed and the patient became rapidly so ill that her life was despaired of by her attendant. When I saw her on the second day she lay in a deep stupor, from which she would be aroused at intervals by the intense pain in the ear. Everything taken into the stomach was forcibly ejected. The head was retracted and the eyes suffused and dry. The respirations were short and hurried and during the acts the right side of the chest remained almost motionless. The pulse was 128 and the temperature 104.8 degrees. There was no cough, but there was dullness and tubular breathing over the right lung below the third rib. The drum membrane was punctured and exit given to a few drops of pus and the patient fell into a quiet sleep, from which she awoke complaining of pain in the right side of the chest. From this time she coughed and expectorated rusty sputæ. The

aural pain did not recur, the discharge soon ceased and hearing was eventually, although slowly regained. The pneumonic fever pursued an ordinary course, with convalescence on the eighth day.⁹⁷

The eyes usually remain unaffected. If there is much cerebral congestion they may be injected, with intolerance of light⁹⁸ and pulsation of the retinal vessels.⁹⁹ In the low forms of the malady there is often dryness of the conjunctivæ, or even conjunctivitis, from an anesthetic condition of the cornea. In some cases, especially infantile, the eyes are remarkable for their brightness and luster.¹⁰⁰ Subconjunctival hemorrhages, due to severe coughing are sometimes encountered—such cases being in my collection. The severe coughing may cause blindness, from intra-ocular hemorrhages, embolism,¹⁰¹ etc. In some cases the cause of the blindness¹⁰² may not be discovered.¹⁰³ The pupils are usually of normal size and responsive to light, but this is not invariably the case. They may be uni- or bi-laterally contracted or dilated and irresponsive to light,¹⁰⁴ especially with cerebral symptoms. Plastic iritis is a complication.¹⁰⁵ In rare cases herpetic vesicles appear upon the cornea,¹⁰⁶ usually in connection with labial or nasal herpes.

There is sometimes a dryness of the Schneiderian mucous membrane, especially in children, with a tendency toward picking at the nose. This may be noticed in an early stage of the attack or it may appear later in connection with the typhoidal condition. Following such dryness there may be a discharge from the nose, which is of good omen. In the early stages,¹⁰⁷ and with the advent of convalescence sneezing is not uncommon. The latter is often one of the first indications of the advent of convalescence and should be viewed as of good import.¹⁰⁸ Aretæus¹⁰⁹ thought that the point of the nose was elevated in this disease, but I have never been able to appreciate the fact—if fact it be.

and even if the place of residence is temporarily changed it must be by and with the consent and knowledge of the Board of Health.

As to the literature, so-called, I think that is of doubtful desirability. Those who spent the summer of 1892 in town, when there was a cholera scare, will remember that there was a great deal of this sort of literature—the papers reeked with it. The evening papers published articles of such a sensational character that the Health Officer was lashed into such a state of hysterics as to propose a quarantine against New York, under the act of Legislature which makes such a proceeding lawful when a contagious disease is “raging in a neighboring city.” The “rage” in this case amounted to four cases in a population of a million in a month. This proposition, however, was not adopted. But while the Board of Health was thrown into spasms of terror, there was enough that was ludicrous in this literature to throw the community into spasms of laughter, and we had a rather cheerful summer. It can not be hoped that this view will always be taken when, instead of a scare of two or three weeks, it will last ten or fifteen years, while from forty to fifty are dying a week. It is then possible that this literature may lash the whole community into a panic, and that instead of regarding the unfortunate victims of consumption as objects of compassion they will be looked upon as peripatetic fountains of danger, and a feeling of hostility to them will arise. This may last for years, for during the whole period of softening they are regarded as sources of danger. In fact, they are to be treated as criminals guilty of consumption. As I said before, their residences, however temporary, are to be disinfected and their miserable lives are to be rendered more wretched by being haunted by the familiars of the inquisition. It is asserted that if these radical measures are carried out tuberculosis will be eradicated in a few years; of that, it is said, there is no doubt. Now no other contagious disease has ever been extinguished, even with the added protection of vaccination in smallpox. Those of us who are not in the intimate confidence of Nature find it difficult to understand how an hereditary disease can be eradicated by measures which only limit its spread by contagion; and if it is not hereditary, whence come those forms of tuberculosis other than pulmonary? It can not be pretended that babies, a year or two old, get tubercular meningitis by contagion, nor can white swelling, nor suppurating glands, nor the many other exhibitions of scrofula come from contagion. I think very few of us will concur in this sanguine expectation. There are several other suggestions; one is likely to be very popular; it is that all persons working in factories and the like who are affected with pulmonary tuberculosis, in the softening stage, shall be withdrawn and, when necessary, supported by pensions. In this country we have a large experience of pensions; pensions have bankrupted the treasury of the United States. It is easy to believe that people unwilling to work could get the necessary certificate from some two-penny doctor and be supported by the State. As to the more serious part of the matter, the treating of persons so unfortunate as to have pulmonary tuberculosis, as criminals guilty of consumption, is something so frightful that I implore the College to interpose its remonstrance against such an outrage on common sense and common humanity.

DR L. F. FLICK—Together with other Fellows, I would like to bring up the entire subject for discussion, and, without wishing to find fault with Council in referring back the resolution in amended form, I should like to offer a substitute, which will bring up both registration and special hospitals for the treatment of the consumptive poor. The substitute is as follows:

WHEREAS, Tuberculosis is now known to be a contagious disease; and

WHEREAS, The methods by which the disease is conveyed from the sick to the well are now clearly understood; and

WHEREAS, It has been shown that the room which is occupied by a consumptive during the infectious period of the disease, and the furniture and the bedclothing which have been used by him, become infected and are liable to convey the disease to others who may occupy or use them subsequently; and

WHEREAS, Tuberculosis, owing to its long duration, cripples the bread-earning capacity of the family, when it occurs among the poor, to such an extent that the want and hardships which follow in its wake prepare the healthy members of the family for the disease; therefore be it

Resolved, That we recommend to the Board of Health of the City of Philadelphia the registration and disinfection of houses which have been infected by tuberculosis;

Resolved, That we recommend to the City Council of the City of Philadelphia the establishment of a Municipal Hospital for the treatment of persons suffering from tuberculosis.

The question of contagion seems to be admitted, and can, therefore, be eliminated from the discussion. I will then take up the question of prevention.

In reply to what has been said by Dr. Wister, I may state that the paper from which he quoted was a scientific paper covering the entire subject. He ought to have told you that the author pleads in that paper only for a beginning in preventive measures.

The contagion of tuberculosis being admitted, what measures are necessary for its prevention? The careful investigation of this subject from many points of view by Dr. Cornet, Dr. DeForest, and myself, show beyond doubt that there is a local infection—that the consumptive in his home is bound in his ordinary daily life to infect his room, the furniture, and the bedclothing. The experiments made by Cornet illustrating this subject are most elaborate. They covered a period of two years, during which time he perseveringly followed out his line of research. He examined the dust gathered from the floor, the walls of the room, the bed-posts, and the bedclothing of persons in advanced stages of consumption confined to their beds. He found by inoculation with this dust that he was able to produce tuberculosis. He found, moreover, that where a patient was so sufficiently intelligent and obedient to follow the instructions to always spit in the sputum-cup and never into a handkerchief or on the floor, inoculation with the dust produced no effect; but where the patient occasionally spat into a handkerchief, or into a nook in the room, inoculation with dust from the surroundings of these places was effective. He was able to demonstrate that in proportion to the obedience and cleanliness of the patient the extent of the infected environment decreased. Where the patient was cleanly and took ordinary precautions, but not absolute precautions, the infection extended to only a limited space, possibly four or five feet. Where the patient was uncleanly and spat indiscriminately, not only the bed-posts and the floor but also the walls were capable of conveying the infection. The clinical investigations which I made in this city, and some illustrations of which I shall throw upon the screen, and the clinical investigations made by Dr. DeForest in New Haven, corroborate these results in such a way that their meaning can not be misunderstood.

I wish here to refer briefly to the results which I obtained in my investigations in the Fifth Ward of this city, and I shall throw on the screen sections of a map. This Ward contains 16,000 people and has 3,500 houses. I have tabulated the deaths from tuberculosis during twenty-five years:

Slide No. 1 shows probably the least infected section of the Ward. There were comparatively few deaths from consumption in this section. Where deaths are noted, they occur in groups—that is, in adjoining houses.

Slide No. 2. In this section some of the houses have had a number of deaths, while the majority are free.

During the twenty-five years there were 1,500 deaths from tuberculosis in the entire Ward, and they occurred in 650 houses.

Slide No. 3. This shows a section of the city inhabited largely by the colored race. Here the houses that have had the disease have had it frequently recurring. In this small street there is a house in which there have been deaths in five different families in succession, all the deaths occurring within a few years. I was recently called to visit a rabbi in this house, who had never lived in any other house in the city. He moved in in perfect health and in six months contracted the disease. Many of the other houses tell the same tale.

Slide No. 4. This section tells the same story. The houses that are infected have a large number of cases in succession. These cases have not always been in the same family, but have frequently recurred in different families.

Slides Nos. 5, 6, 7 and 8 show the same state of things.

Slide No. 9 shows a map of New Haven, showing the deaths during seventeen years, which was prepared by Dr. DeForest. His conclusions are exactly the same as mine. He found one interesting fact which I was not able to find, because I did not have the entire city. He found that the most populous districts are almost entirely free. In the First Ward, with thirty inhabitants to the acre, there were scarcely any deaths, while in one section which has a large mortality the population is only six to the acre. That proves conclusively that crowding does not entirely explain the death rate.

Slide No. 10 gives a section of New Haven, and shows the

same grouping as by map. It shows the recurrence of the disease in the same way as in the Fifth Ward of this city.

Now this evidence of infection and retained infection of houses, together with the demonstrations made by Cornet, can point only to one conclusion, and that is, that the houses which have been inhabited by a consumptive for a given period will retain the infection and convey it to others. I have investigated quite a number of cases which illustrate the same point. I have knowledge of a telegraph office down in Maryland in which five consecutive operators contracted tuberculosis and died. The results in these five cases were so striking that people became superstitious in regard to the office. I have been informed by a person who saw the office that the consumptives had spat around the office and that it was lined with tubercular sputa. I have been able in this city to trace a great many cases where persons innocently moved into houses, unsuspecting of any infection, and where within six months a member of the family who was healthy before has taken the disease, and this case has been followed by others.

Dr. DeForest mentions a very striking result of his investigations in New Haven. He investigated the histories of 100 cases coming to the medical clinic of the city, and found that 52 were living in infected houses. In 1888 I carefully examined the deaths that occurred in the Fifth Ward during that year. There were 83 *bona fide* deaths from consumption. Although out of the 3,500 houses only 650 were infected, two-thirds of these cases occurred in these infected houses. Of the remaining third a large number had lived in infected houses and had changed their residences, so that apparently more than two-thirds of the cases in which death occurred in 1888 had contracted the disease while living in infected houses.

If the facts I have related are true, how is it possible to institute any practical preventive measures without registration? The education that is spoken of in the resolutions offered by Council will not accomplish much. Cornet has shown that even when the patient has carried out most of the instructions, the immediate surroundings are infected. As you are well aware, among the very poor there is no nursing. The consumptive is apt to lie on a bench in the kitchen—a small room, perhaps eight by twelve feet. He had to wait on himself, and probably spits everywhere. Under such circumstances he is bound to infect the room, and it has been shown that the disinfection of such a room does not consist in burning sulphur, but special methods are required. One of the most efficient methods is rubbing down the walls with dry bread and then washing with carbolic acid or some other powerful germicide. The furniture and the bedding also require disinfection. You well know that the houses in which the poor live are owned by men who are trying to get as much money as possible out of them. The owners will not disinfect these houses if they can avoid it. It is only by the authority of the Government that this disinfection can be accomplished.

Now, is the profession ready to step forward and say: "We will make an earnest effort to stamp out tuberculosis?" The profession throughout the country has said that it will. The American Public Health Association, during its session in Chicago, adopted resolutions asking that registration should be practiced. The Section on Hygiene of the Pan-American Medical Congress adopted similar resolutions. The Congress of Tuberculosis in Paris, in 1888, passed resolutions asking that tuberculosis be recognized as a contagious disease, and in 1891 passed a resolution asking that disinfection be practiced.

Will disinfection have any effect? It will. I should like to cite one illustration: As far as I know, Berlin is the only city that has taken scientific precautions against tuberculosis. The result is most encouraging. In the city of Berlin there has been a marked reduction in tuberculosis from 1884 to 1891, the most rapid reduction of any city of which I can obtain statistics. In Philadelphia there has been a reduction. In London there has been a vast reduction since the establishment of consumptive hospitals fifty years ago. In Berlin there has been the most rapid reduction; from 1884 to 1891 there has been a reduction of 0.644 per 1,000. In 1884 the mortality in Berlin was 3.45 per 1,000, and in 1891, 2.811 per 1,000. In Philadelphia, where we have been priding ourselves on the reduction, there has been in ten years only a reduction of 0.623 per 1,000. Whether or not registration is being enforced in Berlin I do not know. I have been told by private parties that it is. Contrasting the reduction in Berlin with the reports from other cities, we find that the mortality in Paris was about the same in 1890 as thirty years prior—4.574 per 1,000. Whether or not France will succeed

in establishing preventive measures is yet to be known. I have had no definite information on the subject.

As to the sentiment on this question, it is all on the side of registration. I grant that it may be hard for wealthy people to be recorded as suffering from tuberculosis, but this is a disease of the poor; the vast majority of consumptives are very poor, and the necessities of the poor so demand registration that it should outweigh the sensitiveness of the rich. But the sensitiveness of any one can be overcome by the suggestion embodied in the resolution I offered, a suggestion which was made to me by Dr. James C. Wilson—that is, instead of registering the individual to register the infected house. It would not then be necessary to register tuberculosis among the wealthy, as only houses that had been infected would have to be registered. Where infection can be prevented by proper sanitary measures, there would be no occasion for registration. This would enable us to register those houses that need to be disinfected.

The best place to study this subject is among the poor. It is there that I have learned my lessons. I am satisfied that every man here will reach my conclusions if he will go among the very poor and study this question at the bedside, and see how, one by one, these people die from the disease because they are unable to protect themselves and because, in the endeavor to protect and supply medicine to the stricken one, the healthy fall victims to the disease. It is these who need aid. The College of Physicians should now take a firm stand and do something in aid of these people. It is not necessary to do everything at once. Let us make a beginning. Experiments have been made; let us now come to action. It is not fair to the public that the medical profession, with the knowledge it possesses, should do nothing. The laity can not act because they have not the knowledge. If we, who have the knowledge, do nothing, we are certainly responsible for the deaths of those who otherwise might be saved.

Dr. J. M. DA COSTA—Let me say, in the first place, that I thoroughly admire the enthusiasm which Dr. Flick has for years brought to the study of this question. I think the way in which he has gone about this work is in every respect most commendable, and in its spirit and scope this is one of the best series of observations with which I am acquainted. If I differ with him it is rather in the conclusions than in reference to his mode of investigation and his aims.

When we speak of contagion in consumption, we can not mean that it is markedly contagious. There is no proof that it is. It is not contagious like typhus fever, or small-pox, or scarlet fever, or diphtheria. It is only slightly contagious. It is, indeed, so slightly contagious that some of our best thinkers with the largest fields of observation, notwithstanding the evidence that has been adduced, still hold that it is not contagious at all. For instance, if we take the opinion of a man so long connected with the Brompton Hospital as Dr. Williams, we find in the last edition of his work on "Pulmonary Consumption," that he maintains that no more deaths from consumption occurred in the attendants of the Brompton Hospital than occurred among the same number in ordinary life. The evidence of Dr. Andrew, of the Victoria Park Hospital is in the same direction. When we look at the conclusions of these men and at those of Wilson Fox and many others, it is going too far to assume that the whole profession admits the disease to be contagious.

That it is moderately so, and that it can be communicated under exceptional circumstances, I firmly believe; but that we should regard it as a very contagious disease and take all the precautions that we do in such diseases, I deny. If it be contagious, it is contagious, as every one admits, chiefly through the sputum. Is it to be understood that an inspector from the Board of Health is to come daily to take care of the sputum cup? Is not the intelligent physician the proper health officer? Is not what he says sufficient, and can he not advise and enforce the destruction or the disinfection of the sputum as well as any public officer? Finding bacilli in the bedclothes and on the bedstead, and destroying them, will not eradicate consumption. Tubercle bacilli are widely diffused. They are in the dust of the air we breathe, blown about from the dried sputum of consumptives in the street. They have been demonstrated to exist on the fruit sold in our markets; they are in milk. They may, indeed, be said to be everywhere; and not only in the homes of consumptives. They have been found in churches, in places of amusement. Where will you draw the line as to watching and interfering with the life of the consumptive? Must we not take the broader view, and act on the degree of the communicability, and how far it is practicable to control

it, rather than on the mere abstract question whether tuberculosis be contagious or not? The degree, every observer knows, is extremely slight.

The excellent series of observations about the houses is, I believe, subject to several fallacies. In the first place, unless you know the history of the persons themselves, these observations on the houses supposed to be infected are not conclusive. You must know whether or not the individual inherited tuberculosis. I am one of those who believe that the disease is largely hereditary. Of what use is it to say how many living in these houses die of consumption unless you know the history as well as the number of those who have occupied them?

Again, we should bear in mind when discussing the contagiousness of phthisis, how enormously prevalent the disease is, and how difficult it is to draw conclusions when you have the most prevalent chronic disease to deal with. As bearing upon the question of infection from husband to wife, it has been calculated by Longstaff as a mere matter of statistics without reference to the question of contagion, that of every 148,121 men who die of consumption in the ages of married life, there would be 4,358 wives who would have consumption—that is, about 1 in 33. Thus, for every thirty-three married men who die of consumption there would be one woman have it, as a mere matter of ordinary frequency, whether the disease be contagious or not, and the probability would be a little more for phthisical wives. The number of cases seen in which both husband and wife have been affected is comparatively small. Flint, in over 670 cases, noted but five such instances. My record shows more such instances, including one where a tubercular husband had three tubercular wives. Still I have not met with very many, and the chances are always slight that the husband communicates the disease to the wife, or the wife to the husband. When we take all the facts into account, as well as the strong hereditary tendency of the malady, we must be careful how we draw conclusions in individual instances of apparent contagion.

Mindful of the observations of Dr. Flick, I have for some time questioned myself with reference to houses that I have known for years in which there has been consumption. But I have not taken them in one district, but everywhere. And this seems to me a much fairer way of studying the question, as the indiscriminate selection obviates the likelihood of error from bad hygienic conditions, especially of drainage, that houses near each other might share.

I have many houses in mind in which no case of consumption followed the first. In one, the father died of a slow consumption twenty years ago. The mother is, as regards tubercle, perfectly healthy to this day. The seven children have grown up into exceptionally healthy young men and women. In another house the wife died of consumption about eighteen years ago. The husband continued to live in the same house, and a family of children have grown up healthy. Another house has been occupied for many years by a consumptive who has had the disease for twenty-five years. Neither his wife nor any of the five children have become affected, though he is in the hands of a physician who does not believe in the contagiousness of the disease, and does not direct the sputum to be disinfected. Another house was occupied for years by a consumptive mother, whose husband had died of the disease many years before in another city. The son and daughter remained in the house mentioned for eight years in perfect health. It has since been occupied by a lady whose history I know, who is also healthy. The son got married about seven years ago, and has lived in various places. Within the last two years he has become a consumptive. His strong hereditary tendency determined it. I could go on citing instance after instance. I admit they furnish negative evidence. But negative evidence in a matter of this kind is valuable. I am on the whole quite certain that in by far the larger number of cases where I have known the history of both the house and of the household for a long time, there could not even be any suspicion of house infection. It is true also that in most of the houses cleanliness and ventilation were well attended to.

Further, in the question of house infection, we must not overlook the fact that these supposed centers of infection may adjoin, and have common drainage. And, under any circumstances, does it not suggest that possibly there is something wrong in the drainage or subsoil as much as it does infection of the house? The well-known observations of Bowditch, and of others, have made us familiar with this mode by which consumption spreads in Massachusetts and in the whole of New England.

With reference to hospitals: Consumptive hospitals have

been brought forward as a strong evidence of the non-contagiousness of phthisis, though I can not say that the figures they adduce are to me absolutely convincing, and there may be something in the greater prevalence and concentration of the poison that make consumptive hospitals more likely to be sources of infection. I have already referred to the observations and opinions of Dr. Williams and of Dr. Andrew. But as regards general hospitals in which consumptives are, they certainly can not be shown to be places of infection. I will quote the remarkable results in the General Hospital of Vienna. That Hospital is one of the largest in the world. It is full of consumption, and there were, as we know by some observations made long since, and before the disinfection of the sputum was attended to, in three years 2,736 deaths from phthisis, and not a medical officer or a nurse had become infected. I will refer to the record of the Pennsylvania Hospital, which always has consumptives in its wards. I have taken some pains to ascertain the truth in this matter. In my long connection with the institution there never has been a time when there were not cases of tuberculosis in the medical wards, and there have also been cases of surgical tuberculosis in the surgical wards. Of 147 resident physicians who have been in the Hospital in the last seventy years, and of whom I have traced the medical history, and many of whom I have personally known and examined, but one has died of tubercular disease. Two others have at different times shown tubercular symptoms. One of these is now living in Arizona in fair health. In the other, even bacilli have disappeared from the sputa. The one dying, did not die for over five years after leaving the Hospital. Moreover, before becoming a resident physician, he was in delicate health, so that it is not fair to attribute his death to his having been in the Hospital.

A stronger statement still can be made with reference to the nurses. Of forty male nurses that have been in the Hospital in the last twenty-five years, but one has shown any sign of tubercular disease. He is now a patient in the Hospital. He did not become tubercular until four years after leaving. There have been 163 female nurses whose histories can be fairly well traced. Of fifty-three who have left the Hospital in the last five years we know their present condition accurately. Not a single one of these certainly has had any tubercular symptoms, notwithstanding that there was always tuberculosis in the wards, always some exposure, and until recent years disinfection of the sputum was not practiced, although ventilation was always attended to. There is only one case even doubtful. She has an occasional cough, and is not strong. Her father and mother both died of consumption.

When we take all these facts into account, granting, as I do, that up to a certain extent tuberculosis is contagious, I think that the recommendation of the Council to the Board of Health is the right one. Why fix the brand of leper on a poor unfortunate because he has consumption, when the medical officer can do all that is necessary? He can instruct how to ventilate and keep the house pure, and how to disinfect the sputa. What more could a Board of Health do? What can it do, except in instances of death where proper disinfection may not be carried out? Where death has occurred, and where disinfection is not likely to be practiced, it would be proper for the Board of Health to interfere. Under other circumstances why should we place a stigma on the consumptive, why have him pursued from house to house, why have him a marked man, why have the house a marked one? Why give it a bad name and injure the landlord, because there has been a death from consumption in it? I think that the resolutions offered by the Council cover the whole case. No human being will suffer. It will only enforce on medical men the necessity to insist on proper disinfection and proper hygiene. It will do as much as possibly can be done, and as much as any Board of Health can do.

With reference to hospitals for the consumptive, there is a great deal to be said on both sides of the question. Undoubtedly larger means of separating the sick from the well are desirable. But whether this can be made in any way obligatory is doubtful; large social questions and questions of finance arise which take the matter far beyond our power materially to influence.

We must not overlook the strong hereditary tendency to the disease. If you want ever to get rid of consumption, it is not going to be simply by the disinfection of sputa and similar means. It will be largely by the prevention of the marriage of tuberculous patients. There you strike at the root of the evil. Until hygiene, preventive medicine, and

law have reached that point, I think that we must let this question take care of itself, doing the best we can to limit the ravages of the disease. I admit that it would be most desirable if we could separate the consumptive from the well. If the State were rich enough to make colonies in climates in which consumption will not flourish, that would be a most admirable means.

Let me say that it is not because I do not believe that phthisis is communicable that I oppose the contemplated action of the Board of Health to declare the disease contagious, and to register consumptives, but because I believe that the means proposed will produce hardship without corresponding value, and that they are both unnecessary and insufficient. The Board of Health has already the right, and may well enforce it, to have any house that, whatever the cause, has a bad sanitary record, put in better order. Moreover, it can do much in destroying other sources of infection, such as from diseased meat, from the milk of tuberculous cows, in improving drainage, in favoring open spaces that air and sunlight may get into the houses. But let it leave the care of the individual where it belongs—to the conscientious physician.

DR. JOHN B. ROBERTS—It seems to me that this question is almost exactly the same as the one with which surgeons struggled ten years ago. I was one of the conservative ones who did not at first practice antiseptics, but employed half-way measures and saw all my cases suppurate. This is the point to which the question of tuberculosis has come.

I think that Dr. Da Costa's statement that there are a large number of cases all over the country, which he uses as evidence that the disease is not certainly infectious, is really an argument on the other side. It is so because there is infection. There are so many hereditary cases because infection of the parents has so weakened the tissues that a lowered resistance is transmitted to the children, and they can not repel the action of the bacilli.

It is said that the doctor can do all that is necessary, but Dr. Da Costa has said that he has known of cases where the physician would not take any precautions. That is a reason that the Board of Health should step in among the poor and see that the houses are clean. We see this in diphtheria. It is not a question of damage to landlords. It would be an advantage if every one knew that every house was disinfected, either by the willing efforts of the people, or owners, or by the Board of Health. There seems to be no reason why there should not be a report to the Board of Health if it will act in a reasonable manner. There is no expectation that the Board of Health would take the same measures as in typhus or typhoid fever. It is only a few years since typhoid fever was placed on the contagious list. If the matter had been discussed publicly there would no doubt have been many men on both sides—some for, some against, putting typhoid fever on the infectious list.

It might be well to mention what has been done in other places. In February, 1892, at a conference of the medical staff of the Manchester (England) Hospital, with the medical officers of health and others, it was unanimously resolved that it was desirable that certain cases of phthisis should be notified to the medical officer.

Dr. Hermann G. Biggs, the Chief Inspector of Pathology, Bacteriology and Disinfection in the Health Department, has sent to the Health Board a long statement regarding the contagiousness of tuberculosis, accompanied by a number of recommendations. He says:

"1. Tuberculosis is a contagious disease and is distinctly preventable.

"2. It is acquired by the direct transmission of the tubercle bacilli from the sick to the well, usually by means of the dried and pulverized sputum floating as dust in the air.

"3. It can be largely prevented by simple and easily applied measures of cleanliness and disinfection."

His recommendations include:

"That there be systematically disseminated among the people by means of circulars, publications, etc., the knowledge that every tubercular person may be a source of actual danger to his associates, and his own chances of recovery diminished, if the discharges from the lungs are not immediately destroyed or rendered harmless.

"That all public institutions, such as asylums, homes, hospitals, dispensaries, etc., be required to transmit to the Board of Health the names and addresses of all persons suffering from pulmonary tuberculosis.

"That all physicians practicing their profession in the city be requested to notify this Board of all cases of pulmonary tuberculosis coming under their professional care."

The North London Hospital for Consumption issues directions to its out-patients and to its ward patients, recognizing the contagious nature of tubercular phthisis and suggesting precautions.

The Royal National Hospital for Consumption, Ventnor has this to say:

"Patients are earnestly requested not to spit on the ground, floor, or fire-place, but to expectorate into the proper vessel. When this is not possible, the handkerchief should be used without fail; but in order that the expectoration may not become dry it has been arranged that a clean pocket handkerchief shall be supplied to each patient daily, the soiled one being at the same time removed for the double purpose of disinfection and washing. *It is to be distinctly understood that spittoons shall always be used when possible, and that the handkerchief is only supplementary to prevent spitting upon the ground.*"

The Manchester Hospital for Consumption takes similar ground:

"All matter coughed up from the chest should either be spat in the fire or should be received into a vessel lined in such a way with a piece of paper that the paper and its contents may be lifted out and burnt.

"Rags that can be burnt should be used instead of pocket handkerchiefs, and if a pocket handkerchief be used it should be well boiled before the matter upon it has had time to become dry and powdery.

"N. B.—The Medical Officer of Health for Manchester undertakes to purify, *free of cost*, any house that may be notified to him by competent medical men."

Last year the Northwestern Branch of the Society of Medical Officers of Health drew up a memorandum on the subject, which has been pretty widely distributed in the North of England. In this memorandum the infectious nature of consumption is definitely laid down, and dried sputum in the form of dust is indicated as the vehicle of contagion.

The County Borough of Oldham, England, gives similar "precautions against taking consumption."

The French *Ligue Preventive contre la Phthisie Pulmonaire* says:

"The most frequent and powerful source of infection lies in the expectoration of consumptive patients. Although almost harmless so long as they remain in the liquid state, the sputa becomes especially dangerous when they are reduced to dust. They quickly take on this form when they are projected on to the ground, the floor, the walls, when they soil clothing, counterpanes, bedclothing, curtains, etc., when they are received into handkerchiefs, napkins, etc."

With this evidence of scientific work in other places, can the College of Physicians of Philadelphia deny the contagiousness of phthisis, or doubt the advisability of the Board of Health knowing and registering the houses of at least the poor and careless, in which the germs of tubercular consumption are threatening the public safety?

While there may be a few who believe in the non-contagiousness of consumption, the vast majority does believe that it is contagious to a certain extent. It is the same old story of antiseptics and sepsis. The College of Physicians should go on record that consumption is contagious more strongly than appears in the report of Council. In the second place, something should be done. That seems to me to be in the direction of letting some officer know that the consumption bacilli are to be found in a certain locality. Not the physician, but some central authority should have the authority to know and the authority to enforce such measures as will limit the spread of the disease among the poor. If we limit it among the poor, we limit it among the rich.

(To be Continued.)

WISCONSIN STATE BOARD OF HEALTH.—At the last annual meeting Dr. S. C. Johnson retired as President and was succeeded by Dr. Solon Marks. Dr. J. T. Reeve, of Appleton, resigned as Secretary and was succeeded by Dr. U. O. B. Wingate of Milwaukee. Dr. Henry Day of Eau Claire was appointed to succeed Dr. Sharney, resigned. The voluntary retirement of the veteran sanitarian, Dr. Reeve, was in the nature of a surprise to the Board. Dr. Reeve had served since its organization as Secretary with distinguished success. The new Secretary, Dr. Wingate, is a man of fine presence, great executive ability, energetic, and thoroughly informed on sanitary subjects.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO. 68 WABASH AVE., CHICAGO, ILLINOIS.

F. J. REBMAN, LONDON AGENT, 11 Adam Street, STRAND, LONDON.

W. H. LOWDERMILK & CO., WASHINGTON, AGENTS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Duglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, FEBRUARY 17, 1894.

MEDICAL EXPERTS.

"The fruit of a surgeon's experience is not the history of his practice, and his remembering that he has cured four people of the plague, and three of the gonit, unless he knows how hence to extract something whereon to form his judgment, and to make us sensible that he is become more skilful in his art; as in a concert of instruments, we do not hear a lute, a spinette or a flute alone, but one entire harmony of all together. If travel and offices have improved them, 'tis a product of their understanding to make it appear. 'Tis not enough to reckon experiences; they must weigh and sort them, digest and distill them, to extract the reasons and conclusions they carry along with them."—MONTAIGNE.

Within a recent period there have been several trials in the city of Chicago which have called for the testimony of expert medical witnesses. Some of these witnesses were expert in the true sense; others were unfit to be considered in any such capacity. One medical gentleman who occupies a position of honor in the city government by the grace of some alderman, was quite at a loss to answer the simplest question in anatomy; the "Island of Reil" was a *terra incognita* to him, and he was hopelessly tangled in trying to explain an error in a type-written document wherein the words, "hypostatic condition," were inserted instead of "hypostatic congestion." There were other persons placed on the stand as alleged "experts" who made an equally painful exhibition of their innocence of the rudiments of an ordinary medical education.

As is but natural, such an exhibition excited both pity and disgust, and at the last meeting of the Practitioners' Club of Chicago, the question of the employment of medical experts was the topic of discussion.

DR. ARCHIBALD CHURCH, who opened the discussion, said in substance that

"the present method of giving expert testimony had been gravely criticized, and a suggestion was made that a commission of physicians called by both sides in a case before court would be more conducive to justice. He thought the present plan was a good one, but opposed the cross-examination of experts as to their capacity, because such cross-examination had degenerated into brow-beating the wit-

ness. In conclusion he said: 'If we are to progress in this matter we should first provide that experts shall be experts; we should eliminate the brow-beating, discourteous and dishonorable attitude of counsel; we should elevate the moral standard of the judge who presides on the bench, and lastly we should secure those men to act as experts who have a personal knowledge of the case under consideration.'"

DR. D. R. BROWER said the lawyers called in doctors of their own way of thinking and the trouble would never be settled until the court called in men competent to give evidence without regard as to which side it would bear upon. DR. H. M. LYMAN thought physicians should cultivate the habit of intelligible testimony and confine their language to plain English. DR. D. A. K. STEELE asserted that as long as the doctors were experts for the fee that attached to their testimony all the evidence needed by one side or the other could be secured.

DR. DEWEY had in view the Prendergast case when he said that insanity as viewed by the court was entirely different from insanity as known by the physician. The law held that a man was not insane who knew the difference between right and wrong, while a physician knew that a man was capable of appreciating the distinction and of committing a crime with malice aforethought and yet be wholly insane. He held that expert testimony should be placed entirely under the regulation of the court and given by persons of known reputation selected through the discretion of the court and not by the partisan counsel. DR. BELFIELD urged the establishment of non-partisan medical testimony. The expert should be beyond the position of a mere witness and placed on a level with the judge.

The definition of an expert is thus given in Chambers Encyclopedia:

"EXPERT. (Lat. *expertus*, from *ex peritus*, specially skilled). A man of special practical experience or education in regard to a particular subject; a word commonly applied (after the French) to medical or scientific witnesses in a court of justice, when selected on account of special qualifications, as in case of an analysis of the contents of the stomach in suspected poisoning. The term is similarly applied to a person professionally skilled in hand-writing, for detection of forgery of deeds and signatures."

Webster says:

"EXPERT.—An expert, skilful, or practiced person; one who has skill, experience, or peculiar knowledge on certain subjects of inquiry in science, art, trade, or the like; a scientific or professional witness."

Zell's Encyclopedia:

"EXPERT—(Law.) A person selected by the court, or by parties in a cause, on account of his knowledge or skill, to examine, estimate and ascertain things, and make a report of his opinion."

The discovery of truth, so far as it lies within his knowledge, for the information of the court and jury, should be the sole object of the expert witness, and the efforts of counsel to distort the truth to one side or the other, should lead the expert to be on his guard.

Much of this bias toward one or the other side, frequently arises from their being employed practically as assistant counsel, to coach the attorneys. In our judgment, a witness should be ineligible to give evidence as an expert, who has acted as adviser to counsel in the case at issue. If the judge should have the power to accept or reject a witness tendered as an expert, and would exercise it, after due examination of the qualifications of the witness, much would be gained to the cause of justice and the honor of the profession.

The German Government has solved the expert problem in a very satisfactory way. In that country the "*Gerichts Arzt*" is a medical referee appointed by the Government for a particular district. He can only receive appointment after a rigid examination by a Government Board, and when appointed and assigned to a district he is a salaried officer of the State, and his reports ("*Gudachten*,") are final on medical questions.

It is quite possible that an Act of the Legislature which would authorize the State Board of Health, or State Board of Medical Examiners, to give certificates to medical gentlemen, stating in what particular branch of medical science the recipient was qualified to give evidence as a skilled witness, would remedy the evil; at least it would be a great advance on the present system, which is not only unsatisfactory to everybody, but a blot on the jurisprudence and scientific standards of the age.

But no test of ability can insure honesty of purpose or of character; there the personal equation of the witness must stand for what his reputation in the community is worth.

The Medico-Legal Society of Chicago held a meeting Feb. 10, and adopted the following resolution:

To guarantee the interest of society and of the accused in all medico-legal investigations at least two experts shall be employed. These experts shall be appointed by the Judge.

It was unfortunate that the Society was so managed as to discuss the issues of a case still pending in the Supreme Court, as it gave a pretext for the assertion that the meeting was a pre-arranged attempt to influence the Court, and a "sharp dodge of the defense."

THE VISITS OF THE CLERGYMAN TO OUR PATIENTS.

In the sick room and at the bedside of the suffering, the clergyman and the physician meet. The one looking to the spiritual, the other to the material welfare of the patient. The spiritual healer knows, or ought to know, that it is only in a sound body the best mental achievements can be realized, while the physician understands equally well that unless the mind is at rest, the bodily healing is of doubtful certainty. In such a case can they afford to make war on each other? Each in his chosen profession will feel like exalting the line which he follows, as conducting to a successful issue; but may he be able to do this without the coöperation of the other? "No man liveth to himself; no man dieth to himself," is the declaration of Holy Writ. With this interdependence between the workers can it be otherwise than that the most satisfactory results will only be reached by mutual coöperation? Hence follows the obligation to good will and a clear under-

standing of the duties of each in the matter of mutual support.

This desire, however strongly felt, is complicated by that indefinable territory lying in the patient, where the material ends and the psychical and moral begins. This territory seems to be in some sort related to both, and hence the danger of physician and clergyman acting in antagonism to each other. Suppose, for example, that the physician finds his patient in such a critical situation that he regards it as necessary that the sick man should not know the danger until the crisis is past, and the clergyman, knowing the danger, feels that the man's soul must not be put in peril by leaving him to pass away without due preparation for the passage, will they not honestly endeavor to counteract each other's work? By this means intensifying the man's sufferings, and so rendering the labors of both abortive.

It will not require any great stretch of the fancy to see that in the case supposed it would be far better for both to work together to the same end. The clergyman might make things lively by telling some of his best stories, and join with the physician in drawing the sick man's mind away from himself, and both together could demonstrate that "two are better than one." In such an emergency the sick room should, if possible, be made the pleasantest room in the house. We remember medical men who had cultivated cheerfulness to such a degree, that their very presence was an invitation to come into the light, and clergymen, too, who had the good man so strongly presented in their faces that the children hailed their coming with delight. Let two such spirits meet in the sick room and they would almost carry everything before them. The grace of cheerfulness has never been cultivated for half its worth in this work-a-day world of ours.

We offer these thoughts to our brethren in the hope that while the "times are hard," everything that may reasonably be done to alleviate suffering, will be duly considered, and that sympathy will be cheerfully given whenever there is a possibility of making men happier and better. As specialists men work into grooves from which it seems almost impossible to draw them. They isolate themselves and so circumscribe their own usefulness.

We do not propose to trespass upon the peculiar domain of the clergy, but we do desire that when our labors lie in the same fields, that a friendly sympathy shall render our mutual labors more efficient. Physicians have not done the best work of which they are capable, and never shall, until the inspiring power in the support of kindred spirits shall be more fully realized than at the present time. The trend of mankind is toward fellowship in these days as never before. Let our profession not be laggards in the race.

WEATHER AND DISEASE.

A country physician with large practice, was deploring his inability, from constant work, to make original researches, or to read books, and expressed the opinion that no one with a large country ride could contribute much to the science of medicine. This is a common error which a little reflection will quickly disprove. As an illustration take the common theme of all conversation, the weather. The physician with long rides in the country, and time for observation and reflection, can be an expert and contribute facts in this field as important to science as those found in the laboratory and by the microscope. By the weather we mean the moisture, temperature, pressure, winds, clouds, ozone, electricity, sudden changes of heat and cold, storms and sunlight. From the earliest times these forces have been recognized as all-powerful in the production of disease. In our climate prolonged hot or cold periods very clearly affect the death rate, but how and to what extent is unknown. Certain diseases are retarded or accelerated by those forces. The unknown and psychic effect of the weather on all, both sick and well, are within the observation of every one, and yet very little study has been made in this direction. The prayer book recognizes this fact, in petitions for favorable weather, and protection from lightning and sudden storms. Even the POPE has prepared a manual to be used by the clergy in bad or unfavorable weather.

DR. FARR of England, and other authorities, have said that the thermometer would register very largely the disease mortality and even criminality of a community. The weather proverbs of the almanacs and the observations of persons who live in the country, are practical store houses of obscure half facts, that await study in the future. Thus everywhere these variable forces we call weather, affect and influence the physical and psychical conditions of both men and animals. The physician in the country is in the most favorable condition to study these facts. The surroundings are always more sensitive to these changes than in the city, where artificial states largely control disease. The country and country village are the real laboratories where these unknown forces can be watched and determined.

A vast literature of facts invested in superstition and delusions, cover this region, and the country physician should of all others be a teacher here.

A barometer and thermometer costing only a small sum, to measure the pressure and temperature of the air, hung up on the office stoop, and a blank book in which any member of his family can record the readings of these instruments three or four times a day, with the directions of the winds from the weather vane, this with his daily record of cases, will be the starting point.

He will soon begin to trace some connection in his cases of fevers, and the obscure nerve troubles and exhaustions, to these sources, and a new field will open for original work, the fascination of which will relieve the drudgery, and make the long rides moments for pleasing reflection. From this point the facts of the weather influence on disease will accumulate and widen, suggesting other methods of observation and other means of measurement by instruments to give accuracy to the facts. The physician in the mountain region will accumulate facts that are peculiar to the special cosmic conditions of that section, and the physician in the river valley will have a new range of facts for his section.

The observers on the sea shore or lake border, or on the open prairie or wooded country, will each have a different story; each have different facts, which will be parts of great laws of the highest practical value. In a large manufactory where three thousand men are employed, the daily product varies with the weather from 5 to 12 per cent. less. Days that are bright and clear bring out the best work in the largest quantity, and days that are stormy and cloudy are followed by poor work, from 5 to 12 per cent. less. The local physician was appealed to, to explain this fact. Had he made a study of these common influences, which are the subject of every day's greeting, he should have been able to throw some light on this problem.

A noted surgeon thinks his cases recover more quickly when operated on in clear bright days; a physician of some prominence gives his drugs on dark days, and believes narcotics act more profoundly at these times. These facts and opinions are almost innumerable and can be found in every community. Who will enter this field to explain these phenomena? The physician who has full opportunity for observation, and time to reflect, must do this work. The village and country doctor is better situated for this than any others.

This is only one field of study that can be carried out in long lonely rides and practice in the country. The absence of professional contact, and the physical weariness of exposure to all sorts of weather, has its full compensation in opportunity to become students of nature, and master the facts that are spread out everywhere. The country physician can not only become eminent in medicine, but in other fields of science. All that is essential is powers of observation, and disposition to study the facts that, like an open book, are all about him.

 LIABILITY FOR DISMISSAL OF PATIENT.

The liability of a physician in dismissing a patient is passed upon by the Supreme Court of Iowa in the case of *Mucci v. Houghton*, decided Jan. 17, 1894. This was an action brought to recover damages for

alleged malpractice. The former had sustained a fracture of his left arm between the wrist and elbow. Both of the bones of the arm were broken. He employed the doctor sued to reduce the fracture and treat the injury. The latter at first bound up the arm in splints, and afterward incased it in a plaster cast. After giving attention to the injury for a little less than two months by examining the condition of the fracture the cast was removed, and the surgical attention ceased. The ground of the complaint was that the doctor treated the injury so unskillfully that when the treatment ceased the injury was not cured, but a false joint was created between the elbow and wrist at the place of fracture. There was a trial by jury, and a verdict and judgment for the party suing, which is affirmed by the Supreme Court on appeal.

One paragraph of the trial court's charge to the jury was as follows: "If a physician or surgeon be sent for to attend a patient, the effect of his responding to the call, in the absence of a special agreement, will be an engagement to attend the case as long as it needs attention, unless he gives notice of his intention to discontinue his services, or is dismissed by the patient; and he is bound to exercise reasonable and ordinary care and skill in determining when he should discontinue his treatment and services. If you find from the evidence that the condition of the plaintiff's arm is due to his having been dismissed when he ought not to have been dismissed, the defendant would be liable, unless the evidence further satisfies you that the defendant, in dismissing him, if he did dismiss him, used ordinary and reasonable care and skill in determining when to dismiss him; and, if he dismissed him under a mistaken judgment, he would be liable, and you should hold him liable unless you find from the evidence that, in making up his mind when to dismiss him, he exercised reasonable and ordinary care and skill and had regard for, and took into account, the well-settled rules and principles of medical and surgical science."

It was argued that the last part of this instruction required a greater degree of diligence and skill than the law imposed upon a physician and surgeon in the practice of his profession. He was required by the instruction, in determining whether his patient had so far recovered as to require no further medical or surgical attention, to exercise reasonable and ordinary care and skill, and to have regard to and take into account the "well-settled rules and principles of medical and surgical science." This the court holds was not erroneous, especially as the jury were told in another part of the charge that the law required a surgeon to have and exercise the average or ordinary skill possessed by members of his profession in his locality.

It may also be noted that in this case it is further held that it was not improper to permit the plaintiff, as a witness, to state in general terms that he complied with the instructions given by the doctor, as it would not be practicable for him to state what he was told to do, and then relate the particulars of what he did.

CORRESPONDENCE.

Ligation of Uterine and Ovarian Arteries.

To the Editor:—In your issue of Feb. 10, 1894, a report of a case is made by J. B. Greene, M.D. of Mishawaka, Ind. The report consists of a description of *ligating the uterine arteries and both ovarian arteries*. The writer said: "Accordingly I made the ligation of the uterine arteries and a part of the broad ligament, after the method described by Martin, but found it impossible to reach the ovarian arteries per vaginam. I then cut through the abdomen and with considerable difficulty was enabled to pass a ligature around both ovarian arteries, passing my needle under the Fallopian tubes and then back and around the vessel, tying close to the uterus. The uterus showed such a great engorgement of blood that I felt certain there would be no danger of gangrene of the uterus, as there was sufficient collateral circulation from branches of the ovarian arteries to maintain life in the organ."

As this report appears in one of the best journals of this country I deem it proper and just to criticise it.

Just think of ligating both ovarian and uterine arteries in a living woman. They are the only source of life to the uterus. I state this from some sixty careful dissections of the human uterus by my own hand. For in no single case could the uterus be kept alive by the tiny little branch which springs from the deep epigastric that runs toward the uterus on the round ligament. Besides, the writer says, the tumor would likely weigh ten pounds, and yet he cut off the nourishing arteries of ten pounds of tissue. But no gangrene followed, for months afterward the same operator examined and found that she was menstruating regular. The writer said he tied both ovarian arteries and both uterine arteries and then "felt" there was sufficient collateral circulation to maintain life in the uterus. Where is such collateral circulation found? It can not be in the artery of the round ligament, and anatomy so far has not demonstrated any other.

The fact is, that such reports are dangerous, and they show how new operations may be abused by those unacquainted with natural facts. Any one familiar with anatomic facts of uterine circulation would expect nothing but gangrene if he ligated both ovarian and uterine arteries, especially when the uterus is large. If the ovarian and uterine arteries are ligated the uterus can be cut out of its place with anatomic certainty without fear of hemorrhage being fatal. There is no doubt that the operator in this case did not secure either ovarian artery, as in cases of tumor it frequently is situated a considerable distance below the tube. The reporter, in this case, combined Dr. Martin's operation of vaginal ligation of the uterine arteries with the operation that I presented some time ago, which is, to ligate the ovarian arteries and the uterine as it courses along the side of the uterus. But these two operations must not be done at the same time on the same patient. Such a procedure will bring gynecology into disrepute. Large active viscera will nearly always gangrene by suddenly cutting off the arterial supply. The change is so sudden that they have not time to atrophy. Sloughing of uterine tumors is not a rare matter,

even without the interference of surgery. No doubt the intended view in this operation missed its mark and saved the life of the woman. But in any case it was such a radical, ill-advised and hasty application of the operation that, no doubt, had the surgeon time to reflect he would not even attempt it with an understanding of anatomic facts.

I do not think that any expert could go into court and support any physician who would ligate both ovarian and uterine arteries and not extirpate the uterus. Even if no disaster followed (which is anatomically and physiologically contrary to known laws), I would consider it an unjust experiment to ligate both uterine and ovarian arteries. Again, the physician who will ligate both uterine arteries and one ovarian artery at one operation is, so far as we know at present, putting the life of a patient in jeopardy.

I wish the reporter of this case to understand that I have no ill feeling to present, as I am not acquainted with him personally. The report appears in public print, and it is the right of liberty to criticise in public print. It may be the means of restricting the attempt of the ligation of both uterine and ovarian arteries on the same patient at the same time.

F. BYRON ROBINSON, M.D.

CHICAGO, Feb. 13, 1894.

"Superfluous Spectacles."

CHICAGO, Feb. 9, 1894.

To the Editor:—The editorial in the JOURNAL of February 3, under the above title, is on the whole excellent. I had read Dr. Pooley's article which was the text for the editorial carefully and with much pleasure, and in the main concur in his conclusions. There are some points in the editorial, however, which are not deducible from Dr. Pooley's article, and others which are entirely apart from it, which, it seems to me, are open to criticism. First, you seem to argue, though that is not very clear, that if a patient when out of health has glasses prescribed which he wears with relief and comfort until the general health improves and then voluntarily relinquishes them, that the glasses were of no service. As well might you argue that the tonic or restorative medicine taken when out of health was of no benefit because not needed when the health is restored. I believe it is a very common practice with oculists (it certainly is with me) to prescribe lenses with the distinct expectation that they can be taken off when the general health and the eye health improves. The rest given to the eyes by the glasses assists the eyes to so recuperate that they may be used comfortably without glasses; and the relief given thereby to the nervous and muscular systems, is, I am sure, a potent factor in the general restoration of health. It is not at all uncommon to find young persons suffering from almost constant headache from eye-strain, and in whom the headache is relieved at once and entirely by proper lenses, after a time gradually leaving off of those lenses, without a return of the headache. Does that prove that the glasses were of no use? Does it not rather prove that the eyes have been so strengthened and improved by the glasses that they are now able to do their proper work without the fatigue and pain formerly experienced? In such cases, where there is a moderate degree of ametropia only, I invariably instruct my patients that the glasses are a means, not an end, and that it is to be hoped that they may later be able to discard them wholly or in part. You ask: "Does every optic defect need correction?" Certainly not, nor do I think that any prominent ophthalmologist so teaches. It seems to me that the indications for lenses are and should be very distinctly kept in view. They are but two, the relief of discomfort in the use of the eyes and the improvement of vision. If there is no discomfort from the use of the eyes but vision is improved by lenses

the patient may, I think, elect whether he will wear glasses or not. If the bother of wearing glasses is greater than the pleasure of improved sight he may with propriety refuse them. (Except in progressive myopia which is foreign to this topic.) If on the other hand there is discomfort from the use of the eyes which can be relieved more easily by the use of lenses than by any other means, I care not whether the required lens be of high or low power, such lenses should be prescribed and worn so long as, and no longer than they are beneficial. And this leads to the consideration of what it seems to me is a most important misconception in your editorial when you comment on the use of low degree spherical and cylindrical lenses. You argue that the eye can not appreciate a less degree than 0.75 D. sphere and a less degree than an 0.50 D. cylinder. If this were so it would very much simplify our trial cases of test lenses. There is no logic in saying that the eye can not appreciate less than 0.75 D. S. below 0.75 D. and yet can appreciate a shorter interval above that; or that the eye can not appreciate less 0.50 D. C. below 0.50 D. and can appreciate less than that above. So that, if your statement is correct our trial cases instead of having, as usually now, twelve pairs each of spherical and cylindrical lenses up to 3.00 D. need have but four pairs of spheres viz: 0.75 D., 1.50 D., 2.25 D., and 3.00 D., and eight pairs of cylinders viz: 0.50 D., 1.00 D., 1.50 D., 2.00 D., 2.50 D., and 3.00 D. The fact is, however, that the ordinary eye can appreciate a difference of one-fourth of a diopter in either a sphere or cylinder between one and three diopters and one-eighth of a diopter below one diopter. But the ability of the eye to appreciate such small differences is no proof that such differences are of practical importance; that must be determined by clinical experience. In regard to that you say: "The majority of oculists have learned from their own experience, as well as from the failures of the champions of the 0.25 D. cylinder, that such weak glasses are merely of mythical value." I think you are mistaken in that statement. So far as I have been able to learn and observe, the oculists who believe that such weak glasses are of merely mythical value have not used them. They do not believe that such lenses can have any value and so have never tried them. While those who now use them have many of them, like myself, started in skepticism to try weaker glasses than were formerly used and finding them helpful have tried again and again until now, speaking for myself, I should rather lose any other one lens from my trial case than the 0.25 D. cylinder. Again you say, "It is true that a cylinder of 0.25 D. is not only employed but even highly recommended by a few prominent oculists, but they have as yet furnished no proof that such lenses benefit their patients." Now that statement surprises me very much, for I thought a great deal of proof of such benefit had been furnished. I will therefore make this proposition, for if such proof has not been presented it should, if available, be before the profession. If you will indicate what proof you consider conclusive, I will endeavor to furnish the proof to establish the fact, if it is a fact, as well as any fact in medicine is established, that an 0.25 D. cylinder is a most valuable therapeutic agent.

HORACE M. STARKEY, M.D.

An Undignified Letter.

To the Editor:—The complaint of Dr. Cohen, published in the JOURNAL several weeks ago, was no doubt prompted by a keen sense of professional propriety; but did he not forget his high aim in the unprofessional and undignified tone of the latter part of his communication? As a matter of fact, a portion of it should not have been printed.

CONSTANCY.

BOOK NOTICES.

The National Dispensatory. Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain and Germany, with numerous references to the French Codex. By ALFRED STILLE, M.D., LL.D., Professor Emeritus of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania; JOHN M. MAISCH, Ph.M., Phar.D., late Professor of Materia Medica and Botany in Philadelphia College of Pharmacy, Secretary to the American Pharmaceutical Association; CHARLES CASPARI, JR., Ph.G., Professor of Pharmacy in the Maryland College of Pharmacy, Baltimore, and HENRY C. MAISCH, Ph.G., Ph.D. New (fifth) edition thoroughly revised, according to the new United States Pharmacopœia (7th Decennial Revision, 1894). In one magnificent imperial octavo volume 1,910 pages, with 320 elaborate engravings. Cloth, \$7.25; leather, \$8.00. With Ready Reference Thumb-letter Index, cloth, \$7.75; leather, \$8.50.

The sweeping changes made by the last United States Pharmacopœia necessitated corresponding changes in the well-known dispensatories, which are really "companions" to the Pharmacopœia. No physician can well afford to do without the work, and to the pharmacist it is indispensable. The work under consideration has been thoroughly revised, many of the older articles have been rewritten, and a large number of new ones introduced descriptive of all the latest synthetic remedies and unofficial preparations now in use. Prof. Stillé says:

In preparing a work under the conditions imposed on the present one, it is impossible, even with scrupulous vigilance, to prevent a certain commingling of fact and speculation, for the most cautious reporter can not always avoid mistaking the one for the other. The present writer claims only to have striven assiduously to maintain a separation between facts and theories, believing that whatever fate may await the latter, the former are in their nature indestructible; '*Opinionem commenta delet dies; naturae judicia confirmat.*' The deplorable results of following physiologic experiment and chemic composition, instead of clinical experience, as the chief teacher and guide in therapeutics, have led to the rejection by practical physicians of many medicines which not long before were introduced with loud acclaim.

The work is well indexed and the publishers state that the therapeutic and general indexes contain 25,000 references. The revision is not perfunctory, but a conscientious one, and the fifth edition is a worthy successor of the editions that have preceded it. The dosage has been given throughout in the decimal system, and the metric weights and measures are used throughout, which will be of great service to those wishing to write their prescriptions in the (now almost universal) metric system.

The Johns Hopkins Hospital Reports. Vol. iii, Nos. 7, 8, 9. Report in Gynecology. Paper. Pp. 762. Baltimore: The Johns Hopkins Press. 1894.

This handsomely printed and well-illustrated volume contains ten articles by Howard A. Kelly, M.D., and articles by Mary Sherwood, M.D., Albert L. Staveland, M.D., Hunter Robb, M.D., W. W. Russell, M.D. and A. S. Murray. In addition to the foregoing there is a record of the deaths occurring in the Gynecologic Department of the Hospital from June, 1890, to May, 1892.

The volume appropriately opens with a picture and description of the gynecologic operating room.

The topics are: 1, "An External Direct Method of Measuring the Conjugate Vera;" 2, "Prolapsus Uteri without Vesical Diverticulum, and with Anterior Enterocele;" 3, "Lipoma of the Labium Majus;" 4, "Deviations of the Rectum and Sigmoid Flexure associated with Constipation a Source of Error in Gynecological Diagnosis;" 5, "Operations for the Suspension of the Retroflexed Uterus;" 6, "Potassium Permanganate and Oxalic Acid as Germicides against the Pyogenic Cocci;" 7, "Intestinal Worms as a Complication in Abdominal Surgery;" 8, "Gynecologic Operations not involving Cœliotomy;" 9, "The Employment of an Artificial Retroposition of the Uterus in covering extensive

denuded areas about the Pelvic Floor;" 10, "Some Sources of Hemorrhage in Abdominal Pelvic Operations;" 11, "Photography applied to Surgery;" 12, "Traumatic Atresia of Vagina, with Hematomolpos and Hematometra;" 13, "Urinalysis in Gynecology;" 14, "The Importance of Employing Anesthesia in the Diagnosis of Intra-pelvic Gynecologic Conditions;" 15, "Resuscitation in Chloroform Asphyxia;" 16, "One Hundred Cases of Ovariectomy performed on Women over Seventy Years of Age;" 17 and 18, Statistical Tables. The work is valuable, and is creditable in every particular to the great University.

Operative Surgery. By TH. KOCHER, M.D., Professor at the University and Director of the Surgical Clinic at the Berne University. With 163 Illustrations. New York: Wm. Wood and Company. 1894.

Prof. Senn, in his "Four Months Among the Surgeons of Europe," says on page 148:

"From my acquaintance through literature I had always considered Kocher of Berne, one of the ablest of living surgeons, and in this opinion I was only confirmed by a personal acquaintance."

Thus introduced to English-speaking Americans, a book in English by Professor Kocher will be received with great attention and deference. The book is divided into four parts, the first of which is devoted to the introduction, general remarks on anesthesia, the treatment of wounds and the selection of the direction of the incision. Part II includes special operations; incisions; the relations of the cerebral convolutions to the skull; trephining, and operations on the face; the upper lateral cervical triangle; the anterior cervical triangle; the lower lateral cervical triangle; the nuchal region; the thorax; the spinal column; the lumbar region; the abdomen; the perineum; the sacral region; the upper extremity; the lower extremity; the thigh; the leg; and the foot. Part III gives the resections, and Part IV the amputations and exarticulations.

The book is remarkable for its extreme simplicity of style, its entire freedom from superfluities of any sort, and its directness. These are, indeed, always characteristics of a master, whether the topic be war, religion, law or medicine. These characteristics were possessed by Cæsar and General Grant, St. Paul and Bishop Bossuet, Cicero and Blackstone, Hippocrates and Celsus. The nearer the approach to the simple models, the more enduring the work.

Kocher's book is of that character that in times to come it is quite likely to be taken for the exponent of the method of operating of our epoch. The book itself does not record the beginning of a procedure, or trace the planting of the seed; it simply reproduces the full-blown flower, as this century's surgeons have developed it.

Treatment of the Diseases of the Stomach and Intestines. By DR. ALBERT MATHIEU, Physician to the Paris Hospitals. Cloth, pp. 294. New York: Wm. Wood & Co. 1894.

This book purports to contain a general summary of the therapeutics of diseases of the stomach and intestines. At the outset there is an excellent chapter on diagnostic technique, and as the French have always excelled in diagnosis we find the book here very strong.

The diagnostic study of the author falls under the following heads: 1, External Examination; 2, Internal Examination, together with a chemical study of the Gastric Juice; 3, Study of the Excreta.

In the external examination of the stomach the author regards the elastic siphon as essential. The giving of a test meal, forced feeding, and washing out the stomach, are all of importance, according to our author. He prefers the Frémont tube to any other, and it is the one he habitually uses:

Frémont's tube is smooth like that of Debove, and a little less rigid.

It is, however, stiff enough to enable it to pass readily the isthmus of the pharynx, even in patients who have never submitted to the operation before. It is longer than other tubes, and this increases the aspiratory power of the siphon. A small glass tube is inserted in its course, which enables us to see whether the fluids to be passed into or withdrawn from the stomach flow readily. This is especially useful when gavage is practiced. Finally, the gastric extremity of Frémont's tube is provided with a wide opening, so that it is less easily pinched by the walls of the stomach than are the other tubes; and it is more apt to remain patulous during the giving of a test meal.

The author, however, does not use the other parts of the Frémont apparatus, and seldom uses the aspirator for extraction, preferring Ewald's method of expression, which is thus practiced:

"The sound being introduced, whether during fasting or after a test meal, the patient is told to cough. He ought to cough especially with the diaphragm, in such a way as to cause a series of blows against the stomach. This suffices in most cases to fill the tube, and the gastric fluids then flow out on the principle of siphonage."

As it is not yet considered desirable to make a fistulous opening into the stomach, *a la* Alexis St. Martin, every time it is desired to examine the fluids of the stomach, a test meal is given the patient and "removed at end of an hour counting from the time the first mouthful is taken."

Space will not permit us to give further extracts from this highly interesting and truly scientific volume, which should be read by every medical practitioner desiring to keep pace with the advances of the profession.

The book is marred by an excess of zeal on the part of the translator, who has translated most of the formulæ into ounces, scruples, drachms and grains, instead of allowing them to remain in the simple and easily understood metric system now employed throughout the civilized world, except by the British.

Politzer's Text-Book of the Diseases of the Ear and Adjacent Organs. For Students and Practitioners. Translated by OSCAR DODD, M.D., Assistant Surgeon at the Illinois Charitable Eye and Ear Infirmary; Clinical Instructor of the Eye and Ear in the College of Physicians and Surgeons, Chicago. Edited by SIR WILLIAM DALBY, F.R.C.S., M.B. Cantab., Consulting Aural Surgeon to St. George's Hospital. With 330 original illustrations. London: Baillière, Tindall and Cox. 1894. Third edition, pp. 740.

This is a great work. It marks an epoch in the progress of otology and portrays with conservatism the present status of the specialty. The coming of this book has been looked for with more than ordinary interest by American aurists, who largely draw their inspiration from the accomplished author. Indeed, so marked is the confidence and esteem with which he is regarded by the many on this side of the Atlantic who have been taught in his Vienna clinics, that we might aptly confer on him the title of Politzer, our patron saint.

The publishers have produced a handsome volume, with abundant, well executed illustrations. Dr. Dodd deserves our thanks for the very creditable manner in which he has performed, for our benefit, the arduous duties of the translator. The purity and perspicuity of his English will be appreciated. Another point to gladden the heart of the evening reader—the paper is not glazed.

There are two subjects concerning which otologists will be particularly anxious to know Prof. Politzer's present views. The operations for the removal of the ossicles, and on the mastoid process. Detailed descriptions of the various methods for opening the mastoid are given, especially those of Stacke, Schwartze and Bergmann.

An advanced position is taken on the question of operative procedures. The necessity of operations in many cases can be easily seen from this observation on page 489: "With every acute middle ear suppuration, pus is found in the cells of the mastoid process, as I have proved by numerous dissections." Probably no other aurist has made as many valuable dissections. His collection of specimens exhibited in

Berlin, at the last Congress in Chicago last summer and at the Pan-American Medical Congress were the delight of lovers of aural anatomy and pathology.

In advising practice for operating he remarks: "To become sufficiently skilful the operation should be done at least forty times on the cadaver."

The author speaks much more favorably of excision of the membrana tympani and ossicula for dry catarrh than did those who participated in the discussion of this subject at the large meeting of otologists in Berlin in 1890. It was treated with much disfavor at that time. Yet he does not really commit himself in favor of it. He believes that "the operative treatment for disturbances of hearing caused by the adhesive processes after suppuration of the middle ear is exhausted has a greater future than the operative treatment of the non-suppurative adhesive processes." Concerning the recently reported sixteen cases by Jack, in which favorable results followed extraction of the stapes, he says: "The reports of Jack should taken with great caution."

Examiners for life insurance will be interested in the rules proposed here for admission and rejection of applicants with ear affections. The rules are not only safe but stringent. Here, as everywhere, the author's commendable conservatism is apparent.

It is frequently remarked that European otologists pay far less attention to naso-pharyngeal diseases as etiologic factors in ear diseases than American specialists, but here are eighty-four pages devoted to the subject. It is somewhat surprising, however, to find the inhalations of the strongly irritating vapors of acetic acid, ammonia, etc., recommended for acute catarrh, and to see the Weber nasal douche, a pernicious instrument, mentioned except for condemnation. But excellent precautions for its use, and warnings are given, for those who will use it.

Pilocarpine injections into the tympanic cavity, that have been very favorably reported on by the author, have been tried and abandoned by a number of Americans as affording negative results.

Concerning Lucae's sound he speaks rather discouragingly, but recommends Delstanche's masseur for the mechanical treatment of adhesive processes.

The cut on page 114, illustrating Politzer's method is wrong, for it represents the current of air as being propelled in the direction of the frontal sinus, or nasal duct, instead of the orifice of the Eustachian tube, where it is intended to go. This is an important point. The cuts on pages 94 and 101 give the correct position. There are some typographical and other errors that ought not to have escaped the attention of the proof reader, but they are comparable to blemishes on a great man's face; they do not dwarf his greatness.

Trephining in the Ancient and Modern Aspect. By JOHN FLETCHER HORNE, M.D., D. Sc. (Hon.), F.R.S.Ed. Honorary Surgeon to the Barnsley Beckett Hospital, and late Assistant Resident Surgeon to Leeds General Infirmary. Cloth, 16mo., pp. 133. London: John Bale & Sons. 1894.

Dr. Horne has produced a very entertaining book, and one which seeks to give proper credit where it is due, from the beginning down to the present time. He points out that all the changes from former methods "may not be improvements in the best sense of the word; time and experience will surely separate that which is valuable from that which is useless. A careful weighing of the evidence at present obtainable may be advantageous. It is one of the functions of the literary worker to rescue valuable matter from oblivion and to render it more accessible." . . . "No apology is needed for the frequent references I have made to American surgery; I can not but admire the genius and assiduity of the surgeons of that country, nor can we grudge

them a large share of the honor for the great advances made in the department of brain surgery."

The book is essentially a historical review of ancient and modern practices, and with the exception of a few case reports of interest, there is little original matter. In summing up the literature the author compliments the editor of this JOURNAL by quoting from his "Address on Surgery," delivered at the annual meeting at Detroit,¹ as follows:

"Dr. J. B. Hamilton has well expressed our conclusions: But however interesting from an historical point of view to revive these lessons of the past, we must remember that, as science is progressive, so the practice keeps equal step with that progress. In the past, practice was in advance of scientific knowledge. Tradition governed, instead of history and inductive reasoning. In the modern practice of the surgery of the brain and its envelopes we have, indeed, little to offer that is new in the practice—the slightest glance at medical history forbids that conclusion, but the reasons for our methods belong to us alone; and our century, although the heir of the accumulated wisdom of ages that are past, will have more to give to posterity in solid knowledge than any half dozen centuries that have preceded it, and particularly in the matter of diagnosis."

Dr. Horne did not give the date or place of publication of the foregoing remarks, but he paid an even more delicate compliment to the editor of this JOURNAL, for we find that he adopted the abstract quotations as given in the address of Prof. Hamilton, as his own, even to the Shakesperian quotation with which the address closed. As the quotations themselves are good enough to bear repetition, we reproduce some of them as follows:

PROF. HAMILTON'S ADDRESS,
JUNE, 1892.

Salvianus mentions a lunatic who by accident had the skull broken and was "excellently cured," and another who "breaking his head with a fall from on high, was instantly recovered from his dotage." (Burton). Gordonius recommended "the head to be shaved and bored to let out fumes, which without doubt will do much good. I saw a melancholy man wounded in the head with a sword, his brain pan broken; so long as the wound was open he was well, but when his wound was healed his dotage returned again." Gulianerius cured a nobleman in Savoy by boring alone, "leaving the hole open a month together, by means of which, after two years melancholy and madness, he was delivered." (Burton).

Celsus followed the Hippocratic method, which for four hundred and sixty years had been practiced almost without change; and we are thus able to see that the ancients anticipated us in these operations on the bony walls of the brain.

Dr. Andrew Smart reports that Prof. Chiene trephined for basal hemorrhage in a woman lying at the point of death, and saved his patient. There was an antecedent injury, and Prof. Chiene at first trephined at the right parietal eminence, but finding the result negative, again applied the trephine lower down, and forward. The exact position is unfortunately not stated. There was free hemorrhage from the membranes, but the breathing became normal, and after incising the dura there was evident relief to the cerebral pressure and tension. (*Brain*, London and New York, 1891, pages 287, 288).

Dr. Laplace of Philadelphia, by a brilliant operation, removed clots from the base of the brain, and the patient recovered. The patient was a boy of ten years who while at play had fallen on a broken fencing foil. The steel had penetrated the left orbit between the inferior orbital ridge and the eyeball. The child became unconscious, with deepening coma, right hemiplegia, left facial paralysis, complete aphonia, respirations 30, pulse 140, temperature 104.5 degrees. The wound was explored without result, and thir-

DR. HORNE'S BOOK, 1894.

Salvianus mentions a lunatic who by accident had the skull broken and was "excellently cured," and another who "breaking his head with a fall from on high was instantly recovered from his dotage." (Burton). Gordonius recommended "the head to be shaved and bored to let out fumes, which without doubt will do much good. I saw a melancholy man wounded in the head with a sword, his brain pan broken; so long as the wound was open he was well, but when his wound was healed his dotage returned again." Gulianerius cured a nobleman in Savoy by boring alone, "leaving the hole open a month together, by means of which, after two years melancholy and madness, he was delivered." (Burton).—Horne, page 26.

Celsus, A. D. 30, followed the Hippocratic method, which for four hundred and sixty years had been practiced almost without change.—Horne, page 26.

Another case recorded of trephining for basal hemorrhage and a most interesting case it is, by Prof. Chiene on a patient of Dr. Andrew Smart. The Professor gave us a résumé of the case at the Bournemouth meeting. I operated on a person comatose, etc., etc.

In this case there was an antecedent injury, and Prof. Chiene at first trephined at the right parietal eminence, but finding the result negative, again applied the trephine lower down, and forward. The exact position is unfortunately not stated. There was free hemorrhage from the membranes, but the breathing became normal, and after incising the dura there was evident relief to the cerebral pressure and tension.—Horne, page 74.

Dr. Laplace of Philadelphia, by a brilliant operation, removed clots from the base of the brain, and the patient recovered. The patient was a boy of ten years, who whilst at play fell on a broken fencing foil, which penetrated the left orbit between the inferior orbital ridge and the eyeball. This was followed by unconsciousness, with deepening coma, right hemiplegia, left facial paralysis, complete aphonia, respirations 30, pulse 140, temperature 104.5 degrees. The wound was explored without result, and thirteen days later tre-

phining was performed low in the temporal fossa. Laplace devised an instrument for the removal of the clots. I quote from his report:

"To reach the center of the base of the brain for the removal of the suspected clot, a miniature egg beater, consisting of four loops of platinum wire, had been improvised. This was perfectly malleable, and could be insinuated between the dura mater and the skull without wounding the cerebral structure. Having reached the cavernous groove, the instrument could be pushed no farther. It was then turned on its axis for the purpose of catching coagula in its loops. This was effectually accomplished, and about a teaspoonful of clotted blood removed piecemeal. While dragging more out, considerable venous hemorrhage took place. The trephined opening was then immediately plugged with iodoform gauze, and the usual dressings were applied. The wound was entirely healed in three months, and in six months afterward the patient had equal use of both extremities."

Dr. Laplace emphasizes "the safety of trephining near the base of the skull, the ease of arresting violent hemorrhage from the sinuses of the dura mater, and the importance of drainage in all cases of cerebral injury." (*Medical News*, Philadelphia, Dec. 5, 1891).

In regard to the treatment of epilepsy, Dr. Sachs in the *New York Medical Journal* for Feb. 20, 1892, says: "What can we expect from the surgical treatment of epilepsy?"

Simple trepanation seems to be more successful in these epilepsies associated with infantile palsies than in the traumatic forms, probably because of the still greater frequency of cysts in these cases than in the traumatic forms. Forty-four per cent. of all cases of infantile paralysis develop epilepsy. Of all cases of epilepsy a very fair proportion were developed in connection with infantile palsies. As soon as epileptic symptoms appear, the paralysis has the value of a focal symptom. In children excision of a center is a less serious affair than in the adult, for in the former, other parts of the cortex are capable to a greater degree of assuming the functions of the destroyed part. Under favorable conditions the surgeon may be able to cure a few cases of epilepsy. He will be able to improve many.

It will be seen that while there has been a distinct gain in many branches of cerebral surgery there is yet very much to be perfected, but all this wonderful advance is directly due to the great discovery of Pasteur, and the practical genius of Lister. Antiseptic methods have alone made advance on the old lines possible. The Rip Van Winkle of the profession may well rub his eyes and quote the lines of "Macbeth":
"The times have been; that
When the brains were out,
The man would die and
There an end; but now they
rise again."

Sydney Smith, in his review of Seybert's *Annals of the United States*, in 1820, said: "In the four quarters of the globe, who reads an American book?" We are of opinion that our esteemed friend, Dr. Horne, might answer this question with some emphasis.

NECROLOGY.

E. F. Latta, M.D., of Unadilla, Neb., January 29.

C. D. Smith, M.D., of Raleigh, N. C., February 5.

J. T. Doyle, M.D., of Wilkesbarre, Pa., February 9, aged 57.

Walter Noyes, M.D., of Butte City, Mont., died of pneumonia February 29.

phining was performed low in the temporal fossa.

To reach the center of the base of the brain for the removal of the suspected clot, a miniature egg beater, consisting of four loops of platinum wire, had been improvised. With this he was able to remove a teaspoonful of clotted blood. Whilst dragging more out, considerable venous hemorrhage took place. The trephined opening was plugged with iodoform gauze, and the usual dressings were applied. The wound was entirely healed in three months, and in six months the patient had equal use of both extremities.

Dr. Laplace emphasizes the safety of trephining near the base of the skull, the ease of arresting violent hemorrhage from the sinuses of the dura mater, and the importance of drainage in all cases of cerebral injury.—Horne, page 74.

Dr. Sachs, in answer to the implied question, "What can we expect from the surgical treatment of epilepsy?" says:

"Simple trepanation seems to be more successful in these epilepsies associated with infantile palsies than in the traumatic forms, probably because of the still greater frequency of cysts in these cases than in the traumatic forms. Forty-four per cent. of all cases of infantile paralysis develop epilepsy. Of all cases of epilepsy a very fair proportion were developed in connection with infantile palsies. As soon as epileptic symptoms appear, the paralysis has the value of a focal symptom. In children excision of a center is a less serious affair than in the adult, for in the former, other parts of the cortex are capable to a greater degree of assuming the functions of the destroyed part. Under favorable conditions the surgeon may be able to cure a few cases of epilepsy. He will be able to improve many."—Horne, page 87.

These have been removed by the introduction of antiseptic surgery and the investigation of the relations of internal and external parts. Surgery now interposes where it formerly held aloof, and looking back on the marvelous results of recent years, the limit of its power seems to be still far off. And may we not now say in the words of the immortal bard in "Macbeth":

"The times have been; that
When the brains were out,
The man would die and
There an end; but now they
rise again!"

—Horne, page 131.

J. C. Armentrout, M.D., Professor of Physiology in the Keokuk Medical School, February 7.

B. F. Spann, M.D., died February 2 suddenly of heart disease, at Anderson, Ind., aged 65 years. He was a prominent physician, and had held many State offices, and was at the time of his death one of the Trustees of the Indiana State Normal School. During the war he was appointed by Governor Morton to look after the sick and wounded Indiana soldiers in the hospitals at Nashville.

Deaths of Eminent Foreign Medical Men.—Dr. Krahmer, Professor of Pharmacology in the University of Halle. Dr. Mergit, formerly Professor of Medical Physics in the Bordeaux School of Medicine. Dr. Lellman, Professor of Chemistry in Giessen, from influenza, while in the prime of life. He was a pupil of Lothar Meyer, and was first Privat-Dozent and afterwards Extraordinary, in Tubingen, which he only left in 1892 on his appointment to Giessen. His paper on the "Principles of Organic Synthesis," which was published in 1887, is well known amongst chemists.

James W. Pittines, M.D., who died in Philadelphia on February 2, was one of the last representatives of a family identified with that city almost since its foundation. He was a graduate of the Philadelphia Medical College, and lectured on chemistry and materia medica. In the early days of the war he became connected with the Army Medical Corps, and spent four years in hard service, making quite a reputation as a surgeon. The Army Medical Museum at Washington gives evidence of the character of his service. In 1864 he had charge of the hospital at Camp Parole. He there contracted chronic bronchitis, which was ultimately the cause of his death. The past few years he has been out of practice entirely.

J. F. Hartigan, M. D., U. S. Consul at Trieste, Austria, formerly a resident of that city, died recently in Trieste. Dr. Hartigan was for many years Coroner's Physician for the District of Columbia, and was a member of the Grand Army of the Republic. He had yellow fever while a prisoner of war at Newbern, N. C., in 1864, and in 1888 was sent by Surgeon General Hamilton as an Inspector of the Marine Hospital Service to Florida towns to investigate their condition. In the performance of this duty, his health at no time robust gave way, and he was appointed Consul at Trieste, partly in the hope that the warm climate of that place would be beneficial to him. He had never given up the idea of returning to Washington and engaging in practice, and was on intimate terms with many members of the medical profession in Trieste. He had been for many years a member of the AMERICAN MEDICAL ASSOCIATION.

Robert Bentley, M.R.C.S., Eng., F.L.S., died on the 24th ult., at his residence in London, from pneumonia. After he became qualified he devoted himself to the study of botany and materia medica. In 1863 he was chosen Dean of the Faculty of Medicine at King's College, and continued in that position for twenty years. Botany was his favorite study, and he contributed many papers on this subject. He was intimately associated with the Pharmaceutical Society as Professor of Botany and Materia Medica, as a Fellow of the Linnean Society and a member of the Council, and as Vice-President of the Royal Botanic Society, before which for many years he delivered an annual course of lectures. Mr. Bentley's most important contributions to botanical science are his "Manual of Botany" and the "Medicinal Plants," published in collaboration with Dr. Trimeu. The former was first published in 1861, and it is distinguished from all other botanical text-books by the extent and value of its information on the economic products derived from the various natural orders, especially those connected with pharmacy. The "Medicinal Plants" was printed in four large octavo volumes, with colored plates, and will always be regarded an invaluable work of reference.

ASSOCIATION NEWS.

The *Journal of the American Medical Association* points out that it leads all the weeklies in the number of papers published, etc. The *Medical News* quotes the same figures to show that it is next, while the *Medical Record* thinks quality is better than quantity.—*American Lancet*.

Who Constitute the Membership of the American Medical Association?—It is widely claimed that the AMERICAN MEDICAL ASSOCIATION represents directly or indirectly every county in the United States, and that every grade of the profession is actually present at the annual meetings. We understand that its actual membership is just now over four thousand—we have not the exact figures at hand.

In a late issue of the *Railway Age*, our friend, Dr. R. Harvey Reed makes the statement that if there be abstracted from the profession the railway surgeons, the Army, Navy, and Marine Hospital surgeons, the insurance and pension examiners, the hospital staffs and "like distinguished personages," so few will remain that "it will require a military band to muster them close enough together to be seen with a fifth-objective microscope." According to this, the membership of the ASSOCIATION and the entire profession is practically composed of those holding distinguished offices of honor and profit.

We are told by Polk's Medical Directory of the United States that there are over a hundred thousand doctors in the United States, and we are rather staggered to be informed that aside from those holding official positions of honor or emolument, there are not enough doctors to occupy the field of a fifth-objective microscope. Our good friend informs us that the Code Committee of the ASSOCIATION is wrestling to determine whether the railway surgeon is entitled to honorable membership in that body. The source of his information he does not reveal, and we have no other knowledge concerning it. His point is that if the Committee finds the railway surgeons and their allies unworthy of membership, there will be no material left to form an ASSOCIATION. From the facts at hand it would seem as if there were many tens of thousands of doctors at present neither members of the bodies he mentions or of the ASSOCIATION. Certainly there would remain abundant material for a magnificent organization if every person in the profession holding an official position of any sort were transported to another land.

It is expected that the Committee referred to will report such a study of existing conditions surrounding the medical profession as will make it practicable for all honorable, educated physicians to work in greater harmony for the attainment of the best interests of the entire nation. . . .
—*American Lancet*.

Obstacles to Medical Ethics.—The Code of Medical Ethics is founded upon a so much higher principle than anything that has been offered by those physicians who are constantly making some attempt to induce the profession to disown it, that a fair-minded person can only conclude that they are endeavoring to lower it to a plane with themselves for the sake of personal aggrandizement. No one, not even the most extreme anti-Code man, can deny with an honest eye, that what disrespect is shown to the Code by the press and laity is due to the fact that its teachings are violated by the members of the profession themselves. The work is acknowledged to be a classic but, like all other just documents, it interferes with the practices of that class which cares little for the profession, except as an instrument to increase their own gains. While they have assailed openly the clause which relates to consultation, that is not the only one which they disregard at every opportunity. They attack the Code at what they consider its most vulnerable point, but if they

once broke through, sad havoc would be played with the grand old work. Unfortunately, a few monkeys have broken into the higher ranks of our profession and, emboldened by their temporary success, are endeavoring to teach us some antics. Knowing that our facial contour is not adaptable to the usual grimaces, they have begun with the somersault act. Some have taken to the trick quite naturally and have even commenced the facial distortion. But there is a majority in the medical profession that this doesn't suit, and they will never condescend nor submit to any such knavery.

We have always favored and labored for a united medical profession, but we now see that the warfare carried on by the anti-Code men is in an underhanded manner, they losing no opportunity to stab the upright members of the profession in the back and in dark places. Beaten on every occasion, they realize that they *can not* conform to fair and square laws and, with the determination born of despair, seek to do by stealth and secrecy what they see they can accomplish in no other way.

Knowing of this guerilla warfare, the members in good standing in the profession should meet it with military sternness. There are members of our profession in high standing who see that the Code is being violated, and feel that they are being injured by conforming to its teachings strictly, while giving the outlaws every advantage. They may say, as we have heard them, that in this way the Code works harm to the upright. We understand their feelings, but say that it is not the Code that does it but the men who violate that instrument. Here we have only to deal with those who are violating and endeavoring in every way to break down medical ethics, and suggest this manner. The homeopath is known by his sign, and for that reason is not in a position to do so much harm as the traitor. Then, as soon as these men become known, which must be sooner or later, brand them and place them with the goats. If they will not be governed by the laws of the profession, let them form into a body of their own and make laws to suit their own necessities. But in our dealings thereafter with them we should refuse to use the courtesy we do to our professional brethren, prescribed by the Code. Then they will have no advantage. It would soon be seen who had the best of the fight, and they would quickly cry for quarter or settle on a lower plane. The trouble with medical ethics has been not that the Code was wrong, but that its supporters have allowed themselves to be placed on the defensive, instead of carrying the war into the enemy's territory.

We have felt that their puny efforts would only hasten their own destruction, as like

"The feeble sea-birds, blinded in the storms,
On some tall lighthouse dash their little forms,
And the rude granite scatters for its pains
Those small deposits that were meant for brains.
Yet the proud fabric in the morning sun
Shines all unconscious of the mischief done;
Still the red beacon pours its evening rays
For the lost pilot with as full a blaze,
Nay, shines all radiant o'er the scattered fleet
Of gulls and boobies brainless at its feet."

But the matter is one of more seriousness. Corporations, in their crack at the balance of creation, have aimed a blow at the medical profession and seek on every occasion to batter down the breastworks furnished by the Code. Of course the means at their command have found those willing to serve their interests even at the sacrifice of professional courtesy to their brother practitioners, though the corporation physician expects on other occasions to have this courtesy extended to him. We are glad to say that there are some corporation physicians and surgeons who refuse to be dictated to by these officials, but we regret that the number is becoming gradually less. Where they do lose sight of professional courtesy to others they too should be branded and treated on all occasions with the same kind of medicine. We are strictly for the profession in this matter, and, if necessary, are willing to take up the cudgel and show who are derelict.

This is a question that has arisen since the Code was adopted, and needs some discussion and likely some alteration. A great part of the gall manifested by those who are fighting against medical ethics is instigated and shown in response to the patting on the back by these moneyed powers.

We will not deny that as new customs arise there may be occasion for changing, slightly, the Code, but this *must not* be done by its enemies. The name "anti-code men" may express their views, but medical anarchists is a more appropriate name, and the profession is not yet ready to accept anarchy.—*Medical Progress*, February.

SOCIETY NEWS.

Association of American Medical Colleges.

Meeting held at the Grand Pacific Hotel, Chicago, Wednesday Afternoon, Feb. 7, 1894.

[Reported exclusively for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.]

Abstract of proceedings of the meeting of the Committee of the Association of American Medical Colleges, appointed to consider the practicability of adopting a four years course of medical study.

There were present, the following: Dr. Perry H. Millard of St. Paul, representing the University of Minnesota; Dr. E. L. Holmes of Chicago, Rush Medical College; Dr. Victor C. Vaughan of Ann Arbor, the University of Michigan; also Hon. Hermann Kiefer of Detroit, member of the Board of Regents; Dr. N. S. Davis, Jr. represented the Chicago Medical College; Dr. H. O. Walker of Detroit, Detroit Medical College; Dr. A. R. Baker, Medical Department University of Wooster, Cleveland, Ohio; Dr. John C. Shrader, University of Iowa; Dr. Flynn, Medical College of Indiana; Dr. Hall, College of Physicians and Surgeons, Minnesota; Dr. Marie J. Mergler, Woman's Medical College, Chicago; Dr. Wm. E. Quine of Chicago, College of Physicians and Surgeons; Dr. C. B. Stemen, Fort Wayne College of Medicine; Dr. P. S. Connor, Dandridge Miami Medical College, Cincinnati; Dr. Dudley S. Reynolds, Central University of Kentucky; Dr. Bayard Holmes of Chicago, and others.

The meeting was called to order by the Secretary of the Association, Dr. PERRY H. MILLARD of St. Paul, who said: A word in regard to the object of this meeting. As Secretary of this body, I received a communication on Dec. 10, 1893, from the Registrar of Rush Medical College, stating that at a Faculty meeting held Dec. 7, 1893, the Faculty by unanimous vote passed a resolution to the effect, that all students who begin their studies in 1895 with a view of graduating in 1899 will be required to attend four full courses of lectures in a medical college of not less than six months each. Providing that graduates of universities and colleges which give a suitable scientific course may be admitted to the second year in the medical college, and also that graduates from schools of pharmacy that require three years of study and an adequate preliminary education, and graduates of dental schools requiring two years of study and adequate preliminary education, will be admitted to the second year in the college.

The above resolution is an amendment to Section 5, Article 3, of the Constitution of the Association of American Medical Colleges. The present wording of Section 5, Article 3, of the Constitution, is as follows:

"Candidates for the degree of Doctor of Medicine shall have attended three courses of graded instruction of not less than six months each, in three separate years."

It will be observed that the adoption of the proposed amendment will require of all matriculates of 1895, an attendance upon four full courses of instruction before receiving the degree of M.D. As the result of this most important action by the Faculty of Rush Medical College, after consultation with the officers of the Association, it was deemed prudent to call together representatives of the College Association in conference, to decide whether we shall, at this time, with the submission of this amendment which is proposed by Rush Medical College, submit, at the meeting to be held in San Francisco, a minimum of curriculum suitable to a four years' course. It is recognized that our Constitution at present is defective. We really have no minimum requirements adapted to a three years' course. I find, likewise, as the result of a series of investigations conducted in the last year, that we have colleges, members of this Association, that are not living up even to our present requirements. I will say, however, that this is confined to very few schools, and schools that have not been heartily in sympathy with this Association since its organization. It was thought best not to call a special meeting of the College Association, because it would not be proper to take definite action upon our Constitution and By-Laws except at a regular meeting. What is done here to-day will be submitted in legal and proper form to the meeting to be held in San Francisco on June 6, of this year; and in appointing an informal committee and inviting you to meet with us to-day in conference, the chairmanship of this committee has been assigned to Dr. E. L. Holmes, who has taken an active part in this measure, and is a representative

of the school that has taken the initiative in the proposed amendment.

Dr. HOLMES then took the chair. He said: I do not know that it is necessary for me to make any remarks introductory to the proceedings of this conference. The purposes have been set forth clearly by the Secretary, as well as by the published announcement in our various medical journals, and I presume the sooner we introduce and adopt a resolution bearing upon this subject, the more quickly will we finish our work. I would like to say, however, that while I am heartily in favor of the four years' course, and while I am in favor of the proposed minimum curriculum, we have found in our own college, in former times, that the plan of instruction for a four years' course is going to take one or two years for us to perfect. We can formulate certain definite ideas and live up to them, I think, but, at the same time, we are confronted with certain difficulties in arranging the courses of instruction properly for each year, so as not to bring confusion and to interfere with each other; so that the studies shall be carried on in such a way that at the end of the fourth year, students will not have forgotten what they have learned during the first year. That will necessitate a review of the studies, and we are planning courses of recitation by which every student as he passes through from year to year will have a review of what goes before. For instance, when a student has seen a certain number of cases of typhoid fever in the college clinics or hospital, as he studies them he will recite from the text-book, so that the text-book is not going to be a dry recitation for a person who knows nothing of the subject, but it will be needful for a student who is advanced, who has seen a sufficient number of cases to understand the general principles that he reviews in his recitation. He will be required to recite upon the anatomy of the parts involved, physiology, and materia medica, so that in this way we hope to devise a plan by which there will be a constant review of every organ, its anatomy, physiology and the remedies that are used in the treatment. But we find certain difficulties in planning such a curriculum.

Then there is another point in regard to the minimum study required for the examination. I do not know as that comes in at all in this meeting, but we have found some difficulty in formulating a plan which every college can easily live up to. I will take no more of your time, but whatever you have to offer we will discuss.

Dr. N. S. DAVIS, JR.—In the notices sent out, I believe there were a series of topics to be discussed, and I think it would be well to take them up, one by one, so as to cover the whole ground systematically.

Dr. MILLARD—In response to the circular-letter, sent out by myself, I have received information or advice from twenty-eight colleges in regard to their wishes or desires for the four years' course, and I can state definitely that twenty of these colleges are in favor of the adoption of the four years' course at this time, or at the San Francisco meeting, to be held in June next; that two colleges are endowed, and four or five colleges are opposed to it at this time, deeming it impracticable so shortly after adopting the three years' course, one college making the proposition that they will support it if we make it apply to 1896 instead of 1895.

In talking with Dr. N. S. Davis, Sr., the Chairman of the Association, it would seem that the program required by the Constitution would be about as follows: The proposed amendment already submitted to be official by Rush Medical College, would come before the Association for definite action in San Francisco in June. Now, the object of this conference to-day is to formulate a minimum of requirements, a course of study adapted to a four years' course, which would come before the Association as a separate amendment from the one submitted by Rush Medical College. At this conference, it is my opinion there are certain matters of great importance to the Association that should be acted upon. For instance, our By-Laws need immediate attention, and we should informally select a committee to re-arrange our By-Laws and submit them to the San Francisco meeting for adoption. The By-Laws governing the Judicial Council have not yet been acted upon definitely. The committee to be appointed at this conference can go over our present By-Laws and make such changes as may seem necessary to be submitted at the June meeting.

Dr. VAUGHAN—I desire to make a few general remarks before we get at the discussion proposed in the circular. It seems to me that we have reached a point in medical education in the United States, when those who have been engaged in it for a long while ought to be able to say what subjects should be embraced in the course of medical study.

I find the greatest diversity in the various medical colleges regarding subjects that are taught, and others not taught. I do not see any need of having a four years' course unless we teach certain things. What shall we teach? What subjects must be taught in our schools by members of this Association? How shall those subjects be taught, and how much minimum time shall be given to them? Shall we teach bacteriology? Let us decide the question. If so, how shall we teach it? How long shall we teach it? In this way, it seems to me, we can get at something definite. We ought to know just what is necessary in order to fit a man for the practice of medicine. We have been teaching (some of us) a good many years, and we ought to be able to decide that question. I think it is the most important thing that can come before us. I hope to see the time when the best medical colleges in America will have practically the same curriculum, and that a student can take one semester in one college and get credit for that semester in going to another college, and take another semester if he wants to, and so on, and that he will not be compelled to spend three or four years at a given medical college. It seems to me that most of the curricula of medical colleges are now gotten up for the express purpose of compelling a student to stay there for the whole of his three or four years. I look upon this as being a little too narrow and beneath the dignity of the teachers of medicine in this country. In order to do that, we must agree upon what subjects must be taught and agree upon the minimum of teaching of those subjects, and how this minimum shall be taught. It seems to me the best method of getting to work this afternoon would be to decide what subjects shall be taught? I do not know, but I think that is the best way of getting at it. Then we can take up *how* long the subjects shall be taught, and *how* they shall be taught. As it now stands, we can not accept the year's work that a student has done in the University of Pennsylvania, for instance, because the work he has done there during his first year is entirely different from the first year's work he may do in some other college; as, for example, the medical department of the University of Michigan. During his four years, however, he may do just as good work as the students in our institution. There is no general plan upon which these curricula are laid out, and my idea is that this would be the best way of getting at it. The University of Pennsylvania begin teaching therapeutics the first year. We do not do that, and if a student, who has studied therapeutics the first year in the University of Pennsylvania, comes to the University of Michigan, we can not accept him because we do not consider him fit to study therapeutics, as he knows nothing about anatomy and physiology, and we think it is radically wrong. The teachers of the various medical colleges ought to be able to decide this point, which I think is of more importance than trying to compel all the colleges to have a four years' course. We should decide what subjects shall be taught and, if possible, when and how they shall be taught.

Dr. REYNOLDS—I regret very much that Dr. Vaughan has not submitted a curriculum embodying the ideas he has expressed. We have nothing to act upon. His remarks have been very clearly and wisely expressed, and I desire to indorse every word of them. It would have been better, however, if he had submitted them in writing so as to give us something to act upon.

Dr. VAUGHAN—The schedule of studies we have we think the best, but we are perfectly willing to be governed by the majority. There may be some changes made in the schedule. We teach during the first year in lectures and recitations in the first semester, osteology and descriptive anatomy, general chemistry and bacteriology; in the second semester, descriptive anatomy, physics, organic chemistry and histology; laboratory work the first year includes anatomy, chemistry and bacteriology. There might be some discussion as to whether these are the proper things to teach during the first year, and I am not altogether satisfied.

Dr. REYNOLDS—That is about what we teach, but we do not teach physics.

Dr. VAUGHAN—We accept the diplomas of students from reliable high schools. The physics taught in the majority of high schools is a failure. A student knows very little about the laws of refraction, of heat, light, magnetism, etc. We find that many of our students must have this instruction before they can study ophthalmology properly, and we give such instruction during the second semester of the first year. We do not compel all our students to take that course. Those who have had the proper course in the high schools, colleges and universities, are excluded from it. We find it impossible to teach ophthalmology successfully to the great

mass of students, who come to us, and more particularly to give them instruction in physics. I shall be glad to have the committee take up one of these subjects and discuss whether they should be taught, and in what way they should be taught. We may have some things that should not be taught at all, and others that should be taught at some other time and in some other way.

THE CHAIRMAN—If the gentlemen will excuse me for making some further remarks, I will say that what Dr. Vaughan has said, coincides with my own ideas. We find it difficult to arrange a curriculum of studies for different years. I think the same fault applies to the average high school in the West. When a boy leaves the high school, then works to get money to pay his tuition in a medical college he has forgotten what he has learned in physics, so that he can not state definitely the leading principles of a double convex lens on a ray of light; and so with hydrostatics, electricity, etc. I think it would be useful for us if we could formulate a plan of study and instruction by taking the four years' course that Ann Arbor has tried, and make such modifications as might be beneficial.

DR. MILLARD—To get the work in tangible form, I move that the entrance requirements, as now provided by the College Association, remain in force. These should come before us. Let us consider if we can make any change in the requirements. The subject of uniform entrance requirements is attracting considerable attention. I have received three communications from different Deans, and I have requested Dr. Quine, who is President of the Board of Health of this State, to give the matter some consideration and to submit something to-day. Seconded.

DR. WALKER—Will you please state the entrance requirements?

The Secretary then read from Article 3 of the Constitution of the Association of American Medical Colleges, the following:

SECTION 1.—Members of this Association shall require of all matriculates an English composition, in the handwriting of the applicant, of not less two hundred words; an examination by a Committee of the Faculty, or other lawfully constituted Board of Examiners, in higher arithmetic, algebra, elementary physics and Latin prose.

SEC. 2.—Graduates or matriculates of reputable colleges or high schools of the first grade, or normal schools established by State authorities or those who may have successfully passed the entrance examination provided by the statutes of the State of New York, may be exempt from the requirements enumerated in Section 1.

SEC. 3.—Students conditioned in the branches enumerated as requirements for matriculation, shall have time until the beginning of the second year to make up such deficiencies provided, however, that students who fail in any of the required branches in this second examination shall not be admitted to a second course.

DR. CONNOR—What is really meant by these requirements? Let us take, for instance, the subject of Latin. We require a certain amount of knowledge of Latin. There ought to be some indication as to what that amount really is. There is an enormous difference in this matter. There should be some definite statement as to what amount of knowledge is required, or how far the individual must have gone in his Latin study. So in regard to mathematics and algebra. The requirements, as I have understood them as read by the Secretary, are very indistinct, and they practically cover nothing. The trouble has been all the time since this question of requirements was first raised, that there has been no definite statement as to what is demanded. It is all well enough to say that a man must have a knowledge of this thing and that thing, but it is not an easy matter to say *how* much of the ground he shall cover. This not only relates to one, but to all of the subjects of preliminary examination. There are seventy-one colleges connected with this Association, and there are seventy-one different opinions as to what these requirements mean. There are colleges that have not lived up to the agreement, that are wilfully and persistently violating the requirements, and yet some of the members of those colleges belong to the Association and are going to vote for an increased curriculum. I know the increased requirements will not be lived up to, just as the requirements already demanded have not been lived up to. Let us adopt something definite.

DR. REYNOLDS—I am delighted to hear my neighbor, Dr. Connor, speak so plainly. Those of you who were present at Washington when the matter was discussed will doubtless remember how anxiously I tried to prevent the introduction of the Latin language, and the subjects which we

have met to discuss this afternoon are of vital importance to the Association of American Medical Colleges. We are here to consider the practicability of extending the requirements to a four years' course of graded instruction. The preliminary requirements I regard as of secondary importance, for, as Dr. Connor has said, there will be great diversity of opinion in regard to them. I live in an atmosphere that enables me to breathe more freely and fully the varied sentiments of the profession on this subject than some of you gentlemen do, and I know that if the Association of American Medical Colleges at its forthcoming session should determine to require four courses of graded instruction instead of three, the so-called Southern Medical College Association will take a new life; it will acquire new membership from neighboring territory, and although its members are pledged to the adoption of the three years' course, they are not pledged to the adoption of the graded system. With about fifteen hundred medical students in Louisville, seven or eight hundred in Nashville, and something like that number in Atlanta and the Tulane University of New Orleans, which is one of the most magnificently equipped medical colleges in the world, not complying with our present exactions as yet, it seems to me very unwise to do anything which would tend to reduce our membership.

DR. SHRADER—In regard to the indefiniteness of some of the requirements which have been read by the Secretary, the Constitution says that students may be "conditioned in one or more of the branches enumerated as requirements for matriculation." Does that mean they will be conditioned in all of them?

DR. REYNOLDS—My understanding is that it means any one of them.

DR. SHRADER—I wish to say a word or two in regard to the extension of time. The medical department of the State University of Iowa has instructed me through its Faculty to report here that we are fully in accord with the advances that are being made, but we prefer to have this change made, that where colleges desire it, they may put in twenty-four months of study in three years, of eight months each, instead of extending the time to four years of six months each. Our collegiate year extends to about eight and one-half months, commencing the first of October and lasting until the middle of June. This is the sense of the Faculty, and I was so instructed to report at this meeting. We prefer to do this.

Medical students in the West have not any too much money to undergo four years of instruction, and it would cost them much less money to continue for two or three months longer the courses of lectures. They would save their traveling and other expenses. We can arrange our curriculum accordingly. Our Faculty is not quite ready to vote for a four years' course at this time, but it may be at the San Francisco meeting.

In regard to the preliminary requirements, we have found the same difficulty that has been pointed out by the preceding speakers. We appointed a committee of three on preliminary requirements, and no two of this number could agree as to how much Latin was required. Some time ago, in order to avoid diversity of opinion in this regard, we appointed an instructor in Latin, and a large number of our students took the Latin course, and it proved a very enthusiastic one. We believe that it has cleared up the matter of requirements of Latin, and we are in favor of retaining the instructor.

DR. WALKER—I belong to an institution whose faculty are in favor of adopting a four years' course, if other institutions are willing to do so. To extend the time to four years of six months each seems to me to be a waste of time. Send a student to a medical college for six months in a year, then let him leave, and in the majority of instances he forgets largely what he has already learned. If he takes such a course as is adopted by the University of Michigan—four years of nine months each—there is no such likelihood of his forgetting what he has previously learned. But the question arises, whether the medical colleges of this country are in a position to accept the proposed change. There are colleges connected with this Association, whose representatives come here and accept everything and even more, and go home and do nothing. That is the situation we are in. There is nothing compulsory about it. If we belong to this Association and adopt a four years' course of six or nine months each, as the case may be, and other institutions do the same, let us live up to it. The institution with which I am connected is progressive and is willing to do anything that this Association does, but we do not want to do anything that is suicidal. I am authorized to say that our col-

lege will do just what other institutions will do. Regarding the preliminary requirements, we have specified in our catalogue the amount of Latin we require; the same with botany, zoology, etc.

DR. QUINE—Mr. Chairman, I have not up to this time been able to discover what question, if any, is before the Association for consideration. Although the remarks that have been made have been highly interesting and instructive, it has seemed to me that they have been somewhat aimless. I agree fully with the sentiments expressed by the Secretary of this meeting, to the effect that the most important failing of all in respect to a medical education is to start right, and it seems to me important that this Association should settle the question of entrance requirements before it proceeds to the consideration of a minimum schedule of educational requirements. I am opposed to the entrance examination. I know it to be a sham; I know it to be an imposition upon the credulity of those who repose any faith in it. I believe that every medical teacher of experience can cite numerous instances wherein applicants for admission to one institution have been denied and have immediately thereafter gone to a neighboring institution and have triumphantly passed the entrance examination. I am in favor of abolishing the entrance examination; of taking it out of the hands of medical colleges altogether. I am in favor of requiring of every applicant for admission to a college that he present credentials equivalent in grade to a second grade teacher's certificate. If he have not such credentials at the time he presents himself to a medical college, let him go to the Superintendent of Schools and get such credentials. I may say in reference to this phase of the question that the Illinois State Board of Health has already adopted a requirement to this effect; that it has refused to recognize any entrance examinations conducted by any representative of any medical faculty; and it stipulates that every medical student who has a diploma or certificate from a recognized institution of learning shall present himself to some county superintendent of schools and sustain before that functionary a legalized examination to obtain a second grade teacher's certificate. If we have honest requirements, the adjustment of other medical questions will be in my opinion comparatively easy.

THE CHAIRMAN—The motion is, Shall the requirements, as laid down in the Constitution, be confirmed?

DR. VAUGHAN—I desire to offer a substitute, that we take up the requirements *seriatim* to see whether any changes are to be made or not. Seconded.

The Secretary accepted the substitute.

DR. VAUGHAN—I should dislike to see Dr. Quine's idea carried out. I know many medical colleges in this country that have not been influenced in conducting their preliminary examinations. Those colleges which are influenced in conducting such examinations are the sufferers themselves. There is nothing that can kill a medical college quicker than by accepting students who are unfit. Such colleges may thrive for a time, but in the long run they will suffer. While there are members of this Association that are not, perhaps, living up to the present requirements, so far as admission is concerned, they are the great sufferers themselves.

After further discussion on the requirements for admission, participated in by Drs. Reynolds, Connor, Stemen, Davis, Walker, Baker, Mergler, Bayard Holmes, Flynn and the Secretary, the Committee discussed Sections 1, 2 and 3, as laid down in the Constitution, and agreed upon the following pre-requisites to admission to the seventy-one colleges forming the Association:

1. English composition in own handwriting of not less than two hundred words, said composition to include spelling, punctuation, paragraphing and construction.
2. Examination in arithmetic, algebra through quadratics, and elementary physics.
3. Latin to the extent of one year's study, as indicated by Harkness' Latin reader.
4. Graduates or matriculates of reputable colleges and high schools of the first grade, or normal schools established by State authority, or who have successfully passed the examination provided by the State of New York, may be exempt from the requirements named.
5. Students deficient in one or more branches named as requirements shall have until the beginning of the second year to make up such deficiency, provided, however, that students who fail in any two of the requirements in this second examination shall not be admitted to the second course.

DR. QUINE offered the following resolution:

Resolved, That the management of entrance examinations

and the determination of the value of the entrance credentials be intrusted to a committee of this Association, consisting of five members appointed by the Chair, which committee shall have the authority to arrange for entrance examinations in every city in which a medical college connected with this Association is located.

Seconded.

The above resolution, after being thoroughly discussed by Drs. Stemen, Connor, Vaughan, Bayard Holmes, Reynolds, Baker, the Secretary, Flynn and others, was lost.

DR. VAUGHAN then offered the following:

Resolved, That this committee recommend to the Association of American Medical Colleges at its next meeting in June, to be held in San Francisco, that no medical college shall be permitted to remain or become a member of the Association that does not provide, either for a three years' course of eight months study, or a four years' course of not less than six months each, to take effect in 1895.

Seconded by Dr. Walker and carried.

The Secretary moved that a committee of five be appointed to prepare a curriculum of studies, providing for the minimum of time and lectures to be devoted to each one, and that the committee report at the San Francisco meeting.

Seconded and carried.

The Chairman appointed on this committee Drs. Davis, Connor, Quine, Stemen and Vaughan.

There being no further business before the committee, the meeting adjourned.

Congress of American Physicians and Surgeons.—Preliminary program of the Congress of American Physicians and Surgeons, to be held in Washington, D. C., May 29, 30, 31, and June 1, 1894.

President.—Alfred L. Loomis, M.D., New York City.

Vice-Presidents, ex-officio.—Dr. George C. Harlan, President of the American Ophthalmological Society, Philadelphia, Pa.; Dr. Gorham Bacon, President of the American Otological Society, New York City; Dr. B. Sachs, President of the American Neurological Association, New York City; Dr. William T. Lusk, President of the American Gynecological Society, New York City; Dr. Robert B. Morison, President of the American Dermatological Association, Baltimore, Md.; Dr. D. Bryson Delavan, President of the American Laryngological Association, New York City; Dr. Andrew H. Smith, President of the American Climatological Association, New York City; Dr. Reginald H. Fitz, President of the Association of American Physicians, Boston, Mass.; Dr. George Chismore, President of the American Association of Genito-Urinary Surgeons, San Francisco, Cal.; Dr. A. M. Phelps, President of the American Orthopedic Association, New York City; Dr. Henry P. Bowditch, President of the American Physiological Society, Boston, Mass.; Dr. Harrison Allen, President of the Association of American Anatomists, Philadelphia, Pa.; Dr. J. Ewing Mears, President of the American Surgical Association, Philadelphia, Pa.

Chairman of the Executive Committee, Landon Carter Gray, M.D., New York City; Treasurer, John S. Billings, M.D., Washington, D. C.; Secretary, William H. Carmalt, M.D., New Haven, Conn.

PROGRAM.

The meetings of the Congress will all be held in Metzerott's Music Hall, corner of Twelfth and F Streets, N. W.

TUESDAY—MAY 29.

3 P.M.—Congress opened by the Chairman of the Executive Committee.

3:30 to 5 P.M.—General Session of the Congress under the direction of the Association of American Anatomists.

WEDNESDAY—MAY 30.

3 to 3:30 P.M.—General Session of the Congress under the direction of the American Climatological Association.

3:30 to 5 P.M.—General Session of the Congress under the direction of the American Dermatological Association.

7 P.M.—Dinner to the Guests of the Congress at the Arlington Hotel.

THURSDAY—MAY 31.

2 to 3:30 P.M.—General Session of the Congress under the direction of the American Association of Genito-Urinary Surgeons.

3:30 to 5 P.M.—General Session of the Congress under the direction of the American Gynecological Society.

7:30 P.M.—Address by the President of the Congress, Dr. Alfred L. Loomis, Professor of Pathology and the Practice of Medicine in the University of the City of New York, on The Influence of Animal Experimentation on Medical Science. To be followed by a Reception.

FRIDAY—JUNE 1.

1:30 P.M.—Business Meeting of the Congress.

2 to 3:30 P.M.—General Session of the Congress under the direction of the American Laryngological Association.

3:30 to 5 P.M.—General Session of the Congress under the direction of the American Neurological Association.

SUBJECTS FOR DISCUSSION.

By the Association of American Anatomists: "Morphology as a Factor in the Study of Disease." Opened with a paper by Dr. Harrison Allen of Philadelphia, and discussed by Dr. Thomas Dwight of Boston, Dr. Frederic H. Gerrish of Portland, Me., Dr. Frank Baker, Georgetown, and Dr. Burt C. Wilder of Ithaca, N. Y.

By the American Climatological Association: "Sewer Gas." The Bacteriology, by Dr. Alexander C. Abbott of Philadelphia. As a Cause of Disease, by Dr. Abraham Jacobi of New York City.

By the American Dermatological Association: "The Distribution and Control of Leprosy in the United States." The Distribution, opened with a paper by Dr. J. Nevins Hyde, Chicago, and discussed by Dr. Wm. A. Hardaway, St. Louis, and Dr. James E. Graham, Toronto, Canada. The Prophylaxis and Treatment, with a paper by Dr. James C. White, Boston, and discussed by Dr. Geo. H. Fox, New York City; Surgeon-General W. C. Wyman, U. S. M. H. Service, and Surgeon-General Joseph D. Bryant, New York City.

By the American Association of Genito-Urinary Surgeons: "Nephritis in its Surgical Aspects." Opened with a paper by Dr. Edward L. Keyes, New York City, followed by a paper from Dr. George M. Sternberg on "The Bacteriology of Nephritis," and discussed by Dr. Geo. Chismore, San Francisco, Cal.; Dr. L. Bolton Bangs, New York City; Dr. Francis S. Watson, Boston, Mass., and Dr. W. N. Wishard, Indianapolis, Ind.

By the American Gynecological Society: "The Conservative Surgery of the Female Pelvic Organs." Papers will be read by Dr. Wm. M. Polk, New York City, and Dr. Wm. Goodell, Philadelphia Pa.

By the American Laryngological Association: "The Surgery of the Accessory Sinuses of the Nose." To be discussed by Dr. F. H. Bosworth, New York, Dr. J. N. Mackenzie, Baltimore, Md., Dr. J. H. Bryan, Washington, D. C., Dr. J. G. Roe, Rochester, N. Y., and others.

By the American Neurological Association: "The Influence of Infectious Processes on the Nervous System." Pathology and Etiology, by Dr. James J. Putnam, Boston. The Relation to General Nervous Diseases, by Dr. E. C. Seguin, New York. The Relation to Mental Disease, by Dr. Charles K. Mills, Philadelphia; and The Therapeutics, by Dr. F. X. Dercum, Philadelphia.

New York State Medical Society.—The eighty-eighth session of the New York State Medical Society was held in Albany February 6, Dr. Herman Bendell of Albany, presiding.

Dr. Bendell asserted that the number of physicians in the State is increasing, while the number of quacks and those without education is decreasing.

He alluded to the change in apportionment and claimed all parts of the State should be fully represented. During the year there were 327 examinations of medical students; of these 267 were admitted. The State Medical Library should be enlarged. The principal part at present is the 5,000 presented by the Albany Medical College. The law of 1861 should be amended by making an appropriation of a sufficient amount to care for it. The President recommended the holding of every third meeting elsewhere than in Albany.

He named the prominent members of the Society who had died during the year: Dr. Hewitt, Dr. Johnson, Dr. Green, Dr. Douglass, Dr. White, Dr. Fordyce, Dr. Peters, Dr. Melius.

Dr. Eugene Beach presented a resolution that the Committee on Legislation are requested to take such action as they may deem necessary in obtaining such legislation as will tend to the restoration of medical control subject to proper State supervision; adopted.

Dr. Wey moved that the President's address be referred

to Dr. W. W. Potter, Dr. L. Pitcher, Dr. Beach, Dr. C. R. Heaton and Dr. Brush; carried.

The following Board was appointed by the President to suggest the names of four persons to the Board of Regents from whom they shall select two to whom to grant a degree: Dr. D. B. St. John Roosa, A. Jacobi, A. Vanderveer, Dr. A. W. Suites, Dr. B. F. Sherman.

Dr. Fletcher thought the Society should name the Board. His remarks caused debate and he afterwards withdrew them.

Papers presented. It was decided to limit the reading of papers to twelve minutes. Several essays of interest to the profession were read and the Society adjourned until afternoon.

In the afternoon the following Nominating Committee was appointed: Dr. W. J. Morton, Joseph Hasbrouck, Dr. D. V. O'Leary, Dr. John E. Burdick, Dr. J. H. Glass, Dr. H. D. Whey, Dr. Albert L. Beahan, Dr. W. D. Eli and Dr. William H. Bailey.

Dr. Abraham Jacobi of New York, offered a resolution in regard to the office of Coroner. It advocated a certificate of graduation as practicing physician, as the necessary eligibility to a nomination. The resolution was adopted, after brief remarks.

Dr. M. J. Lewi, from the State Examining Board, read his annual report. It showed eight examinations during the past year, at which 326 candidates were examined. Two hundred and ninety-six possessed the necessary qualifications—being over 21 years of age, of good moral character and having completed a three years' course in a reputable medical college. Twenty were rejected. Under the existing laws, quacks are prevented from gaining any foothold in this State. The fees collected during the year were \$245, and the expenses \$7,800. Any attempt to reduce the examination fee from \$25 to \$5 would be a step towards nullifying the law. The committee had selected Dr. William C. Wey, President, and Dr. M. J. Lewi, Secretary, for the ensuing year.

Dr. D. B. St. John Roosa from the committee to select names to be sent to the Board of Regents, recommended the following: Dr. W. W. Potter, Buffalo; Dr. W. S. Ely, Rochester; Dr. M. J. Lewi, New York; Dr. J. W. Roosevelt, New York; Dr. E. Van Slyke, Albany; George C. Seymour, Utica; adopted.

Syracuse Academy of Medicine.—The Syracuse Academy of Medicine met February 6, Dr. H. D. Didama in the chair. Dr. John Van Duyn was to have presented a history of the Syracuse Medical Association of which the Academy is an outgrowth, but as he had not finished the paper he merely outlined its contents and will submit the finished history at a future meeting. It will be a comprehensive and thorough work and will be a valuable part of the archives of the new organization. Dr. J. C. Carson, Superintendent of the State Institute for Feeble-minded Children, presented a very interesting treatise on juvenile insanity, explaining the methods of treatment employed at the Institute. Dr. Gregory Doyle, gave some general observations on fractures and their treatment. He was followed by Dr. F. W. Marlow, Professor of Ophthalmology in the Medical College, who reported a number of cases of injury to the eyeball. Each of the papers was followed by a general discussion by the members. Dr. H. D. Didama, President of the Academy, made an address in which he spoke of the many benefits which are to come from the Academy and bespoke the hearty cooperation of all the members.

The following resolution was carried:

Moved that a committee of three be appointed by the chair to report at their convenience on the organization, methods and work of the City Board of Health with such reflections as they may see fit to make; that Dr. Donohue, on account of his position as President of the State Board of Health be chairman of this committee.

The chair appointed Drs. Donohue, Van Duyn and Halstead. The Academy's room is now completely furnished, and a library has been started.

Rome, Ga., Medical Society.—The Rome (Ga.) Society of Medicine held its annual meeting January 31. The following officers were elected: Dr. H. H. Battey, President; Dr. W. A. Johnson, First Vice-President; Dr. J. N. Cheney, Second Vice-President; Dr. R. P. Cox, Secretary; Dr. L. P. Hammond, Treasurer. None of the old officers were reelected.

Dr. Robert Battey was elected President of the Society when it was organized one year ago, and under his able administration it has prospered and accomplished a great deal of good. He was the unanimous choice of the Society for its highest officer this year, but owing to his pressing duties he was unable to accept and declined reelection.

Denver and Arapahoe Medical Society.—At the fifth annual meeting of the Denver and Arapahoe Medical Society, Jan. 9, 1894, the following officers were elected for the ensuing year: President, Dr. Wm. P. Munn; Vice-President, Dr. I. B. Perkins; Recording Secretary, Dr. H. H. Bucknum; Reporting Secretary, Dr. Chas. H. Manley; Treasurer, Dr. E. J. Rothwell; Board of Censors, Drs. E. R. Axtell, W. J. Rothwell, J. N. Hall, Robt. Levy, J. C. Herrick.

Illinois State Medical Society.—The Executive Committee of the Illinois State Medical Society, held a meeting in Chicago February 14 for the purpose of perfecting the arrangements for the annual meeting of the Society to be held in Decatur, May 15, 16 and 17. The President, the Permanent Secretary, the Secretary of the Committee of Arrangements and the chairmen of the several committees were present.

Jamestown, N. Y. Medical Society.—The Jamestown Medical Society met February 6. President William Marvin Bemus, M.D., was the host at a dinner which preceded. There were present, Dr. Laban Hazeltine, Dr. Morris N. Bemus, Dr. R. N. Blanchard, Dr. L. H. Snow, Dr. H. P. Hall, Dr. J. H. Wiggins, Dr. S. Z. Fisher, Dr. C. J. Phillips, Dr. E. C. Lyman, Dr. Mary Armstrong, Dr. J. W. Morris, Dr. Lundgren, Dr. Parks, Dr. Parker, Dr. Wellman, Dr. A. H. Bowers, Dr. Eastman, Dr. Sharpe of Lakewood and Dr. Smith of Falconer.

President Bemus made an address; and also Dr. Hazeltine. Before adjourning, the Society by vote acknowledged the hospitality of the President.

Corning Academy of Medicine.—The annual meeting of the Corning Academy of Medicine, New York, was held February 5. The session was spent in the discussion of a paper read by Dr. Carpenter. The following officers were elected for the ensuing year: President, Dr. H. M. Bourne; Vice-President, Dr. C. W. Hayt; Secretary and Treasurer, Dr. W. S. Cobb; Censors, Drs. Tillotson and Smith of Corning, and Carr of Caton.

MISCELLANY.

New Port Physician.—Dr. Walter D. Green has been appointed Port Physician of Philadelphia.

Dr. O. H. Fretz of Quakertown, has been appointed Clinical Assistant in the Eye Department of Jefferson Medical College, Philadelphia.

Typhus Fever.—A telegram of February 9, states that typhus fever in its most malignant form is prevailing at Sherwood, Iron County, Texas. If it is typhus fever it must have been brought from Mexico.

Professor Crile.—Dr. George W. Crile of Cleveland, has been appointed Professor of the Principles of Surgery by the Faculty of Wooster Medical College, and Dr. Fred. C. Taylor was elected Secretary.

Monument to Charcot.—Professor Brouardel has been elected chairman of the committee to collect subscriptions. M. Pasteur is the Honorary President of the committee. The sum of \$600 has been collected by the *Progrès Medical*.

University of Utrecht.—Of a total of 800 students now on the register of the University of Utrecht, 326 belong to the medical faculty. In 1893 the degree of Doctor of Medicine was conferred on five candidates.

Dr. Lassar, the dermatologist, who, it will be remembered was General Secretary to the International Medical Congress in Berlin in 1890, has had the title of Professor conferred upon him.

Dr. Harrison Allen has been elected Professor of Laryngology and Rhinology; and Drs. A. L. Vansant and Walter J. Freeman, Adjunct Professors of Laryngology, in the Philadelphia Polyclinic. Prof. A. W. MacCoy will continue to give clinical instruction in the same branch, at the dispensary of the Pennsylvania Hospital.

Cholera.—On February 2 a cablegram from Berlin announced that on information received from Thom, a town near the frontier, that cholera was prevailing in two districts of Poland near the Prussian line, and another on the 9th, from Warsaw, stating that "there has been a recrudescence of cholera here and many deaths from the disease are occurring."

Germany's Doctors.—Germany, whose population is about 50,000,000, had 21,621 physicians in 1893, against 20,500 in 1892; that is, an increase of 1,521. That makes about 4.37 doctors for every 10,000 inhabitants, but they are not equally divided throughout the Empire; for in some regions there are not even two doctors for every 10,000 inhabitants, while in other districts there are 30 of them for the same number of population. Germany possesses also 915 dentists and 4,988 druggists.—*New York Tribune*.

Clinical Teaching in Spain.—As a good deal of dissatisfaction has from time to time been expressed by the Spanish medical journals and by students of medicine as to the inadequate provision for clinical instruction in the medical schools of the Peninsula, the Minister of Education has commissioned Dr. Amalio Gimeno, Professor in the Medical Faculty of the University of Madrid, Senator of Spain, and lately Inspector General of Public Health, to make an official inquiry into the matter.

Midwinter Fair.—The San Francisco *Chronicle* of January 28, in a magnificent number of thirty pages tells the story of the opening of the great Midwinter Fair. The scenes are very like those attending the similar exercises in Chicago at the opening of the World's Fair. Our readers will all have the opportunity of seeing the California way of conducting the Exposition by attending the next annual meeting of the AMERICAN MEDICAL ASSOCIATION June 5. The Fair will not close until July 1.

The Way of the Transgressor is Hard.—A press dispatch says: Barbrick and Richards, traveling specialists, advertised medical services and surgical treatment free. Consultation was free, but medicine came high, and they realized over \$300. They have been arrested for obtaining money under false pretenses. Two hundred dollars was recovered. They hustled for their bill, and finally, after paying attorneys, officials, and refunding, they were permitted to go. They showed no diplomas. Inquiry at Cincinnati brought the information that they were not registered there as claimed. They are billed for other towns.

The New York National Guard.—The medical officers of the New York National Guard met at Albany February 7. The meeting was called to order by Surgeon-General Joseph D. Bryant, in the Armory of the Tenth Battalion, and was attended by about fifty medical officers of the Guard. An organization was formed for purposes of mutual advancement and for the improvement of the service. A constitution and by-laws was adopted, and Surgeon-General Bryant was chosen President ex-officio. The following officers were elected: Vice-Presidents, First Brigade, Major Daniel Stimson, Seventh Regiment; Second Brigade, Major William Spencer, Twenty-third Regiment; Third Brigade, Major Herman Bendel, Brigade Surgeon; Fourth Brigade, Major A. H. Briggs, Sixty-fifth Regiment; Secretary, Lieutenant D. S. Burr, Assistant Surgeon Twenty-sixth Separate Company; Treasurer, Col. Henry, Assistant Surgeon-General.

It is provided that each Vice-President is to be presiding officer of the association in his brigade.

Minnesota Lunatics.—It will be remembered that the Supreme Court of Minnesota recently decided in the Blaisdell case, that the law under which the insane in Minnesota have been committed to the State hospitals for the insane was unconstitutional, and steps will have to be at once taken to secure their re-commitment under the old law, either by action taken by the friends of the patient, the probate court of the county from whence they were committed, or this failing, by proceedings instituted by the hospital authorities in the probate court of the county where the hospital is situated.

According to the *Pioneer Press* of February 8: "The board of trustees after discussing all the serious phases of the situation, instructed the superintendent to notify the judges of probate of the respective counties, from which patients were committed, and the friends of the patients to come and remove them, and, in case of their refusal or neglect, to set the patients at liberty after a reasonable time.

Notification of Infectious Diseases.—It will be seen from the following taken from the Paris correspondence of the *Lancet* of January 20, that the French have finally adopted compulsory notification of infectious diseases. The forms are very guarded, and intended to cause as little friction between practitioner and patient as possible:

"*Compulsory Notification of Infectious Diseases 'un fait accompli' in France.*—On Dec. 30, 1893, there appeared in the *Journal Officiel* the Ministerial Decree fixing the list of infectious diseases that must henceforth, once the diagnosis is made, be reported to the authorities by Doctors of Medicine, *officiers de santé*, and *sages-femmes*. Postal cards will be supplied gratuitously to each practitioner. On the card must be filled in the name of the malady and precise directions regarding the situation of the infected premises. The declaration must be dated and a delicate provision is made enabling the practitioner to avoid direct mention of the name of the malady, which will be indicated only by a number (a list of maladies with their corresponding numbers is supplied on the first page of the *carton*). The medical man is not obliged to sign his declaration, a number printed on each leaf of the *carton* sufficing to distinguish his identity; nor need the name and address of the patient be filled in should the informant be able to give sufficiently explicit directions for finding the house infected. A small space is reserved in the declaration sheet for the (optional) mention by the medical attendant of the appropriate sanitary measures that should in his judgment be taken. In the country districts the declaration must be sent to the mayor of the commune and to the subprefect, in chief towns to the mayor of the *arrondissement* and to the prefect, and in Paris to the mayor of the *arrondissement* and to the prefect of police. Negotiations are now being conducted between the Minister of the Interior and the Minister of Commerce as to the free postage of the declarations. Each book supplied to practitioners will contain twenty double declaration forms. The list of declarable diseases is as follows: typhoid fever, typhus fever, smallpox and modified smallpox, scarlet fever, diphtheria (including croup), sweating sickness, cholera and choleraic diseases, pest, yellow fever, dysentery, puerperal fever (excepting when professional secrecy as to the existence of pregnancy has been claimed by the patient), and ophthalmia of the newly born. It will be noticed that measles, rubeola, chickenpox, mumps, scabies and ringworm are absent from the list."

Hospital Notes.

An Emergency Hospital has been established at Evanston, Ill.

St. Joseph's Hospital at St. Paul opened a training school for nurses February 1.

Dr. J. T. Duryea, Superintendent of the Flatbush L. I. Hospital for the Insane, has tendered his resignation to take effect February 28.

A Bill has been introduced in the Virginia Legislature providing for female physicians for the female patients in each asylum for the insane in the State.

The Memorial Hospital for Women and Children in Brooklyn was damaged by fire February 6. This hospital was occupying temporary quarters, on Prospect Place. The in-

mates were rescued with some difficulty, and several physicians aided the fire department in carrying the sick from the building. The loss is about \$10,000.

Hospital Internes at Dinner.—The fifth annual meeting of the Alumni Association of the Internes of the Methodist Episcopal Hospital of Brooklyn, was held at the Montauk Club February 2. A dinner was served, and the meeting was afterward called to order by Dr. P. H. Sturgis, the President, who, after a few preliminary remarks, introduced the speakers of the evening. "The Alumni Association" was responded to by Dr. H. B. Delatour of the surgical staff; Dr. J. F. McCaw, late House Surgeon, responded to the toast, "The Younger Members; Dr. James P. Warbasse of the surgical staff, spoke upon "Forecasts;" Dr. H. P. DeForest discoursed upon "Benedicts;" Dr. G. R. White spoke of the "M. E. H." from a New York standpoint; "Medicine versus Surgery," was responded to by Dr. A. D. Bogart, House Physician.

The following officers were elected for the ensuing year: President, Dr. J. P. Warbasse; Secretary and Treasurer, Dr. James F. McCaw.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from February 3, 1894, to February 9, 1894.

Major ROBERT M. O'REILLY, Surgeon U. S. A., is granted leave of absence for two months, with permission to go beyond sea.

First Lieut. BENJAMIN BROOKE, Asst. Surgeon, is relieved from duty at Ft. Leavenworth, Kan., to take effect upon the arrival of First Lieut. WILLIAM H. WILSON, Asst. Surgeon, at that post, and ordered to Camp Pilot Butte, Wyo., for duty.

The following named officers of the Medical Department are relieved from duty in Washington, D. C., to take effect upon the completion of the present course of instruction in the Army Medical School, and are assigned to duty at the stations hereinafter designated: First Lieut. WILLIAM W. QUINTON, Asst. Surgeon, Ft. Riley, Kan.; First Lieut. THOMAS S. BRATTON, Asst. Surgeon, Ft. Niohrara, Neb.; First Lieut. DEANE C. HOWARD, Asst. Surgeon, Ft. Buford, N. Dak.; First Lieut. ALEXANDER S. PORTER, Asst. Surgeon, Ft. Keogh, Mont.; First Lieut. WILLIAM H. WILSON, Asst. Surgeon, Ft. Leavenworth, Kan.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending February 10, 1894.

Asst. Surgeon FRANK C. COOK, ordered to Naval Laboratory and Department of Instruction, New York.

MEDICAL EXPERT TESTIMONY.

BY HENRY M. LYMAN, A.M., M.D.
CHICAGO, ILL.

At a recent meeting of the Practitioners' Club in this city, an hour was devoted to a discussion of the subject of expert medical testimony. There appeared to be a feeling that the method of eliciting such testimony now in vogue in the law courts of the country is imperfect, and unjust to both the accuser and the accused. An ideal picture was presented for admiration, in which judges, jurors and lawyers were depicted at the feet of an impartial and omniscient medical expert (appointed by some rather nebulous power dimly visible in the back-ground), calmly engaged in registering his decrees in all cases of medical jurisprudence. Undoubtedly, this would be the best way in an ideal society, where medical experts were omniscient and every one else was eager for the truth, the whole truth, and nothing but the truth. Unfortunately, however, we do not live under such a dispensation of Providence. In an Utopia such as we delight to contemplate, crimes would be unknown, and medical experts would be unneeded. We must look to a lower sphere—such an one as we now occupy—for the opportunity to deploy medical expert testimony. In our human law courts one soon discovers that the truth, the whole truth, and nothing but the truth is by no means the object of research. On the contrary, the entire effort is directed to the winning of the suffrages of a jury in favor of one of two hypotheses which are laid before it. The success of a given hypothesis is the main thing in view; the conformity of that hypothesis with truth is quite a secondary consideration in the minds of the contestants. For this reason, in our American courts of law the power of the judge has been largely taken from him, so that he can not, like an European judge, intervene to any considerable extent, in the interest of truth and justice. For this reason, the majority of lawyers would resent the appointment of an impartial expert who should act as an assessor with the judge, and should instruct the jury in their course of action. So long as our judges are active politicians, selected by politicians for their availability rather than for their ability, their appointment of experts would always be liable to challenge for want of impartiality. The experiment of placing in their hands the work of appointing certain officers has been tried in past years, without giving to the public any better results than those obtained by the ordinary methods of popular election.

For these reasons it seems to me very improbable that, under existing conditions, any improvement upon the present methods of selecting medical experts can be expected. At present, each side in a

court of law selects the experts in whom it feels the most confidence. Trivial cases conducted by inferior lawyers bring forward so-called experts who belong to the same level; while important cases involving great interests seldom fail to secure the services of the leaders in the professions of law and medicine. So long as the contestants are satisfied it is hardly expedient for us to complain. If the practice of law should ever rise to the level of the pursuit of the exact sciences in its devotion to truth, and its impartial search for facts, it will then be time to change the present method of selecting medical expert witnesses.

The outcry that is made against the present method of employing expert testimony has its origin, not so much with the heedless public, or with the self-satisfied lawyers, as with certain medical gentlemen who have sometimes found themselves at variance with the opinions of other physicians whose qualifications they are disposed to underrate. Such differences of opinion are seldom concerned with demonstrations of fact, but with matters of inference. For example, there is seldom any difference regarding the acceptance of proven symptoms as either genuine or fictitious. It is not often difficult to decide from an array of facts, whether a given individual is or is not of perfectly sound mind; but it is often very difficult to decide how far such an individual may or may not be responsible for his acts. Here lies the difficulty of agreement. This difficulty is increased by the fact—too often overlooked—that responsibility is a variable quantity. No one can listen to or read the autobiographic narratives of the insane without being impressed with this fact. The growth and progress of irresponsibility, the constant see-saw of conflict between opposing motives, and the final submergence of prudential considerations are the most interesting features of such histories. It is not among the chronic and violently insane patients who populate our asylums that these things are to be studied. It is among the slightly defective examples of idiocy and paranoia who still enjoy their freedom, and are yet unknown to the asylum physician, that these incipient degrees of irresponsibility must be investigated.

The difficulty of agreement among experts in the matter of insanity is farther increased by the fact that law and medicine do not approach the subject by the same paths. The physician simply endeavors to find out whether or no there is deviation from the normal standard of development or of health. If there be such deviation, he is naturally impressed by that fact, and feels that it should have weight in determining the degree of responsibility of the patient. Here lies the difficulty, and here begins the divergence of opinions. Uniformity of opinion regarding a variable quantity is out of the question; nor should its absence be urged as an argument against expert testimony, any more than the fact that

misdemeanors are lightly punished by one judge, but are severely visited by another, should be thrown in the face of an honorable judiciary. Furthermore, while the physician occupies himself with the scientific aspects of the case, the lawyer cares little for the physical condition of the malefactor—he is chiefly concerned with the results of his action and with the question of his responsibility. If, now, the lawyer were zealous only for the determination of the degree of responsibility, he would not often find himself in conflict with the physician. On the contrary, however, he assumes at the outset for the prisoner a certain arbitrarily asserted degree of responsibility; and during the course of the trial he seeks to include all testimony that is in harmony with that proposition, and to exclude everything that tends to controvert his assumption. This method of proceeding is favored by the whole process of the courts, in which the judge possesses little power beyond that of a moderator. The introduction of hypothetic questions also renders it possible to extract a favorable opinion from almost any witness who speaks about matters of inference. Additional doubt may be also created by the discord between legal and medical definitions of insanity; for it is a fact that a man may be legally sane though medically insane.

In all cases involving a question of responsibility, the medical witness must seek to avoid all show of active partisanship. He is free to demonstrate every defect, degeneration or disease that may tend to impair such responsibility, but he must not assume that all responsibility is necessarily abolished by the existence of such defect, degeneration or disease. Nor is it for him to determine, under our laws, the degree of extenuation that should be allowed in any given case of diminished responsibility. That is a question for the jury alone to decide. While we admit that in some respects our criminal law needs amendment, it must not be forgotten that the semi-barbarous social condition of our people renders the administration of even-handed justice impossible in many cases. Until we provide security that the criminal insane shall be permanently placed where they shall be permanently harmless to society, we must expect that the plea of weakened responsibility will often fall upon deaf eared jurors, and that medical experts will often seek to ascertain how much responsibility, rather than how little, can be established in any case that is submitted for their opinion. These unfortunate social conditions do undoubtedly render more difficult than it should be the task of the conscientious medical witness, but they can not be urged in justification of a practice that exists in our law courts, of introducing medical testimony merely for the purpose of raising unfounded doubts in the minds of ignorant jurors.

A medical witness should be free to comment upon testimony and, if necessary, to show its insufficiency; but he should not be licensed to befog the minds of jurors by the expression of hypotheses (guesses) for which there is no possible foundation in the evidence before him. In many instances the opinion of a medical witness can not be the expression of absolute certainty, but is merely the utterance of an inference based upon a necessarily incomplete presentation of facts. In all such cases the expert must remember that he is dealing only with probabilities, and he must take care that his inferences are the legitimate and logical consequences of accessible facts, and that they be not colored and vitiated by any inclusion of

unproven possibilities. The neglect of this precaution has sometimes led to flagrant injustice.

For the reasons thus briefly set forth, I am not inclined to expect much benefit from any proposed change in the employment of medical expert testimony. Human nature and the mode of legal procedure must be improved, before any real advance can be made in this matter. Fortunately, we are not responsible for the defects of human nature, nor for the imperfection of the courts of law. Let us attend to our own affairs, and improve the quality of our experts; for in this way we may accomplish something of a substantial character for the benefit of society.

LECTURE ON DRINKING WATER.

AN ABSTRACT.

BY CHARLES SMART, M.D.

SURGEON U. S. A.

A lecture on drinking water was delivered by Dr. Charles Smart, U. S. Army, on the 5th inst., under the auspices of the Sanitary League of Washington, D. C. The lecturer spoke first of waters generally and their constituents, dividing the latter into inorganic matters, dead organic matter and living organic matter. The first of these he represented as not necessarily a sanitary impurity, for the human system required and assimilated from articles of food and drink over an ounce of just such salts daily. If a water is saline to the taste, or alkaline or chalybeate, or is so hard as to curdle the soap in washing instead of forming a foaming lather, it will probably cause intestinal disorders. Otherwise the analyst has little interest in the inorganic salts as the totality of their amount is insufficient to occasion harmful effects. The dead organic matter is of importance because it was once alive and because it is likely to be associated with that which is still alive. It is not specially dangerous in itself,—in fact it is seldom harmful unless present in quantity sufficient to give a taint or odor to the water. Nor do the living organisms ordinarily seen in the sediment of a water have much bearing on the quality of the water.

“You will observe, then, that since the saline matters and the dead organic matter are not specially unwholesome except when present in quantities appreciable to the taste, and since most of the living organisms present in a water have little influence on its quality, the question of wholesomeness becomes reduced to a determination of the presence or absence of certain organisms which we know to be the germs of disease and to be sometimes contained in water supplies. These are the germs of malarial and typhoid fevers and of cholera. It is to the microscopist and bacteriologist that we would naturally look for the detection of these, but bacteriology is yet in its infancy—a lusty infant, it is true, and giving promise of a phenomenal manhood. There may be in the distributing reservoir of a large city enough of the germs of typhoid fever to cause sickness and sorrow in many a household in the course of a year, but what chance has the microscopist of discovering them in the part of a drop which covers the field of his microscope? There may be several specimens of four-leaved clover in the meadows, but what are our chances of finding one in a handful plucked at random?”

“Extravagant ideas of the powers of scientific in-

vestigators are sometimes published. Not long ago, I saw it asserted that a cholera germ had no more chance of passing along the current of the Potomac undetected by the bacteriologist, than a mad dog had of careering along Pennsylvania Avenue at midday without being discovered. Indeed, it is because of the inability, so far, of the bacteriologist to detect the germs, that an appeal for information is made to the sanitary chemist. The chemist examines the dead organic matter in the water. Malarial infection is a product of a soil in which the decay of vegetable organic matter is in progress. Waters draining from such a soil carry with them the malarial infection, and also more or less of the decaying organic matter. The presence of the latter, discovered by the chemist, suggests the likelihood of the concurrent presence of the former. When the germs of typhoid fever or of cholera are present in a water, they generally enter the water along with sewage, for it is known that these pathogenic or disease-breeding organisms are cast out of the sick person by way of the intestinal canal. Hence, when the presence of animal matter or sewage is detected by the chemist, the likelihood of the concurrent presence of the bacillus of typhoid fever is suggested. Chemistry makes no pretense of discovering the germs of disease, but merely suggests the likelihood of their presence—the presence of malaria in association with vegetable matter; the presence of the bacillus of typhoid in association with animal matter.”

The lecturer then divided waters for his sanitary inquiry into: Rain or cistern waters, surface waters, subsoil or ground waters and deep or subterranean waters. The first he showed to be pure and wholesome when ordinary care is taken in their collection and storage. The second, or surface waters, are pure or impure according to the nature and condition of the shedding surface. He instanced the Rio Grande as a malarious surface water, and the cause of the malarial fevers which rendered Fort Brown, Texas, the most insalubrious of the United States military posts until a new and pure water supply was provided, when with the discontinuance of the river water the post became as healthy as an Atlantic summer resort. The epidemic at Plymouth, Pa., in 1885 was brought forward as an illustration of typhoid fever propagated by surface waters.

“Local outbreaks of typhoid fever have been traced so frequently to the use of the water of shallow wells that the health officers of most of our municipalities have interdicted their use. But on the other hand, if the soil is fresh and unpolluted by the filth that is unavoidably associated with a long continued occupancy a free supply of soft wholesome water may be obtained. Brooklyn, Long Island, is supplied in part by sub-soil water piped from a clean filtering area at some distance from the city. At isolated country houses the dangerous character of the shallow well arises from the proximity of cesspools, pits, garbage heaps and manured ground; and not unfrequently the handsome trees that throw a grateful shade over the cool waters of the well form channels of entry for unfiltered seepage along the course of their roots. The distinguished bacteriologist, Prof. Koch, attributes any unwholesomeness of such wells to unfiltered inflow from the surface, but whether the contamination is from unfiltered inflow or from the inefficiency of the subsoil as a filter, the facts remain that such waters are found by the chemist to contain much or-

ganic matter, vegetable and animal, and by medical observers to be associated with the propagation of both malarial and typhoid fevers.

“The deep or subterranean waters are those that falling on high ground sink into broken edges of some porous stratum which underlies the clay beds of the bottom lands. The waters percolate through and along the porous stratum underneath the impermeable clay which supports the subsoil water. When tapped by digging or boring they are the waters of our deep wells, originally pure, but often valueless for domestic or manufacturing purposes on account of the large amount of mineral salts which they have dissolved in their subterranean course. If the pervious layer be one of sand and gravel the water may be as pure as distilled water. The discovery of such water 350 feet below the surface of the city of Memphis, Tenn., solved the water question for that city at a time when its citizens were debating whether the million dollars which they could raise for a water supply should be expended in bringing in the clay-laden waters of Wolffe River or the sewage-polluted waters of the Mississippi. The thorough filtration to which this deep-lying water is subjected in its subterranean course freed it from all germs, whether of malaria or of typhoid.”

Dr. Smart then gave some interesting practical illustrations of the methods followed by chemists in testing waters to discover the presence of various kinds of impurities.

The simplest single experiment employed by the chemist is the charring or burning of the residue after evaporation. If there is merely a slight darkening without fumes or odor the water is free from organic matter. If there is much blackening which is dissipated with difficulty and with the evolution of peaty or pyroligneous odors the matter is vegetable. If there is a strong nitrogenous odor and the carbonaceous blackening disappears with incandescent sparkles and nitrous fumes the matter is animal. This is but a rude and primitive experiment but it gives valuable information in the absence of facilities for more elaborate methods. The organic purity of a pure water may be demonstrated by it, as well as the impurity of a notably bad water.

Purification by sedimentation was then discussed, as it is by this process that the Potomac River supply of Washington is supposed to be treated. The inefficiency of the local arrangements was pointed out and the high death rate of the city from typhoid fever was attributed to this inefficiency. “The greater the care taken in the purification of a city’s water supply the less is the death rate of that city from malarial and typhoid fevers. Brooklyn has an annual death rate from typhoid fever of 15 in every 100,000 of its population; New York 26; London 28; Baltimore 40; Boston 45; Cincinnati 63; Philadelphia 66; Chicago 69, and Washington, according to Dr. Billings’ recent census work, 75. We do not have this high rate because our sewerage system is defective, for Baltimore has no sewerage system, nor because our houses are overcrowded and unventilated, back yards filthy and undrained and streets narrow and unclean. No. We have it because the germs of the disease are distributed along with the clay particles of the Potomac water. The inflow of the sewage into the Potomac River above the Great Falls is small, but there is enough of it to give us more typhoid fever than is found in Baltimore, New

Orleans and other cities that lack many of our sanitary advantages."

The Army engineers in charge of the water supply are aware of the defects in the system, and have excellent plans for remedying them; but money is required to carry them to completion. Dr. Smart closed by urging the expenditure.

"Think of the 75 deaths from typhoid fever annually in every 100,000 of the population, 60 deaths more than in the city of Brooklyn, and more than we would have in this city if our water was as pure as that of Brooklyn. Putting our population at a quarter of a million, we have 150 unnecessary deaths every year. Ah! but the cases! To find the number of cases we must multiply the deaths by twenty! Three thousand cases of serious sickness, each lasting from two to six weeks. Three thousand cases of disease that might be prevented by the expenditure of a little money. Think of the suffering, anxiety and sorrow involved in the history of these three thousand cases, and then say whether an appropriation having in view the purification of the city water supply is a good investment or a bad one."

DESCENT OF THE TESTICLE IN ADULT LIFE.

BY ALBERT H. TUTTLE, M.D.

CAMBRIDGE, MASS.

As such cases as the following must be of extreme rarity, and as they shed a great amount of light on the phenomena of earlier and normal descent, and at the same time perhaps instruct us somewhat as to the manner in which we should deal with cases of undescended testicle; cases where the majority of opinion has been in favor of the complete removal of the organ when it interferes with the comfort of the patient, is caught in the inguinal rings, or complicates a hernia, I have deemed this instance one worthy of consideration.

Not long ago I operated for strangulated hernia complicated with undescended testicle, and after closing the hernial sac and rings, drew the testicle, which was enclosed in the sac, into the scrotum and fastened it there with the tunica by means of stitches. This procedure necessitated the invagination in part of the scrotum. The result was perfect, but after the operation the gentlemen present, some four members of the profession, expressed as their opinion that I should have sacrificed the testicle, and questioned the result. When they said such testicles do not prove of much practical value, I could only answer that I had been consulted by patients with one undescended testicle who were willing to undergo a surgical operation in order to satiate their desire for a second testicle in the scrotum. They simply echoed the general opinion of the profession. But the time has come when we must deal more rationally with these cases, and it is already heralded by various reports in our latest journals.

E. W. L., aged 31 years, was born with a congenital hernia on the right side and an undescended testicle on the left. He wore a truss on the right side until 12 years old; it was then discarded until the age of 21, when he put on a double truss and wore it until six months ago; since, he has employed simply a suspensory bandage to keep the bowel in place.

I saw him for the first time about two years ago; an examination showed an absence of the left testicle, and a dilated condition of the inguinal rings on both sides. In the standing position the abdominal wall bulged outward at the site of the rings, and an impulse was felt on coughing.

It was obvious that the sac was not a great one, and that the gut at that time would not descend far along the cord, although it had at an earlier date, according to the statement of the patient. He consulted me for an attack of gonorrhœa at this time, and informed me that he had had a similar attack some six years previous. During his first attack he had a swollen testicle on the right side and sharp pain deep in the left groin. Since, he has had a swollen testicle on the right side without any apparent cause. I recognized the condition of the patient at the first visit, and recommended an operation for the radical cure of the hernia.

He went to Europe shortly afterwards, and I saw nothing of him until a few weeks ago. I now find the testicle on the left side of the scrotum, the inguinal rings smaller than when I first examined them, and, without artificial support, the gut does not distend the abdominal wall or give an impulse on coughing to the contents of the scrotum. The patient experiences no discomfort without the truss, and only about once a week a "lump" appears in the left groin "in the evening when the muscles are tired;" this disappears on lying down, or on pressure.

The following history of the descent of the testicle is given in the words of the patient as nearly as possible: About a year and three months ago a skin, like a bag full of water, came down, and kept getting larger toward evening; the bag became about egg-size, and could be emptied by pressure; in about three months—a year ago—he was sitting writing a letter in the evening, when something was suddenly felt below (in the scrotum); he looked and found the testicle had come down. It disappeared the same evening, but returned to the scrotum a week later, when he tied it down with a piece of tape. In this manner he kept it down for a week; it then returned to the abdomen, and remained concealed three days, and when it came down stayed longer. It has kept going up and coming down, each time staying longer in its normal condition, until now it has remained in the scrotum for about four months.

When the "bag of water" first appeared, it made the scrotum red and hot and somewhat uncomfortable; it disappeared during the night, and on lying down.

He has been married for about one year. Since the attack of gonorrhœa two years ago, he has had at times bloody urethral discharges with the seminal ejections, or immediately after intercourse. Examination by the microscope shows nothing abnormal in the seminal fluid except the presence of blood, which probably mixes with it somewhere in the genital tract, external to the testicle. This bloody discharge, for which he recently consulted me, is a complication of the old gonorrhœa, and in my opinion has nothing to do with the lately descended testicle.

It seems possible that by care this case will obtain a spontaneous cure of the hernia.

TRACHOMA.—(GRANULATED LIDS).

Read before the South Kansas Medical Society at Wichita, Kan., Nov. 21, 1893.

BY FLAVEL B. TIFFANY, M.D.

PROFESSOR OF OPHTHALMOLOGY IN THE UNIVERSITY MEDICAL COLLEGE OF KANSAS CITY, MO.; OCUList TO GERMAN AND ALL SAINTS HOSPITALS, ETC.

Trachoma (from the Greek *τραχὺς*, rough), is the term intended to designate a certain disease of the lining of the lids or palpebral conjunctiva; but it has been so indiscriminately used by physicians and some oculists when speaking of the different forms of conjunctivitis that there is much confusion as to its real signification. To most physicians, it means any form of granular conjunctivitis, be it simple, acute, subacute or chronic; especially if there is much roughness of the lining of the lids. In acute conjunctivitis we have a swelling of the papillæ, giving a very rough condition of the palpebral mucous membrane, but this is not trachoma.

In catarrhal ophthalmia, and especially in purulent ophthalmia, the papillæ swell enormously, also the different glands, those of Moll and the Meibomian as well as the trachoma glands; but again, this is not trachoma. Inflammation of the conjunctiva may pass through the different stages, from simple

hyperemia, acute, catarrhal, purulent, subacute and chronic even; and yet not reach that stage or condition which the word, trachoma is intended to signify. It is believed by most authorities that trachoma is consecutive to the different forms and stages of inflammation of the conjunctiva; and according to my own observations and study I am inclined to believe that this view is the proper one. It is, as a rule, a disease confined to the common or lower classes, especially to those who are exposed to irritants and subjected to bad air and other poor hygienic conditions. It is particularly a disease of the so-called scrofulous people; and of the offspring of parents of blood relation; in other words, it is often due to consanguinity.

Of the different kinds of conjunctivitis we have acute, subacute and chronic; we have also what is known as catarrhal and purulent ophthalmia, any or all of which may be precedent to trachoma; that is to say, if these inflammations are permitted to continue through the consecutive stages, they may finally reach or produce the condition of true trachoma. Acute catarrhal ophthalmia is characterized by a turgescence and swelling of the papillæ with more or less congestion and swelling of the whole palpebral conjunctiva. The papillæ may become quite hypertrophied, turgescerent, red and succulent; the conjunctiva itself is thickened, especially in purulent or in pronounced catarrhal ophthalmia. In these latter diseases the conjunctiva is so swollen and congested as to be thrown into folds or rugæ, and the adenoid tissue assumes a velvety appearance. The turgescence and hypertrophied papillæ are usually more pronounced at the retrotarsal folds, especially near the canthi. Sometimes the papillæ with the mucous membrane are so enormously swollen and engorged as to be thrown into such large folds and excrescences they resemble a cauliflower; and when the lid is everted, it resembles, as Dr. Noyes has said, the everted rectum of a horse after defecation.

In the simple acute conjunctivitis there is little or no purulent discharge, although the excrescences are frequently so turgid as to be made to bleed at the least provocation.

In catarrhal and purulent conjunctivitis a similar condition exists, but the nature of the disease is different. In acute conjunctivitis there is a slight discharge, but not of a purulent character; it is more of a mucoid nature. The follicles of the conjunctiva are usually also swollen and give the appearance of fish spawn or of tapioca grains; the papillæ, however, frequently rise above the follicles and completely hide them. In subacute conjunctivitis the follicles are more pronounced and the papillæ are less hypertrophied. The granules in the subacute form are frequently more prominent upon the lower lid or may be almost entirely confined to the lower lid, where the fish or frog spawn or tapioca appearance is to be seen. The chronic form, or what is usually called trachoma, is quite a different condition from the other two; in this form we not only have hypertrophy of the papillæ, the follicles and trachoma glands, with the glands of Moll, but we have true neoplasms of follicular infiltration. The lymphatic stomata are filled with leucocytes and follicular deposits. The infiltration of leucocytes into the stroma and the adenoid tissue of the lid assume a true granular condition with connective tissue cells or nuclei surrounded by connective tissue fibers and

atrophy of the normal connective tissue. *In real trachoma we have, then, hypertrophic succulent papillæ, hypertrophic follicles, hypertrophic glands of Moll, hypertrophic trachoma glands and, besides, neoplasms of a granular character predominating. There is an infiltration of connective tissue substance throughout the conjunctiva. The normal stroma becomes atrophied and, to a certain extent, gives place to the neoplasms similar in appearance to the ordinary tubercle of phthisis.* Within these cells or nuclei of the neoplasm, have been found numerous microbes called trachoma bacilli.

Chronic conjunctivitis or trachoma is thought to be contagious. Frequently this disease develops seemingly quite independent of the acute or subacute form of conjunctivitis, and exists for many months before it is discovered.

The different forms of conjunctivitis, if not timely and properly treated, may assume a chronic condition and this condition by some has been called trachoma. Trachoma, however, is something more than this. As before said, in trachoma we not only have hypertrophy of the papillæ, of the glands of Moll, the Meibomian glands, a swelling and thickening of the whole conjunctiva; but we also have follicular infiltration into the mucous membrane and the adenoid tissue; we have a breaking down of the normal tissue, a derangement of the histologic structure with atrophy, with cicatricial tissue and the follicular neoplastic infiltrations resembling tapioca or sago grains.

Conjunctivitis in other forms can be cured by proper treatment in a short time, but it is far different with true trachoma; here the disease is most persistent, frequently resisting any and all treatment, marching on its destructive way for months, even years, before it can be subdued or scarcely checked in its course. Some authors will tell you of several forms of trachoma; but trachoma is trachoma wherever you find it. That there are different stages and exacerbations we grant. That there are different complications existing we well know. In some cases the papillæ are much more congested and hypertrophied than in others; again, in some cases the follicular infiltration is so enormous that the neoplasms stand out in such bold relief as to resemble cauliflower growth. *The chief distinguishing feature, then, of trachoma is the cicatricial formation and neoplastic follicular growths, and this seems to be a consecutive outgrowth from the acute to the simple catarrhal or purulent, to the subacute, and thence on to the chronic.* Whether there is a specific microbe that comes in now to play his part is a question. Others claim that the disease is of a specific nature due to a particular microbe, and with this bacillus or micrococcus they can inoculate the lower animals, and produce there a true trachomatous inflammation. We all well know that the conjunctival sac swarms with many forms of microorganisms, but it would be difficult to say which, if any one, is responsible for the disease. Nearly every oculist who has claimed to have found the bacillus or micrococcus producing trachoma has a microbe differing from all others. As yet, it is wholly speculative whether the disease has its etiology in any specific organism or germ.

One of the most frequent provoking causes of trachoma is some error of refraction, especially that of hypermetropia or hyperopic astigmatism. In my experience, the majority of these patients are hyperopic, and

many are astigmatic. There is another factor that comes in as a cause, and that is the use of tobacco, especially if chewed; and I have found that patients having chronic granular conjunctivitis or trachoma, can not be cured so long as they continue the use of tobacco.

It would seem that the swallowing of the juice which all chewers of tobacco do to a certain extent, poisons the lymphatic system, and so affects the lymphoid and adenoid structures, and until this poisonous nicotine is entirely eliminated from the system it is next to an impossibility to effect a cure. So confident am I that tobacco thus affects the system and prevents the cure of these cases that I absolutely refuse to take a patient using the weed who will not promise to discontinue its use in toto. I have made a careful record of all my patients, and have given special attention to this subject of tobacco, and its effect when used by the patient or having been used by his progenitors; and I have found that a large per cent. suffering from persistent trachoma either use tobacco or their immediate ancestors did before them; and I have also satisfied myself that patients who are not contaminated by the weed get well in a much shorter time than those whose system is under its influence.

I have also experienced that patients suffering for many months and years with trachoma, having received the most approved and continued treatment from the hands of competent physicians and oculists, are cured by the ordinary treatment in a very short time, as soon as they discontinue the use of tobacco.

We know that it is a fact that this disease, trachoma, is more often found among the Irish and American people than among those of other nationalities, and we also know that it is a fact that the chewing of tobacco is limited almost entirely to the Irish and American people.

That trachoma is contagious there is some question, but that it is infectious, there is no doubt.

SYMPTOMS OF TRACHOMA.

The patient complains of a gritty feeling beneath the lids as though there were sand or other foreign bodies lodged there. There is more or less dread and intolerance of light, the photophobia varying in intensity according to the stage and intensity of the disease. The secretion glues the lids together, especially in the morning after sleep, forming a yellow crust at the roots of the lashes. Frequently there is paresis of the levator palpebræ superioris, and in consequence, more or less ptosis (falling of the lid). Sooner or later the cornea is almost sure to be affected, when the ocular conjunctiva is also involved. There is turgescence of the ocular conjunctiva with, perhaps, the blood vessels of the subconjunctiva extending into and upon the cornea with more or less swelling of the margin of the cornea; and this vascular opacity of the cornea is called *pannus*. The pannus, as a rule, begins at the upper part and the vascular opacity may extend upon, midway or even across the cornea, completely obscuring the iris and pupil. This pannus is due to the friction of the rough granular lid and it begins at the upper part of the cornea where it may be confined, for it is usually the upper lid that is mostly involved, and as there is much more motion of the upper lid upon the ball than of the lower, this adds to the corneal complication. It is not infrequent, however, that both superior and

inferior lids are granulated at one and the same time, but usually the upper one is far more diseased. The irritation of the rough lids upon the delicate cornea often produces ulceration here, and any existing pterygium is aggravated and may rapidly increase.

PROGNOSIS.

Acute conjunctivitis may run its course in a few weeks and spontaneously get well, but if neglected or improperly treated it may pass into a chronic form, when months and years may be required to effect a cure; and even then with much impairment, if not loss of vision, from some one or many of the complications and sequelæ of the disease. From the infiltration there is atrophy of the stroma with cicatrices; the cul-de-sac or pouch formed by the conjunctiva as it folds over from the lid upon the globe, and which is so necessary to the freedom of movement of both lid and eyeball, becomes obliterated; that is to say, instead of the conjunctiva folding back and forming the cul-de-sac the two surfaces, the palpebral and ocular, are grown together, and the membrane of the lid passes directly to the eyeball. This condition not only interferes with free movement of the lid and ball, but it also tends to contract the lid and invert its free edge, thus drawing the lashes down upon the ball, or even turning the edge of the lid with the lashes so much as to completely fold them in against the palpebral conjunctiva and upon the eyeball; in other words, produce what is termed *entropion*, which condition is most harassing and destructive to the cornea. This entropion is also further favored by atrophy of the intra-marginal space of the lid, thus allowing the cilia to drop down and change their normal outward curve to an inward direction. If the disease is seen before these sequelæ arise, and timely and proper treatment judiciously given, it can be cured with little or no damage to vision.

TREATMENT.

In simple acute conjunctivitis, the treatment consists in looking after the hygienic condition of the patient; after his general health; and removing or rectifying any provoking cause, as of a foreign body, or any anomaly of refraction. See that the general health is up to the standard; that food, drink and clothing are good. Tonics, if necessary, should be given; however, it is frequently the case that we find this disease among those of robust plethoric people otherwise in perfect health with ravenous appetite; in fact, the majority of my patients suffering from granular conjunctivitis are from the country, and are well nourished and full of blood. In these cases, it is best to diet them, and I have frequently found that depletion is beneficial. As a local treatment, hot water should be freely used. As a collyrium, the chlorid of zinc is my favorite, $\frac{1}{2}$ to 1 grain to the ounce of water, dropped into the eye night and morning; atropin $\frac{1}{2}$ per cent. to 1 per cent. used once a day, if not continued too long, does good. Other astringents, as sulphate of zinc, alum, borax, sulphate of copper, etc., may be used with equal efficacy. If the disease has assumed the subacute stage, more vigorous treatment may be necessary; here the lids should be everted and the mucous membrane bathed with a solution of nitrate of silver, 1 to 2 per cent., every other day, and in the meantime a solution of boracic acid in warm water 8 per cent. (a

saturated solution being 33 per cent.), can be used three times a day, the patient bathing the lids by means of absorbent cotton saturated with the solution, allowing some of the fluid to go into the eye. A little vaselin, plain, or with yellow oxid of mercury, 1 per cent., should be smeared on the margin of the lids at night to prevent them from gluing together. If the disease has gone on to the chronic form or true trachoma, we then have a far more formidable affection to contend with.

TREATMENT OF TRUE TRACHOMA.

Trachoma frequently baffles the most skilled and approved treatment, and goes on for months and years even before it is thoroughly subdued. At one time it was thought by some as incurable, for if once seemingly subdued, when treatment was discontinued the disease would surely return. From its rebellious character and destructive sequelæ it has compelled the profession to give it much attention. Nitrate of silver solution and sulphate of copper in crayons are the two remedies that have been found most efficient, and in ordinary cases they are most to be relied upon. Nitrate of silver may be used as strong as 10 per cent. or 15 per cent., but it is a question in my mind if such strong solutions do more good, or even as much, as weaker ones; besides, if they come in contact with the cornea, they are liable to do much damage to this delicate structure. The strength that I have found most satisfactory is from 2 to 4 per cent.; that is, 10 or 20 grains to the ounce of water, brushed on to the everted lids two to six times a week. In using the strong solution of nitrate of silver, it should be applied by means of absorbent cotton wrapped around a wooden toothpick or any applicator dipped into the solution, and after the solution has remained a second or so, until the mucous membrane begins to turn white, the excess should be washed away by plain cold water. Care must be taken not to allow the solution to come in contact with the cornea, lest it provoke ulceration of this delicate bloodless structure. No solution of nitrate of silver stronger than $\frac{1}{4}$ per cent. or $\frac{1}{2}$ per cent. should be dropped into the eye. If the sulphate of copper is used, it is best applied as a crayon, and the pencil must be perfectly smooth, for if not, the rough surface will irritate and do harm instead of good.

In treating trachoma, care must be taken that the application be within the retrolarsal folds as well as upon the palpebral conjunctiva. The point of the copper crayon can be passed quite into the cul-de-sac. The copper should not be used oftener than three times a week. If it is dipped into vaselin or glycerin before applying it, it is not so painful, but quite as efficacious. The sulphate of copper treatment is very painful, and in sensitive people, cocain may be used previous to the treatment; however, I have found that the reaction of cocain is bad, and if it is long continued, it is decidedly prejudicial. If there are any abrasions, ulcerations, or pannus of the cornea, sulphate of copper should not be used, as it will most likely aggravate these corneal diseases. Here nitrate of silver is far more beneficial. The yellow oxid of mercury salve, five or six grains to the drachm, is a favorite treatment of the European oculists, but I have never been able to use it so strong on my patients without the most excruciating pain, with intense irritation, causing the eyelids and ball to be all aglow; indeed, four or five grains to

the ounce of vaselin is as strong as my patients will tolerate, and if I use it stronger, I have to combine cocain with it. The formula I mostly use at my clinic is ten grains each of cocain and yellow oxid of mercury to the ounce of albolene. I have the mercury thoroughly ground in a mortar until there are no particles visible, it being thoroughly mixed with the albolene, for if but a very small particle exists not comminuted in the albolene, it will prove an unbearable irritant. The salve seems to be less active after it has been made for a time than when it is first put up. I frequently use it alternately with the silver or copper treatment. Nitric acid is sometimes used, but it is dangerous and is liable to leave eschars and cicatrices, thus irretrievably injuring the lids and eye; if used at all, it should be applied by means of a pine stick dipped into the acid. After the acid has soaked into the stick, the latter may be cautiously drawn across the granules. Charlatans used this treatment frequently, subduing the granules, but as frequently permanently injuring the parts by the cicatrices left.

In pronounced chronic trachoma the most speedy and radical treatment is that of expression of the granulations either by the thumb nails, the trachoma forceps, or toothbrush. In using the trachoma forceps Dr. Knapp's pattern is best; some prefer Prince's. The patient should first be anesthetized, as the operation is so painful that cocain is insufficient. The lids everted, the forceps are applied by shoving one stirrup beneath into the cul-de-sac, the other at the everted margin of the lid, and with the forceps firmly compressed careful traction is made. Care must be taken not to tear the tissues, only sufficient force being exerted to roll out or scrape off the granules. It is the cauliflower growth, excrescences, and hypertrophied papillæ and glands that we thus remove with some of the neoplasms. I have found that it is necessary to make subsequent treatment for weeks and months after the use of the forceps, even after the most thorough use of the instrument; but certainly they cut short the disease as, by their use, a few weeks, generally with application of nitrate of silver or copper, will accomplish as much as could be gained in as many months by the usual treatment without their use.

Of very recent date I have used the stiff brush, (toothbrush). After first removing all the granulations possible by means of the forceps, I then take the toothbrush (cut down short), and with the lids everted thoroughly brush the conjunctival surface until all neoplasms and hypertrophies are removed (the lids appearing thin and pliable). There is not as much reaction from this treatment as one would suppose; but the results are not always satisfactory, for even with the brush in addition to the forceps, I have found it is still necessary to follow up this by a slight astringent and in some cases, from the brush, I have had with the cicatricial contraction, pronounced entropion. In case of pannus, which frequently persist even after the trachoma is cured, syndectomy, as my experience proves, is the most satisfactory treatment; this consists in making an incision around the cornea through both conjunctiva and subconjunctiva about three or four mm. distant from the limbus, and then dissecting the intervening portion up from the sclera to the margin of the cornea and snipping it off by means of the scissors. This girdling the cornea, as it were, cuts off all the

blood vessels of the cornea. The vascular opacity of the cornea immediately diminishes and rapidly disappears, also the neoplastic hypertrophied tissue of the cornea is quickly absorbed and the cornea gradually clears up. The conjunctiva recedes from the limbus upon the globe, the tension is relieved, thus allowing the retrotarsal folds to spring back and the margin of the lids to recover their normal position.

Jequirity.—In very chronic obstinate cases of opacity, *jequirity infusion*, after all other means have been exhausted, may accomplish still more good; but it should be used with caution, as it sometimes produces ulceration of the cornea. It can be used with more safety after syndectomy has been made, for if there be much swelling of the conjunctiva, even though it has been re-attached to the sclera, its attachment will give way and so prevent any pent up pus or strangulation of the cornea.

Inoculation—of purulent conjunctivitis is too dangerous to be recommended, except in rare cases where, perhaps, there is dense, persistent, vascular opacity with plastic infiltration of the cornea, with chronic trachoma; and even then, if the malignant inflammation caused by the inoculation is not carefully guided, it is liable to cause ulceration and destruction of the cornea; but the danger is much lessened if peritomy or syndectomy has previously been made; for as the conjunctiva becomes infiltrated with intense chemosis, the incised periphery near the cornea is loosened, thus avoiding the pent up secretion or engorged vessels, and hence lessening strangulation of the cornea. If there be strangulation, thus impairing the nutrition of this vulnerable part of the eye in its enfeebled state, it is in great peril, for the deadly specific microbe burrows and chisels its way into the cornea, thus causing abscess and sloughing of this part of the eye, for it is the weaker and devitalized tissues always that these germs prey mostly upon. And so I repeat that the operation of syndectomy or peritomy indemnifies or insures the cornea to a certain extent against the destructive force of the inoculation. The effect of the purulency by inoculation is frequently so very striking, clearing as it does, the opacity of the cornea and ridding the lids of all infiltration and granulation, that it is very seductive and alluring; but if one has ever tried it, wrestled with it days and nights, as I have, to prevent its destroying the eye and finally at last having suppuration of the cornea, he will not feel like repeating the experiment.

I remember years ago having a case of most persistent chronic trachoma with dense pannus and infiltration of the cornea which for months and years resisted all treatment. I finally screwed up my courage to try gonorrhoeal pus. I inoculated one eye and soon an intense inflammation followed; the lids swelled enormously, became fiery red and pus flowed out upon the cheeks; the boy, a Swede of 14, screamed with pain; soon the other eye was attacked and the lad fairly howled with agony, creating a general consternation in the neighborhood. I went to see him several times a day and during the night for a period of more than a week, expecting every hour that the eyes would burst; but my relief of mind and my joy, you may well imagine when the inflammation began to subside without any destruction of the cornea. In this case I had previously made a syndectomy, and although the conjunctiva had attached itself to

the sclera and the intervening space was replaced by new tissue, during the intense swelling and chemosis, the conjunctiva gave way again all round the cornea, allowing free vent to the secretion and there was no strangulation. To this I attributed the success of conducting the suppurative inflammation to its happy issue. In this case, the cornea cleared perfectly and the lids were rid of all granulation, and the boy regained good vision with splendid looking eyes.

This was, and probably will be my only case, unless it be as a last resort, after long and faithful trial of all other means, and even then when there is no vision, where there is nothing to lose but everything to gain. However, the *jequirity* will accomplish nearly as much and with much less danger.

The form of jequirity to be used.—Take eight beans, crush or grind them, and macerate in an ounce of warm water for twenty-four hours. Strain, put up in blue bottles, and keep in a cool, dark place. Of the solution, instill one or two drops into the conjunctival sac, or if a more thorough application is desired, it may be made by everting the lids, and applying the solution by means of absorbent cotton. The effect of the drug thus applied is not manifested until five to eight hours when the symptoms of catarrhal ophthalmia begin. The inflammation continues to increase when it assumes more of the symptoms of purulent ophthalmia, there being more or less suppuration of a muco-purulent nature. Soon there is a false membrane formed not unlike that of diphtheria. If the inflammation thus exerted proves too severe, it may be held in check by the use of hot water; otherwise, no further treatment is necessary, except to keep the lids cleansed by means of absorbent cotton and warm water.

The *jequirity* infusion will spoil in a short time, especially in warm weather; therefore a fresh solution is necessary. Parke, Davis & Co. keep a solution on hand which I have found quite reliable. This solution is strong, but may be reduced by adding a few drops to as many more of water before applying. If a prolonged action of the drug is desired, one drop of the reduced solution may be instilled into the conjunctival sac daily or every other day for a week or ten days when the eye should be allowed to recover entirely from the effect, and then after an interval of a few weeks the solution may be repeated if necessary.

In treating trachoma we should look well after the hygienic condition of the patient and also to existing provocative influences, such as the errors of refraction, especially hyperopia and astigmatism, also the different forms of heterophoria. Very frequently there is some disease or obstruction of the lachrymal apparatus that has to be relieved or treated ere a cure of the trachoma can be produced. Frequently have I effected a speedy cure of trachoma that had been resisting the ordinary treatment for many months, by simply slitting up the canaliculus and passing a probe into the nasal duct, thereby securing a free drainage of the pent up diseased fluids, relieving the irritation caused by their presence.

Tobacco in all forms must be prohibited in toto; also alcoholic liquors, except when indicated as mild stimulants. General baths give tone and health to the system and are always indicated.

ON PRESERVING EMBRYOLOGICAL MATERIAL.

BY ADOLF MEYER, M.D.

DOCENT IN NEUROLOGY, UNIVERSITY OF CHICAGO; PATHOLOGIST OF THE ILLINOIS EASTERN HOSPITAL FOR THE INSANE, KANKAKEE.

Preparing some work on the development and the anatomy of the brain, I beg to bring the following appeal for coöperation before the members of the profession:

It is necessary to start the work on as broad a basis as possible, and for this reason it can not be done without the active coöperation of the practitioners. It is my desire to show that a large city like Chicago can, notwithstanding its short existence, make up for a long period of preparation with its youthful energy and take at once, as it did in many respects through the Fair, a place in the foremost ranks of scientific centers. This energetic progress shows itself in every line of scientific research, and I feel confident that an appeal for help in promoting our knowledge of the nervous centers will not be in vain.

Embryological material becomes of value only if a sufficient number of stages are collected and displayed in an instructive series of development. Such a museum will, I hope, be one day the pride of Chicago and furnish the best ways of instruction, far superior to book learning and drawings. The preparation of the material is not connected with much inconvenience. It is, however, necessary that certain rules should be observed, which increase the value of the specimens materially.

Very early stages which are sometimes found in the blood-clots of "very profuse menstruations" are best put into a 10 per cent. solution of nitric acid for a quarter of an hour and then into an abundant quantity of 70 per cent. alcohol. If the fixation with nitric acid is not possible, it will be quite sufficient to put the ovum at once into the 70 per cent. alcohol.

This method will answer its purpose up to the fourth month. From the fifth month, however, it will be preferable to preserve the material in Müller's fluid (bichromate of potash $2\frac{1}{2}$ per cent. and sulphate of iodine 1 per cent. dissolved in water). This method is somewhat more complicated, inasmuch as it requires a little more attention. The fetus—in later stages only the head and perhaps the spine—is immersed in a large quantity of the fluid. It is best to open carefully the cranial cavity in order to give direct access to the fluid; the removal of the parietal bones or at least their partial removal will answer best the purpose. On the second and fourth day the fluid should be changed. Under all circumstances the fluid must be abundant.

Preference is given to Müller's fluid in the later stages of embryonic life and in the new-born child, because not only the surface anatomy (convolutions, etc.), is of importance in these stages, but especially the development of the medullary sheaths of the fiber tracts which takes place at different times and affords a most useful help for the study of special tracts.

With regard to the jars, preserve jars of an appropriate size can be obtained in every grocery store. It will not be inconvenient to keep a 5-gallon jug of Müller's fluid and a gallon or two of 70 per cent. alcohol ready all the time.

The specimens should be accompanied by a short note on time of last menstruation, time of beginning

abortion or labor, and time of expulsion and further the time when put into the hardening fluid. All the specimens will be duly acknowledged.

It is evident that monstrosities offer much of interest with regard to the nervous system. The same would hold for pathological conditions in children and adults. With regard to the transportation, specimens may be sent for when brought to one of the Chicago down-town offices, or they may be sent to the Kankakee Hospital by express.

Kankakee, Ill., Jan. 27, 1894.

DISLOCATION OF CERVICAL VERTEBRA. DEATH—CASE RECORD AND NECROPSY.

BY G. W. BROOKE, M.D.

ELLSWORTH, OHIO.

Early on Wednesday morning Nov. 29, 1893, I was hastily summoned to visit a neighbor, Mr. Chester Allen, a strong, healthy man, age 50 years, living but a short distance from my residence. I found him in his barn, and learned that he had fallen a distance of about seven feet, through a hatchway, to the floor beneath. As near as could be ascertained, the accident occurred about three-quarters of an hour before. He was insensible for a time after he fell; how long a period he was unable to say, and when consciousness returned, he found that he was entirely helpless, and unable to make himself heard. He complained of intense pain in his neck, a few inches below the occiput, and on examination, I found complete paralysis, and loss of sensation below the seat of injury; heart's action very slow and feeble; pulse imperceptible at the wrist; extremities cold. Without waiting to make further investigation, he was immediately taken to the house, and on careful examination, the neck was found to be dislocated, the head turned considerably to the right side, and the deformity apparently about the fifth cervical vertebra, and very marked. As soon as the diagnosis was clearly made, I grasped the head firmly with both hands, and used all the strength I could command by way of extension, at the same time gently rotating the head so as to bring it in line with the body, as the extension was continued. This procedure occupied but a moment of time, and one of the friends who was bending over the patient, assisting me in the operation, says that he distinctly heard a grating sound, when the dislocation was reduced.

The moment the dislocated vertebra was put in position, the patient could see; before this he was entirely blind. He also expressed himself as feeling much relieved by the operation; extension, however, had to be continued almost constantly, or the pain in the neck would recur with great severity.

Vigorous efforts were now made to warm the patient, and bring on reaction—stimulants and heart tonics were administered liberally, the patient swallowing fairly well, and as the pain in the neck grew worse, morphin was used hypodermically. In about six hours reaction was fully established; the pulse beating 50 per minute, strong and regular, respiration from 10 to 12. The thoracic and abdominal muscles, however, were unable to participate in the respiratory movement, so that respiration was very imperfectly performed. The patient could now speak audibly. He took sparingly of nutritious liquids, which required some care in swallowing. His mental faculties were not in the least disturbed by his unfortunate condition, and he was able to transact business as intelligently as though nothing had occurred.

The case continued in this condition for about eight days, when the pulse became gradually more frequent, and weaker, the breathing more hurried, the inability to swallow greater, prostration more marked, sleep more fitful and disturbed. It is needless, perhaps, to say that the catheter had to be used. The kidneys, after the first twenty-four hours, acted freely, and so continued while he lived. His bowels moved freely, in response to cathartics and enemas, the sixth day after the accident, and continued to move, passively, after this, up to the time of his death.

On Thursday evening, December 7, the unfavorable symptoms all became more aggravated, the heart's action was exceedingly feeble, and the patient himself was conscious that his dissolution could not be delayed much longer. He died at 1 P.M. the following day.

When I first explained to him the very serious character of the injury he said to me: "I am in your hands. Do with me and for me as you may think best."

During the entire time of his existence, after he rallied from the effects of the shock, his intellect and mind were as active and bright as when in health.

I have, in the army and elsewhere, seen many cases of injury and death from violence, but never before had a patient that possessed such a remarkable fund of fortitude and patient endurance as Mr. Allen manifested under such painful and distressing circumstances.

He was one of the bravest, best and most philosophical patients that I ever had. In addition to this, his Christian profession, faith and character were from the time of the accident to the close of his life, made more manifest and more deeply intensified, as he approached the end.

At the autopsy, held on Monday the eleventh, the following named gentlemen were present: Drs. Wagner, Hughes and Brooke, Messrs. Kirk, Ressler and McNeilly, Dr. Wagner making the examination. All of the cervical, and one or two of the dorsal vertebræ, were removed. It was found that the dislocation involved the fifth and sixth cervical vertebræ, the attachment between these bones being completely torn asunder, and at the time of the injury, the vertebræ were widely separated, but *now* in proper position. The ligamentum nuchæ was lacerated a short distance from its attachment to the spinous process of the vertebra; considerable clotted blood was found near the seat of injury in the muscular tissue, adjacent to the spinal column. On examination of the cord, the membranes were found ruptured, at a point corresponding with the injury to the spinal column. The cord at this point and below as far as examined was softened, and completely disorganized. The line of demarkation between the softened cord, at and below the injury, and its firmness and elasticity above, was very distinct and well marked, showing plainly that the vitality of the cord, below the seat of injury, was destroyed when the accident occurred.

OVARIOTOMY IN THE AGED.

Read before the Mississippi Valley Medical Association at Indianapolis.

BY RUFUS B. HALL, M.D.

PROFESSOR OF CLINICAL GYNECOLOGY, MIAMI MEDICAL COLLEGE,
CINCINNATI, OHIO.

To define clearly the limits of my topic, ovariectomy in the aged, I will take the Biblical division, that of three-score and ten years, and confine my remarks to patients who are 70 or more years of age. It is generally conceded as true, that any operation upon the old does not promise as good results as the same operation would upon the young, or patients in middle life. Especially is this true, in reference to all abdominal operations necessitating a hard strain upon the system from shock, or from traumatism to vital organs during the operation, as we not infrequently have in the removal of large ovarian tumors. Most writers, in reporting their operations upon the old women, and most textbooks, would have us believe that women 70 years old and upward are exceedingly bad subjects for ovariectomy. I am strongly inclined to the opinion that this is an error, and it is for this reason that I bring the subject before you at this time. Taking all of the reported cases of ovariectomy at my disposal, performed on women of 70 or more years of age, the

mortality is very low. Especially when we take into consideration the complications, which necessarily had to be overcome in making the operations, with the facts that a large majority of these operations were delayed operations with many adhesions, large tumors and lowered vitality. The death rate is not greater in my judgment than usually follows the same delayed class of operations on women between 40 and 50 years of age. It has been asserted by one of the most distinguished writers upon this subject, that the last word on ovariectomy has been uttered; that the mortality has been reduced to a minimum, and the technique completed. While this may be true, I am inclined to believe that there are some points in reference to operations upon the aged, on which the profession are not united. It is possible that some operations upon the aged have not reached us through medical literature, yet we must believe that most of them have, and if we take them as our guide in making our deductions we certainly can not regard ovariectomy upon this class of patients as dangerous an operation as is generally supposed. I have had but three ovariectomies upon women above 70 years of age. In each of the first two cases, the friends of the patients hesitated to have the operation made on account of the advanced age of the patients, just as long as it could possibly be postponed. In each of these, the operation was deferred until the patient was in extremis.

Case 1.—Mrs. K., age 70, residence South Salem, Ohio. The operation was reported in full at the Ohio Medical Society in 1887, and can be found in the Transactions of that Society for that year. She had been conscious of the existence of the tumor for more than two years. Owing to an accident which occurred some forty years before the operation, injuring the patient's hip, she had led a very sedentary life, and had been considered an invalid for more than thirty years. For three months before my first visit she was unable to leave the room. When I first saw her Aug. 26, 1886, she was sitting half reclining in a chair, which position she had been compelled to keep for more than two months. Her pulse had been frequent and feeble for many years, and at that time as she reclined in the chair the radial pulse was barely perceptible. For two months she had anasarca of the legs, which were twice their natural size below the knees and from an abrasion upon each the dropsical fluid was discharged in great quantities. It was decided to tap the cyst with the hope of relieving her. This was done and four gallons of fluid withdrawn. This relieved her urgent symptoms somewhat for a short time, but at the end of four weeks she was again unable to rest in bed and was compelled to assume a sitting posture. She now insisted upon an operation which was performed Sept. 23, 1886. The cyst was firmly adherent to the whole anterior wall of the abdomen, as well as to the omentum, which had to be divided between successive ligatures. The posterior surface of the cyst was adherent to the small intestine and three separate coils of intestine of about one foot each were removed from the cyst with great difficulty. The bladder was spread out over the front of the cyst like a great fan and was very firmly adherent and had to be dissected from it. The hemorrhage was severe and a great number of vessels were tied. The tumor and contents weighed fifty-nine pounds. Her recovery was uninterrupted and on the twenty-fourth day she was able to leave her room, and is now at the age of 77 years, enjoying good health.

Case 2.—which has also been reported in full in the *Lancet Clinic*, is Mrs. C., age seventy years and six months. Aug. 31, 1891, while alighting from a street car she slipped and fell, causing a sharp pain in the abdomen, yet she was able to walk a short distance to her home. Two days afterwards she called her family physician, Dr. George Coner of Cincinnati, who found her suffering from acute peritonitis. She gave a history of having some abdominal enlargement for the past six months. The Doctor had no difficulty in detecting the tumor which was irregular in outline. The abdomen was very much distended. I was asked to see her in consultation the same day, July 2, and had no hesitation

in saying, from the history of the case, that the cause of the peritonitis was a ruptured ovarian tumor. An immediate operation was advised and urged, but was refused by the patient and her friends. I was again asked to see her on July 13. The abdominal distension was not so marked, yet it was evident that the patient would not long survive unless she could be relieved by an operation. So little encouragement could be given at that time, if the operation was made, that the friends were yet undecided whether to have it made or not, but consented, on the evening of July 16, to have the operation, and it was made early the following morning. At that time the patient had a pulse of 138 and a temperature of 103 degrees. The exhaustion was very marked and she had the appearance of approaching dissolution. When the abdomen was open, a gallon or more of thick dark-colored fluid escaped. The cyst which was yet about the size of an adult's head was removed. One large cyst cavity which had an exceedingly thin wall had a long rent in it and was collapsed. A tumor of about the size of a cocoa-nut was removed from the opposite side. There was septic peritonitis for eighteen days before the operation was made. The cavity was thoroughly irrigated and drained. She made an uninterrupted recovery and was able to leave her bed at the end of the four weeks.

Case 3.—Mrs. H., age 72 was seen, in consultation with Dr. Willard A. Hall of Chillicothe, Ohio, May 15, 1893. The patient had been conscious of the existence of some abdominal enlargement for about six months. She had been an invalid for more than two years suffering from bronchitis, and attributed the abdominal enlargement to dropsy. She was quite surprised when informed by her physician of the presence of a tumor, and asked to have the tumor removed as soon as possible. The patient was a feeble woman, looking much older than she really was. The abdomen was well filled and the tumor had caused some discomfort from pressure for the past five or six weeks yet she had never suffered any pain from its presence. Ovariectomy was made May 23, 1893, and a multilocular cyst removed. There were no adhesions; the cyst and contents weighed thirty pounds. The patient recovered without a single bad symptom.

Ovariectomy, when made by men thoroughly trained in abdominal surgery, and in hospitals equipped for the work, shows the lowest mortality of any of the capital operations. Judging from the low mortality of the reported cases, and from the work of the best-known operators, I am constrained to believe that ovariectomy in old women, if the kidneys are healthy, is as safe as in middle life.

154 W. Eighth Street.

IMPROVED SURGICAL ENGINE AND NEW INSTRUMENTS FOR BONE OPERATIONS;

INCLUDING A SPIRAL OSTEOTOME FOR OPENING THE SKULL IN BRAIN SURGERY.

BY M. H. CRYER, M.D., DD. S.

PHILADELPHIA, PA.

I have read with great interest the paper on new devices for cutting bone, by Dr. De Vilbiss, in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* for Dec. 30, 1893, and though not agreeing with him in all things, heartily support his advice to the profession to the effect that there should most certainly be insisted on a better mechanical education among surgeons in general.

Too often, as Dr. De Vilbiss states, the operator does not even properly understand the use of mallet and chisel, and naturally condemns a more complicated though far superior means.

Dr. De Vilbiss' paper gives me the impression, however, that he is not familiar with the most recent surgical engines and their appliances. The engine the Doctor describes is in all its essential points similar to one introduced here some ten years ago, being light and made to fasten to the operating table or stool. It is turned by a crank, and the power conducted by means of a flexible cable many times stronger than the one used in the dental engine.

There are many objections to engines of this character. They lack sufficient power, and the limited flexibility of the cable will not allow the hand-piece to be carried in all directions, or to all parts of the body. There is also more or less vibration and backlash of the instruments, when in use, which greatly interfere with delicacy of touch.

In the *Dental Cosmos* for September, 1893, there is published a paper read by me at the World's Columbian Dental Congress of Chicago, on Aug. 15, 1893, giving the essential features of a surgical engine to meet practical requirements, and the development of the instrument, from the ordinary dental engine, through various machines, to the one I had the pleasure of introducing at the surgical clinics of that Congress; and with which demonstrations were made showing its range of applicability in bone surgery, especially in that of the head.

Since that time, operations have been successfully performed with it at the Hospital of Oral Surgery by Prof. J. E. Garretson, M.D.; in the Medico-Chirurgical Hospital by Prof. E. Laplace, M.D., and at the Orthopedic Hospital, in an extensive operation for the removal of the Gasserian ganglion, by Prof. W. W. Keen, M.D., all of Philadelphia.

A machine for operations of this kind must have motive power sufficient to give its revolving instruments a high velocity, and maintain its speed under varying pressure. In my paper, alluded to, I advocated a minimum speed of from 2,000 to 3,000 revolutions of the cutting instruments per minute; later experience has convinced me that better results are to be had with a speed of not less than 4,000 to 5,000 revolutions.

The hand-piece and chuck should be light, capable of easy adjustment, and of such arrangement that the instrument used can be freely directed to any part of the body. There should be no appreciable vibration, as it interferes with tactile recognition of the character of the tissue being cut. The device for clamping instruments in the hand-piece should permit of easy and quick exchange and they must be firmly held. The hand-piece must be easily taken apart to be cleaned and sterilized. The source of the driving power is of little import, but should be under perfect control and insure steadiness and uniformity of speed.

After using various means and devices for cutting bone, the following engine (Fig. 1), embodying suggestions from the writer, was made by the S. S. White Dental Manufacturing Co., Philadelphia, Pa.

The general appearance is similar to what is known as the cord dental engine, but it includes some distinct special features; it is many times stronger and the mechanism is of the highest grade. It will be seen that the engine is driven by hand. The crank, turning a set of gear wheels, made so true that they run noiselessly. This turns the driving wheel which is proportionately heavy, giving high speed and steadiness to the cutting instruments; near it is a pulley, T, that carries the driving cord which is likewise strong, and so arranged on the pulley wheel as to bring it into contact with more than the usual amount of the periphery of the driving wheel, giving it a grip which prevents slipping without producing the defect of an extra tension on the cord. The upright shaft has an arrangement, B, for tightening the cord and in the arm at H there is an automatic appliance for maintaining the tension

of the belt while in motion. The hand-piece is large and its arrangements for carrying various instruments are very good. It has a space, P, at its point for adjustment of different guards, etc. By removing two thumb-screws, L and M, it can be taken apart to be cleaned and made thoroughly aseptic. The arrangement of the arm and the wrist gives great lati-

Figure 1.

tude for position and movement of the hand-piece, as great as that of the human arm and hand, while at the same time the machine may be firmly held in one position. A velocity of from 10,000 to 12,000 revolutions per minute can be attained with great steadiness and regularity of speed.

A smaller engine and hand-piece is made on the

same type, and driven by the foot of the operator or that of an assistant, such an engine being all that is required for nasal or other light bone operations.

It is evident that Dr. De Vibbiss and the writer have been working toward the same end, to improve bone-cutting appliances. With an earnest desire to offer any assistance to the profession, of which I may be capable in this line, I wish to describe some of the most important instruments that have been made for the above engine.

Figs. 2 and 3 were designed about a year ago for making fenestra in the skull to furnish access to the brain in operations for removal of clots, tumors, etc., and for internal nerve resections.

The superiority of the circular saw, run at high speed by the surgical engine, over the usual method of chisel and mallet has been abundantly demonstrated. Fig. 2 represents the end of the hand-piece with circular saw one inch in diameter and one-sixteenth of an inch in thickness, inserted for use. The guard, F, is attached to the end of the hand-piece; the thumb-screws, B, are used to adjust and fix the guard to define the depth the saw is to cut.

Figure 2.

Figure 3.

Fig. 3 is a guard that can be used with the saw of Fig. 2 instead of guard F. The foot-piece of the guard, in which there is a slight groove, passes below the saw; the curved shaft is thinner than the saw and passes up back of it and is attached to the point of the hand-piece through the shank at D, Fig. 2. The object of this guard when in position is for it to be passed through a small, previously-made opening in the skull, then by putting the saw in motion the guard and saw are carried in the direction in which the brain case is to be cut. The guard pushes the dura from the bone and passes between the saw and the membrane. The objection to this device is that none but nearly straight cuts can be made.

The first of these appliances, Fig. 2, was used successfully last October by the writer, in making the initial bone section in an extensive operation performed at the Orthopedic Hospital by Prof. W. W. Keen, for the removal of the Gasserian ganglion.

The advantage gained by the use of this saw was the rapidity with which it cut, yet perfection seemed lacking, in that the mallet and chisel had to be called into requisition for supplementary work. This case, as well as a series of carefully conducted experiments upon the cadaver shows, however, that all danger of wounding the dura is not absolutely eliminated, even by the use of the guard which is attached to the mandrel of the saw to prevent the penetration of its cutting edge beyond a previously determined depth. The danger exists in the fact that brain-cases vary in thickness, and even the individual skull is thicker in some parts than others, thus making it impossible to accurately fix the guard.

A number of experiments have been carried out by the writer, with the hope of overcoming the danger of wounding the membranes, either with the saw or in the final cutting of the bone with the chisel and mallet, the latter adding materially to the shock, and not being free from the possibility of puncturing the brain.

The following instrument, "Spiral Osteotome," was described by the writer in the *Dental Cosmos* for January, 1890, and the *Medical News*, Jan. 6, 1894, substantially as follows:

After many trials of variously constructed burs, the following arrangement was hit upon, which seems to completely fulfill the requirements. The cutting portion of this "spiral osteotome," (Fig. 4) is one-half inch in length, one-eighth inch in diameter, and tapers slightly from base to point. By three spiral grooves, each having a turn of 120 degrees through the half inch from base to point of the cutting end, it is divided into three blades, giving it an appearance somewhat similar to a twist-drill. The effectiveness of these blades is enormously increased by a spiral screw, forty-four threads to the inch, cut around the blades of the instrument. This device necessarily adds twenty-two teeth to the edge of each cutting blade. The individual teeth are so arranged with reference to one another that the cut made by one tooth is overlapped by that of the one next following, while the spiral arrangement of these teeth, in connection with the three spiral grooves, makes the bur perfectly self-cleaning, the debris being rapidly thrown out backward by the revolution of the instrument. The point of the bur when in use is guarded by a rounded button-like attachment, connected with the nose of the hand piece by means of a shank and collar, as shown in Fig. 5 at A. The free end of the bur is dovetailed into a seat in the guard, B, in which it revolves, which steadies the whole arrangement when in use, gives an added rigidity to the bur-shank, and holds the bur and guard in permanent relationship to each other.

Figure 4.
Twice the size of cutting-tool.

Figure 5.
Full size of instrument.

It will be seen that the principle involved in the instrument described is simply that of a saw arranged to cut in a line with the axis of the shaft of the bur, and not at right angles to it, as in the circular saw. Such an arrangement allows of cutting in any direction and upon curved lines. This feature is especially valuable in resections of the brain-case, inasmuch as fenestra of any desired shape or size may be speedily made.

In operating for the removal of a portion of the brain-case with the spiral bur after division of the soft tissues by the scalpel, a small opening is first made with a trephine, Fig. 6, mounted in the engine hand-piece; this trephine has a diameter of five-sixteenths of an inch, and is passed completely through both tables of the skull, and the button of bone removed. There is no danger of injuring the dura with the trephine if it be carefully used. The opening thus made affords a means of entrance for the cutting bur, which, with its protecting guard, is next inserted in the opening, and the section made along the lines previously determined, by running the engine at high speed and forcing the bit laterally in the direction desired.

The button like guard at the point of the bur absolutely prevents injury to the dura, which is pressed or dissected away by it from its attachment in the line of the cut as the instrument progresses.

The detailed description here given is of an instrument that I have called a "spiral osteotome," and is designed for the special operation of opening the brain-case. Simple modifications of this instrument have been made for other operations upon bone. The same instrument as Fig. 4 with a rounded end and longer shaft, made in pairs of right and left, are excellent for removing diseased or nodulated bones from the nasal cavities. The great advantage of these side cutting instruments, especially in the nose, is that they do away with the to-and-fro movement of the saw and obviate the danger of cutting or injuring other tissue. The to-and-fro movement of the saw, driven by an engine through the connection of a pitman wheel and bar, was used by the writer some

twelve years ago, but this character of a saw was not found to be satisfactory.

Figs. 7 and 8 are for resection of long bones, as of the femur in any part of its length, or even at the head while in the acetabulum. This form of instrument makes very fine drills. Burs of various sizes and shapes (Fig. 9) are made by increasing the number of spiral tooth blades in definite relation to the size of the cutting instrument required.

Fig. 10 represents a bur five-sixteenths of an inch in diameter. The cutting end is somewhat convex, and sides parallel, which prevents the instrument from binding. Smaller instruments of the same character are also used in mastoid trephining; when the opening made is not wide enough it can be enlarged by the side cutting portion of bur.

In the last paragraph of Dr. De Vilbiss' paper he says: "It is true, in making the mastoid operation the use of the drill has been condemned, but the

Fig. 10. Fig. 6. Fig. 9. Fig. 7. Fig. 8.

reason for it is this; that until now there has been no convenient way of running with speed a drill large enough, with precision as to depth, to make a sufficient opening." Prof. Garretson has used an engine before a large class in his clinics, and in his private practice, for at least fourteen years, which drives various sized drills and side-cutting burs up to the size of three-eighths of an inch in diameter, at the rate of from 8,000 to 10,000 revolutions per minute. Guards have also been used with some of the drills, but they are usually in the way. A few weeks ago the writer removed a diseased portion of the mastoid process of the temporal bone down to the membranes of the brain, depending only on tactile recognition. For opening into the frontal, maxillary, or any other sinuses, or, in case of osteomyelitis, guards would be very much in the way, and as no two bones are of the same thickness the guards are practically useless.

The secure fixation of the cutting instrument in the hand-piece is an obvious necessity, as any failure in this respect during an operation might possibly lead to disastrous results. In the improved surgical engine here described, the instruments pass completely through the hand-piece and are fastened in by the thumb-screw, Fig. 1 M. These chucks are made of two kinds, one to hold instruments of the size of the ordinary dental burs; the other, and the more important one for surgical work, holds instruments that are many times larger and longer in the shafts, and are held absolutely secure.

To accomplish the drilling or trephining through bones into cavities, without injuring the tissue below, the hand-piece of the engine must be free from all vibration or interference of any kind. Then the educated hand of the surgeon will distinguish the depth and character of tissue being cut.

The writer would discard all mechanical guards for drills, burs and trephines, and would indorse the following from Dr. De Vilbiss: "The surgeon must educate his hands how to execute that which he theoretically knows."

A number of the *Medical News* (April 23, 1893,) contains an article upon

"Closure of the Ear by Growths of Bone; Removal of Bony Obstructions; Cure of Otorrhea and of Deafness. Three Cases; Description of Operations, Instruments, etc." By Robert Barclay, A.M., M.D., St. Louis, Mo., in which, speaking of past and present methods for the surgical treatment of these cases, he says:

"To those afflicted with the disease in former days, grave must have been the prognosis declared, to compel, as it did, their submission to the intense and prolonged agony inevitable upon the surgical operation before the days of anesthesia and perfected mechanical arts.

"Consider, on the other hand, the manifold advantages of our modern method of dealing with such aurai bony growths by means of the dental engine. In operating with this instrument, the hand-piece may be held and guided like a pen, skill and attention being addressed principally to directing the reamer or bur, inasmuch as this operates with but slight manual pressure, mainly by the rapid revolution of its cutting edges. A little experience in the use of the dental engine and drill is sufficient to educate the operator in determining by touch and resistance the nature or condition of the tissue upon which the tool is operating, thereby affording another and more reliable indication as to the desirability of extending or terminating the process of operation at that particular spot. With this there is a minimum of risk of injury to contiguous or neighboring healthy parts through direct or through transmitted force. In careful hands this instrument can not slip away or plunge. No concussion, no cracking, no roughness, no projecting splinters, no splinters of bone,—only a smooth, clean cut surface marks its trail."

THE DIAGNOSTIC VALUE OF EHRlich'S DIAZO REACTION.

Inaugural Thesis read before the Minnesota Academy, Nov. 1, 1893.

BY CHAS. L. GREENE, M. D.

PROFESSOR OF SURGICAL ANATOMY IN THE UNIVERSITY OF MINNESOTA.

More than ten years have elapsed since Ehrlich announced the discovery of an urinary test which should determine the presence or absence of typhoid fever; yet up to this time the members of the medical profession of our country have not determined its proper place in our diagnostic armamentarium.

The importance of such a discovery, if genuine, makes this apathy seem at first glance almost inexplicable, but reference to the literature upon the subject offers a ready and sufficient explanation. It would seem a very easy matter for scientific observers to arrive at harmonious results in the performance of a simple experiment terminating in a definite color reaction, yet we find in the published accounts of these observations, statements so contradictory and confusing as to lead one to believe that scientific accuracy in this department at least is little better than a name. Carelessness in diagnosis and utter disregard for the instructions of Ehrlich, as to the manner of making a test, account in a considerable measure for the discrepancies of statement, but it is per-

haps the failure to insist upon the appearance of the proper color in the reaction which has caused most of the error.

The discovery of this reaction was in a measure accidental, Ehrlich being engaged at the time (1882) in an effort to isolate some of the unknown aromatic bodies of the urine by the use of the diazo compounds, substances so named by Peter Griess, their discoverer, who obtained them by treating amido derivatives of the hydro-carbons with nitrous acid in a nascent state. These bodies, extremely unstable, enter readily into combination with a large number of substances. The chemical chosen by Ehrlich as being cheap and easily obtained was sulfanilic acid, which when treated with nitrous acid in a nascent state, forms in solution diazo-benzine sulphonic acid. The following are the formulæ at present recommended:

Solution 1.	Hydrochloric acid C. P.	50.
	Aqua distillata Q. S.	1000.
	Sulfanilic acid ad. sat.	
Solution 2.	Solution sodium nitrite	½%
Test solution.	Solution No. 1	40
	Solution No. 2	1.

Mix.

This last solution should be freshly made each day. Solution No. 2 should be kept in a black bottle and in a cool place, being renewed at intervals of thirty days.

Ehrlich's original instructions have been modified somewhat and he now directs that, before testing, the urine should be diluted with absolute alcohol in the proportion of one volume of the former to five or six of the latter, then filtering and adding test solution to filtrate, lastly adding an excess of ammonia. For delicacy and greater rapidity of work, however, the method of Chas. E. Simon is much to be preferred, and has been used in most of the tests described in this paper. It is applied in the following manner:

Equal parts of the test solution and urine are thoroughly mixed in a small test-tube, then 1 or 2 c.c. of ammonia water are allowed to flow gently from a pipette down the sides of the tube so as to overlay the mixture. If the reaction be present, there appears at the zone of contact a beautiful colored band, and this color is apparently the rock upon which most observers have split. It is best described as carmine or blood red. Please note, particularly, that it is not yellow nor yet orange, nor should there in the opinion of the writer, be any material admixture of these colors, for were this rule adhered to order would arise from chaos, and we would not find an observer like Rutimeyer stating that the reaction is almost invariably present in a certain disease, and wrecking his observation by adding that the characteristic reaction in such cases is a yellow color. Another possible source of error arises in the presence of an excess of phosphates, the addition of a few drops of acetic acid often bringing out strongly a color reaction previously indistinct.

As to the diseases in which the reaction occurs, one can only say that the reports of the most careful and scientific observers including Ehrlich, himself, show the reaction to be present in typhoid, pulmonary tuberculosis and the exanthemata, while other observers have reported it as being present in practically every disease known to the medical profession. In view of these discrepancies of statement, therefore, this paper will be based absolutely upon the writer's own experience; as shown by the accompanying list of cases in which careful and painstaking tests were made with the sole object of ascertain-

ing the value or worthlessness of the reaction in diagnosis. The urines of about two hundred and fifty cases have been carefully examined with fairly uniform results as the following tables will demonstrate. Care has been taken to use only *fresh specimens* and a fresh and reliable test solution exactly measured. No oranges or yellows have been recognized, a well-defined carmine or blood red band being insisted upon in all cases. So, also, doubtful diagnoses have been excluded. What, then, is the result and what the inference to be drawn? We may properly dwell

for the most part upon its relation to typhoid fever, and I wish to emphasize the fact that in nineteen early cases diagnosed by general symptoms as typhoid the reaction is found to be present in eighteen. In the one case remaining, the diagnosis was changed to malarial fever. In eighteen out of nineteen cases, therefore, the reaction was present, and allowing for possible error in diagnosis we may fairly claim that Ehrlich's reaction is uniformly present in this disease. It was found as early as the fourth day and as late as the end of the third week. Its intensity apparently keeps pace with the virulence of the infection and it will probably be found to reappear in true relapse. It is quite possible, therefore, that its intensity and persistence may give a hint as to our prognosis. You will note, also, that in twenty-five

cases of pulmonary phthisis it was present in twenty-three.¹ It must be stated, however, that these cases were for the greater part advanced in the third stage. In such advanced cases, therefore, the reaction may be said to be constant; the two cases of hip joint disease were far advanced and there was considerable septic intoxication. It may easily be that the same element of sepsis was acting in the cases of advanced phthisis before referred to. In two well marked cases of tuberculosis of the prostate in which diagnosis was confirmed by the demonstration of bacilli in the urine the reaction was absent. The relation of the reaction to tubercular diseases must be predicated upon a far more careful and extended series of diagnoses and examinations than are available at the present time. Proceeding to the exanthematous diseases we note its constant presence; also its occasional presence in tertiary syphilis and its still greater frequency in the secondary stage. Here, in fact, an almost typical reaction was obtained in every case examined, though only four of the six were admitted to the table as being absolutely above suspicion.

It is interesting to note the presence of the reaction or one indistinguishable from it in diabetes mellitus, due to action of the acid upon glucose.

Its absence in a well marked and fatal case of tetanus was somewhat surprising and the fact that the cases of malaria, acute rheumatism, and the simple diarrheas failed to show it is certainly of diagnostic importance. Septicemia does, and lobar pneumonia may give, the reaction.

In view of these facts, let us discuss at this time more particularly the value of this test in the diagnosis of typhoid; that disease of which Jaccoud has spoken as "being to-day one of the most difficult of medical problems." We seem really to have made but little advance since the day of Louis so far as our means of diagnosis are concerned. Consider, for a moment, a few of the prominent symptoms which we now hold to be diagnostic; first, the prodromal symptoms; often difficult to elicit, inconstant and indefinite to the last degree; then that "characteristic" temperature chart, so beautifully demonstrated in the text-books, but of which a typical case will rank almost as a curiosity in the wards of our Northwestern Hospitals; or, take the abdominal tenderness and gurgling symptoms which may exist in any diarrheal affection; the enlarged spleen, not always so easy to demonstrate as the text-books would lead us to imagine in a disease so frequently associated with tympanites and, moreover, common to malaria, tuberculosis, pyemia and typhoid; a rash which does not appear until the eighth or ninth day, somewhat variable and elusive in its manifestations and lacking in 20 per cent. of our cases. Even the characteristic bacillus fails to give us that positive aid in diagnosis which we might reasonably expect, for even Sternberg admits that none but bacteriologic experts can, even with reasonable certainty differentiate it from its compatriots, either by the simpler method of staining and direct microscopic examination or by more elaborate culture methods. Indeed, no better evidence of the paucity of our diagnostic resources could be produced than is to be found in recently published articles in our medical journals upon this topic. Montifusco considers a local rise of temperature in the region of the right iliac fossa, spleen and kidneys to be of the utmost diagnostic importance, Filipovitch and Skio-

¹ See supplementary remarks.

nevski have noted as peculiar to this disease a certain induration and yellowish tint on the exposed plantar and palmar surfaces, while Baruch believes that diagnosis may be predicated upon the resistance of the rectal temperature to a bath of 75° F. continued for fifteen minutes with friction. Probably almost any medical man reading these articles would be inclined to put these statements to the test when occasion might offer, yet it is unlikely that they have a fractional part of the importance of the diazo reaction. Are we then so well equipped as to rightly throw aside a means of diagnosis which seems to be the equal of any we now possess in positive value, and superior as a practical negative sign? For while the writer would not claim that Ehrlich's reaction is pathognomonic of typhoid, he nevertheless feels safe in saying that any case in which this does not appear should not be called typhoid, and if further experimentation shall continue to show that the reaction is absent in malarial fever, simple febrile diarrheas and acute rheumatism, its claim as a valuable aid to differential diagnosis will be established.

Please note, also, that the reaction may precede the roseola by full five or even seven days, a point of the utmost importance to patient and physician.

One is prepared to hear the reaction denounced as valueless because it is found in a considerable number of diseases, but such a criticism is both weak and unfair, for no other antemortem sign of typhoid fever is peculiar to it alone, and we should not deny the value of the diazo because it in a measure follows this general rule of our symptomatology. No other sign is more definite and constant. Shall we deny the importance of albuminuria as a symptom, because it is incident to a variety of pathologic conditions? We should not insist that our reaction must differentiate typhoid fever from all other diseases, before admitting its value as a clinical sign; on the contrary we ought to give it due credit for the large amount of assistance which it bids fair to give us.

We may fairly hope that it will be of great service in differentiating typhoid from malaria, acute rheumatism and the simple fevers with diarrhea. Opportunities for testing the reaction of appendicitis have not yet presented themselves to the writer.

To sum up, then, this much neglected reaction gives us in typhoid fever much positive, a considerable amount of differential, and a very large amount of negative information. It is not in accord with the high standing of our practitioners in this Section that this method is not at the present time on trial in all of our hospital wards, and without asking that you accept these views as your own, the writer would earnestly urge all present to make use of the test, feeling confident that their trouble will be well and fully repaid. Materials are cheap and easily obtained, the formulæ are practical and simple, but to obtain good and uniform results the following rules should be strictly observed: 1, *Freshly passed specimens of acid urine must be used, decomposed urine being discarded, and all alkaline or neutral urines acidified.*

2. No color but red should be accepted.

3. The test solution should be freshly prepared for each day's use and measured with extreme care.

4. Sodium nitrite solution should be renewed frequently and kept from light and heat.

5. Finally, and most important of all, the exact method of procedure must be carefully followed out in every

detail on the lines heretofore laid down. One might add, be absolutely certain of your diagnosis before you criticize the test. For it has again and again proven the error of a hasty diagnosis. The experiments of which this paper is the record have but the limited value of a preliminary report; they should be extended and multiplied, and the results carefully analyzed, before we may pass finally upon the merits of the test. The writer can only speak for himself, when he states positively that the test has been and is now of very considerable value to him, personally, in his clinical work, and having previously been a skeptic it is possibly with the added fervor of the proselyte that he urges its more general adoption.

SUPPLEMENTARY REPORT OF THE RESULTS OBTAINED BY A MODIFICATION OF EHRlich'S METHOD OF TESTING THE URINE IN TYPHOID FEVER.

The reading of my original paper having been postponed, I have occupied the intervening time in making new tests for the further extension of my tables, and in the hope of more sharply defining the limits of occurrence of the diazo reaction. For some time I have felt convinced that such a change in the test solutions might be made as would eliminate some of the doubtful reactions, and possibly show that in tuberculosis, etc., there were either qualitative or quantitative differences acting to obscure the results. Using a concentrated test solution with the sodium nitrite in excess, I found the reaction or one closely resembling it even in normal urine, and acting upon this hint the process was reversed, and instead of the 1:40 solution prescribed by the authorities I have used a solution containing but one part No. 2 to 100 parts No. 1, and find that by so doing the oranges and mixed reds and yellows mostly disappear. Pulmonary tuberculosis and pneumonia fail to yield a reaction, while it remains distinct and perfectly defined in septicemia, typhoid and advanced malignant disease. The following table will show the result of the modified test:

TABLE II.

	Cases.	Plus.	Minus.
Typhoid	10	10	0
Septicemia	3	0	3
Varicella	1	0	1
Typhoid relapse	2	2	0
Pseudo-relapse	1	0	1
Scarlatina	1	0	1
Phthisis pulmonalis	12	0	12
Lobar pneumonia	3	0	3
Febrile diarrheas	2	0	2
Pleurisy	2	0	2
Syphilis—second stage	3	0	3
—third stage	2	0	2
Malarial fever	2	0	2
Carcinoma advanced	2	2	0
Chronic rheumatism	3	0	3
Simple anemia	1	0	1
Heart disease	4	0	4
Chronic nephritis	6	0	6
Tuberculosis of hip and elbow joints	1	0	1
Arterio sclerosis	2	0	2
Cirrhosis of liver	2	0	2
Oxaluria	3	0	3
Gastric ulcer	1	0	1
Acute bronchitis	2	0	2
Chronic constipation	1	0	1
	75		

You will note that by this method of testing

typhoid fever, cancer and septicemia alone give the reaction. It is probable that the severer exanthemata would also show it. In typhoid it was found present as early as the third day, and persists as long as fever is present. *It positively does not occur in lobar pneumonia or pulmonary tuberculosis*, if this method of testing be used, though present in both diseases when the 1:40 solution is used. This modification would seem therefore to add considerably to the value of the test, both in direct and differential diagnosis, and still more strongly suggests its utility in general diagnosis. You will note, for example, that it does not occur in chickenpox, while it has been invariably reported as present in variola. That it is absent in rotheln though present in measles, while its appearance in cases of malignant disease, if shown to be constant, would be of the greatest value in the diagnosis of obscure abdominal affections and the differentiation of malignant and benign growths. In typhoid relapse, as in the original disease, I have found it present as early as the third day of temperature. Before closing, I desire to emphasize the importance of verifying the color test by shaking and carefully noting the appearance of the surface foam. If the reaction be present, this foam invariably shows a delicate pink or rose-red coloration, while in doubtful or negative cases the foam is yellow. This little expedient greatly simplifies the test. I sincerely trust that further reports upon this matter will be forthcoming, and am positive that the verdict founded upon actual experience will be favorable to the test.

INEBRIETY.

BY W. P. HOWLE, M.D.
ORAN, MO.

I am just through reading a paper by R. M. Wigginton, M.D., of Waukesha, Wis. He refers to his Missouri friend, meaning me, because I do not believe with him that "the drink habit," is a *disease*. His reasons, as given in his paper, for believing that it is a disease are many, well stated and seemingly true, but he, like other men who have a theory they wish others to believe, presents only one side of the question. They never mention facts that would seem to contradict their views. I will now state a few reasons why I do not believe in this modern theory. I say modern, because, as far as I know, this theory is of recent date. Drunkenness or inebriety has for centuries been looked upon as a *vice* and all governments of which I have any knowledge have laws to prohibit inebriety and penalties for violation of said laws. Our Government is not an exception, but I do not believe there is any law to punish men for becoming ill. Every citizen has a legal right to be sick. The law-making power makes quite a distinction between the two conditions. It follows from this, that the ablest men in our Government do not consider inebriety a disease. Legislators for centuries have said by their acts: Inebriety is a vice and not a disease (as some of the learned medical men would have us believe). The Doctor says: "It is generally conceded by the scientific world that inebriety is a disease." Why, then, does the scientific world not convince the law-making power that such is true?

The senators and congressmen of our Government are thought to be our ablest men. You do not hear them saying anything about inebriety being a dis-

ease. If you were to approach one of them who goes on an occasional jag and tell him he was diseased and not fit to be a senator, but ought to be sent to some asylum for inebriates, you would see how much he believed in this modern fad. Every believer in this theory knows of one or more of his neighbors who have gone to every extreme which drunkenness will induce, and who have reformed, lived on in the same neighborhood, become good citizens, had the confidence of all, who never took a dose of medicine for this so-called disease. Will any of you please point out just what ailed these men? You assert that the drunkard is diseased in every cell and has no moral power. If so, how did these, your neighbors, reform? Can a man who has no moral power reform; and if these reformed men are diseased, why do they not show some manifestation of disease? They eat, drink, sleep and work like well men. They have normal temperature, circulation and digestion; are men mentally able to practice medicine, law, or preach the Gospel; can do any kind of business they are called upon to do. You say they are diseased. How do you know? I venture the assertion (I believe it is a fact) that more men have been reformed by moral suasion than in any other way. If moral suasion will cure disease, and especially one so serious as my opponents make inebriety to be, why will it not have at least some effect in other maladies? I believe large quantities of alcohol taken into the stomach would produce gastritis. Now will any one assert that moral suasion would have any effect on gastritis? So I might enumerate the whole catalogue of diseases produced by excessive drinking, and moral suasion would never be thought of as a remedy. Yet by moral suasion, alone, the worst drunkards on record have been reformed and restored to usefulness. No man can explain this process from a standpoint of *disease and cure*.

Suppose some of my opponents should claim that they were having wonderful success in curing pneumonia, and say they were using only *moral suasion*. Would they not be called cranks? There is as much sense displayed in such a claim as there is in saying inebriety is a *disease*, and moral suasion will cure more cases than any other one remedy. No one will pretend to deny that the drink habit is being cured every day by moral suasion—also by religious influence. Now, this being true, if the drink habit is a disease and religious influence will cure it, it follows that religious influence has power to change diseased cells into healthy ones, and having this power would be a sovereign remedy in disease, but the medical profession have "sat down" very hard on the christian science frauds. They hoot at *faith cures*, but if their theory is true, the faith cure gentlemen ought to have due credit for their work. Christian science has a right to a top seat if inebriety is a disease. Why? Because religion cures more drunkards than medicine cures. But the facts in the case are these: The drink habit is *not* a disease and the so-called christian science is a fraud, and this argument knocks the *disease* side of the question into a "cocked hat." Now for a few reasons why this theory won't go: It is contrary to the teachings of the Bible and the justice of God. The Bible says: "No drunkard shall inherit the Kingdom of Heaven." Would the God of Heaven shut the gates against sick people? If God had not considered drunkenness a crime He would never have issued a decree against it. Ask

any man who gets drunk whether he considers it right or wrong? Ask him what the Bible says about it? Let every reader ask himself what he thinks about it, and my word for it the universal verdict will be: Drunkenness is a vice, a sin against God's commandments and against one's own present and future happiness. If the Bible teaches truly, it is evident that inebriety is a sin and not a disease.

A word or two as to heredity and I am done. A man may inherit an *appetite* for whisky, but craving an article is not possession of it. A man may want many things that he will never get. A man must drink to become a drunkard. A born drunkard is a misnomer. A man must eat to become a glutton. He must smoke to become a cigarette fiend. My opponents have the cart before the horse. They say the man drinks because he is sick. I say he is sick after he drinks, not before. They say illness caused the drinking. I say the drinking caused the illness. I do not expect to convince them of their error, but write only in defense of what I believe.

A CASE OF DIPHTHEROID CHANCRE ON THE POSTERIOR WALL OF THE PHARYNX.

BY JAMES HARVEY RAYMOND, M.D.
CHICAGO.

Instructor in Surgical Pathology in Rush Medical College; Assistant to the Clinic Department, Nose, Throat and Chest, Rush Medical College; Attending Physician at Central Free Dispensary Department, Nose, Throat and Chest.

A chancre is the primary lesion of syphilis, which makes its appearance at the seat of inoculation, usually from twenty-one to thirty days after contact with the essential cause of the disease, which at the present time is not definitely known.

The physician who has had the opportunity of observing patients suffering with the disease in its various phases, skeptical though he may be, must yield to the preponderance of clinical evidence, which favors the consideration of this being a disease caused by microorganisms or their ptomaines.

This theory is strongly supported by the fact that certain phases of the disease or its deleterious effects upon the tissues of the body, produce pathologic conditions analogous in character to other well-known diseases of microbic origin, viz.: yaws, glanders and other granulomata. While the clouds of uncertainty are hanging over us regarding this disease, the search light is still in the hands of modern pathologists who by patient and diligent scientific research, it is hoped, will soon point out and prove positively its true cause.

Reviewing the etiology of syphilis, we find foremost among those who have studied by experimental research and have expounded the theory of microbic infection, the names of Lustgarten, Doutrelepoint and Schutz; Matterstock, Markuse, Andromico, Zeissl, Marcus, Disse and Taguchi; Eve and Klebs. (Senn, *Surgical Bacteriology*, 2d edition, pp. 243-246.)

But none of the above pathologists have satisfactorily shown the constancy of the microbe they claim as the cause, and as no uniform results have been obtained we are still in the dark, and the true etiology remains to be shown by future investigation.

A chancre may exist on any part of the cutaneous or mucous surface of the body;—the most common seat is on the penis, glans, prepuce or urethra. It is

also found about the anus, lips, mouth, tongue, palatine arches, tonsils, cheek, nipples, etc. It is the *extra genital* class that is the subject of this article and that is by far of greater interest to us from a diagnostic point of view, as its somewhat varying and peculiar characteristics are too apt to be overlooked by the inexperienced or busy practitioner of medicine, or taken for a more simple ailment, the patient thereby being allowed to harbor an affection that sooner or later will claim him as a victim of its ravages and perchance cause like suffering in many others.

The macroscopic appearance and consistency of a chancre vary according to its anatomic situation; it makes its initial appearance in the form of a small papule, hard and painless, gradually enlarging and becoming more indurated, especially about the edges, until finally it presents the appearance of a hard, circumscribed mass, the center of which is somewhat depressed.

When it is found upon mucous surfaces, e. g., in the mouth, it appears as a patch, white or yellowish gray in color, circumscribed, and elevated above

a. Ulcerative surface. b. Epithelial edge. c. Dense small cell infiltration. d. Lymphatics encompassing an artery, filled with small round cells.

the surrounding tissue and presenting a variable degree of induration about its edges and base. When the tissue about the center becomes favorable for the growth of pus microbes, the center becomes cup-shaped, due to the ulcerative process extending downward, and contains the histologic elements of pus.

Microscopic examination of chancre reveals a dense, small, round cell infiltration of the tissue, which by pressure from beneath towards a point of low resistance, causes the upper stratum to become greatly attenuated at the center of the lesion, the atrium of infection. About the edges the papillæ of the derma are seen to be hypertrophied, the tunica adventitia of the blood vessels is sclerosed and the lymph spaces become filled with round cells. As the process of the proliferation continues, the cells, owing to the weakened condition of the tissues at the center, work their way towards the surface and very often burst through, causing a granular excoriated or abraded appearance.

The amount of induration about the edges is due to the degree of hypertrophy of the tissue and sclerosis of the tunica adventitia of the vessels in the

papillæ, together with the concomitant round cell infiltration of the adjacent lymphatics and peri-vascular tissue. Various kinds of bacteria are found, and can be seen in great abundance, and if ulceration takes place, it is caused by the specific action of pyogenic microorganisms upon the histologic elements of the lesion, which furnish a favorable medium for their growth and multiplication.

A rare variety of the initial lesion of syphilis is the diphtheroid chancre of Dr. Morrow, in which a large portion of the glans penis is covered with a glistening grayish-white coating of a leathery consistency, simulating in all its characters a diphtheritic exudation. He states that in one case in which a patient confessed the rôle *fellatrix*, the appearance of the throat suggested a malignant diphtheria, though lacking adherent membrane. Clerc, also, has observed this form of lesion and describes it: "As a kind of false membrane presenting some resemblance to the diphtheritic patches, which characterize certain forms of syphilitic symptoms, affecting mucous membranes, but usually occupies only the center of the chancre, its edges shading off into a reddish circumference."

Cornil found in the transparent fluid on the surface of a chancre, pus corpuscles, fine albuminous or fatty granules, very small spores separate or forming rows, rod-shaped bacteria and corneous cells of the rete mucosum undergoing destruction.

The frequency with which the extra genital chancre is found in the throat, in the practice of the average physician, may be estimated from the reports made during the past few years by the following syphilologists and laryngologists. The late Sir Morell McKenzie in all his extensive experience met with but seven cases of chancre of the pharynx, and states: "The rarity of chancre of the pharynx may be estimated from the fact that of 673 examples of chancre in all situations, not one was found behind the anterior pillars of the fauces."

The primary lesion of syphilis, when situated in the pharynx, is most always found on one of the tonsils. Desnos attributes this to the structure of these glands, the lacunæ of which are likely to receive and retain the syphilitic virus when introduced into the throat.

Dr. Morrow, in his most excellent work on syphilology, of recent publication, says that chancre of this region is most frequently found on the tonsil, the posterior wall of the pharynx being most singularly exempt.

Diday met with eight cases of chancre of the tonsil.

Dr. L. D. Buckley of New York, (*New York Medical Record*, May 27, 1893, p. 645) states that in twenty years of practice more than two thousand cases of syphilis came under his observation, 5 per cent. of which were extra genital, fifteen of these being found on the tonsil.

Dr. Cæsar Boeck states that in Norway, chancre of the pharynx is next in frequency to the genital regions, attributing this to the customs of living, having observed one large family all using the same spoon, without cleansing. M. S. Usass showed at a recent meeting of the St. Petersburg Russian Syphilological and Dermatological Society, a married woman, age 41, with chancre of the right tonsil and posterior pillar of the fauces. A. I. Budngoff also presented a recruit, age 24, and S. Serdnekoff relates

two cases of chancre of the tonsil, with chancre of the right tonsil. Neuman saw but one case, of eighty-eight extra genital chancres; eight were of the tonsil. Columbini of Sienna, and Cartaz of Paris, have recently reported cases of chancre in a similar location. It is said that the majority of cases of extra genital chancre are found on the lips and tongue, next in frequency the tonsils. But the rarest of all as shown by the foregoing facts and reports is that of the *posterior wall of the pharynx*. It is owing to the fact of its great rarity in this location, that I am pleased to be able to report a case, and add the notes made while the patient was under close observation.

Mr. F. came to the Chicago Polyclinic (Department Nose and Throat) for treatment; his age 31; unmarried. Had never had any disease, other than ailments incidental to childhood; had not been directly exposed to any infectious disease. Family history good. Three weeks previous felt a sensation of dryness and had a desire to hawk and clear the throat; was languid; appetite poor; had headache and considerable jactitation; felt slightly feverish. The following day he noticed a white patch the size of a nickel on the posterior wall of the pharynx in the median line, which seemed to be rapidly spreading and in less than twelve hours had extended down the pharynx into the naso-pharynx and on to the anterior pillars of the fauces.

This condition had continued three weeks, with no change of the above symptoms, except that the fever was higher, and deglutition painful, owing to soreness of throat. The appetite was very poor, voice hoarse and of marked nasal quality. Examination of the pharynx revealed the presence of a smooth yellowish-gray membrane, one-sixteenth of an inch in thickness, symmetrically covering the posterior wall of the pharynx, extending down about half an inch, and into the naso-pharynx one-third of an inch, and about a quarter of an inch on the anterior pillars of the fauces. It was quite adherent to the underlying tissues—the edges were elevated and the tissues about the periphery were greatly indurated and quite deeply congested. The tonsils were very slightly enlarged.

The membrane was removed with some difficulty and when detached gave rise to slight bleeding. When removed in toto, the floor upon which it had rested presented a faintly granular appearance, the edges of which were quite markedly indurated. There was no perceptible ulceration. The glands in the cervical region at the angle of the jaw on either side, were greatly enlarged. The temperature registered 101.3-5; pulse 92, regular, feeble. The appearance of the throat and clinical history, though not typical, seemed to justify at least a suspicion of diphtheria. The patient was isolated. The following treatment was instituted. Having used, with considerable success, in acute tonsillitis and pharyngitis pure guaiacol locally, it seemed rational to try it in this case, knowing its efficient antiseptic properties. I made the application at 5 P.M. on January 6, and saw the patient the following day at 1 P.M. The temperature was 98.6-10, pulse 90. Guaiacol was again applied and at 6 P.M. same day, pulse was 80, temperature 100. The patient had enjoyed a good night's rest—his headache had passed away and he felt very much improved. Guaiacol was continued five days, the temperature in the meantime ranging from 98.6-10 to 99; pulse 72 to 100.

R Ferri et quininae citratis, grs. iii.
Ext. nucis vomicae, grs. ss.

Was given before each meal and at bed time.

Guaiacol was withdrawn, after which the pain seemed more intense, pulse slightly accelerated and temperature elevated. At this time he complained of inability to swallow fluids readily on account of regurgitation into the nose. The nasal quality of voice seemed more perceptible and a well-marked paresis of the pharynx and palate had developed.

Antiseptic gargles, nasal douches and all other symptomatic treatment was promptly given, but from the start it seemed at best only palliative, there being no perceptible change either for better or worse.

The membrane was examined microscopically for the Klebes-Löffler bacillus; and cultivation experiments carried out—negative results. The case was examined by Dr. E. Fletcher Ingals who was of the opinion that it was very strongly suspicious of diphtheria. After having had the patient under close observation for two weeks, I noticed a

few personal peculiarities that to me were strange and suspicious. He was not effeminate in his appearance, but at times quite so in actions. About this time I noticed a friend, as he called him, his room-mate, whom I saw for the first time. He was very effeminate, both in appearance and actions and was the signal for arousing strong suspicions of the character of the patient. A typical papular syphiloderm shortly made its appearance over the entire body of the patient; one or two mucous patches were seen on the lips and mouth. The patient was confronted with the fact that his history was well known and asked at what time he had peculiarly exposed himself, according to the custom of a certain class of sexual perverts. He hesitated at first, but finally confessed that he had been addicted to these practices since childhood. Hydrargyri proto-iodid grs. $\frac{1}{4}$ t. i. d. was given, and in the course of ten days the subjective symptoms had completely subsided and the membrane disappeared.

Portions of the membrane had been prepared for microscopic examination in the following manner: After standing in dilute alcohol for a few days thin sections were made. When these were carefully teased with needles, they were found to be torn with considerable difficulty, and were quite elastic. A section was stained with fuchsine, mounted and examined with a high power, and was seen to consist

Fig. 2.—Central portion of membrane from diphtheroid chancre of posterior wall of pharynx, five weeks after its initial appearance.—J. H. Raymond.

A. Dense round cell infiltration. B. Fibrinous reticulum. C. Large rod-shaped bacteria. D. Pus corpuscles. E. Streptococci. F. Colonies of staphylococci.

of a dense felt-like mass of fibrils. Upon examination at the edges of very small fragments, obtained by teasing, the fibrils are seen to divide and sub-divide into short branching prolongations, resembling stag horns. This reticulum, fibrinous in character is no doubt fibrin. A certain amount of coagulation necrosis attends the formation of fibrinous organization wherever met, e. g. pleuritic exudate. Densely infiltrating this reticulum can be seen small round cells. A few streptococci, colonies of staphylococci, pus corpuscles and a great many rod-shaped bacteria are also present.

From the clinical facts and microscopic findings in this case, which are identical with the histologic elements of chancre as given by Cornil, Hamilton and others, and the fact that there was a prompt response to anti-syphilitic treatment, I am confident that we have been dealing from the start with a case of diphtheroid chancre of the posterior wall of the pharynx.

36 Washington Street.

REGISTRATION OF TUBERCULOSIS.

Special meeting of the College of Physicians and Surgeons of Philadelphia, held Jan. 12, 1894, the President, S. WEIR MITCHELL, M. D., in the Chair.

TO CONSIDER THE PROPOSED ACTION OF THE BOARD OF HEALTH IN REFERENCE TO THE REGISTRATION OF TUBERCULOSIS.

(Continued from page 226).

DR. WILLIAM OSLEA, Baltimore—The question may be thus briefly stated:

1. Following a primary law of parasitism, the bacillus tuberculosis frequents chiefly that organ in its host which communicates most freely with the exterior. Just as countless thousands of ova are thrown off from the intestine of the bearer of a tapeworm, so from tuberculous lungs in a state of softening and cavity formation, countless millions of bacilli are cast out daily with the sputa.

2. The widespread diffusion of the parasite outside of the body has been demonstrated in the infectiveness of the dust and of the scrapings of the walls of rooms and wards occupied by patients with pulmonary consumption. Moreover, the greater prevalence of tuberculosis in crowded communities, the enormous mortality from the disease in prisons and institutions, and its frequent occurrence as a house malady, suggest that the conditions favoring its continuance are those which foster the growth and spread of a specific contagion.

3. In the language of parasitology the lungs constitute the chief seat of election! But, apart also from gross pulmonary lesions, the proportion of autopsies in which the bronchial glands are found tuberculous, speaks unmistakably for direct infection in the exercise of their function as dust filters.

On these grounds I believe that the registration of pulmonary tuberculosis would be beneficial—enforcing attention to those sanitary details so apt to be slighted or overlooked, and diminishing directly the danger of contagion in the community.

Infection through food is closely related also to the endemic prevalence of tuberculosis. The incidence of the disease in the mesenteric glands of infants indicates that the gastro-intestinal canal is a portal of infection only a little less wide than that of the respiratory system.

The question of tuberculosis is not, however, settled with the disinfection of the sputa of consumptive patients.

The hereditary transmission of the disease must be accepted, though an estimate of the frequency of this mode of infection must necessarily be uncertain, but for certain forms Baumgarten's theory of latency is particularly suggestive. Tuberculosis has been well called the *pébrine* of the human race. The analogy is striking, for not only as you will remember, is the parasite of the silkworm disease transmitted by direct contagion, but it also infects the eggs, which hatch and may pass through various stages of development before they are finally destroyed.

Lastly, and here is consolation, the conditions which render individuals more or less immune scarcely yield in importance to those which maintain the vitality of the tubercle bacilli in a community. So widespread is the seed that few of us escape infection, and the statistics of the Paris morgue show that in more than 50 per cent. of adults the germs not only gain an entrance, but actually effect a lodgment. As a factor in tuberculosis, the *soil*, then, has a value equal almost to that which relates to the *seed*, and in taking measures to limit the diffusion of the parasite let us not forget the importance to the possible host of combating inherited weakness, of removing acquired debility, and of maintaining the nutrition at a standard of aggressive activity.

DR. H. C. WOOD—I came here not to speak but to learn, and thus far have been quite successful. I wish to quote a letter from Dr. Billings which has been placed in my hands. He says: "I should like very much to hear the discussion, but probably should have little to say, since I am doubtful as to what the decision of the College should be on this point. I presume that there are about six thousand people in Philadelphia affected with consumption, and that a considerable proportion of these have contracted the disease in infected houses. If it were possible by a systematic notification for the Board of Health to locate a considerable number of these infected houses, what steps would it take to purify them? How would it deal with those of the poorer classes who are affected with this disease, and with their furniture, bedding and rooms? Until these questions are

answered, I do not find it possible to form a definite opinion as to whether it is worth while to put in force a compulsory system of notification. Some of the worst infected rooms are probably those occupied by the criminal class, which is especially liable to this disease. For example, the Eastern Penitentiary is certainly thus infected; but in this I presume the Board has no jurisdiction.

"It occurs to me, that if the system of notification is to be tried, it might be best to commence with a limited area of the city in which the death-rate is now high; for example, the Seventeenth or the Seventh Ward, and see what results in diminishing the proportion of cases in this area can be obtained in the course of two or three years."

This thought has occurred to me, and has not been touched upon by any of the speakers. In a case of diphtheria the Board of Health is notified. The patient dies or gets well and the room is disinfected. Suppose, however, a case of consumption; the Board of Health is notified, the house is disinfected to-day but reinfection occurs tomorrow, and the end need not come for four or five years. Unless you add the power to forcibly remove the patient and shut him up in a hospital-jail where you can confine and permanently disinfect him, I do not see how you are going to get any good results from the process of disinfection. As far as disinfection goes, unless you can prevent to-morrow's reinfection, I see little use in to-day's disinfection. If, however, the Board of Health could disinfect houses in which phthisic cases have died, something might be achieved, but the ordinary death notice is all the notification required for this.

DR. THOMAS J. MAYS—In the charts which are presented to us it is to be noted that the disease is less frequent in those parts of the Fifth Ward in the neighborhood of Spruce and Pine Streets, and becomes more prevalent as we approach the poorer portion of the city. Dr. Flick's investigations extended over only a limited period of time, say twenty-five years. In that time he finds that about 25 per cent. of the houses in the Fifth Ward have become infected. I hold that if the investigations had extended over a longer period—say fifty, seventy-five, one hundred, or one hundred and twenty-five years—he would have been able to show that nearly every house in that ward was infected, according to the contagion theory, that in nearly every house in that ward a consumptive had lived and died. The same argument holds against the investigations made in New Haven. I have in my possession a book reporting similar investigations made by Dr. Riffel in two old towns along the Rhine in Germany. He investigated the death-rate from phthisis in these towns for fifty, seventy-five, one hundred, and in some cases one hundred and fifty years back. He found that in one town at least—Karlsdorf—that at some time or other nearly every house had had a case of phthisis in it. I think the same thing would hold in regard to the Fifth Ward of this city if the statistics extended back sufficiently long. But as these only cover a period of about twenty-five or thirty years this is out of the question.

Dr. Flick also refers to the diminution of the phthisis mortality in Berlin, London and Philadelphia. I think that if he had consulted the death-rate from phthisis in these cities he would have found a gradual diminution in the death-rate from consumption before the bacillus area began in 1882. I went over this subject some years ago and I found that in every large city there was a gradual diminution in the death-rate. Dr. Flick claims that the diminution in the death-rate of consumption, since 1882, in this city has been due to the disinfection of the sputum. His own figures show, however, that there occurred a larger number of deaths from this disease during the nine years following 1882 than during the nine preceding years. In what way this makes a favorable showing for the theory of disinfection I am at a loss to understand. So far as I know there has been no Board of Health regulation in this city. So far as I know there has been no Board of Health regulation in Berlin, or London, or any other city, yet their deaths are gradually diminishing in number. If the gentlemen on the other side will look backward a hundred years they will find that the very experiment which they are so anxious to try now was tested with the utmost rigor, from 1782 to about 1855, in Naples. It was decreed that every physician who neglected to report a case be fined \$180; that the ceilings, walls, floors, doors, and windows of the room in which consumptives died be torn out and burned; that the bedding and furniture be also burned, and that such dwellings were not to be occupied for a year. The result was that the family with phthisis was shunned and driven to want. Houses in which consumptives died depreciated in value.

The sick were neglected and left to die inhumanly away from their families and friends. Did any good result from these laws? Brehmer states: "Concerning a diminution in the rate from phthisis in Naples the medical historians of that period are ignorant." According to Uffelmann (*Berlin klin. Wochenschrift*, 1883, p. 369) Dr. de Renzi, the medical historian of Italy, states that the injury which had been inflicted on Naples by these laws was simply indescribable and denounces the Neapolitan faculty in the severest terms for participating in their introduction.

In Vol. xlv., p. 112, of the *British and Foreign Medico-Chirurgical Review* it is stated that Drs. Spatuzzi and Somma, "who have paid great attention to the mortuary returns in that city (Naples, about 1860), affirm that one-sixth or a seventh of the whole mortality is due to phthisis," and that Dr. de Renzi "marvels greatly (in 1863) that the city of Naples is fully as much liable to phthisis as either London or Paris, though the salutary condition of the climate should render it far less common."

If the death-rate from consumption was the same in Naples at the time segregation ceased, as it was in other cities in which segregation was not practiced, it is self-evident that such a measure can have no influence in diminishing the death-rate from this disease.

DR. JAMES TYSON—I had intended to say something this evening on this important subject, but almost every point which occurred to me has been so well treated by others that I hesitate to add anything. I admit all that has been said with regard to the contagiousness of phthisis, as determined by experiment, but as to the actual spread of consumption from one person to another as the result of association—as to the degree of contagiousness, in a word—I agree entirely with Dr. Da Costa. Admitting the correctness of Dr. Flick's studies and Cornet's observations, it still comes to this, that the physician is competent to take care of this question without the intervention of the Board of Health. Just as the surgeon is qualified to take care of the matter of antiseptics and a sepsis in his management of surgical cases, so the physician is competent to take care of the disinfection utensils used by consumptives and the destruction of the germs which may be the cause of the disease, the more especially as such disinfection is acknowledged to be of the easiest kind. What Dr. Roberts has just said with regard to the situation ten years ago as to sepsis and antiseptics, could as well be alleged in favor of the position that I take—that the physician is competent to handle the difficulties. The surgeon did not call in the Board of Health to help him under like circumstances but fought the battle alone, and won it triumphantly. The question has been studied experimentally and chemically, and we know exactly where to put our fingers to check the spread of consumption as far as this is possible. We must attack the disease in two ways: 1, the contagion must be destroyed as far as possible with the means at our disposal; and 2, we must seek to change the soil on which it is known that the bacillus flourishes, by improving the general health of the individual, and thus increase his ability to repel the invader. I feel that we are entirely competent to handle this question without the aid of the Board of Health.

DR. ABBOTT—I have listened with much interest to both sides of the discussion, but must confess that I am not yet quite secure in my mind as to the proper course to be pursued. I am strongly inclined to the views expressed by Dr. Billings in his letter to the President. Tuberculosis is a widespread disease with manifold expressions, and if our efforts are to be directed against it, in the full sense of the term, the problem is certainly beset with many difficulties.

In connection with the subject under discussion, the question that has constantly presented itself to me is: If the College sees proper to recommend that all houses in which the disease is located be reported to the authorities, has it any guarantee that their conditions will be improved? The object in reporting these houses is to secure complete disinfection of them, a process requiring conscientious attention to most minute details, to say nothing of a full knowledge of the requirements of the cases. If the Board of Health is in a position to assure us that these demands can and will be met, then I am in favor of the resolution. If not, then we have had a long discussion with but little result.

The ultimate object arrived at in the resolution I consider as most desirable, but will it be attained if the resolution is passed? We have abundant evidence in justification of the belief that localities occupied by persons suffering from the pulmonary form of tuberculosis, particularly, may and do become centers of infection, and it is highly desirable that such places should receive the attention that their charac-

ter demands. Much has been said here this evening concerning the prevention of the spread of this disease by disinfecting the sputum, and this point has been accentuated as if the danger ended here. The danger does not end here. Sputum collected in a receptacle may remain perfectly harmless without disinfection or any other treatment whatever. The danger lies in the sputum *not* collected, but spat upon the floor, dried, ground into dust by the feet of passers-by, and ultimately inhaled into the lungs—a condition of affairs often seen in dwellings of the poor. The predominance of pulmonary tuberculosis over other manifestations of the disease is certainly, in part, accounted for in this way. Dr. Da Costa in his remarks has said that "bacilli" are everywhere present, and if this is the case how are we to escape them, etc.? His use of the term, bacilli, in its generic sense is misleading; I can hardly think he meant that *tubercle bacilli* were everywhere present, for this is not the case. They *may be* present everywhere that tuberculous individuals are present or have been present, but to say that they *are* present in all places does not accord with the results of observation.

DR. FRANK WOODBURY—The facts collected with so much commendable diligence by Dr. Flick are susceptible of quite another interpretation. They certainly do not prove consumption a contagious disease, or that the bacillus tuberculosis is its sole cause. If he had confined himself to the task of showing that want of sunlight, dampness and other mal-hygienic conditions were efficient causes of phthisis his data would have been equally applicable. Or if he had intended to prove that the habitations of some of the poorer inhabitants of this city were likely to act injuriously upon the occupants, so as to predispose them to phthisis, we might have been willing to go with him almost to any extent in making application to the Board of Health to destroy these sources of disease. We might admit that by adopting such drastic measures the mortality from tuberculosis would undoubtedly be greatly reduced. The total extinction of pulmonary consumption, under present conditions of civilized life, however, is entirely impracticable.

It may be admitted, if the proposed plan of registration and inspection were rigorously carried out, that the results would apparently support the claims of the author. The number of cases reported would certainly diminish to a remarkable degree; but the real explanation, however, of the diminution would be that a large number of cases would be concealed, and deaths would be reported as from other causes. Moreover, a large number of cases would object to the solicitude of the Board of Health for their welfare and leave the city. Physicians would have their sympathies appealed to by relatives, who might wish to conceal from the patient the fatal character of the malady, and would be in a dilemma between duty to their patients and duty to the State. In fact, registration would eventually divide physicians into classes—those who reported their consumptive patients and those who did not. The physicians having the reputation of not reporting their cases would naturally have a larger clientèle than others.

The discussion of the registration of consumption manifestly brings up the question of the nature of phthisis. It is true that there are other clinical conditions which resemble tuberculosis of the lungs and which are not due to the presence of tubercle bacilli. Assuming, however, for the moment that all cases of consumption are tubercular, we may ask how large a part in disseminating the disease is played by contagion? We know that Dr. Brush calls attention to an infected milk supply as the principal source of tuberculosis in our cities. Bowditch showed conclusively that dampness of the soil is a very powerful factor in the causation of phthisis. Other authors claim that it is mainly due to inheritance. If these views may be regarded as well established, then the infection sinks to a secondary place. If tuberculosis is the *pébrine* of the human race, as has been stated, this invites a consideration of the subject from the standpoint of comparative pathology. If phthisis is analogous to the fungous diseases of the lower animals and plants, then the results of treatment in the latter may throw light upon the therapeutics of human tuberculosis. In a communication made by Dr. George B. Wood, in 1869, to the American Philosophical Society he referred to a discovery which he had made, and which, I think, has a very important bearing upon this subject. He proved by experiments upon a large number of fruit trees, which were prematurely dying by progressive decay (now recognized as some form of fungous disease), that by simply adding potash to the soil the trees were restored to their early vigor and they resumed fruit bearing; in fact, the crops were larger

than ever before, "many branches breaking down with their load of peaches." This is a striking illustration of the importance of supplying to the soil some chemical agent which may be deficient, rather than devoting our time and energies to the destruction of germs. Pulmonary consumption is certainly curable. How many have been cured solely by an antiseptic or a parasiticide treatment? Not one; but many have been restored to health by hygienic methods alone.

Let me briefly quote, without comment, a case in point: It is that of a distinguished Fellow of the College, the late Dr. Joseph Parrish. Dr. George B. Wood, who delivered the obituary address before this College, thus alludes to Dr. Parrish's illness: "When about twenty-five years of age the doctor was affected with a severe and lasting cough, and considered himself in danger of pulmonary consumption, to which he believed that he had a family predisposition, having lost a brother and sister by that complaint. Under a course, however, of vigorous exercise, and from exposure to the air, without the use of medicines, he ultimately surmounted the threatening symptoms. The existence of cicatrices in the upper portion of the lungs, discovered upon postmortem examination, proves that his apprehensions were well founded, and at the same time affords strong evidence in favor of the plan of treatment which he adopted in his own case, and always strongly advocated."

Recent investigations into the etiology of tuberculosis seem to lead us away from the germ theory, and to point to the fact that in the tissues of the phthisical patient some chemie agent is deficient, which if we can supply, the symptoms will disappear and the case will proceed to recovery. This agent may not be the same in different patients. Cases of consumption have been cured by the hypophosphite treatment advocated by Churchill; others have been restored to health by alcohol; yet others have been equally improved by drinking blood at the abattoirs, or by eating raw beef. Codliver oil, advocated by Bennett, seems to supply the needed element in some; an abundant milk-diet has been successful in others. The agent may be a simple salt-like lime hypophosphite or sodium phosphate, or organic in its nature like tuberculocidin or nuclein. Whatever it may prove to be, one thing is certain, that the results from following out this lead have been more successful than those from parasiticide treatment. They do not strengthen the argument of those wishing to class tuberculosis among contagious diseases.

In conclusion, I might point out the fact that if the Board of Health should force physicians to make diagnoses this would involve the compulsory use of all modern methods, including the microscope and culture tubes. The fact has just been announced that ex-Vice-President Morton's fine herd of Jersey cattle, recently exhibited at the World's Fair, has been found to be infected with tuberculosis. It is said that the animals presented no symptoms of disease whatever, and the diagnosis was made by the subcutaneous injection of tuberculin. Can physicians be compelled to resort to this in all suspected cases in the human subject?

DR. SOLIS-COHEN—The question to be considered is simply this: Granting all that may be said concerning the etiologic relations of the bacillus of Koch to tuberculosis, and granting all that is said as to the spread of infection from persons affected with tuberculous disease—on the whole, will the health and comfort of the community, including both the well and the sick, be better promoted by having all cases of tuberculosis registered or by not having them registered? So far as the sick are concerned, the disadvantages of registration are obvious. So far as the well are concerned, my distinguished teacher, the Vice-President of the College, has shown that the reasons advanced in support of the proposition that it is necessary to have cases of tuberculosis registered in order to protect the health of the community, can not withstand critical analysis. I believe, moreover, that registration would be a detriment to the community, for the reason that when of two measures to prevent an evil, attention is concentrated on the less efficacious, the more efficacious is likely to be neglected. If we direct our attention too strongly toward germicidal measures we shall lose sight of the more important measures that relate to the general sanitation of cities, of houses, and of individuals. Tuberculosis among men is to be prevented by increasing the vitality of the race, by preventing the marriage of tuberculous and otherwise unfit persons, and by perfecting the sanitary environment and life of the individual. The true prophylaxis against tuberculosis begins, therefore, before conception; but as society has not reached the stage of development where such prophylaxis can be generally insti-

tuted, it becomes all the more necessary to insist upon those practical measures of individual and civic hygiene which must be our greatest dependence and to oppose whatever shall tend to obscure their importance.

As has been said by Dr. Woodbury, if Dr. Flick had started out to prove that consumption flourishes in overcrowded places and where misery, poverty, filth, and vice are congregated, his statistics could not be more admirably adapted to enforce that conclusion; but to prove that tuberculosis is contracted only or chiefly by living in houses in which persons having tuberculosis have previously resided, would require that a census be taken to find out concerning every house in the city whether at any time there had been a patient with tuberculosis living or dying in the house, and if so, how many cases had followed and at what intervals, and also to determine how many cases of tuberculosis had developed among those living in houses where no one having tuberculosis had previously resided. Until statistics of this character are at hand, the case against the so-called infected houses, in districts where the city, the houses, and the lives of the people furnish so many potent cases of impaired vitality, is at least "not proven." But grant that the proof of infection in houses is conclusive. Suppose that the houses are thoroughly disinfected, and even, referring to Dr. Wood's point, guarded against reinfection—what have we gained? We are told—and I invite correction from Dr. Abbott, if I am in error—we are told by the highest authority that the bacillus of tubercle is about us everywhere. It exists, save at certain altitudes, or upon the sea, or in other specially favored regions, in the air we daily, momentarily breathe. Every one is at some time exposed to the danger of inhaling it, and that it is inhaled by everybody is shown by the results of autopsies upon persons having no tuberculosis elsewhere, but in whom the bronchial glands are infected with the tubercle bacillus. I believe that, according to some statistics, the proportion of persons so infected has been placed at 50 per cent. Is it not clear that, as was said by the President of the College in his Annual Address, in order to make the Board of Health laws effective, there would have to be instituted a system of espionage so that the tuberculous patient could be followed every day from the time of his rising up to that of his lying down, while seated in his house, or while walking by the way, to make sure that by no possibility should his sputum be deposited into any place where it could become dry and be carried into the air—a thing which is manifestly impossible. But if instruction only is to be given and no such rigorous supervision of individuals attempted, it is within the province and within the power of the attending physician to instruct his patients, and the intervention of the municipal officer is not required.

Therefore, because of the impracticability of this registration to effect anything positively, and because, negatively, it will have the effect of diverting attention from the fact that these streets or alleys, to which Dr. Flick directs our attention, should be cleansed and widened, the houses properly drained and ventilated, the people properly fed and clothed, and otherwise protected from exhausting and depressing influences, I consider it to be the duty of the College to place its strong word on record against the proposed legislation.

Were the proposition in favor of a municipal hospital for tuberculosis, separated from the other recommendation, and properly safeguarded, I should be glad to vote for it.

DR. RICHARD A. CLEEMAN—One very important point has not been alluded to. Statistics show that the death rate from the disease is almost the same in every community, year after year. If there is any diminution, it is very small. This is directly opposed to the idea of the contagiousness of the disease. All other contagious diseases vary very much in their death rate at different times. There is only one explanation by which we can conceive that phthisis is contagious and the death rate always the same, and that is, that the whole of the community is thoroughly infected with the tubercle bacillus, and that in the community there is a fixed number who are susceptible to the disease. Just, as statistically, we can calculate how many giants or how many dwarfs are in a community, so can we estimate the number of persons susceptible to phthisis.

In this view of the case, with the bacillus tuberculosis spread over the whole city, measures to be effective must be of a very extensive character. The mere reporting of a case now and then—for I believe the rule will be often neglected—will have very little effect. Measures to be effective must be thorough and they are the methods of general hygiene.

DR. JAMES B. WALKER—We must look at the practical side

of this matter, and ask what will be the benefit from registration? How much has typhoid fever in this city been diminished by the fact that we report our cases? Not in the least. The disinfection of the stools which the physician has directed has lessened the number of cases, as similar attention to the sputum may in phthisis. I am against placing phthisis on the list of diseases to be reported, for many reasons. I do not believe that this would confer a single benefit upon the city or its inhabitants. The physician is capable of doing all that the Board of Health can, without the manifold evils and annoyances of public registration. The College should go on record against the registration of the disease. It should go on record also as believing that the disease is possibly contagious, and should recommend physicians to use the most strenuous efforts to prevent the transmission of the contagion.

DR. DA COSTA—I used the expression that the tubercle bacilli were everywhere. A bacillus that is on the pavements and in houses, that is watted about in the air, that exists in milk, and on fruit sold in the markets and, as has recently been demonstrated, is on the very money that we handle, may well be described as a bacillus that is everywhere. The tubercle bacillus is so diffused that it can, indeed, be considered as everywhere present, and it is scarcely a figure of speech to so describe it.

With every word that Dr. Roberts has said, I agree. There is not a direction he has read I would not subscribe to and endeavor to enforce as an officer of an institution, or in private life. I hope, indeed, that every Fellow will go away to-night imbued with the necessity of carrying out all measures that have been brought forward with the view of destroying this scourge. But is it not better that we should do this as individual health officers, than to have it done in a necessarily perfunctory way by a Board of Health? The only way that the Board of Health could radically act to destroy the tuberculous material would be to burn every house that was supposed to be really infected, separate the tubercular husband from the wife, take every child away, and cause such an upheaval in society as no community would submit to.

DR. FLICK—Dr. Williams of Brompton Hospital, has been quoted as an opponent of the theory of contagion, but he has written a paper in which he shows that a large number of nurses of the Brompton Hospital have contracted tuberculosis. I think that he has traced some fifteen or twenty cases.¹

As to the ubiquity of the tubercle bacillus, Koch and Cornet have disproven it. They have shown that the contagious environment of tuberculosis is limited. Cornet has made experiments with dust taken from the streets and other places at random, and was unable to produce infection by inoculation. He has, moreover, made an investigation of the health of the street-cleaners of Berlin, and has found them freer from tuberculosis than any other class. It must be borne in mind that the isolated cases of infection of fruit and other articles which have been referred to are traceable to handling by consumptives. Many of the fruit-stand dealers have consumption.

With regard to the endeavor to ascribe the occurrence of the disease in certain houses to dampness, that can be disposed of in a moment. If you will take one of the worst infected streets in the Fifth Ward, say Bay Street, you will find that at least 20 per cent. of the houses have not had a death from tuberculosis, although the sanitary condition is as bad as in the infected houses. Dampness can have no influence here.

As regards infection in hospitals, as I have said, Williams has written a paper in which he shows that fifteen to twenty nurses have contracted the disease in the Brompton Hospital. Cornet has written an elaborate history of hospital infection. He has taken the general hospitals of Germany, in which the nurses are permanent, and he finds that as high as 62 per cent. had tuberculosis. In my own class of residents at Blockley, sixteen in number, two died within three years of the disease, and I myself was believed for a time to be a victim.

It has been argued that we ought to trace the history of these houses for a longer period, say one hundred years. There is a limit to the infectious power of tubercle contagion. What that limit is I can not say; probably not very long. Unless cases occur within a few years of each other to keep up the chain of infection, the houses are no longer infected houses.

Italy has been quoted as an evidence of the non-effective-

¹ British Medical Journal, Sept. 30, 1882.

ness of preventive measures. I am surprised that this quotation is made so frequently after what has been written. Those who have seen my paper on tuberculosis in Italy will be in a position to refute this statement. I have proven in that paper, by careful quotations from contemporary authorities—and authorities that can not be doubted—that at the time when the laws were instituted in 1782 the mortality was about 10 per 1,000, and that when the preventive measures were abandoned, the mortality was so low in the extreme southern part of Italy that it was practically nil, 0.19 per 1,000. Instead of there being no result, the mortality was reduced from 10 to a fraction of 1 per 1,000. Many who have written upon the subject have overlooked the fact that it is not Naples but the Kingdom of Naples that is spoken of. This comprised the southern half of Italy and Sicily. At first the northern part of Italy opposed the view of contagion and refused to accept any preventive measures. After some years it adopted preventive measures, but even at this day the mortality in the northern part of Italy is twice what it is in the southern part. These preventive measures proved another point, and that is the local infection. The only practices that were of any benefit in the Kingdom of Naples were first, isolation; and second, compulsory disinfection. The preventive measures circled entirely about the household. The Italians did not know where the infection came from, but adopted crude measures of prevention. Yet with their crude measures they reduced mortality to a minimum, and except for the fact that Italy became a health resort for tuberculosis, it probably now would have no tuberculosis. If you will study the statistics you will find that those parts of Italy that are health resorts for tubercular patients run up the mortality. This has been as high as 4 per 1,000 in some of the resorts, but if you take the rest of the Kingdom of Naples, the mortality is a fraction above 1 per 1,000.

As to the competency of the physician to meet this question: In connection with this subject, we must bear in mind that every infectious disease is a law to itself. It is not fair to apply to tuberculosis the laws which govern diphtheria, smallpox, etc. The infecting material in tuberculosis is easily controlled. It comes from a single source. In smallpox it is difficult to control. If it were possible to sterilize all the sputa of consumptives we would not need disinfection. Such a thing is impossible, however, and therefore it is necessary that the room be disinfected. This requires great care, and unless the family is willing to undergo the expense it can not be accomplished. If the physician were to devote half of his time to bring about proper disinfection he could not do it effectively.

Dr. Cleeman has advanced an argument against contagion which, strange to say, has been made for the other side by Dr. De Forest. Dr. De Forest claims that inasmuch as the number of infected houses is limited, the mortality rate should remain the same every year, because the number of exposures remain the same. The centers of infection remaining the same, the deaths should remain the same.

Tuberculosis and typhoid fever have been compared. The reporting of typhoid fever can not bring about any results unless the lessons taught are acted upon. If the water supply were made better we should have no typhoid fever. There is no analogy between typhoid fever and tuberculosis. Tuberculosis is infectious from the point at which it exists; typhoid fever infects our drinking water. There is little danger from the room occupied by the typhoid fever patient. The cases are not at all analogous.

Dr. Mays—When this question was discussed before the County Medical Society, about four months ago, I quoted Dr. Williams, the same authority to which Dr. Da Costa referred tonight in support of the non-contagiousness of the disease in the Brompton Hospital.

I read his conclusions from his book, "Pulmonary Consumption," pp. 87-89, published in 1888, in which he emphatically states that contagion in the wards of this Hospital is absolutely unknown.

In concluding the discussion of that evening, Dr. Flick said that in a private communication, which he had not with him, but which he received from Dr. Williams since the book I quoted from was published, the latter admitted that his ideas had undergone a change in this matter, and that now he believed that about thirty or forty cases of phthisis had arisen in the Brompton Hospital through contagion, during the time over which his research extended. This seemed to me so extraordinarily strange and surprising, for, besides the conclusions set forth in Dr. Williams' book, I heard him say in one of his lectures at the Brompton, in 1883, that not a single clear case of contagion had occurred in the wards of that institution, that I determined to write him and ask

for the cause of this change of opinion on his part. I received his reply last October, in which he states that he has not changed his views on the infectiousness of phthisis materially, since he summed them up in the second edition of his work on "Pulmonary Consumption," pp. 87-89 (precisely that which I quoted), and that there are certainly no records to support the statement that thirty or forty cases of infection occurred in the wards of the Brompton Hospital. In fact, he says: "The evidence of the Brompton Hospital is all against infection, but we ought to admit that infection is possible through dried sputum under very exceptional circumstances, but that the slightest attention to cleanliness precludes any chance of this infection."

In this evening's discussion Dr. Flick again refers to this private evidence which he received from Dr. Williams, but he now states that instead of thirty or forty cases of phthisis which could be traced to infection in the Brompton Hospital, during the time referred to there were only fifteen or twenty. It seems to me, therefore, that for the sake of scientific accuracy, and for the purpose of enlightenment, Dr. Flick ought not to withhold from us any longer the information which he claims to possess on these contradictory points.

Dr. Flick—The statements which I made are contained in an article by Dr. Williams, which appeared in the *British Medical Journal*, Sept. 30, 1882.

Dr. Charles W. Dulles—This is a discussion in which exactness is of great importance, and in which approximate figures and inferences must not be permitted to take the place of actual numbers and of facts. The danger of venturing on unfamiliar ground is exemplified in the comments on what Dr. Cleeman has said in regard to typhoid fever. Those who have specially investigated the sanitary condition of Philadelphia and the condition of its water supply know that what Dr. Cleeman says on these subjects can be relied upon, for he has given to them unusual and unusually conscientious study.

Although when I came here I had no idea of speaking, I think it might be said for some who have so far kept silent, that we do not tonight hear for the first time of Cornet, or of the Brompton Hospital and Dr. Williams, or of the Ventnor Hospital. The facts and theories emanating from these are all things about which we know something and about which we have already opinions.

In regard to the improbability of the effectiveness of measures of inspection instituted by the Board of Health, I agree with Dr. Walker. We have all probably had personal experience of the unsatisfactory way in which the Board of Health carries out its regulations in regard to diseases now returnable as contagious.

In passing upon the question before us, I feel sure that the College will act in keeping with its traditions of a hundred years, and give a new illustration of the fact that it is a body in which prudent and conservative counsels prevail, and I have no fear that it will hastily commit itself, as a sister society has done, under the ingenious arguments of those strongly infected with the idea of the infectiousness of tuberculosis.

A vote was then taken on the amendment offered by Dr. Flick; it was lost, and the original resolutions, as proposed by the Council, adopted, the President being requested to appoint a committee of five to present them to the Board of Health.

SOCIETY PROCEEDINGS.

American Electro-Therapeutic Association.

The Third Annual Meeting Held in Chicago, Sept. 12, 13 and 14, 1893.

AUGUSTIN H. GOELET, M.D., President.

(Continued from page 165.)

SECOND DAY, SEPTEMBER 13—AFTERNOON SESSION.

The meeting was called to order at 3:10 P.M.

THE INFLUENCE OF FREQUENCY OF INTERRUPTIONS AND CHARACTER OF INDUCED CURRENT WAVES UPON PHYSIOLOGIC EFFECT.

Discussion opened by WILLIAM J. MORTON, M.D.

Some months since, when I gladly consented to open this discussion, I had made arrangements with a distinguished electrical engineer to experiment in his laboratory with periodic currents in relation to the frequency and the character of the induced current wave, but his illness has rendered this impossible.

I must content myself, therefore, at present with a very brief opening.

For convenience, at the outset, we may put the question in a simpler manner and ask, what is the physiologic effect of induced currents, referring to induced currents which have not been rectified into continuous currents, but still retain their fundamental periods, whether these be alternations or intermittences. An attempt to answer this general question is facilitated by an analysis of induced currents into two of their prominent characteristics, designated by the title of this discussion, namely: *a*, the frequency of their periods in a given time, for instance, per second; *b*, the character of the induced current wave.

The frequency of the periods of the induced current is originated in two ways:

1. By mechanical devices, as in the induction coil and in the alternating and intermitting dynamo-electric machine.

2. By a natural law of electro-physics as in the oscillating discharge of condensers:

The character of the induced current wave is identified by mechanical devices which record the rise and fall of its potential and other of its characteristics, upon the Marey registering drum or other registering apparatus.

We have, therefore, at our disposal three mechanisms, artificial or natural, or both combined, for exciting induced currents; these are: 1, the induction coil; 2, the dynamo-electric machine; 3, condensers (Leyden jars, etc.)

1. The induction coil.

The induction coil has long been in medicine a therapeutic means of exciting physiologic effect. This effect in the main has been to stimulate the motor and sensory nerves, namely, to produce powerful muscular contractions and to produce pain. In recent years physicians have given attention to improving the induction coil and we have heard much about the "long and fine wire" and the "short and coarse wire" secondary windings and their effects. But such modifications as regards the length or fineness of the wire of the secondary coil is of little account in advancing our knowledge of induction coils. For, in fact, familiar as this little instrument is to all of us, it is yet full of difficulty and unsolved problems. Elements of difficulty are the "lag" between the primary and secondary, the self induction in each, the effect of the magnetic resistance of the iron core or magnetic "lag" and the difference in the wave-curve of magnetization and demagnetization, and the irregularities of the vibrator; again, the frequency of the interruptions of the current in the primary circuit is limited by reason of the delay in magnetizing and demagnetizing the vibrator, ranging from 200 to 2,000 per second. We are furthermore ignorant of the character of the induced wave of the induction coil.

I find a record of the graphic curve of coils in the *Electrical Engineer* of Aug. 3, 1892. The experiments were made with the apparatus of Dr. Frolich of Messrs. Siemens & Halske of Berlin. The induction coil was so arranged that the core which consisted of a bundle of iron wires, could be removed at will. The two windings were precisely similar and consisted of 4,900 turns of wire, the resistance of each being 200 ohms.

CORE REMOVED.

Figure 15. Primary.

Figure 16. Secondary.

Fig. 15 shows the curve of the current in the primary winding with core removed, while the secondary current is shown in Fig. 16. In this case the primary current attains its maximum quickly while the induced secondary, changes as quickly as did the current in the case of a condenser without resistance.

CORE IN POSITION.

Figure 17. Primary.

Figure 18. Secondary.

Figs. 17 and 18 represent the primary and secondary respectively, with iron core in position. The effect of the core is very marked. The primary current gradually attains its maximum on making the battery current. By breaking the battery current and short-circuiting the primary coil on itself the current gradually falls to zero.

The secondary does not, as in the case without the core, suddenly fall away, but as one would expect, it gradually falls to zero.

In these experiments the time of a complete impulse was from 1-10 to 1-20 second.

It is a matter of congratulation that we shall have a paper upon induction coils presented before us by so able an electrician as Mr. A. E. Kennelly. What he has to say will fill many gaps left open in this discussion.

Medically we have apparently reached, and long ago, our limits in the effects to be expected of induction coils; we stimulate motor and sensory nerves, we increase metabolism, to the extent that muscles, caused to contract, increase it; we do not yet get pronounced sedation unless Dr. Hutchinson can demonstrate his electrical anesthesia.

To increase the precision and usefulness of periodic currents in medicine we must carefully study the form of the current wave. We must turn to other apparatus, other electrical or mechanical devices. This is what Prof. A. D'Arsonval of Paris, has done and with remarkable results, namely, the development of the sinusoidal current in new and unexpected relations to physiologic effect and its introduction into medicine.

Desiring to get a true sine curve he discarded iron in his armature and caused a magnetic field to be revolved close to a stationary wire coil without iron core; desiring to increase his frequency of alternations he was enabled to do so with the same mechanism by increasing the rate of its revolutions. He was able to reach a speed of 10,000 alternations per second.

And this is what he has taught us of the sinusoidal current of low frequency, (50 to 60 per second). The nerve and the muscle are not excited, there is neither pain nor muscular contraction, but a remarkable effect occurs, the nutritional processes of the subject are stimulated, the internal respiration or interchange of material between the blood and the tissue is increased to the extent that the amount of oxygen consumed is augmented by nearly 50 per cent. while there is likewise a correlative increase in the carbonic acid and urea excreted.

And, concerning the physiologic effects of increasing the frequency, the following interesting data were established. At 20 to 30 excitations the muscle is tetanized; the tetanization reaches its maximum at 2,500 to 5,000 excitations per second, and from this point the energy of the muscular contractions gradually diminishes up to 10,000 per second where it is *nil*.

In other words the neuro-muscular excitability, after a certain maximum is reached diminishes with the increase in the frequency.

Now this is a remarkable fact, and one which the expert electricians, interested in developing the resources and particularly the *safety* of industrial alternating currents had not been slow to observe. The fact may be expressed crudely in this way. Of two currents which are delivering exactly the same total amount of energy to a living person or animal, the one an alternating current infrequently alternating (100 to 10,000 per second), the other frequently alternating (10,000 to 1,000,000 per second); the former or

the one with long periods would instantly kill the person while the latter with short periods would be harmless, or indeed if carried to the highest frequencies would produce no sensations whatever.

It is here purely a question of *physiologic* effect for these same innocuous currents exhibit torrents of sparks, cause incandescent lamps to glow and perform other mechanical work. But the nerves and the muscles are not excited.

In one of D'Arsonval's experiments six lamps of 125 volts and 0.8 ampères, were brought to incandescence held in a circuit formed by the arms and person of the subject, the latter experiencing no sensation due to the passage of the current. The amount of energy traversing the body was 900 volts and 0.8 ampères = 720 watts.

But the facts of the experiment have led us a little in advance. Prof. D'Arsonval, as has been seen, did not cease his labors with a frequency of 10,000 per second.

His next step was to go beyond this frequency. And in taking this step he approached the labors of others, like those of Elihu Thomson, Dr. Tatum and Nicola Tesla, with a remarkable simultaneousness in time, and some of them like those of Morton, anticipatory in some essential features by thirteen years. He stepped into the region of high frequency high potential currents.

A brief glance at the historical sequence, the mechanisms and the physiologic effects of each observer will here suffice to point out the interesting and new field laid open to electro-therapeutics by the changes in the element of frequency as well also as in that of the graphic curve, could that always be ascertained.

The high frequency high potential current by aid of discharging rods and a condenser in the primary circuit was first discovered by Dr. W. J. Morton in 1880. His mechanism, then published, is the fundamental electrical mechanism necessary to produce these currents, now so thoroughly familiarized by the labors of Tesla, Elihu Thomson and D'Arsonval. In a paper read before the New York Academy of Medicine, March 3, 1881, and printed in the *New York Medical Record*, April 12, 1881, Dr. Morton described "A New Induction Current in Medical Electricity," derived from an influence machine, (Holtz machine). The current was obtained by the aid of Leyden jar condensers, one attached to each prime conductor. Rheophores and wet sponge electrodes were connected to the outer coatings of the jars and the discharging rods were approximated without quite touching. Upon actuating the Holtz machine a person holding the electrodes received a peculiar current causing widely diffused muscular contractions with a minimum of pain to excessive currents followed by a marked analgesic effect in the parts treated. These effects were carefully noted. Again in December, 1890, Dr. Morton read a second extended paper upon the same subject before the New York Neurological Society. (*New York Medical Record*, Jan. 24, 1891.)

The following diagram among many others was used to illustrate the connections to produce this high frequency high potential current:

Figure 1.

"Static Induced Current." Person, condenser and circuit-breaker in same circuit, connecting-rod between condensers removed, and discharging-rods of machine serving as circuit-breaker. The make and break in the primary is accompanied with a current in the secondary.

The interesting feature of this publication is that in 1881, Dr. Morton had already discovered the method of producing a secondary current of high frequency and high potential by means of a primary circuit which included discharging

rods (with air gap) and condensers in this circuit, and had pointed out peculiar physiologic effects.

Referring to the sensory effects of the current it was remarked: 1, that it fails to excite, or may even annul, to an extent, the sensation of pain and that there was experienced a peculiar sensation of lightness and buoyancy and a feeling as if the arms were made of cork, while of the effects upon the muscles it was noted that: 2, a great diffusiveness of the action, whereby large groups of muscles were simultaneously caused to contract with a minimum of pain.

Figure 2.

Figure 2 represents one form of Dr. Morton's transformer. A primary wire extends between the two outer coatings of the Leyden jars and this primary is surrounded by the secondary. Oil insulation is used. This apparatus was constructed many years ago and in several forms by the Waite & Bartlett Manufacturing Co. of New York, but was only described publicly in a paper read at Columbia College, before the New York Electrical Society and the American Institute of Electrical Engineers, May 17, 1893. This paper has appeared in their transactions.

Dr. Morton also exhibited at the Columbia College meeting alluded to, the illumination of vacuum lamps, having one entering conductor and a second of tinfoil upon the outside of the globe.

Tesla's first publication was in the *Electrical World* of Feb. 21, 1891, under the title of "Phenomena of Alternating Currents of very High Frequency." He made this interesting concluding observation: "The writer's experiences tend to show that the higher the frequency the greater the amount of electrical energy which may be passed through the body without serious discomfort."

Mr. Tesla's mechanism consisted of a high frequency dynamo-electric machine whose current enters a primary wire, a secondary wire within whose circuit is included a condenser and discharging rods, and again a coil to which a part of the secondary wire acts as primary.

The current produced after this special method has not been tested in medicine.

Prof. Elihu Thomson at just about the same time was engaged in studying the physiologic effects of increasing the frequency of the periods. His apparatus consisted of an alternating dynamo machine having 800 armature coils and capable of producing 8,000 alternations per second. This machine was intrusted to Dr. Edward Tatum of Yonkers, N. Y., who conducted extensive physiologic experiments with it.

Dr. Tatum's report, embodied in a letter to Prof. Thomson, Dec. 29, 1890, and published in March, 1891, brought important facts to view, and deserves much higher recognition than it has received. He established:

1. That the fatal effects of alternating currents upon animals were in inverse ratio to the frequency.
2. That the cause of pain which limits voluntary toleration lies chiefly in the muscular contraction produced.
3. That the cutaneous nerves were distinctly less painfully affected at the high rate.
4. That the visual mechanism was not excited at the high rate even by a pressure of 15 volts so as to cause a sensation of flashes of light, although two or three volts similarly applied at 120 oscillations caused such flashes very energetically.
5. That the sensation of vertigo produced by the low rate was not produced by the high.
6. That sensations of taste were absent to the high rates.

7. That exposed motor nerves of frogs were less excitable to the high rate than to the low rate.

The fact that when the number of oscillations is extremely high there is no excitation of the nerves and muscles, D'Arsonval communicated to the Biological Society of Paris, Feb. 24, and April, 1891. His recent conclusions as to the physiologic effects of high rates of frequency are:

1. No effect upon the organs of feeling.
2. No muscular contraction.
3. Diminution of the sense of pain.
4. Dilatation of the blood vessels.
5. Increased perspiration.
6. Increased tissue change, manifested by increased absorption of oxygen and increased elimination of carbonic acid.
7. No increase of bodily temperature.

As to why periodic currents excite nerve and muscle in inverse relation to their frequency, we are confronted thus far, for answer, only by hypotheses. Prof. Houston believes it is because currents of this nature do not sufficiently penetrate beneath the surface of the conductor. Prof. D'Arsonval offers as explanation that the nerves and their centers, if not all the tissues, respond only to excitations of a certain frequency and that, therefore, if these currents fail to excite pain or contraction, it is because their periods do not coincide with the periods of the nerves producing pain and contraction.

Other explanations not here essential to adduce have been offered.

It will, however, be borne in mind that though nerve and muscle may not be stimulated so as to produce pain or contraction, still there take place other effects of far higher importance, viz.: stimulation of the nutritional processes of life.

Dr. Morton then exhibited a medical induction alternator devised by Mr. A. E. Kennelly at his suggestion.

This small medical alternator has twelve poles; each pole is wound with a primary and secondary winding on one spool. The exciting current in the primary circuit is less than one ampère; frequency, twelve periods per revolution; speed attainable, 6,000 revolutions per minute; frequency attainable, 1,200 periods per second; armature of laminated iron plates, running in self-oiling bearings; field frame, laminated sheet iron supported in cast iron guides.

Dr. Morton also presented a wheel, or mechanical means of securing sinusoidal interruptions from galvanic batteries, and for operating faradic machines, devised by Mr. R. G. Brown, electric engineer, for him.

The apparatus consists, as you see, of some forty contacts or segments arranged in a circle and insulated one from the other. Projecting through the center of the circle there is a shaft carrying an arm to the end of which is affixed a small, flexible wire brush, so adjusted as to rub over the face of the segments. On the end of the shaft there is a pulley wheel, and this was connected by belt to an eighth of a horse power motor making 1,500 revolutions per minute. Now, beginning at one point of the circle and numbering all the segments from one up, all those of even numbers were connected together and carried to a positive battery, while those segments of uneven numbers were similarly connected to a negative battery—each of three cells Leclanché. One end of the primary coil was then connected to the trailing brush and the other end of the coil connected to the other end of the batteries. It will be readily seen, that as the trailer rotates over the forty contacts or segments, this primary coil will be successively charged with positive and negative currents—20+ and 20—, and as the trailer is making 1,500 revolutions per minute, we have 40 times 1,500, or 70,000 alternations, each of equal duration, passing through this primary coil.

Another experiment was made, in which a single battery and only one-half the number of segments were employed. The segments of even numbers were connected to one pole of the battery, the intervening segments being left disconnected. With this arrangement the action is similar to that derived where an ordinary vibrator is employed, except that the "make" and "break" is of equal duration.

No more important question has ever arisen in electro-therapeutics than the one presented under the title of this discussion. It is natural that considerable confusion will arise and many conflicting statements be called forth in this, the first attempt to elicit a general expression of opinion upon a subject still in embryo in its physical, and equally undeveloped in its physiologic principles. We can only begin this work at this meeting.

Heretofore with a long fine wire coil, patients have ob-

tained relief in a great variety of cases. Dr. Morton's personal experience with the sinusoidal current entirely verifies the claims made for it by D'Arsonval that in this current electro-therapeutics gains the most important addition made to it in recent years. And he believes that the sinusoidal apparatus must eventually, to a great extent, replace the induction coil.

MR. A. E. KENNELLY'S paper on

INDUCTION COILS,

was then read by MR. E. M. SMILES.

Induction coils are instruments in which electro-motive forces are generated by the variation of their permeating magnetic flux. They were first constructed by Faraday in England, and Henry in America, and are now familiar to us under numerous variations of form and design; but with little variation in their fundamental principles, which we propose to here consider with special regard to apparatus employed in electro-therapeutics.

Every magnet, or every current-conveying helix acting like a magnet, has, we know, its complete magnetic circuit. In other words, magnetic flux knows no terminus, and is arrested by no barrier, but always appears in closed paths or reëntrant channels. If a small compass needle could be advanced along the direction that it selects from instant to instant, it would in any constant magnetic system, travel round and round some loop in space, unless arrested in its passage by geometrical barriers such as the iron core of an electro-magnet. By tracing out a sufficient number of such loops or flux lines in different portions of the magnetic field, we should come to regard the magnetic circuit as resembling a bundle of numerous separate and invisible endless chains densely packed within the magnet, but spreading out beyond its ends.

An electrical conductor, e. g., a copper wire, encircling all the flux lines of such a magnetic circuit without threading through any, is apparently unaffected by their vicinity, but so soon as it passes once (or some odd number of times) through flux lines, thus becoming linked with them, its electrical condition is influenced by their presence. No change can be detected in the wire, so long as it remains at rest relatively to the flux chains, but should motion take place between them in such a manner that the wire becomes linked with more or fewer chains, or should the magnetic circuit so alter as to increase or diminish the flux lines linked with the wire, an electro-motive force becomes developed along the conductor during the motion. Increasing the linkages of flux develops an electro-motive force in one direction through the wire, while decreasing the linkages sets up the reverse. The electro-motive force will produce a current of electricity through the wire if the circuit of the latter be complete.

The magnitude of the electro-motive force developed in such cases is readily determined. Suppose a copper wire to be bent into a loop with its ends in close proximity, but not actually in contact, so that no current can be sustained in the wire. If we take this loop from some position in which it was linked with 50,000,000 units of magnetic flux (50,000,000 of unit magnetic chains), and deposit it in such a position that it is linked with 150,000,000 units, then the increase in the flux linkages to the extent of 100,000,000 units will establish an electro-motive force in the wire during the transfer. Assuming that the operation lasted for one second of time, and was so controlled that the rate of flux admission or linkage increase was uniform, then the electro-motive force in the loop would be maintained at one volt throughout the motion, for by definition the volt is the electro-motive force induced in an electric circuit when magnetic flux enters it at the rate of 100,000,000 of units (C. G. S.) per second. Had the transference been effected in the one-thousandth part of a second, the rate of linkage would either have been uniform during that time, and equal to 100,000,000,000 units per second, or variable but averaging this amount, so that the electro-motive force induced in the loop would either have been steady at 1,000 volts, or variable but averaging 1,000 volts during the same interval. But although the magnitude and the character of the induced electro-motive force thus depends upon the manner in which the transfer takes place, the total quantity of electricity that this electro-motive force can deliver through a constant resistance is unaffected by the circumstances of the motion. For if the ends of the looped wire are connected through a fixed resistance, a rapid transfer will induce a large electro-motive force, and accordingly strong current of brief duration, while a slowly executed trans-

ference would entail a small electro-motive force and a feeble current through a correspondingly longer time. For a given admission or withdrawal of flux through the closed conducting loop, a definite quantity of electricity must flow round the latter, depending only upon its resistance.

These principles may be applied directly to the analysis of the ordinary Ruhmkorf or faradic coil. We may suppose this to be of the DuBois Raymond type, in which the outer and secondary coil slides freely over the inner and fixed primary coil. To simplify matters at the outset, we may first suppose that, contrary to usual practice, currents are supplied to the primary coil in such a manner that the flux in the magnetic circuit rises steadily and falls at a uniform rate, and with a definite number of alternations per second. The maximum flux through the magnetic circuit of an ordinary small faradic coil is about two thousand units, so that if this flux made 500 alternations or 250 periods per second, the condition of the magnetic circuit in regard to time may be represented by the zig-zag line in upper Fig. 1, oscillating between 2,000+ and 2,000- in the five-hundredth part of a second, corresponding to a rate of change in flux of 2,000,000 units per second. A single turn of secondary conductor closely surrounding the primary coil and core at the center of length, would develop, if linked with all these flux lines, an induced electro-motive

turns at the center at L, K. If, then, in the preceding case the most favorably situated turns developed an induced electro-motive force of 0.02 volts each, the aggregate electro-motive force would be less than 80. volts.

It is evident, therefore, that the induced secondary electro-motive force for a given arrangement of core, primary, and winding space, depends upon the number of turns in the secondary coil. A large number of turns necessitates the use of fine wire of great length and high resistance, but these are incidental qualities only. Fig. 2 shows that with a given winding space or length of wire, there is a gain in electro-motive force, obtained by slightly piling up the turns at the center and denuding the ends of the coil, thus securing the maximum total flux linkage, but the advantage is not usually considered of sufficient importance to pursue.

We may now replace the arbitrary primary current supply with the usual battery and spring vibrator. The frequency of vibration will depend upon the length and cross section of the spring, the elastic quality of its material and the mass and form of its iron armature or head. These conditions determine the fundamental or free vibration, but we know that forced vibrations can also be produced, whose frequency depends upon the strength and graduation of the magnetic flux, the position of the contact point, the play of

Figure 1.

force of $\frac{20000000}{1000000000} = 0.02$ volt, and supposing that the secondary coil consisted of 4,000 turns all embracing the same flux, the total electro-motive force induced in the coil would be 80 volts, alternately positive and negative at a frequency of 250 periods, as shown in lower Fig. 1.

When the secondary coil is entirely removed from the primary, the electro-motive force induced in it must disappear, and even when placed immediately over the primary in the most effective position, the electro-motive force developed in every turn will not be quite equal. The flux through the iron core diverges in such a manner that the turns near the ends of the secondary coil are not linked with so much flux as those at the center and inner layers. This is shown diagrammatically in Fig. 2, where P, Q, represents a longitudinal section of the iron core through its axis, and A, I, B, C, K, D, E, I, F, II, M, G, the section of a secondary coil. The turns at the outer edges, AG and BH, have a much smaller share of the total flux linkage than

Figure 2.

vibration allowed, and the tension imparted to the spring. Under any circumstances, however, the spring rests in contact with the platinum faced screw point during a certain fraction of each vibration, and the current from the battery finds access to the primary coil spring during this portion of the cycle. The primary current does not, however, instantly reach its full value, for that would entail a nearly instantaneous culmination of the flux, and a brief but enormously high induced electro-motive force in the secondary coil, contrary to observation. As soon as the primary current commences to flow, flux springs into existence in the magnetic circuit. This flux penetrates the convolutions of the primary winding, as well as those of the secondary, and consequently develops in the primary coil an electro-motive force always in opposition to that of the battery. This counter electro-motive force of self-induction retards the growth of the primary current and magnetic

flux, which then increases at a rate determined by the electrical conditions of the complete circuit.

As soon as the vibrator spring leaves the contact point, the primary circuit is metallicly disconnected. If the primary current stopped instantly, the flux in the magnetic circuit would almost instantly disappear, entailing an enormously great but brief induced secondary electro-motive force in the opposite direction to that on making contact. This fails to occur, however, because the withdrawal of flux from the magnetic circuit not only induces electro-motive force in the secondary coil, but in the primary also, and in such a direction as to sustain the battery current. A spark therefore forms at the break, and through the column of heated air the primary current is for a short interval sustained. The result is that the flux is withdrawn from the circuit not instantaneously, but more rapidly than it entered, and it is well known that the induced electro-motive force of "breaking" is much greater than that at "making."

These conditions for the case of a vibrator making 100 periods per second is shown diagrammatically in Fig. 3. The broken line ABCDEFG represents the relative magnitudes of the primary current and the circual flux during 0.016 second or about one cycle and a half. The vibrator spring

Figure 3.

makes contact between A and B during the sixth part of the cycle, and the current and flux ascend the curved line AB. The spring then leaves the contact and the current and flux fall rapidly to the zero line at C. The dotted line a, a', a'' b, c, d, d'', e, f, g, indicates the corresponding induced electro-motive force in the secondary but open circuited coil. At the moment of contact, a, the induced voltage becomes — 50, and at the moment of breaking contact has fallen to — 35. Immediately the break occurs, the electro-motive force rises quickly to about 250 volts, and after a brief interval falls again to zero. The wave of induced electro-motive force is quite unsymmetrical with respect to the zero line, but the area a, a', a'' b, is equal to the area b, b', c.

Having outlined the electro-magnetic condition of the faradic coil while the secondary coil is disconnected, we may now consider that the secondary circuit is closed through an external resistance.

Currents will now flow through the secondary circuit and circulate round the secondary coil. These currents will generate a new magnetic circuit just as though this coil were excited by those currents as an independent primary.

The oscillation of this new flux will induce new electro-motive forces both in the primary and secondary circuits. In the primary the current from the battery will be correspondingly modified during the periods of contact. In the secondary the new electro-motive force known as the counter electro-motive force of self-induction, will always oppose and reduce the main induced electro-motive force, but the balance of the latter will be available for producing currents in the secondary circuit.

For a given external resistance in the secondary circuit, these conditions rapidly arrive at mutual adjustment, such that the primary current at any instant during periods of contact, follows Ohm's law, when the counter electro-motive force of self-induction, and the electro-motive force induced by the secondary currents, are deducted from the electro-motive force of the battery; also the secondary currents at any instant follow Ohm's law, when the counter electro-motive force of self-induction is deducted from the electro-motive force induced by the adjusted primary current.

These conditions, varying with the character of the external secondary circuit, however readily apprehended in the main, are difficult to determine in accurate detail, by either observation or computation. Broadly, however, the effect of loading the secondary circuit of a faradic coil by reducing the external secondary resistance, is to increase the main strength of the primary current supplied, to prolong

Figure 4.

the duration of the secondary current waves, and to diminish the effective secondary electro-motive force.

Fig. 4, indicates the latter influence as observed in a sample faradic coil whose vibrator made about 150 periods per second.¹ The effective electro-motive force at secondary terminals was 116 volts on open circuit, but when the external resistance was gradually reduced to 5,600 ohms, and the secondary current raised to 5 milliamperes, the terminal electro-motive force fell along the curve to 28 volts. That is to say, 28 volts continuously sustained on the 5,600 ohms would generate through that resistance the same amount of heat in a given time as the very variable electro-motive force then active at secondary terminals. The fall of secondary pressure with load was here almost entirely due to the counter electro-motive force of self-induction, aided by the influence of secondary reaction on the primary circuit, for the drop of voltage due to 5 milliamperes, the strongest current shown, would only have amounted to 1.4 volts, in the resistance of the secondary coil, a comparatively negligible loss.

¹ This coil had a core 9.25 cms. long and 1 cm. in diameter, formed of iron wires 0.085 cm. in diam. weighing in all 52 gms. The primary coil had 90 feet, 330 turns, 0.76 ohm, and 7.5 millihenrys the secondary coil 1,100 feet, 3,440 turns, 285 ohms, and 456 millihenrys, the mutual induction was 111 millihenrys. The battery had an electro-motive force of 1.5 volts, and a resistance with leads of 0.35 ohm.

The secondary electro-motive force of faradic coils can only be accurately measured by electrometers or electro-static methods, since the feeblest measuring current in the secondary coil exercises so powerful an influence upon apparatus of this size. It is usually more important, however, to know the effective secondary current strength rather than the effective secondary electro-motive force. The duty of a faradic coil is only to supply a certain strength of alternating current, at a given frequency, and of a certain wave character, and the electro-motive force in the coil is merely an attendant property for the production of that current. Any strength and frequency of current within the usual limits can be provided for in design, but probably no two coils give precisely similar wave characters. Short secondary windings with few turns, tend to generate abrupt and sharply varying currents, while long secondary windings with many turns, tend to deliver smoother and more slowly changing current waves, especially at high frequencies and on heavy loads. This is owing to the fact that their large number of turns entails a large linkage with their own flux, and any abrupt change in the currents they deliver sets up immediately a powerful induced opposing electro-motive force checking the variation.

The only advantages that can be gained by modifying the forms of faradic coils operated by existing types of spring vibrator, must be looked for in economy of weight or material, in convenience of operation, or in modification of current wave character. The disadvantage of the vibrator is the irregularity and dissymmetry of the currents it causes to be generated. The ordinary form of spring vibrator rarely supplies more than 250 periods per second, while ribbon vibrators in which the spring is clamped at each end, and capable of being tightened, enable frequencies of 1,000 periods to be readily attained, but the dissymmetry and irregularity of current wave character must attach to both forms.

Figure 5.

For measuring the effective current strength in the secondary circuit, a sensitive electro-dynamometer calibrated for milliampères of alternating current is convenient, for the currents are usually feeble, and the resistance and self-induction of the measuring instrument should be reduced as far as possible.

The simplest form of alternating current wave type is the sinusoidal, or simple harmonic wave, represented in Fig. 5. This wave possesses several remarkable properties. It conveys, for example a given quantity of electricity, at a given frequency, with the minimum possible average abruptness or rate of change in current. It is also a persistent form and difficult to destroy. A sinusoidal electro-motive force acting upon the primary of an induction coil, will induce exact or very nearly exact sinusoidal waves of current and induced electro-motive force in the secondary circuit, thus greatly facilitating all measurements, deductions, and reproductions. If an effective current strength of 5 milliampères be supplied by the secondary of an ordinary faradic coil at a frequency of, say, 250 periods there will be considerable uncertainty as to the current wave character and as to the maximum values of current during the cycle, but if the primary coil were excited from a source of sinusoidal currents at the same frequency, all the particulars of the current delivered would be accurately determinable and reproducible. Five milliampères of a sinusoidal alternating current, as measured by a properly calibrated instrument, would always accompany a maximum current in each wave of 7.07 milliampères, but 5 milliampères of current from the ordinary faradic coil

might require maxima of 10 milliampères negative, and 70 milliampères positive, in each cycle.

IN MEDICAL INDUCTION COILS, HOW DOES THE CURRENT OF THE PRIMARY DIFFER FROM THAT OF THE SECONDARY? AND WHAT INFLUENCE HAS THIS DIFFERENCE UPON THE RESPECTIVE PHYSIOLOGICAL EFFECTS?

By H. NEWMAN LAWRENCE, Esq. of London, England, was then read by the Secretary in the absence of the author.

I will assume that the currents I am asked to speak about are obtained from an ordinary well made medical coil wherein the primary and secondary helices are quite separate from each other, and the wire of the former is short and of low resistance, while that of the latter is long and of high resistance. Further, that the rate of vibration does not exceed 200 per sec.

Such coils are transformers of electrical energy and not producers of it. They transform a current of low voltage and (comparatively) large ampèreage to one of (comparatively) high voltage and small ampèreage. In this process a portion, often as much as a third or even more, of the initial energy put into the coil is lost in the act of transforming.

The primary current consists of continuous current from the charging source, be it battery or direct current dynamo, interrupted by the vibrator and also possessing the extra current of self induction. The charging current can be measured, both as regards voltage and ampèreage and thus the initial energy put into the coil is arrived at.

The secondary current is a series of alternating impulses derived by induction from the primary, and depending for the form of its resultant energy, i. e., the relative values of voltage and ampèreage, upon the number of turns it makes round the primary, the strength of the charging current and the rate of interruption of the vibrator.

The difference between the two appears to be:

a. As regards direction.

Primary—Flows in one direction, though interrupted at intervals.

Secondary—Flows as a series of impulses, alternating in direction and more or less interrupted owing to the interruptions of the primary. Quite interrupted at low speed vibrations, but wave-like or undulating at high speed.

b. As regards voltage.

Primary—Comparatively low voltage, say 50 volts.

Secondary—Comparatively high voltage, say 300 volts.

c. As regards ampèreage.

Primary—Comparatively great ampèreage say 500 ma.

Secondary—Comparatively small ampèreage say 7 ma.

Perhaps a few figures will help illustrate the transformation of electrical energy in a coil.

Assume that our coil has a maximum of 12 ohms in primary and 1,000 ohms in the secondary.

The initial energy is 500 ma. at 6 volts = 3 watts. This when transformed in the primary by self induction may become 60 ma. at 50 volts or thereabouts.

The secondary, taking the total loss of energy as a third will give out 7 ma. at 300 volts, which equals 2 watts.

Taking these figures as an example it will be seen that the arrangements of the primary current are such that increased ampèreage is obtainable almost up to the full amount in accordance with the possible reduction of a patient's resistance. In saying this, however, we must not overlook the fact that the patient is not put into the direct current but into a loop or shunt circuit and consequently only receives such ampèreage as belongs to the shunt in inverse proportion to the resistance in it, i. e., of the patient, electrodes and connections.

In the secondary the resistance of the patient is not of so much importance, as the values of ampèreage and voltage are such that the maximum of the former is decidedly small and the discharge in this respect approximates to that of a static machine.

Physiological effects.

Primary—*Electrolytic* owing to its flow in one direction, but this effect must be small, owing to the interruptions.

Cataphoric to a like extent and for the same reasons.

Muscle contracting by reason of the interruptions, these contractions being distinctly painful owing to the sharpness of the interruptions and the strength of ampèreage.

Secondary—Neither *electrolytic* nor *cataphoric*, to any appreciable extent, owing to the alternations and the very small ampèreage. *Muscle contracting* by reason of the alternations, these contractions being less painful than those obtained from the primary, owing to the wave-like

character of the alternations and the very small ampère.

My experience is, that the muscle contraction may be produced by an infinitesimal ampère, provided it be sufficiently concentrated; and that the pain of such contractions increases with the ampère, other things being equal.

Speaking generally, therefore, when muscular contraction is required the primary current is the more painful to use; though at the same time, owing to its definite direction and cataphoric properties it may sometimes be found less painful than the secondary when applied to nerves.

The rate of vibration has a marked influence upon both the primary and the secondary, with their consequent effects; but it does not seem that one is affected by it more than the other, at any rate within the limit named (200 per sec.)

That effects of the electric energy of the secondary, presented as it is with an apparent superfluity of voltage and a corresponding paucity of ampère over and above those already referred to may exist, seems possible, but such existence is at present open to doubt.

Probably it is only by investigating the extreme of such condition, as illustrated by Teslaic coils or Dr. Morton's static induction currents, that this problem can be solved. The conditions in each case are similar, i. e., alternations, superfluity of voltage and paucity of ampère (these terms are here intended to refer to action upon the body only), and the difference seems to me to be merely one of degree.

In conclusion, I apologize for the sketchy nature of these remarks, but must plead that the subject is a very intricate one, both in its physical and physiological aspects; and that to do the matter justice would require a far abler pen than mine, with time and attention considerably in excess of the limits laid down for this discussion.

(To be continued.)

SCIENTIFIC OBSTETRICS IN PRIVATE PRACTICE.

Read in the Section on Obstetrics and Diseases of Women, at the Forty-fourth Annual Meeting of the American Medical Association.

BY EDWARD P. DAVIS, A. M., M.D.

PROFESSOR OF OBSTETRICS IN THE PHILADELPHIA POLYCLINIC; CLINICAL LECTURER ON OBSTETRICS AND GYNECOLOGY IN JEFFERSON MEDICAL COLLEGE, ETC.

If one were asked the meaning of the word, "scientific," a proper definition would be found in a phrase indicating the possession and dissemination of knowledge. A scientific journal is one that contains and disseminates knowledge of the subject of which it treats. Modern medicine is a science in so far as it contains valuable knowledge concerning human life and disease, and scientific obstetrics is the theory and practice of this branch of medicine, characterized by accurate knowledge.

In this one point of the possession or absence of accurate knowledge rests the difference between the obstetric practice common in the United States twenty-five years ago, and the theory and practice taught at the present day. Impressed with the ability of nature to deal successfully with the emergencies of labor, the practitioner who attended obstetric cases has been wont to comfort himself with the axiom that labor is a natural process, of which he need not seek to ascertain too minutely the details. The condition of pregnancy he regarded as naturally normal, and hence without especial tendency to disease. The lying-in period was to him a natural stage in the life of the individual, and required at his hands no especial scrutiny. An accurate diagnosis as to the factors present in a given labor was rarely made, unless some serious emergency arose.

There have been many reasons for this condition of affairs. The comparatively recent discovery of anesthetics placed at the disposal of obstetricians a means of diagnosis of inestimable value. The employment of antiseptics has rendered possible manipulations

for the diagnosis and treatment of labor that formerly were impracticable. Methods of diagnosis are now commonly taught and practiced that, at the period mentioned, were only to be seen in practice in the large hospitals of Europe. Modern obstetrics has, then, great advantages in its opportunities to acquire thorough knowledge of the patient and of her labor, and this, too, without the infliction of additional pain, or the incurment of added risk to life. The characteristic of modern obstetrics is its scientific element, as shown in the accurate knowledge that it requires concerning matters formerly thought to prosper inevitably through the kind coöperation of nature.

Scientific obstetrics is the rule in the modern hospital, but it is often "more honored in the breach than in the observance" in private practice. The reasons for this are many. First, among all, is the common belief, derived largely from physicians and nurses, that, because labor is a natural process it is bound to proceed successfully without intelligent supervision. If this is true, why should a patient tolerate palpation, auscultation, or pelvimetry; or why should she take an anesthetic when the mechanism of labor is interrupted, and a thorough examination of the condition present becomes necessary? A common belief that has descended from the days of the early craniotomist, or man-midwife, as he was termed, is that any interference with labor means, practically, the use of forceps, and hence the objection to critical examination in an emergency. Again, it not infrequently happens that a complicated labor terminates spontaneously, and apparently with success to mother and child. It does not occur to the patient and her friends that complications may have arisen, by reason of the long continuance of the spontaneous labor, that could have been avoided had intelligent interference been practiced.

There is especial need for scientific obstetrics in private practice, because the practitioner is more directly responsible for the condition of his patient than when he is engaged in hospital practice. He lacks in private the experienced observation of trained nurses; he misses the intelligent coöperation of resident physicians; and experiences the great disadvantage that the absence of order and discipline, so common in a private house entails upon him. It is, therefore, especially necessary that he gain thorough knowledge of his patient by personal observation and study, and this knowledge is the essential of scientific obstetrics. The fact that the best results in obstetric practice are observed in hospitals, draws attention to the need for scientific work in private cases.

Omitting a consideration of the minor details of private obstetric practice, we urge the importance of a thorough examination by the practitioner of all pregnant patients. We are well aware of the fact that many cases are not seen by their attendants until labor is far advanced, and no opportunity has been given to examine the patient during pregnancy. This is growing to be, however, less the case than formerly, and especially in first pregnancies, when the natural dread of an untried experience brings the patient to the physician comparatively early. This scrutiny of the pregnant patient should be directed especially to ascertaining the condition of the organs of elimination, and the success attending their action. The examination of the urine should be an invariable practice, and valuable information will be given by

ascertaining not only the presence or absence of albumen, but by careful microscopic study of the sediment, and also an estimation of the amount of urea excreted. In the Maternity Department of Jefferson Medical College Hospital we have for some time derived valuable information regarding a patient's eliminative powers by ascertaining the quantity of urea excreted. The presence of albumen is of itself a trifling matter, unless the microscope reveals evidence of decided structural change in the kidney.

At or after the seventh month of pregnancy it becomes the duty of the attendant physician to ascertain the mother's size, and the relative size of the fetus and the position that it occupies in the mother's pelvis. This is a procedure commonly thought unnecessary, and reserved for the lectures of those who teach obstetrics. That such is not the case is well exemplified by two fatal cases, seen by me recently in consultation, in both of which embryotomy upon the dead fetus was necessary. Two well-developed male children were sacrificed to a lack of diagnostic skill on the part of the medical attendant, and to complete the unfortunate history of those two cases, the lives of the mothers were lost on account of the stupid laziness of the physicians, who neglected to use antiseptic precautions during labor. In both cases the child had perished before the consultation, and the embryotomy was performed to spare the medical attendant from reproach and criticism for his failure to deliver the mother. These four lives could have been saved had proper precautions been taken.

The practice of general medicine, including obstetrics, in country towns or villages, often taxes to the utmost the skill and wisdom of the so-called "country doctor." As a result, he has a range of experience unknown to his city brother, and becomes by natural development more assured, self-reliant, and efficient. He is the man who, above all others, can appreciate the value of any method of practice that shall add to the positive knowledge he has of his patient. We do not ask him to provide himself with elaborate or costly pelvimeters, or instruments for diagnosis but, as is our custom in lectures at the Philadelphia Polyclinic, we do urge upon the general practitioner a knowledge and practice of palpation, auscultation, and of such a method or methods of estimating the size of the mother's pelvis and the relative size of the fetus as may be within the scope of his possibilities. No student graduates from a well-appointed medical college who is not in the possession of this knowledge, and certainly the general practitioner already established can not afford to be behind the recent graduate in his resources. The objections urged against the examination of pregnant patients, including the measurement of the pelvis, are based upon needless exposure of the patient, or rude and unskilful manipulation. We have yet to find a private patient, of whatever station in life, who offers the slightest objection when her physician asks that he be given an opportunity to acquire a knowledge that shall the better enable him to care for his patient, particularly if, by so doing, he subjects her to no exposure, nor to tedious and painful manipulation. The abdomen of the patient may remain covered by one thickness of cotton or linen, without in the least inconveniencing the physician, and medical students under my instruction are taught to make their examinations in this manner.

One of the great advantages accompanying this mode of practice is the lessening of vaginal examinations, which are a source of considerable danger to the patient. It is perfectly possible by palpation alone to follow the head of the child as it descends through the pelvic canal and impinges upon the pelvic floor. The character and efficiency of the pains of labor may also thus be accurately observed, and oftentimes, valuable assistance can be rendered by external pressure gently and judiciously applied.

When the mechanism of labor is interrupted, a thorough internal examination is at once indicated. This is often impracticable without the administration of an anesthetic. The practitioner should be prepared to interfere for the assistance of the patient. Forceps should be prepared and ready. The rectum and bladder should be emptied, and, while it is not necessary to state to the patient that an operation is to be performed, yet while she is under the influence of the anesthetic, it may be found wise to terminate the labor. It is often impossible to accurately diagnose a faulty position of the head without an anesthetic, the resistance and suffering of the patient being so great that sufficient of the hand can not be introduced to make a thorough examination. When, however, such an examination has been made, and before the examining hand has been withdrawn, the forceps may often be accurately applied to the sides of the child's head, and the labor brought to a successful termination. In other cases, version and extraction may be found necessary. In either event, examination of the patient under anesthesia will spare her hours of suffering, and will often save the life of an infant, and sometimes that of the mother.

The same thoroughness in treatment should obtain in the diagnosis and treatment of injuries to the genital tract. By the term, "laceration of the perineum," we understand a solution of continuity that extends more deeply than the posterior commissure or fourchet. We are aware that a laceration in the median line may extend beyond the fourchet, and still not impair the supports of the uterus to any appreciable degree. When we read and hear of large numbers of cases of labor in which no laceration of the perineum has occurred, we are impressed with the fact that those who record such extraordinary experiences either consider that a laceration of the perineum usually extends into the rectum, or else that they did not accurately examine the cases. The examiner may be readily deceived by a superficial examination by the finger only of the genital canal, soon after labor. Clotted blood often fills a torn surface, giving to the finger the same continuity of smoothness that marks the uninjured mucous membrane. It is only by the thumb and finger, one inserted in the rectum, or, better still, by actual inspection, that the condition of the genital tract after labor can be accurately ascertained. Considerable observation of labor cases, and the careful employment of the best known means for preventing laceration of the perineum, have convinced me beyond reasonable doubt that such an injury is inevitable in many cases. It is negligent not to discover it; it is lazy and dishonest not to endeavor to repair it.

Fortunately, in these matters, public sentiment is demanding the advantages of scientific obstetrics. We recently had occasion to tell a young woman that she had sustained a laceration of moderate extent that ought to be closed. She said that if such was the

case, she earnestly desired that it be at once repaired, as her sister had suffered from the neglect of her physician in not suturing a similar laceration. We are furthermore helped in dealing with these questions by the fact that experience shows us that excellent results may be obtained as late as twenty-four or thirty-six hours after the occurrence of a laceration. It is far better practice to give the patient and physician twenty-four hours' rest after a trying labor, and then, under anesthesia, or with the use of cocaine, close a laceration under favorable circumstances, than to further exhaust a weak patient, and with poor light and laboring under great fatigue, to improperly perform the physician's duty. If torn surfaces are found glazed over, the simple expedient of scraping them with the blade of a pair of scissors, or with a curette, will suffice to secure union by first intention.

It is burdening you with a trite observation to speak of the importance of obstetric antisepsis or asepsis, and yet the same reasoning that enables the practitioner to assert that in his 1,000 cases he has never had a lacerated perineum, leads him likewise to claim that in his 1,000 cases he has never had a case of puerperal septic infection. He may have avoided signing a death certificate for a patient recently delivered, the certificate bearing the words, "peritonitis," "blood-poisoning," "inflammation of the bowels," or "puerperal fever"; but cases occasionally perish some weeks after labor, with "jaundice," "pneumonia," "congestion of the liver," or "malaria," that, on closer study will be found to be the results of puerperal septic infection. The faithful practice of aseptic or antiseptic precautions greatly lightens the load of responsibility that the practitioner of obstetrics must carry.

Not the least of the advantages derived from the scientific practice of obstetrics lies in the avoidance of interference by those who have no right to molest the patient. The practitioner's best efforts are often thwarted by ignorant and meddlesome persons. He can not, however, honestly forbid interference, unless he knows positively that there is no occasion to molest the patient. He will obtain the best results in obstetric practice who does the work himself, unless he can command, for certain things, the assistance of a trained nurse. Thoroughness in diagnosis, the faithful observance of antisepsis in treatment, and the protection of his patient from meddlesome interference, will give the best results. Such a method of procedure is thoroughly scientific, for it demands the best knowledge, the most careful and skilful manipulation, and, above all, an honest and fearless attempt to meet the difficulties that may arise. In the present stage of medical science, every woman has a right to demand such treatment, and if a practitioner of medicine can not give his patient such care, he must inevitably, by the inexorable law of the "survival of the fittest," give place to those who can.

PUBLIC HEALTH.

Woman's Health Protective Association.—At the recent Sanitary Convention at Harrisburg, a paper was read by the Director of Public Safety of Philadelphia, Mr. A. M. Beitler, in which he paid a handsome tribute to the recent public work of an organization, the Woman's Health Protective Association of Philadelphia, for the great interest they take

in the city's cleanliness and for the success they have had in forwarding complaints to the proper bureau for registry. The Director of Public Safety believes that the women of Philadelphia, through this quite inexpensive organization, will yearly make their work tell on the city's good order and for the observance of sanitary regulations already provided; that they will be potent aids in preserving the health of Philadelphia. This city, by its plan, and its favorable building developments, of a single house to one family, should have the smallest death rate of any in the world, for in no large city are the bulk of the people so comfortably and decently housed. It only needs the education of the individual householder to do his or her part in every way, by vigilance and by voting, by setting an example both in personal care of premises and in reporting at once all nuisances in the neighborhood; an example, also, on the part of each voter in choosing loyal and business men to conduct the city's business in councils; it only needs this to have, in a few years, a transformed city, with clean water to drink, all places of pollution shown up and cleaned out, and not only the smallest death rate in the world, but the most comfortable city to live in. All of this the women may bring about if they will be ceaselessly vigilant and fearlessly outspoken.

Smallpox.—The Reading, Pa., Berks County Board of Health, reports that three new cases of smallpox occurred in that city during the two weeks ending Feb. 5, 1894. These cases occurred prior to Jan. 26, 1894. The total number of cases in that city since the outbreak in February, 1893, have been 713, with 18 deaths to date. Only seven cases are now in the Emergency Hospital, all of whom will shortly be discharged.

An outbreak of smallpox has occurred at Tyrone Forges, near Tyrone, Blair County. The inspector reports seven cases of smallpox and five cases of varioloid as existing on February 8th instant. This epidemic has been traced to Reading, Berks County. One fatal case of smallpox is reported at Puttstown, Bedford County, traced to Tyrone. One case of smallpox exists at Williamsport, Lycoming County, origin not known, and one case of the same disease is reported from Wilkesburg, near Pittsburg, Allegheny County.

Five cases of smallpox in Pittsburg, Allegheny County, origin unknown. One case of smallpox in Philadelphia, origin unknown. Yours truly, BENJAMIN LEE, Secretary.

Yellow Fever.—Propositions adopted by the Conference of Gulf Quarantine Authorities, held in New Orleans, Feb. 2 and 3, 1894.

Your committee to whom was referred the consideration of the several propositions relative to the regulations of the fruit trade during the quarantine season, beg to report as follows:

1. In order to secure prompt and reliable information as to the existence of yellow fever in the various ports of the West Indies and Central and South America from which fruit is shipped, it is deemed essential that medical inspectors should be stationed at said ports with the understanding that the inspectors stationed in the larger towns may have jurisdiction over smaller places within the district.

2. The duties of the inspectors shall be to report by each and every vessel, and if necessary by cable when practicable, on the sanitary condition of their respective districts; on the existence of contagious or infectious diseases within the same; on the compliance by vessels with the regulations issued for their guidance and to perform such other duties as may from time to time be required of them.

3. It is recommended that vessels engaged in this trade shall, whenever practicable, be manned by acclimated crews.

4. In the absence of yellow fever, it is considered unnecessary to place any restrictions upon the manner of loading vessels, or upon the character of cargo carried, further than to rigidly exclude household effects, personal baggage, hides, horns, bones and fertilizers.

5. After the discharge of the cargo every vessel shall be subjected to mechanical cleansing by washing, and afterwards thoroughly disinfected.

6. In the event of yellow fever occurring at any fruit port, trade with that port may be continued under the following additional precautions:

Each vessel to be required to carry a duly accredited medical officer whose duty it shall be to see that all quarantine regulations are strictly carried out. No member of the crew shall be allowed to go on shore nor any one, except an acclimated loading crew, to come on board. The loading crew to be kept isolated in a locality sufficiently remote from the infected district and while on board the vessel to be kept separate from the crew. Vessels are not to be allowed to remain at any wharf or near shore after sunset, but must anchor in the open bay at such distance from shore as may be prescribed by the medical officer in charge, and must not return before sunrise. The cargo carried shall be restricted to fruit, rubber and specie. Rubber not to be packed in any textile fabrics, and specie to be disinfected by immersion in boiling water.

7. Should a vessel having yellow fever on board and carrying a cargo of fruit arrive at a quarantine station, the fruit may be lightered by acclimated crews or by the crew of the vessel, after which the vessel shall be subjected to the usual detention and disinfection. The clothing of the laborers to be disinfected by steam heat after the discharge of the cargo shall have been completed.

8. Any vessel engaged in the fruit trade, which carries passengers, should forfeit all special privileges and be subjected to the same quarantine restrictions as other vessels carrying passengers.

9. Inasmuch as the quarantine laws and regulations of the United States as promulgated by the Secretary of the Treasury April 4, 1893, are not in accord with certain of the foregoing propositions, it is recommended that such modifications be made in said laws as shall make them to coincide with the views expressed by this Conference.

JEROME COCHRAN, M.D.
R. W. HARGIS, M.D.

SELECTIONS.

Extirpation of the Gall Bladder.—After reviewing the history of this operation which was first attempted by Jean Louis Petit, in 1743, and which was given a renewed impetus by Langenbuschen ten years later, the author then cites two cases operated on by Helferich.

The first was that of a man 21 years of age who first appeared in the clinic Jan. 18, 1892, complaining of a severe hepatic colic to which was added a transient jaundice.

On the under surface of the liver a flat pear-shaped tumor was discovered which proved to be the gall-bladder, its walls thickened and shrunken, and containing nine to ten small faceted stones, after the removal of which the gall-ducts appeared to be intact. Convalescence was retarded by the formation of an abscess, which two weeks later was evacuated through the lower aspect of the abdomen.

The second case, a man 42 years of age, first came under observation in July, 1892. He exhibited a tumor near the under surface of the liver, which during its growth was the cause of much pain and considerable gastric disturbance. The swelling lay in the right hypogastric region, about the size of a man's fist, and disappeared on deep inspiration.

On incision the tumor seemed to consist of the distended gall bladder to which the transverse colon was adherent.

On its lower circumference there was a thimble-shaped pocket or sac, containing about one-fourth liter of a yellow purulent fluid in which were fat corpuscles and sediment. In the lumen of the cystic duct, a gall-stone about the size of a cherry-seed, was so firmly impacted that it could only be removed after first breaking with forceps. As it was so firmly held in its situation by the minute projections on its surface, and as its removal by a lithoclast would injure the

duct, it was deemed advisable to extirpate the gall-bladder and duct at a point just above the site of the stone. The remaining portion of the duct was carefully closed with Lembert sutures. Convalescence was uninterrupted, no febrile reaction taking place.

The author then discusses the results of the cholecystectomies; of seventy-two cases observed by himself only sixteen resulted in death, only seven of which could be attributed to the effects of the operation.

The different reports concerning the importance of extirpation of the gall-bladder as an operative procedure, against the operation for gall-stones, have not yet been decided in favor of either.

Lauenstein, however, upon his own experience, is opposed to this operation. He has treated cases exactly like those above related, and quite as successfully, by merely opening the gall-bladder. Among thirty cases in which an operation was indicated, in only two was the gall-bladder removed, and then only on account of a secondary complication in the form of a biliary fistula.—C. LAUENSTEIN in the *Centralblatt für Chirurgie*, January, 1894. [Abstracted for the JOURNAL.]

The Use of Ether in Incarcerated Hernia.—Gussenbaur has tried Finkelstein's method of using ether in incarcerated hernias, on a number of cases from the Prague surgical clinic. Of 135 cases which came under observation, 108 required operative interference, and in only five of these the ether treatment was unsuccessful. The remaining twenty-seven, among which were sixteen inguinal, one ventral and three femoral, were all successful.

Gussenbaur recommends the practice of the American physician, H. Koch, of protecting the thighs and scrotum from the ether fumes. The danger of an explosion when artificial light is used must be borne in mind.

Among the twenty successful cases mentioned above, spontaneous reposition without taxis resulted in three of the cases. One patient succeeded in reducing his hernia himself after the application of the ether. All the others were reduced by the surgeon in from one to three hours. In only two cases was a longer time than three hours required.

Gussenbaur considers this method of ether application worthy of more notice. He believes the results would have been still better had he attempted this operation earlier than he did, as forcible taxis had already been attempted.

It should be understood, however, that the operation of herniotomy should not be entirely excluded. The ether treatment can be tried when this operation is contra-indicated, as in cases where incarceration is accompanied with symptoms of gangrene or peritonitis.—"JAFFE," in the *Centralblatt für Chirurgie*, January, 1894. [Translated for the JOURNAL.]

NECROLOGY.

A. G. Standiford, M.D. of Westville, Ind., died February 10.

J. T. Doyle, M.D. of Wilkesbarre, Pa., died February 10.

Dr. Lingensfelder, 50 years old, of St. Louis, Mo., a passenger on the North German Lloyd steamer, *Sprea*, which arrived Feb. 15, from Bremen, died from a disease of the liver on the voyage. His body was sent to St. Louis.

A. Dunlap, M.D. of Springfield, Ohio, died February 17. He was a delegate from the AMERICAN MEDICAL ASSOCIATION to the International Medical Congress in London, Eng., in 1881, and one of the earliest physicians to demonstrate the operation of laparotomy, having performed over 400 operations in various parts of the United States.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunlison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNLISON, M.D., Lock Box 1274, Philadelphia, Pa.

SATURDAY, FEBRUARY 24, 1894.

BRITISH CHOLERA MICROBES.

The press dispatches report that the International Sanitary Commission at Paris, has succeeded in inducing the British Government to agree to proper international quarantine at Red Sea ports, and that the Turkish Government on its part agreed to purify the "holy" well at Mecca.

For this much we should be thankful, but the great measures of sanitation should include the proper enforcement of sanitary regulations of pilgrims to and from the holy city, and beside, some really adequate hygienic measures in India.

The whole world has known for a long time that the awful responsibility of maintaining cholera centers, has rested with the Indian Government and that of Turkey, and that these countries have at last agreed to even this feeble step is acknowledgment that they recognize it.

An international quarantine at Suez has been maintained for several years under French auspices, but the British ships have frequently evaded it, and when proper inspection was submitted to, it was done with an ill grace.

When Great Britain seized the reins of government in India, she became morally responsible for the innumerable cholera centers in her stolen territory. That responsibility can not be shaken off by the Anglican practice of raising a cloud of objections to the theory and practice of quarantine, and the mandate of other nations should be, that England should no longer be allowed to afflict the globe by her indifference to the exportation of cholera microbes.

These microbes once Indian, are now British, and whether or not we agree with Mr. HART that they are "waterborne," we can not fail to notice that instead of vigorous action in destroying them, she has heretofore not only placed no obstacle in the

way of their exportation, but has actually tried to break down the barriers erected by other nations in self-defense.

SOME OBSERVATIONS ON THE CAUSE
OF JAUNDICE.

Jaundice is a condition characterized by a more or less deep yellow, or greenish yellow color of the skin and conjunctiva and by the presence of bile or bile coloring matters of the urine. It invariably depends upon causes which either completely obstruct the flow of bile, or which modify the pressure under which the bile normally flows along the biliary ducts. When, from any cause, the pressure increases in the bile ducts, the bile coloring matter and the bile acids enter the lymphatics of the liver and are conveyed in the lymph through the thoracic duct into the blood.¹

If the thoracic duct, and as well the common bile duct be ligatured, no jaundice results, and biliary constituents can not be detected in the urine. Dogs survive this operation, sometimes for seventeen days without apparent inconvenience, without jaundice and without bilirubin or bile acids appearing in the urine.

It therefore appears to be proved beyond the possibility of doubt, that it is only through the lymphatic paths that biliary constituents can leave the liver and enter the blood.²

The theoretic explanations of "Jaundice Independent of Mechanical Obstruction of the Bile Ducts," given by Dr. Murchison, in Quain's Dictionary of Medicine, and quoted by the recent writers on practice are now obsolete, and it is only within a comparatively recent period that facts have accumulated which prove that jaundice is always due to an obstruction to the normal efflux of already secreted bile. By hepatogenic jaundice is meant jaundice due to obstruction. By hematogenic jaundice is meant non-obstructive jaundice, which does not exist. Stern has shown,³ that contrary to Harley's views, the bile acids and bile coloring matter are both formed in and by the liver. In ducks and geese, the secretion urine continues after the ligature of all vessels to the liver.

If the liver be extirpated the urine remains free from biliary constituents; Minkoski and Naunyn having discovered that ducks and geese, after the inhalation of arseniuretted hydrogen, excrete bile coloring matter with urine, they exposed them to this agent after removing the liver. In the time intervening between the poisoning, and the death of the bird, urine was excreted which contained hemoglobin, but was free from bile coloring matter.

They thus succeeded in demonstrating that in the

¹ Fleischl, Kunkel, Gamgee, *Physiological Chemistry*, p. 359.

² Gamgee, p. 361.

³ Gamgee, p. 365.

most typical cases of supposed hemotogenic jaundice, the excretion of bilirubin is necessarily connected with and dependent on, the liver.⁴

More recent research has proved that there is not, at present, any sound basis for the conclusion that the bile pigment occurring in jaundice has any source other than the liver. According to our view, every form of jaundice is occasioned by obstruction.⁵

THE DIFFUSION OF SMALLPOX.

In Pennsylvania there are not as many cases of smallpox as there were on January 1, and although the disease seems to be under control there were three fresh cases at Reading within the last two weeks, one at Saxton, Bedford County, one death at Pittstown, Bedford County, and seven cases of smallpox and five of varioloid at Tyrone Forges, the disease at the latter locality traced directly to Reading. A mild case of varioloid has also been found in Philadelphia in the person of a young lady who contracted the disease in Connecticut. This is the first case in that city for some time.

In New York City the number of cases is gradually increasing, and there are cases at several points throughout the State. There are still cases at Winchester and Norfolk, Conn., and on February 9 a case was found on a railroad train in that State. The disease still exists in Boston, but seems to have been stamped out at Somerville, Worcester, Holyoke, Lowell and Brookline.

Fresh cases are reported at Lewisburg, West Va., and a case of varioloid at Walliston, Anson County, N. C., one at Shelby, Ohio, one at South Bend, Ind., also at Otsego, Mich., and at Janesville and Milwaukee, Wis. Cases are also reported at Manhattan, Round Grove, and the poorhouse, Edwardsville, Ill., Duluth, Minn., and Luverne, Keosauqua, Marion, Council Bluffs, Keokuk, Fort Madison and New Hampton, Iowa. The Chicago health authorities daily find new cases.

Taking everything into consideration, the efforts to control and prevent the spread of the disease have been very successful, especially in some localities, where the infection did not spread beyond the first cases attacked. The Wisconsin and Iowa State Boards of Health have ordered the vaccination of all the school children in their respective States, and the Illinois Board has extended the scope of the vaccination order of that Board. It is undoubtedly the duty of the health authorities to secure the vaccinal protection of every one they possibly can. We shall no doubt have many more outbreaks, owing to the diffusion of the contagion over so large an area, in addition to the fact of the presence of the disease in New York and Chicago, the greatest distributing centers in the country, and the increase of the tramp

element. The suggestion of DR. PROBST, Secretary of the Ohio State Board of Health, that all railway employes should be vaccinated, is a good one, and should be carried out. The low death rate by the disease is still notable, and another feature that is marked is the great number of cases that are found in general hospitals in the large cities. The latter is, no doubt, owing to the fact that the poor seek hospital shelter much sooner than usual, and thus make the control of this disease more difficult.

There are now in the United States twenty-eight suspected places, a greater number than we have had at any time since 1882. In England there are about the same number of places, but we do not have so many cases. There are now in the United States about 375 cases, while the fresh cases for the past week have been about 175.

In Paris, smallpox has been prevailing for some time and is increasing, owing to the neglect of vaccination. Vaccination matinees have been the order there, but this has not been found sufficient to check the disease, and there is now to be general and obligatory vaccination in all the communal schools, primary and secondary, and the Assistance Publique has organized a system of public gratuitous vaccination, at stated hours, at twelve of the hospitals located in different parts of the city.

THE CAUSE OF DEATH.

The cause of death and a number of other medico-legal questions, as many as would hardly, ordinarily, be raised and decided in a half dozen or more cases, are exhaustively considered by the United States Circuit Court of Appeals, Sixth Circuit, in the case of the Manufacturers' Accident Indemnity Company v. Dorgan, decided Nov. 6, 1893, and just reported in the advance sheets of 58 Federal Reporter, page 945. This was an action brought to recover for the death of a person who had gone on a fishing excursion, and was found by one of his companions, twenty minutes after he was seen playing a trout, lying in the brook, with his face downward and submerged in six inches of water, dead. The points decided of special interest to the medical profession, taken seriatim, are as follows:

While the opinion of a non-expert witness is not admissible in evidence on facts which it is possible for him to detail to the jury so that the latter can draw its own inference therefrom, a physician who performs an autopsy may be asked his judgment of the conditions which he has found in the body of the deceased person, and what they indicate as to the cause of death.

But a question is incompetent, which asks a physician, not present at an autopsy, whether in his judgment, from the testimony offered with regard to the autopsy, he would say that the autopsy was such as

⁴ Gamgee, p. 365.

⁵ Bugee Physiological Chemistry, p. 379-380.

to enable a physician to state with any degree of certainty the cause of death, because it asks him to make his own inference as to what the evidence of the other witnesses tends to show, and then, upon such inference to give his opinion. To properly elicit his opinion as to the character of the autopsy, and its usefulness in showing the cause of death, counsel should state the scope and character of the autopsy, as he understands it, so that the jury, in weighing the answer of the witness, can know exactly upon what facts it is based. The difference between this question and a similar one put to the physician performing the autopsy, is that here the witness is asked to weigh other men's evidence, a function peculiarly belonging to the jury, while there the witness is asked an expert opinion of bodily conditions seen with his own eyes. Had the physician, whose judgment of the autopsy is thus asked, been present at the autopsy, a question calling for his opinion as to its evidential weight in determining the cause of death would be a proper one.

A physician who has made an autopsy may testify as to whether there was any occasion for making other than those he made, as, for example, an air or water test with the heart of the deceased, where the sufficiency of the autopsy to show the normal or abnormal condition of the heart is questioned because of a failure to make such tests. He may also be asked as to the purpose and scope of his investigation. And on the same ground, his testimony that he cut open and examined the stomach to see if there was any trace of alcohol in it may be corroborated by showing that his attention had been directed to the fact that deceased had been drinking on the day of his death.

The words, "voluntary exposure, unnecessary danger, and hazardous adventure," as used in an insurance policy exempting the insurer from liability for death produced by such exposure, do not refer to such exposure as men usually are going to take—such as is incident to the ordinary habits and customs of life. In order to constitute a defense as a contributing cause, the exposure must be something beyond the ordinary, or a wanton, a piece of gross carelessness, as we would term such in our designation of a person's conduct in the usual walks of life.

An involuntary death by drowning is a death by external, violent, and accidental means.

If a person suffers death by drowning, no matter what is the cause of his falling into the water, whether disease or a slipping, the drowning, in such case, will be the proximate and sole cause of the disability or death, unless it appears that death would have been the result, even had there been no water at hand to fall into. The disease is but the condition; the drowning is the moving, sole, and proximate cause. A precedent on this point is furnished in a

case where the insured was seized with an epileptic fit and fell into a stream, and was there drowned while suffering from the fit. It was there held that the death was within the risk covered by the policy, and not excluded by a provision of the policy that it should not extend to any injury caused by, or arising from, natural disease or weakness, or exhaustion consequent upon disease. This doctrine has also been approved by the Supreme Court of the United States.

On the other hand, an "accidental" death by drowning results from, and is caused indirectly by, fits, vertigo, or other disease, if the fall into the water, from which drowning ensues, is caused by such disease. And if an insurance policy provided that it should not apply to an accident to which a fit contributed indirectly, the insurer would not, under some of the decisions be liable.

The court concludes that the jury in this case might, from the circumstances, properly have found the verdict which they did find, namely, that the unconscious and helpless condition of the insured in which drowning ensued, arose, not from disease, but from indigestion or want of food, or some other temporary cause, and that judgment of the court below, on the verdict in favor of the beneficiary of the insurance policy in controversy should be affirmed.

CORRESPONDENCE.

Medical Legislation in Ohio.

TROY, OHIO, February, 1894.

To the Editor:—I desire to call the attention of the members of the AMERICAN MEDICAL ASSOCIATION in Ohio, to a medical bill now pending in the Legislature, known as the Mosgrove substitute bill. This bill provides for an examining and registry board composed of seven physicians as follows: "Representation shall be given to the different schools of practice in the State as nearly as possible in proportion to their *numerical strength in the State*, provided, however, that *no one school of practice shall have a majority of the whole board.*" The last clause of the bill destroys the apparent fairness of the first one, inasmuch as there are now engaged in active practice in the State six regular physicians to one of all other schools combined. The composition of this board under the law would necessarily be four irregulars and three regulars, the one irregular in active practice in the State would be represented by four members of the board, while the six regulars in the State would be represented by three on the board, a shameful discrimination against the majority and against the regular school. The irregulars having the majority would be able to control the board and elect a president, secretary and treasurer of their own liking; have power to establish grades determining the standing of medical colleges; countersign permits to practice and in fact practically control the business affairs of the board. The irregulars can always be relied on to stand together in a question against the regular profession and as four is a majority over three, we would be outvoted every time when a question of schools was involved.

The Code of Ethics of the AMERICAN MEDICAL ASSOCIATION, Art. IV, Sec. 1, forbids the holding of professional consultation with irregulars. Yet this bill puts these unworthy

practitioners in the State of Ohio practically in charge of the profession. The bill provides that each physician must receive a permit from the board and have the same placed in his office. It no doubt will be a pleasure for the regulars of the State to gaze on a framed certificate permitting them to practice medicine and surgery, signed by some disciple of Hahnemann as president, and some equally obnoxious physiomedist or eclectic as secretary.

What appears strange is that a bill so unjust should receive the sanction from an assemblage of doctors of all schools called together for the purpose of formulating a medical bill, a former editor of the *JOURNAL* presiding, and who gave his assent and now advocates its passage. God save us from our friends in the regular profession. There are many other features of the bill that are objectionable and not up to the standard of medical legislation in other States, nor in line with the spirit of advanced medical education. It permits uneducated midwives and doctors who are now engaged in practice under a defective law to continue without an examination, while young men who may have graduated from the best schools of the world must undergo an examination by this board, a majority of whom are irregular doctors.

I consider any legislation defective that does not require all doctors who have no diploma, as evidence of a medical education, to be examined by the board, as well as all midwives. No injustice should be done to any school of medicine; and this can be done by establishing different boards or give fair numerical representation to the different schools. Better let the State be overrun with quacks who are flocking here from other States which have enacted laws that "smoked them out," than to pass a law so unjust and humiliating to the regular profession as this bill proposes. It is about time the regulars woke up in the State and entered their protests against this bill. As it now stands it is evidently not in the hands of our friends.

W. R. THOMPSON, M.D.

Superfluous Spectacles.

To the Editor:—Replying to the comments in your editorial columns Feb. 3, 1894, under the caption of "Superfluous Spectacles," which is evidently designed to stimulate a so-called "healthy reaction against the one-sidedness which has of late years permeated American ophthalmological literature," permit us to say that we were not aware that any very disastrous results had followed the application of glasses in any and all cases in which they were indicated, and indeed in the majority of cases great benefit has ensued. So firmly are we of this belief that we would respond to the query, "Does every optical defect need correction, and is every case of painful vision curable by glasses?" Yes; every optical defect sufficient in degree to give rise to the disagreeable train of symptoms called asthenopia should be corrected and in all cases of refractive error, pure and simple, accompanied by painful vision we can, with the institution of the modern ideas of treatment, remove the difficulty; and while we rigidly adhere to this rule, we have never deemed an eye possessing a high degree of refractive error equal in working power to a normal or emmetropic eye, notwithstanding full correction. The mere fact that many cases of comparatively high degrees of uncorrected refractive error cause little or no visual disturbance proves nothing, as it has yet to be shown by competent statistics that the persons who have experienced little or no difficulty with their eyes despite the presence of a palpable refractive error, have been placed under the same conditions of eye-strain; and I think that if the cases recorded by Dr. Roosa were subjected to careful scrutiny it would be seen that

they were eyes that had been subjected to little or no strain, so far as close work is concerned; for we all appreciate that many ametropic individuals are capable of performing general all-around work which does not require constant application of the eyes, (and particularly is this true of hypermetropic cases) with comparative comfort, but no sooner are they placed under conditions requiring constant use of their accommodative mechanism prevailing during close eye work, combined with deficient illumination, close atmosphere, malposition, etc., and we have the requisite factors conducing to speedy development of asthenopia, which then demands the oculist's attention.
